town-hall, built entirely by convict labour, stands on an eminence in the very heart of the city; opposite to it are the government offices, housed in a four-storied structure in the style of the French Renaissance. The mint, opened in 1809, is a massive freestone building. There are a public library, built as a memorial of Queen Victoria's Jubilee in 1897, a Scots college, two museums (the mechanics' institute, a museum, and a fine Wesleyan church-house, known as Queen's Hall. The Perth Park, containing about 1200 acres, is connected by tram with the city, and in it is a well-equipped observatory. There are several smaller parks and squares in the city, while the esplanade gardens are a feature of the place, being thrown out like a pier into Perth Water. There is a good cricket ground, and three race-courses are in easy reach. South Perth, on the other side of the river, is connected by bridges and steam ferry; and adjoining the city on the north-west are the suburban municipalities of Leederville and Subiaco. Outlying suburbs are Belmont, Victoria Park, Burswood, Claremont, Cottesloe, Peppermint Grove and Bayswater. The city is lighted by electricity, and has a good service of electric trams. Perth has an agreeable climate, the mean temperature is 64° F., and the average rainfall 33 in. Perth was founded in 1829, received its municipal charter in 1836, and was created a city in 1880. Between 1891 and 1901 the growth of the city was remarkably rapid; in 1891 the population was only 8,447, but in 1901 it had grown to 27,471 in the city proper, and to 36,199 including the suburbs.

PERTH, a city, and royal, municipal and police burgh, and county town of Perthshire, Scotland, 32 m. N. by W. of Edinburgh by rail, and 477 m. by the North British railway, via the Forth Bridge and Kinross Junction. Pop. (1901), 33,566. It is situated on the right bank of the Tay, between the meadows of the North Inch (98 acres) and those of the South Inch (72 acres), both laid out as public parks. The river is crossed by St John's Bridge of nine arches, completed in 1772 from the designs of John Smeaton and widened a century later; by Victoria Bridge, a modern structure connecting South Street with Dundee Road; and farther south (at the end of Tay Street) by a footway alongside of the viaduct belonging to the Caledonian railway. Of earlier bridges one, which crossed at High Street, was swept away by the flood of 1821, and another, constructed by General Wad. in 1725-1726, was apparently the predecessor of Smeaton's bridge. The left bank of the river is lined by the suburb of Bridgend and Kinnoull Hill (729 ft.). To the south are the wood-clad heights of Moncrieffe Hill (725 ft.), Magdalenes Hill (596 ft.), Kirkton Hill (540 ft.) and Craigie Wood (407 ft.). In the river are Friarton or Moncrieffe Island and the Stanners.

Notwithstanding the importance of Perth in former times, almost the sole relic of the past is the church of St John the Baptist, a large Decorated cruciform building surmounted by a massive square central tower 155 ft. high. The original edifice is believed to have been erected in the time of Columba, but the transept and nave of the existing structure date from the early part of the 13th century, the choir from the 15th. The church was restored in 1891, and is now divided into the East, Middle and West churches. The silver-gilt communion cup used in the Middle Church is said to have been presented by Queen Mary. In May 1559 John Knox preached in St John's his famous sermon in denunciation of idolatry. The Dominican or Blackfriars' monastery, founded by Alexander II. in 1231, occupied a site near the west end of St John's Bridge; in what is now King Street stood the Carthusian monastery, founded by James I. in 1425; the Franciscan or Greyfriars' monastery, founded in 1460 by Laurence, first Lord Oliphant, stood on the present Greyfriars' Cemetery; the Whitefriars' monastery, founded in 1260, stood west of the town. The tombstone of James I. and his queen, who were buried in the Charterhouse, was afterwards removed to St John's East Church. During the period between the beginning of the 12th century and the assassination of James I. in 1437, many of the Scottish parliaments were held in Perth. The building in which they met stood on High Street and was only cleared away in 1818, its site being occupied by the Freemasons' Hall. The earl of Gowrie's palace, built in 1520, stood in spacious grounds near the river and was removed in 1805 to provide room for the county buildings. The castle of Perth stood on the north of High Street, not far from St John's. It was probably built about 860 and demolished about 1400. The Spey or Spy tower, the most important fortress on the city wall, guarded the south gate close to the river, but it was taken down early in the 19th century. The market cross, erected in High Street in 1669 to replace the older cross which Cromwell destroyed, was removed in 1765 as an obstruction. The huge fortress, 466 ft. square, which Cromwell erected in 1651 on the South Inch, close to the river and the Greyfriars' burying-ground, was demolished in 1663. The house of Catherine Glover, the "Fair Maid of Perth," still stands in Curfew Row. James VI.'s Hospital, founded in 1569, occupies the site of the Carthusian monastery, the original structure having been pulled down by Cromwell's orders. The pensioners now live out and the hospital has been converted into artisans' dwellings. Among modern public buildings the principal are St Ninian's Episcopal Cathedral, in the Early Middle Pointed style, an important example (completed 1809) of the work of William Butterfield (1814-1900); the municipal buildings (1881); the city-hall; the Marshall Memorial Hall (1823), housing the public library and the museum of the Perth Literary and Antiquarian Society; the Perthshire natural history museum; the Sandeman public library (1869), founded by a bequest of Professor Sandeman of Owens College, Manchester. The general prison for Scotland, south of the South Inch, was originally erected in 1812 as a depot for French prisoners, but was remodelled as a convict prison in 1840 and afterwards enlarged. North-west of the city are the military barracks built in 1793-1794. Besides the regular elementary schools there are the Perth Academy (1807) with which was subsequently amalgamated the Burgh Grammar School, an institution supposed to date from the 12th century; Sharp's institute (1866); the Stewart's free school, an industrial school for girls, and the Fechny industrial school. The charitable institutions comprise the royal infirmary, in the Italian style, considerably enlarged since its foundation in 1836; the Murray royal lunatic asylum in Bridgend; the Hillside House in Kinnoull and the small-pox hospital.

From the south the city is entered by the North British railway and the Caledonian railway (which also runs west to St Fillans, east to Dundee and north-west to Aberdeen); and from the north by the Highland railway, the three systems utilizing a general station in the south-west of the town. During the season there is communication with Dundee and other river ports by steamer. The navigation of the stream is considerably obstructed by sandbanks, but vessels of 200 tons can unload at the quays, which, with the town and Friarton harbours, lie below the South Inch. The greatest tidal rise is 13 ft. The chief imports are Baltic timber, coal, salt and manure; and the exports, manufactured goods, grain, potatoes and slates. Perth has long been famous for its dyeing and bleaching, the bleach-fields being mostly situated outside of the city, in convenient proximity to the Tay and Almond. The other leading industries include manufactures of gauge-glasses, ink, muslins, India shawls, jute goods, woollens and wineces, floorcloth, and boots and shoes. There are iron foundries, breweries, distilleries, rope and sail works, coach-building yards, steam joinery works, and brick and tile works. The salmon fisheries of the Tay yield a substantial revenue. Perth is under the jurisdiction of a town council, with a lord provost and bailies, and returns one member to parliament.

PERTH, Old. — During the time of the Romans, a period estimated at 320 years, the city was called Victoria; but shortly after their withdrawal it seems to have borne the Celtic appellation of Aber-tha ("at the mouth of the Tay"). The transition to the Latinized form Bertha and later to Perth (the Gaelic name being Peart) appears obvious. On the conversion of the original Pictish inhabitants and the dedication of the first church to St John the Baptist, the town
was designated St Johnstoun, and it continued to be known indifferently by this name and that of Perth down to the 17th century. Roman remains have often been found in excavations carried out within the existing boundaries, which suggests that the Roman settlement was at least twenty feet below the present surface. The obscurity of the early annals of the town is explained by the circumstance that Edward I. caused the records to be removed. Perth is stated to have been a burgh in 1106 and was made a royal burgh by William the Lion in 1210. During the Scottish wars of the Independence its fortifications were strengthened by Edward I. (1298). Robert Bruce several times ineffectually attempted to seize it, but in 1311 he succeeded in scaling the walls during a night attack. This was the fourth and most brilliant of the seven sieges which the city has sustained. Taken by Edward III. in 1333, it was recaptured in 1339. In 1346 the combat between the Clan Chattan and the Clan Quhle, described in Scott's Fair Maid of Perth, took place on the North Inch in presence of Robert III. and his queen, Annabella Drummond. The Blackfriars' monastery was the scene of the murder of James I. by Walter, earl of Atholl, in 1437. In consequence Perth lost its status as capital, in which it had succeeded to Scone, and the Parliament Courts were transferred to Edinburgh in 1482. Gowrie Palace was the scene of the mysterious "Gowrie" conspiracy against James VI. in 1600. The town was taken by Montrose in 1644, by Cromwell in 1651, and was occupied by Viscount Dundee in 1689. In 1715 the Old Pretender was proclaimed king at the Mercat Cross (Sept. 16), and the chevalier himself appeared in the city in the following January, only to leave it precipitately on the approach of the earl of Argyll. Prince Charles Edward spent a few days in Perth from the 3rd of September 1745. In both rebellions the magistrates took the side of the Crown and were supported by the townsfolk generally, the Jacobites drawing their strength mainly from the county noblemen and gentry with their retainers. Since then the city has devoted itself to the pursuits of trade and commerce. Perth was visited by plague in 1512, 1585-1587, 1608 and 1645; by choler in 1832; and the floods of 1721, 1761, 1740, 1773 and 1814 were exceptionally severe.

PERTH AMBOY—PERTHES, J. G. J.

PERTHES, FRIEDRICH CHRISTOPH (1772-1843), German publisher, nephew of Johann Georg Perthes (q.v.), was born at Rudolstadt on the 21st of April 1772. At the age of fifteen he became an apprentice in the service of Adam Friedrich Böhme, a bookseller in Leipzig, with whom he remained for about six years. In Hamburg, where he settled in 1793 as an assistant to the bookseller B. G. Hoffmann, he started in 1796 a book-selling business of his own, and in 1798 he entered into partnership with his brother-in-law, Johann Heinrich Besser (1775-1826). By his marriage in 1797 with a daughter of the poet, Matthias Claudius, he was brought into intimate relation with a group of Protestant writers, who exercised a powerful influence on the growth of his religious opinions. This, however, did not prevent him from being on friendly terms with a number of eminent Roman Catholic authors. Perthes was an ardent patriot; and during the period of Napoleon's supremacy he distinguished himself by his steady resistance to French pretensions. His zeal for the national cause led him, in 1810-1811, to issue Das deutsche Museum, to which many of the foremost publicists in Germany contributed. For some time the French made it impossible for him to live in Hamburg; and when, in 1814, he returned to that city he found that his business had greatly diminished. In 1821, his wife having died, he left Hamburg, transferring his business there to his partner, and went to Gotha, where he established what ultimately became one of the first publishing houses in Germany. It was owing to his initiation that the Börseverein der deutschen Buchhändler (Union of German Book-sellers) in Leipzig was founded in 1825. When the foundation-stone of the fine building of the Union was laid in 1834, Perthes was made an honorary freeman of the city of Leipzig, and in 1840 the university of Kiel conferred upon him the degree of doctor of philosophy. Perthes died at Gotha on the 18th of May 1843. His Life was written by his son, Klemens Theodor Perthes (1809-1867), professor of law in the university of Bonn, and author of Das deutsche Staatsleben vor der Revolution (Hamburg and Gotha, 1845), and Das Herbgewesen der Handwerksge sellschaften (Gotha, 1856, and again 1883), whose son, Hermann Friedrich Perthes (1840-1888), was a well-known member of the Friedericianum at Dauers Platz. The publishing business at Gotha was carried on by Perthes' younger son, Andreas, (1813-1890) and his grandson, Emil (1841— ), until 1880, when it was handed over to a company.

See also O. Adler, Friedrich and Karoline Perthes (Leipzig, 1900).

PERTHES, JOHAN GEORG JUSTUS (1749-1816), German publisher, was born at Rudolstadt on the 11th of September 1749. In 1785 he founded at Gotha the business which bears his name (Justus Perthes). In this he was joined in 1814 by his son Wilhelm (1793-1853), who had been in the establishment of Justus' nephew, Friedrich Christoph Perthes, at Hamburg. On the death of Justus at Gotha on the 2nd of May 1816, Wilhelm took entire control of the firm. He laid the foundation of the geographical branch of the business, for which it is chiefly famous, by publishing the Hand-atlas (1817–1823) of Adolf Stieler (1775–1836). Wilhelm Perthes engaged the collaboration of the most eminent German geographers of the time, including Heinrich Berghaus, Christian Gottlieb Reichard (1738-1837), who was associated with Stieler in the compilation of the atlas, Karl Spruner (1805-1892) and Emil von Sydow (1812-1875). The business passed to his son Wilhelm, who was associated with August Petermann (under whose direction the well-known periodical Petermanns Mitteilungen was founded) and Bruno Hassenstein (1839-1902); and subsequently to his son Bernard (1857— ). In 1863 the firm first issued the Almanach de Gotha, a statistical, historical and genealogical annual (in French) of the various countries of the
PERTHSHIRE, an inland county of Scotland, bounded N. by the shires of Inverness and Aberdeenshire, E. by Forfarshire, S. E. by the Firth of Tay and the counties of Fife and Kinross; S. by the shires of Clackmannan and Stirling; S. W. by the counties of Stirling and Dumfriesshire; W. by Argyllshire and N. W. by Inverness-shire. It is the fourth largest county in Scotland, having an area of 1,959,774 acres, or 2493 sq. m., including the island of Maudrach in the Firth of Tay. By far the greater part of the county is mountainous. Including the hills on the confines of Inverness-shire and Argyllshire, there are at least fifty mountains exceeding 3000 ft. in height. Of these the most familiar are Ben Lawers (3084 ft.) near Loch Tay, Ben More (3543) east of Crieff, Ben Lui (3708) on the Argyllshire border, Schiehallion (3547) south of Loch Rannoch, Ben Vannoch (3125) west of Loch Lyon, and Ben Chonzie (3048) near the head of Glen Almond. Of the immense number of bills of lesser altitude there may be mentioned four that have been popularized by the Lady of the Lake—Ben Ledi (2875) and Uam Var (2170) near Callander, and Ben Venue (2393) and Ben A'an (1750), guides of the Trossachs. The Ochils divide Perthshire from the shires of Clackmannan, Kinross and Fife. The chief stream is the Tay, which rises on the Argyllshire frontier and discharges into the North Sea off Dunoon Ness, after a course of 117 m., being thus the longest river in Scotland. Its head-waters are the Fillan and Dochart, and among its affluents are, on the right, the Brann, Almond and Earn and, on the left, the Lyon, Tummel, rising in Argyllshire and receiving the Garry on its left, and Isla. The Earn flows out of Loch Earn and enters the Firth of Tay 63 m. below Perth. The Forth, the principal natural boundary of the shire on the south, properly belongs to Stirlingshire, in which it rises, but its leading left-hand affluents are Perthshire rivers, namely, the Teith, the Goodie, rising from the lake of Menteith, and the Allan, rising in the Ochils near Sheilburne. All the lakes are narrow, scarcely one exceeding a mile in width. Loch Ericht, belonging partly to Inverness-shire, is 14½ m. long. Loch Tay (14½ m. long), situated about the centre, is the largest lake in the county. In the south are the series of lakes which the Lady of the Lake has justly immortalized. Of these Loch Achray (1½ m. long), Loch Katrine (about 8 m. long); to the west of Aberfoyle is Loch Ard (3 m. long) and to the east, Lake Menteith (1½ m. long). Nearly all the glens possess striking natural features, among them, from south to north, being Glens Aray, Auchterarder, Ogle, Lochay, Lyon, Garry, Shey, Bruar and Tilt; while the Trossachs, Killiecrankie, Birnam and Leny are the loveliest passes in the Highlans.. The low-lying country is represented mainly by Strathmore, Strath Gartney, Strathallan, noted for its annual "gathering" or games, Strathearn, Strath Brann, Strath Tay and Strath Fillan, but more particularly by the fertile alluvial belts of the Carse of Gowrie, on the northern slope of the birth of Tay, and the Carse of Stirling. The Moor of Rannoch on the borders of Argyllshire is a moor of boulder-strewn waste, and Flanders Moss, to the south-east of Lake Menteith, is a vast boggy tract, which, being gradually reclaimed, and brought under cultivation.

Geology.—The Highland portion of this county is built up of a great series of schists and metamorphosed rocks grouped as "Dalradian" or "Eastern Schists". The general direction of the strike of these rocks is W.S.W. N.E., but off the north-eastern extremity of Red Sandstone, which occupies most of the remainder of the county, by the great fault which traverses the county somewhat to the north of Criffel, 262 miles long, which the A85 road traverses. Further for some distance north and east of Crieff the boundary between these two formations is unconformable one. In the neighbourhood of the fault line the Highland schists are less metamorphosed than they are farther north. The fill of Callander basin contains cherts, greywackes and igneous rocks with radiolarian cherts and black shales. There is suggestive of the rocks of Arenig age in south Scotland. At Aberfoyle, Crieff and Dunkeld roofed slate beds are worked and massive limestones occur in Glen Tilt, Pitlochry, Callander, Blair Atholl, Rannoch and other places. A gritty series comes on above the slates and is well seen forming the summit of Ben Vorlich. A great variety of schists form the bulk of the series; but granite masses are present near in Loch Ochil, and in Glen Tilt, and there are numerous acid and intermediate dikes which are themselves traversed by later basaltic dikes. The Old Red Sandstone consists in the lower portion mainly of coarse volcanic sediments, and in the upper portion of sandstones, schists, sandstones and marls. The lowest beds are exposed along the crest of the Ochil Hills which like the Sidlaw Hills are antediluvian in structure, while between the Ochils and the Highland fault the rocks have been folded into synclines; near the fault they become very steeply inclined and even inverted, and it is interesting also to note that the sediments become coarser as the fault is approached. They are of Old Red Sandstone or Carse of Gowrie. The rocks are mainly sandstones and marls, let down between two parallel east and west faults but between the Bridge of Earn and Forgandenny, they are more30°. The Carse of Callander, and thus the Old Red Sandstone of Carse of Earn and it extends beneath the marine platform of the Carse of Gowrie. The rocks are mainly sandstones and marls, let down between two parallel east and west faults but between the Bridge of Earn and Forgandenny, they are more...
direction via Perth. At Crieff junction it sends off a branch to Crieff and at Perth branches to Dundee and Lochearnhead. The skirmish line of the army was the same, and the army crossed the shire from Dunblane to Tyndrum. The Highland railway runs northward from Perth, and has a branch at Ballinluig to Aberfeldy. Branches of the North British railway reach Perth from Mawriscaw in Kinrossshire and Ladybank in Fife; part of the branch from Buchlyvie on the Forth and Clyde line runs to Aberfoyle, and the West Highland railway skirts the extreme west of the shire. At several points, too, the trains supplement the rail. The tourist season typically on Loch Tay and Loch Katrine, and otherwise a service on the Tay between Perth and Dundee.

Population and Administration.—In 1861 the population amounted to 122,185 and in 1901 to 123,283, or 49 persons to the sq. m. The rate of increase was the smallest of any Scottish county for the decade. In 1901 there were 78 persons speaking Gaelic only and 11,446 Gaelic and English. The chief towns are Perth (pop. 32,873), Crieff (2508), Blairgowrie (3738), Dunblane (2516), Auchterarder (2756), Coupar-Angus (2064), Rattray (2010). Among lesser centres may be mentioned Aberfeldy (568), a favourite resort on the Tay, well known for the falls of Moness, mentioned in Robert Burns's song "The Birks of Aberfeldy"; Abernethy (629), the seat of an early bishopric, retaining one of the three ancient round towers in Scotland; Alyth (1969); Callander (1458); Comrie (1118), a holiday resort on the Earn; Pitlochry (1541); and Stanley (1953), on the Tay. Of old the county was divided into hereditary jurisdictions, which were abolished in 1748, and in 1705 the county was divided into districts for administrative purposes, a system which continued until 1889, when county and district councils were established. The sheriffdom is divided into an eastern and western district, the seat of the one being Perth and the other Dunblane. For parliamentary purposes the county is also divided into an eastern and a western division, and the city of Perth returns a member. The shire is under school-board jurisdiction, and there are secondary schools at Perth and Crieff, and Trinity College in Glen Almond is a well-known public school on the English model.

History.—In 83 Agricola explored the lands beyond the Forth and in the following year penetrated to the Grampians, defeating the Caledonians under Galgacus with great slaughter. The site of this battle is conjectured by William Forbes Skene to have been near Meklehur, south of Blairgowrie, but other writers have it westwards to Dalginross, near Comrie; to Ardach (where there are the most perfect remains of a Roman encampment on the British Isles); and even as far north as Raedykes, near Stonehaven in Kincardineshire. The Romans did not pursue their victory, and the Picts were left undisturbed for a considerable period. At this time, according to Ptolemy, the territory now known as Perthshire was occupied by three tribes—the Damnonii, the Vencones and the Vacomagi. The Damnonii held Menteith, Strathearn and Fothrith (the western part of modern Fife and Kinross), with Alloa (Allan), just above Stirling, Lindum (Ardoch) and Victoria (believed by some authorities to be Lochore in Fifehire, and by others to be Perth city), as their chief towns. The Vencones inhabited north-western Fife and the adjoining tract of Perthshire, with Orron (probably Abernethy) as their chief town and a station at Ardargie. The Vacomagi dwelt in the Highland region, with stations at Inchtuthil (a peninsula in the Tay above Kinclaven) and Banatia (Buchanthy on the Almond). The growing lawlessness of the southern Picts and their frequent raids in the more settled country in the south at last compelled the attention of the emperor Severus. He arrived in Britain in 208, but though he led a strong army to the shores of the Moray Firth, he was unable effectually to subdue the tribesmen. The road he constructed ran from Stirling to Ardoch (where there are notable remains) and thence by Stragean, near Muthill, where it branched north-westwards to Dalginross and Buchanthy, and north-eastwards to Knockando and so forth. When the Romans finally withdrew from Britain, the Picts established their capital first at Abernethy and then at Forteviot. Abernethy was the centre of the Celtic church after the conversion of the natives by Ninian, Palladius and other missionaries in the 6th and 7th centuries. On the burning of Forteviot by the Norsemen in the 8th century, the seat of Pictish government was removed to Scone. In the latter half of the 9th century Dunkeld—to which Kenneth Macalpine had brought some of the relics of Columba from Iona—became the scene of monastic activity, the abbots proceeding to the position of the abbot of Iona, and exercising great influence for nearly a hundred years. The Danes periodically harried the land, but a crushing defeat at Luncarty in 961 put an end to their inroads in this quarter. In 1054 Macbeth was defeated at Dunnsinane by Siward, earl of Northumberland, who had invaded Scotland in the interests of his kinsman, Duncan's son, who, on the death of the usurper three years later, ascended the throne as Malcolm III., called Canmore. With Malcolm's accession the Celtic rule of the monarchy of Scone came to an end. Nevertheless, the Scottish sovereigns (excepting James II., James III. and Mary) continued to be crowned at Scone, which also retained the position of capital until the beginning of the 12th century, when it was displaced by Perth. From the time of Alexander I. (d. 1124), therefore, the history of the shire is merged in that of the county town, with the exception of such isolated incidents as the removal of the Coronation Stone from Scone to Westminster in 1296, the defeat of Robert Bruce at Methven in 1366, the battle of Dupplin in 1332, the victory of Dundee at Killicrankie in 1689 and the indecisive contest at Sheriffmuir in 1715. Among archaeological remains may be mentioned the hill-fort on Dunnsinane; the ship-barrow of the Vikings at Rattray, weems (or earth-houses) in the parishes of Monzie, Alyth and Bendochy; the witch-stone near Cairnibeddie, one of the numerous spots where Macbeth is in all civil and military the witches, but probably a sepulchral memorial of some forgotten battle; standing stones near Pitlochry, and an extraordinary assemblage of sculptured stones near Meigle.

Bibliography.—Robertson, Comitatus de Athelcia (Edinburgh, 1800); P. R. Drummond, Perthshire in Bygone Days (London, 1879); Marshall, Historic Scenes of Perthshire (Perth, 1860); Beveridge, Perthshire-on-Forth (2 vols., London, 1885); R. B. Cunningham-Greene, Notes on the District of Menteith (London, 1895); Hutchison, The Lake of Menteith (Stirling, 1896).

Pertinax, Publius Helvius (A.D. 126-153), Roman emperor, the son of a charcoal-burner, was born at Alba Pompeia in Liguria. From being a teacher of grammar he rose through many imperial offices, both civil and military, to the consulate, which he held twice. Chosen, at an advanced age and against his will, on the 1st of January 193, to succeed Commodus, he was himself assassinated in a mutiny of the soldiers, on the 28th of March 193.

Pertz, Georg Heinrich (1795-1876), German historian, was born at Hanover on the 28th of March 1795. From 1813 to 1818 he studied at Göttingen, chiefly under A. H. L. Heeren. His graduation thesis, published in 1819, on the history of the Merovingian mayors of the palace, attracted the attention of Baron Stein, by whom he was engaged in 1820 to edit the Carolingian chroniclers for the newly-founded Historical Society of Germany. In search of materials for this purpose, Pertz made a prolonged tour through Germany and Italy, and on his return in 1823 he received at the instance of Stein the principal charge of the publication of Monumenta germaniae historica, texts of all the more important historical writers on German affairs down to the year 1500, as well as of laws, imperial and regal archives, and other valuable documents, such as letters, falling within this period. Pertz made frequent journeys of exploration to the leading libraries and public record offices of Europe, publishing notes on the results of his explorations in the Archiv der Gesells. f. deutsche Geschichtskunde (1824-1825). In 1823 he had been made secretary of the archives, and in 1827 principal keeper of the royal library at Hanover; from 1832 to 1857 he edited the Hannoversche Zeitung, and more than once served as a representative in the Hanoverian second chamber. In 1842 he was called as chief librarian to Berlin, where he shortly afterwards was made a privy councillor and a member of the Academy of Sciences. He resigned all his appointments in
1874, and on the 7th of October 1876 died at Munich while attending the sittings of the historical commission.

The *Monumenta* began to appear in 1826, and at the date of his resignation 24 volumes folio (Scriptores, Leges, Diplomata) had appeared. This work for the first time made possible the existence of the modern school of scientific historians of medieval Germany. In connexion with the *Monumenta* Peritz also began the publication of a selection of sources in octavo form, the *Scriptores rerum germanicarum in usum scholarum*; among his other literary labours may be mentioned an edition of the Gesammelte Werke of Lehmitz, and a life of Stein (Leben des Ministers Freiherrn vom Stein (6 vols., 1849-1855)); also, in an abridged form, *Aus Steins Leben* (2 vols., 1856).

**PERU**

(see map)

---

PERU (apparently from Biru, a small river on the west coast of Colombia, where Pizarro landed), a republic of the Pacific coast of South America, extending in a general N.N.W.-S.S.E. direction from lat. 3° 21' S. to about 18° S., with a sea-coast of 1,240 m. and a width of 300 to 400 m., exclusive of territories in dispute. Its area in 1906, including Tacna and Arica, and other disputed territories occupied by neighbouring states, was officially estimated at 1,757,442 sq. kilometers, or 676,638 sq. m.; exclusive of these territories, the area of Peru is variously estimated at 439,000 to 480,000 sq. m., the Gotha measurements being 1,137,000 sq. kilometers, or 439,014 sq. m.

With the exception of parts of the Ecuador, Brazil, and Bolivia frontiers, all the boundary lines have been disputed and referred to arbitration—those with Colombia and Ecuador to the king of Spain, and that with Bolivia to the president of Argentina, on which a decision was rendered on the 9th of July 1899. There have been misunderstandings with Ecuador in regard to some small areas in the Chira valley, but it may be assumed that the line is fixed between Santa Rosa (3° 21' S.) on the Gulf of Guayaquil, and the Chinchipe river, a tributary of the Marañon. At the junction of the Cauchas with that river, that Ecuadorian line descends the Chinchipe to the Marañon, and the Peruvian ascends to a point where it is intersected by a line following the eastern Cordillera northward to the head-waters of the Caquetá, or Japura, which forms the northern boundary down to the Brazilian frontier. This claim covers all eastern Ecuador and a large part of south-eastern Colombia. In 1903 there were encounters between small bodies of Peruvian and Ecuadorian troops on the disputed frontier. After arbitration by the king of Spain had been agreed upon, the question was considered by two Spanish commissions, and modifications favouring Peru were recommended. These became known prematurely, and in May 1910 war was threatened between Peru and Ecuador in spite of an offer of mediation by the United States, Brazil, and Argentina under the Hague Convention.

From the Japura southward to the Amazon, in 4° 13' 21' S., 69° 35' W., and thence up the Javary, or Yavari, to its source in 7° 8' 4° S., 73° 46' 36° W., as determined by a mixed commission, the line has been definitely settled. From near the source of the Javary, or lat. 7° 1' 17' S., a line running eastward to the Madeira in lat. 6° 52' 15' S., which is half the distance between the mouth of the Mamoré and the mouth of the Madeira, divides the Spanish and Portuguese possessions in this part of South America, according to the provisions of the treaty of San Ildefonso of 1777. This line has been twice modified by treaties between Bolivia and Brazil, but without the consent of Peru, which claimed all the territory eastward to the Madeira between the above-mentioned line and the Beni-Madidi rivers, the line of demarcation following the Pablo-bamba, a small tributary of the Madidi, to its source, and thence in a straight line to the village of Conima, on Lake Titicaca. The dispute with Brazil relates to the territory acquired by that republic from Bolivia in 1867 and 1903, and was to be settled, according to an agreement
of 1908, by direct negotiation if possible, or, failing this, by arbitration. The decision of the president of Argentina of the 9th of July 1909, in regard to the remainder of this extensive territory, was a compromise, and divided it into two nearly equal parts. The line adopted starts from Lake Suches, the source of a small river of that name flowing into the north of Lake Titicaca, crossing the Cordillera by the Puno and the Titicaca routes, and following the course of the Lanza, a branch of the Heath river, which forms the dividing line down to its junction with the Madre de Dios, descends to river to the mouth of the Torosonmas, thence in a straight line north-westerly to the intersection of the Tahuan-manu river by the 69th meridian, and thence north on that meridian to the Brazilian frontier. This decision at first gave offence to the Bolivians, but friendly overtures from Peru led to its acceptance by both parties with the understanding that modifications would be made in locating the line wherever actual settlements had been made by either party on territory awarded to the other. With Chile the de facto line is that of the Camarones ravine which separated the old department of Moquegua, and the provinces of Tacna and Arica from that of Tarapacá. The de facto line is that of the Sama river (usually dry), which opens on the coast a little south of Sama point, near 18° S, Chile retaining possession of the two above-mentioned provinces in violation of the treaty of Ancon, which she forced upon her defeated antagonist.

**Physical Geography.**—Peru is divided longitudinally into three well-defined regions, the coast, the sierra and the montaña. The coast, extending from the base of the Western or Mariné Cordillera to the Pacific Ocean, consists of a sandy desert crossed at intervals by rivers flowing through narrow, fertile valleys. The sierra is the region of the Andes, and is about 250 m. in width. It contains subpericline hills, arid table-lands, warm and temperate valleys and ravines. The montaña is the region of tropical forests within the valley of the Amazon, and skirts the eastern slopes of the Andes.

The only large body of water on the coast at no very distant geological epoch, and is nearly as destitute of vegetation as the African Sahara. It is watered, however, by fifty streams which cross the desert at intervals. Half of these have their origin in the mountains of the Andes, and run with a permanent supply of water into the sea. The others, rising in the outer range, which does not reach the snow-line and receives less moisture, carry a volume of water to the sea during the rainy season. The snows that fall on the high mountains are very considerable, though by no means oppressive, heat. From June to September the sky is obscured for weeks together by fog, which is often accompanied by drizzling rain called garua. When it is drizzling is called algarrobo; in the desert it is raining heavily in the Andes, and the rivers are full. When the rivers are at their lowest, the garua prevails on the coast. The climate of the parts of the coast, however, is modified by local circumstances.

The Western Cordillera, overshadowing the Peruvian coast, contains a long line of volcanic mountains, most of them inactive, but their peaks are frequently visited by earthquakes, especially in the southern section of the coast. Since 1579 seventy violent destructive earthquakes have been recorded on the west coast of South America, but the register is incomplete in this respect. The 1568 earthquake, for example, destroyed Callao, on the 28th of October, and there were 220 shocks in the following twenty-four hours. The town was overwhelmed by a vast wave, which rose 80 ft.; and the shocks continued until the following February. On the 15th of August 1868 an earthquake nearly destroyed Arequipa, and great waves rolled in upon the province of Parinacochas. In the 9th of May 1877 nearly all the southern ports were overwhelmed.

The deserts between the river-valleys vary in extent, the largest being more than 70 m. across. On their western margin steep hills rise directly from the alluvial plains. Where the alluvial slope is very gentle, in some places slightly undulating, in others with ridges of considerable height rising out of it. The surface is generally hard, but in many places there are large accumulations of drifting sand, and the sand is also drifted over the surface, generally of a half-moon shape, having their convex sides towards the trade-wind. They are from 1 to 20 ft. high, with an acerate crest, the inner side perpendicular, the outer side and back with a slope of 45°. It is a musical noise in the desert, like the sound of distant drums, which is caused by the eddying of grains of sand in the heated atmosphere, on the crests of the medanos.

Apparently the deserts are destitute of all vegetation; yet three kinds of herbs exist, which bury themselves deep in the earth, and survive long periods of drought. One is an amaranth that grows on the coast under a dry climate. Hearty, another is the Coast Flora. The third is the Martynia and Anisiea, which maintain a subterranean existence during many years, and only produce leafy stems in those rare seasons when sufficient moisture penetrates to the roots. It is made by the algarrobo, a low shrub which along the coast is distributed along the shores of the lakes, and in the valleys of the rivers. It is made by the algarrobo, a low shrub which along the coast is distributed along the shores of the lakes, and in the valleys of the rivers. The leaves of this shrub are used for pasture, and horses enjoy the pendent yellow pods.

For purposes of description, the coast of Peru may be divided into five sections, the principal one from the north: (1) the Plura region; (2) the Lambayeque and Trujillo section; (3) the Santa valleys; (4) the section from Lima to Nasca; (5) the coast.

The great desert-region of Peru extends for nearly 200 m. from the Gulf of Guayaquil to the borders of the Morrope Valley, and is traversed by three rivers—the Tumbes, Chira and Pluta, the last of which forms the boundary between the Plura region and the Tumbes province. On this section, also extending for 200 m., contains the valleys of Santa, Nepeña, Cosma, Huarmey, Fortaleza, Pativilca, Supé and Huaura. The river Santa, which rises in the lake of Conococha, 12,907 ft. above sea-level, carries 500,000,000 cu. m. of water annually. Thence it flows for 125 m. and passes between the central ridge and the eastern valley. The Santa and Nepeña valleys are separated by a desert 8 leagues in width, on the shores of which there is a good anchorage in the bay of Ferrol, where the port of Chimbote is the terminus of the line of the North American mail. The river Viru, which rises on the slope of an outer range called the Cordillera Negra, and are consequently dry during the great part of the year. Wells are dug in their beds, and the fertility of the valleys is thus maintained. The Pativilca (or Barranca) river and the Huaura break...
PERU

through the outer region from their distant sources in the snowy Cordillera, and have a perennial supply of water. There are five branches of the Maranon, the Nea, the Urubamba, the Cuzco, the Urripa, and the Ucayali, which form the Amazon. The name of the river is attributed to the neighboring country of the Ucayali, on whose coast it flows near Carora, the ancient capital of the Peruvian nation, and to the Andes, which are excelled only by the mountains of the Cordillera Occidental and the Cordillera Central of Chile, under which various local names forms the eastern margin of the coastal desert belt from Tacna to northward into Peru. It is an important volcanic region, containing the volcanoes of Tacna, Tocor, Tacora, and Arica. Volcanic eruptions are frequent, and generally these volcanoes are quiescent. Farther north is the Misti volcano rises on the city of Arequipa in a perfect cone to a height of about 20,013 ft., and near its base are the hot sulphur and iron springs and sultry plain of Parinacota. It is said that this is 19,000 ft. above the sea, and in the mountains above Lima the passes attain a height of more than 15,000 ft. In latitude 10° S. the maritime channel separates into two branches, which run parallel for more than 1,000 m., enclosing the remarkable ravine of Callejón de Huaylas—the eastern or main branch being known as the Cordillera Nevada and the western as the Cordillera Negra. On the western peak, overhanging the town of Yungay, is 19,945 ft. high; and most of the peaks in this part of the chain reach a height of 19,000 ft. During the rainy season the mountains are clear at dawn, and the magnificent snowy peaks are clearly seen. But as the day advances the clouds collect. In most parts of the Peruvian Andes the line of perpetual snow is at 16,400 ft.; but on the Cordillera Nevada, above the Callejón de Huaylas, it sinks to 15,000 ft. This greater cold is caused by the intervention of the Cordillera Negra, which intercepts the warmth from the coast. As this lower chain does not reach the snow-line, the streams rising from it are scanty, while the Santa, Pativilca and other coast-rivers which break through it from sources in the snowy chain have a greater volume from the melted snows. At the point where the river Santa breaks through the Cordillera Negra that range begins to subside. There Cordillera continues as one chain to and beyond the frontier of Ecuador.

The Central Cordillera is the true water-parting of the system. No river, except the Maraña, breaks through it to the east or west, while more than twenty coast streams rise on its slopes and force their way through the maritime chain. The Central Cordillera consists mainly of crystalline and volcanic rocks, on each side of which are the lofty Cordilleras, or mountain-knots, strata run stratified and vertical. In 14° 30’ S. the Cordillera central extends with the Eastern Andes by the transverse mountain-knot of Vilca-ñota, the peak of that name being 17,651 ft. above the sea. The great inland basin is formed. The eastern branch of the Maraña, which runs to run parallel with the Maritime Cordillera until, at Cerro Pasco, another transverse knot connects it with the Andes in 10° 30’ S. lat. It then continues northward, separating the basins of the Maraña and Marañon. The Cordillera continues and at the northern frontier of Peru it is at length broken through by the Maraña flowing eastward.

The Eastern Andes is a magnificent range in the southern part of Peru, of Silurian formation, with talcose and clay slates, many quartz veins and true peneis of Saratoga. Mr. Forbes says that the peaks of Illampu (21,709 ft.) and Illimani (21,014 ft.) in Bolivia are Silurian and fossiliferous to their summits. The eastern range is cut through by six rivers in Peru, namely, the Maraña and Huallaga, the Punu and Ucayali, the last five being tributaries of the Ucayali. The range of the Andes in south Peru has a plateau to the west and the vast plains of Punu, Huallaga, and Ucayali. The Sihuas is highly arid, and the precipices of the strata are not less than 10,000 ft. It is nowhere disturbed by volcanic eruptions, except at the very edge of the formation near Lake Titicaca, and in this respect it resembles the northern frontier of Peru. In the eastern, numerous spurs extend for varying distances into the great plain of the Amazonas.

The Andes lose their majestic height to the northward; and beyond Cerro del Pisco the great mountain-knot of the Ichun-cocha and Huallaga and Ucayali. But throughout the length of Peru the three ranges are clearly defined.

For purposes of description the Sierra of Peru may be divided into two parts—the eastern, containing the valleys of the Marañon and Huallaga, and the western, containing the Lake of Chinchay-cocha and the basin of the river Xauxa. The eastern part extends 250 m. to the Knot of Vilcanota with the basins of the Pampas, Apurimac, Vilcamayu and Paucartambo. The fourth is the basin of Lake Titicaca.
Lake Junin, or Chinchay-cocha, in the second section, is 36 m. long by 7 m. broad, and 13,332 ft. above the sea. Its marshy banks are overgrown with reeds and inhabited by numerous water-fowl. From this lake the river Xauxa flows southwards through a depression in the Cordillera, and joins the gull-shaped lake Titicaca (see BOLIVIA), in the fourth or southern section, is divided between Peru and Bolivia. It receives a number of short streams from the ranges shutting in the upper end of the valley; the finest is that from the huge mountain of Don Aranzao, both coming from the Knot of Vilaesota to the north. The Xauxa, which has its source in Lake Xauxa, falls into Lake Titicaca on the north-west side, as well as the Ylpa and Yaye. The principal stream of the Titicaca flows northwards through the peninsula of Copacabana, Campanaria (9 m. from the east shore), Soto and Esteves. There are two other lakes in the Collon, as the elevated region round Titicaca is called. Lake Arapa, a few miles west of and near the east shore of Lake Titicaca, and Lake Umayo is on higher ground to the westward. The lake in Peru which is third in size is that of Parinacochas on the coast west of the foot of the Andes, the jercu (Sambusiri persuina), long by 6 broad, but has never been visited and described by any modern traveller. The smaller alpine lakes, often forming the sources of rivers, are numerous.

The great rivers of the sierra are the Marañon, rising in the lake of Lurincocha and flowing northward in a deep gorge between the Maritime and Central Cordilleras for 350 m., when it forces its way through the mountains at the famous Pongo de Manseriche and enters the opposite valley. The Ucayali, called the Ucayali also, flows northwards into the Peruvian portion of Lake Massua, and, passing Huauco, flows northwards on the other side of the Central Cordillera for 300 m. It breaks through the range at the Pongo de Chasanta and falls into the Marañon. The other great river of the sierra, the Vilcanata, is formed by the joining of the two rivers which flow from the Knot of Cerro Pasco, joins the Pichacate, which is the most important northern affluent of the Ucayali. The Xauxa, becoming afterwards the Mantaro, takes the drainage of Xauxa, Huauco and the Ucayali, and joins the Pichacate. These rivers of this part of the sierra furnish streams which form the main rivers of Rapers, Pampas, Pachuchaca and Pucumirica. These, uniting with the Mantaro, form the End, and the End and Perené (which drains the province of Tambo) form the Tambo. The Vilcanata rises on the Knot of Vilaesota, flows north through a lovely valley, received the Yanatilde and Pauca on its right bank, and, uniting with the Tambo, forms the End and Perené, the most important of these rivers. There are found gorges in a tropical climate, while the upper slopes yield products of the temperate zone, and the plateaux are cold and bleak, affording only pasture and the hardest cereals. Cotton production belongs to every zone. There is a tropical flora in the deep gorges, higher up a sub-tropical, then a temperate, then a sub-arctic flora. In ascending from the coast-valleys there is first an arid range, where the great-branched cacti rear themselves up among the rocks. Farther inland, where the rains are more plentiful, is the cultivation of the quinoa (Chenopodium quinoa), with edible roots—the oco (Oxalis tuberosa), ullucu (Ullucus tuberosus), massua (Tropauliun tuberosum), and leartó (Polymnia sancholcia). Among the first wild shrubs and trees that are met with on ascent are the Paramo (Berberis), the Prickly lettuce, the Mutisía acuminata, with beautiful red and orange flowers, several species of Senecio, calcareolarias, the Schinum molle, with its graceful branches and bunches of red berries, and at higher elevations the blossoms of the begonias. The mounts, 15 000 ft.

Geology.—The Eastern Cordillera, which, however, is but little known, appears to consist, as in Bolivia, chiefly of Palaeozoic rocks; the western ranges of the Andes are formed of Mesozoic beds, together with some Tertiary deposits; these deposits are followed by the Jurassic, where the coast are composed of granite, sienite and other crystalline rocks, sometimes accompanied by limestones and sandstones, which are probably of Lower Cretaceous age, and often covered by marine limestones and sandstones. The Cordillera Negra of the country correspond broadly with the geological divisions.

The constitution of the Mesozoic band varies. Above Lima the western chain of the Andes is composed of porphyritic tuffs and heavy limestones, while the longitudinal valley of the western coast is hollowed in carbonaceous sandstones. From the analogy of the neighbouring countries it is possible that some of the tuffs may be Jurassic, but the other deposits probably belong for the most part to the Pliocene and Tertiary periods. The limestones are composed of the Gault fossils. Like the similar sandstone in Bolivia, it includes seams of coal and is frequently impregnated with cinnabar. It is in this sandstone that the rich mercury mines of Huancavieja are worked.

Further north, in the department of Ancash, the Mesozoic belt is composed chiefly of sandstones and shales, and the limestones which occur on the coast west of their present limit are likewise of Mesozoic age. The Cordillera Negra in this region is in many places cut by numerous dikes of diorite, and it is near these dikes that silver ores are chiefly

found. In the Cordillera Nevada the Mesozoic rocks which form the chain are often covered by masses of modern volcanic rock. Similar rocks are also found in the Cordillera Negra, but the volcanic centres appear to have been in the Sierra Nevada.

Population.—The first trustworthy enumeration of the people of Peru was made in 1795, when there were 617,700 Indians, 241,225 mestizos (Indian and white inter-mixture), 136,311 Spaniards, 42,337 negro slaves and 41,404 mulattos, making a total of 1,026,677, exclusive of the wild Indians of the montaña. Viceroy Toledo's enumeration of the Indians in 1575 gave them a total of 8,000,000, the greater part of whom had been sacrificed by Spanish cruelty. Others had withdrawn into the mountains and forests, and in the native villages under Spanish administration the birth rate had dropped to a small part of what it had been because the great bulk of the male population had been segregated in the mines and on the estates of the conquistadors. This tells a story of depopulation under Spanish rule, to which the abandoned terraces (andenes) on the mountain sides, once highly cultivated, bear testimony. Several diverse totals have been published as the result of the census taken in 1876, which is considered imperfect. One estimate places the total at 2,660,881, comprising about 13·8% whites, 57·6% Indians, 1·9% negroes, 1·9% Asias, chiefly Chinese, and 24·8% mixed races. In 1906 estimates were made under official auspices (see A. Garlant, Peru in 1906, Lima, 1907), which gave the population as 3,547,829, including Tacna (8000). It is believed, however, that this and other larger estimates are excessive. There is no considerable immigration.

The population of Peru is mixed, including whites, Indians, Africans, Asians, and their mixtures and sub-mixtures. The dominant race is of Spanish origin, to a considerable extent mixed with Indian blood. The Indians are in great part descendants of the various tribes organized under the rule of the Incas at the time of the Spanish conquest. There are two distinct general types—the coast tribes occupying the fertile river valleys, who are employed on the plantations, in domestic service in the cities, or in small industries of their own, no longer numerous; and the sierra tribes, who are agriculturists, miners, stock-breeders and packers, still comparatively numerous. In addition to these are the tribes of wild Indians of the montaña region, or eastern forests, who were never under Inca rule and are still practically independent. Their number is estimated at 150,000 to 300,000. Their tribal organization is for the most part as ancient as the customs and material condition. Some live in settled communities and roughly cultivate the soil. Others are hunters and fishermen and are nomadic in habit. Others are intractable forest tribes, having no relations with the whites. The sierra or upland Indians, the most numerous and strongest type, belong largely to the Quichu and Aymara families, the former inhabiting the regions northward of Cuzco, and the latter occupying the Titicaca basin and the sierras of Bolivia. These Indians are generally described as Choles, a name sometimes mistakenly applied to the mestizos, while the tribes of the eastern forests are called Chunchos, barbaros, or simply Indians. The Choles may properly be estimated at about 175,000, or almost one-fifth of the larger part of the sierra population. Practically all the industries and occupations of this extensive region depend upon them for labourers and servants.

The mestizos are of mixed Spanish and Indian blood. There are two general classes—the costeros or those of the coast, and the serranos or those of the sierras. The mestizos of the coast are usually traders, artisans, overseers, petty officers and clerks, and small politicians. In the sierras they have the same general occupations, but there are no social bars to their advancement, and they become lawyers, physicians, priests, merchants, officials and capitalists. The African and Asiatic elements furnish only about 1·6% of the population. The African stock was not taken as slaves even after the conquest, because the coast Indians were physically incapable of performing the work required of them on the sugar estates. All the heavy labour in the coast provinces was performed by them down to 1859, when African slavery was abolished. They have since preferred to live in the towns, although many continue on the plantations. The first Chinese coolies were introduced in 1849 to supply labourers on the sugar estates, which had begun to feel the effects of the suppression of the African slave traffic. At first the coolies were treated with cruelty. The scandals that resulted led to investigations, and their treatment was improved, and it has now become a matter of voluntary contract, usually for two years. Large-scale fair dealing and good treatment are the rule. Many Chinese are also settled in the coast cities. Commercial relations have also been opened with Japan, and a small Japanese colony has been added to the population. The Spanish and African coast is to be seen in the mulattos, quadroons and octoroons that inhabit the warm coast cities. Other race mixtures consist of the zambo (the African-Indian cross), an Asiatic graft upon these various crosses, and an extremely confusing interchange of the various crosses, for which the Spanish races have descriptive appellations. The foreign population is chiefly concentrated in Lima and Callao, though mining and other industries have drawn small contingents to other places.

Education.—Universities and colleges were founded in Peru soon after the conquest, and Lima, Cuzco, Arequipa and Chuquisaca (now the Bolivian town of Sucre) became centres of considerable intellectual activity. Several schools were founded, mainly for the Indian "nobility," schools being created at Lima and Cuzco. The university of San Marcos at Lima is the oldest collegiate institution in the New World, originating in a grant from Charles V. in 1551 to the Jesuits to found a university for natives of the Indies. It was opened at Lima. Its present name, however, was not adopted until 1574, two years after its first secular rector had been chosen. The college of the Salesians in Caralca, founded in 1579 under the presidency of Dr. Unanue, was opened at Cuzco. The university of San Antonio Abad was founded in 1598, and the college of San Geronimo at Arequipa in 1616. The instruction given in these institutions was of the milagro type, that is to say it was such that "under the supervision of the Church. Independence opened the way for a larger measure of intellectual and educational progress, especially for the lower classes. As organized under the law of the 5th of June, 1865, primary schools are free and denominational, and is under the control of the national government. The primary schools are divided into two grades: a free elementary course of two years, and a higher course of three years, in a school called the "correos." The higher centres, such as the University of Lima, were 1508 elementary schools and 862 scholastic centres in 1906. There are, besides these, a large number of private schools, which in 1906 carried about 22,000 pupils on their rolls, or three times the number in the public primary schools. To provide teachers six normal schools have been established, two of which (one for males and one for females) are in Lima. For intermediate or secondary instruction there are fourteen national secular colleges, or professional colleges, and three similar colleges for girls, in Ayacucho, Cuzco and Trujillo. In these the majority of pupils were under the direction of Belgian and German instructors. The private schools of Lima are still numerous and still more are found in other cities and towns that belong to the same category. For higher instruction there are in the various universities: the Universidad Mayor de San Marcos at Lima, and three provincial institutions at Arequipa, Cuzco and Trujillo. All these have faculties of letters and law, and San Marcos alone has in addition faculties of theology, medicine, mathematics and science, philosophy and administrative and political economy. The professional schools include a school of civil and mining engineering at Lima (created 1876), a military school at Chorrillos under the direction of French instructors, a naval school at Callao, nine episcopal seminaries (one for each diocese), a national agricultural school in the vicinity of Lima (created 1902), and a few commercial and other technical schools. At Lima devoted to the education and training of youthful delinquents.

Science and Literature.—Towards the end of the 19th century scientific studies began to receive attention in Peru. Dr. G. Godoy, a native of the French colony of Peru, won a prize of the meridian near Quito, became professor of mathematics at San Marcos in 1750; and the botanical expeditions sent out from Spain gave him an opportunity to study and excavate in the high sierras. A native of Huamantanga in the Maritime Cordillera, studied un der Dr. Jussieu, and became an eminent botanist. Don Hipolito Unanue, born at Arica in 1755, wrote an important work on the geography of the coast, and was sent to scientific expeditions in the south. A native of Huanca in the province of Lima, and an officer in the navy, the periodical was started in 1791 at Lima, the contributors forming a society called "amantes del pais," and it was completed in eleven volumes. It contains many valuable articles on history, topography, science, and literature. A national statistical society in Lima was begun by the learned geographer Dr. Cosme Bueno, and continued by Dr. Unanue, who brought out his guides at Lima from 1793 to 1798. In 1794, a nautical school was founded at Lima, with Andres Buleato as instructor and Pedro Alvarez as teacher of the use of instruments. Buleato also constructed a map of Peru.
A list of Peruvian authors in viceregal times occupies a long chapter in the life of St Toribio of Montalvo; and the bibliographical labours of the Peruvian Leon Pinoelo are still invaluable to Spanish students. The most prolific author of colonial times was Dr Pedro de Arvelo (1658-1733), who wrote more than sixty works, including an epic poem entitled "Lima fundada".

The topographical labours of Cosme Bueno and Unanue were ably continued at Lima by Admiral Don Eduardo Carrauso, who completed the memoirs of the noted Peruvian geographer Don Mariano Felipc Paz Soldan (1821-1886), whose "Geografia del Peru" appeared in 1861. His still more important "Memorias histórico-geograficos del Peru" has been published by the Lima Geographical Society (founded in 1888) in three volumes by Sebastian Lorente (d. 1884); Mariano Rivero has discussed its antiquities; and Manuel Fuentes has edited six volumes of memoirs written by Spanish viceroys and a volume of his own important, but hitherto unpublished, works. The Lima Geographical Society, founded in 1888, is the best and most active scientific organization in the republic. Its special work covers national geographical exploration and study, archaeology, and the preservation of the earth's resources and its invaluable information. The society receives a government subsidy, and its rooms in the national library in Lima are the principal centre of scientific study in Peru. It had an active membership of 163 in 1906, besides 170 honorary and corresponding members.

The historical institute of Peru, also at Lima, is charged by the government, from which it receives a liberal subsidy, with the work of collecting, preparing and publishing documents relating to Peruvian history, and of preserving objects of archaeological and historic character. Its museum, which is of great historical and artistic value and includes a collection of portraits of the Peruvian viceroys and presidents, is in the upper floors of the Exposition Palace. An institute linked with the government is the "Arqueologia," founded in 1877 as the "literary club," and reorganized in 1887 under its present title. Its purpose is to foster learning and literary work, and it is a popular and prominent feature in the intellectual life of the city.

Religion.—According to the constitution of 1866 "the nation professes the apostolic Roman Catholic religion; the state protects the religious observance of all consciences, and exempts the members of the Catholic church from a certain degree of tolerance, however, and the Anglican and some of the evangelical churches are permitted to establish missions in the country, but not always without hostile demonstrations from the Catholic priesthood. There are Anglican churches in Lima and Cuzco, belonging to the diocese of the Bishop of the Falkland Islands; but their existence is illegal and is ignored rather than permitted. In its ecclesiastical organization Peru is divided into nine dioceses: Arequipa, Arequipa, Huancayo, Huaraz, Trujillo, and Chachapoyas. These dioceses are subdivided into 613 curacies, presided over by curas, or curate-vicos. Each diocese has its seminary for the education of the priests that of Arequipa is distinguished by its influence in church and affairs. Arequipa, like Cordoba and Chiquisca, is a stronghold of clericalism and exercises a decisive influence in politics as well as in church matters. There are a number of fine churches in Lima and in the sees of the various dioceses. Monasteries and nunneries are numerous, dating back to the 16th and 17th centuries, but their influence is now less potent than in those days and the monastic life is not so flourishing. In modern times many of the convents have been devoted to educational work, especially for girls, which is an obstacle to the successful development of a public school system in the country.

Political Divisions.—The empire of the Incas was divided into four main divisions, Chinchay-suyu to the north of Cuzco, Anti-suyu to the east, Colla-suyu to the south and Cunti-suyu to the west, the whole empire being called Tahuantin-suyu, or the four governments. Each was ruled by a vicereign under whom were the "huarancas-camayocs," or officers ruling over thousands, and inferior officers, in regular order, over 500, 100, 50 and 10 men. All disorders and irregularities were checked by the periodical visits of the tucuywicos or inspectors. The Spanish conquest destroyed this complicated system. In 1569 the governor, Lope Garcia de Castro, divided Peru into corregimientos under officers named corregidores, of whom there were 77, each in direct communication with the government at Lima. An important administrative reform was made in 1784, when Peru was divided into 7 intendencias, each under an officer called an intendente. These intendencias included about 6 of the old corregimientos, which were called partidos, under officers named partidores. Thus the intendencia system was established, and Lima was reduced from 77 to 7, a great improvement. The republic adopted the same system, calling the intendencias departments, under a prefect, and the partidos provinces, under a sub-prefect. Peru is divided into 18 departments, 2 litorral provinces, and what is called the constitutional province of Callao. This is exclusive of Tacna and its 3 provinces. The departments, which contain 98 provinces, with their areas, capitals and estimated populations of 1906, are as follow: the
Apart from the departmental capitals there are few towns of size and importance. The so-called coast towns are commonly at some distance from the seashore, and their shipping ports are little more than a straggling collection of wretched habitations in the vicinity of the landing-stage and its offices and warehouses. Callao (q.v.) is a noteworthy exception, and Paita and Pisco are something more than the average coast village. Near Lima, on the south, there are three bathing resorts, Chorrillos, Miraflores and Barranco, which have handsome residences and large populations. Most of Lima is the port and bathing resort of Ancon, in an extremely arid locality but having a fine beach, a healthy climate and a considerable population in the season. The towns of the coast region are usually built on the same general plan, the streets crossing each other at right angles and enclosing squares, or quarlas. In the sierra there is the same regular plan wherever the site is level enough. High-pitched red tiled roofs take the place of the flat roofs of the coast. The upper storey often recedes, leaving wide corridors under the overhanging eaves, and in the “plazas” there are frequently covered arcades. In addition to the capitals of the departments, Tarma (about 4000 ft.), Xexa, Chos, Jasia (about 6600 ft.), are of importance in this region. In the montaña there are no towns of importance other than the capitals of the departments and the small river ports.

Communications.—The problem of easy and cheap transportation between the coast and the interior has been a vital one for Peru, for upon it depends the economic development of some of the richest parts of the republic. The arid character of the coastal zone, with an average width of about 80 m., permits cultivation of the soil only where water for irrigation is available. Only in the sierra and montaña regions is it possible to maintain a large population and develop industries upon which their success as a nation depends. During colonial times and down to the middle of the 19th century pack animals were the only means of transportation across the desert and over the rough mountain trails. Railway construction in Peru began in 1848 with a short line from Callao to Lima, but the building of railway lines across the desert to the inland towns of the fertile river valleys and the Andean forests did not begin until twenty years later. These roads added much to the productive resources of the country, but their extension to the sierra districts was still a vital necessity. Under the administration of President José Balta the construction of two transcontinental main lines was begun, but their completion became impossible for want of funds. Balta’s plans covered 1281 m. of state railways and 749 m. of private lines, the estimated cost to be about $37,380,000—a sum far beyond the resources of the republic. This plan was abandoned, but the two transcontinental lines were the famous Oroya railway, running from Callao to Oroya (1893), which crosses the Western Cordillera at an elevation of 15,645 ft., and later on to Cerro de Pasco (1904), the Goilariosquía coal mines (1904) and Hauri (1906); and the southern line from Mollendo to Lake Titicaca, which reached Aréquipa in 1896, Puno in 1871 and Checcacuero (Cuzco branch) in 1906. Surveys were completed in 1904 for an extension to Arica, 850 m. north of the Pacific to the northwest of Lima, which would take the railroad to the mouth of the Ucayali, and a new railroad line to the east of the Apurímac in northern Peru. From the eastern end of the line on the coast near Pisco eastward to the Ucayali, and another transandine line frequently discussed is projected from Paita across the Andes to the mouth of the Marañon, or Iquitos River.

The most important means of communication in the republic is that of its river system, comprising, as it does, the navigable channels of the Marañon, or upper Amazon, and its tributaries. In this regard the upper Marañon system is the chief, for from its source to Iquitos near 20,000 m. of connected railways navigable at high water for all descriptions of boats, or 10,000 m. for steamers of 20 to 2 ft. draught, which is reduced to 5800 m. at low water. The rivers forming the lower Marañon system are the Maynas and Huallaga, and are connected with the Marañon by a series of canals. From the Brazilian frontier (484 m.), the Japurá, Putumayo, Javyary, Napo, Tigre, Huallaga, Ucayali, Pachitea, Jururí, Purús, Acre, Curaray and Aguaro are all navigable over parts of their courses by small craft. The chief important river port is Iquitos, on the Marañon, 335 m. above the Brazilian frontier and 2653 m. from the mouth of the Amazon. It is served by ocean-going steamers, and is the centre of the Peruvian river transport system in the interior. The principal rivers south of Iquitos are the Marañon, Huallaga, and Purús, on the Ucayali, 143 m. from the mouth of that river and 528 m. from Iquitos, with which it is in regular communication. There are small ports, or trading posts, on all the large rivers, and sometimes the smaller streams, where there is no regular steam navigation, but from which furs, rubber and other forest products are shipped. The rivers farther south, which discharge into the Amazon through the Madeira, the Madre de Dios alone offers an extended navigable channel, with some difficulties. The rivers of the Heath and Chandelier. Of a widely different character is the navigation of Lake Titicaca, where steamers ply regularly between Puno and Titicaca. The latter is connected by river from east with the Madre de Dios also offers an extended navigable channel, with some difficulties. The turning of the lake is 135 m. long and from 70 to 80 m. wide and has a 4 ft. draught.

There are two submarine cable lines on the Peruvian coast—the (American) Central and South American Co., extending from Panama to Valparaiso, and the (British) West Coast Cable Co., subsidiary to the Eastern Telegraph Co., with a cable between Callao and Valparaiso. The inland telegraph service dates from 1864, when a short line from Callao to Lima was constructed, and state ownership from 1875, when the government assumed control of the system. It now extends within the city limits from 130 points, and is handed over to private administration. They connect all the important cities, towns and ports, but cover only a small part of the interior. The communication of the interior with the coast is more difficult, and the montaña and sierra regions is too great to permit their extensive use, and the government is seeking to substitute wireless telegraphy. From Puerto Bermúdez, on the Pachitea or Pichicuy, and Lurin, on the Chanchamayo, important telegraph and wireless system connects with Massisca on the Ucayali, and thence with Iquitos, on the Marañon—a distance of 930 m. by steamer, which is much shortened by direct communication between the three stations. This service was opened to Iquitos on the 8th of July 1906, the first section to Puerto Bermúdez and Massisca having been pronounced a success. The Peruvian telegraph system connects with those of Ecuador and Bolivia. The importance of the cable service is increased by the fact that the islands of the South American coast are all in the same time zone, and are therefore well served in the communication with the South American countries. Peru belongs to the international postal union, and had in 1906 a money order and parcels exchange service. The post-office is that an extra charge of 2 cents for each letter and 1 cent for each post-card is collected when they are sent across the isthmus of Panama. No charge is made for the transmission of registered mail. The use of registered mail is restricted to importers for over 15 grams, or 10 cents to foreign countries in the postal union.

Commerce.—Owing to political disorder, difficulty in land communications, and the inheritance of vicious fiscal methods from Spanish times and from the national debt, the foreign commerce of Peru has been slow and erratic. There are many ports on the coast, but only eight of them are rated as first class, viz., Paita, Ica, Eten, Pacasmayo, Salaverry, Callao, Pisco, Mollendo and Lo, of which are ports of call for foreign coasting steamers. The inland port of Iquitos, on the Marañon, is also rated as first class, and enjoys special privileges because of its distance from the national
capital. The second-class ports are Tumbes, Talara, Pimentel, Chimbote, Samancos, Casma, Huacho, Cerro-Azul, Tambo de Mora, Lomas and Chala, on the coast, Puno on Lake Titicaca, and Lima. After the withdrawal of the Spanish, Callao (q.v.) is the chief port of the republic and monopolizes the greater part of its foreign trade. Its harbour, one of the best on the west coast of South America, is enabled by the port works begun under the administration of President Balta. Paita and Chimbote have good natural harbours, but the others, for the most part, are open roadsteads or unsheltered bays. Montevideo is a smaller port devoted for the greater part of the year to the export of fish from Puno. There were 12 foreign steamship lines trading at Peruvian ports in 1908, some of them making regular trips up and down the coast at frequent intervals and carrying much of its coastwise trade. Only the carrying trade was permitted to engage in this traffic, but permission is given to steamships on application and under certain conditions. The imports were valued in 1907 at $5,147,870 soles (10 soles = £1 s. gt.) and the exports at $5,320,810. In 1906, $5,362,172 were exported, and the imports reached $5,443,297. The increase and the latter a small decrease in comparison with 1906. The exports consist of cotton, sugar, cocaine, hides and skins, rubber and other forest products, wine, gum, paper and mineral products. The most important export is sugar, the product of the two ranking second. The largest share in Peru's foreign trade is taken by Great Britain, Chile ranking second and the United States third.

Products.—Although her mining industries have been the longest and most widely known, the principal source of Peru's wealth is agriculture. This seems incompatible with the arid character of the land. The great caracoles, or irrigation ditches, which have been successfully employed in the fertile valleys of the coast.

Agriculture.—Sugar-cane is cultivated in most of the coastal valleys and in the mountainous districts of those in the Canete, Rimac, Chancay, Huaura, Supe, Santa, Chicama, Pacasmayo and Chichayso. Some of the large estates are owned and worked by British subjects. The industry was nearly ruined by the Caracoles in 1904, but its recovery is largely due to the war and the irrigation has been steadily increasing. At the outbreak of the war the production was about 80,000 tons; in 1905 the production of sugar and molasses amounted to 161,851 metric tons, or of which 109,414 were exported. In 1906 the total production reached 169,148 metric tons. Next in importance is cotton, which is grown along the greater part of the Peruvian coast, but chiefly in the department of Chanchamayp. The chief kind is the cotton or "vegetable wool," sea island, brown or Mitafifi, and smooth or American. Production is steadily increasing, the export having been 80,000 metric tons in 1900, 17,386 in 1903 and 20,000 in 1906. The consumption required about 2900 of the mines ranking second. The largest share in Peru's foreign trade is taken by Great Britain, Chile ranking second and the United States third.

commercial asset of the republic. The large revenues derived from these sources undoubtedly became a cause of weakness and demoralization and eventually resulted in bankruptcy and the loss of Peru. The production and export of the large shipments of over a half-century, but the export in 1905 was 73,859 tons, valued at £285,729.

Mining—Mining was the chief industry of Peru under Spanish rule. The agricultural and pastoral people, but the abundance of gold and silver in their possession at the time of the conquest shows that mining must have received considerable attention. They used these precious metals to decorate their ornaments and with the assistance of Indian slaves thousands of mines were opened, many of them failures, some of them becoming famous. There was a decline in mining enterprise after the revolt of the colonists in 1810, and the later breaking up of the extensive state of the country, and this decline continued in some measure to the end of the century. The mining laws of the colonial régime and political disorder together raised a barrier to the employment of the large amount of capital needed, while the frequent outbreak of civil war made it impossible to work any large enterprise because of its interference with labour and the free use of ports and roads. The Peruvians were impoverished, and under such conditions forced labour could not be employed. In 1876 new mining laws were enacted which gave better titles to mining properties and better regulations for their operation, but the outbreak of the war with Chile again raised the question of disorganization and partisan strife defeated their purpose. Another new mining code was adopted in 1901, and this, with an improvement in political and economic conditions, has led to a renewal of mining enterprise.

Practically the whole Andean region of Peru is mineral-bearing—a region 1500 m. long by 200 to 300 m. wide. Within these limits are to be found most of the minerals known—gold, silver, quicksilver, copper, lead, zinc, iron, manganese, wolfram, bismuth, thorium, vanadium, mica, coal, &c. On or near the coast are coal, salt, sulphur, borax, nitrates and petroleum. Gold is found in lodes and alluvial deposits; the former on the Pacific slopes of Salpo, Quinua, and Puni; the latter on the slopes of Lacte, Ica, Nancagua, Andaray and Arequipa, and on the table-lands and Amazon slope at Pataz, Huaynuco, Chiquitambo, Huancavelica, Cuzco, Cota- bamba, Aymares, Pucarramata, and Arequipa. The district of Junin, the latter wholly on the Amazon slope, in the country about the Pongo de Manseriche and at Chucullamba, both on the upper Marañon, in the districts of Pataz, Huaynuco, Aymares and Antabamba, in the province of Huanca, is known as the pampas. The Aporoma deposit, in the district of Sandia, is the best known. Long ditches with stone-paved sluices for washing this mineral-bearing material have long been used by the Indians, who also employ the large number of crosses across the rillies and hold the deposited grains of gold. Modern methods of hydraulic mining have been introduced to work the auriferous banks of Poto; elsewhere antiquated methods only are employed. The numerous small gold mines have not been designated. The number of mines worked is small and there is not much foreign capital invested in them. The gold ores of Peru are usually found in ferruginous quartz. The production in 1906 was valued at £121,000.

Peru has been known chiefly for its silver mines, some of which have been marvelously productive. The Cerro de Pasco district, with its 374 mines, is credited with a production in values of £40,000,000 between 1784 and 1889, and is still productive, the output for 1906 being valued at £972,958. The principal silver-producing districts, the greater part on the high table-lands and along the northern slope of the Andes, are Huancavelica, Huaylas, Huaura, Recuay, Cajatambo, Yauyos, Cerro de Pasco, Morococha, Huarochiri, Huancavelica, Quepísipa, Castro-virreyna, Lucasas, Lampay, Cajlloma and Puno, but there are hundreds of others outside their limits. Silver is generally found as red oxides (locally called resiciter), sulphides and argentiferous galena. Modern machinery is little used and many mines are practically unworkable for want of pumps. In the vicinity of some of the large gold mines large quantities of silver are found. Wood timber is scarce on the table-lands. The dried dung of the llama (touca) is generally used as fuel, as in pre-Spanish times, for roasting ores, as also a species of grass called chu (Shipa indica), and a species of tobacco (Anchira umbrilera) which grows on the rocks at elevations exceeding 12,000 ft. The methods formerly employed in reducing ores were lixiviation and amalgamation, but these methods are being modified and cast into use. Quicksilver is found at Huancavelica, Chonta (Anancha), and in the department of Puno. The mine first named has been worked since 1566 and its total production is estimated at 60,000 tons, the annual product being about 670 tons for a long period. The metal generally occurs as sulphide of mercury (cinnabar), but the ores vary greatly in richness—from 2½ to 20%. The lead is found, always in association with silver, as galena and argentiferous pyrites, which are gangue minerals. There are large deposits of copper, chiefly at Ayacucho, Cajamarca, Huancayo, Huazlla, Junin, Huancavelica, Ica, Arequipa, Andahuaylas and Cuzco—chiefly situated in the province of Huanca, of which Ica is the capital and includes the Cerro de Pasco, Yauyos, Morococha and Huallay groups of mines, all finding an outlet to the coast over the Oroya railway. These mines are of recent development, the Cerro de Pasco, Yauyos, Morococha and Huallay groups being in the hands of capitalists. A smelting plant was erected in the vicinity of Cerro de Pasco designed to treat 1000 tons of ore daily, a railway was built to Oroya to connect with the state line terminating at that point, and a branch line 62 m. long was built to connect the mine with the Southern Railway.

The Cerro de Pasco mines are supposed by some authorities to be the largest copper deposit in the world. In addition to the smelting works at Cerro de Pasco there are other large works at Casapalca, between Oroya and Lima, which belong to a British company, and smaller plants at Huallanca and Huinac. The production of copper is steadily increasing, the returns for 1906 being 2947 tons and for 1907 3,874 tons, valued respectively at £476,824 and £996,095. Of other minerals, lead is widely distributed, its chief source being a high grade galena accompanied by silver. Iron ores are found in Piura, the Huaylas valley, Aya, Huancavelica and several other districts, but the producing deposits are few, most being worked out. Barite is found in large beds on the coast at Piura, and at Goallarquisgua. The Cerro de Pasco mines are known for their lead, iron, copper, tin, antimony, and copper ores. There have been large copper deposits in the district of Zaña, of which the most important is the Cerro de Pasco, which has been worked for many years.

The number of mining claims (pertenencias) registered in 1907 was 10,000, representing an annual mining expenditure of £100,000. The number of operating mines is 300, of which 150 are in the province of Lima, 20 are in the province of Ancash, and 60 are in the province of Junin, where the largest mines are found. The principal copper mines are at Chancay, Pampa de Punta, and the district of Arequipa. The copper deposits in the province of Junin are situated at several points on the coast in the department of Piura, and near Lake Titicaca in the department of Puno. The most productive of the Piura wells are at Talara and Zorritos, where refineries have been established. The crude oil is used on some of the Peruvian railways.

The mining industry of Peru is confined chiefly to the treatment of agricultural and mineral products. The manufacture of sugar and rum from sugar cane, textiles from cotton and wool, wine and spirits from grapes, cigars and cigarettes from tobacco, and paper from the peba and man, are large industries. The manufacture of crude petroleum, cocaine from coca, and refined metals from their ores. Many of the manufacturing industries are carried on with difficulty and maintained only by protective duties on competing foreign goods. The greatest strides have been made in the manufacture of artificial or counterfeit spirits and liqueurs in Callao and Lima. There are breweries in Arequipa, Callao, Cuzco and Lima, and the consumption of beer is increasing. There are large cigarette factories in Lima, and others in Arequipa, Callao, Puno and Trujillo. The plating of Panama hats from the specially prepared fibre of the "toquilla" palm is a domestic industry among the Indians at Cucuco (Piura) and Eten (Lambayeque). Panama hats are made at other places, as well as hammers, baskets, &c.

Government.—Peru is a centralized republic, whose supreme law is the constitution of 1860. Like the other states of South America its constitution provides for popular control of legislation and the execution of the laws through free elections and comparatively short terms of office, but in practice these safeguards are often set aside and dictatorial methods supersede all others. Namely the people are free and exercise
sovereign rights in the choice of their representatives, but the
government is accorded to all Peruvians over the age of 21 and
to all married men under that age, and the right of suffrage to
all citizens who can read and write, or possess real estate
or workshops, or pay taxes. In all cases the exercise of
citizenship is regulated by law.

The government is divided into three independent branches,
executive, legislative, and judicial, of which through force
of circumstances the executive has become the dominating
power. The executive branch consists of a president and two vice-
presidents elected for terms of four years, a cabinet of six
ministers of state appointed by the president, and various
subordinate officials who are under the direct orders of the
president. The president is chosen by a direct popular election
and cannot be re-elected to succeed himself. He must be not
less than 33 years of age, a Peruvian by birth, in the enjoyment
of all his civil rights, and domiciled in the republic ten years
preceding the election. The immediate supervision and dispatch
of public administrative affairs is in the hands of the cabinet
ministers—interior, foreign affairs, war and marine, finance
and commerce, justice and public instruction, and public works
and promotion (fomento). The execution of the laws in the depart-
ments and provinces, as well as the maintenance of public
order, is entrusted to prefects and sub-prefects, who are appoint-
ees of the president. A vacancy in the office of president
is filled by one of the two vice-presidents elected at the same
time and under the same conditions. Inability of the first
vice-president to assume the office opens the way for the
second vice-president, who becomes acting president until a
special election is held to fill the vacancy. A rainy election is
for the presidency during their occupancy of the supreme
executive office, nor can the ministers of state, nor the general-
in-chief of the army, while in the exercise of their official duties.

The legislative power is exercised by a national Congress—
chamber and senate of deputies—meeting annually on the
28th of July in ordinary session for a period of 90 days. Sena-
tors and deputies are inviolable in the exercise of their duties,
and cannot be arrested or imprisoned during a session of Congress,
including the month preceding and following the session, except
in flagrante delito. Members of Congress are forbidden to
accept any employment or benefit from the executive. Senators
and deputies are elected by direct vote—the former by de
mans, the latter by Departments—proportioned to the population.
With both are elected an equal number of substitutes, who
may be in case of vacancy.

Departments with eight and more provinces are entitled to four
senators, those of four to seven provinces three senators, those
of two to three provinces two senators, and those of one province
one senator. The deputies are chosen to represent 15,000 to 30,000
population each, but every province must have at least one
deputy. Both senators and deputies are elected for terms of six
years, and both must be native-born Peruvian citizens in the full
enjoyment of their civil rights. A senator must be 35 years of age,
and have a yearly income of $1000. The age limit of a deputy is
25 years, and his income must be not less than $500. In both
cases the candidates are chosen by popular vote, except in the
lieu of the pecuniary income. No member of the executive
branch of the government (president, cabinet minister, prefect,
sub-prefect, or governor) can be elected to either chamber, nor can
any judge or "fiscal" of superior and first-instance courts from their
judicial districts, nor any military officer from the district where
he holds office, unless he renounces his portfolio at the time of
election. Congress is provided with more and better safeguards against electoral
and official abuses than is Peru, and yet few countries suffered
more from political disorder during the 19th century. The president
has no veto power, and the right of appeal to the supreme
court is allowed on all matters except with comments within a period of ten days. Should the act be again
passed without amendments it becomes law; if, however, the
suggested amendments are accepted, the president must
submit the bill to the Congress, so as to be re-appro
motion. Congress may also sit as a court of impeachment—
the senate hearing and deciding the case, and the chamber acting
as prosecutor. The president, ministers of state and judges of the
supreme court may be brought before this court.

Justice. — The judiciary is composed of a supreme court, superior
courts and courts of first instance, and justices of the peace. The
president of the supreme court is elected for a term of four years by the
court of 11 judges and 2 "fiscales" or prosecutors. The judges
are selected by Congress from lists of nominees submitted by the executive.
The judges of the superior courts are chosen by the presi-
dent, who makes up the list of nominees. Questions of jurisdiction between the superior and supreme
courts, as well as questions of like character between the supreme
court and the executive, are decided by the senate sitting as a
court of review. The supreme court and the courts of provinces and their judges are chosen by the supreme courts of
the districts in which they are located. The independence of
the Peruvian courts has not been scrupulously maintained, and there
has been much criticism of their administration.

The national executive appoints and removes the prefects of the
departments and the sub-prefects of the provinces, and the
depot of the court of each district. The courts of first instance are
distributed throughout the republic are also appointed by the
president and are under his command.

The courts of justice are divided into supreme courts, with
a jurisdiction limited to each of the four districts, and to the
capital. There are also one or more first-instance courts in
each of these districts, which have jurisdiction over all
questions except those of national importance. In the province of
Lima, there are a supreme court and a Court of Justice.

1830 the debt and accumulated interest owing in Peru amounted to £2,310,767, in addition to which there was a home debt of 17,183,577 dollars. In 1848 the two London loans and accumulated interest amounted to £6,000, and so much of the debt was partially liquidated, the sale of guano giving the treasury ample resources. Lavish expenditure followed and the government was soon anticipating its revenues by obtaining advances from foreign banks on unfledged claims, and the debt was increased by new loans. There was another conversion loan in 1862 in the sum of £5,500,000 and in 1864 still another loan of £10,000,000, of which £7,000,000 only were issued. Then followed a period of financial depression which lasted until 1870.

In 1876 interest payments on account of this debt were suspended and in 1879-1882 the war with Chile deprived Peru of her principal source of income—the guano deposits and the Tarapacá nitrates. In the subsequent foreign debt, including advances of the European banks, which was nominally £54,000,000, and in the following year a contract was signed with the Peruvian Corporation, a company in which the bondholders became shareholders, for the transfer to it for 66 years of the state railways, the free use of certain ports, the right of navigation on Lake Titicaca, the exploitation of the remaining guano deposits up to 3,000,000 tons, and thirty-three annual subsidies of £80,000 each, in consideration of the cancellation of the debt. Some modifications were subsequently made on the contract, as there was a failure to meet the annual subsidies and the corporation's failure to extend the railways agreed upon. This contract relieved Peru of a large foreign debt, increased the national credit, and apparently heavy loss to the bondholders into a possible profit.

In 1910 the foreign debt stood at £3,140,000, composed of (1) Peruvian Corporation £2,160,000; (2) wharves and docks, £90,000; (3) loan of 1856 converted in 1906.

Currency.—The single gold standard has been in force in Peru since 1897 and 1898, silver and copper being used for subsidiary coinage.
The monetary unit is the Peruvian pound (libra) which is uniform in weight and fineness with the British pound sterling. Half and fifth pounds are also coined. The silver coinage consists of the sol (100 cents), half sol (50 cents), and pieces of 20 (peso), 10 and 5 cents; and the copper coinage of 1 and 2 cents.
The silver coins were used for everyday purposes and were, in fact, making the British pound sterling legal tender in the republic and establishing the legal equivalent between gold and silver at 10 soles to the pound. The coinage in 1906-1907 was about £150,000 gold and £8,000 silver, and the total circulation in that year was estimated at £1,400,000 in gold coin and £600,000 in silver coin. Previous to the adoption of the single gold standard in 1897 the monetary history of Peru had been unfortunate. The first national coinage was established in 1531, on the silver arroba, and that system was continued until 1863. Although the double standard was in force, gold was practically devaluated by the monetary reform of 1872 because of the failure to fix a legal ratio between the two metals. Experience with silver alone even silver coinage was unsuccessful. The treasury administration (1872-1876) of President Pardo the government borrowed heavily from the banks to avoid the suspension of work on the railways and various public and port improvements. These banks enjoyed the privilege of issuing notes against a contingent of their deposits, which enabled them to obtain cash in hand without regard to their commercial liabilities. A large increase in imports, caused by fictitious prosperity and inability to obtain drafts against guano shipments, led to the exportation of silver and gold in coin to meet commercial obligations, and this soon reduced the currency circulation to a paper basis. The government being unable to repay its loans from the banks compelled the latter to suspend the conversion of their notes, which began to depreciate in value. In 1875 the banks were granted a moratorium, to enable them to obtain coin, but without result. The government in 1877 contracted a new loan with the banks and assumed responsibility for the interest, but the banks declined to have anything to do with about 100,000,000 soles, and were worth barely 10% of their nominal value. At last their depreciation reached a point where their acceptance was generally refused and silver was imported for commercial needs, when the government suspended their legal tender quality and allowed them to disappear.

Weights and Measures.—The French metric system is the official state system, and measures and weights are in use in the custom-houses of the republic and in foreign trade, but neither weights nor measures are commonly used among the people. These are the ounce, 1,104 oz. avoirdupois; the libra, 1,014 lb avoirdupois; the quintal, 101,44 lb avoirdupois; the arroba, 15 lb; the arroba, 21 lb; ditto; the vara, 4-70 imperial gallons; the gallon, 74 of an imperial gallon; the vara, -972 yard; and the square vara, -899 square yard. (A. J. L.)

History.—Cyclopean ruins of vast edifices, apparently never completely, exist at Titauanaco near the southern shore of Lake Titicaca. Remains of a similar character are found at Huara in the north of Peru, and at Cuzco, Ollantay-tambo and Huiaque between Huaraz and Tituauanaco. These works appear to have been erected by powerful sovereigns with unlimited command of labour, possibly with the object of giving employment to subjugated people, while feeding the vanity or pleasing the taste of the conqueror. Of their origin nothing is historically known. It is probably, however, that the settlement of the Cuzco valley and district by the Incas or "people of the sun" took place more than 300 years before Pizarro landed in Peru. The conquering tribe or tribes had made their way to the sierras from the plains, and found themselves a new land sheltered from attack amidst the lofty mountains that hem in the valley of Cuzco and the vast lake basin of Titicaca, situated 12,000 ft. above the sea level. The first historical records show us these people already possessed of a considerable civilization, and speaking two allied languages, Aymara and Quichua. The expansion of the Inca rule and the formation of the Peruvian Empire was of modern growth at the time of the Spanish conquest, and dated from the victories of Pachacutic Inca who lived about a century before Huayna Capac, the Great Inca, whose death took place in 1532, the year before Pizarro first appeared on the coast. His conquests extended from the river Maranon north of Quito to the river Maule in the south of Chile. The Incas had an elaborate system of state-worship, with a ritual, and frequently recurring festivals. History and tradition were preserved by the bards, and dramas were enacted before the sovereign and his court. Roads with post-houses at intervals were made over the wildest mountain-ranges and the bleakest deserts for hundreds of miles. A well-considered system of land-tenure and of colonisation provided for the wants of all classes of the people. The administrative details of government were minutely and carefully organized, and accurate statistics were kept by means of the "quipus" or system of knots. The edifices displayed marvellous building skill, and their workmanship is unsurpassed. The world has nothing to show, in the way of stone-cutting and fitting, to equal the skill and accuracy displayed in the Inca structures of Cuzco. As workers in metals and as potters they displayed infinite variety of design, while as cultivators and engineers they excelled their European conquerors. (For illustrations see AMERICA, Plate V.)

The story of the conquest has been told by Prescott and Help, who give ample references to original authorities; it will be sufficient here to enumerate the dates of the leading events. On the 10th of March 1526 the contract for the conquest of Peru was signed by Pizarro, Diego de Almagro and Hernando de Luque. Gaspar de Espinosa, another of Pizarro's associates, was named as Pizarro's successor. Pizarro, after enduring fearful hardships, first reached the coast of Peru at Tumbes. In the following year he went to Spain, and on the 20th of July 1529 the capitulation with the Crown for the conquest of Peru was executed. Pizarro sailed from San Lucar with his brothers in January 1530, and landed at Tumbes in 1531. The civil war between Huascar and Atahualpa, the sons of Huayna Capac, had been fought out in the meanwhile, and the victorious Atahualpa was at Cajamarca on his way from Quito to Cuzco. On the 15th of November 1532 Pizarro with his little army, made his way to Cajamarca, where he received the friendly welcome from the Inca, whom he treacherously seized and made him prisoner. He had with him only 185 men. In February 1533 his colleague Almagro arrived with reinforcements. The murder of the Inca Atahualpa was perpetrated on the 29th of August 1533, and on the 15th of November Pizarro entered Cuzco. He allowed the rightful heir to the empire, Manco, the legitimate son of Huayna Capac, to be solemnly crowned on the 24th of March 1534. Almagro then undertook an expedition to Chile, and Pizarro founded the city of Lima on the 18th of January 1535. In the following year the Incas made a brave attempt to expel the invaders, and closely besieged the Spaniards in Cuzco during February and March. Almagro, returning from Chile, raised the siege on the 18th of April 1537. Immediately afterwards a dispute arose between the brothers, Francisco, Juan and Gonzalo Pizarro and Almagro.
as to the limits of their respective jurisdictions. An interview took place at Mala, on the sea-coast, on the 15th of November 1537, which led to no result, and Almagro was finally defeated in the battle of Las Salinas near Cuzco on the 26th of April 1538. His execution followed: His adherents recognized his young half-caste son, a gallant and noble youth generally known as Almagro the Lad, as his successor. BITTERLY discontented, they conspired at Lima and assassinated Francisco Pizarro on the 26th of June 1541. Meanwhile Vaca de Castro had been sent out as governor of Peru by Charles V., and on hearing of the murder of Pizarro he assumed the government of the country.

On the 16th of September 1542 he defeated the army of Almagro the Lad in the battle of Chupas near Guananga, and the boy was beheaded at Cuzco.

Charles V. enacted the code known as the "New Laws" in 1542. "Encomiendas," or grants of estates on which the inhabitants were bound to pay tribute and give personal service to the grantee, were to pass to the Crown on the death of the actual holder; a fixed sum was to be assessed as tribute; and forced personal service was forbidden. Blasco Núñez de Vela was sent out, as first viceroy of Peru, to enforce the "New Laws." Their promulgation aroused a storm among the conquerors. Gonzalo Pizarro rose in rebellion, and entered Lima on the 28th of October 1544. The viceroy fled to Quito, but was followed, defeated and killed at the battle of Ancahuato on the 18th of January 1545. The "New Laws" were weakly revoked, and Pedro de la Gasca, as first president of the Audiencia (court of justice) of Peru, was sent out to restore order. He arrived in 1547, and on the 8th of April 1548 he routed the followers of Gonzalo Pizarro on the plain of Sasahuanzam near Cuzco. Gonzalo was executed on the field. La Gasca made a redistribution of "encomiendas" to the loyal conquerors, which caused great discontent, and left Peru before his scheme was made public in January 1550. On the 23rd of September 1551 Don Antonio de Mendoza arrived as second viceroy, but he died at Lima in the following July. The country was then ruled by the judges of the Audiencia, and a formidable insurrection broke out, headed by Francisco Hernández Giron, with the object of maintaining the right of the conquerors to exact forced service from the Indians. In May 1554 Giron defeated the army of the judges at Chuquipina, but he was hopelessly routed at Pucará on the 11th of October 1554, captured, and on the 7th of December executed at Lima. Don Diego de Haro, brother of Mendoza, took command at Lima as third viceroy of Peru on the 6th of July 1555, and ruled with an iron hand for six years. All the leaders in former disturbances were sent to Spain. Corregidores, or governors of districts, were ordered to try summarily and execute every turbulent person within their jurisdictions. All unemployed persons were sent on distant expeditions, and moderate "encomiendas" were granted to a few deserving officers. At the same time the viceroy wisely came to an agreement with Sayri Tupac, the son and successor of the Inca Manco, and granted him a pension. He took great care to supply the natives with priests of good conduct, and promoted measures for the establishment of schools and the foundation of towns in the different provinces. The introduction of European domestic animals was introduced. The next viceroy was the Conde de Nieva (1561-1564). His successor, the licentiate Lope Garcia de Castro, who only had the title of governor, ruled from 1564 to 1566. From this time there was a succession of viceroys until 1824. The viceroy was chief magistrates, but in legal matters they had to consult the Audiencia of judges, in finance the Tribunal de Cuentas, in other branches of administration the Juntas de Gobierno and de Guerra.

Don Francisco de Toledo, the second son of the count of Oropeza, entered Lima as viceroy on the 26th of November 1569. Toledo was the last court of the Inca Tupac Amaru and his Administracion (who had succeeded his brother Sayri Tupac) might become a focus of rebellion, he seized the young prince, and unjustly beheaded the last of the Incas in the square of Cuzco in the year 1571. After a minute personal inspection of every province in Peru, he, with the experienced aid of the learned Polo de Ondegardo and the judge of Matienzo, established the system under which the native population of Peru was ruled for the two succeeding centuries. His Libro de Tasos fixed the tribute to be paid by the Indians, exempting all men under eighteen and over fifty. He found it necessary, in order to secure efficient government, to revert in some measure to the system of the Incas. The people were to be directly governed by their native chiefs, whose duty was to collect the tribute and exercise magisterial functions. The chiefs or "curacas" had subordinate native officials under them called "pichca-pachacas" over 500 men, and "pachacas" over 100 men. The office of curaca or cacique was made hereditary, and its possessor enjoyed several privileges. Many curacas were descended from the imperial family of the Incas, or from great nobles of the Incarerial court. In addition to the tribute, which was in accordance with native usage, there was the "mita," or forced labour in mines, farms and manufactories.

Toledo enacted that one-seventh of the male population of a village should be subject to conscription for this service, but they were to be paid, and were not to be taken beyond a specified distance from their homes.

The Spanish kings and viceroys desired to protect the people from tyranny, but they were unable to prevent the rapacity and lawlessness of distant officials and the country was depopulated by the illegal methods of enforcing the mita. Toledo was succeeded in 1581 by Don Martin Henriquez, who died at Lima two years afterwards. The Spanish colonies suffered from the strict system of monopoly and protection, which was only slightly relaxed by the later Bourbon kings, and from the arbitrary proceedings of the Inquisition. Between 1581 and 1766 as many as fifty-nine heretics were burned at Lima, and there were twenty-nine "autos"; but the Inquisition affected Europeans rather than natives, for the Indians, as catechumens, were exempted from its terrors. The curacas sorrowfully watched the gradual extinction of their people by the operation of the mita, protesting from time to time against the exactions and cruelty of the Spaniards.

At length a descendant of the Incas, who assumed the name of Tupac Amaru, rose in rebellion in 1780. The insurrection lasted until July 1783, and cruel executions followed its suppression. This was the last effort of the Indians to throw off the Spanish yoke and the rising was by no means general. The army which overthrow Tupac Amaru consisted largely of such men as

Viceroyalty.

Peru.

The centre of Spanish power, and the viceroy had his military strength concentrated at Lima. Consequently the insurrection of the Incas in 1780, while it lasted, was purely anti-Spanish, and had no support from the Spanish population. The movement for independence, which slowly gained force during the opening decade of the 19th century, did not actually become serious until the conquest of Spain by the French in 1807-1808. The Creoles (Criollos) or American-born Spaniards had for long been aggrieved at being shut out from all important official positions, and at the restrictions placed upon their trade, but the bulk of the Creole population was not disloyal.

congress of Peru became the sovereign power of the state. After a short period of government by a committee of three, the congress elected Don José de la Riva Aguero to be first president of Peru on the 28th of February 1823. He displayed great energy in facing the difficulties of a turbulent situation, but was unsuccessful. The aid of the Colombians under Simon Bolivar was sought, and Aguero was deposed.

Bolivar arrived at Lima on the 1st of September 1823, and began to organize an army to attack the Spanish viceroy in the interior. On the 6th of August 1824 the cavalry action of Junin was fought with the Spanish forces under the command of a French adventurer, General Canterac, near the lake of Chacabuco. It was won by a gallant charge of the Peruvians under Captain Suarez at the critical moment. Soon afterwards Bolivar left the army to proceed to the coast, and the final battle of Ayacucho (Dec. 9, 1824) was fought by his second in command, General Suarez. The viceroy and all his officers were taken prisoners, and the Spanish power in Peru came to an end.

General Bolivar ruled Peru with dictatorial powers for more than a year, and though there were cabals against him there can be little doubt of his popularity. He was summoned back to Colombia when he had been absent for five years and, in spite of protests left the country on the 3rd of September 1826, followed by all the Colombian troops in March 1827.

General José de Lamar, who commanded the Peruvians at Ayacucho, was elected president of Peru on the 24th of August 1827, but was deposed, after waging a brief but disastrous war with Colombia on the 7th of June 1829. General Agustin Gamarra, who had been in the Spanish service, and was chief of the staff in the patriot army at Ayacucho, was elected third president on the 31st of August 1829.

For fifteen years, from 1829 to 1844, Peru was painfully feeling her way to a right use of independence. The officers who fought at Ayacucho, and to whom the country felt natural gratitude, were all-powerful, and they had not learned to settle political differences in any other way than by the sword. Three men, during that period of probation, won a prominent place in their country’s history, Generals Agustin Gamarra, Felipe Santiago Salaverry, and Andres Santa Cruz. Gamarra, born at Cuzco in 1785, never accommodated himself to constitutional usages; but he attached to himself many loyal and devoted friends, and, with all his faults he loved his country and sought its welfare according to his lights. Salaverry was a very different character. Born at Lima in 1806, of pure Basque descent, he joined the patriot army before he was fifteen and displayed his audacity and valor in many battles. Feeling strongly the necessity that Peru had for repose, and the guilt of civil dissension, he wrote patriotic poems which became very popular. Yet he too seized the supreme power, and perished by an iniquitous sentence on the 18th of February 1836.1 Andres Santa Cruz was an Indian statesman. His mother was a lady of high rank, of the family of the Incas, and he was very proud of his descent. Unsuccessful as a general in the field, he nevertheless possessed remarkable administrative ability and for nearly three years (1836–1839) realized his lifelong dream of a Peru-Bolivian confederation.2 But the strong-handed intervention of Chile on the ground of assistance rendered to rebels, but really through jealousy of the confederation, ended in the defeat and overthrown of Santa Cruz, and the separation of Bolivia from Peru. But Peruvian history is not confined to the hostilities of these military rulers. Three constitutions were framed—in 1828, 1833 and 1839. Lawyers and orators are never wanting in Spanish-American states, and revolution succeeded revolution in one continuous struggle for the spoils of office. An exception must be made of the administration of General Ramon Castilla, who restored peace to Peru, and showed himself to be an honest and very capable ruler. He was elected constitutional president on the 20th of April 1845, Ten years of peace and increasing prosperity followed. In 1859 the regular payment of the interest of the public debt was commenced, steam communication was established along the Pacific coast, and a railroad was made from Lima to Callao.

After a regular term of office of six years of peace and moral and material progress Castilla resigned, and General José Echenique was elected president. But the proceedings of Castilla’s government in connection with the consolidation of the internal debt were disapproved by the nation, and, after hostilities which lasted for six months, Castilla returned to power in January 1855.

From December 1856 to March 1858 he had to contend with and subdue a local insurrection headed by General Agóstino Vivanco, but, with these two exceptions, there was peace in Peru from 1844 to 1879, a period of thirty-five years. Castilla retired at the end of his term of office in 1862, and died in 1868. On the 2nd of August 1868 Colonel Juan Balta was elected president. With the vast sum raised from guano and nitrate deposits President Balta commenced the execution of public works, principally railroads on a gigantic scale. His period of office was signalized by the opening of an international exhibition at Lima. He was succeeded (Aug. 2, 1872) by Don Manuel Pardo (d. 1878), an honest and enlightened statesman, who did all in his power to retrieve the country from the financial difficulty into which it had been brought by the reckless policy of his predecessor, but the conditions were not capable of solution. He regulated the Chinese immigration to the coast-valleys, which from 1860 to 1872 had amounted to 58,606. He promoted education, and encouraged literature. On the 2nd of August 1876 General Mariano-Ignacio Prado was elected.

(C. R. M.; X.)

On the 5th of April 1879 the republic of Chile declared war upon Peru, on the alleged pretext lacing that Peru had violated an offensive treaty, directed against Chile, with Bolivia, War with a country with which Chile had a dispute; but the publication of the text of this treaty made known the fact that it was strictly defensive and contained no just cause of war. The true object of Chile was the conquest of the rich Peruvian province of Tarapacá, the appropriation of its valuable guano and nitrate deposits, and the spoliation of the rest of the Peruvian coast. The military events of the war, calamitous for Peru, are dealt with in the article Chile-Peruvian War. Suffice it here to note that, after the crushing defeat of the Peruvian forces at Arica (June 7, 1879) Señor Nicolas de Piélera assumed dictatorial powers, with the support of Andes Cáceres as commander-in-chief, but the defeats at Chorrillos (Jan. 13, 1881) and Mirafloros (Jan. 15) proved the Chilean superiority, and put Lima at their mercy though desultory fighting was maintained by the remnants of the Peruvian army in the interior, under direction of General Cáceres. An attempt was made to constitute a government with Señor Calderón as president of the republic and General Cáceres as first vice-president. The negotiations between this nominal administration and the Chilean authorities for a treaty of peace proved futile, the Chilean occupation of Lima and the Peruvian seaboard continuing uninterruptedly until 1883. In that year Admiral Lynch, who had replaced General Baquedano in command of the Chilean forces after the taking of Lima, sent an expedition against the Peruvians under General Cáceres, and defeated the latter in the month of August. The Chilean authorities now began preparations for the evacuation of Lima, and to enable this measure to be effected a Peruvian administration was organized with the support of the Chileans. General Iglesias was nominated to the office of president of the republic, and in October 1883 a treaty of peace, known as the treaty of Ancon, between Peru and Chile was signed. The Chilean army of occupation was withdrawn from Lima on the 22nd of October 1883, but a strong force was maintained at Chorrillos until July 1884, when the terms of the treaty were finally approved. The
principal conditions imposed by Chile were the absolute cession by Peru of the province of Tarapacá, and the occupation for a period of ten years of the territories of Tacna and Arica, the ownership of these districts to be decided by a popular vote of the inhabitants of Tacna and Arica at the expiration of the period named. A further condition was enacted that an indemnity of 10,000,000 soles was to be paid by the country finally remaining in possession—a sum equal to about £1,000,000 to-day. The Peruvians in the interior refused to recognize President Iglesias, and at once began active operations to overthrow his authority on the final departure of the Chilean troops.

Affairs continued in this unsettled state until the middle of 1883. Cárcoles meanwhile steadily gaining many adherents to his side of the quarrel. In the latter part of 1883 President Iglesias abdicated.

Under the guidance of General Cárcoles a junta was then formed to carry on the government until an election for the presidency should be held and the senate and chamber of deputies constituted. In the following year (1886) General Cárcoles was elected president of the republic for the usual term of four years. The task assumed by the new president was no sinecure. The country had been thrown into absolute confusion from a political and administrative point of view, but gradually order was restored, and peaceful conditions were reconstituted throughout the republic. The four years of office for which General Cárcoles was elected passed in uneventful fashion, and in 1890 Señor Morales Bermudez was nominated to the presidency, with Señor Solar and Señor Borgoña as first and second vice-presidents. Matters continued without alteration from the normal course until 1894, and in that year Bermudez died suddenly a few months before the expiration of the period for which he had been chosen as president. General Cárcoles secured the nomination of the vice-president Borgoña as chief of the executive for the unexpired portion of the term of the late president Bermudez. This action was unconstitutional, and was bitterly resisted by the other candidate, Señor Solar, who by right should have succeeded to the office. Armed resistance to the authority of Borgoña was immediately organized in the south of Peru, the movement being supported by Señores Nicolas de Pierola, Billinghurst, Durand and a number of influential Peruvians. In the month of August 1894 General Cárcoles was again elected to fill the office of president, but the revolutionary movement rapidly gained ground. President Cárcoles adopted energetic measures to suppress the outbreak: his efforts, however, proved unavailing. The close of 1894 finds the country districts in the power of the rebels and the authority of the legal government confined to Lima and other cities held by strong garrisons. Early in March 1895 General Cárcoles issued his proclamation near the outskirts of Lima, and on the 17th, 18th and 19th of March severe fighting took place, ending in the defeat of the troops under General Cárcoles. A suspension of hostilities was then brought about by the efforts of H.B.M. consul. The loss on both sides to the struggle during these two days was 2800 killed and wounded. President Cárcoles, finding his cause was lost, left the country, a provisional government under Señor Candamo assuming the direction of public affairs.

On the 5th of September 1896 Señor Pierola was declared president of the republic for the following four years. The Peruvians were now heartily tired of revolutionary conditions and disturbances, and an insurrectionary outbreak in the district of Lliputos met with small sympathy, and was speedily crushed. In 1896 a reform of the electoral law was sanctioned. By the provisions of this act an electoral committee was constituted, composed of nine members, two of these nominated by the senate, two by the chamber of deputies, four by the supreme court, and one by the president with the consent of his ministers. To this committee was entrusted the task of the examination of all election returns, and of the proclamation of the names of successful candidates for seats in congress. Another reform brought about by Pierola was a measure introduced and sanctioned in 1897 for a modification of the marriage laws. Under the new act marriages of non-Catholics solemnized by diplomatic or consular officers or by ministers of dissenting churches, if properly registered, are valid, and those solemnized before the passing of this act were to be valid if registered before the end of 1899. Revolutionary troubles again disturbed the country in 1899, when the presidency of Señor Pierola was drawing to a close. In consequence of dissensions amongst the members of the election committee constituted by the act of 1896, the president ordered the suppression of this body. A group of malcontents under the leadership of one Durand, a man who had been prominent in the revolution against General Cárcoles in 1894-95, conspired against the authorities and raised several armed bands, known locally as montoneras. Some skirmishes occurred between these insurgents and the government troops, the latter generally obtaining the advantage in these encounters.

In September 1899 President Pierola vacated the presidency in favour of Señor Romano, who had been elected to the office as a popular candidate and without the exercise of any undue official influence. President Romano was educated at Stonyhurst in England, and was a civil engineer by profession. The principal political problem before the government of Peru was the ownership of the territories of Tacna and Arica. The period of ten years agreed upon for the Chilean occupation of these provinces expired in 1899. At that date the peace of Peru was so seriously disturbed by internal troubles that the government was quite unable to take active steps to bring about any solution of the matter. After 1894 negotiations between the two governments were attempted from time to time, but without any satisfactory results. The question hinged to a great extent on the qualification necessary for the inhabitants to vote, in the event of a plebiscite being called to decide whether Chilean ownership was to be finally established or the provinces were to revert to Peruvian sovereignty. Peru proposed that only Peruvian residents should be entitled to take part in a popular vote; Chile rejected this proposition, on the ground that all residents in the territories in question should have a voice in the final decision. The agreement between Chile and Bolivia, by which the disputed provinces were to be handed over to the latter country if Chilean possession was recognized, was also a stumbling-block, a strong feeling existed among Peruvians against this proceeding. It was not so much the value of Tacna and Arica that put difficulties in the way of a settlement as the fact that the national pride of the Peruvians ill brooked the idea of permanently losing all claim to this section of country. The money, about £1,000,000, could probably have been obtained to indemnify Chile if occasion for it arose.

In the controversy of the delimitation of the frontier between Peru and the neighbouring republics of Ecuador, Colombia, and Brazil also cropped up at intervals. A treaty was signed with Brazil 1876, by which certain physical features were accepted by both countries as the basis for the boundary. In the case of Ecuador and Colombia a dispute arose in 1894 concerning the ownership of large tracts of uninhabited country in the vicinity of the headwaters of the Amazon and its tributaries. An agreement was proposed between Peru and Ecuador in connexion with the limits of the respective republics, but difficulties were created to prevent this proposal from becoming an accomplished fact by the pretensions put forward by Colombia. The latter state claimed sovereignty over the Napo and Marañon rivers on the grounds of the ecclesiastical jurisdiction exercised over this section of territory during the period of Spanish dominion, the government of Colombia asserting that these ecclesiastical rights to which Colombia became entitled after her separation from the Spanish crown carried also the right of absolute ownership. In a treaty signed by the three interested states in 1895 a compromise was effected by which Colombia withdrew a part of the claim advanced, and it was agreed that any further differences arising out of this frontier question should be submitted to the arbitration of the Spanish crown. The later development of the boundary question is dealt with at the outset of this article.
PERU

The city of Perugia, or Perù, was the birthplace of the famous sculptor and architect Francesco di Giorgio Martini, who was born in 1439. His works, including the Castello di Vicenza, are some of the finest examples of the Renaissance style in Italy. The city is also known for its rich cultural heritage, with numerous museums and galleries, including the Uffizi Gallery, which houses some of the most important works of Renaissance art.

In 1905 the value of the factory products was $1,703,417 (27.3% more than in 1900). Petroleum is found in the vicinity. Perú was settled in 1834 and was chartered as a city in 1867.

PERUGIA (anc. Perusia), a city and archiepiscopal see of Italy, the capital of the province of Perugia (which forms the entire compartimento of Umbria) situated 1444 ft. above sea-level. Pop. (1900), 22,321 (town); 65,527 (commune). The town is finely situated upon a group of hills nearly 1000 ft. above the valley of the Tiber. Its outline is very irregular; from the centre of the town—and the Virgin's wedding-—parts of it extend for a considerable distance along their summits, being divided from one another by deep valleys. This is the extent enclosed by the medieval walls; within them are considerable remains of the lofty terrace walls of the Etruscan period. The so-called Arco di Augusto is a town gate with a Decorated superstructure, perhaps of the Etruscan period, bearing the inscription Augusta Perusia; above this again is a Renaissance loggia. The superstructure of a similar gate (Porta Marzia), which was removed in 1540 to make way for the citadel, but is depicted in a fresco by Benedetto Bonfigli (between 1461 and 1477). it was re-erected in the substitution walls of the citadel.

It bears the inscription Colonica Vibia Augusta Perusia, so that the town must have become a colony in the reign of the emperor C. Vibius Tribonianus Gallus (A.D. 251–253), who was a native of it. Four other gates of the Etruscan period can be traced (F. Noack in Römische Mitteilungen, 1897, 166 sqq.). In the garden of the church of S. Elisabetta was found in 1876 a fine mosaic in black on a white ground representing Orpheus in the midst of the beasts (Notizie degli scavi, 1876, 181; 1877 300).

The citadel was erected by Pope Paul III. in 1540–1546, after the plans of Antonio da Sangallo the younger, and demolished in 1860 (see Bacile di Castiglione in L’Arte, 1903, 547). The old Duomo is the dome of 1440, on the north of the Corso. One side stands the cathedral of S. Lorenzo, a Gothic structure of the 14th and 15th centuries, in the plan of a Latin cross, with nave and aisles of equal height; on the other the Palazzo del Municipio, presenting two fine Gothic façades, of the 14th century (though the building was not completed till 1445), with the figures of the Perugian Griffin and the Guelph lion above the outside stair; and in the centre the marble fountain constructed in 1277–1280 by Arnolfo di Cambio, and adorned with statues and statuettes by Niccolo and Giovanni Pisano. The cathedral contains the burial-place of Urban IV. and Martin IV.—the remains of Innocent III. were removed to Rome in 1812 and placed in the basilica of S. Giovanni Laterano—and the Virgin's wedding-ring; and at the north-east corner is a sitting statue of Pope Julius III. by Vincenzo Danti, erected in 1555 by the people of Perugia in gratitude for the restoration of their civil privileges.

On the decoration of the Sala del Cambio, or old exchange, Perugino put forth the full force of his genius. Most of the movable paintings have since 1863 been collected in the Pinacoteca Vanni, established in the Palazzo del Municipio; besides a considerable number of pieces by Perugino, there are specimens of Niccolò Alumni, Bonfigli, Pinturicchio, &c. A very interesting and important exhibition of Umbrian art was held here in 1906. The pictures, in the Friedlander collection, and a splendid pietra dura embroidery from S. Francesco at Assisi, the vestments of Pope Benedict XI., and the majolica of Perugia and Deruta, a village 10 m. south, were especially noteworthy (see U. Gnoli, L’Arte umbra alla mostra di Perugia, Bergamo, 1908). The illuminated MSS. of the communal library, the cathedral and the church of S. Pietro, from the 7th century onwards, were also exhibited.

The formation of the Pinacoteca Vanni has impaired the interest of several churches but in others it remains undiminished.

San Domenico, a Gothic edifice originally designed by Giovanni Pisano but rebuilt in 1614, contains the monument of Pope Benedict XI. (attributed to Giovanni Pisano by Vasari), and in its east front a Gothic window with stained glass by Fra Bartolommeo of Perugia (1441). San Pietro de’ Cassinensi (outside the Porta Romana) is a basilica
with nave and aisles, founded in the beginning of the 11th century by San Pietro Vinciol on the site of a building of the 6th century, and remarkable for its conspicuous spire, its ancient granite and marble columns, its walnut stall-work of 1535 by Stefano de' Zambellis da Bergamo, and its numerous pictures (by Perugino, &c.). The oratory of S. Bernardino has an early Renaissance polychrome façade, richly sculptured, of 1457-1461, by Agostino d' Antonio di Duccio of Florence. S. Severo contains Raphael's first independent fresco (1505), much damaged by restoration. The circular church of S. Angelo, with sixteen antique columns in the interior, probably dates from the middle of the 6th century. The university dates from 1307, and has faculties of law, science and medicine; it had 318 students in 1902-1903. It contains an important museum of Etruscan and Roman antiquities. Three miles to the S.S.E. the Etruscan necropolis of the ancient city was discovered in 1870. The large tomb of the Volumni (3rd century B.C.) hewn in the rock, with its carved chasonry urns, is interesting.

The ancient Perugia first appears in history as one of the twelve confederate cities of Etruria. It is first mentioned in the account of the war of 310 or 309 B.C. between the Etruscans and the Romans. It took, however, an important part in the rebellion of 295, and was reduced, with Vulsciuni and Arretium, to seek for peace in the following year. In 216 and 205 it assisted Rome in the Hannibal war, but afterwards it is not mentioned until 41-40 B.C., when L. Antonius took refuge there, and was reduced by Octavian after a long siege. A number of lead bullets used by slingers have been found in and around the city (Corpus inscr. lat. xi. 1212). The city was burnt, we are told, with the exception of the temples of Vulcan and Juno—the massive Etruscan terrace-walls, naturally, can hardly have suffered at all—and the town, with the territory for a mile round, was allowed to be occupied by whoever chose. It must have been rebuilt almost at once, for several bases exist, inscribed Augusto sacrum Perugia restituta; but, as we have seen, it did not become a colony until A.D. 251-252. It is hardly mentioned except by the geographers until the middle of the 6th century, when it was captured by Totila after a long siege. In the Lombard period it is spoken of as one of the principal cities of Tuscia. In the 9th century, with the consent of Charles the Great and Louis the Pious, it passed under the popes; but for many centuries the city continued to maintain an independent life, warring against many of the neighbouring lands and cities (Foligno, Assis, Spoleto, Montepulciano, &c.). It remained true for the most part to the Guelphs, but on various occasions the popes found asylum within its walls, and it was the meeting-place of the conclaves which elected Honorius II. (1124), Honorius IV. (1285), Celestine V. (1294), and Clement V. (1305). But Perugia had no mind simply to sur vive the papal interests. At the time of Rienzi's unfortunate enterprise it sent ten ambassadors to pay him honour; and, when papal legates sought to coerce it by foreign soldiers, or to exact contributions, they met with vigorous resistance. In the 13th century power was at last concentrated in the Baglioni family, who, though they had no legal position, defied all other authority. Gian Paolo Baglioni was lured to Rome in 1520 and beheaded by the French, and his nephew, Cardinal Rodrigo de' Borgia, was defeated by Pier Luigi Farnese, and the city, captured and plundered by his soldiery, was deprived of its privileges. The citadel was begun six years later "ad coerdemend Perusiorum audaciam." In 1797 Perugia was occupied by the French; in 1832, 1838 and 1845 it was visited by earthquakes; in May 1849 it was seised by the Austrians; and, after a futile insurrection in 1859, it was finally united, along with the rest of Umbria, to Piedmont, in 1860.

See G. Contestabile, I Monumenti di Perugia eurum and romanum (Perugia, 1855); M. Symonds and L. Duff Gordon, Perugia ("Medley", 1888); C. Conestabile, Perugia (Bergamo, 1905); W. Heywood, Hist. of Perugia (1919). (T. A.)

PERUGINO, PIETRO (1446-1524), whose correct family name was VANNUCCI, Italian painter, was born in 1446 at Città della Pieve in Umbria, and belongs to the Umbrian school of painting. The name of Perugino came to him from Perugia, the chief city of the neighbourhood. Pietro was one of several children born to Cristoforo Vannucci, a member of a respectable family settled at Città della Pieve. Though respectable, they seem to have been poor, or else, for some reason or other, to have left Pietro uncared for at the opening of his career. Before he had completed his ninth year the boy was articled to a master, a painter at Perugia. Who this may have been is very uncertain; the painter is spoken of as wholly mediocre, but sympathetic for the great things in his art. Benedetto Bonfigli is generally surmised; if he is rejected as being above mediocrity, either Floreno di Lorenzo or Niccolò da Foligno may possibly have been the man. Pietro painted a little at Arezzo; thence he went to the headquarters of art, Florence, and frequented the famous Brancacci Chapel in the church of the Carmine. It appears to be sufficiently established that he studied in the atelier of Andrea del Verrocchio, where Leonardo da Vinci was also a pupil. He may have learned perspective, in which he particularly excelled for that period of art, from Piero de' Franceschi. The date of this first Florentine sojourn is by no means settled; some authorities incline to make it as early as 1467, while others, with perhaps better reason, postpone it till 1479. Pietro at this time was extremely poor; he had no bed, but slept on a chest for many months, and, bent upon making his way, resolutely denied himself every creature comfort.

Gradually Perugino rose into notice, and became famous not only throughout Italy but even beyond. He was one of the earliest Italian painters to practise oil-painting, in which he evinced a depth and smoothness of tint, which elicited much remark; and in perspective he applied the novel rule of two centres of vision. Some of his early works were extensive frescoes for the Ingegati fathers in their convent, which was destroyed not many years afterwards in the course of the siege of Florence; he produced for them also many cartoons, which they executed with brilliant effect in stained glass. Though greedy for gain, his integrity was proof against temptation; and an amusing anecdote has survived of how the prior of the Ingegati dozed out to him the costly colour of ultramarine, and how Perugino, constantly washing his brushes, obtained a surreptitious hoard of the pigment, which he finally restored to the prior to shame his stingy suspiciousness. A good specimen of his early style in tempera is the circular picture in the Louvre of the "Virgin and Child enthroned between Saints.

Perugino returned from Florence to Perugia, and thence, towards 1483, he went to Rome, where he was a member of the Sixtine Chapel which is now immortalized by Michelangelo's "Last Judgment." was assigned to him by the pope; he covered it with frescoes of the "Assumption," the "Nativity," and "Moses in the Bulrushes." These works were ruthlessly destroyed to make a space for his successor's more colossal genius, but other works by Perugino still remain in the Sixtine Chapel; "Moses and Zipporah" (often attributed to Signorelli), the "Baptism of Christ," and "Christ giving the Keys to Peter." Pinturicchio accompanied the greater Umbrian to Rome, and was made his partner, receiving a third of the profits; he may probably have done some of the Zipporah subject.

Pietro returned to Rome after the completion of the Sixtine paintings in 1486, and in the autumn of that year he was in Florence. Here he figures by no means advantageously in a criminal court. In July 1487 he and another Perugian painter named Aulista di Angelo were convicted, on their own confession, of having in December waylaid with staves some one (the name does not appear) in the street near S. Pietro Maggiore. Perugino limited himself, in intention, to assault and battery, but Aulista had made up his mind for murder. The minor and more illustrious culprit was fined ten gold florins, and the major one exiled for life.

Between 1486 and 1499 Perugino resided chiefly in Florence, making the journey thither and back, and several to Perugia. He was in many other parts of Italy from time to time. He had a regular shop in Florence, received a great number of commissions, and continued developing his practice as an oil-painter, his
system of superposed layers of colour being essentially the same as that of the Van Eyscks. One of his most celebrated pictures, the "Pietà" in the Pitti Gallery, belongs to the year 1495. From about 1498 he became increasingly keen after money, frequently repeating his groups from picture to picture, and leaving much of his work to journeymen. In 1499 the gild of the cambio (money-changers or bankers) of Perugia asked him to undertake the decoration of their audience-hall, and he accepted the invitation. This extensive scheme of work, which may have been finished within the year 1500, comprised the painting of the vault with the seven planets and the signs of the zodiac (Perugino wining the designs and his pupils most probably the executive work) and the representation on the walls of two sacred subjects—the "Nativity" and "Transfiguration"—the Eternal Father, the four virtues of Justice, Prudence, Temperance and Fortitude, Cato as the emblem of wisdom, and (in life size) numerous figures of classic worthies, prophets and sibyls. On the mid-pilaster of the hall Perugino placed his own portrait in bust-form. It is probable that Raphael, who in boyhood, towards 1496, had been placed by his uncles under the tuition of Perugino, bore a hand in the work of the vaulting. It may have been about this time (though some accounts date the event, in the few years that separate the two, in the 15th century, and in a hand and to his pupil, the beautiful wife, the object of his fond affection; he loved to see her handsomely dressed, and would often deck her out with his own hands. He was made one of the priori of Perugia in 1501. While Perugino, though by no means stationary or unprogressive as an executive artist, was working contentedly upon the old lines and carrying out the ancient conceptions, a mighty wave of new art flooded Florence with its rush and Italy with its rumour. Michelangelo, twenty-five years of age in 1500, following after and distancing Leonardo da Vinci, was opening men's eyes and minds to possibilities of achievement as yet unsurpassed. Vannucci in Perugia heard Buonarroti bruit abroad, and was impatient to see with his own eyes what the stir was all about. In 1504 he allowed his apprentices and assistants to disperse, and returned to Florence. Though not openly detracting, he viewed with jealousy and some grudging the advances made by Michelangelo; and Michelangelo on his part replied, with the intolerance which pertains to superiority, to the faint praise or covert dispraise of his senior and junior in the art. On one occasion, in company, he told Perugino to his face that he was "a bungler in art" (gaffo nell' arte). Vannucci brought, with equal indiscretion and ill success, an action for defamation of character. Put on his mettle by this mortifying transaction, he determined to show what he could do, and he produced the chef-d'œuvre of the "Madonna and Saints" for the Certosa of Pavia. The constituent parts of this noble work have now been asunder. The only portion which remains in the Certosa is a figure of God the Father with cherubim. An "Annunciation" has disappeared from cognisance; three compartments—the Virgin adoring the infant Christ, St Michael, and St Raphael with Tobias—are among the choicest treasures of the National Gallery, London. The current story that Raphael bore a hand in the work is not likely to be true. This was succeeded in 1505 by an "Assumption," in the Cappella dei Perugini, in the church of St. Mary in Florence. The painting may have been executed chieflly by a pupil, and was at any rate a failure: it was much decrèd; Perugino lost his scholars; and towards 1506 he once more and finally abandoned Florence, going to Perugia, and thence in a year or two to Rome.

Pope Julius II. had summoned Perugino to paint the Stanza in the Vatican, now called that of the Incendio del Borgo; but he soon preferred a younger competitor, that very Raphael who had been trained by the aged master of Perugia; and Vannucci, after painting the ceiling with figures of God the Father in different guises, in five medallion-subjects, found his occupation gone; he retired from Rome, and was once more in Perugia from 1512. Among his latest works in his own city is an altar-piece (painted between 1512 and 1517) of S. Agostino in Perugia; the component parts of it are now dispersed in various galleries.

Perugino's last frescoes were painted for the monastery of S. Agnese in Perugia, and in 1522 for the church of Castello di Fortignano hard by. Both series have disappeared from their places, the second being now in the Victoria and Albert Museum. He was still at Fortignano in 1524 when the plague broke out, and he died. He was buried in unconsecrated ground in a field, the precise spot now unknown. The reason for so obscure and unwonted a mode of burial has been discussed, and religious scepticism on the painter's own part has been assigned as the cause; the fact, however, appears to be that, on the sudden widespread outbreak of the plague, the panic-struck local and civil authorities ordained that all victims of the disorder should be at once interred without any waiting for religious rites. This leads us to speak of Perugino's opinions on religion. Vasari is our chief, but not our sole, authority for saying that Vannucci had very little religion, and was an open and obdurate disbeliever in the immortality of the soul. For a reader of the present day it is easier than it was for Vasari to suppose that Perugino may have been a materialist, and yet just as good and laudable a man as his orthodox Catholic neighbours or brother-artists; still there is a strong discrepancy between the quality of his art, in which all is throughout Christian, Catholic, devotional, and which moves in the domain of miracle or the supernatural, and the tenor of the doctrine of immortality. It is difficult to reconcile this discrepancy, and certainly not a little difficult also to suppose that Vasari was totally mistaken in his assertion; he was born twenty years before Perugino's death, and must have talked with scores of people to whom the Umbrian painter had been well known. We have to remark that Perugino in 1504 painted his own portrait, now in the Uffizi Gallery of Florence, and into this he introduced a scroll lettered "Timete Deum." That an open disbeliever should inscribe himself with "Timete Deum" seems odd. The portrait in question shows a plump face, with small black eyes, a short but well-cut nose, and sensuous lips; the neck is thick, the hair bushy and frizzled, and a general air imposing. The latter portrait in the Cambio of Perugia shows the same face with traces of added years. Perugino died possessed of considerable property, leaving three sons.

Among the very numerous works of Perugino a few not already named require mention. Towards 1496 he painted the "Crucifixion," in S. Maria Maddalena dei Pazzi, Florence. The attribution to him of the picture of the marriage of Joseph and the Virgin Mary (the "Sposizio") now in the museum of Capri, is considered indisputably as the original, to a great extent, of the still more famous "Sposizio" which was painted by Raphael in 1504, and which forms the "Last Supper" of the latter artist in the church of S. Maria del Popolo in Rome. This is now questioned, and it is assigned to Lo Spagna. A vastly finer work of Perugino's is the "Ascension of Christ," which, painted a little earlier for S. Pietro of Perugia, has for years past been in the Duomo of Lyons; but this great picture has been dispersed in other galleries. In the chapel of the Disciplinati of Città della Pieve is an "Adoration of the Magi," a square of 21 ft. containing about thirty life-sized figures; this was executed, with scarcely credible celerity, from the 13th to the 25th of March (or thereabouts) in 1505, and must no doubt be in great part the work of Vannucci's pupils. In 1507, when the master's work had for years been in a course of decline and his performances were generally produced, nevertheless, one of his best pictures—the "Virgin between St Jerome and St Francis," now in the Palazzo Pitti in Florence, and which, if not inspired work; it has been ascribed to Perugino by some connoisseurs, by others to Raphael; it may more probably be by some different pupil of the Umbrian master.

PERUZZI—PESCADORES

common term for all types of artificial heads of hair. Perugino is sometimes confused to the heavy full-bottomed wigs worn from the reign of Charles II. to the introduction of the light, tailed wig of the 18th century.

PERUZZI, BALDASSARE (1481–1530), Italian architect and painter of the Roman school, was born at Ancanjano, in the diocese of Volterra, and passed his early life at Siena, where his father resided. While quite young Peruzzi went to Rome, and there studied architecture and painting; in the latter he was at first a follower of Perugino. The choir frescoes in Sant’ Onofrio on the Janiculan Hill, usually attributed to Pinturicchio, are by his hand. One of the first works which brought renown to the young architect was the villa on the banks of the Tiber in Rome now known as the Farnesina, originally built for the Sienese Agostino Chigi, a wealthy banker. This villa, like all Peruzzi’s works, is remarkable for its graceful design and the delicacy of its detail. It is best known for the frescoes painted there by Raphael and his pupils to illustrate the stories of Psycho and Galatea. One of the loggie has frescoes by Peruzzi’s own hand—the story of Medusa. On account of his success Peruzzi was appointed by Leo X. in 1520 architect to St Peter’s at a salary of 250 scudi; his design for its completion was not, however, carried out. During the sack of Rome in 1527 Peruzzi barely escaped with his life, on condition of his painting the portrait of Contable de Bourjon, who had been killed during the siege (see VASARI). From Rome he escaped to Siena, where he was made city architect, and designed fortifications for its defence, a great part of which still exist. Soon afterwards he returned to Rome, where he made designs for a palace for the Orsini family, and built the palaces Massimi and Vidoni, as well as others in the south of Italy. He died in 1536, and was buried by the side of Raphael in the Pantheon.

Peruzzi was an eager student of mathematics and was also a fair classical scholar. Like many of the great artists of his time, he was remarkable for the varied extent of his knowledge and skill. A most able architect, a fair painter, and a scientific engineer, he also practised minor arts, such as stucco-work in relief, sgraffito, and the decorative painted arabesques which the influence of Raphael did so much to bring into use. His best existing works in fresco are in the Castel di Belcaro and the church of Fontegiusta in Siena. For Siena Cathedral he also designed a magnificent wooden organ-case, painted and gilt, rich with carved arabesques in friezes and pilasters; he also designed the high altar and the Cappella del Battista.

His chief pupil was the architect Serlio, who, in his work on architecture, gratefully acknowledges the great debt he owed to Peruzzi’s instruction. The English National Gallery possesses an interesting drawing by his hand. The subject is the “Adoration of the Magi,” the presentation of the gifts, and it is of special interest, because three of the kings are portraits of Michelangelo, Raphael, and Titian. The Uffizi and the library at Siena contain a number of Peruzzi’s designs and drawings, many of which are now of priceless value, as they show ancient buildings which have been destroyed since the 16th century.

Hey, Leoe (1782) in the Accademia d’ arti e mestieri (1680–1840); Lanzi, Storia pittoresca (1804); and Platen, Beschreibung der Stadt Rom (1830–1842).

1 PERVIGILIAM

PERVIGILIAM1 VENERIS, the Vigil of Venus, a short Latin poem. The author, date, and place of composition are unknown. The poem probably belongs to the end or 3rd century A.D. An article signed L. Racquetus in the Classical Review (May 1905) assigns it to Sidonius Apollinaris (4th cent.). It was written professedly in early spring on the eve of a three-nights’ festival of Venus (probably April 1–3). It describes in poetical language the annual awakening of the vegetable and animal world through the goddess. It consists of ninety-three verses in trochaic septenary, and is divided into strophes of unequal length by the refrain:

"Cras amet qui nunquam amavit: quique amavit cras amet."

1 PERVIGILIAM was the term for a nocturnal festival in honour of some divinity, especially Bona Dea.

Edictio princeps (1577): modern editions by F. Bühler (1859), A. Riese, in Anthologia latina (1869), E. Bährers in Undeierte lateinische Gedichte (1877); S. G. Owen (with Catullus, 1893). There are translations into English verse by Thomas Stanley (1651) and Thomas Forrest, author of The Hermit. On the text see J. W. Mackail in Journal of Philology (1888), vol. xvii.

PESARO (anc. Pisaurum, q.v.), a city and seaport of the Marches, Italy, the capital of the province of Pesaro and Urbino, situated on the coast of the Adriatic 37 m. N.W. of Ancona by rail, on the right bank of the Foglia, the ancient Pisaurum. The ground on which it is built is only from 10 to 40 ft. above the sea, but it is surrounded by hills—on the E. by Monte Ardisio, on the W. by Monte Accio or San Bartolo, which derives one of its names from the tradition that the Roman dramatist L. Attius was born and buried on the spot. Upon this hill stands the Villa Imperiale, the foundation stone of which was laid by the emperor Frederick III., built by the Sforza, and decorated with fine stucco ceilings and wall paintings and pavements of majolica plaques. A new palace was begun in 1530 by the Genga for Eleonora Gonzaga, but never finished. The city walls were in 1830 transformed into a public promenade. Besides the ancient cathedral of the Annunciation (restored since 1860) with a 12th-century mosaic pavement, there are a number of smaller churches, several with Gothic portals. One of these, the church of San Francesco, now used as a cathedral, contains the "Coronation of the Virgin" by Giovanni Bellini, the largest and most important of his works outside Venice. The most conspicuous buildings are the prefecture (a palace originally erected in 1455–1465 by the Dalmatian architect Luciano da Laurana for the Sforza, and restored by Francesco Maria della Rovere in the 16th century, the Rossini theatre (opened in 1818), the fortress of Rocca Costanzia (built by Costanzo Sforza in 1474, Laurana being the architect), and the large lunatic asylum. The composer Gioacchino Rossini, who was a native of Pesaro, left all his fortune to found a musical lyceum in the city, and his statue by Marochetti (1864) stands near the railway station. The Olivieri library (established by the antiquary of that name, author of Marmora pisaurensia, &c.) contains about 14,000 volumes, MSS. of Tasso, &c., inscriptions and various antiquities, and a very fine collection of majolica (one of the best in Italy) from the old Urbino and other manufactories. The Museo Mosca, left by its owner to the town, contains important collections of faience, furniture, &c. Among the industries of Pesaro are the growing, spinning and weaving of silk, tanning, iron-working, and the manufacture of glass and pottery. It is also the centre of a rich agricultural district. The harbour is of no great importance, but there is a small export trade in wine, olives, silk and glass. Pop. (1901), 14,708 (town); 24,832 (commune).

Although besieged by Vitiges the Goth, the town was restored and strengthened by Belisarius, and afterwards along with Ancona, Fano, Senigallia, and Rimini formed the Pentapolis Maritima. In the course of the 13th century Pesaro was sometimes under the government of the popes, sometimes under that of the emperors; but the Malatesta family, which first took root in the city about 1285, gradually became the real masters of the place. In 1445 they sold their rights to Francesco Sforza; and in 1512, under the influence of Julius II., the Sforza were supplanted by his nephew Francesco Maria, duke of Urbino. Leo X. took the city away from Francesco and gave it to Lorenzo de’ Medici; but on Lorenzo’s death Francesco was restored and Pesaro became the ordinary residence of the dukes of Urbino till the death of Francesco Maria II. in 1631, when it reverted to the States of the Church. It has formed part of the present kingdom of Italy since 1860. Terenzio Mamiani della Rovere, poet and statesman, was born at Pesaro in 1860.

PESCADORES (i.e. fishers,) a group of islands (called by the Japanese Hōko 10 or Hōko Gunō) lying 30 m. west of Formosa, from which they are separated by the Pescadores Channel, about the tropic of Cancer. The islands number 48 (21 inhabited), have a coast-line of 98–67 miles, a total area of 85–50 sq. m., and a population of about 55,000, principally Chinese. Flat and with unproductive soil, they are swept during one
half of the year by violent N.E. winds, and also lie full in the path of the numerous typhoons that rush up the Strait of Formosa. Meteorological observations taken by the Japanese during a period of three years show that the annual average number of stormy days is 237. The anchorage is at Mako (Makū or Makun) on the principal island of Penghu. The chief industry is fishing (whence the old Spanish name which has come into general use) and dried fish are exported.

**PESCARA, FERNANDO FRANCESCO DAVALOS, MARQUIS OF (1489-1553).** Italian condottiere, was born at Naples, his family being of Spanish origin. Rodrigo (Ruy) Lopez Davalos, his great-grandfather, a noble of Toledo, who had taken an active part in the civil wars of Castile in the reign of John II. (1407-1454), had been driven into exile, and died at Valencia. Inigo (Ignacio), his father, entered the service of Cardinal Francesco of Aragon of Naples, followed him to Italy, and there, making an advantageous marriage with a lady of the family of Aquino, was created marquis of Pescara. His son Alphonso, who succeeded him in the marquisate, married a lady of the Sicilian branch of the Spanish family of Cardona, and when he was treacherously killed, during a French invasion of Naples, his only son Fernando, or Ferrante, was a child in arms. At the age of six the boy was betrothed to Vittoria Colonna (q.v.), daughter of the general Fabrizio Colonna, and the marriage was celebrated in 1509. His position as a noble of the Aragonese party in Naples made it incumbent on him to support Ferdinand the Catholic in his Italian wars. In 1512 he commanded a body of light cavalry at the battle of Ravenna, where he was wounded and taken prisoner by the French. Thanks to the intervention of one of the foremost of the French generals, the Italian J. J. Trivulzio, who was his connexion by marriage, he was allowed to ransom himself for 6000 ducats. He commanded the Spanish infantry at the battle of La Morta, or Vicenza, on the 7th of October 1513. It was on this occasion that he called his men before the charge to take care to step on him before the enemy did if he fell. From the battle of Vicenza in 1513, down to the battle of La Bicoca on the 29th of April 1515, he continued to serve in command of the Spanish forces, as the colleague rather than the subordinate of Prosper Colonna. It was only by the accident of his birth at Naples that Pescara was an Italian. He considered himself a Spaniard, spoke Spanish at all times, even to his wife, and was always surrounded by Spanish soldiers and officers. His opinion of the Italians as fighting men was unfavourable and was openly expressed. After the battle of La Bicoca Charles V. appointed Prosper Colonna commander-in-chief. Pescara, who considered himself aggrieved, made a journey to Valladolid in Spain, where the emperor then was, to state his own claims. Charles V., with whom he had long and confidential interviews, persuaded him to submit for the time to the superiority of Colonna. But in these meetings he gained the confidence of Charles V. His Spanish descent and sympathies marked him out as a safer commander of the imperial troops in Italy than an Italian could have been. When Francis I. invaded Italy in 1524 Pescara was appointed as lieutenant of the emperor to repel the invasion. The difficulties of his position were very great, for there was much discontent in the army, which was very ill paid. The tenacity, patience and tact of Pescara triumphed over all obstacles. His influence over the veteran Spanish troops and the German mercenaries kept them loyal during the long siege of Pavia. On the 24th of February 1525 he defeated and took prisoner Francis I. by a brilliant attack. Pescara's plan was remarkable for its superior audacity and for the skill he showed in destroying the superior French heavy cavalry by assailing them in flank with a mixed force of harquebusiers and light horse. It was believed that he was dissatisfied with the treatment he had received from the emperor; and Girolamo Morone, secretary to the duke of Milan, approached him with a scheme for expelling French, Spaniards and Germans alike from Italy, and for gaining a throne for himself. Pescara may have listened to the tempter, but in fact he was loyal. He reported the offer to Charles V. and put Morone into prison. His health however had begun to give way under the strain of wounds and exposure; and he died at Milan on the 4th of November 1525. Pescara had no children; and his Angevin possession in the kingdom of Naples descended to the marquis of the Vasto, also a distinguished imperial general.

**AUTHORITIES.**—The life of Pescara was written in Latin by Paolo Giovio, and is included in the *Vitae illustrium virorum*, printed at Basel 1578. Giovio's Latin Life was translated by L. Domenichi, the translator of his other works, and published at Florence, 1531. The Spaniards published *Historia del turrius del predilectissimo capitanei Dom. Hernando de Avalos*, by El Maestro P. Vallés (Antwerp, 1553), as also a translation of Giovio. See also Migner, *Rivalité de François 1er et de Charles Quint* (Paris, 1875), which gives references to all authorities.

(D. H.)

**PESCARA,** a river of Italy, formed by the confluence of the Glieco and Aterno, and flowing into the Adriatic at the small town of Pesaro, in the province of Ancona. This town occupies the site of the ancient Aternum, and the terminus of the Via Claudia Valeria, and up to 1807 a fortress of some importance. The railway from Sulmona follows the Pescara valley and joins the coast line to Brindisi at Pesaro. In this valley, 22 m. from the sea, was the site of the ancient Interpromontium, a town belonging probably to the Paeligni; and not far off is the very fine Cistercian abbey church of S. Clemente di Casarua, founded by the emperor Louis II. in 871. The present building belongs to the 12th century. The sculptures of the portals, the pulpit, the Paschal candelabrum, &c., and the bronze doors of this period are important. The chronicle of the abbey, of the end of the 11th century, is in the Bibliothèque nationale at Paris.

**PESCHIERA SUL GARDA,** a fortress of Venetia, Italy, in the province of Verona, on an island in the Mincio at its outlet from the lake of Garda, 77 m. by rail E. of Milan. It was one of the famous fortresses of the Quadrilateral, the chief bulwark of the Austrian rule in Italy until 1866 (Mantua, Legnago and Verona being the other three) and has played a prominent part in all the campaigns conducted in north Italy, more especially during the Napoleonic wars. It was taken by the Piedmontese from the Austrians, after a gallant defence by General Rath lasting six weeks, on the 30th of May 1848, and since that date has been in Italian hands.

**PESCIA,** a town of Tuscany, Italy, in the province of Lucca, from which it is 15 m. E.N.E. by rail, 203 ft. above sea-level. Pop. (1901), 12,400 (town); 18,000 (commune). The cathedral, restored in 1603, contains the fine chapel of the Turini family, built for Baldassare Turini (d. 1540) by Giuliano di Baccio of Florence, with his tomb by Raffaello da Montelupo. The town also has some buildings by Lazzaro Buggianio, the pupil and adoptive son of Brunelleschi. It has silk and paper manufactures.

**PESETA,** a silver coin and unit of value, the Spanish equivalent of the French, Belgian and Swiss franc, the Italian lira and the Greek drachma in the Latin monetary union. The *peso* (Lat. *pensum*, weight), of which *peseta* is a diminutive, was a Spanish coin of gold, *peso de oro*, or silver, *peso de plata*, once current in Spain and her colonies, and now the name of a silver coin of many South American states. The *peso* is also the name of the Mexican dollar.

**PESHAWAR,** a city of British India, the capital of the North-West Frontier Province, giving its name to a district. The city is situated near the left bank of the river Bara, 11 m. from Jamrud at the entrance of the Khyber Pass, the railway station being 1588 m. north-west of Calcutta; pop. (1901), 95,747. Two miles west of the native city are the cantonments, forming the principal military station of the North-West Frontier Province. Peshawar lies within a horseshoe ring of hills on the edge of the mountain barrier which separates India from Afghanistan, and through it have passed nearly all the invaders from the north. The native quarter is a huddle of flat-roofed houses within mud walls, crowded along narrow, crooked alleys; there is but one fairly wide street of shops. Here for many centuries the *Povindkas*, or Afghan travelling merchants, have brought their caravans from Kabul, Bokhara and Samarkand every autumn. They
bringing horses, wool, woollen stuffs, silks, dyed-goods, dried fruits, precious stones, carpets and poshtins (sheepskin clothing), fighting and buying their way to the British border where, leaving their arms, they are free to wander at will to Delhi, Agra and Calcutta. The chief speciality of Peshawar consists of bright-coloured scarves called lungis; wax-cloth and ornamental needle-work are also local products, as well as knives and small arms.

The district of Peshawar has an area of 2611 sq. m.; pop. (1901), 758,707, showing an increase of 10-3% in the decade. Except on the south-east, where the Indus floods, it is encircled by mountains which are inhabited by the Mohmand, Utman Khel and Afridi tribes. The plain consists of alluvial deposits of silt and gravel. The district is naturally fertile and well watered, and is irrigated by the Swat River Canal. The principal crops are wheat, barley, maize, millets and oil-seeds, with a little cotton and sugar-cane. Peshawar also produces a fine variety of rice, known as "Bara rice," after the river which irrigates it. The North-Western railway crosses the district from Attock, and has been extended from Peshawar city to Jamrud for military purposes. The district is chiefly inhabited by Pathans; there are some Hindus engaged in trade, Sindis, bankers, merchants and shop-keepers.

In early times the district of Peshawar seems to have had an essentially Indian population, for it was not till the 15th century that its present Pathan inhabitants occupied it. Under the name of Gandhara it was a centre of Buddhism, and especially Graeco-Buddhism. Rock-edicts of Asoka still exist at two places; and a stupâ excavated in 1909 was found to contain an inscription of Kanishka, as well as relics believed to be those of Buddha himself. The last of the Indian Buddhist kings was conquered by Mahmud of Ghazni in 1009. The Mogul emperors always found difficulty in maintaining their authority over the Afghan border tribes, who finally established their independence during the reign of Aurangzeb. Peshawar was a favourite residence of the Afghan dynasty founded by Ahmed Shah Durrani, and here Mountstuart Elphinstone came as ambassador to Shah Shujah in 1809. A few years later Ranjt Singh crossed the Indus, and after much hard fighting Sikh authority was firmly established under General Avitabile in 1834. In 1848 the whole of the Punjab passed to the British. During the Mutiny, after the sepoys regiments had been disarmed, Peshawar was a source of strength rather than of danger, though Sir John Lawrence did at one time contemplate the necessity of surrendering it to the Afghans, in order to preserve the rest of Northern India.

**PESHIN, or PESHIN**, a district of Baluchistan. Area 2717 sq. m. Pop. (1901), 50,300. It consists of a large plain surrounded on three sides by hills, which formerly belonged to Afghanistan but was ceded to the British by the treaty of Gandamak in 1879. This plain is of considerable strategic importance, as it forms the focus of a great number of routes leading from Sind and the Punjab frontier districts to Kandahar, and is intersected by the Sind-Peshin railway. The agricultural wealth of Peshin, and consequently its revenues, have increased greatly under British administration.

**PESHTITO, or PESTITO** (i.e. "simple"), the standard version of the Bible in the Syriac language. It was long supposed to be the original Syriac version, but is now generally recognized as representing a revision made by Rabhulla, bishop of Edessa, early in the 5th century, an attempt at standardizing the Syriac text such as Jerome had made for the Latin in his Vulgate. (See *Bible*.)

**PESHWA** (Persian for "leader," "guide"?), the title of the head of the Marhatta confederacy in India. Originally the peshwa was only prime minister, but afterwards he supplanted his master and became chief of the state, founding an hereditary dynasty, with the capital at Poona. The last peshwa, Baji Rao, came into collision with the British, and was dethroned in 1818. His adopted son, Nana Sahib, took a leading part in the Mutiny of 1857, in revenge for being deprived of what he considered his rights.

**PESSIMISM** (from Lat. *pesimus*, worst), a word of modern coinage, denoting an attitude of hopelessness towards life, a vague general opinion that pain and evil predominate in human affairs. It is the antithesis of "optimism," which denotes the view that on the whole there is a balance of good and pleasure, or at least that in the long run good will triumph. Between optimism and pessimism is the theory of "meliorism," according to which the world on the whole makes progress in goodness. The average man is pessimist or optimist not on theoretical grounds, but owing to the circumstances of his life, his material position, his original health, his general temperament. Perhaps the most characteristic example of unsystematic pessimism is the language of Ecclesiastes, who concludes that "all is vanity."

Pessimism and optimism have, however, been expressed in systematic philosophical forms, a brief summary only of which need here be given. Such systems have been elaborated chiefly by modern thinkers, but the germs of the ideas are found widely spread in the older Oriental philosophies and in pre-Christian European thought. Generally speaking, pessimism may be found in all pantheistic and materialistic systems. It is important, however, to point out an essential distinction. The thinker who sees man confronted by the infinite non-moral forces presumed by natural pantheism inevitably predominating over the finite powers of men may appear to the modern Christian theologian or to the evolutionist as a hopeless pessimist, and yet may himself have concluded that, though the future holds out no prospect save that of annihilation, man may yet by prudence and care enjoy a considerable measure of happiness. Pessimism, therefore, depends upon the individual point of view, and the term is frequently used merely in a condemnatory sense by hostile critics. The attitude of a man who denies the doctrine of immortality and rejoices in the denial is not strictly pessimistic. A Christian again may be pessimistic about the present; he must logically be optimistic about the future—a reasonable view of the universe implies optimism on the whole; the agnostic may be indifferent to, or pessimistic, regarding the future, while exceedingly satisfied with life as he finds it.

This complex view of life is exemplified by Plato, whose general theory of idealism is entirely optimistic. In analysing the world of phenomena he necessarily takes a pessimistic view because phenomena are merely imitations more or less removed from reality, *i.e.* from the good. Yet the idealistic postulate of a *summa bonum* is in result optimistic, and this view predominated among the Stoics and the Neoplatonists. The Epicureans, on the other hand, were empirically pessimistic, able to derive a measure of enjoyment from life in spite of the non-existence of the orthodox gods; yet this enjoyment is on the whole negative, the avoidance of pain. A similar view is that of the ancient sceptics.

Oriental pessimism, at least as understood by Europeans, is best exemplified in Buddhism, which finds in human life sorrow and pain. But all pain and sorrow are incidental to the human being in his individual capacity. He who will cast aside the "Bonds," the "Intoxications," the "Hindrances," and tread the Noble Eightfold Path (see *Buddhism*) which leads to Nirvana, will attain the ideal, the "Fruit of Arahatship," which is described in terms of glowing praise in the Pali hymns. This, the original doctrine of the Buddha, though not adopted in the full sense by all his followers, is in fact at least as optimistic as any optimism of the West. To call it "pessimism" is merely to apply to it a characteristically Western principle according to which happiness is impossible without personality. The true Buddhist on the contrary looks forward with enthusiasm to this absorption into eternal bliss.

In Europe on the whole the so-called pessimistic attitude was commoner in the Teutonic north than in the Mediterranean basin. But even here the hopefulness as regards a future life, in which the inequalities of the present would be rectified, compensated for the gloomy fatalism with which the present was

1 The earliest example given in the *New English Dictionary* is in S. T. Coleridge's *Letters* (1794).
regarded. The advent of Christianity, with its categorical assertion of future happiness for the good, to a large extent did away with pessimism in the true sense. In Leibnitz we find a philosophic or religious optimism, which saw in the universe the perfect work of a God who from all possibilities selected the best. Kant, though pessimistic as regards the actual man, is optimistic regarding his moral progress. To Hegel similarly the world, though evil at any moment, progresses by conflict and suffering towards the good.

Passing over the Italian Leopardi we may notice two leading modern pessimists, Schopenhauer and von Hartmann. Schopenhauer emphasizes the pessimistic side of Hegel's thought. The universe is merely blind Will, not thought; this Will is irrational, purposeless and therefore unhappy. The world being a state of unhappiness, and the satisfaction of desire is therefore merely the removal of pain. Von Hartmann's doctrine of the Unconscious is in many respects similar to Schopenhauer's doctrine of the Will. The Unconscious which combines Will and Reason is, however, primarily Will. The workings of this Will are irrational primarily, but, as in its evolution it becomes more rationalized and understands the whole meaning of the Weltschmerz, it ultimately reaches the point at which the desire for existence is gone. This choice of final nothingness is different from that of Schopenhauer in being collective and not individual. The pessimism of Schopenhauer and Hartmann does not, however, exclude a certain ultimate mysticism, which bears some analogy to that of Buddhism.

Pessimism is naturally connected with materialist, optimism with idealist, views of life. The theories of the modern evolutionist school, however, have introduced into materialistic theory a new optimistic note in doctrines such as that of the survival of the fittest. Such doctrines regard the progress of humanity as on the whole tending to the greater perfection, and are marked by optimism in contrast with earlier theories that progressive differentiation is followed by development and even the decay. Similarly the cynical contempt which Nietzsche shows for morality and the conventional virtues is counterbalanced by the theory of the Übermensch, the highest type of manhood which by struggle has escaped from the ordinary weaknesses of normal humanity.

See James Sully, "Pessimism; A History and a Criticism" (1877); Carl Ludwig von Hegel, "Philosophie der Religion" (1881); William James, "The Will to Believe" (1892); Dühring, "Die Religion der Zukunft" (1879); Pfeiffer, "Der moderne Pessimismus" (1879); Hartmann, "Der Immaterialismus und seine Gegner" (1879); Gassendi, "Optimismus und Pessimismus" (1879); Rehme, "Die Philosophie des Whiltscherz" (1879); Huber, "Der Pessimismus" (1879); von Goltz, "Der Pessimismus" (1879); Paulsen, "Schopenhauer, Freiherr von Schmettau" (1900); Grottstein, "Der Pessimismus" (1900).

PESSINUS (Πεσσίνος, Πέσσινος), an ancient city of Galatia in Asia Minor, situated on the lowest southern slope of Mt. Dindymus, on the left bank of the river Sangarius, not far from its source. It was discovered by Texier, lie round the village of Bala-Hissar, 8 or 9 m. S.E. of Sivri-Hissar. They include a theatre in partial preservation, but they have been mostly cleared away, as the town was largely built out of them. Originally a Phrygian city, probably founded by the Persians on the Royal Road, it became the capital of the Gallic tribe Tolistares and the chief commercial city of the district. It contained the most famous sanctuary of the mother of the gods (Cybele), who were here known by the name of Agdistis, and was associated with the god Attis, as elsewhere with Sabazius, &c. Hcr priests were also princes, who bore rule not only in the city (the coinage of which, beginning about 100 B.C., was for long issued by them) but also in the country round, deriving a large revenue from the temple estates; but in the time of Strabo (A.D. 19-20) their privileges were much diminished. The high-priest always bore the title of Emperor in the crisis of the second Punic War (205 B.C.), when the Romans lost faith in the efficacy of their own religion to save the state, the Senate, in compliance with an oracle in the Sibyl line books to the effect that the foreign foe could be driven from Italy if the Idaean Mother (Cybele) were brought from Pessinus to Rome, sent ambassadors to the town, who obtained the sacred stone which was the symbol of the goddess and brought it to Rome, where the worship of Cybele was established. But the goddess continued to be worshipped in her old home; her priests, the Galli, went out to welcome Manlius on his march in 189 B.C., which shows that the town was not yet in the hands of the Tolistobogii. Soon after this a splendid new temple of the goddess was built by the Pergamene kings. Some time before 164 B.C. Pessinus fell into the power of the Gauls, and the membership of the priestess was then either divided between the Gauls and the old priestly families. Like Anycra and Tavium, Pessinus was Romanized first and Hellenized afterwards. Only about A.d. 165 did Hellenic ways and modes of thought begin to be assumed; before that we find a deep substratum of Celtic feeling and ways, on which Roman elements had been superimposed without filtering through a Hellenic medium. Christianity was introduced late; it cannot be traced before the 4th century. When Galatia was divided into two provinces (A.D. 386-395) Pessinus was made the capital of Galatia Secunda or Salutaris, and it became a metropolitan bishopric. After the 16th century it disappears from history, being supplanted, from the beginning of the period of Saracen invasion, by the impregnable fortress Justinianopolis (Sivri-Hissar), which became the capital and the residence of the bishop, thenceforward called "archbishop of Pessinus or of Justinianopolis." (J. G. C. A.)

PESTALOZZI, JOHANN HEINRICH (1746-1827), Swiss educational reformer, was born at Zürich on the 12th of January 1746. His father died when he was young, and he was brought up by his mother. At the university of Zürich he was associated with Lavater and the party of reform. His earliest years were spent in schemes for improving the condition of the people. The death of his friend Bluntschli turned him however from politics, and induced him to devote himself to education. He married at twenty-three, and bought a piece of land at Neuhof in Aargau, where he attempted the cultivation of rye. Pestalozzi knew nothing of business, and the plan failed. Before this he had opened his farm-house as a school; but in 1780 he had to give this up also. His first book published at this time was The Evening Hours of a Hermit (1789), a series of aphorisms and reflections. This was followed by his masterpiece, Leonard and Gertrude (1781), an account of the gradual reformation, first of a household, and then of a whole village, by the efforts of a good and devoted woman. It was read with avidity in Germany, and the name of Pestalozzi was rescued from obscurity. The French invasion of Switzerland in 1798 brought into his truly heroic character. A number of children were left in Canton Unterwalden on the shores of the Lake of Lucerne, without parents, home, food or shelter. Pestalozzi collected a number of them into a deserted convent, and spent his energies in reclaiming them. During the winter he personally tended them with the utmost devotion, but in June 1799 the building was required by the French for a hospital, and his charges were dispersed. In 1801 Pestalozzi gave an exposition of his ideas on education in the book How Gertrude teaches her Children. His method is to proceed from the easier to the more difficult. To begin with observation, to pass from observation to consciousness, from consciousness to speech. Then come measuring, drawing, writing, numbers, and so reckoning. In 1799 he had been enabled to establish a school at Burgdorf, where he remained till 1804. In 1802, he went as deputy to Paris, and did his best to interest Napoleon in a scheme of national education; but the great conqueror said that he could not trouble himself about the alphabet. In 1805 he removed to Yverdon on the Lake of Neuchâtel, and for twenty years worked steadily at his task. He was visited by all who took interest in education—Talleyrand, Cap.d'Istria, and Mme de Staël. He was praised by Wilhelm von Humboldt and by Fichte. His pupils included Ramsauer, Delbrück, Blochmann, Carl Ritter, Fröbel and Zeller. About 1815 dissensions broke out among the teachers of the school, and Pestalozzi's last ten years were
chequered by weariness and sorrow. In 1825 he retired to Neuhof, the home of his youth; and after writing the adventures of his life, and his last work, the Swan's Song, he died at Brugg on the 17th of February 1827. As he said himself, the real work of his life did not lie in Burgdorf or in Yverdon. It lay in the principles of education which he practised, the development of his observation, the training of the whole man, the sympathetic application of the teacher to the taught, of which he left an example in his six months' labours at Stanza. He had the deepest effect on all branches of education, and his influence is far from being exhausted.

Petraloli's complete works were published at Stuttgart in 1819-1826, and an edition by Seyffarth appeared at Berlin in 1881. Volumes on his life and teaching have been written by De Gulpeus (1889), Barnard (1862), Krüsl (1875) and Pinloche (1901).

PETALITE, a mineral species consisting of lithium aluminium silicate, LiAl\(3\)Si\(2\)O\(8\). The monoclinic crystals approach spodumene (q.v.) in form, which is also a lithium aluminium silicate with the formula LiAl\(3\)Si\(2\)O\(8\). There is a perfect cleavage parallel to the basal plane, and the mineral usually occurs in platy cleavage masses; on this account it was named, from Gr. πτέρων (a leaf). The hardness is 6\(\frac{1}{2}\) and the specific gravity 2\(\frac{1}{4}\) (that of spodumene being 3\(\frac{1}{2}\)). The mineral is colourless or occasionally reddish, varies from transparent to translucent, and has a vitreous lustre. It was discovered in 1800 as cleavage masses in an iron mine on the island of Utö in the Stockholm archipelago, where it is associated with lepidolite, tourmaline (rubellite and indicolite) and spodumene. A variety known as "caster" is found as transparent glassy crystals associated with pollex (q.v.) in cavities in the granite of Elba. (L. J. S.)

PETARD (Fr. pétard, pét er, to make a slight explosion), a device formerly used by military engineers for blowing in a gate or other barrier. It consisted of a small metal or wooden cage, usually of sugar-loaf shape, containing a charge of powder and fired by a fuse.

PETAU, DENYS (1583-1652), Jesuit scholar, better known as DIONYSIUS PETAVIUS, was born at Orleans on the 21st of August 1583. Educated at Paris University, he came under the influence of Isaac Scaliger, who directed his attention towards the obscure fathers of the Church. In 1603 he was appointed to a lectureship at the university of Bourges, but resigned his place two years later, in order to enter the Society of Jesus. For many years he was professor of divinity at the Collège de Clermont, the chief Jesuit establishment in Paris; there he died on the 18th of December 1652. He was one of the most brilliant scholars in a learned age. Carrying on and improving the chronological labours of Scaliger, he published in 1627 an Opus de doctrina temporum, which has been often reprinted. An abridgment of this work, Rationarium temporum, was translated into French and English, and has been brought down in a modern reprint to the year 1849. But Petavius's eminence chiefly rests on his vast, but unfinished, De theologis dogmatibus, the first systematic attempt ever made to treat the development of Christian doctrine from the historical point of view.

PETCHENEG, or PATZINAKS, a barbarous people, probably of Turkish race, who at the end of the 5th century were driven into Europe from the lower Ural, and for about 300 years wandered about the northern frontier of the East Roman Empire. (See TURKS.)

PETER, ST., the chief of the Twelve Apostles. He is known also by other names: (a) "Simon" (Sim\(\nu\)os) in Mark four times and Luke seven times. This use is only found in narrative before the story of the mission of the apostles: it is also found in speeches; Matthew once, Mark once and Luke twice. (b) "Simon who is called Peter" is found in Matthew twice and Acts four times. (c) "Simon Peter" is found in Matthew once, Luke once, John seventeen times (and perhaps also in 2 Peter i. 1, where the text varies between Simon and Symeon). (d) "Peter" is found in Matthew nineteen times, Mark eighteen times, Luke sixty times, Acts fifty-one times, John fifteen times, Galatians twice, 1 Peter once. (e) "Cephas" is found in John once, Galatians four times, 1 Corinthians four times. (f) Symeon (S\(\nu\)mob) is found in Acts once. It appears that the apostle had two names, each existing in a double form—Greek and Hebrew, Symeon (S\(\nu\)mob) which was Gracized according to the sound into Simon, and Cephas (S\(\nu\)phas) which was Gracized according to the meaning into Peter (I\(\nu\)rov). Symeon and Simon are both well-known names in Aramaic and Greek respectively, but Cephas and Peter are previously unknown. Symeon was no doubt his original Aramaic name, and the earliest gospel, Mark, which has some claim specially to reproduce Petrine tradition, is careful to employ Simon until after the name Peter had been given, and not then to use it again. The Gospels agree in regarding Cephas or Peter as an Aramaic name by which was given by Christ. But they differ as to the occasion. According to Mark iii. 13 sqq. it was given on the occasion of the mission of the Twelve. According to John i. 42 it was given at his first call. According to Matt. xvi. 13 sqq. it was given after the recognition of Jesus as Messiah at Caesarea Philippi. This last account is the only one which describes any circumstances (for a further discussion see § 3 (c) below).

According to the Gospels Peter was the son of John (\(\tau\)o\(\rho\)mos, John i. 42, xxii. 15 seq.) or Jonas (\(\tau\)o\(\rho\)\(\alpha\)\(s\)s, Matt. xxvi. 17). According to Mark i. 29 he was a fisherman of Capernaum, but John i. 44 describes him and his brother Andrew as of Bethsaida. From Mark i. 30 he is seen to have been married, and 1 Cor. ix. 5 suggests (but another interpretation is possible) that his wife went with him on his missionary journeys. In 1 Pet. v. 13 Mark is referred to as his son, but this is usually interpreted of spiritual kinship. According to legend (Acta Neroni et Achillei, Acta Philippi) he had a daughter Petronilla, but there is no reason for thinking that this is historical.

The Gospel narratives are unanimous in describing Peter as one of the first disciples of Christ, and from the time of his call he seems to have been present at most of the chief incidents in the narrative. He formed together with the sons of Zebedee to some extent an inner circle within the Twelve, and this favoured group is specially mentioned as present on three occasions—the raising of the daughter of Jairus (Mark v. 22-43; Matt. ix. 18-36; Luke viii. 41-50), the transfiguration (Mark ix. 2 sqq.; Matt. xvii. 1 sqq.; Luke ix. 28 sqq.) and the scene in the Garden at Gethsemane (Mark xiv. 32 sqq.; Matt. xxvi. 36 sqq.). He is also specially mentioned in connexion with his call (Mark i. 16-20; Matt. iv. 18 sqq.; Luke iv. 1 sqq.; John xxi. 1 sqq.; Matt. x. 31 sqq.; Matt. xi. 27 sqq.; Matt. xii. 14 sqq.; Luke iv. 38 sqq.); the mission of the Twelve Apostles (Mark iii. 13 sqq.; Matt. x. 1 sqq.; Luke vi. 12 sqq.); the storm on the Lake of Galilee (Mark vi. 45 sqq.; Matt. xiv. 22 sqq.; John vi. 16 sqq.); the Messianic recognition at Caesarea Philippi (Mark vii. 27 sqq.; Matt. xvi. 16 sqq.; Luke ix. 18 sqq.); the incident of the payment of tribute by the coin found in the fish caught by Peter (Matt. xvii. 25 sqq.) and with various questions leading to parables or their explanations (Mark xii. 36 sqq.; Luke xi. 41; Matt. xviii. 21 sqq.; Mark x. 28; Matt. xix. 27; Luke xviii. 28). In the week of the Passion he appears in connexion with the incident of the withered fig-tree (Mark xi. 21; Matt. x. 13), the eschatological discourse (Mark xiii. 3 sqq.) and as prominent during the Last Supper (Luke xxii. 8 sqq.; John xiii. 4 sqq.; Matt. xiv. 27 sqq.; Matt. xxvi. 31 sqq.).
was present in Gethsemane, and tried to offer some resistance to the arrest of Jesus (Mark xiv. 47; Matt. xxvi. 51; Luke xxii. 50; John xviii. 10). After the arrest he followed the Lord to the scene of the trial, but denied him and fled. The message of the young man at the tomb (Mark xvi. 4) was especially addressed to Peter and it is clear that the genuine conclusion of Mark must have contained an account of an appearance of the risen Lord to him.

Out of this mass of incidents the following are central and call for closer critical consideration.

1. The Call of St Peter.—(Mark i. 16-20; Matt. iv. 18-22; Luke v. 1-11; John i. 40-42). This account in Matthew is practically identical with that in Mark and is no doubt taken from the Marcan source, but Luke and John have different traditions. The main points are as follows: according to Mark, at the beginning of the Galilean ministry Jesus saw Peter and Andrew fishing. He called them, and they joined him. After this he went with them to Capernaum, preached in the synagogue, and healed Peter’s wife’s mother. Luke, who certainly used Mark, has partly rearranged this narrative and partly rejected it in favour of a different version. According to him the visit to Capernaum and the healing of the wife’s mother preceded the call of Peter, and this was associated with a tradition of a miraculous draught of fishes. The advantage of the Lucan reconstruction, so far as the first part is concerned, is that it supplies a reason for Peter’s ready obedience, which is somewhat difficult to understand if he had never seen Jesus before. But it seems probable that this is the motive which led to the redactional change in Luke, and that the Marcan account, which is traditionally connected with Peter, ought to be followed. With regard to the narrative of the miraculous draught of fishes, the matter is more complicated. Luke obviously preferred this narrative to the Marcan account, but the fact that the same story comes in John xxi. suggests that there was an early tradition of some such incident of which the actual occasion and circumstances were undetermined. Luke may have connect it with the call of Peter, the writer of John xxi. with his restitution; probably both are of the nature of redactional guesses, and the Marcan account must be regarded as preferable to either. The Johannine account of the call of Peter is quite different. According to this it took place immediately after the baptism of Jesus, in Judæa not in Galilee. It is connected with the giving of the name Peter, which in Mark was not given until much later.

2. The Confession of Peter at Caesarea Philippi.—(Mark viii. 27-33; Matt. vii. 13-23; Luke ix. 18-22). According to Mark, Peter, in answer to the question of Jesus, recognized that he was the Messiah, but professed a doubt as to the Messiahship. According to Matthew this statement is made after Jesus had delivered the parable of the talents (Mark ix. 24, 25). Matthew’s account is parallel to the latter part of Mark’s; he is not, however, connected with it, but states it as an exordium to a new narrative. According to Mark, Peter did not stay with the disciples and returned home immediately to Galilee (according to the Galilean tradition) nor sought hiding in Jerusalem (according to the Jerusalem tradition), but followed the Lord at a distance and was a witness of at least part of the trial before the Sanhedrim. He was detected and accused of being a disciple, which he denied, and so fulfilled the prophecy of Jesus that he would deny Him before the cock crowed.

But putting this incident aside, the Galilean and Jerusalem traditions do not admit of reconciliation with one another. The former is represented by Mark. According to it the disciples all fled after the betrayal (though Peter waited until the denial), and afterwards saw the risen Lord in Galilee. But the details of this narrative are unfortunately lost, as the genuine conclusion of Mark is not extant. But Mark xiv. 28 and xvi. 7 clearly imply a narrative which described how the disciples returned to Galilee, there saw the risen Lord, and perhaps even how they then returned to Jerusalem in the strength of their newly recovered faith, and so brought into existence the church of Jerusalem as we find it in the Acts. It is also clear from Mark xvi. 7 that Peter was in some special way connected with this appearance of the risen Lord, and this tradition is confirmed by 1 Cor. xv. 5, and perhaps by Luke xxiv. 34.

The Jerusalem narrative is represented especially by Luke and John (excluding John xxi. as an appendix). According to this the disciples, though they fled at the betrayal, did not return to their homes, but remained in Jerusalem, saw the risen Lord in that city, and stayed there until after the day of Pentecost. Attempts to reconcile these two narratives seem to be found in Matthew and in John xxi.

Obviously the choice which has to be made between these traditions cannot be adequately discussed here: it must suffice to say that intrinsic and traditional probability seem to favour the Galilean narrative. If so, one must say that after the denial Peter returned to Galilee—probably to resume his trade of fishing—and he there saw the risen Lord. This appearance is referred to in 1 Cor. xv. 5, and was certainly described in the lost conclusion of Mark. An account of it is preserved in John xxi., but it is here connected—probably wrongly—with a miraculous draught of fishes, just as the account of his call is in Luke.

Immediately after the resurrection there is a missing link in the history of Peter. We know that he saw the risen Lord, and, according to the most probable view, that this was in Galilee; but the circumstances are unknown, and we have no account of his return to Jerusalem, as at the beginning of the Acts the disciples are all in Jerusalem, and the writer, in contradiction to the Marcan or Galilean narrative, assumes that they had never left it. The first part of the Acts is largely concerned with
the work of Peter. He appears as the recognized leader of the
Apostles in their choice of a new member of the Twelve to take
the place of Judas Iscariot (Acts i. 15 sqq.); on the day of
Pentecost he seems to have played a prominent part in explaining
the meaning of the scene to the people (Acts ii. 14 sqq.); and soon
afterwards was arrested by the Jews on the charge of being a ring-
leader in the disorders caused by the healing of the lame man at
the “Beautiful” gate of the temple, but was released. After
this he appears as the leader of the apostles in the story of
Ananias and Sapphira, who perished at his rebuke for their
duplicity (Acts v. i—i1). The last episode of this period is
another arrest by the priests, which ended in his being scourged
and released (Acts v. 17 sqq.).

After this Peter’s attention was directed to the growth of
Christianity in Samaria, and he and John made a journey of
inspection through that district, laying hands on those who had
been baptized in order that they might receive the Holy Spirit.
Here Simon Magus (q.v.) was encountered. He was a magician
who had been converted by Philip and baptized; he desired to
obtain the power of conferring the Spirit, and offered Peter
money for this purpose, but was indignantly repulsed. After
this Peter and John returned to Jerusalem.

During the following stay in Jerusalem, the duration of
which is not defined, Peter was visited by Paul (Acts ix. 26—29;
Gal. i. 18), and a comparison of the chronological date afforded
by Gal. i. and ii. points to a year not earlier than 33 (Harnack)
or later than 38 (C. H. Turner) for this meeting. According
to Galatians, Paul saw none of the apostles on this occasion except
Peter and James: it is therefore probable that none of the others
were then in Jerusalem.

After this Peter made another journey, visiting especially
Lydda, Joppa and Caesarea. His stay at Lydda was marked by
the healing of Aeneas (Acts ix. 32—4) and at Joppa by the
resurrection of Tabitha or Dorcas. While at Joppa he stayed
with Simon the tanner, and thence was summoned to Caesarea
to Cornelius the centurion. He hesitated whether to go, but
was persuaded by a vision and the injunction to call nothing
unclean which God had cleansed. Cornelius was accordingly
baptized. This is an important incident, as being the first
admission of a Gentile into the church: but he was already “ God-
fearing,” φοβομένος τοῦ θεοῦ (Acts x. 1), which probably
denotes some sort of connexion with the Jewish synagogue,
though it is difficult to say exactly what it was. After this inci-
dent Peter returned to Jerusalem. The members of the Church
were somewhat shocked at the reception of a Gentile, the
idea apparently was that the only road to Christianity was through
Judaism. They were, however, persuaded by Peter’s speech
(Acts xi. 1—17); but it is uncertain how far their concession went,
and in the light of subsequent events it is probable that they still
regarded circumcision as a necessary rite for all Christians.

After the return of Peter to Jerusalem the most important
events were the famine at Jerusalem, and the persecution of the
Church by Herod. During the latter Peter was put in prison
(Acts xii. 3 sqq.), but was released by an angel; he first went to
the house of Mary, the mother of John Mark, and afterwards
went to “ another place.” This expression has been interpreted
not to mean another, and is perhaps a simple repetition of the
previous phrase: it is somewhat unceremonious that the road to
Rome was made known to the apostles before that to Jerusalem.
This last assumption, improbable though it be, is his-
torically important. The persecution of Herod seems to have
been in his last year, which was probably a.d. 43—44. There
was a marked tendency to make the duration of Peter’s episcopate
at Rome twenty-five years; and a combination of this tendency
with the explanation that the έτερος τότος is Rome probably is
the origin of the traditional dating of the martyrdom of Peter
in a.d. 67—68. There is, however, no justification for this view,
and έτερος τότος need not mean more than another house in
Jerusalem.

The famine referred to in Acts xi. 27 sqq. probably began
before the death of Herod, but it continued after his death, and
the relief sent by the church at Antioch to Jerusalem through
Paul and Barnabas probably arrived about the year 45. It is
not stated in the Acts that Peter was present, and it is therefore
usually assumed that he was absent, but Sir W. M. Ramsay has
argued in his St Paul the Traveller that the visit of Paul to
Jerusalem with the famine relief is the meeting between Paul
and Peter referred to in Gal. ii. as the occasion of an agreement
between them as to the preaching of the gospel to Jews and
Gentiles. This view is not generally accepted, but it has the
great advantage of avoiding the difficulty that otherwise Paul
in Gal. ii. 1 sqq. must describe as his second visit to Jerusalem
what was really his third. According to Ramsay, then, Peter
was present during the famine, and made a private agreement
with Paul that the latter should preach to the Gentiles, and so
far Gentile Christianity was recognized, but the conditions of
the intercourse between Gentile and Jewish Christians were not
defined, and the question of circumcision was perhaps not finally
settled. According to the more popular view the description
in Gal. ii. applies to Acts xv. the so-called council of Jerusalem.
This council met after the first missionary journey (c. a.d. 49)
of Paul to discuss the question of the Gentiles. Peter, who was
present, adopted the view that Gentile Christians were free from
the obligation of the law, and this view was put into the form of
the so-called Apostolic decrees by James (Acts xv. 22 sqq.).
The next information which we have about Peter is given in
Gal. ii. 11 sqq. According to this he went to Antioch and at
first accepted the Gentile Christians, but afterwards drew back
and was rebuked by Paul. On the ordinary interpretation this
must have taken place after the council, and it is exceedingly
difficult to reconcile it with the attitude of Peter described in
Acts xv., so that Mr C. H. Turner thinks that in this respect
the account in Gal. ii. is not chronological, and places the visit
of Peter to Antioch before the council. If, however, we take the
theory of Sir W. M. Ramsay the matter is simpler. We thus
get the compact between Paul and Peter during the famine,
then a visit of Peter to Antioch, during which Peter first adopted
and afterwards drew back from the position which he had agreed
to privately.

This vacillation may then have been one of the causes which
led up to the council, which may have been held before, not, as
is usually thought, after the sending of the Epistle
to the Galatians. For this we have no knowledge
details for which the same certainty can be claimed.
There are, however, various traditions of importance.
The following points are noteworthy. 1 Cor. i. 12 suggests the
possibility that Peter went to Corinth, as there was a party
there which used his name. It is, however, possible that this
party had merely adopted the principles which, as they were
then told, perhaps falsely, were supported by Peter during the
twelve. Dionysius of Corinth (c. 170) states that Peter was in
Corinth. This may represent local tradition or may be an
inference from 1 Cor. i. 12. 1 Peter suggests a ministry in
the provinces of Asia Minor. There is, of course, nothing improb-
able in this, and even if 1 Peter be not authentic, it is early
tradition for such a tradition, but it is also possible that Peter
grew to convert others whom he had not personally made.
This tradition is found in Origen (Eus. H. E. iii. 1), Epiphanius
(Hær. xxvii., vil.), Jerome (De Vir. ill. 1) and other later writers;
but it is possible that it is merely an inference from the epistle.
This inference connects Peter with Antioch, and has been
said to have been the first bishop. The first writer to mention it
is Origen (Hom. vi. in Lucan.), but it is also found in the Clementine
Homilies and Recognitions (Hom. 20, 23; Recog. 10, 68) and
probably goes back to the lists of bishops which were drawn up
in the 2nd century. Other important references to this tradition
are found in Eus. H. E. iii. 26, 2; Apost. Const. vili. 46; Jerome,
De Vir. ill. 1; Chronicon paschale; and Liber pontificum.
The tradition of work in Antioch may well be historical. Otherwise
it is rather a wild elaboration of Gal. ii. 11. The most important
and widespread tradition is that Peter came to Rome; and
though this tradition has often been bitterly attacked, it seems
probable that it is at least outline quite historical. The
evidence for it is earlier and better than that for any other
tradition, though it is not quite convincing.

The earliest witness to a residence of Peter in Rome is probably
1 Peter, for (see Peter, Epistles of) it is probable that the reference to Babylon ought to be interpreted as meaning Rome. If so, and if the epistle be genuine, this is conclusive evidence that Peter was in Rome. Even if the epistle be not genuine, it is evidence of the same tradition. Nor is corroborating lack: Clement (c. A.D. 97) refers to Peter and Paul as martyrs (1 Clem. 3-5) and says that "To these men ... there was gathered a great company of the elect who ... became an example to us." This points in two ways to a martyrdom of Peter in Rome, (i) because Peter and Paul are co-ordinated, and it is generally admitted that the latter suffered in Rome, (2) because they seem to be joined to the great Peter tradition upon who are the martyr example to the Church in Rome. Similarly Ignatius (c. A.D. 115) says to the Romans (Rom. iv.), "I do not command you as Peter and Paul." The suggestion obviously is that the Romans had been instructed by these Apostles. By the end of the 2nd century the tradition is generally known: Irenaeus (3, 1, 1), Clement of Alexandria (comment. on 1 Peter), Origen (Hom. vi. in Lucam), Tertullian (Scorp. 15, and several passages) are explicit on the point, and from this time onwards the tradition is met with everywhere. There is also a tradition, found in Irenaeus (3, 3, 1) and in many later writers, and supported by 1 Pet. vi. 11, that Clement, Marcion, Papias (Eus. H.E. 3, 39, 15 sq.) and Mark acted as Peter's assistant in Rome and that his gospel is based on recollections of Peter's teaching.

This evidence is probably sufficient to establish the fact that Peter, like Paul, had a wide missionary career ending in a violent death at Rome, though the details are not recoverable. The chronological question is more difficult both as regards the beginning and the end of this period of activity.

The Acts, in describing the visits of Peter to Samaria, Joppa, Lydda and Caesarea, justify the view that his missionary activity began quite early. Gal. ii. 11 and 1 Cor. ix. 5 show that Acts minimizes rather than exaggerates this activity; the Antiochian tradition probably represents a period of missionary activity with a centre at Antioch; similarly the tradition of work in Asia is possibly correct as almost certainly is that of the visit to Rome. But we have absolutely no evidence justifying a chronological arrangement of these periods. Even the silence of Paul in the epistles of the captivity proves nothing except that Peter was not then present; the same is true of 2 Tim., even if its authenticity be undoubted.

The evidence as to the date of his death is a little fuller, but not quite satisfactory. The earliest direct witness is Tertullian, who definitely states that Peter suffered under Nero and that his crucifixion. Origen also relates the latter detail and adds that at his own request Peter was crucified head downwards. Probably John xxi. 18 seq. is a still earlier reference to his crucifixion. Fuller evidence is not found until Eusebius, who dates the arrival of Peter at Rome in 43 and his martyrdom twenty-five years later. But the whole question of the Eusebian chronology is very confusing and difficult, and the text of the Chronicon is not certain. The main objection to this date is based partly on general probability, partly on the language of Clement of Rome. It is more probable on general grounds that the martyrdom of Peter took place during the persecution of Christians in 64, and it is urged that Clement's language refers to this period. It is quite possible that an error of a few years has crept into the Eusebian chronology, which is probably largely based on early episcopal lists, and therefore many scholars are inclined to think that 64 is a more probable date than 67. As a rule the discussion has mainly been between these two dates, but Sir W. M. Ramsay, in his Church in the Roman Empire, has adopted a different line of argument. He thinks that 1 Peter was written c. A.D. 80, but that it may nevertheless be Petrine; therefore he lays stress on the fact that whereas the tradition that Peter was in Rome is early and probably correct, the tradition that he was martyred under Nero is not found until much later. Thus he thinks it possible that Peter survived until c. 80 and was martyred under the Flavian emperors. The weak point of this theory is that Clement and Ignatius bring Peter and Paul together in a way which seems to suggest that they perished, if not together, at least at about the same time. If this view be rejected and it is necessary to fall back on the choice between 64 and 67, the problem is perhaps insoluble, but 64 has somewhat more intrinsic probability, and 67 can be explained as due to an artificial system of chronology which postulated for Peter an episcopate of Rome of twenty-five years—a number which comes so often in the early episcopal lists that it seems to mean little more than "a long time," just as "forty years" does in the Old Testament. On the whole 64 is the most probable date, but it is very far from certain: the evidence is insufficient to justify any guess of a precise date.

For further information and discussion see especially Harnack's Chronologie, and Bishop Chace's article in Hastings' Dictionary of the Bible. The latter is in many ways the most complete statement of the early tradition.

Calus, who lived in the beginning of the 3rd century (see Eus. H. E. 2, 25), stated that the ἀναθήματα (i.e. probably the burial place, not that of execution) of Peter and Paul were on the Vatican. This is also found in the Acta Petri, 84 (in the Lib. Pont., ed. Duchesne, p. 52 seq., 118 sq.), from this place it appears that the relics (whether genuine or not) were moved to the catacombs in A.D. 258 (cf. the Deposita martyrum, and see Lightfoot's Clement, i. 249); hence arose the tradition of an original burial in the catacombs, found in the Hieronymian Martyrology.

Peter I., called "the Great" (1672-1725), emperor of Russia, son of the tsar Alexius Mikhailovich and Natalia Narishkina, was born at Moscow on the 9th of May 1672. His earliest teacher (imitating the legendary Scotchman Menzies) was the dyak, or clerk of the council, Nikïia Zotov, subsequently the court fool, who taught his pupil to spell out the liturgical and devotional books on which the children of the tsar were brought up. After Zotov's departure on a diplomatic mission, in 1688, the lad had no regular tutor. From his third to his tenth year Peter shared the miseries and perils of his family. His very election (1688) was the signal for a rebellion. He saw one of his uncles dragged from the palace and butchered by a savage mob. He saw his mother's beloved mentor, and his own best friend, Artamon Matveev, torn, bruised and bleeding, from his retainer's grasp and hacked to pieces. The haunting memory of these horrors played havoc with the nerves of a supersensitive child. The convulsions from which he suffered so much in later years must be partly attributed to this violent shock. During the regency of his half-sister Sophia (1682-1689) he occupied the subordinate position of junior tsar, and after the revolution of 1689 Peter was still left pretty much to himself. So long as he could indulge freely in his favourite pastimes—ship-building, ship-sailing, drilling and sham fights—he was quite content that others should rule in his name. He now found a new friend in the Swiss adventurer, François Lefort, a shrewd and jovial rascal, who not only initiated him into all the mysteries of profanity (at the large house built at Peter's expense on the German settlement), but taught him his true business as a ruler. His mother's attempt to wean her prodigal son from his dangerous and mostly disreputable pastimes, by forcing him to marry the beautiful but stupid Eudoxia Lopukhina (Jan. 27, 1688), was a disastrous failure. The young couple were totally unsuited to each other. Peter practically deserted his unfortunate consort a little more than a year after their union.

The death of his mother (Jan. 25, 1694) left the young tsar absolutely free to follow his natural inclinations. Tiring of the great lake at Peryashlav, he had already seen the sea for the first time at Archangel in July 1683, and on the 1st of May 1694 returned thither to launch a ship built by himself the year before. Shortly afterwards he nearly perished during a storm in an adventurous voyage to the Solovetsky Islands in
the White Sea. His natural bent was now patent. From the first the lad had taken an extraordinary interest in the technical and mechanical arts, and their application to military and naval science. He was taught the use of the astrolabe (which Prince Yakov Dolgorukiy, with intent to please, had brought him from Paris) by a Dutchman, Franz Timmerman, who also instructed him in the rudiments of geometry and fortifications. He had begun to build his own boats at a very early age, and the ultimate result of these pastimes was the creation of the Russian navy. He had already surrounded himself with that characteristically Petrine institution—"the jolly company," or "the company," as it was generally called, consisting of all his numerous personal friends and casual acquaintances. "The company" was gradually developed into the Russian navy, and the founder and first head of this extraordinary institution, both as to his personal qualities and the nature of his labours, as well as to the part he suddenly and without any forewarning assumed, might be said to have been the Midas of his time. It was said of him that he led a life resembling nothing so much as that of the Greek king of Thrace, in that he was responsible for a new and extraordinary wealth, and shared not only the orgies but also the labours of the state. Merit was the sole qualification for promotion, and Peter himself set the example to the other learners by gradually rising from the ranks. In 1695 he had only advanced to the post of "skipper" in his own navy and of "bombardier" in his own army. It was, however, the disreputable Lefort who, for the sake of his own interests, diverted the young tsar from mere pleasure to serious enterprises, by persuading him first to undertake the Azov expedition, and then to go abroad to complete his education.

By this time the White Sea had become too narrow for Peter, and he was looking about him for more hospitable waters. The Baltic was a closed door to Muscovy, and the key to it was held by Sweden. The Caspian remained; and it had for long been a common saying with foreign merchants that the best way of tapping the riches of the Orient was to secure possession of this vast inland lake. But so long as the Turks and Tatars made the surrounding steppes uninhabitable the Caspian was a possession of but doubtful value. The first step making for security was to build a fleet strong enough to provide against the anarchical condition of those parts; but this implied a direct attack not only upon the Crimean khan, who was mainly responsible for the conduct of the Volgan hordes, but upon the khan's suzerain, the Turkish sultan. Nevertheless Peter did not hesitate. War against Turkey was resolved upon, and Azov, the chief Turkish fortress in those regions, which could be approached by water from Moscow, became the Russian objective. From the 8th of July to the 22nd of September 1695 the Muscovites attempted in vain to capture Azov. On the 22nd of November Peter re-entered Moscow. His first military expedition had ended in undisputed disaster, yet from this disaster is to be dated the reign of Peter the Great.

Immediately after his return he sent to Austria and Prussia for as many sappers, miners, engineers and carpenters as money could purchase, and took the greatest care to prevent the Turkish fleet from relieving Azov. The guards and all the workmen procurable were driven, forthwith, in bands, to all the places among the forests of the Don to fell timber and work day and night, turning out scores of vessels of all kinds. Peter himself lived among his workmen, himself the most strenuous of them all, in a small two-roomed wooden hut at Voronezh. By the middle of April two warships, twenty-three galleys, four fireships and numerous smaller craft were safely launched. On the 3rd of May "the sea caravan" sailed from Voronezh. "Captain Peter Alexeyevich commanding the galley-flotilla from the galley Principium," built by his own hand. The new Russian fleet did all that was required of it by preventing the Turks from relieving Azov by water; and on the 18th of July the fortress surrendered. Peter now felt able to advance along the path of progress with a quicker and a firmer step. It was resolved to consolidate the victory by establishing a new naval station at the head of the Sea of Azov, to which the name of Taganrog was given. But it was necessary to guarantee the future as well as provide for the present. Turkey was too formidable to be fought single-handed, and it was therefore determined to send a grand embassy to the principal western powers to solicit their co-operation against the Porte. On the 10th of March 1697 this embassy, under the leadership of Lefort, set out on its travels. Peter attached himself to it as a volunteer sailorman, "Peter Mikhailov," so as to have greater facility for learning ship-building and other technical sciences. As a political mission it failed utterly, the great powers being at that period far more interested in western than in eastern affairs. But personally Peter learnt nearly all that he wanted to know—gunnery at Königsberg, ship-building at Saardam and Deptford, anatomy at Leiden, engraving at Amsterdam—and was proceeding to Venice to complete his knowledge of navigation when the revolt of the stryeltsy, or musketeers (June 1698), recalled him to Moscow. This revolt has been greatly exaggerated. It was suppressed in an hour's time by the tsar's troops, of whom only one man was killed. Immediately by December 1698 which Peter on his return to Russia wreaked upon the captive musketeers was due not to any actual fear of these antiquated warriors, but to his consciousness that behind them stood the reactionary majority of the nation who secretly sympathized with, though they durst not assist, the rebels.

Peter's foreign tour had more than ever convinced him of the inherent superiority of the foreigner. Imitation had necessarily to begin with externals, and Peter at once fell foul of the long beards and Oriental costumes which symbolized the arch-conservatism of old Russia. On the 26th of April 1698 the chief men of the tsarom were assembled round his wooden hut at Preobrazhenskoye, and Peter with his own hand deliberately clipped off the beards and moustaches of his chief boyaars. The ukaz of the 1st of September 1698 allowed as a compromise that beards should be worn, but a graduated tax was imposed upon their wearers. The wearing of the ancient costumes was forbidden by the ukaz of the 4th of January 1700; henceforth Saxon or Magyar jackets and French or German hose were prescribed. That the people themselves did not regard the reform as a trifle is plain from the numerous rebellions against it. By the ukaz of the 20th of December 1699 it was next commanded that henceforth the new year should not be reckoned as hitherto, from the 1st of September, supposed to be the date of the creation, but from the first day of January, anno domini.

The year 1700 is memorable in Russian history as the starting-point of Peter's long and desperate struggle for the hegemony of the north. He had concluded peace with the Porte (June 13, 1700) on very advantageous terms, in order to devote himself wholly to a war with Sweden to the end that Russia might gain her proper place on the Baltic. The possession of an ice-free seaboard was essential to her natural development; the creation of a fleet would follow inevitably upon the acquisition of such a seaboard; and she could not hope to obtain her due share of the trade and commerce till she were herself possessed of the merchant marine. The conquests seemed favourable to Peter. The Swedish government was in the hands of an untried lad of sixteen; and the fine fleets of Denmark, and the veteran soldiers of Saxony, were on the same side as the myriads of Muscovy. It seemed an easy task for such a coalition to wrest the coveted spoil from the young Charles XII.; yet Peter was the only one of the three conspirators who survived the Twenty-one Years' War in which they so confidently embarked during the summer of 1701. He was also the only one of them who got anything by it. Charles's "immersion in the Polish bog" (1702-1707), as Peter phrased it, enabled the tsar, not without considerable expense and trouble, to conquer Ingria and lay the foundations of St. Petersburg. In these early days Peter would very willingly have made peace with his formidable rival if he had been allowed to retain these comparatively modest conquests. From 1707 to 1709 the war on his part was purely defensive; Charles would not hear of peace till full restitution had been made and a war indemnity paid, while Peter was fully resolved to perish rather than surrender his "paradise," Petersburg. After Pultava (June 26, 1709), Peter, hitherto commendably cautious even to cowardice, but now pulled up with pride, rashly plunged into as foolhardy an enterprise as ever his rival engaged in. The campaign of the Pruth (March to July 1711) must have been fatal to the
tsar but for the incalculable behaviour of the omnipotent grand vizier, who let the Russian army go at the very instant when it lay helpless in the hollow of his hand. Even so, Peter, by the peace of the Pruth, had to sacrifice all that he had gained by the Azov expedition fifteen years previously. On receiving the tidings of the conclusion of the peace of Nystad (August 30, 1721), Peter declared, with perfect justice, that it was the most profitable peace Russia had ever concluded. The gain to Russia was, indeed, much more than territorial. In surrendering the pride of her Baltic provinces, Sweden had surrendered along with them the hegemony of the north, and all her pretensions to be considered a great power.

The Great Northern War was primarily a training school for a backward young nation, and in the second act of the death of the materials of revolution a natural process of internal domestic reformation had been slowly but unceasingly proceeding. Brand-new institutions on Western models were gradually growing up among the cumbersome, antiquated, worn-out machinery of old Muscovy; and new men, like Menshikov, Goloykin, Apraksin, Osterman, Kurakin, Tolstoy, Shafirov, Prokopovich, Yaguzhinsky, Yavorsky, all capable, audacious, and brimful of new ideas, were being trained under the eye of the great regenerator to help him to carry on his herculean task. At first the external form of the administration remained much the same as before. The old dignities disappeared, but the system accorded with the deaths of their holders, and the new men, those nearest to Peter, did not require them. "The Administrative Senate" was not introduced till 1721, and only then because the intolerable war, which required Peter's prolonged absence from Russia, made it impossible for him to attend to the details of the domestic administration. Still later came the "Spiritual Department," or "Holy Synod" (January 1721), which superseded the ancient patriarchate. It was established, we are told, "because simple folks cannot distinguish the spiritual power from the sovereign power, and suppose that a supreme spiritual pastor is a second sovereign, the spiritual authority being regarded as higher and better than the temporal." From the first the regenerator in his uskaz was careful to make everything quite plain. He was always explaining why he did this or that, why the new was better than the old, and so on; and we must recollect that these were the first lessons of the kind the nation had ever received. The whole system of Peter was deliberately directed against the chief evils from which old Muscovy had always suffered, such as dissipation of energy, dislike of co-operation, absence of responsibility, lack of initiative, the tyranny of the family, the insignificance of the individual. The low social morality of all classes, even when morality was present at all, necessitated the reformation of the nation against its will, and the process could therefore only be a violent one. Yet the most enlightened of Peter's contemporaries approved of and applauded his violence; some of them firmly believed that his most energetic measures were not violent enough. Thus Ivan Poroshkov, Peter's contemporary, the father of Russian political economy, writes as follows: "If any land be over-much encouraged with weeds, corn cannot be sown thereon unless the weeds first be burned to fire. In the same way, our ancient inveeterate evils should also be burnt with fire." Peter himself carried this principle to its ultimate limits in dealing with his unfortunate son the Tsarevich Alexius (q.v.). From an ethical and religious point of view the deliberate removal of Alexius was an abominable, an inhuman crime: Peter justified it as necessary for the welfare of the new Russia which he had called into existence.

The official birthday of the Russian empire was the 22nd of October 1721, when, after a solemn thanksgiving service in the Troitsa Cathedral for the peace of Nystad, the tsar proceeded to the senate and was there acknowledged: "Father of the Fatherland, Peter the Great, and Emperor of All Russia." Some Russians would have preferred to proclaim Peter as emperor of the East; but Peter himself adopted the more patriotic title.

Towards the end of the reign the question of the succession to the throne caused the emperor some anxiety. The rightful heir to the primogeniture was his eldest daughter, Grand Duke Peter, son of the Tsarevich Alexius, a child of six; but Peter decided to pass him over in favour of his own beloved consort Catherine. The ustaw, or ordinance of 1722, heralded this unheard-of innovation. Time-honoured custom had hitherto reckoned primogeniture in the male line as the best title to the Russian crown; in the ustaw of 1722 Peter denounced primogeniture in general as a stupid, dangerous, and even unscriptural practice of dubious origin. The ustaw was but a preliminary step to a still more sensational novelty. Peter had resolved to crown his consort empress, and on the 25th of November 1723 he issued a second manifesto, explaining at length the reason of his new departure from the ancient custom. It should be observed, however, that he had considered themselves necessary explanations the coronation of a woman was in the eyes of the Russian people a scandalous innovation in any case, and the proposed coronation was doubly scandalous in view of the base and disreputable origin of Catherine herself (see Catherine I.). But Peter had his way, and the ceremony took place at Moscow with extraordinary pomp and splendour on the 7th of May 1724.

During the last four years of his reign Peter's policy was predominantly Oriental. He had got all he wanted in Europe, but the anarchical state of Persia at the beginning of 1722 opened up fresh vistas of conquest. The war which lasted from May 1722 to September 1723 was altogether successful, resulting in the acquisition of the towns of Baku and Derbent and the Caspian provinces of Gilan, Mazandaran and Astarabad. The Persian campaigns wore out the feeble health of Peter, who had been ailing for some time. A long and fatiguing tour of inspection over the latest of his great public works, the Ladoga Canal, during the autumn of 1724, brought back another attack of his paroxysms, and he reached Peters burg too ill to rally again, though he showed himself in public as late as the 16th of January 1725. He expired in the arms of his consort, after terrible suffering, on the 28th of January 1725.

Peter's claim to greatness rests mainly on the fact that first to last he clearly recognized the requirements of the Russian nation and his own obligations as its ruler. It would have materially lightened his task had he placed intelligent foreigners at the head of every department of state, allowing them gradually to train up a native bureaucracy. But for the sake of the independence of the Russian nation he resisted the temptation of taking this inviting but perilous short-cut to greatness. He was determined that, at whatever cost, hardship and inconvenience, Russia should be ruled by Russians, not by foreigners; and before his death he had the satisfaction of seeing every important place in his empire in the hands of capable natives of his own training. But even in his most sweeping reforms he never lost sight of the idiosyncrasies of the people. He never destroyed anything which he was not able to replace by something better. He possessed, too, something of the heroic nature of the old Russian bogatirs, or demigods, as we see them in the skazki and the bulinui. His expansive nature loved width and space. No doubt this last of the bogatirs possessed the violent passions as well as the wide views of his prototypes. All his qualities, indeed, were on a colossal scale. His rage was cyclonic: his hatred rarely stopped short of extermination. His banquets were orgies, his pastimes convulsions. He lived and he loved like one of the giants of old. There are deeds of his which make humanity shudder, and no man equally great has ever descended to such depths of cruelty and treachery. Yet it may generally be allowed that a strain of nobility, of which we occasionally catch illuminating glimpses, extorts from time to time an all-forgiving admiration. Strange, too, as it may sound, Peter the Great was at heart profoundly religious. Few men have ever had a more intimate persuasion that they were but instruments for good in the hands of God.

PETER II. (1715—1730), emperor of Russia, only son of the Tsarevich Alexius, was born on the 15th of October 1715. From his childhood the orphan grand duke was kept in the strictest seclusion. His grandfather, Peter the Great, systematically ignored him. His earliest governesses were the wives of a tailor and a vintner from the Dutch settlement; a sailor called Norman taught him the rudiments of navigation; and, when he grew older, he was placed under the care of a Hungarian refugee, Janos Zeikin, who seems to have been a conscientious teacher. During the reign of Catherine I. Peter was quite ignored; but just before her death it became clear to those in power that the grandson of Peter the Great could not be kept out of his inheritance much longer. The majority of the nation and three-quarters of the nobility were on his side, while his uncle, the emperor Charles VI., through the imperial ambassador at St Petersburg, Rabutin, persistently urged his claims. The matter was arranged between Menshikov, Osterman and Rabutin; and on the 18th of May 1727 Peter II., according to the terms of the supposed last will of Catherine I., was proclaimed sovereign autocrat. The senate, the privy council and the guards took the oath of allegiance forthwith. The education of the young prince was wisely entrusted to the vice-chancellor Osterman. Menshikov, who took possession of Peter II. and lodged him in his own palace on the Vasily island, had intended to marry Peter to his daughter Maria; the scheme was frustrated by his fall (Sept. 21, 1727), but Peter only fell into the hands of the equally unscrupulous Dolgoruki, who carried him away from Petersberg to Moscow. Peter's coronation was celebrated at that city on the 25th of February 1728. He was betrothed to Catherine, second daughter of Alexius Dolgoruki, and the wedding was actually fixed for the 30th of January 1730; but on that very day the emperor died of small-pox.

PETER III. (1728—1762), emperor of Russia, only son of Charles Frederick, duke of Holstein-Gottorp, and of Anne, eldest surviving daughter of Peter the Great, was born at Kiel on the 21st of February 1728. In December 1741 he was adopted by his aunt, Elizabeth Petrovna, as soon as she was safely established on the Russian throne, and on the 18th of November 1742 was received into the Orthodox Church, changing his original name of Karl Peter Ulrich for that of Peter Fedorovich. On the 21st of August 1745, by the command of his aunt, he married the princess Sophia Augusta Frederica of Anhalt-Zerbst, who exchanged her name for that of Catherine Alexseyevna. The union between a prince who physically was something less than a man and mentally little more than a child, and a princess of prodigious intellect and an insatiable love of enjoyment, was bound to end in a catastrophe. But there is no foundation for the stories of Peter's neglect and brutality. It took the spouses five years to discover that their tastes were divergent and their tempers incompatible. Even when Peter III. succeeded his aunt on the 4th of January 1762, he paid off all the debts that Catherine had contracted without inquiring what they were for. On her birthday, in April, he made her a present of domains worth 500,000 per annum, though he had already readjusted her establishment on a truly imperial scale. A great deal has been made of Peter's infidelity towards his consort; but the only one who really suffered from his liaison with the ugly, stupid and vicious countess Elizabeth Vorontsova was the unfortunate emperor. So far from being scandalized by the juxtaposition of "Das Fräulein" in the Winter Palace, Catherine accepted it as a matter of course, provided that her own relations with the handsome young guardsman, Gregory Orlov, were undisturbed. Nor was Peter's behaviour to his consort in public of such an outrageous character as has been led to suppose. Peter, in fact, was too good-natured and inconsequent to pursue, or even premeditate, any deliberate course of ill treatment. No personal wrongs, but the deliberate determination of a strong-minded, capable woman to snatch the reins of government from the hands of a semi-imbecile, was the cause of Peter's overthrow, and his stupendous blunders supplied Catherine with her opportunity. Peter's foreign policy was the absolute reversal of the policy of his predecessor. He had not been on the throne for two months when he made public overtures to the well-nigh vanquished king of Prussia, whom he habitually alluded to as "the king my master." Peter's enthusiastic worship of Frederick resulted in a peace (May 5) and then (June 19) in an offensive and defensive alliance between Russia and Prussia, whereby Peter restored to Prussia all the territory won from her by Russia during the last five years at such an enormous expense of men and money, and engaged to defend Frederick against all his enemies. This was followed up by a whole series of menacing rescripts addressed by Peter to the court of Vienna, in which war was threatened unless Austria instantly complied with all the demands of the king of Prussia. Finally he picked a quarrel with Denmark for not accepting as an ultimatum the terms to be submitted by Russia to a peace conference to meet at Berlin for the purpose of adjusting the differences between the two powers. On the 6th of July the Russian army received orders to invade Denmark by way of Mecklenburg. This advance was only arrested, when the opposing forces were almost within touch of each other, by the tidings that a revolution had taken place at St Petersburg, and that Peter III. was already a prisoner in the hands of his consort. The coup d'état of the 9th of July 1762 properly belongs to the history of Catherine II. (q.v.). Here only a few words must be said as to the mysterious death of Peter at the castle of Kopsha, to which he was removed immediately after the announcement of the House of Romanov's return from the evening of the 9th to the afternoon of the 18th of July. At first Catherine, and her counsellors could not make up their minds what to do with "the former emperor." Imprisonment in Schlüsselfeld for life, or repatriation to Holstein, were proposed only to be rejected as dangerous. The Orlov's had even stronger motives than Catherine for suppressing the ex-emperor, for Gregory Orlov aspired to win the hand as well as the heart of his imperial mistress, and so long as Catherine's lawful husband lived, even in a prison, such a union would be impossible. The available evidence points to the irresistible conclusion that on the after- noon of the 18th of July 1762, Peter III., with his consort's connivance, was brutally murdered at Kopsha by Alexius Orlov, Theodore Baryatinski, and several other persons still unknown.

See R. N. Bain, Peter III., Emperor of Russia (London, 1902); V. A. Bilbasov, History of Catherine II. (Russ.), vol. i. (Berlin, 1900).

PETER (Pedro), the name of several Spanish kings.

Peter I., king of Aragon (d. 1104), son of Sancho Ramirez, the third in order of the historic kings of Aragon, belonged to times anterior to the authentic written history of his kingdom; and little is known of him save that he recovered Huesca from the Mahomedans in 1096.

Peter II., king of Aragon (1174—1213), son of Alphonso II. and his wife Sancia, daughter of Alphonso VIII. of Castile, was born in 1174. He had a very marked and curious personal character. As sovereign of lands on both sides of the Pyrenees, he was affected by very different influences. In his character of Spanish prince he was a crusader, and he took a distinguished part in the great victory over the Almohades at the Navas de Tolosa in 1212. But his lands to the north of the Pyrenees brought him into close relations with the Albigenses. He was a favourer of the troubadours, and in his ways of life he indulged in the laxity of Provencal morals to the fullest extent. We are told in the chronicle written by Deceleo soon after his time,
that Peter was only trapped into cohabiting with his wife by the device which is familiar to readers of Measure for Measure. In the year after the battle of Muret, Peter de Trastamara took up arms again, but the Crusaders of Simon of Monfort, moved not by sympathy with the Albigenses, but by the natural political hostility of the southern princes to the conquering intervention of the north under pretence of religious zeal. His son records the way in which he spent the night before the battle of Muret with a crudity of language which defies translation, and tells us that his father was too exhausted in the morning to stand at Mass, and had to be lifted into the saddle by his squires. Peter none the less showed the greatest personal valour, and his body, recognizable by his lofty stature and personal beauty, was found on the field after the rout (Sept. 12, 1213).

See chronicles of Aragon, translated by J. Forster (London, 1883); and Life and Times of James the First the Conqueror, by F. Darwin Swift (Oxford, 1894).

Peter III., king of Aragon (1236–1286), son of James the Conqueror, and his wife Yolande, daughter of Andrew II. of Hungary, was born in 1236. Having married Constance, daughter of Manfred of Beneventum, he came forward as the representative of the claims of the Hohenstaufen in Naples and Sicily against Charles, duke of Anjou. Peter began the long strife of the Angevines and the house of Capet, and was born in 1236. Having married Constance, he earned the surname of "the Great." He repelled an invasion of Catalonia undertaken by the king of France in support of Charles of Anjou, and died on the 8th of November 1286.

For the personal character of Peter III., the best witness is the Chronicle of Ramonde Muntanez—reprinted in the original Catalan by R. Lanz, Literarische Verein fur Slavistik, vol. vii. Stuttgart, (1879). The French has been published in Coll. des chroniques nationales (Paris, 1824–1828). See also O. Cartellieri, Peter von Aragon und die Sizilianische Vesper (Heidelberg, 1904).

Peter IV., king of Aragon (d. 1387), son of Alphonso IV. and his wife Teresa d'Entrecha, is known as "The Ceremonious" and also as "he of the dagger." He acquired the first title by the rigid etiquette he enforced, as one means of checking the excessive freedom of his nobles. The second name was given him because he wounded himself with his dagger in the act of cutting to pieces the so-called "charter of the Union," which authorized the rebellions of his nobles, and which he forced them to give up, after he had routed them at the battle of Epila in 1348. Of no man of the 14th century can it be more truly said that his life was a warfare on earth. He had first to subdue his nobles, and to reannex the Balearic Islands to the crown of Aragon. When he had made himself master at home, he had to carry on a long and fierce contest with his namesake Peter the Cruel of Castile, which only terminated when Henry of Trastamara succeeded, largely with Aragonese help, in making himself King of Castile in 1350.

Peter succeeded in making himself master of Sicily in 1377, but ceded the actual possession of the island to his son Martin. He was three times married: to Mary, daughter of Philip of Evreux, king of Navarre; to Eleanor, daughter of Alphonso IV. of Portugal; and to Eleanor, daughter of Peter II. of Sicily, his cousin. The marriage of his daughter by his third marriage, Eleanor, with John I. of Castile, carried the crown of Aragon to the Castilian line when his male representatives became extinct on the death of his son Martin in 1410.

See Zurita, Anales de Aragon (Saragossa, 1610).

Peter, "the Cruel," king of Castile (1333–1369), son of Alphonso XI. and Maria, daughter of Alphonso IV. of Portugal, was born in 1333. He earned for himself the reputation of monstrous cruelty which is indicated by the accepted title. In later ages, when the royal authority was thoroughly established, there was a reaction in Peter's favour, and an alternative name was found for him. It became a fashion to speak of him as El Justiciero, the executor of justice. Apologists were found to say that he had only killed men who themselves would not submit to the law or respect the rights of others. There is this amount of foundation for the plea, that the chronicler Lopez de Ayala, who fought against him, has confessed that the king's fall was regretted by the merchants and traders, who enjoyed security under his rule. Peter began to reign at the age of sixteen, and found himself subjected to the control of his mother and her favourites. He was immoral, and unfaithful to his wife, as his father had been. But Alphonso XI. did not imprison his wife, or cause her to be murdered. Peter certainly did the first, and there can be little doubt that he did the second. He had not even the excuse that he was passionately in love with his mistress, Maria de Padilla; for, at a time when he asserted that he was married to her, and when he was undoubtedly married to Blanche of Bourbon, he went through the form of marriage with a lady of the family of Castro, who bore him a son, and then deserted her. Maria de Padilla was only the second of his harems of whom he never became quite tired. At first he was controlled by his mother, but emancipated himself with the encouragement of the minister Albuquerque and became attached to Maria de Padilla. Maria turned him against Albuquerque. In 1354 the king was practically coerced by his mother and the nobles into marrying Blanche of Bourbon, but deserted her at once. A period of turmoil followed in which the king was for a time overpowered and in effect imprisoned. The dissensions of the party which was striving to coerce him enabled him to escape from Toro, where he was under observation, to Segovia. From 1356 to 1366 he was master, and was engaged in continual wars with Aragon, in which he showed neither ability nor daring. It was during this period that he perpetrated the series of murders which made him odious. He confided in nobody save the Jews, who were his tax-gatherers, or the Mahommedan guard he had about him. The profound hatred of the Christians for the Jews and Mudjares, or Mahommedans settled among them, dates from the years in which they were the agents of his unbridled tyranny. In 1366 he was assailed by his bastard brother Henry of Trastamara at the head of a host of soldiers of fortune, and fled the kingdom without daring to give battle. Almost his last act in Spain was to murder Suer, the archbishop of Santiago, and the dean, Peralvaz. Peter now took refuge with the Black Prince, by whom he was restored in the following year. But he disgusted his ally by his faithlessness and ferocity. The health of the Black Prince broke down, and he left Spain. When thrown on his own resources, Peter was soon overthrown by his brother Henry, with the aid of Bertrand du Guesclin and a body of French free companies. He was murdered by Henry in du Guesclin's tent on the 23rd of March 1369. His daughters by Maria de Padilla, Constance and Isabella, were respectively married to John of Gaunt, and Edmund, duke of York, sons of Edward III., king of England.

The great original but hostile authority for the life of Peter the Cruel is the Chronique of the Chancellor Pero Lopez de Ayala (Madrid, 1824). The best modern history is the Prospective of France, Hist. de Don Pierre I., roi de Castille (Paris, 1848).

(P. D.)

PETER DES ROCHES (d. 1238), bishop of Winchester under John and Henry III., and conspicuous among the foreign favourites to whom these sovereigns owed much of their unpopularity, was a Poitevin by extraction. He received the office of chamberlain towards the close of Richard's reign, and under Richard's successor became an influential counsellor. In 1205, doubtless through John's influence, he was elected to the see of Winchester. His election was disputed but, on appeal, confirmed by Pope Innocent III., who honoured Peter by consecrating him in person. None the less, the new bishop stood by his royal patron during the whole period of the interdict. In 1213 he was made justiciar in succession to Geoffrey Fitz Peter. This promotion was justified by the fidelity with which Peter supported the king through the barons' war. At the battle of Lincoln (1217) Peter led a division of the royal army and earned some distinction by his valour; but he played a secondary part in the government so long as William Marshal held the regency. After Marshal's death (1219) Peter led the baronial opposition to Hubert de Burgh, with varying success. At first the justiciar was successful. In 1221 Peter meditated going on crusade; 1223–1224 saw his party broken up by Hubert's energetic measures; in 1227 he was himself dismissed from his office and
PETER LOMBARD—PETER OF COURtenAY

turned his back on England to join the crusade of the emperor Frederick II. He was absent from England until 1231; but in the meantime he enhanced his reputation as both a soldier and diplomatist. After the fall of De Burgh he kept in the background, but offices and honours were heaped on his dependants, especially on his nephew, Peter des Rievaux, and other Poitvians. This foreign party triumphed over the revolt which was headed by Richard Marshal in 1233. But the primate, Edmund Rich, voiced the general feeling when he denounced Peter as "a mischief maker, and demanded that he should be dismissed from court. The king complied, and threatened the bishop with charges of malversation. Peter was however permitted to leave the country with a pardon (1233); he returned to Lombardy (Paris, 1893), and rendered efficient aid in a war with the citizens of Rome (1235) and in the next year returned without molestation to his see. He was invited to go as the king's envoy to the court of Frederick II, but refused apparently on the score of ill health. His public reconciliation with De Burgh (1236), effected through the mediation of the papal legate, provided a dramatic close to their long rivalry, but had no political significance, since both were now living in retirement. Peter died in 1238, and was buried at Winchester.

He was undoubtedly a man of a winning personality, a good diplomat and financier, a statesman whose unpopularity was due in a large measure to his freedom from the insularity of the Englishmen, against whom he was used to point, but his name is associated with a worthless clique of favourites, dealt with in the first steps which were taken by Henry III. to establish a feeble and corruptocracy.

PETER LOMBARD (c. 1100-c. 1160), bishop of Paris, better known as Magister Sententiarum, the son of obscure parents, was born about the beginning of the 12th century, at Novara (then reckoned as belonging to Lombardy). After receiving his education at Bologna, he removed to France, bearing a recommendation to Bernard of Clairvaux, who first placed him under Lotolf at Reims, and afterwards sent him to Paris with letters to Gilduin, the abbot of St. Victor. He soon became known as a master, and obtained a theological chair in the cathedral school. His famous treatise, the Collectio Sententiarum, written between 1145 and 1150. On the 29th of June 1159 he became bishop of Paris. The accounts of his bishopric are satisfactory. There is a charge that he was guilty of simony, having received his office through the favour of Philip, brother of Louis VII., his former pupil. The date of his death is uncertain. According to one account he died on the 26th of July 1160, and as Maurice de Sully became bishop that year the statement seems probable. Yet there is evidence for a later date, and he may have been set aside for simony.

His famous theological handbook, Sententiarum libri quattuor, as the title implies, primarily a collection of opinions of the fathers, "sententiae patrum." These are arranged, professedly on the basis of the aphorism of Augustine, Lombard's favourite authority, that "omnis doctrina vel rerum est vel signorum," into four books, each section of which is divided into chapters, the third of the incarnation, the work of redemption, and the virtues, and the fourth of the seven sacraments and eschatology. The Sententiae show the influence of Abelard, both in method and arrangement, but lack entirely the daring of Sic et Non. Compared with that book they are tame. Gratian's Concordia discordantium canonum, as he called his Decretum, was another strong influence, Lombard's chief authority other theology what Gratian did for the canon law. The influence of Hugo of St. Victor is marked in the relation to the "sentences" of a Gandulph of Bologna (still unpublished) has not been established. The most important thing in the book was its systematisation of the doctrine concerning the sacramental system, by the definite assertion of the seven sacraments and the acceptance of a definition of sacrament, not merely as "a sign of a sacred thing," but as itself "capable of conveying the grace of which it is the symbol," and the fixing of the number of the seven sacraments. The sentences soon attained immense popularity, ultimately becoming the text-book in almost every theological school, and giving rise to endless controversies, over 180 of these being written in England. In 1300 the theological professors

of Paris agreed in the rejection of sixteen propositions taken from Lombard, but their decision was far from obtaining universal currency.

Besides the Sententiae, Lombard wrote numerous commentaries (e.g. on the Psalms, Canticles, Job, the Gospel Harmony, and the Epistles of St. John), some of which were printed in MS. Glossae seu commentarii in psalmis Davidis, were first published at Paris in 1533.

His principal collected works have been published in J. P. Migne's Patrologie latine, Tome 191 and 192. See supra Ditale and Chantilly, Chardariarum universitatis parisiensis, Tome i. (Paris, 1889); Protos, Pierre Lombard, son époque, sa vie, ses écrits, son influence (Paris, 1889); K. B. Petzoldt, Pierre de lombard in seiner Stellung zur Philosophie des Mittelalters (Leipzig, 1897); K. B. Petzoldt, Dagmengeschichte, Bd. iii. (1890; Eng. trans. 1894-1899); and the article in Herzog-Hauck's Realencyclopadie, Bd. xi. (Leipzig, 1902).

PETER OF AIGUEBLANCHE (d. 1268), bishop of Hereford, belonged to a noble family of Savoy and came to England in 1236 with his master, William of Savoy, bishop of Valencia, being in attendance on Eleanor of Provence, the bride of Henry III. A year or two later he is found residing permanently in England as a member of the king's court; before 1239 he was archdeacon of Salop, and in 1240 he was chosen bishop of Hereford. In 1255 Peter acted as Henry's principal agent in the matter of accepting the kingdom of Sicily from Pope Alexander IV. for his son Edmund, and his rapacious and dishonest methods of raising money for this foolish enterprise added not a little to the unpopularity which surrounded the king and his foreign favourites. When civil war broke out between Henry and his barons the bishop remained loyal to his master, and whilst residing, almost for the first time, at Hereford he was taken prisoner in May 1263. He was, however, released when the king and his enemies came to terms, and after a stay in France he retired to Savoy, where he died on the 27th of November 1268.

See F. Magnier, Les Savoyards en Angleterre au XIIIe siècle et Pierre d'Aigueblanche (Chambry, 1890).

PETER OF BLOIS [PETRUS BLESENSIS] (c. 1135-c. 1205), French writer, the son of noble Breton parents, was born at Blois. He studied jurisprudence at Bologna and theology in Paris, and in 1167 he went to Sicily, where he became tutor to the young king William II., and keeper of the royal seal (sigillarius). But he made many enemies and soon asked permission to leave the country; his request was granted and about 1170 he returned to France. After spending some time teaching at Paris and serving Rotrou de Perse, archbishop of Rouen, as secretary, Peter entered the employ of Henry II. of England about 1173. He quickly became archdeacon of Bath and soon afterwards chancellor, or secretary, to Richard, archbishop of Canterbury, and to Richard's successor, Baldwin, being sent on two occasions to Italy to plead the cause of these prelates before the pope. After the death of Henry II. in 1189, he was for a time secretary to his widow, Eleanor, in Normandy; he obtained the posts of dean of Wolverhampton and archdeacon of London, but he appears to have been very discontented in his later years. He died some time before March 1204.

Peter's writings fall into four classes, letters, treatises, sermons and poems. His Epistole, which were collected at the request of Henry II., are an important source for the history of the time; they are addressed to Henry II. and to various prelates and scholars, including Thomas Becket and John of Salisbury. They include De Jerosolimitano peregrinatione adducta, an exhortation to take part in the third crusade, and Dialogus inter regem Henricum II. et fratrem Bernardum, his extant sermons number 65 and his poems are unimportant. Peter's works have been published in several collections, including the Petologia of J. P. Migne and the Historiae francorum scriptores of A. Duchesne. Of separate editions the last are those by Pierre de Goussainville (Paris, 1667) and J. A. Giles (Oxford, 1846-1847).

PETER OF COURtenAY (d. 1219), emperor of Romania (or Constantinople), was a son of Peter of Courtenay (d. 1183), and a grandson of the French king, Louis VI. Having, by a first marriage, obtained the counties of Nevers and Auxerre, he took
for his second wife, Yolande, (d. 1219), a sister of Baldwin and Henry of Flanders, who were afterwards the first and second emperors of the Latin Empire of Constantinople. Peter accompanied his cousin, King Philip Augustus, on the crusade against the Albigenses, and was present at the battle of Bouvines in 1214. When his brother-in-law, the emperor Henry, died without sons in 1216, Peter was chosen as his successor, and with a small army set out from France to take possession of his throne. Consecrated emperor at Rome, in a church outside the walls, by Pope Honorius III. On the 9th of April 1217, he borrowed some ships from the Venetians, promising in return to conquer Durazzo for them; but he failed in this enterprise, and sought to make his way to Constantinople by land. On the journey he was seized by the despots of Epirus, Theodore Angelus, and, after an imprisonment of two years, died, probably by foul means. Peter thus never governed his empire, which, however, was ruled for a time by his wife, Yolande, who had succeeded in reaching Constantinople. Two of his sons, Robert and Baldwin, became in turn emperors of Constantinople.

PETER OF DUISBORG (d. c. 1326), German chronicler, was born at Duisburg, and became a priest-brother of the Teutonic Order. He wrote the Chronicon terrae Prussiae, dedicated to the grand-master, Werner of Orseln, which is one of the chief authorities for the history of the order in Prussia. There is a rhyming translation in German by Nicholas of Jeroschin, which, though written against the original, is published in Bd. I. of the Scriptores rerum prussiarum (Leipzig, 1861).

See M. Tüppen, Geschichte der preussischen Historiographie (Berlin, 1853); and W. Fuchs, Peter von Duisburg und das Chronicon oliensis (Königsberg, 1884).

PETER OF MARICOURT (13th century), a French savant, to whom his disciple, Roger Bacon, pays the highest tribute in his opus tertium and other works. According to Bacon he was a recluse who devoted himself to the study of nature, was able to work metals, invented armour and assisted St Louis in one of his expeditions more than his whole army. According to Emile Charles (Roger Bacon sa vie, ses ouvrages, ses doctrines, 1861), Peter of Maricourt is the Pierre Pergrin (or Pellerin) de Maricourt (Méharicourt in Picardy), known also as Petrus Peregrinus of Picardy, one of whose letters, De maugere, is partly reproduced in Libri II. Hist. des sciences mathématiques en Italie (1838), II. 70-71, 487-505.

PETER OF SAVOY (c. 1203-1268), earl of Richmond, younger son of Thomas I. (Tommaso), count of Savoy, was born at Susa. After spending some years as an ecclesiastic he resigned his preferments, and in 1234 married his cousin Agnes, daughter and heiress of Aymon II., lord of Faucaigy. Accepting an invitation from the English king, Henry III., who had married his niece, Eleanor of Provence, Peter came to England in 1240, and was created earl of Richmond, receiving also large estates and being appointed to several important offices. During several visits to the continent of Europe Peter had largely increased his possessions in Vaud and the neighbourhood, and returning to England in 1252 he became associated with Simon de Montfort, retaining at the same time the king's friendship. Having been employed by Henry to negotiate with the pope and with Louis IX. of France, he supported Earl Simon in his efforts to impose restrictions upon the royal power; but, more moderate than many members of the baronial party, went over to Henry's side in 1260, and was consequently removed from the council. In 1263 he left England, and when his nephew, Boniface, count of Savoy, died in the same year he assumed the title of count of Savoy. This was also claimed by another nephew, Thomas; but Peter compelled the inhabitants of Turin to submit to him and secured possession of the county. He died on the 16th or 17th of May 1268, leaving an only child, Beatrice (d. 1310). Peter gave to the castle of Chillon its present form, and his name to the Savoy palace in London. He has been called le petit Charlemagne, and was greatly praised for his valour and his wisdom.

See L. Wurstenberger, Peter der Zweite, Graf von Savoyen (Zürich, 1858); F. Mugnier, Les Savoyards en Angleterre (Chambéry, 1890); and C. Bémont, Simon de Montfort (Paris, 1884).

PETER THE HERMIT, a priest of Amiens, who may, as Anna Comnena says, have attempted to go on a pilgrimage to Jerusalem before 1096, and have been prevented by the Turks from reaching his destination. It is uncertain whether he was present at Urban's great sermon at Clermont in 1095; but it is certain that he was one of the preachers of the crusade in France after that sermon, and his own experience may have helped to give fire to his eloquence. He soon leapt into fame as an emotional revivalist preacher: his very ass became an object of popular adoration; and thousands of peasants eagerly took the cross at his bidding. The crusade of the papeeres, which forms the first act in the first crusade, was his work; and he himself led one of the five sections of the papeeres to Constantinople, starting from Cologne in April, and arriving at Constantinople at the end of July 1096. Here he joined the only other section which had succeeded in reaching Constantinople—that of Walter the Penniless; and with the joint forces, which had made themselves a nuisance by pillaging, he crossed to the Asiatic shore in the beginning of August. In spite of his warnings, the papeeres began hostilities against the Turks; and Peter returned to Constantinople, either in despair at their recklessness, or in the hope of procuring supplies. In his absence the army was cut to pieces by the Turks; and he was left in Constantinople without any followers, during the winter of 1096-1097, to wait for the coming of the princes. He joined his hosts in winter quarters in the Euphrates valley; and, seeking the man to whom he seems to have collected, and marched with them through Asia Minor to Jerusalem. But he played a very subordinate part in the history of the first crusade. He appears, in the beginning of 1098, as attempting to escape from the privations of the siege of Antioch—showing himself, as Guibert of Nogent says, a "fallen star." In the middle of the year he was sent by the princes to invite Kerbogha to settle all differences by a duel; and in 1099 he appears as treasurer of the alms at the siege of Arca (March), and as leader of the supplcatory processions in Jerusalem which preceded the battle of Ascalon (August). At the end of the year he went to Laodicea, and sailed thence for the West. From this time he disappears; but Albert of Aix records that he died in 1153, as prior of a church of the Holy Sepulchre which he had founded in France.

Legend has made Peter the Hermit the author and originator of the first crusade. It has told how, in an early visit to Jerusalem, before 1096, Christ appeared to him in the Church of the Sepulchre, and bade him preach the crusade. The legend is without any basis in fact, though it appears in the pages of William of Tyre. Its origin is, however, a matter of some interest. Von Sybel, in his Geschichte des ersten Kreuzzuges, suggests that in the camp of the papeeres (which existed side by side with that of the knights, and grew increasingly large as the crusade told more and more heavily in its progress on the pursuers of the crusaders) some idolization of Peter the Hermit had already begun, during the first crusade, parallel to the similar glorification of Godfrey by the Lorrainers. In this idolization Peter naturally became the instigator of the crusade, just as Godfrey became the founder of the kingdom of Jerusalem and the legislator of the assizes. This version of Peter's career seems as old as the Chansons des chéfts, a poem which Raymond of Antioch caused to be composed in honour of the Hermit and his followers, soon after 1130. It also appears in the pages of Albert of Aix, who wrote somewhere about 1130; and from Albert it was borrowed by William of Tyre. The whole legend of Peter is an excellent instance of the legendary amplification of the first crusade—an amplification which, beginning during the crusade itself, in the "idolizations" of the different camps (idoles castorum, if one may pervert Bacon), soon developed into a regular saga. This saga found its most piquant beginning in the Hermit's vision at Jerusalem, and there it accordingly began—alike in Albert, followed by William of Tyre and in the Chanson des chéfts, followed by the later Chanson d'Antioche.

The original authorities for the story of Peter the Hermit are: for the authentic Peter, Anna Comnena and the Gestis Frisonorum; --
for the legendary Peter, Albert of Aix. The whole career of the Hermit has been thoroughly and excellently discussed by H. Hagen- meyer, Peter der Hämelnase (Leipzig, 1879).

PETER THE WILD BOY (f. 1725-1785), a Hanoverian imbecile of unknown parentage, who, having been found living wild in the woods near Hanover in 1725, was brought to England by George I., whose interest had been aroused in the unfortunate youth by the extraordinary amount of curiosity and speculation concerning Peter was excited in London, and the craze was the subject of a biting satire by Swift, and of another entitled The Most Wonderful Wonder that ever appeared to the Wonder of the British Nation, which has been attributed to Swift and Arbuthnot; Defoe also wrote on the subject, and Lord Monboddo in his Origin and Progress of Language presents the idiot Peter as an illustration of his theory of the evolution of the human species. He lived to an advanced age, was seen by Lord Monboddo in 1782, and died in 1785.

PETER, EPISTLES OF, the two books of New Testament traditionally ascribed to the apostle Peter.

1 PETER

This epistle is addressed to "the elect who are sojourners of the Dispersion [Diapora] in Pontus, Galatia, Cappadocia, Asia and Bithynia." The "Diapora" was the name generally given to the Jews who were scattered abroad. It suggests that the letter was intended for Jews and Christians in the same situation. But i. 14, 15; ii. 9, 10; iv. 3 point rather to Gentile Christians, and it is better to take this view, and interpret the "Diapora" metaphorically as referring to the isolated position of Christians among the heathen. The general impression made by the epistle is that the central idea was to strengthen the courage of the recipients, who were likely to undergo persecution, and to enjoin on them conduct which would remove all reasonable excuse for thinking that Christianity ought to be regarded as a crime.

Ch. i. 3-12 is an introduction of praise to God that he had caused the recipients of the epistle to be born again to the living hope in a glorious salvation. The rest of the epistle may be divided into three parts: (a) i. 3-ii. 10, mainly hortatory injunctions to live holy lives in accordance with this new birth and to grow up as God's people in communion with Christ; (b) ii. 11-iv. 6, particular directions as to the line of conduct to be pursued towards the Gentiles and toward themselves, with some reference to the relations of slaves to masters, of wives and husbands to each other, and of Christians to one another; to the first of these a passage is appended dealing with the sufferings of Christ as an example (ii. 21-25), and the concluding part (iv. 6-11). There are extant copies of some of the earliest parts, but the whole letter, and especially the sympathy in suffering, the light of the sufferings of Christ and the blessings given by them both to the living and to the dead; (γ) iv. 7-ν. 11, has less cohesion. It begins with exhortations not to forget prayer and love, then the believers are warned to be careful to suffer only as Christians, not as breakers of the laws. The elders and the younger men are reminded of their duties to the community and to one another. The whole is brought to a close with an exhortation to all to fight manfully against the devil, and to persevere in doing good.

Date and Authorship.—These two questions are so closely connected that they cannot be considered separately. The external evidence of tradition is that the epistle was written by St Peter. This can be traced back to Irenaeus (iv. 9, 2) and Clement of Alexandria (Strom., iii. 18, 110), and it is thought by many writers that 2 Peter iii. 1, even if it be not itself Petrine, is good evidence that the writer regarded 1 Peter as apostolic. Evidence for its use, without mention of its name, may be found in Polycarp, but probably not in the other apostolic fathers (cf. The N.T. in the Apostolic Fathers, Oxford, 1905, p. 137). It is, however, possible that Papias made use of it. It is doubtful whether Justin Martyr used it, but probable that it was known to Theophilus of Antioch. It is not mentioned in the canon of Muratori. Thus external evidence, though unanimous in favour of the Petrine authorship, is not sufficient to settle the question. The internal evidence consists of (α) evidence bearing on the date in connexion with the persecution of Christians, (β) evidence establishing the relation of the epistle to other documents in early Christian history, and (γ) evidence concerning St Peter personally.

(a) It is clear from 1 Peter i. 6, ii. 12, iv. 12-19, ν. 9, that the epistle was written during a time of persecution. The question which is doubtful is to which persecution the description best applies. The traditional opinion was that the persecution referred to Nero. But it has been argued that the Neroine persecution according to Tacitus (Ann. xv. 44) was not a persecution of Christians as such, but was rather the result of false accusation. However there is no proof that there was any persecution of Christians at that time according to Roman law. The use of "persecution in the provinces of Asia Minor. Therefore many critics have felt obliged to bring the epistle into connexion with the epistle of Pliny to Trajan, written c. 112, and asked for an explanation as to the procedure to be followed in trials of Christians. This is the clearest evidence which implies organized persecution in the provinces in question, and therefore Holzmann, Weizsäcker and others regard this as fixing the date of the epistle in the beginning of the 2nd century, and excluding the Petrine authorship. Against this view it may be argued that the epistle describes the beginning of persecution. The writer still hopes that Christians will not be obliged to suffer "for the name," and is clearly aware of false accusations of crime. On the other hand Pliny's letter implies a time when Christianity was in itself a crime and was recognized as such. Thus it is urged, probably correctly, that the epistle belongs to the beginning of a period of which Pliny's letter marks a later development, and we can only say that c. 112 is the terminus ad quem. The terminus a quo is more difficult to find. We do not know with certainty when Christianity became a recognized offence, and scholars have accepted various dates as the time of the beginning. If Pliny's letter is right, and Sunday think that even under Nero it was criminal to be a Christian; Neumann thinks that this was first the case under Domitian; Sir W. M. Ramsay believes that this attitude was one of the results of the Jewish War of 70, and attributes it to Vespasian. If we adopt this date the Petrine authorship is almost excluded, and it is difficult to reconcile the traditional date of St Peter's martyrdom with Ramsay's theory.

(b) The relations of 1 Peter to other books in early Christian literature is shown in the following table:

</table>

From this table it is sufficiently plain that 1 Peter is closely connected with Romans, Ephesians, James, and Polycarp. The majority of scholars are agreed that in the case of Romans the dependence is on the side of 1 Peter, and in the case of Polycarp on the side of Peter. It is not possible to decide whether the dependence is in the case of Romans, however, we think that 1 Peter may have survived this persecution and suffered at the beginning of the persecutions which, he thinks, were initiated by the Flavian emperors (see Peter, et al.: § 5, 4 ad 1).

The whole question of authorship and date is thus a complex of smaller problems, many of which do not seem to admit of any definite answer. If St Paul's epistle to the Ephesians be genuine, and it was really known to the writer of 1 Peter, then the theory of Petrine authorship demands that it was written by Peter between 59 and 64. On the Petrine hypothesis this is the most probable view. The weak point is that it assumes a great spread of Christianity in the provinces of Asia Minor outside the activity of Paul, and the official persecution of Christians as such began throughout the Roman Empire under Nero, for neither of which is there
corroborative evidence. On the non-Petrine hypothesis a date is demanded some time before the letter of Pliny; this suits the internal evidence better than any possible on the Petrine hypothesis, but it fails to explain the really considerable and early evidence for the Petrine authorship, and necessitates some purely hypothetical suggestion, such as Harnack's view that the epistle was originally anonymous, and that the opening and closing sentences (i. 1 sqq., v. 12 sqq.) were added between A.D. 150 and 175, perhaps by the writer of 2 Peter.

The Provenance of the Epistle.—This is defined in 1 Peter v. 13 as Babylon. It has sometimes been argued that this is Babylon in Mesopotamia in which there were, until the time of the Persian Caisas, many Jews; but no good tradition connects St Peter with the evangelization of Mesopotamia, and this district would have had little in common with the Graeco-Roman world of Asia Minor. Another suggestion is that the Egyptian Babylon is meant (Old Cairo); but in the 1st century this was probably merely a fortress. Thus there is an overwhelming weight of opinion in favour of the view that Rome, the Babylon of Apocalyptic literature, is intended. This also agrees with the tradition in 2 Tim. iv. 11, which (cf. 1 Pet. v. 13) suggests that St Mark was in Rome.

Reception in the Canon.—1 Peter seems to have been the earliest of the Catholic epistles to obtain recognition. By the year 200 it was accepted everywhere except in two places—the church of Edessa, which did not receive the Catholic epistles until the 5th century, and, if the canon of Muratori is to be trusted, the church of Rome. It should, however, be noted that Zahn emends the text of the Muratorianum (rather violently) so as to include the epistle (see also Bible: New Testament Canon.)

The Theology of 1 Peter.—The simplicity of the theology is marked, and affords an argument for an early date. Jesus is the Messiah of whom the prophets had spoken, and Spirit of Christ' is identified with the spirit which was in them. His suffering for sin had rescued the elect, and was also an example for Christians to follow. After his death he preached to the "spirits in prison," the source of Christian life is on the one hand belief in God who raised the Messiah from the dead, and on the other hand baptism which "saves . . . through the resurrection of Jesus Christ." The members of the community are "a royal priesthood, a holy nation"—i.e. inherit the promises made to the Jews, but this inheritance is bound up with the strongly eschatological doctrine that Christians are strangers in the world, the end of which is at hand.

The Church Organisation of 1 Peter.—This is also very simple and primitive, and closely based on the Jewish model. The leaders are called preachers or elders, and their duty is to act as shepherds to the flock. Beyond this there is no sign of a developed organization: each is to act in accordance with the gift (2756) which he has received, and there is no trace of a distinct ministerial authority for the service of the community or for teaching, as to which the only limitation given is "If any man speak let him speak as the oracles of God," i.e. probably, in accordance with the Old Testament.

2 Peter

This epistle may be divided into five parts. (1) The writer who describes himself as "Simon (var. lect. Symeon) Peter, a servant and apostle of Jesus Christ," exhorts his readers to become perfect in knowledge and virtue, so as to enter the kingdom of Christ (i. 3–11). (2) He then explains his desire once more to testify to the power of Jesus, and bases his testimony partly on his own experience in the Holy Mount (apparently a reference to the Transfiguration), and partly on the "word of prophecy" (i. 12–21). (3) The mention of prophecy leads him to deal with the doctrine of false prophets, who are accused of false doctrine and immoral practices. In this section is incorporated almost the whole of the epistle of Jude (ii. 1–22). (4) He then discusses a special feature of the false teaching, viz. doubts thrown on the Parousia, the certainty of which for the future he defends (iii. 1–13). Finally he warns his hearers that they must be found spotless at the Parousia, and emphasizes the agreement of his teaching with St Paul's (iii. 14–18).

The main object of the epistle is to be seen in the attack made on the false teachers, and in the defence of the certainty of the Parousia of the Lord.

Authorship.—The traditional view is that it was written by St Peter from Rome after 1 Peter. This view is however untenable for the following reasons. (1) The epistle is not quoted by any writer of the 2nd century, and Origen, who is the first to mention it as Petrine, admits that its authorship was disputed. (2) The style and language differ greatly from that of 1 Peter; this argument may however fairly be met by the suggestion that it is improbable that he wrote Greek with ease, and that he may have used a variety of amanuenses. (3) The growth of immorality and false teaching to which it witnesses seems irreconcilable with a very primitive period of church life. (4) It has incorporated the greater part of Jude in a wholesale manner difficult to reconcile with apostolical authorship. (5) It seems to attribute a position of scriptural authority to the Pauline epistles, and this is improbable either in the mouth of Peter, or during the 1st century.

Any one of these arguments would be weighty by itself; in combination they form an irresistible cumulative argument against the Petrine authorship of 2 Peter.

Date.—If the Petrine authorship be abandoned, the terminus ad quem of the epistle is its use by Origen (or, just possibly, by Clement of Alexandria), and the terminus a quo is fixed by the following considerations: (1) the activity of an immoral Gnosticism; (2) the attainment by the Pauline epistles of great authority, and their perversion by heretics; (3) the use made of the epistle of Jude.

It is difficult to define the exact date to which these indications point, but there is a general agreement that it must be sought in the 2nd century, and perhaps the decades immediately before and after the year A.D. 150 are the most probable.

Place of Origin.—There is hardly any evidence on this point: but the most probable place seems to be Egypt, as the letter has points of connexion with Philo, Clement of Alexandria and the Apocalypse of Peter, and seems first to have been used in the church of Alexandria. It should however be noted that Doss- mann argues on lexical grounds in favour of Asia Minor (Bibl. Stud. pp. 277–284).

Relation to other Early Christian Documents.—The documents with which 2 Peter has the greatest affinities are the epistle of Jude, and the Apocalypse of Peter, of which a fragment was found in Akhmim in 1892 by M Bouriant. In each case the affinity is very close, and is capable of more than one explanation. Roughly speaking 2 Peter ii. reproduces Jude: it is possible therefore either that Jude is an epistle of 2 Peter or that the writer of 2 Peter used Jude. The former hypothesis has a few supporters, notably T. Zahn and Spitta, but most writers are emphatic in thinking that 2 Peter has incorporated Jude, and think that it is almost indecent to suggest otherwise.

The connexion with the Apocalypse of Peter is more complicated: the evidence of a comparison between the two documents (which is made in full in F. H. Chase's article in Hastings's Dictionary of the Bible) is to show that either one document is dependent on the other, or both were written by the same person, or both come from the same circle. Of these theories there is least to be said for the dependence of the Apocalypse on 2 Peter, and perhaps most for the dependence of 2 Peter on the Apocalypse.

Reception in the Canon.—2 Peter was the last of the Catholic epistles to be accepted as canonical. It was first regarded as such in Alexandria, perhaps originally in connexion with the Apocalypse of Peter rather than with St Peter. Thence it passed into the canon used by the church of Constantinople, in the 4th century made its way into the Roman canon, and in the 6th was accepted last of all by the Syria church (see also Bible: New Testament Canon.)

The Theology of 2 Peter.—The theology of the epistle is specially marked by two characteristics: its high Christology and its eschatological character. Christ is referred to as "our God and Saviour," and the fatherhood of God is apparently only regarded as referring to the Divine Son. The work of Christ was the redemption of the elect, and this redemption awaits its consummation in the Parousia. This is the central point of the teaching of the epistle and is obviously directed against that of 1 Peter. The writer looks forward to the destruction of the present world by fire,
when the wicked, whether angels or men, who have been reserved for judgment will be finally condemned, and a new era of happiness for the world.

**Church Organization.**—There is very little in Peter which throws light on church organization. From his silence it would appear that the monarchical episcopate existed, yet exist in the writer belonged, and perhaps the text were still the chief guides, but the argument from silence cannot be pressed. In any case the growth of false and immoral proverbs, which ultimately led to the introduction of an expression of this order, was far advanced, and was one of the reasons which led to the writing of the epistle.

**PETERBOROUGH,** a town and port of entry of Ontario, Canada, and capital of Peterborough county, situated 70 m. N.E. of Toronto, on the Otonabee river and the Grand Trunk and Canadian Pacific railways. Pop. (1901), 11,239. The five falls of the Otonabee at this point, with a total descent of 50 ft., furnish power for a large and increasing number of manufacturing establishments, whilst its canalization as part of the Trent canal gives communication with Lake Ontario and Georgian Bay. Peterborough has an electric railway, and contains important manufactories of electrical machinery and supplies, iron and steel bridges, agricultural implements and cordage, saw, flour and woollen mills.

**PETERBOROUGH** is a municipal and parliamentary borough of Northamptonshire, England, 76 m. N. from London by the Great Northern railway; served also by the London & North Western, Great Eastern and Midland railways. Pop. (1891), 25,171; (1901), 30,872. It is built chiefly along the river Nene, on the north side, and on the western border of the Fen country.

The cathedral of St Peter is the third church that has occupied the site; the first, founded under Penda, King of the Mercians, about 650, was entirely destroyed by the Danes in 870, and the second, founded in King Edgar's reign, was accidentally burnt in 1116. The present building, founded in the following year, went through many vicissitudes. The most important of these was the consecration on the 4th of October 1237. It embraces in all, however, eight periods of construction, and in no other building can the transition be better studied through the various grades of Norman to Early English, while the later addition is an admirable example of Perpendicular.

The erection proceeded as usual from east to west, and, while an increase in elegance is perceptible in each part, the character of the earlier buildings was so carefully kept in mind that no sense of incongruity is produced. A series of uniform windows were added throughout the church in the 14th century, and their effect is rather to enhance than detract from the unity of design. The choir, early Norman, terminating in an apse, was founded in 1117 or 1118 by John de Saiss or Sez, and dedicated in 1140 or 1143; the aisles of both transepts and the whole of the south transept were built by Martin of Bec, 1140-1155, the remaining portions of the transepts and the central tower, of three stories, were completed by William de Watervile, 1155-1175; the nave, late Norman, was completed by Abbot Benedict, 1177-1193, who added a beautiful pinnacle of the middle of the central tower; but the tower, late Norman, was the work of Abbot Andrew, 1193-1200; the western front, actually a vast portico of three arches, the unique feature of the building, and one of the finest specimens of Early English extant, must have been built between 1200 and 1250, during which period there were several abbots; but there exists no record of its reconstruction. The lady chapel, built parallel with the choir by William Parys, prior, was consecrated in 1200; the bell-tower was erected in 1247; the nave and aisles were completed in 1248; the spire, the pinnacle of the flanking tower of the west portal, and the enlargement of the windows of the nave and aisles were the work of Henry de Morcot in the beginning of the 13th century; the "new building of the nave" is in the Perpendicular style, begun in 1435, was not completed till 1528. In 1541 the church was converted into a cathedral, the abbot being made the first bishop. The extreme length of the building is 471 ft., and of the nave 211 ft., the breadth of the west front being 153; the height of the central tower, in the 14th century, was 150, that of the spires and tower of the west front is 156 ft. In 1643 the building was restored by the soke, the majority of the brasses and monuments, burnt the ancient records, levelled the altar and screen, defaced the windows, and demolished the cloisters. To obtain materials for repairs the lady chapel was taken down. In the latter part of the 18th century the church was repaired. In 1831 a throne, stalls and choir-screen were erected and other restorations completed. On account of the insecure state of the central tower in 1853 it was taken down; and its reconstruction, which was begun in 1857 with the exception of the four corner towers, had been completed in 1886. The choir was reopened in 1889 after being closed, for thorough restoration, for six years.

The restoration of the west front and other parts was begun in the face of considerable adverse criticism; but the work was carried on with the utmost care. During the carrying out of this work many interesting discoveries were made, the most important evidencing the age of the central tower as under the transept. Catherine of Aragon was interred in the cathedral in 1536, and Mary Queen of Scots in 1587, but the body of the Scottish queen was removed to Westminster Abbey in 1612. Both interments were supervised by Robert Scarlett the sexton, commonly known as "Old Scarlett," whose portrait, a copy of the original, hangs in the west transept. He died in 1594 at the age of 98. Of the monastic buildings there are some interesting remains. The cathedral is approached by a Norman gateway, above which is the chapel of St Nicholas, built by Abbot Benedict, and now used as the music school, and on the left the chapel of St Thomas Aquinas, built by Abbot de Wonda, in the 13th century, but originally Norman. The gateway to the bishop's palace, formerly the abbot's house, was built by Abbot Godfrey de Croyland in 1319, and the deanery gate by Abbot Kirton about 1520. One of the canons' houses is formally preserved from a hall of the 13th century.

Peterborough is intended for civil purposes in the parish of St John the Baptist, but for ecclesiastical purposes it is divided into five additional parishes being St Mary's Boongate (1587), St Mark's (1858) and St Paul's (1866). The old parish church of St John originally stood to the east of the cathedral, but was rebuilt on its present site in the centre of the city (1400-1407) in Perpendicular style. The educational establishments include the Henry VIII. grammar or charter school, which used the chapel of St Thomas à Becket until 1885; the St Peter's training college for schoolmasters for the dioceses of Peterborough, Ely and Lincoln, erected from designs of Sir Gilbert Scott (1874); and Deacon's and Ireland's charity school, established in 1721 for the clothing and educating of twenty poor boys. The principal public building is the market house (1767), used for an agricultural gallery. The industries of the town are chiefly due to the trade caused by the junction of so many railway lines. Adjoining the town are extensive works and sheds connected with the Great Northern and Midland railways. The principal manufacturer is that of agricultural implements. The parliamentary borough returns one member (since 1885). The municipal borough, incorporated in 1874, is under a mayor, 6 aldermen and 18 councillors. Area, 1878 acres. The soke or liberty of Peterborough, with a population of 41,123, constitutes a separate administrative county (1888). The diocese of Peterborough includes the whole of Rutland, nearly all Leicestershire and Northamptonshire, and small portions of Derbyshire and Huntingdonshire.

**Peterborough (Burga, Burgus sancti Petri)** is proved by its original name Medehamstede to have been a Saxon village before 655 when Saxulf, a monk, founded the monastery on land granted to him for that purpose by Penda, king of Mercia. Its name was altered to Burgh between 902 and 1005 after Abbot Kenulf had made a wall round the minister, but the town does not appear to have been a borough until the 12th century. The burgesses received their first charter from "Abbot Robert," probably Robert of Sutton (1262-1273). Until the 15th century the dean and chapter, who succeeded the abbot as lords of the manor, appointed a high bailiff, and the town and other in the later years were elected at their court leet, but the corporation was incorporated in 1574 under the government of a mayor, 6 aldermen and 18 councillors. Among the privileges claimed by the abbot as early as the 13th century was that of having a prison for felons taken in the soke and borough. In 1576 Bishop Scambell sold the lordship of the hundred of Nassaburgh, which is coextensive with the soke, to Queen Elizabeth, who
gave it to Lord Burghley, and from that time until the 19th century he and his descendants, marquesses of Exeter, had a separate gaol in Peterborough for prisoners arrested in the soke. The trades of weaving and woolcombing were carried on in Peterborough in the 14th century. The abbot formerly held four fairs, of which two, one called St Peter's fair, granted in 1189 and now held on the second Tuesday and Wednesday in July, and the other called the Bridge fair, granted in 1439 and held on the first Tuesday, Wednesday and Thursday in October, still survive and were purchased by the corporation from the ecclesiastical commissioners in 1876. Peterborough sent two members to parliament for the first time in 1547.

**Peterborough and Monmouth, Charles Mordaunt, Earl of** (c. 1628–1735), English soldier and statesman, was born about 1628. His father, John Mordaunt, was created Viscount Mordaunt of Avalon and Baron Mordaunt of Reigate, Surrey, in 1628; his mother was Elizabeth, the daughter and sole heiress of Thomas Carey, the second son of Robert Carey, 1st earl of Monmouth. He matriculated at Christ Church, Oxford, on the 11th of April 1647. When about sixteen years of age he joined Sir John Narborough's fleet in the Mediterranean, and won his first distinction in the battle of Lepanto. On the restoration of Charles II he served in the fleet under Benbow, and was present at the capture of Tripoli. His father died on the 5th of June 1675, and Charles Mordaunt succeeded to the peerage as Viscount Mordaunt. On his return from the second expedition to Tangier he plunged into active political life as a zealous Whig and an unsparing opponent of the duke of York. But his continued hostility to James II. forced him to repair to Holland in 1686, when he proposed to William of Orange to invade England. The disposition of the cold and cautious William had little in common with the fierce and turbulent Mordaunt. His plan was rejected, though the prudent prince of Orange deemed it judicious to retain his services. When William sailed to Torbay his friend accompanied him, and when the Dutch prince was safely established on the throne of England honours without stint were showered upon Lord Mordaunt. He was sworn of the privy council on the 14th of February 1689, on the 8th of April of the same year appointed first lord of the treasury, and a day later advanced in the peerage by creation as earl of Monmouth.

In less than a year he was out of the treasury, but he still remained by the person of his monarch and was with him in his dangerous passage to Holland in January 1691. He was one of the eighteen peers who signed the protest against the rejection, on the 7th of December 1692, of the motion for the appointment of a committee to inquire into the conduct of the war. Though William had refused his consent to a bill for triennial parliaments in the previous session, Lord Monmouth did not shrink from reintroducing it in December 1693. This led to a disagreement with the court, though the final breach did not take place until January 1697, when Monmouth was accused of complicity in Sir John Fenwick's conspiracy and of the use of "undutiful words" towards the king. He was committed to the Tower, staying in confinement until the 30th of March 1697, and deprived of his employments. Some consolation for these troubles came to him on the 19th of June of the same year, when he succeeded to the earldom of Peterborough, by the death of his uncle Henry Mordaunt, 2nd earl.

The four years after his release from the Tower were mainly passed in retirement, but on the accession of Anne he plunged into political life again with avidity. His first act was to draw down on himself in February 1702 the censure of the House of Commons for the part which he took in the attempt to secure the return of his nominee for the borough of Malmesbury. Through the fear of the ministry that his restless spirit would drive him into opposition to its measures if he stayed at home, he was appointed early in 1705 to command an expedition of English and Dutch troops in Spain. He was created the sole commander of the land forces in April 1705 and joint-commander with Sir Cloudesley Shovel of the fleet on the 1st of May, after he had been reinstated a member of the privy council on the 29th of March. He arrived at Lisbon on the 20th of June 1705, sailed for Barcelona (Aug. 1705) on an expedition for the conquest of Catalonia, and began to besiege that town. For some weeks the operations were not prosecuted with vigour and Peterborough urged that the fleet should proceed to Italy, but the energetic counsels of the Archduke Charles at last prevailed and by the 14th of October the city fell into his hands. On the 24th of January 1706 he entered Valencia in triumph, but these movements had weakened the garrison at Barcelona, which was now besieged by a superior French force under Tézier. The garrison, commanded by the archduke, defended their positions with great bravery, but would have been obliged to surrender had not the fleet of Sir John Leake, answering the appeals of Charles but contrary to the original orders of Peterborough, come to their assistance on the 8th of May, whereupon the French raised the siege on the 11th of May. It is difficult to understand the action of Peterborough, who remained in Spain until the 8th of October, 1706, and is traditional that he was out of sympathy with the movement for placing an Austrian prince on the throne of Spain. When Charles determined upon uniting with Lord Galway's troops and marching to Madrid, the advice of Peterborough again hindered his progress. At first he urged an advance by Valencia as supplies had there been collected, then he withdrew this statement; afterwards he delayed for some weeks to join Galway, who was in need of succour, but ultimately reached the camp on the 6th of August. The leaders of the army differed in their views, and Lord Peterborough was recalled to England to explain his conduct (March 1707).

On his return to England in August he allied himself with the Tories, and received his reward in being contrasted, much to his advantage, with the Whig victor of Blenheim and Malplaquet. The differences between the three peers, Peterborough, Galway and Tyrawley, who had served in Spain, formed the subject of angry debates in the Lords, when the majority declared for Peterborough; after some fiery speeches the resolution that he had performed many great and eminent services was carried, and votes of thanks were passed to him without any division (January and February 1708). His new friends were not desirous of detaining him long on English soil, and they sent him on a mission to Vienna, where he characteristically engaged the ministry by pledges which they disapproved when he returned. His return at this disagreement was softened by the command of a cavalry regiment, and by his appointment as a Knight of the Garter (Aug. 3 and 4, 1713). With the accession of George I. Lord Peterborough's influence was gone. Worn out with suffering, he died at Lisbon on the 25th of October 1735. His remains were brought to England, and buried at Turvey in Bedfordshire on the 21st of November.

Lord Peterborough was short in stature and spare in habit of body. His activity knew no bounds. He was said to have seen more kings and postilions than any man in Europe, and the whole point of Swift's lines on "Mordanto" consisted in a description of the speed with which he hurried to and from the capital. He was eloquent in debate and intrepid in war, but his influence in the senate was ruined through his inconsistency, and his vigour in the field was wasted through his want of union with his colleagues. His first wife, Carey, daughter of Sir Alexander Fraser of Dores, Kincardineshire, died on the 13th of May 1709, and was buried at Turvey. Some years later (1722) he secretly married Anastasia Robinson (c. 1659–1755), a famous dramatic singer (from 1714) of great beauty and sweetness of disposition, daughter of Thomas Robinson (d. 1722), a portrait painter; but she was at first unrecognized as his wife, and lived apart from him (regarded merely as his mistress) with her two sisters at Parson's Green. She remained on the operatic stage, till 1744. It was only a few months before his death that (after a second marriage ceremony) she
was introduced to society as the countess of Petersborough. He had a son John (1681–1710) who predeceased him, and was then succeeded in the title by his grandson, the honours becoming extinct, except for the barony of Mordaunt, which passed to a collateral branch and fell into abeyance in 1836.

BIBLIOGRAPHY.—The best accounts of the career of Petersborough are in the life by William Stebbing (1890), and the War of the Spanish Succession (1739), to which the addenda were intended to be added. Colonel Howard (1689) is the earliest extant history of Captain Peterhead (1728), which was analysed by Colonel Parnell, and dismissed as a fictitious narrative inspired by Swift, in the Eng. Hist. Rev. (1891), vii. 67-151. (W. F. C.)

PETERHEAD, a municipal and police burgh, and seaport of Aberdeenshire, is the most easterly town in Scotland. Pop. (1901), 13,794. It is situated about 33 m. by road E.N.E. of Aberdeen and 444 m. by rail, via Maud Junction, on the Great North of Scotland railway, from which there is a branch line. The town is built of the red granite for which it is famous, and the quay, which is the port of foreign and inter-island use, is an important industry. Among the principal buildings are the town-house (1788), with a spire 195 ft. high, and the Arbroath museum and art gallery. In front of the town-hall is a statue to Field Marshal Keith (born at Inverurie Castle, 2 m. north-west, in 1666), which was presented to the burgh in 1868 by William 1. of Prussia, afterwards German emperor. Peterhead is one of the Elgin district group of parliamentary burghs, with Banff, Cullen, Elgin, Inverurie and Kintore. It formerly had an extensive trade with the ports of the Baltic, the Levant and America, and was once a sub-port to Aberdeen, but was made independent in 1832. It was also for a long period the chief seat of the Greenlaw trade, but the Arctic seal and whale fishery is now extinct. The north and south harbours lie between the town and Keith Inch—a suburb at the extremity of the peninsula on part of which the town is built—and the isthmus dividing them is pierced by a canal crossed by an iron swing-bridge. In the north harbour are two graving docks. A third harbour has been built, the area of the three basins amounting to 21 acres. In addition to the granite quarrying and polishing, the leading industries are ship- and boat-building, agricultural implement works and woollen manufactures. The herring fleet possesses more than 600 boats and the annual catch averages nearly £200,000. About a mile to the south is the convict prison for Scotland. Since 1886 the prisoners have been employed upon the construction of a vast harbour of refuge, for which the breakwater extends from Boddam Point northwards across the bay. This great undertaking (intended to be completed in 1921) was designed by Sir John Coode (d. 1892). Peterhead is the terminus of a cable to Norway. About 6 m. south of Peterhead are the famous Killbuck, or Roarers, of Buchan, an enormous caryon cliff into which the waves pour through a natural arch of granite, with incredible violence, in a storm.

The town and lands belonged of old to the Abbey of Deer, built in the 13th century by William Comyn, earl of Buchan; but when the abbey was erected into a temporal lordship in the family of Keith the superiority of the town passed to the earl marshall, with whom it continued till the forfeiture of the earldom in 1716. The town and lands were purchased in 1720 by a fishing company in England and, on their failure, by the Merchant Maidens' Hospital of Edinburgh for £3000, who are still the owners. Peterhead, made a burgh of barony in 1593 by George Keith, fifth earl marshall, was the scene of the landing of Charles I. on Christmas Day 17th of January, 1644.

PETERHOF, a town of Russia, in the government of St Petersburg, 18 m. W. of the capital, on the south coast of the Gulf of Finland. It was founded in 1711 and has grown up round the palace built by Peter the Great in 1720; pop., 11,300. Peterhof is almost exclusively a residential town, but gem-cutting and the manufacture of agricultural implements are carried on. The palace has undergone alterations and additions, e.g. by Catharine II., but retains a distinct Petrine stamp. It is built on a height 50 ft. above the sea, and contains portraits of the Russian imperial family and other pictures. A statue of Peter the Great was presented by Francis I. of France in 1806, a gift from the town of Havre to Nicholas II. Peterhof is connected with Oranienbaum on the west and with Stryelna on the east by series of gardens and villas.

PETERMANN, AUGUST HEINRICH (1822–1878), German cartographer, was born at Bleicherode, near Nordhausen, on the 18th of April 1822. At the age of seventeen he entered the Geographical School of Art in Potsdam, and in 1845 proceeded to Edinburgh to assist Dr Keith Johnston in the production of an English edition of the Physical Atlas of Berghaus. In 1847 he came to London, and published among other works, an account of Barth's expedition to Central Africa (1855). In 1854 he became director of the geographical institute of Justus Perthes in Gotha, and editor of the well-known Petermanns Mitteilungen. His work did much towards elucidating the geography of the interior of Africa and of the North Polar regions. Queen Victoria, at the suggestion of Bunsen, appointed him physical geographer-royal. Petermann died by his own hand at Gotha on the 25th of September 1878.

PETERS (or PETER), HUGH (1598–1660), English Independent divine, son of Thomas Dyekwoode, alias Peters, descended from a family which had quitted the Netherlands to escape religious persecution, and of Martha, daughter of John Treffry of Treffry in Cornwall, was baptized on the 29th of June 1598, and was educated at Trinity College, Cambridge. Having experienced conversion, he preached in Essex; returning to London he took Anglican orders and was appointed lecturer at St Sepulchre's. He entertained, however, unorthodox opinions, and eventually left England for Holland. He visited Gustavus Adolphus in Germany about 1632, and afterwards became the minister of the English church at Rotterdam. Here his unorthodox leanings again attracted attention, and Peters made a further move to New England. He was connected with John Winthrop through his wife, and had already formed several friendships with the American colonists. He arrived at Boston in October 1635 and was given charge of the church at Salem. He took a leading part in the affairs of the colony, and interested himself in the founding of the new colony in Connecticut. In 1641 he returned to England as agent of the colony, but soon became involved in the political troubles which now began. He became chaplain to the forces of the adventurers in Ireland, and served in 1642 in Lord Forbes's expedition, of which he wrote an account. On his return he took a violent part in the campaign against Laud, and defended the doctrines of the Independents in a preface to a tract by Richard Mather entitled "Church Government and Church Covenant discussed..." (1643). He gained great reputation as a preacher by his discourses and exhortations at public executions, and as army chaplain. In the latter capacity he accompanied Lord Warwick's naval expedition to Lyme in 1644 and Fairfax's campaigns of 1645 and 1646, when his eloquence is said to have had a marvellous effect in inspiring the soldiers and winning over the people. At the conclusion of the war, Peters, though greatly disliked by the Presbyterians and the Scots, had attained great influence as leader of the Independents. In his pamphlet "Last Report of the English Wars" (1646) he urged religious toleration, an alliance with foreign Protestants, and an active propagation of the gospel. In the dispute between the army and the parliament he naturally took the side of the former, and after the seizure of the king by the army in June 1649 had interviews with Charles at Newcastle and Windsor, in which he favourably impressed the latter, and gave advice upon the best course to pursue. He performed useful services in the second Civil War, procured guns for the besiegers at Pembroke, raised troops in the midlands, and arranged the surrender of the duke of Hamilton at Uttoxeter. Though at the Restoration he denied any complicity in the king's death, it is certain that in his sermons he justified and supported the trial and sentence. In August he accompanied Cromwell to Ireland, and was present at the fall of Wexford,
while later he assisted the campaign by superintending from England the despatch to Cromwell of supplies and reinforcements, and was himself destined by Cromwell for a regiment of foot. In 1659 he was in South Wales, endeavouring to bring over the people to the cause, and subsequently was present at the battle of Worcester. At the conclusion of the war Peters was appointed one of the preachers at Whitewall and became a person of influence: Parliament had already voted him an annuity of £200, and Laud’s library or a portion of it had been handed over to him in 1644. He was one of the committee of twenty-one appointed to suggest legal reforms, and he published his ideas on this subject, which included a register of wills and land titles and the destruction afterwards of the ancient records, in his tract, “Good Work for a Grand Magistrate” (1651), addressed to R. Vokes, the Bishop of London and Primate. He strongly disapproved of the war with Holland, and his interference brought upon him some sharp reprimands. In July 1658 he was sent to Dunkirk to provide apparently for the spiritual wants of the garrison. He preached the funeral sermon on Cromwell, and after the latter’s death took little part in political events, though strongly disapproving of the removal of Richard. He met Monck at St Albans on the latter’s march to London, but met with no favour from the new powers, being expelled from his lodgings at Whitehall in January 1660. On the 17th of May his arrest was ordered. On the 22nd the Act of Indemnity was declared and apprehended on the 23rd of September at Southwark. He sent in a defence of himself to the Lords, denying any share in the king’s death. He was, however, tried on the 13th of October and found guilty of high treason. His execution took place at Charing Cross on the 16th of October, when he behaved with great fortitude, and was undismayed by the mangling of the body of John Cook, his fellow sufferer, upon which he was forced to look. Before his death he wrote “A Dying Father’s Last Legacy” to his only child, Elizabeth, in which he gave a narrative of his career. His death was viewed with greater rejoicings than perhaps attended that of any of the regicides, which is the more surprising as Peters possessed many amiable qualities, and several acts of kindness performed by him on behalf of individual Royalists are recorded. But he had incurred great unpopularity by his unrestrained speech and extreme activity in the cause. He was a man, however, of a rough, coarse nature, without tact or refinement, of strong animal spirits, undeterred by difficulties which beset men of higher mental capacity, whose energies often outran his discretion, intent upon the realities of life and the practical side of religion. His conception of religious controversy, that all differences could be avoided if ministers could only pray together and live together, is highly characteristic of Peters, and shows the vague and empty character of his opinions and at the same time the limits of his intellectual imagination. Peters married (1) Elizabeth, daughter of Thomas Cooke of Pembran in Essex and widow of Edmund Read, and (2) Deliverance Sheffield, by whom he had one daughter, Elizabeth.

PETERS, KARL (1856-1945), German traveller in Africa, one of the founders of German East Africa, was born at Neuhaus on the Elbe on the 27th of September 1856, the son of a Lutheran clergyman. He studied at Göttingen, Tübingen and Berlin, and in 1879 was awarded a gold medal by the Berlin University for his Frieden zu Venedig. After visiting London to study English principles of colonization, he returned to Berlin and promoted the German Colonization Society (Deutsche Kolonialverein).

In the autumn of 1884 he proceeded with two companions to East Africa, and concluded in the name of his society treaties with the chiefs of Useghua, Nguru, Usagara and Ukami. Returning to Europe early in 1885, he formed the German East Africa Company, which speedily obtained an imperial charter. The story of this enterprise, the first step in the formation of a German colony in East Africa, is told under Africa, § 5. In 1888 Peters undertook an expedition from the east coast of Africa, avowedly for the relief of Emin Pasha. This expedition was not sanctioned by the German government and was regarded by the British authorities as a filibustering exploit. One of its objects was to extend the sphere of German influence, and reaching Uganda early in 1890, Peters concluded a treaty with the king of that country in favour of Germany. He left Uganda hastily on the approach of a representative of the British East Africa Company, and on reaching Zanzibar learned that his treaty was useless, as an agreement had been come to between Germany and Great Britain whereby Uganda was left in the British sphere. On his return to Germany Peters was received with great honours, and in 1891 published an account of his expedition entitled Die deutsche Emin Pasha Expedition, which was translated into English. In 1891 he went out again to East Africa as imperial high commissioner for the Killimanjaro district, and in 1892 he published his travels in that region, and the Anglo-German boundary in that region. In June 1892 accusations were brought against him of excesses in his treatment of the natives, and after three investigations had been held he was, in 1897, deprived of his commission for “misuse of official power.” (He was regranted his title of imperial commissioner in 1906.) During 1893–1895 Peters was employed in the colonial office at Berlin. In 1896 he removed to London, where he occupied himself in schemes for exploiting parts of Rhodesia and Portuguese East Africa. In the interests of a company he formed, Peters explored the Fura district and Macombe’s extensive lands in 1899. In 1900 he discovered ruins of ancient cities and deserted gold mines. He returned in 1901 and gave an account of his explorations in The Eldorado of the Ancients (1902). In 1905 he again visited the region between the Zambezi and Sahi rivers.

Besides the books already mentioned and some smaller treatises Peters published a philosophic work entitled Willenswelt und Welt- seele (1863), and a dissertation on early gold production entitled Das goldene Ophir Salomos (1895), translated into English in 1898.

PETROSBURG, a city and port of entry of Virginia, U.S.A., on the Appomattox river, at the head of navigation, about 11 m. from its mouth, and 22 m. S. of Richmond. Pop. (1890), 22,680; (1900), 21,810, (1910), 24,127. It is served by the Atlantic Coast Line, the Seaboard Air Line and the Norfolk & Western railways. The river, which is here spanned by two steel bridges and one frame bridge, is navigable to this point for vessels of 5 ft. draught at mean high water, and has been greatly improved by the Federal government, which in 1909 was engaged in deepening the whole channel to 12 ft. at mean high water and in excavating at Petersburg a new channel into which to deflect the river. In and about the city there is much of historic and scenic interest. At Blanford, a suburban hamlet, is the picturesque old Blandford church, erected about 1734. Petersburg has two public parks, and among its institutions is the Confederate Orphan Asylum for girls and another for negroes, the state central hospital for the insane (negroes), the southern female college (non-sectarian, 1865), the university school for boys, the Bishop Payne divinity school (Protestant Episcopal) for negroes, and the Virginia normal and industrial institute (opened in 1883), also for negroes. There are two national cemeteries near Petersburg—Poplar Grove (about 4 m. south), containing about 6200 graves, and City Point (about 9 m. east), containing about 5100 graves; and in Blandford cemetery there are about 30,000 graves of Confederate dead. In this cemetery General William Phillips is buried, and there is a monument to Captain McRae, commander of the “Petersburg Volunteers,” whose bravery in 1812–1813 prompted President Madison to call Petersburg the “Cockade City.”"The falls above the city furnish abundant water-power, and the city has various manufactures. The factory product was valued at $5,800,574 in 1905, 11.3% more than in 1900; in both 1900 and 1905 Petersburg ranked fourth among the cities of the state in the value of factory products. From Petersburg are shipped quantities of trunks and bags, peanuts, tobacco and cotton. In 1900 the foreign trade, wholly imports, was valued at $360,774. The city was formerly in Chesterfield, Dinwiddie and Prince George counties, but is now independent of county government.
An Indian village formerly stood on or near the site of the present city, and Fort Henry was built here by the whites in 1845. Petersburg was founded in 1733 by Colonel William Byrd (1674-1744) and Peter Jones, and was named (first Peter's Point, and then Petersburg) in honour of the latter; in 1748 it was incorporated as a town. On the 25th of April 1781 a skirmish was fought in front of Petersburg between a British force of about 3000 under General William Phillips (1733-1781) and about one-third of that number of American militia under Baron Friedrich Wilhelm von Steuben; the Americans were defeated, and the British occupied the town. In the following month the British again entered Petersburg (General Phillips dying here on the 13th), but they were soon dislodged by Lafayette who shelled the town. General Winfield Scott was born near Petersburg, and practised law here for two years before he entered the army. Petersburg was chartered as a city in 1858.

PETERSBURG CAMPAIGN (1864-65). The name of Petersburg is associated with operations in the American Civil War, which formed the sequel of the Wilderness Campaign (q.v.) and the last act in the struggle between the armies of Grant and Lee for supremacy. Petersburg (see above) and Richmond, Virginia, were the two chief fortified points on the east coast. Grant, with the Army of the Potomac, entered the City Point road discovered strong earthworks, and General Kautz attacking on the Jerusalem Plank road experienced a repulse: the total force of the Federals was 4500, and Wise's brigade (2400) had been quickly reinforced from Beauregard's central position at Bermuda Hundred. A week later a more serious attempt was made to break through the defences, while General Lee's main army was detained north of Richmond. Grant detached the II. and XVIII. corps under Generals Smith and Hancock, who were to unite and operate along the City Point railroad and capture the outer line of works about 2 m. from Petersburg while a demonstration was made along the Norfolk railroad by cavalry under General Warren. On the 15th of June Smith attacked and captured five redans before Hancock came up, and when next day Burnside's corps (IX.) arrived and General Meade assumed control of the three corps, he attacked again at 6 p.m. On the 17th of June Warren's (V.) corps arrived, and Meade made a third assault with two corps (V., IX.). On the 18th of June the attack was renewed with three corps (II., V., IX.) late in the afternoon, and the results of the four days' fighting were so far satisfactory that ground was won which could be entrenched and held against any sortie of the Petersburg garrison. Probably on the 18th of June the town of Petersburg might have been captured by Meade, for at this crisis General Lee was in temporary eclipse. On the 18th of June Lee had refused to credit any report to the effect that Grant was crossing the James: his cavalry could not ascertain that the enemy in his front at Malvern Hill (VI. corps and Wilson's cavalry division), despite its menacing attitude towards Richmond, was only a flank guard for a movement to the south.

It was late on the 17th of June when General Beauregard, who had for three days valiantly held his main lines south of Richmond with some 14,000 infantry against three Federal corps, succeeded in convincing General Lee that the main army was again (as in 1862 on the Chickahominy) in the wrong place at the wrong time. But when at last the Confederate leader was aroused to a sense of his danger he soon filled every road with divisions marching to save Petersburg: they marched all night; they slept in the trenches on arrival, and on the 19th of June these reinforcements convinced General Meade that his main attack between the Appomattox river and the Jerusalem Plank road was delivered a day too late. At a cost of 10,000 casualties Meade had gained half a mile of ground, but the Confederates in falling back had concentrated, and now that the new plan of operations was exposed and the main bodies were again face to face the power of defensive tactics reasserted itself.

Yet June was not to close without adding some 8000 men to the Federal casualties, for in addition to daily losses by sharpshooting along the front, over 5000 men fell or were captured in the four days' fighting on the Weldon and other railways. Grant had resolved to deprive his enemy of these lines of supply: his plan was to prolong his line of investment westward and construct redoubts (such as Fort Davis, Fort Steedman and Fort Sedgwick) as a continual menace to the Confederate garrison and a defence against sorties, while his cavalry and portions of five corps (II., V., VI., IX. and XVIII.) engaged in enterprises which it was hoped would tempt General Lee to fight outside his works. A decisive victory in the field, a successful assault on the defences between Richmond and Petersburg, or the complete destruction of the railways, would precipitate disaster to the South, and of these three methods the last would be the surest in its effects. But such a method was necessarily slow. General Wilson's cavalry (5500) destroyed 30 m. of the Lynchburg or South Side railroad, and 30 m. of the Danville railroad, together with Burkesville Junction and Ream's Station on the Weldon railroad; but Wilson was caught by the Confederate cavalry 100 m. from Petersburg and escaped only by destroying his wagons and limbers and abandoning twelve guns. Even the Virginia Central railroad could not be held by the Federals after Sheridan with the main body of the cavalry had been called back to White House on the Pamunkey to escort a great column.

By the end of June the whole of the rival forces were concentrated about the Richmond-Petersburg defences, and General A. P. Hill had already sailed out on the 21st of June to drive the II. corps from the Weldon railroad. Federal policy and Federal strategy, surmounting the crisis of Cold Harbor, were, however, at last in unison. Grant had a free hand in respect both of his dispositions and his resources in men and money, and had resolved to use unsparingly the resources placed at his disposal. Early in July Grant, however, found himself compelled to detach a corps (VI.) to strengthen the garrison at Washington, for General Early had frustrated Hunter's attempt against Lynchburg (see SHENANDOAH VALLEY), driving Hunter into West Virginia, and then, pushing down the Shenandoah and across the Potomac, had arrived within a day's march of the Federal capital. This operation checked Grant's enterprises about Petersburg and restricted the Federal front to the ground east of the Weldon railroad.

On the 25th of July Grant resolved to weaken the enemy on his front by a demonstration north of the James, and accordingly moved a corps (II.) and two cavalry divisions across the river to Malvern Hill under cover of Foster's corps (X.). But Lee possessed the inner line, and the Federal detachment found two cavalry divisions in its front, and the Richmond defences had been strengthened by three divisions of infantry. The expedition then returned to take part in a fresh enterprise, which ended disastrously to the Federals. A Confederate redan faced Burnside's IX. corps 100 yds. distant, and this strong work was
to be destroyed by mining operations. The mine was fired and produced a crater 150 ft. long, 60 ft. wide and 25 ft. deep, into which the Federals poured another demonstration against Richmond was planned. But Lee’s troops could not be got farther before the Confederate counter-attack was upon them, and Burnside’s corps lost 4300 men.

In August Sheridan was detached to operate against General Early in the Shenandoah Valley, and in order to prevent Lee reinforcing it was determined to destroy the railroad and mine the Union lines. But Lee again strengthened his left and the result of the fighting was a loss to the Federals of nearly 5000 men. Meanwhile another attack on the Weldon railroad by Warren’s corps was met by General A. P. Hill at Chaffin’s Bluff, and the possession of the road cost the Federals 3000 men. A further attempt on this railroad by Hancock’s II. corps and Gregg’s cavalry division at a point 3 m. south of Ream’s Station was repulsed by A. P. Hill, now aided by XLVII and XII corps, which had arrived, and the Federals here lost 2372 men and nine guns. The Confederates therefore still retained possession of the railroad to a point within one day’s hauling by wagon to Petersburg. During September another Federal enterprise north of the James with two corps (X and XVIII) resulted in the capture of Fort Harrison near Chaffin’s Bluff, and when General Lee reinforced his left and counter-attacked his troops were repulsed with heavy losses. The Federals lost over 2000 men and failed in the attempt to take Fort Gilmer, Confederate gunboats below Richmond aiding in the defense. While this operation was in progress on the Confederate left under General Grant’s personal supervision General Lee was apprised of attacks on his extreme right at Peebles Farm by four divisions, which captured a Confederate redoubt covering the junction of 120 routes to the south-west. General A. P. Hill prevented a further advance of the enemy by a vigorous counterattack which caused Warren and Parke (IX) a loss of 2000 men, of whom nearly three fourths allowed themselves to be captured; for the ranks, since the losses of the May battles, had been swamped with new and substitute recruits of poor quality and almost insignificant training. The Federals had, however, by these operations pushed their entrenchments beyond the Weldon railroad westward and established new works within a mile of the Confederate right. A minor engagement north of the James on the 7th of October between the Confederates and troops of the Army of the James was without result. At the end of the month, however, General Grant resolved to make a serious effort to bring the South Side lines within his lines and destroy the enemy of this important line of supply. Parke (IX), Warren (V) and Hancock (II.) took each some 11,000 infantry with four days’ rations on pack animals, Gregg’s cavalry (3000) were attached for the operation, and both Grant and Meade accompanied the troops. General A. P. Hill encountered this force with three divisions (14,000) and Hampton’s cavalry (5500), and he contrived to hold two corps with one division and attack Hancock (II.) with his main body. The Federals were stopped when 6 m. from the railway, and Hancock lost 1500 men at Hatcher’s Run on the 27th of October.

General Lee meanwhile had been called to Chaffin’s Bluff, where again Butler was demonstrating with the Army of the James to the approach to Richmond. But General Longstreet signaled his return to duty with the Army of Northern Virginia by driving Butler off with a loss of over 1000 men (action of Fair Oaks, Oct. 27). General Warren in December contrived to evacuate A. P. Hill and destroy the Weldon railroad at a point on the Meherrin river 40 m. from Petersburg. There seemed now little to tie Lee to the lines he had so painfully constructed, for his army was without coffee, tea or sugar, and though of foreign meat they had 34 million rations and 62 million rations in reserve, the troops lived chiefly on corn-bread. A. P. Hill on the right held on from Hatchers’ Run to Fort Gregg, where Gordon and Anderson prolonged to the left as far as the Appomattox River, and Longstreet continued the line northwards along the Bermuda front the James as far as White Oak Swamp (37 m. in all). The winter was very severe, and the continual trench-work and outpost duty overtaxed the patriotism of Lee’s 50,000 infantry and stimulated desertions. Supplies were brought in by wagons, as the rolling stock on the railways was torn, and on the 5th of February 1865 General Gregg moved out to the Boydton Plank road to intercept the Confederate convoys. He was supported by Warren, while Humphreys’s (II.) corps connected the detachment with the left of the Federal entrenchments. Gregg failed to locate the wagons, and General Lee, hearing of the expedition, sent out A. P. Hill and Gordon, who drove him back with a loss of 1500 men. Sheridan, after driving Early from the Valley in October, destroyed the railways about Staunton, Charlottesville, Gordonsville, and Lynchburg, and even rendered the James Canal useless as a line of supply.

Grant recalled Sheridan to the main army in March, and at the end of the month prepared for a turning movement westward with the object of drawing Lee out of his lines. General Lee had anticipated such an attempt, and had resolved to abandon his lines and unite with Johnston in North Carolina, but the roads were not

![Map of Petersburg, 1864-5](image-url)
yet in a state for the movement of artillery and wagons, and it was to gain time that he now ventured upon a bold offensive stroke—a night attack upon a strong point in the Federal right called Fort Steedman—the success of which might cause Grant to call in the detachments on his left and so facilitate the proposed movement of the Confederates towards Danville. General Gordon was selected to conduct the attack, and his corps was strongly reinforced for the occasion. The opposing lines east of Petersburg were only 150 yds., and the sentries of each side 50 yds. apart. Gordon’s men dashed across the intervening space at 4:30 a.m. on the 25th March, surprised the garrison and occupied Fort Steedman, but when day broke light and the Federal guns could be brought to bear the fort was found to be untenable. Parke’s corps (IX.) recaptured the work at a cost of 1000 men, and Gordon fell back, leaving nearly 2000 men in the hands of the Federals. The encounter would have proved a more desperate one if reinforcements on both sides had arrived in time, but Gordon had cut the telegraph which connected Fort Steedman with Grant’s headquarters at City Point, and the Confederate train service broke down. Gordon was then ordered from Richmond of reinforcements for Gordon. Meanwhile, 6 m. westward, Humphreys’ corps (II.) attacked A. P. Hill’s defences and gained some local success, seizing the Confederate picket line between the Weldon railroad and the Boydtown Plank road, which was at once occupied and strengthened by the Federals.

Grant had resolved to attempt. Grant meanwhile had ordered Warren to support Sheridan in an attack on Pickett at daybreak. Sheridan advanced on the 1st of April and at 3 p.m. issued his orders for attack, explaining verbally a diagram he had prepared for the use of divisional commanders. Pickett held a front of 2 m. with a division of cavalry on either flank and Rosser’s cavalry guarding the baggage behind Hatcher’s Run, and when attacked at 4 p.m. he was with Rosser 1½ m. In rear. Before Pickett was made aware of a battle being in progress his left was destroyed. General Lee seems to have made no arrangements to support Pickett in this direction. Pickett’s right was held by W. H. F. Lee against the attack of Custer’s cavalry division. The position was finally carried by Sheridan’s cavalry under Devin dismantling and storming the entrenchments frontally, taking three guns and 100 prisoners. Warren’s corps claimed to have captured a battery and 3244 prisoners. Yet Sheridan was dissatisfied with Warren’s conduct of the battle and deprived him of his command. Pickett’s routes were piled against the South Side railroad and incorporated with General Anderson’s command. But the Confederate had lost White Oak road, and unless General Lee was capable of a vigorous counterstroke on his extreme right it was evident he must also lose the South Side railroad. Grant, fearing such an enterprise, at once reinforced Sheridan and ordered Humphreys’ corps (II.) to attack in his front if necessary to prevent Lee moving troops westward, but Lee made no effort, and so Sheridan was free to operate farther in the direction of the enemy’s right and rear, while Humphreys held the enemy in his front. Sheridan remained inactive for a few days, and Lee hoped still to gain time for the roads to be cleared, the roads, that is, by burning houses, lines and removing his stores and ammunition by wagons towards Lynchburg.

But a crisis was approaching. Sheridan’s success at Five Forks induced Grant to deliver a general assault on the 2nd of April. The Federals were on the alert; A. P. Hill extended his right, and Fitzhugh Lee’s cavalry was brought to Sutherland Station. Sheridan had already encountered the cavalry divisions of W. H. F. Lee and Rosser on the south side of Stony Creek, Warren’s corps, moving up the Quaker road, met a force under R. H. Anderson and drove it back to its works on White Oak road. Sheridan got into a flat country of dense forest, tangle undergrowth, streams and swamps, and the soil of clay and sand was impassable for wagons and guns. He was forced to move the enemy’s fire away from the railroad. On the 29th of March General Lee perceived that the object of Grant was to seize the routes south of the Appomattox river, by which a movement south could be made to unite with Johnston’s army, and he endeavoured to cover these roads, including the South Side railroad, without losing his hold upon his works about Richmond and Petersburg, but in such a contest it was evident that numbers must prevail.

Sheridan’s cavalry had reached Five Forks on the White Oak road on the 31st of March, and on his right counterattacked Warren (II. and V.) led the Confederates to their works along Hatcher’s Run astride the Boydtown Plank road; yet General Lee was able to concentrate his three cavalry divisions, and supported them by Pickett’s five infantry brigades. Sheridan was attacked and driven south as far as Dinwiddie Court-House; but Humphreys and Warren held their ground (action of White Oak Ridge) at a cost of 2000 men. Pickett’s cavalry fell back to Five Forks during the night and hastily entrenched, for he had been ordered by General Lee to defend this position; since the Boydtown Plank road could no longer be held, the possession of White Oak road and the South Side railway became necessary for the flank movement which Lee

Lee’s Retreat

Lost 2000 men and the Confederates perhaps twice as many on the 24th of March.

At this time Sherman visited Grant at City Point and proposed to move at the end of ten days on Burkeville Junction and so cut off Lee from Danville and Lynchburg; it was while Sherman was preparing for this operation that Grant finished the campaign. Secure behind his formidable entrenchments, Grant had no fear for his base on the James river, and transferred large bodies of troops to his left without Lee’s knowledge. Sheridan was instructed on the 29th of March to gain the enemy’s right and rear, moving by Dinwiddie Court-House and across Hatcher’s Run. But the Confederates were on the alert; A. P. Hill extended his right, and Fitzhugh Lee’s cavalry was brought to Sutherland Station. Sheridan had already encountered the cavalry divisions of W. H. F. Lee and Rosser on the south side of Stony Creek, Warren’s corps, moving up the Quaker road, met a force under R. H. Anderson and drove it back to its works on White Oak road. Lost 2000 men and the Confederates perhaps twice as many on the 24th of March.
were to be forwarded from Lynchburg to meet the retreating army at Appomattox Station, Pamplin's Station or Farmville Station. The Appomattox River must be crossed two or three times at its bends. Various creeks and swamps must be bridged, and the defenders will move to separate roads so as to be covered by the columns during marches and combats and the infantry to follow the artillery on the roads. Longstreet's corps crossed the Richmond line and the Appomattox at Goode's Bridge. Ewell from Richmond crossed the Appomattox by the Danville railroad bridge north of Goode's Bridge. Anderson commanded the flank guard which moved south of the railroad with Fitzhugh Lee's cavalry. Lee gained a day's start by moving at 8 p.m., for Grant was making preparations to attack the encampments next day (April 3), but the start was lost to President Davis and the government to escape to Richmond. Ewell in turn crossed the railroad early on the 3rd of April near Nanomoc Creek, and at nightfall the Federal advance-guard was at Deep Creek. On the 4th of April Sheridan reached the Danville railroad at Farmville, and on the 5th of April, when Lee had left Amelia Court-House on the railroad to get supplies, the Federals had three corps (III., V., VI.) in support of Sheridan 8 m. nearer than Lee to Sailor's Creek, the point where he must again cross the Appomattox.

Interception was now a fait accompli, though neither side suspected it. Lee was unaware of the enemy's proximity, and Grant believed that Lee would remain at Amelia Court-House, but Lee moved west, crossing the railroad on the 4th of April, to the railroad (Longstreet, marching all night, reached Rice's Station at sunrise on the 6th of April), while the Federals moved northwards on the same day to attack Lee at Amelia Court-House, and on discovering that Lee was beyond the advance-guard, went off to the left and advanced on Deatonsville after bridging Flat Creek. Meanwhile the Federal cavalry under H. E. Davies had located a convoy at Painseville, dropped out of their regular (II.) cavalry), and dashed to the cars, by which the Federal cavalry in turn been attacked by Fitzhugh Lee's cavalry at Amelia Springs and drove back on the main body at Flat Creek. Fitzhugh Lee had then marched to join Longstreet at Rice's Station. The rearguard of Lee's army was Gordon's command, which was a flank guard on the railroad to get supplies. The advance-guards of the armies had passed through at 8 a.m. on the 6th of April. Lee's army stretched out for 15 m., and when its advance-guard was at Rice's Station its rearguard was still at Amelia Court-House. Rice's Station was 62 m. from Lynchburg. Here Longstreet waited all day for Anderson, Ewell and Gordon to close up, and then at night he moved 8 m. to Farmville Station (68 m. south-west of Richmond), where 80,000 rations had arrived. He was compelled to leave his baggage at Lynchburg, but Gordon crossed the Appomattox, and on the 7th of April moved forward towards Lynchburg, covered by Fitzhugh Lee's cavalry. Meanwhile the remainder of Lee's army had been practically destroyed within a few miles of the point where Longstreet had halted. Sheridan's cavalry and two corps (II., V.) had caught the commands of Anderson, Ewell and Gordon, entangled with the trains of the army attempting the passage of Sailor's Creek; and General Ord was already at Longstreet (whom he had met delayed at night) had his marching orders been delayed.

Complete disorganization and demoralization seem to have taken hold of the army. On this day, 14th of April, Richmond andGettysburg once more in eclipse. The Federal cavalry headed the column, the infantry attacked it, and Ewell became the victim of a tactical envelopment after Anderson had been defeated and Gordon had failed to cross the railroad. At midnight, Ewell had crossed the Longstreet in crossing at Farmville had burnt the bridges and thus delayed Ord in pursuit; but Gordon and Mahone, who had crossed at High Bridge (the railroad bridge), failed to check Humphreys' corps from Lynchburg. Ewell and Gordon must have been compelled to possess the long bridge to get across the South Side railroad, seizing the supplies waiting for Lee at Pamplin's Station, and then moving on another 12 m. to Appomattox Station. At nightfall he found that he was astride the enemy's line of operation, which was a false line of march. At midnight General Lee would be compelled to give battle or capitulate on the morrow. General Lee, quitting Farmville heights on the night of the 11th of April changed the order of march during the next day, so that Gordon (6000) was to attack the 12,000 Federals at night 3 m. of Longstreet, who had entrenched near Appomattox Court-House, facing east and covering the road on which Gordon's corps and Sheridan's cavalry were to join. The fighting was so hot that night. But Gordon on the morning of the 9th of April found Sheridan in his front, and in accordance with plans made overnight he commenced an attack, driving the Federals back until he encountered

at 10 a.m. two corps of infantry (V., XXIV.) under General Ord, who had marched 29 m. in order to support Sheridan at the crisis; and when at the same moment Longstreet was threatened by Humphreys and Wright, the situation had arisen in which General Lee considered would justify surrender, an event which had been anticipated on both sides as the result of the fighting about Farmville on the 6th and 7th of April.

The fighting opened March 29th. March to the 9th of April were all in favour of the Federals, but, nevertheless, the historian counts their losses during this period as nearly 10,000 in the five corps and cavalry which constituted General Grant's field army.

On the 9th of April, A. E. B. T. A. the situation had arisen. The leaders exchanged formal documents by which 2862 officers and 25,494 enlisted men were paroled, all that remained in the field as prisoners. The Confederates surrendered at the 9th of March as the army of Northern Virginia on the 9th of March as the army of Northern Virginia at

(P. W. R.)

PETERSFIELD, a market town in the Petersfield parliamentary division of Hampshire, England, 55 m. S.W. from London by the London & South Western railway. Pop. of urban district (1901), 3265. The church of St Peter retains some ornate Norman work. The picturesque market-place contains an ecclesiastical statue of William III. Ecclesiastically a chapel of Buriton, Petersfield, (Peterfield) owes its origin as a borough to the charter granted by William, earl of Gloucester, in the reign of Henry II. and confirmed later by his widow, Hawise. Petersfield is not mentioned in Domesday, but it was probably then included in the manor of Mapledurham.

It was a mesne borough possessing by its first charter the liberty and customs of Winchester together with a market and fair. The charter was granted to Seigniory of John in 1135 and in 1415 Henry V. in addition freed the burgesses from all tolls. No charter of incorporation has been found. Gradually privileges and rights other than those of a mesne borough were usurped by the mayor and burgesses, but were recovered by a suit brought against them by Thomas Hanbury, owner of the borough, in 1611. A mayor continued to be elected until 1885. Petersfield was represented in parliament in 1307. No return was then made until 1552-1553, from which date two members were regularly returned. In 1832 the number was reduced to one, and in 1885 the representation was merged in that of the county. Three-day fairs at the feasts of St Peter and St Andrew were granted in 1255. In 1584 the summer fair then held on the 10th of July was abolished. The autumn fair now held on the 6th of October is for both business and pleasure. The market, which dates from before 1373, formerly held on Saturday, is now held on alternate Wednesdays. In the 17th century Petersfield had important cloth and leather manufacturers.

PETER'S PENCE, Rome, Scort, or Rom-Fego, a tax of a penny on each hearth, formerly paid annually to the popes; now represented by a voluntary contribution made by the devout in Roman Catholic churches. Its date of origin is doubtful. The first written evidence of it is contained in a letter of Canute (997) sent from Rome to the English clergy. At this time it appears to have been levied on all families possessed of land worth thirty pence yearly rental, out of which they paid one penny. Matthew Paris says the tax was instituted by Ofa, king of Mercia (757-796) for the upkeep of the English school and hostel at Rome. Layamon, however, declares that Ina, king of Wessex (688-725), was the originator of the idea. At the Norman Conquest it appears to have fallen into arrears for a time, for William the Conqueror promised the pope in 1076 that it should be regularly paid. By a bull of Pope Adrian IV. the tax was extended to Ireland. In 1213 Innocent III. complained that the bishops kept 100 marks of it, only forwarding 300 marks to Rome. The pope cited in 1260 Clement V. exacted a penny from each household instead of the 20s. 9s. at which the tax appears to have been then fixed. The threat of withholding Peter's pence proved more than once a useful weapon against recalcitrant popes in the hands of English kings. Thus in 1536 and for some years after it was refused on the ground of the pope's obstinacy in withholding his consent to the statute of praemunire. During the 12th century the custom of Peter's pence was introduced into Poland, Prussia and Scandinavia, and in the 11th century Gregory VII. attempted to exact it from France and
Spain. The tax was fairly regularly paid by the English until 1534, when it was abolished by Henry VIII.

PETIS DE LA CROIX (1653-1713), French Orientalist, was born in Paris in 1653. He was son of the Arabic interpreter of the French court, and inherited this office at his father’s death in 1669, afterwards transmitting it to his own son, Alexandre Louis Marie, who also distinguished himself in Oriental studies. At an early age he was sent by Colbert to the East; during the ten years he spent in Syria, Persia and Turkey he mastered Arabic, Persian and Turkish, and also collected rich materials for future writings. He served a short time as secretary to the French ambassador in Morocco, and accompanied as interpreter the French forces sent against Algiers, contributing to the satisfactory settlement of the affair. He was also pleader for peace, which was drawn up by himself in Turkish and ratified in 1684. He conducted the negotiations with Tunis and Tripoli
in 1685, and those with Morocco in 1687; and the zeal, tact and linguistic knowledge he manifested in these and other transactions with Eastern courts were at last rewarded in 1692 by his appointment to the Arabic chair in the Collège Royal de France, which he filled until his death in 1713. He published Contes turcs (Paris, 1707), and Les Mille et un jours (5 vols., Paris, 1710-1712); an Armenian Dictionary and an Account of Ethiopia. But the lasting monument of his literary fame is his excellent French version of Sharaf-uddin 'Ali Yazdi's Zafarnamâ or History of Timur (completed 826 A.H.; A.D. 1425), which was given to the world nine years after his death (4 vols., Paris, 1772; English translation, 2 vols., London, 1789). This work, which contains one of the very rare specimens of a fairly critical history Persia can boast of, was compiled under the auspices of Mirzâ Ibrahim Sultân, the son of Shâh Rukh and grandson of the great Timur. The only error committed by Petis de la Croix in his otherwise very correct translation is that he erroneously ascribed the important share which Ibrahim Sultân had in the Zafar nameh to Timur himself.

PETIT, SIR DINSHAW MANEKCI, Bart. (1825-1901), Parsee philanthropist, was born on the 30th of June 1825. As broker to European firms he amassed a large fortune during the period of speculation in Bombay at the time of the American Civil War. In 1886 he became a member of the governor-general's legislative council. He devoted his wealth to philanthropic objects, among the public and private charities which he endowed being the Towers of Silence and fire temples of the Parsees, a hospital for animals, a college for women, and the Petit hospital. He was knighted in 1887, created a baronet in 1890, and died in February 1901.

PETIT DE JULLIETTE, LOUIS (1841-1900), French scholar, was born in Paris on the 18th of July 1841. Educated at the Jesuit College of Saint-Sulpice, he entered the Sorbonne to study law and later went to Athens, where he received his doctorate in literature in 1868. After holding various posts as a teacher he became professor of French medieval literature and of the history of the French language in the university of Paris in 1886. He died on the 28th of August 1900.

His most important works are: Histoire du théâtre en France, including Les Mystères (2 vols., 1880); Les Comédies en France au moyen âge (1883); La Comédie et les masques au xive siècle (1885); Histoire du théâtre du xve au xve siècle (1886); Répertoire du théâtre comique en France au moyen âge (1886); and Le Théâtre en France, histoire de la littérature dramatique depuis ses origines jusqu'aux temps modernes (1888). Petits de Jullièvet was also the general editor of the Histoire de la langue et de la littérature française (8 vols., 1896-1900), to which he himself contributed some valuable chapters.

PETITION (Lat. for "seeking" or "praying"), a term meaning generally a prayerful request, and in its more important constitutional aspect an application for redress by a person aggrieved to an authority capable of relieving him. It may be made in the United Kingdom to the Crown or its officers, or to either house of parliament, or in certain cases to courts of justice.

Petitions to the Crown.—The right of petitioning the Crown was recognized indirectly as early as Magna Carta in the famous clause, Nulli vendemus, nulli negabimus aut differemus, rectum vel justitiam (25 Edw. I. c. 29), and directly at various periods later, e.g. in the articles of the Commons assented to by Henry IV., by which the king was to assign two days in the week for petitions (Rot. Parl. 8 Hen. IV., p. 555). The case of the seven bishops in 1688 confirmed the right, and finally the Bill of Rights in 1689 formally recognized the right of the subjects to petition the king, and all commitments and proceedings for such petitioning are illegal.” Petitions to the Crown appear to have been at first for the redress of private and local grievances, or for remedies which the courts of law could not grant (May, Parl. Pr., 11th ed., 322). As equity grew into a system, petitions of this kind not seeking legislative remedies tended to become superseded by bills in chancery. Statutes were originally drawn up by the judges at the close of the session of parliament from the petitions of the Commons and the answers of the Crown. Under this system of drafting it was found that the tenor of the petition and answer were not always stated correctly. To obviate this inconvenience demurrers were drawn in the reign of Henry VI. to be drawn up in the form of bills which the Crown could accept or reject, but could not alter (see Anson, Law and Custom of the Constitution, 3rd ed., vol. i. p. 241). In the same reign the words "by authority of parliament" were added to the words of enactment, and from the time of Henry VII. public legislation has been by bill and not by petition. A relic of the old form of statute founded upon petition still remains however in the preamble of Appropriation Acts and other statutes creating a charge upon the public revenue. It runs thus: "We, your majesty's most dutiful and loyal subjects, the Commons of the United Kingdom... do most humbly beseech your majesty that it may be enacted; and be it enacted, &c., from this point following the enacting words common to all statutes. The Crown may refer petitions presented to it to be adjudicated upon to the Privy Council, and any petition found earlier than the reign of Henry IV. is to be referred to the House of Lords, and by that house to its committee for privileges, and in the case of petitions to the Crown in council, which are usually referred to the judicial committee. The Crown may delegate the power of receiving petitions in the first instance.

Petitions to Parliament.—Petitions to either house of the legislature seem to have been later in origin than petitions to the Crown. They are not referred to in the Bill of Rights, but the right of petition is a convention of the constitution. Petitions to the Lords or the whole parliament can be traced back to the reign of Henry III. No petition to the Commons has been found earlier than the reign of Richard II.; but from the time of Henry IV. petitions to the Commons have been freely made. The political importance of petitioning dates from about the reign of Charles I. The development of the practice of petitioning had proceeded so far in the reign of Charles II. as to lead to the passing in 1662 of an act (13 Car. II. c. 5) against "tumultuous petitioning," which is still on the statute book. It provides that no petition or address shall be presented to the king or either house of parliament by more than ten persons; nor shall any one procure above twenty persons to consent or set their hands to any petition for alteration of matters established by law in church or state, unless with the prior consent of the speaker or clerk of the house; and that such petitions must be addressed to the head of the grand jury. And in 1817 (57 Geo. III. c. 19, s. 25) meetings within a mile from Westminster Hall for the purpose of considering a petition to both houses or either house of parliament while either house is sitting were declared to be unlawful assemblies. Up to 1688 petitions to either house usually dealt only with some specific grievance. From that time dates the present practice of petitioning with regard to general measures of public policy. Petitions to the Houses of Lords or Commons must be framed in the form prescribed by the standing orders, must be properly superscribed, and must conclude with a prayer (May, Parl. Pr., 11th ed., 524, 525). They may be sent free by post for the number of copies ordered, but beyond a certain number they must fulfil certain conditions as to weight, &c., (loc. cit. p. 531).

Petitions to the Commons must be in writing, must contain none but genuine signatures, and must be free from disreputable language or imputations upon any tribunal or constituted authority. They must be presented by a member of the house, except petitions to the House of Commons from the corporation of London, which may be presented at the bar by the sheriffs, and from the corporation of Dublin, which may be presented by the lord mayor. There is no means of compelling a member to present a petition. The proper officer of the house of the petitioners, which is generally the Lord advocate, who presents a petition is required to read it to see whether in form and contents it is fit for presentation. In the Lords receivers and treasurers of petitions from Great Britain and Ireland and from Gascony and the lands and countries beyond the sea were appointed until 1886, though their functions had long been obsolete. Applications for leave to bring before either house bills for private or local and personal matters must under the standing orders of both houses be made by petition; and the same rule obtains as to applications for leave to be heard in opposition to such bills. See Clifford, History of Private Bill Legislation (1887); May, Parl. Pr., (11th ed.), c. xxv.

Petitions to Courts of Justice.—Strictly speaking, these are an indirect mode of petitioning the Crown, for in the theory of English law the Crown is the fountain of justice. But it is more convenient to treat them separately, as they now form a part of the practice of the courts. Appeals to the House of Lords and the privy council are prosecuted by petition of appeal. The
original jurisdiction of the privy council to deal with petitions is
confined to proceedings under certain statutes, such as the
Endowed Schools Acts, the Public Schools Acts, the Universities
Acts and the Patents Acts. In most cases the petitions are
referred to the judicial committee of the council. Petitions may
be addressed to the lord chancellor in a few instances, e.g., for
the removal of coroners or county court judges. The House of
Lords at one time claimed original jurisdiction in civil and
criminal matters. As to civil matters the claim is abandoned,
as it is not unlimited to impenitence for crime by the
Commons on the trial for treason or felony of persons having privilege of peerage.

The most important use of petitions in England is in the High
Court of Justice. In the chancery division petitions are presented
either as interlocutory proceedings in the course of an action, or as
original petitions where no litigation exists—a speedy
form of remedy than an action. The cases in which a peti-
tion is admissible and the procedure therein, are in the main regu-
lated by orders 59 and 55 of the rules of the chancery court. Evidence
in support of petitions is usually by affidavit. Petitions in
the course of an action are presented to the court in which the
action is brought. Examples of original petitions are those under the
Lands Clauses Acts, the Trustee Acts and the Companies Acts.
For many proceedings under these acts a simpler and cheaper
form of proceeding by summons has been substituted for that by
petition. The matters above-mentioned are usually dealt with by
the respective courts. As an example of the court of chancery,
petitions are also in use in other courts having equitable jurisdiction,

. e.g., the chancery courts of the counties palatine of Lancaster and
Durham and the county courts as to cases falling within § 67 of the
26th and 27th Vict. c. 68, and proceedings within the jurisdiction
under the Settled Land Acts or the Guardianship of
Infants Act 1886 (County Court Rules, O. 38). In a few cases
petitions may be brought by way of appeal, e.g., under the Charitable
Trustees Act 1862, where the only use of petitions appears to be to initiate proceedings in bankruptcy.
Leave to sue in forma pauperis used to be given on petition but this
is now usually dealt with summarily. In the probate, etc., division
proceedings in matrimonial causes, etc., are begun by petition
but the course of the proceedings closely resembles those of an ordinary
petition. [498]

Scotland.—In Scotland petitions in the Court of Session are either
original or in a pending action. Original petitions are presented
to one of the divisions of the inner house, unless they relate to
matters mentioned in 20 & 21 Vict. c. 56, s. 4, when they are brought
before the junior lord ordinary, or unless, by special statute, pro-
vision, they may be brought before any lord ordinary, as in the case
of petitions under the "Conjugal Rights (Scotland) Amendment
Act 1861," or the Trusts (Scotland) Act 1867. A petition and
copy are sealed with a quasi-amercement, and the petitioner is
interpreted to have the same powers of summary and extraordinary jurisdiction
brought under the notice of the Court of Session. It lies against magistrates
and officers of the law for breach of duty against parties guilty of
encroachment. The same petition with certain other cases is
necessary to a petition and complaint (see Mackay, Court
of Session Practice, i. 439).

Ireland.—The law of Ireland as to petitions is in substance the
same as that of England. It is subject to the same differences of
court jurisdiction as to the cases in which petitions may be made to courts of justice.

United States.—In the United States before the Civil War questions
arose as to the right of petitioning Congress, particularly with refer-
cence to petitions for the restriction of slavery when it was
contended to be a matter of state and not of federal concern
(see Cooley, Constitutional Limitations, 6th ed., 1890, 426). The
right to petitioning the United States government is now secured by
the provisions of the first four amendments of the constitution
(1789-1791), which provides that "Congress shall make no law
... abridging ... the right of the people peaceably to assemble
and to petition the government for a redress of grievances." In
the view of the Supreme Court the Constitution guarantees the
existence of the right of the people to assemble for lawful purposes
and protects it against encroachment by Congress. The right
was not created by the amendment; neither was its continuance
protected guaranteed except as against concurrent interference
in the right of the people to protect in its enjoyment, therefore, the people must look to the
states. The power for that purpose was originally placed there, and
continued. Under the new constitution the right of the people peaceably to assemble for the purpose of petitioning Congress for
remedy of grievances, or for anything else connected with the powers or
duties of the national government is an attribute of national citizen-
ship. The right is a safeguard of the protection and guaranteed by the
United States. The very idea of a government republican in form
implies a right on the part of its citizens to meet peaceably for
consultation in respect to public affairs and to petition for a redress
of grievances." (U.S. v. Cruikshank, 1875, 92 U.S. 542, 552.)

A Bill of Rights is incorporated in the constitution of many
states of the Union, and is made part of the supreme law of
the states (see Hough, American Constitutions, ii. 571). Petitions
may be presented to the federal or state courts of justice under
the same circumstances as in England. "It is a general rule in
cases of habeas corpus that an order in such a case if a writ of
remand are true as far as known to the petitioner, and that those
facts which he states as knowing from others he believes to be true"
(U.S. v. Law Dict).

British Possessions.—There is a right of petition to the king for
the review of decisions in matters criminal or civil) of courts of
justice in the Channel Islands or Isle of Man, and in all other parts
of the empire outside the British islands and of British courts in
foreign countries. This right is cut down by imperial or colonial
legislation in the case of Canada and Australia, see Tarring, Law

The term Petition of Right, in English law, is used in two senses.
(1) It denotes the statute of 1625 (3 Car. I. c. 1.), a parliamentary
declaration of the liberties of the people. (2) It also and more
usually is employed to describe a mode of prosecuting a claim by
a subject against the Crown, said to owe its origin to Edward I.

Petition of right in this sense lies (a) to obtain restitution of real
or personal property of the subject which has found its way into
the hands of the Crown, or compensation if restitution cannot
be made; (b) to recover damages for breach of a contract made
on behalf of the Crown, whether the breach is due to the acts or the
omissions of servants of the Crown. Where the Crown is in
possession of property of the supplaiant, and the title of the Crown
appears by record, as by inquest of office, the remedy is somewhat
different and is called monstrans de drito. Petition of right does
not lie in respect of engagements in the naval, military or civil
service, or in cases of trade, which are as a general rule made " during
pleasure," nor for breach of contract to perform treaty obligations,
or for trespass or negligence or injuries by Crown servants.
Where such acts are wrongful the remedy is
by action against the official as an individual and not in his
official capacity (Raleigh v. Goschen, 1829, L.R. 1 ch. 73).

The procedure on a petition of right is either at common law or
in a pending action. At common law the petition went through its earliest
stages in the chancery. It suggests such a right as controverts the
right of the Crown to act (a case on the Crown, or Petition Sant
droit fait à partie. Thereupon a commission is issued to unfold the
truth of the suggestion. After the return to the commission,
the attorney-general pleads or demurs, and the merits are then
determined as in actions between subject and subject. If the
right be determined against the Crown, judgment of amovae manus
is given in favour of the supplaiant. The Petition of Right Act
1660 (23 & 24 Vict. c. 34, extended to Ireland in 1873, 36 & 37
Victoria c. 43) provides for a quasiprivate action, but the

majesty, if he thinks fit grants his flat that right be done. The
flat is sealed in the home office and issued to the supplaiant
who files it in the central office of the High Court of Justice, and
that office is bound to sue on behalf of the Crown. A demand
is made to a maker to appear or answer on behalf of the Crown.
The subsequent proceedings including those as to disclosing relevant
documents are assimilated as far as possible to those in an ordinary
action. A judgment in favour of the supplaiant is equivalent to
a judgment of amovae manus ouster le main. Costs are payable
to and by the Crown. A petition of right is usually tried in the
chancery or king's bench divisions; but where the subject of
the petition arises out of the exercise of belligerent rights
behalf of the Crown, or would be cognizable in a prize court if
the matter were in dispute between private persons, the supplaiant
may make his petition in the admiralty or other court of
the
lord chancellor may direct the prosecution in that division of
petitions of right under the act of 1860 even when they are not so
intituled (27 & 28 Vict. c. 25, s. 52).

The law as to petition of right applies to Ireland but not to
Scotland, and a right to present such a petition appears to exist
in colonies whose law is based on the common law of
England. But in many colonies legislation has been passed with respect to
such local government which makes it unnecessary to resort to
a petition of right.

PETITIO PRINCIPII, or BEGGING THE QUESTION (Gr. τὸ ἐν ἀρχῇ λαμβάνειν, τὸ ἐν ἀρχῇ σχεδόν), in logic, the fourth of Aristotle's fallacies εἰκῶ τῆς λέξεως ἢ ἀρχήν. Strictly this fallacy belongs to the language of dispute, when the questioner seeks (petitio) to get his adversary to admit the very
matter in question. Hence the word princiumpium gives a wrong impression, for the fallacy consists not in seeking for the
PETITOT—PETO

admission of a principle which will confute the particular proposition—a perfectly legitimate form of refutation—but in laterating the adversary into confessing the contradictory. In the ordinary use, however, "begging the question" consists in assuming in the premises the conclusion which it is designed to prove.

PETITOT, JEAN (1668–1697), French-Swiss enamel painter, was born at Geneva, a member of a Burgundian family which had fled from France on account of religious difficulties. His father, Faule, was a wood carver; his mother's name was Étienne Royaume. Jean was the fourth son, and was apprenticed to a jeweller goldsmith named Pierre Bordier, with whom he struck up a close friendship. The two friends, dissatisfied with the progress they made in Geneva, went into France, and after working for a while with Toutin came to England with letters of introduction to Turquet de Mayeren, physician to Charles I., who presented them to the king, for whom they made a St George for the badge of the order and carried out many commissions for portraits; amongst others preparing two large ones representing Rachel de Ruvigny, countess of Southampton, now at Chatsworth, and Mary Villiers, duchess of Richmond and Lennox, dated 1643, at one time in the possession of the Crown and now in the Pierpont Morgan collection. On the execution of the king, Petiot left England for Paris with the royal household, Bordier remaining in England and carrying out certain important commissions for Cromwell and the parliament. On reaching Paris, Petiot entered into partnership with a goldsmith, Jacques Bordier, a cousin of Pierre, and it seems probable from recent research in contemporary documents that the enamel portraits attributed to Petiot were really the work of the two partners collaborating, the actual drawing being the work of Petiot, while for the enamel process Bordier was mainly responsible.

The two painters were given apartments in the Louvre, received numerous commissions from Louis XIV., and painted portraits of almost every person of importance in his brilliant court. The friendship between the two lasted for thirty-five years, and was only ended by Bordier's death. The enamellers rendered special political services in France for the republic of Geneva, and were practically regarded as the official representatives of the republic, receiving warm thanks from the Syndic for their diplomatic work. On the revocation of the Edict of Nantes, 1685, pressure was brought to bear upon Petiot that he should change his religion. The king protected him as long as possible, and when he was arrested, with his niece, Anne Bordier, sent Bossuet, bishop of Meaux, to convince the old man of the error of his ways. Eventually, in poor health and great despair, Petiot placed his signature to an act of abjuration, and Louis XIV., unwilling to acknowledge the true reason for the imprisonment of Petiot and for his liberation, informed one of his sons, who had been at the court that the painter, on hearing the news, was mad with joy, and the king was told that he was willing to fall in for once with "the whim of an old man who desired to be buried with his ancestors." In 1687 therefore Petiot left Paris to return to Geneva, and, after a long and tedious inquiry, was absolved by the consistory of the church of Geneva from the crime of which they considered he had been guilty, and received back to the Huguenot communion in the church of St Gervais. In Geneva he received a very important commission from John Sobieski, king of Poland, who required portraits of himself and his queen. This was followed by numberless other commissions which the painter carried out. He died of paralysis on the 3rd of April 1691, while in the very act of painting on the enamel a portrait of his faithful wife.

Petiot married in 1641 Marguerite Cuper, and Jacques Bordier married in the same year her younger sister Anne Madeleine. He had seventeen children, and for their benefit wrote out a little octavo volume containing some genealogical information, two delightful portraits, one of himself and one of his wife, and many pages occupied with prayers, meditations and religious advice. He also prepared a second manuscript volume of prayers and meditations for the use of his family, and from these two books and the records of the Huguenot societies of France and England information has been obtained respecting the painter and his family.

Of the works of Petiot the most important collection is in the Jones Bequest at the Victoria and Albert Museum. There are many in the Louvre, sixteen at Chantilly, seventeen at Windsor, 22 at Versailles, 12 in the collection of the Duke of Buckingham, 3 in the collection of the Duke of Richmond, the duke of Marlborough, the Earl of Dartry, Mr. Alfre de Rothschild and the late Baroness Burdett-Coutts. Amongst Lord Dartry's examples are portraits of Petiot and of his son, Joseph, his wife, Madeleine, and her sister. See Petiot and Bordier, by Ernest Stroehlin (Geneva, 1905); "Some New Information respecting Jean Petitot," by G. C. Williamson, Nineteenth Century and After (January 1908), pp. 98–110; the privately printed Catalogue of the Collection of Mr. J. Pierpont Morgan, vol. iii., The History of Portrait Miniatures, by G. C. Williamson, vol. ii. (London, 1904).

PETITOT, JEAN LOUIS (1652–c. 1730), French enamel painter, was the eldest son of Jean Petiot (q.v.), and was instructed in enamelling by his father. Some of his works so closely resemble those of the elder Petiot that it is difficult to distinguish between them, and he was really the only serious rival his father ever had. He settled for a while in London, where he remained till 1682, and painted many enamel portraits of Charles II. In 1682 he removed to Paris, but in 1695 was back again in London, where he died.

His portrait by Mignard is in the museum at Geneva, and another in enamel by himself in the collection of the Earl of Dartry, who also owns two of his wife, Madeleine Bordier, whom he married in 1683. Another portrait believed to represent him is in the collection of Mr. Pierpont Morgan.

PETITS-CHEVAUX (Fr. for "little horses"), a gambling game played with a mechanical device consisting of a board perforated with a number of concentric circular slits, in which revolve, each independently on its own axis, figures of jockeys on horseback, decorated with coloured silks, and which are staked in return for a fixed sum. The player who has the horse which stops nearest a marked goal wins, every player who has staked on that horse receiving so many times his stake. Figures of railway trains and other objects sometimes take the place of horses. In recent years there has been a tendency to supplant the petits chevaux at French resorts by the boule or ball game, on the same principle of gambling; in this a ball is rolled on a basin-shaped table so that it may eventually settle in one of a number of shallow cups, each marked with a figure.

PETO, SIR SAMUEL MORTON, 4th baronet (1809–1885), English civil engineer, was born at Woking, Surrey, on the 4th of August 1809, and was at an early age apprenticed to his uncle, a London builder, who on his death in 1830 bequeathed the business to Peto and another nephew, Thomas Grissell. The partnership between Peto and Grissell lasted till 1846, amongst the many London buildings erected by the firm being the Reform Club, the Lyceum and St James's theatres, and the Nelson column. Peto afterwards entered into partnership with Edward Ladd Betts (1815–1872), and between 1846 and 1872 Messrs Peto & Betts carried out many large railway contracts at home and abroad, notably the more important portions of the South-Eastern and of the London Chatham & Dover lines, and, in conjunction with Thomas Brassey, the Grand Trunk railway of Canada, and the London Tilbury & Southend railway. In 1854–1855 Peto and Brassey constructed a railway in the Crimea between Balaklava and the British entrenchments before Sebastopol, charging the British government, only the actual out-of-pocket expenses, and for his services in this matter Peto was in 1855 made a baronet. Peto entered parliament as a Liberal in 1847, and, with a few years' interval, continued there till 1868, when his firm having been compelled to suspend payment in the financial crisis of 1866, he was forced to resign his seat, though both Mr Disraeli and Mr Gladstone publicly eulogised his personal character. He died on the 13th of November 1885.
PETŐFI, ALEXANDER (1823-1849), Hungarian lyric poet, was born at Kis-Körösöd, Pest county, on New Year’s Day, 1823. The family received its diploma of nobility from the emperor Leopold in 1688, but the ultra-patriotic Alexander early changed the old family name, Petrovics, which pointed to a Croatian origin, into the purely Magyar form of Petőfi. The lad’s early days were spent at Fehérgyárd and Szabadszállás, the most Hungarian parts of Hungary, where he got most of his early education, including a good grounding in Latin. German he learnt subsequently at Pesth, and French he taught himself. He began writing verses in his twelfth year, while a student at the Aszódi gymnasium, where he also displayed a strong predilection for the stage, to the disgust of his rigorous father, who firmly disowned his son, early in 1830, for some trilling peccadillo, and whose tyrannical temper became downright furious when a series of misfortunes ruined him utterly in 1840. For the next three years Petőfi led the wretched life of a strolling player, except for a brief interval when, to escape starvation, he enlisted as a common soldier in an infantry regiment. During the greater part of 1842 we find him a student at the Calvinist College at Pápa, where he made the acquaintance of young Jókai, and wrote the poem "Borosz," which the great critic Bánfalvi inserted in the leading literary review, the Athenaeum (May 22, 1842). In November of the same year the restless poet quitted Pápa to join another travelling troupe, playing on one occasion the Fool in King Lear, and after wandering all over Hungary and suffering incredible hardships, finally settled down at Pesth (1844), where for a time he supported himself by all sorts of literary hack-work. Nevertheless, in the midst of his worst privations he read voraciously, and was at this time profoundly influenced by the dominant Romanticism of the day; while, through Tiek, he learnt to know and value the works of Shakespeare. His first volume of original poems was published in 1844 by the Society Nemzeti Köz, through the influence of the poets Vörösmarty, when every publisher had refused his MS, and the seventy-five florins which he got for it had become a matter of life or death to him. He now became a regular contributor to the leading papers of Pesth, and was reconciled to his parents, whom he practically supported for the rest of their lives out of his literary earnings. His position, if not exactly brilliant, was now at least secure. The little volume published by the Nemzeti Köz was followed by the parody, A Helyeség Kalapadása (1844); the romantic epic János Vitéz (1844); Ciprissomlók Etelke Söjértől, a collection of passionate elegies over his lost love, Etelke Csapó (1845); Ut Jezuistok, an imitation of Heine’s Reisebilder (1845); Szerelem Gyönyörűségekkel (1847); Serelem és hátszerűségei (1848), and many other volumes. The first edition of his collected poems appeared in 1847. Petőfi was not yet twenty-five, and, despite the protests of the classicists, who regarded him with cold dislike, the best heads in Hungary, poets like Vörösmarty and critics like Szemere, already paid him the homage due to the prince of Magyar lyrical poets. The great public was enthusiastic on the same side, and posterity, too, has placed him among the immortals. Petőfi is as simple and genuine a poet of nature as Wordsworth or Christian Wimper, and his ecstasy, inspired throughout by a noble idealism, have all Byron’s force and fervour, though it is perhaps in his martial songs that Petőfi is essentially passionate and devout genius at his best and most triumphantly. On the 8th of September 1847 Petőfi married Julia Szendrey, who bore him a son. When the revolutionary war broke out, he espoused the tenets of the extreme democratic fiction with a heat and recklessness which estranged many of his friends. He took an active part in the Transylvanian campaigns of the heroic Bem; rose by sheer valour to the rank of major; was slain at the battle of Segesvár (July 31, 1849), and his body, which was never recovered, is supposed to have been buried in the common grave of the fallen heroes in the churchyard of Fehérgyárd. The first complete edition of Petőfi’s poems appeared in 1874. The best critical edition is that of Haras, 1894. There are numerous indifferent German translations. See Ferenczi, Petőfi Életrajz; Fischer, Petőfi’s Leben und Werke. (R. N. B.)

PETOSKEY—PETRA

PETOSKEY, a city and the county-seat of Emmet county, Michigan, U.S.A., on Little Traverse Bay, an arm of Lake Michigan, at the mouth of Bear Creek, in the north-west part of the lower peninsula. Pop. (1890), 2872; (1900), 5285, of whom 856 were foreign-born; (1904), 5186; (1910), 4778. It is served by the Père Marquette and the Grand Rapids & Indiana railways and by steamboat lines to Chicago, Detroit, Buffalo and other lake ports. Bear Creek furnishes considerable water-power, and among the manufactures are lumber, paper, leather and furnishing and machine-shop products. Petoskey was settled about 1874, was incorporated as a village in 1879, was chartered as a city in 1895, and in 1902 replaced Harbor Springs as county-seat. It was named after an Ojibwa Indian chief.

PETRA (Philha = the rock), a ruined site, sq. 30°30’ N. and 35°33’ E., lying in a basin among the mountains which form the eastern flank of Wadi el-‘Arâbâ, the great valley running from the Dead Sea to the Gulf of Ḥâlûn. The descriptions of Strabo (xvi. p. 779), Pliny (N.H. vi. 32) and other writers leave no doubt as to the identity of this site with the famous capital of the Nabataeans (q.v.) and the centre of their caravan trade. Walled in by towering rocks and watered by a perennial stream, Petra not only possessed the advantages of a fortress built on the high ground, but commanded the main commercial routes which passed through it to Gaza in the west, to Bostra and Damascus in the north, to Elath and Leucû Comè on the Red Sea, and across the desert to the Persian Gulf.

From the ‘Arâbá travellers approach by a track which leads round Jebel Hârûn (Mt Hor) and enters the plain of Petra from the south; it is just possible to find a way in from the high plateau on the north; but the most impressive entrance is from the east, down a dark and narrow gorge, in places only 10 or 12 ft. wide, called the Siq, i.e. the shaft, a split in the huge sandstone rocks which serves as the waterway of the Wadi Mûsâ. Near the end of the defile stands the most elaborate of the ruins, el-Hazm or “the Treasury of Pharaoh," not built but hewn out of the cliff; a little farther on, at the foot of the mountain called en-Nejr, comes the theatre, so placed as to bring the greatest number of tombs within view; and at the point where the valley opens out into the plain the site of the city is revealed with striking effect. Almost enclosing it on three sides are rose-coloured mountain walls, divided into groups by deep fissures, and lined with rock-cut tombs in the form of towers. The stream of Wadi Mûsâ crosses the plain and disappears among the mountains opposite; on either bank, where the ground is fairly level, the city was built, covering a space of about 1 sq. m. Among the ruins on the south bank stand the fragments of a temple called Kasr Fir‘āun of late Roman date; just beyond this rises a rocky height which is usually regarded as the acropolis.

A position of such natural strength must have been occupied early, but we have no means of telling exactly when the history of Petra began; the evidence seems to show that the city was of relatively late foundation, though a sanctuary (see below) may have existed there from very ancient times. This part of the country was assigned by tradition to the Horites, i.e. probably “cave-dwellers," the predecessors of the Edomites (Gen. xiv. 6, xxxvi. 20-30; Deut. ii. 12); the habits of the original natives may have influenced the Nabataean custom of burying the dead and forming their cities on high ground. But that Petra itself is mentioned in the Old Testament cannot be affirmed with certainty; for though Petra is usually identified with Sela which also means “a rock," the reference in Judges i. 36; Isa. xvi. 1, xii. 11; Obad. 3, is far from clear. 2 Kings xiv. 7 seems to be more explicit; in the parallel passage, however, Sela is understood to mean simply “the rock" (2 Chr. xxv. 12, see LXX). Hence many authorities doubt whether any town named Sela is mentioned in the Old Testament. What, then, did the Semitic

1 Buhl, Gesch. der Edomiten (1891), p. 52.
inhabitants call their city? Eusebius and Jerome (Onom. sacra, 286, 71, 145. 9; 285, 287, 44) apparently on the authority of Josephus (Ant. iv. 7. 10, 7.) assert that Rekem is the native name. But in the Aramaic versions Rekem is the name of Kadesh; Josephus may have confused the two places. Sometimes the Aramaic versions give the form Rekem-Geya, which recalls the name of the village El-jii, south-east of Petra; the capital, however, would hardly be defined by the name of a neighbouring village. The Semitic name of the city, if it was not Sela, must remain unknown. ¹ The passage in Diodorus Siculus (ix. 94-97) which describes the expeditions which Antigonus sent against the Nabataeans in 312 B.c. is generally understood to throw some light upon the history of Petra, though it must be admitted that the story referred to as a natural fortress and place of refuge cannot be a proper name, and the description at any rate implies that the town was not yet in existence. Brünnow thinks that “the rock” in question was the sacred mountain en-Nejr (above); but Buhl suggests a conspicuous height about 16 m. north of Petra, Shobak, the Mont-royal of the Crusaders.² More satisfactory evidence of the date at which the earliest Nabataean settlement begins is to be obtained from an examination of the tombs. Two types may be distinguished broadly, the Nabataean and the Graeco-Roman. The Nabataean type starts from the simple pylon-tombs or sarcophagi in granite, in imitation of the front of a dwelling-house; then, after passing through various stages, the full Nabataean type is reached, retaining all the native features and at the same time exhibiting characteristics which are partly Egyptian and partly Greek. Of this type there exist close parallels in the tomb-towers at el-Hejr in north Arabia, which bear long Nabataean inscriptions,³ and so supply a date for the corresponding monuments at Petra. Then comes a series of tomb-fronts which terminate in a semicircular arch, a feature derived from north Syria, and finally the elaborate façades, from which all trace of native style has vanished, copied from the front of a palace or temple. Dates of exact date cannot be ascertained; it is evident that the Nabataean tomb-towers were not all erected at once; but the development cannot be fixed, for strangely enough few inscriptions of any length have been found at Petra,⁴ perhaps because they have perished with the stucco or cement which was used upon many of the buildings. We have, then, as evidence for the earliest period, the simple pylon-tombs, which belong to the Pre-Hellenic age; how far back in this stage the Nabataean settlement goes we do not know, but not farther than the 7th century B.C. A period follows in which the dominant civilization combines Greek, Egyptian and Syrian elements, clearly pointing to the age of the Ptolemies. Towards the close of the 2nd century B.C., when the Ptolemaic and Seleucid kingdoms were daily drawing nearer to the front; under Aretas III, Philhellene, c. 85-60 B.C., the royal coins begin; at this time probably the theatre was excavated, and Petra must have assumed the aspect of a Hellenistic city. In the long and prosperous reign of Aretas IV, Philopatris, 9 B.C.—A.D. 40, the fine tombs of the el-Hejr type may be dated, perhaps also the great High-place. Then the city became more and more Romanized. In A.D. 106, when Cornelius Palma was governor of Syria, “Arabia belonging to Petra,”⁵ was absorbed into the Roman Empire, and the native dynasty came to an end. But the city continued to flourish. It was visited in A.D. 151 by Hadrian, and stumped by Pausanias under the patronage of the emperor’s benefactions; the superb Haze, probably a temple for the worship of Isis, and the Deī, which resembles the Haze in design, belong to this century. A century later, in the time of Alexander

PETRARCH (1304-1374). Francesco Petrarca, the great Italian poet and first true reveiver of learning in medieval Europe, was born at Arezzo on the 20th of July 1304. His father Petracco held a post of notary in the Florentine Rolls Court of the Riformagioni; but, having espoused the same cause as Dante during the quarrels between the Blacks and Whites, he was expelled from Florence by that decree of the 25th of January 1302 which condemned Dante to lifelong exile. With his wife he

¹ The whole range in which Petra lies is called Jebel esh-Sharāt, but it is doubtful whether the name of the god was derived from that of the mountain, see Ed. Meyer, loc. cit. p. 268 and Cooke, N.S. vii. p. 218.

² Mentioned by E. L. Wilson (1801), rediscovered by G. L. Robinson (1900), described by S. I. Curtis, P. E. F. Q. Sl. (1900), and Savignac, Rev. bldg. (1903); with full plans and photographs.

³ This is the meaning of Arabia Petraea. Dio Cass. lviii. 14.
took refuge in the Gibelline township of Arezzo; and it was here, on the very night when his father, in company with other members of the White party, made an unsuccessful attempt to enter Florence by force, the Francesco first saw the light. He did not remain long in his birthplace. His mother, having obtained permission to return from banishment, settled at Incisa, a little village on the Arno above Florence, in February 1305. Here Petrarch spent seven years of boyhood, acquiring that pure Tuscan idiom which afterwards he used with such consummate mastery in ode and sonnet. Here too, in 1307, his brother Gherardo was born. In 1312 Petracco set up a house for his family at Parma; but soon afterwards, finding no longer care for the exercise of his profession as jurist, he removed them all in 1313 to Avignon. This was a step of no small importance for the future poet-scholar. Avignon at that period still belonged to Provence, and owned King Robert of Naples as sovereign. But the popes had made it their residence after the insults offered to Boniface VIII. at Anagni in 1303. Avignon was therefore the centre of that varied society which the high pontiffs of Christendom have ever gathered round them. Nowhere else could the youth of genius who was destined to impress a cosmopolitan stamp on medieval culture and to begin the modern era have grown up under conditions more favourable to his task. At Avignon and at Pisa he had learned his mother-tongue. At Carpentras, under the direction of Convennelle of Prato, he studied the humanities between the years 1315 and 1319. Avignon, at a distance from the party strife and somewhat parochial politics of the Italian commonwealths, impressed his mind with an ideal of civility raised far above provincial prejudices.

Petrarch's real name according to Tuscan usage was Francesco di Petracco. But he altered this patronymic, for the sake of euphony, to Petrarca, proving by this slight change his emancipation from usages which, had he dwelt at Florence, would most probably have been imposed on him. Petracco, who was very anxious that his eldest son should become an eminent jurist, sent him at the age of fifteen to study law at Montpellier. Like Ovid and many other poets, Petrarch felt no inclination for his father's profession. His intellect, indeed, was not incapable of understanding and admiring the majestic edifice of Roman law; but he shrank with disgust from the illiberal technicalities of practice. There is an authentic story of Petracco's flinging the young student's books of poetry and rhetoric upon the fire, but saving Virgil and Cicero half-burned from the flames at his son's passionate entreaties. Notwithstanding Petrarch's firm determination to make himself a scholar and a man of letters rather than a lawyer, he so far submitted to his father's wishes as to remain at Avignon until the year 1320; when, having obtained the heads of juristic learning, he was compelled, he says, to return to Avignon. Banishment and change of place had already diminished Petracco's fortune, which was never large; and a fraudulent administration of his estate after his death left the two heirs in almost complete destitution. The most precious remnant of Petrarch's inheritance was a MS of Cicero. There remained no course open for him but to take orders. This he did at once on his arrival in Provence; and we have good reason to believe that he advanced in due time to the rank of priest.

A great Roman noble and ecclesiastic, Giacomo Colonna, afterwards bishop of Lombez, now befriended him, and Petrarch lived for some years in partial dependence on this patron.

On the 6th of April 1337 happened the most famous event of Petrarch's history. He saw Laura for the first time in the church of St Clara at Avignon. Who Laura was remains uncertain still. That she was the daughter of Audibert de Noves and the wife of Hugh de Sade rests partly on tradition and partly on documents which the abbé de Sade professed to have copied from originals in the 18th century. Nothing is now extant to prove that, if this lady really existed, she was the Laura of the Canzoneire, while there are reasons for suspecting that the abbé was either the fabricator of a romance flattering to his own family, or the dupe of some previous impostor. We may, however, reject the sceptical hypothesis that Laura was a mere figment of Petrarch's fancy; and, if we accept her personal reality, the poems of her lover demonstrate that she was a married woman with whom he enjoyed a respectful and not very intimate friendship.

Petrarch's inner life after this date is mainly occupied with the passion which he celebrated in his Italian poems, and with the friendships which his Latin epistles dimly reveal to us. Besides the bishop of Lombez he was now on terms of intimacy with another member of the great Colonna family, the cardinal Giovanni. A German, Ludwig, whom he called Socrates, and a Roman, Lello, who received from him the classic name of Laelius, were among his best-loved associates. Avignon was the chief seat of his residence up to the year of 1333, when he became restless and undertook his first long journey. On this occasion he visited Paris, Ghent, Liége, Cologne, making the acquaintance of learned men and copying the manuscripts of classical authors. On his return to Avignon he engaged in public affairs, pleased the cause of the Scaligers in their lawsuit with the Rossi for the lordship of Parma, and addressed two poetical epistles to Pope Benedict XII. upon the restoration of the papal see to Rome. His elocution on behalf of the tyrants of Verona was successful.

It won him the friendship of their ambassador, Azzo di Correggio—a fact which subsequently influenced his life in no small measure. Not very long after these events Petrarch made his first journey to Rome, a long journey, which, he says, lasted seven years. It was a period of intense study, of scholarship, and of work. His only serious pursuit, however, was the love affair, to the neglect of which, he says, he has left us of the impression he received from its ruins. It was some time in the year 1337 that he established himself at Vaucluse and began that life of solitary study, heightened by communion with nature in her loneliest and wildest moods, which distinguished him in so remarkable a degree from the common herd of medieval scholars. Here he spent his time partly among books, meditating on Roman history, and preparing himself for the Latin epic of Africa. In his hours of recreation he climbed the hills or traced the Sorgues from its fountain under those tall limestone cliffs, while odes and sonnets to Madonna Laura were committed from his memory to paper. We may also refer many of his most important treatises in prose, as well as a large portion of his Latin correspondence, to the leisure he enjoyed in this retreat. Some woman, unknown to us by name, made him the father of a son, Giovanni, in the year 1337; and she was probably the same who brought him a daughter, Francesca, in 1343. Both children were afterwards legitimized by papal bulls.

Meanwhile his fame as a poet in the Latin and the vulgar tongues steadily increased, until, when the first draughts of the Africa began to circulate about the year 1339, it became manifest that no one had a better right to the laurel crown than Petrarch. A desire for glory was one of the most deeply-rooted passions of his nature; and in one of his letters he alludes to the fact that he would have died in 1315 if he had not succeeded the humanistic scholars who succeeded him. It is not, therefore, surprising to find that he exerted his influence in several quarters with the view to obtaining the honours of a public coronation. The result of his intrigues was that on a single day in 1340, the 1st of September, he received two invitations, from the university of Paris and from King Robert of Naples respectively. He chose to accept the latter, journeyed in February 1341 to Naples, was honourably entertained by the king, and, after some formal disputations on matters touching the poet's art, was sent with magnificent credentials to Rome. There, in the month of April, Petrarch assumed the poet's crown upon the Capitol from the hand of the Roman senator amid the plaudits of the people and the patricians. The oration which he delivered on this occasion was composed upon these words of Virgil:

"Sed me Parnassi deserta per arduas dulcis
Raptat amor."

The ancient and the modern eras met together on the Capitol at Petrarch's coronation, and a new stadium for the human spirit, which that we are wont to style Renaissance, was opened.

With the coronation in Rome a fresh chapter in the biography of Petrarch may be said to have begun. Henceforth he ranked as a rhetorician and a poet of European celebrity, the guest of princes, and the ambassador to royal courts. During the spring months of 1341 his friend Azzo di Correggio had succeeded in freeing Parma from subjugation to the Scaligers, and was laying
the foundations of his own tyranny in that city. He invited Petrarch to attend him when he made his triumphal entry at the end of May; and from this time forward for a considerable period Parma and Vaucluse were centres of activity for the poet. The one he called his Transalpine, the other his Cisalpine Parnassus. The events of the next six years of his life, from May 1344 to May 1354, may be briefly recapitulated. He lost his old friend the bishop of Lombzo by death and his brother Gherardo by the entrance of the latter into a Carthusian monastery. Various small benefits were conferred upon him; and repeated offers of a papal secretariaship, which would have raised him to the highest dignities, were made and rejected. Petrarch remained true to the instinct of his own vocation, and had no intention of sacrificing his studies and his glory to ecclesiastical ambition. In January 1343 his old friend and patron Robert, king of Naples, died, and the republic of the day, henceforth the office of pope, consequently the government of the church, passed to his successor Joan. The notices which he has left us of Neapolitan society at this epoch are interesting, and, it was now, perhaps, that he met Boccaccio for the first time. The beginning of the year 1345 was marked by an event more interesting in the scholar's eyes than any change in dynasties. This was no less than a discovery at Verona of Ciceron's Familiar Letters. It is much to be regretted that Petrarch found the precious MS. so late in life, when the style of his own epistles had been already modelled upon that of Seneca and St Augustine.

In the month of May 1347 Cola di Rienzi accomplished that extraordinary revolution which for a short space revived the republic in Rome, and raised this enthusiast to titular equality with kings. Petrarch, who in politics was no less visionary than Rienzi, hailed the advent of a founder and deliverer in the self-styled tribune. Without considering the impossibility of restoring the majesty of ancient Rome, or the absurdity of dignifying the medieval Roman rabble by the name of Populus Romanus, he threw himself with passion into the republican movement, and sacrificed his old friends of the Colonna family to what he judged a patriotic duty.

Petrarch built himself a house at Parma in the autumn of 1347. Here he hoped to pursue the tranquil avocations of a poet honoured by men of the world and men of letters throughout Europe, and of an idealistic politician, whose effusions on the questions of the day were read with pleasure for their style. But in the course of the next two years this agreeable prospect was overclouded by a series of calamities. Laura died of the plague on the 6th of April 1348. Francesco degli Alibizi, Mainardo Accursio, Roberto de' Bardi, Sennuccio del Bene, Luchino Visconti, the cardinal Giovanni Colonna and several other friends followed to the grave in rapid succession. All of these had been intimate acquaintances and correspondents of the poet. Friendship with him was a passion; or, what is more true, of Napa, he exchanged friends; so for the maintenance of his intellectual activity at the highest point of its effectiveness. Therefore he felt the loss of these men acutely. We may say with certainty that Laura's death, accompanied by that of so many distinguished associates, was the turning-point in Petrarch's inner life. He began to think of quieting the world, and pondered a plan for establishing a kind of humanistic conven, where he might dedicate himself, in the company of kindred spirits, to still severer studies and a closer communion with God. Though nothing came of this scheme, a marked change was henceforth perceptible in Petrarch's literary compositions. The poems written in Morte di Madonna Laura are greater and of more religious tone. The prose works touch on retrospective topics or deal with subjects of deep meditation. At the same time his renown, continually spreading, opened to him even fresh relations with Italian despots. The noble houses of Gonzaga at Mantua, at Carrassa at Padua, of Este at Ferrara, of Malatesta at Rimini, of Visconti at Milan, vied with Azzo di Correggio in entertaining the illustrious man of letters. It was in vain that his correspon-
dents pointed out the discrepancy between his professed zeal for Italian liberties, his recent enthusiasm for the Roman republic, and this alliance with tyrants who were destroying the freedom of the Lombard cities. Petrarch remained an incurable rhetori-
Violante Visconti, a few years later, was wedded to the English duke of Clarence. Petrarch was now commissioned to congratul-
ate King John upon his liberation from captivity to England. This duty performed, he returned to Milan, where in 1361 he received news of the deaths of his son Giovanni and his old friend Socrates. Both had been carried off by plague.

The remaining years of Petrarch's life, important as they were for the furtherance of humanistic studies, may be briefly con-
densed. On the 17th of May 1362 he settled at Padua, from the
neighbourhood of which he never moved again to any great
distance. The same year saw him at Venice, making a donation of
his library to the republic of St Mark. Here his friend Boccaccio introduced to him the Greek teacher Leontius Platus. Petrarch, who possessed a MS. of Homer and a portion of Plato, never acquired the Greek language, although he attempted to
gain some little knowledge of it in his later years. Homer, he
said, was dumb to him, while he was deaf to Homer; and he could
only approach the Iliad in Boccaccio's rude Latin version. About
this period he saw his daughter Francesca happily married, and
undertook the education of a young scholar from Ravenna,
whose sudden disappearance from his household caused him the
deepest grief. This youth had been identified, but on insufficient
grounds, with that Giovanni Malpaghini of Ravenna who was
destined to form a most important link between Petrarch and
the humanists of the next age of culture. Gradually his oldest
friends dropped off. Azzo di Correggio died in 1362, and Laclius,
Simonides, Barbatto, in the following year. His own death was
reported in 1365; but he survived another decade. Much of this
last stage of his life was occupied at Padua in a controversy with
the Averroists, whom he regarded as dangerous antagonists both
to sound religion and to sound culture. A curious treatise, which
grew in part out of this dispute and out of a previous duel with
physicians, was the book Upon his Own Ignorance and that of
many others. At last, in 1366, tired with the bustle of a town so
large that it was called the Athens of Italy, he undertook a
journey to Euganean hills, where he continued his usual train of
literary occupations, employing several secretaries, and studying unremittingly. All
through these declining years his friendship with Boccaccio was
maintained and strengthened. It rested on a solid basis of
mutual affection and of common studies, the different tempera-
ments of the two scholars securing them against the disagree-
ments of rivalry or jealousy. One of Petrarch's last compositions
was a Latin version of Boccaccio's story of Griselda. On the 18th
of July 1374 his people found the old poet and scholar dead
among his books in the library of that little house which looks
across the hills and lowlands towards the Adriatic.

When we attempt to estimate Petrarch's position in the history of his own and of European literature, what strikes us is that
he was even less eminent as an Italian poet than as the founder of
Humanism, the inaugurator of the Renaissance in Italy. What he achieved for the modern world was not merely to
bequeath to his Italian imitators masterpieces of lyrical art
unrivalled for perfection of workmanship, but also, and far more,
to open out for Europe a new sphere of mental activity. Stand-
ing within the threshold of the middle ages, he surveyed the
kingdom of the modern spirit, and, by his own inexhaustible
industry in the field of scholarship and study, he determined
what we call the revival of learning. By bringing the men of his
own generation into sympathetic contact with antiquity, he gave
a decisive impulse to that European movement which restored
freedom, self-consciousness, and the faculty of progress to the
human intellect. He was the first man to collect libraries, to
accumulate coins, to advocate the preservation of MSS. For
him the authors of the Greek and Latin world were living men—
more real, in fact, than those with whom he corresponded; and
the rhetorical epistles he addressed to Cicero, Seneca and Varro
prove that he dwelt with them on terms of sympathetic intimacy.
So far-reaching were the interests controlled by him in this
capacity of humanist that his achievement as an Italian lyricist
seems by comparison insignificant.

Petrarch's ideal of humanism was essentially a noble one. He regarded the orator and the poet as teachers, bound to
complete themselves by education, and to exhibit to the world an
image of perfected personality in prose and verse of studied
beauty. Self-culture and self-effectuation seemed to him the
highest aims of man. Everything which contributed to the
formation of a free, impassioned, liberal individuality he regarded as
praiseworthy. Everything which retarded the attainment of
that end was contemptible in his eyes. The authors of antiquity,
the Holy Scriptures and the fathers of the Church were valued
by him as one common source of intellectual enlightenment.
Eminently religious, and orthodox in his convictions, he did not
seek to substitute a pagan for the Christian ideal. This was left
for the scholars of the 15th and 16th centuries in Italy. At the
same time, the Latin orators, historians and poets were venerated
by him as depositories of a tradition only second in importance
to revelation. For him there was no schism between Rome and
Gallice, between classical genius and sacred inspiration. Though
the latter took the first rank in relation to man's eternal welfare,
the former was necessary for the perfection of his intellect and
the civilization of his manners. With this double ideal in view,
Petrarch poured scorn upon the French physicians and the Italian
Averroists for their illiberal philo-sophism, no less than for their
materialistic impiety. True to his conception of independent
intellectual activity, he became a liberal and important ecclesiastical
office, and contented himself with paltry benefices which implied no spiritual or administrative duties,
because he was resolved to follow the one purpose of his life—
self-culture. Whatever in literature revealed the hearts of men
was infinitely precious to him; and for this reason he professed
almost a cult for St Augustine. It was to Augustine, as to
a friend or a confessor, that he poured forth the secrets of his
own soul in the book De contemptu mundi.

In this effort to realize his truest self Petrarch was eminently
successful. Much as he effected by restoring to the world a sound
conception of learning, and by rousing that genuine love and
curiosity which had led to the revival, he did even more by im-
pressing on the age his own full-formed and striking personality.
In all things he was original. Whether we regard him as a
priest who published poem after poem in praise of an adored
mistress, as a plebeian man of letters who conversed on equal
terms with kings and princes, as a solitary dedicated to the love
of nature, as an amateur diplomatist treating affairs of state
with pompous eloquence in missives sent to popes and emperors,
or again as a traveller eager for change of scene, ready to climb
mountains for the enjoyment of broad prospects over spreading
champaigns; in all these divers manifestations of his peculiar
genius we trace some contrast with the manners of the 14th
century, some emphatic anticipation of the 16th. The defects
of Petrarchism, which can be charged against no longer than that his
taste and were indeed their complement and counterpart. That
vivid conception of intellectual and moral self-culture which determined his ideal took the form in actual life of all-absorbing
egotism. He was not content with knowing himself to be
the leader of the age. He claimed autocracy, suffered
no rival near his throne, brooked no contradiction, demanded
unconditional submission to his will and judgment. Petrarch
was made up of contradictions. Praising solitude, playing the
hermit at Vaucluse, he only loved seclusion as a contrast to the
society of courts. While he penned dissertations on the futility
of fame and the burden of celebrity he was trimming his sails
to catch the breeze of popular applause. No one professed a more
austere morality, and few medieval writers indulged in cruder
satire on the female sex; yet he passed some years in the society
of a concubine, and his living masterpiece of art is the apotheosis
of chivalrous passion for a woman. These discords of an
undecided nature displayed themselves in his political theories and
in his philosophy of conduct. In one mood he was faint to ape
the antique patriot; in another he affected the monastic saint.
He was clamorous for the freedom of the Roman people; yet
at one time he called upon the popes to re-establish themselves in
the Eternal City; at another he besought the emperor to make it
his headquarters; at a third he hailed in Rienzi the founder of
a new republic. He did not perceive that all these plans were
incompatible. His relations to the Lombard nobles were equally at variance with his professed patriotism; and, while still a housemate of Visconti and Correggi, he kept on issuing invectives against the tyrants who divided Italy. It would not be difficult to multiply these antitheses in the character and the opinions of this singular man. But it is more to the purpose to remark that they were harmonized in a personality of potent and enduring force.

The point to notice in this complex personality is that Petrarch's ideal remained always literary. As philosopher, politician, historian, essayist, orator, he aimed at lucid and harmonious expression—not, indeed, neglecting the importance of the material he undertook to treat, but approaching his task in the spirit of an artist rather than a thinker or a man of action. This accounts for his bewildering versatility, and for his apparent want of grasp on conditions of fact. Viewed in this light Petrarch anticipated the Italian Renaissance in its weakness—that philosophical superficiality, that tendency to ornate rhetoric, that preoccupation with stylistic trifles, that want of profound conviction and stern sincerity, which stamp its minor literary products with the note of mediocrity. Had Petrarch been possessed with a passion for some commanding principle in politics, morality or science, instead of with the thirst for self- glorification which is the ideal of artistic culture, it is not wholly impossible that Italian humanism might have assumed a manlier and more conscientious tone. But this is not a question which admits of discussion; for the conditions which made Petrarch what he was were already potent in Italian society. He did but express the spirit of the period he opened; and it may also be added that his own ideal was higher and severer than that of the illustrious humanists who followed him.

As an author Petrarch must be considered from two points of view—first as a writer of Latin verse and prose, secondly as an Italian lyricist. In the former capacity he was specifically outstripped by more fortunate scholars. His eclogues and epistles and miscellaneous writings of Africano, in which he set such store, exhibit a comparatively limited command of Latin metre. His treatises, orations, and familiar letters, though remarkable for a prose style which is eminently characteristic of the man, are not distinguished by purity of diction. Much as he admired Cicero, it is clear that he had not freed himself from current medieval Latinity. Seneca and Augustine had been too much used by him as models of composition. At the same time it will be conceded that he possessed a copious vocabulary, a fine ear for cadence, and the faculty of expressing every shade of thought or feeling. What he lacked was that insight into the best classical masterpieces, that command of the best classical diction, which is the product of successive generations of scholarship. To attain this Giovanni da Ravenna, Colluccio Salutato, Poggio and Filelfo had to labour, before a Poliziano and a Bembo finally prepared the path for an Erasmus. Had Petrarch been born at the close of the 15th instead of at the opening of the 14th century there is no doubt that his Latinity would have been as pure, as versatile, and as pointed as that of the witty stylist of Rotterdam.

With regard to his Italian poetry Petrarch occupies a very different position. The Rime in Vita e Morti di Donna Laura cannot become obsolete, for perfect metrical form has here been married to language of the choicest and the purest. It is true that even in the Canzoniere, as Italians prefer to call that collection of lyrics, Petrarch is not devoid of faults belonging to his age, and affectations which have imposed themselves with disastrous effect through his authority upon the literature of Europe. He appealed in his odes and sonnets to a restricted audience already educated by the chivalrous love-poetry of Provence and by Italian imitations of that style. He was not careful to exclude the commonplaces of the school, nor anxious to finish a work of art wholly free from fashionable graces and from contemporary conceits. There is therefore a certain element of artificiality in his treatment; and this, since it is easier to copy defects than excellences, has been perpetuated with wearisome monotony by versifiers who chose him for their model. But after making due allowance for peculiarities, the abuse of which has brought the name of Petrarchist into contempt, we can agree with Shelley that the lyrics of the Canzoniere "are as spells which unseen the inmost enchanted fountains of the delight which is the grief of love." Much might be written about the peculiar position held by Petrarch between the metaphysical lyricists of Tuscany and the more realistic amorists of succeeding generations. True in this respect also to his anticipation of the coming age, he was the first Italian poet of love to free himself from allegory and mysticism. Yet he was far from approaching the analysis of emotion with the directness of a Heine or De Musset. Though we believe in the reality of Laura, we derive no clear conception either of her person or her character. She is not so much a woman as woman in the abstract; and perhaps on this very account the poems written for her by her lover have been taken to the heart by countless lovers who came after him. The method of his art is so generalizing, while his feeling is so natural, that every man can see himself reflected in the singer and his mistress shadowed forth in Laura. The same criticism might be passed on Petrarch's descriptions of nature. That he felt the beauties of nature keenly is certain, and he frequently touches them with obvious appreciation. Yet he has written nothing so characteristic of Vaucluse as to be inapplicable to any solitude where there are woods and water. The Canzoniere is therefore one long melodious monody poured from the poet's soul, with the indefinite form of a beauty woman seated in a lovely landscape, a perpetual object of delightful contemplation. This disengagement from local circumstance without the sacrifice of emotional sincerity is a merit in Petrarch, but it became a fault in his imitators. Lacking his intensity of passion and his admirable faculty for seizing the most evanescent shades of difference in feeling, they degenerated into colourless and lifeless insipidities made insupportable by the frigid repetition of tropes and conceits which we are fain to pardon in the master.

Petrarch did not distinguish himself by love-poetry alone in the Italian language. His odes to Giacomo Colonna, to Cola di Rienzo, and to the Virgin, are splendid pieces of rhetorical light. They exhibit the oratorical fervour, the pleader's eloquence, his most perfect lustre, which Petrarch possessed in no less measure than subjective passion. Modern literature has nothing nobler, nothing more harmonious in the declamatory style than these three patriotic effusions. Their spirit itself is epoch-making in the history of Europe. Up to this point Italy had scarcely begun to exist. There were Florentines and Lombards, Guelfs and Ghibellines; but even Dante had scarcely conceived of Italy as a nation, independent of the empire, inclusive of her several component commonwealths. To the high conception of Italian nationality, to the belief in that spiritual unity which underlay her many discords and divisions, Petrarch attained partly through his own-argumentations, partly through partisan, partly through his large and liberal ideal of culture.

The materials for a life of Petrarch are afforded in abundance by his letters, collected and prepared for publication under his own eyes. These are divided into Familiaris Correspondence, Correspondence in Old Age, Divites Letters and Letters without a Title; to which may be added the curious autobiographical fragment entitled the Epistle to Posterity. Next in importance rank the epistles and eclogues in Latin verse, the Italian poems and the rhetorical ad- dresses, especially the Epistola de Erario et ludorum, emulous of antiquity. For the comprehension of his character the treatise De contemptu mundi; addressed to St Augustine and styled his Secret, is invaluable. Without attempting a complete list of Petrarch's works, it may be well to illustrate the extent of his erudition and his activity as a writer by a brief enumeration of the most important. In the section belonging to moral philosophy, we find De remediis utrisque fortunae, a treatise on human happiness Divites Legem de re publica, a novella on Roman law, De religiosis, a essay on monastic life, inspired by a visit to his brother Gherardo in his convent near Marseilles. On historical subjects the most considerable are Rerum memorandarum pars, his history from the fall of the Roman Empire to the usurpation of Othon, an epitome of the histories of Roman worthies. Three polemical works require mention: Contra cujusdam anonymi Gesta, the columnias apologia, Contra medium quemdam ineptitarum et oloti religiosarum; De vita sicuti de multorum permotione—controversies and sarcastic compositions, which grew out of Petrarch's quarrels with the physicians of Avignon and the Averroists of Padua. In this connexion it might also be well to mention the remarkable
PETRE, SIR E. — PETREL

satisfies on the papal court, included in the Epistolae sine titulo. Five public orations have been preserved, the most weighty of which Petre delivered on the occasion of the Revolution of 1688. A speech delivered on the Capitol upon the occasion of his coronation. Among his Latin poems Africa, an epic on Scipio Africanus, takes the first place. Twelve Ælogiae and three books of Epistles in very close choice, list. In his own work he had included odes and sonnets written for Laura during her lifetime, those written for her after her death, and a miscellaneous section containing the three patriotic odes and three famous poetical invectives against the papal court. Besides these odes of his (and commentations are the semi-epic or allegorical Triomphe—Triumphs of Love, Chastity, Death, Fame, Time and Divinity, written in terza rima of smooth and liquid (or archaic) verse. Though these Triumphs, as a whole, are deficient in poetic invention, the second, the Terzetto della morte, in which Petrarch describes a vision of his dead love Laura, is justly famous for reserved passion and pathos teeming with Grandison.

The complete biography of Petrarch forms a considerable volume. Such a work was attempted by Domenico Rossetti (Trieste, 1828). It will be enough to mention the Basel edition of 1831, folio, as the basis for all subsequent editions of his collected works. Among editions of the Canoniere special mention may be made of those of Marsand (Padua, 1820), Leopardi in Le Monnier’s collection, Mestica (1835), and Cardnui (1899). Nor must Fracassetti’s Italian version of the Letters (published in 5 vols. by Le Monnier) be neglected. De Sade’s Life of the poet (Amsterdam, 1674—1676) marks an epoch in the history of his numerous biographies, but this is in many important points untrustworthy, and abundantly supplied by Gustav Koerting’s exhaustive volume on Petrucci’s Leben und Werke (Leipzig, 1897). Georg Voigt’s Wiedereubildung des klassischen Alterthums (Berlin, 1869) contains an estimate of Petrarch’s work and a full relation of the revival of learning. Mezière’s Petrucci (1868) is a more detailed work of merit. English readers may be referred to a little book on Petrarch by Henry Reeve, and to vols. ii. and iv. of Symonds’s Renaissance in Italy. See also Maud F. Jerrold, Francesco Petrarca and the humanist (1900).

PETRE, SIR EDWARD (1631—1699), Jesuit confessor of King James II. of England, was born in Paris. He was the son of Sir Francis Petre, Bart., of Cranham, head of a junior branch of the family of the Barons Petre, and his wife Elizabeth Gage, daughter of Sir John Gage, both strong Roman Catholics. In 1649 he was sent for his education to the Jesuit College at St Omer, and he entered the order under the name of Spencer in 1652, but did not receive the full orders till 1671. In 1679 he succeeded his elder brother in the title and family estates. On the accession of James II. in 1685 he was chosen as confessor by the king, who looked upon him as a steady and undertaking man. During the whole of the king’s reign Petre was one of his advisers who did the most to encourage him in the policy which ended by producing the revolution of 1688. The king considered him as the arch-power of the kingdom, which was then vacant, but the pope, Innocent XI., who was not friendly to the order, would not grant a dispensation to hold it, and even directed Petre’s superiors to rebuke him for his excessive ambition. In 1687 he was made privy councillor. When the revolution broke out Petre was compelled to flee disguised as a woman. After his flight he had no further relations with James II. After a visit to Rome, he became head of the Jesuit College at St Omer in 1683, from whence he was transferred to Walten in Flanders in 1697. He died on the 15th of May 1699. A younger brother Charles (1644—1712) was also a member of the order.

PETRE, SIR WILLIAM (c. 1502—1572), English politician, was a son of John Petre, a Devon man, and was educated at Exeter College, Oxford, afterwards becoming a fellow of All Souls’ College. He entered the public service in early life, owing his introduction therein doubtless to the fact that at Oxford he had been tutor to Anne Boleyn’s brother, George Boleyn, Viscount Rochford, and began his official career by serving the English government abroad. In 1536 he was made deputy, or proctor, for the vicar-general, Thomas Cromwell, and as such he presided over the convocation which met in June of this year. In 1543 Petre was knighted and was appointed a secretary of state; in 1545 he was sent as ambassador to the emperor Charles V. A very politic man, he retained his position under Edward VI., and also under Mary, forsaking the protector Somerset at the right moment and winning Mary’s goodwill by favouring her marriage with Philip II. of Spain. He resigned his secretaryship in 1557, but took some part in public business under Elizabeth until his death at his residence, Ingestane, Essex, on the 13th of January 1572.

His son John Petre (1549—1613) became Baron Petre of Writtle in 1603. The 2nd baron was his son William (1575—1657), whose grandson was William, the 4th baron (c. 1626—1684). Denounced by Titus Oates as a papist, the last named was arrested with other Roman Catholic noblemen in 1678 and remained without trial in the Tower of London until his death. His brother John (1629—1684) was the 5th lord, and the latter’s nephew, Robert (1680—1713), was the 7th lord. It was Robert’s action in cutting a lock of hair from a lady’s head which led Pope to write his poem “The Rape of the Lock.” The Petres have been consistently attached to the Roman Catholic faith, William Joseph, the 13th baron (1847—1893), being a priest of the Roman church, and the barony is still (1911) in existence. One of the 1st baron’s grandsons was William Petre (1602—1677), who translated the Pia sanctorum of Pedro de Ribadenere as Lives of the Saints (St Omer, 1699; London, 1739).

PETREL, the general name of a group of birds (of which more than 100 species are recognized), derived from the habit which some of them possess of apparently walking on the surface of the water as the apostle St Peter (of whose name the word is a diminutive form) is recorded (Matt. xiv. 19) to have done. The petrels, all of which are placed in the family Procellariidae, were formerly associated with the Laridae (see GULL), but they are now placed as the sole members of the suborder Tubinares (the name denoting the characteristic tubular structure of their nostrils) and of the order Procellariiformes (see BIRDS). They are subdivided into four groups or subfamilies: (1) Pterodroma (or Halodrominae), containing some three or four species known as diving-petrels, with habits very different from others of the family, and almost peculiar to high southern latitudes from Cape Horn to New Zealand; (2) Procellariinae, or petrels proper (and shearwaters); (3) Diomedeinae, or albatrosses (see MALLEMUCK); and (4) Oceanitinae, containing small sooty-black birds of the genera Cynodroma, Pelea, Pelagodroma, Garrodia and Oceanites, the distinctive nature of which was first recognized by Coues in 1861.

Petrels are arctic oceanic forms, with great powers of flight, dispersed throughout all the seas and oceans of the world, and some species are apparently never resort to land except for the purpose of nidification, though nearly all are liable at times to be driven ashore, and often very far inland, by gales of wind.1 It would also seem that during the breeding-season many of them are wholly nocturnal in their habits, passing the day in holes of the ground, or in clefts of the rocks, in which they generally nestle, the hen of each pair laying a single white egg, sparsely speckled in a few species with fine reddish dots. Of those species that frequent the North Atlantic, the common Storm-Petrel, Procellaria pelagica, a little bird which has to the ordinary eye rather the look of a Swift or Swallow, is the Mother Carey’s chicken 2 of sailors, and is widely believed to be the petrel of bad weather; but seamen hardly discriminate between this and others nearly resembling it in appearance, such as Leach’s or the Fork-tailed Petrel, Cynchorea leucorhoa, a rather larger but less common bird, and Wilson’s Petrel, Oceanites oceanicus, the type of the Family Oceanitidae mentioned above, which is more common on the American side. But it is in the Southern Ocean that Petrels most abound, both as species and as individuals. The Cape-Pigeon or Pintado Petrel, Daption capensis, is one that has long been well known to mariners and other wayfarers on the great waters, while those who voyage to or from Australia, whatever be the route they take, are

1 Thus Orestrela haeslata, the Capped Petrel, a species whose proper home seems to be Guadeloupe and some of the neighbouring West-Indian Islands, has occurred in the State of New York, near Boulogne, in Norfolk, and in Hungary (Ibis, 1884, p. 202).
certain to meet with many more species, some, as Osisfraga gigantea, as large as Albatuss, and several of them called by sailors by a variety of choice names, generally having reference to the strong smell of music emitted by the birds, among which that of "Stink-pot" is not the most obnoxious. None of the Petrels are endowed with any brilliant covering—sooty-black, grey of various tints (one of which is often called "blue "), and white being the only hues the plumage exhibits.

The distribution of the several species of Petrels in the Southern Ocean has been described by A. Milne-Edwards in the Annales sciences naturelles for 1882 (6th series Zoologie, vol. xii. art. 4, pp. 1-22).

PETRIE, GEORGE (1790-1866), Irish antiquary, was the son of James Petrie, a native of Aberdeen, who had settled in Dublin as a portrait and miniature painter. He was born in Dublin in January 1790, and was educated as an artist. Besides attaining considerable reputation as a painter of Irish landscape, he devoted much time to the illustration of the antiquities of the country. In 1818 he was appointed to conduct the antiquarian and historical section of the ordnance survey of Ireland. In 1832 he became editor of the Dublin Penny Journal, a periodical designed to disseminate information among the masses, to which he contributed numerous articles on the history of the fine arts in Ireland. Petrie may be regarded as the first scientific investigator of Irish archaeology, his contributions to which are also in themselves of much importance. His Essay on Round Towers, for which in 1830 he received the prize of the Irish Academy, still ranks as a standard work. Among his other contributions to Irish archaeology are his Essay on the Military Architecture of Ireland, and his Ancient and Antiquities of Tara Hill. He died on the 17th of January 1866.

PETRIE, WILLIAM MATTHEW FLINDERS (1853- ), English Egyptologist, was born at Carlton on the 3rd of June 1853, being the son of William Petrie, C.E. His mother was the daughter of Captain Matthew Flinders, the Australian explorer. He took an early interest in archaeological research, and between 1875 and 1880 was busily engaged in studying ancient British remains at Stonehenge and elsewhere; in 1880 he published his book on Stonehenge, with an account of his theories on this subject. He was also much interested in ancient weights and measures, and in 1875 published a work on Inductive Metrology. In 1881 he began a long series of important surveys and excavations in Egypt, beginning with the pyramids at Giza, and following up his work there by excavations at the great temple at Tanis (1884), and discovering and exploring the long-lost Greek city of Naucratis in the Delta (1885), and the towns of Am and Daphnae (1886), where he found important remains of the time when they were inhabited by the Pharaohs. Between 1888 and 1890 he was at work in the Fayum, opening up Hawara, Kahun and Lachish; and in 1891 he discovered the ancient temple at Medum. Much of this work was done in connection with the Palestine Exploration Fund. By this time his reputation was established. He published in 1893 his Ten Years' Diggings in Egypt, which was given the honorary degree of D.C.L. by Oxford, and was appointed Edwards Professor of Egyptology at University College, London. In 1894 he founded the Egyptian Research Account, which in 1905 was reconstituted as the British School of Archaeology in Egypt (not to be confused with the Egypt Exploration Fund, founded 1882). Perhaps the most important work which the School has accomplished has been the investigation of the site of Memphis (p.a.)

Tell el Amarna (1895); Koplos (1896); Nagada (1896); Six Temples at Thebes (1897); Desharch (1897); Denderah (1900); Dourouli (1901); Abydos L. (1903); Aydies II. (1905); Palmyra (1904); Egyptians in Sinai and Researches in Sinai (1906); Gizeh and Rifeh (1907); Athisios (1908); Memphis and Urnahe (1909).

PETROU (also called Cha-chang-su), a town and port of Siam, in the division of Pachim, about 45 m. E. of Bangkok. It is the centre of that part of southern Siam which is watered by the Bang Pakong River, and is built up to 10 m. from the mouth of the above river. The population is about 10,000, mixed Siamese and Chinese, the latter slightly predominating. Rice-mills give employment to a large number of indented Chinese coolies, but the inhabitants are chiefly engaged in agriculture. A railway connecting with Bangkok was opened in the spring of 1908.

PETROLEA, a town and port of entry in Lambton county, Ontario, Canada, situated 42 m. W. of London on Bear Creek, an affluent of Sydenham River, and on the Grand Trunk and Michigan Central railways. Pop. (1901), 4135. It is in the midst of the oil region of Canada, and numerous wells in the vicinity have an aggregate output of about 30,000,000 gallons of crude oil per annum, much of which is refined in the town.

PETROLEUM (Lat. petra, rock, and oleum, oil), a term which, in its widest sense, embraces the whole of the hydrocarbons, gaseous, liquid and solid, occurring in nature (see Bitumen). Here the application of the term is limited to the liquid which is so important an article of commerce, though references will also be made to natural gas which accompanies petroleum. Descriptions of the solid forms will be found in the articles on asphalt or asphaltum, albertite, elaterite, gilsonite, hachette and ozokerite. Particulars of the shales which yield oil on destructive distillation are given in the article on paraffin.

Petroleum was collected for use in the most remote ages of which we have any records. Herodotus describes the oil pits near Arderica (near Babylon), and the pitch spring of Zycanthus (Zante), whilst Strabo, Dioscorides and Pliny mention the use of the oil of Agrigentum, in Sicily, for illumination, and Plutarch refers to the petroleum found near Ecbatana (Kerkuk). The ancient records of China and Japan are said to contain many allusions to the use of natural gas for lighting and heating. Petroleum ("burning water") was known in Japan in the 7th century, whilst in Europe the gas springs of the north of Italy led to the adoption in 1226 by the municipality of Saluspended of a system of gas lighting, and at the same time Lefebrer and Marco Polo refers to the oil springs of Baku towards the end of the 13th century; the medicinal properties of the oil of Tegenese in Bavaria gave it the name of "St. Quirinus's Oil" in 1436; the oil of Pechelbron, Elsass, was discovered in 1498, and the "earthsalsam " of Galicia was known in 1506. The earliest mention of American petroleum occurs in Sir Walter Raleigh's account of the Trinidad pitch-lake in 1595; whilst thirty-seven years later, the account of a visit of a Franciscan, Joseph de la Roche d'Allion, to the oil springs of New York was published in Sagard's Histoire du Canada. In the 17th century, Thomas Shirley brought the natural gas of Wigan, in Shropshire, to the notice of the Royal Society. In 1667, Bernard Bernuyanoon, a friar, referred to the oil lumps of the Bolivian Andes, and Antonio Varobasso was the first to note the oil springs in the Dep. de Bermuda of Peru.

"Barbados tar" was then well known as a medicinal agent. A Russian traveller, Peter Kalm, in his work on America, published in 1748, showed on a map the oil springs of Pennsylvania, and about the same time Raicovich referred to the "liquid bitumen" of Rumania.

Modern Development and Industrial Progress.—The first commercial exploitation of importance appears to have been the distillation of the oil at Allerton in Derbyshire by James Young, who patented his process for the manufacture of paraffin in 1850. In 1853 and 1854 patents for the production of this substance from petroleum were obtained by Warren de la Rue, and the discovery was submitted to the "Rangoon oil" brought to Great Britain from Yenanyuang in Upper Burma. The active growth of the petroleum industry of the United States began in 1830, though in the early part of the century the petroleum of Lake Seneca, N.Y., was used as an emboce.
name of "Seneca oil," and the "American Medicinal Oil" of Kentucky was largely sold after its discovery in 1829. The Pennsylvania Rock Oil Company was formed in 1854, but its operations were unsuccessful, and in 1858 certain of the members founded the Seneca Oil Company, under whose direction E. L. Drake started a well on Oil Creek, Pennsylvania. After drilling had been carried to a depth of 60 feet, on the 28th of August 1859, the tools suddenly dropped into a crevice, and, on the following day the well was found to have "struck oil." This well yielded 25 barrels a day for some time, but at the end of the year the output was at the rate of 15 barrels. The production of crude petroleum in the United States was officially reported to have been 2000 barrels in 1859, 4,215,000 barrels in 1869, 19,914,146 barrels in 1879, 35,163,513 barrels in 1889, 57,084,428 barrels in 1899, and 126,493,936 barrels in 1906. From Oil Creek, development spread first over the eastern United States and then became general, subsequently embracing Canada (1862), recently discovered fields being those of Illinois, Alberta and California (44,854,757 barrels in 1908).

For about 10 years Pennsylvania was the one great oil producer of the world, but since 1870 the industry has spread all over the globe. From the time of the completion on the Baku field of the first flowing well (which was unmanageable and resulted in the loss of the greater part of the oil), Russia has ranked second in the list of producing countries, whilst Galicia and Rumania became prominent in 1878 and 1880 respectively. Sumatra, Java and Borneo, where active development began in 1883, 1886 and 1896, bid fair to rank before long among the chief sources of the oil supplies of the world. Similarly, Burma, where the Burmah Oil Company have, since 1899, rapidly extended their operations, is rising to a position of importance.

Physical and Chemical Properties.—Although our information respecting the chemical composition of petroleum has been almost entirely gained since the middle of the 19th century, a considerable amount of empirical knowledge of the substance was possessed by chemists at an earlier date, and there was much speculation as to its origin. In his Sylva zylarum (1627), Francis Bacon states that "the original concretion of bitumen is adapted and varied, that it attracts the naphtha of Babylon, and for this reason that flame "attracts" the naphtha of Babylon "safar off."" P. J. Macquer (1764), T. O. Bergman (1784) Charles Hatchett (1798) and others also expressed views with regard to the constitution and origin of bitumens. Of these early writers, Hatchett is the most explicit, the various bituminous substances being by him classified and defined. Jacob Joseph Winterl, in 1788, appears to have been the first to examine petroleum chemically, but the earliest systematic investigation was that carried out by Professor B. Silliman, Jun., in 1835, who then reported upon the results which he had obtained with the "rock oil or petroleum of Venango county, Pennsylvania. This report has become a classic in the literature of petroleum."

The physical properties of petroleum vary greatly. The colour ranges from pale yellow through red and brown to black or greenish, while by reflected light it is, in the majority of cases, of a green hue. The specific gravity of crude petroleum appears to range from 0.771 to 1.06, and the flash point from below 0° to 370°F. Viscosity increases with density, but oils of the same density often vary greatly; the coefficient of expansion, on the other hand, varies inversely with the density, but bears no simple relation to the change of fluidity of the oil under the influence of heat, this being most marked in oils of paraffin base. The calorific power of Baku oil appears to be highest, while those of oils consist in solid hydrocarbons, of which the American petroleum contains moderate quantities, and the Upper Burma oils the largest amount. The boiling point, being determined by the character of the constituents of the oil, necessarily varies greatly in different oils, as do the amounts of distillate obtained from them at specified temperatures.

Even prior to the discovery of petroleum in commercial quantities, a number of chemists had made determinations of the chemical composition of several different varieties, and these investigations, supplemented by those of a later date, show that petroleum consists of about 84% by weight of carbon with 12% of hydrogen, and varying proportions of sulphur, nitrogen and oxygen. The principal elements are found in various combinations and association, the Pennsylvania oils being mainly paraffins (g.v.), while those of Canada and Rumania for the most part to the naphthenes, isomer with the olefines (g.v.).

Paraffins are found in all crude oils, and olefines in varying proportions in the majority, while acetylene has been found in Baku oil; members of the benzene group and its derivatives, notably benzene and toluene, occur in all petroleum. Naphthenes are the chief components of some oils, as already indicated, and occur in varying quantities in many others. Certain crude oils have also been found to contain camphenes, naphthalene and other aromatic hydrocarbons. It is found that transparent oils under the influence of light absorb oxygen, becoming deeper in colour and opalescent, while strong acidity and a penetrating odour are developed, these changes being due to the formation of various acid and phenylated compounds, which are also occasionally found in fresh oils. The residues from petroleum distillation have been shown to contain very dense solids and liquids of high specific gravity, having a large proportion of carbon and possessed of remarkable fluorescent properties.

Natural gas is found to consist mainly of the lower paraffins, with varying quantities of carbon dioxide, carbon monoxide, hydrogen, nitrogen and oxygen, in some cases also sulphuric hydrogen and possibly ammonia. This mixture dissolves in petroleum, escaping when the oil is stored, and conversely it invariably carries a certain amount of water and oil, which is deposited on compression.

Occurrence.—Bitumen is, in its various forms, one of the most widely-distributed of substances, occurring in strata of every geological age, from the lowest Archean rocks to those now in process of deposition, and in greater or less quantity throughout both Europe and America, South America and Australia. In Japan, California to Japan. The occurrence of commercially valuable petroleum is, however, comparatively limited, hitherto exploited deposits being confined to rocks younger than the Cambrian and older than the Quaternary, while the majority of developed oil-fields have been discovered north of the equator.

The main requisites for a productive oil or gas field are a porous reservoir and an impermeable cover. Thus, while the mineral may be formed in a stratum other than that in which it is found, though in many cases it is indigenous to it, for the formation of a natural reservoir of the fluid (whether liquid or gas) it is necessary that there should be a surface which may be a depression in the land or rock, typically exemplified by a coarse-grained sandstone or conglomerate, while a limestone may be naturally porous, or, like the Trenton limestone of Ohio and Indiana, rendered so by its compaction into dolomite, and to dolomitic limestone due to shrinkage—a change occurring only in the purer limestones. Similarly it is necessary, in view of the hydrostatio relations of water and mineral oils, and the volatile character of the latter, that the porous stratum should be protected from water and air by an overlying shale or other impervious deposit. Water, often saline or sulphurous, is also found in these porous rocks and replaces the oil as the latter is withdrawn.

In addition to these two necessary factors, structural conditions play an important part in determining the accumulation of oil and gas. The main supplies have been obtained from strata which have been subjected to a combination of anticlinal or terrace structure, however slightly marked or limited in extent, exerts a powerful influence on the creation of reservoirs of petroleum. These tectonic arches often extend for long distances and are great reservoirs for the transportation of sidereal anitclines, which themselves play a not unimportant part in the aggregate of the oil. Owing to the difference of density the oil and water in the anticlines separate into two layers, the upper one occupying the oil which been increased by the structure, and the lower part of the oil. Any gas which may be present rises to the summits of the anticlines. When the slow folding of the strata is accompanied by a gradual local descent, a modified or "arrested" structure is formed. This is marked by the continued downward action at that part being sufficient only to arrest the descent which would otherwise occur. The terraces may thus be regarded as flat and extended anticlines. They need not be horizonal, and sometimes have a dip of a few feet per mile, as in the case of the Ohio and Indiana oil fields, where the amount varies from...
PETROLEUM

go to ten feet. These slight differences in level, however, are found to have a most powerful effect in the direction already mentioned.

In the resident that accurate knowledge of the character and structure of the rock-formations in petroliferous territories is of the greatest importance in enabling the expert to select favourable sites for drilling operations; hence on well-conducted petroleum-prospecting in the United States, New York, Texas, and California, the development of the strata perforated by the drill, so that a complete section may be prepared from the recorded data. In some cases the depth of the strata are stated with reference to sea-level, instead of being taken from the surface. It is greatly facilitating the utilization of the records.

Oil and gas are often met with in drilled wells under great pressure, which is highest as a rule in the deepest wells. The closed pressure in the Trenton limestone in Ohio and Indiana is about 200-300 lb. per square inch, though much higher pressure has been registered in many wells. The gas wells of Pennsylvania indicate about double the pressure of those drilled in the Trenton limestone, 600-900 lb. per square inch, and have been recorded. The extremely high pressure under which oil and gas are met in drilled wells in some parts of the Russian oil fields is a matter of common knowledge, and a fountain or spouting well resulting therefrom is one of the "sights" of the country. A famous fountain in the Gronzy oil field in the northern Caucasus, which began to flow in August 1895, was estimated to have thrown up during the first three days 1,200,000 poors (over 4,500,000 gallons, or about 18,000,000 cu. ft.) It has deranged the normal conditions, and gradually diminishing quantity, for fifteen months; afterwards the flow became intermittent. In April 1897 there was still an occasional outburst of oil and gas.

Three theories have been propounded to account for this pressure:

1. That it results from the weight of the overlying strata.
2. That it is due to very high pressure, as in artesian wells ("hydrostatic" or "artesia" theory).
3. That it is caused by the compressed condition of the gradually accumulating gas.

Of these the first has been proved untenable, and while in some instances (e.g. certain wells in Ohio), the second has held good, the third appears to be the most widely applicable.

The conditions of formation and accumulation of petroleum properties have been the principal subject of the work of the last three or four years, which, with the work of the previous reservoirs, which will be exhausted in the course of years, as in the case of the decreasing yield of certain of the American fields. But new deposits are continually being exploited, and there may be a great many localities in which the greatest discoveries have yet to be made, that might be expressed at the present time in regard to the probable duration of the world's supply of oil and gas.

As already stated, every one of the great geological systems appears to have produced some form of bitumen, and in the following table an attempt has been made to classify on this basis the various localities in which petroleum or natural gas has been found in large or small quantities:

- **Permian.**—New Mexico, Texas, South Dakota, Wyoming, Colorado, Oklahoma, and Arkansas.
- **Triassic.**—New Mexico, Texas, Louisiana, Mississippi, and Alabama.
- **Cretaceous.**—New Mexico, Texas, Louisiana, and Arkansas.
- **Tertiary.**—California, Oregon, Washington, and British Columbia.

Early Methods.

The United States. The first oil well drilled in the United States may be considered to date from the year 1859, when the first well awfully drilled for the production of oil was completed by E. L. Drake. The present method of drilling has been evolved from the earlier methods in a well system which was adopted in 1865.

Oil Derrick.

After the selection of the site, the first operation consists in the erection of the rig. The chief portion of this rig is the derrick, which consists of four strong uprights or legs placed in position by ties and braces, and resting on strong wooden sills, which are preferred, as a foundation, to concrete. For drilling the deeper wells, the derrick, on account of the additional height of 'standing' of the coiled-cord, is increased to 70 ft. high, about 20 ft. wide at the base, and 4 ft. wide at the summit. The whole derrick is set up by keys, no mortices or tenons being used, and thus the complete rig may be readily taken down and set up on a new site. The samsen-post, which supports the string of tools, works parallel with the main sills.

The boiler generally used is of the locomotive type and is usually stationary, though sometimes it is mobile. The ccord-horse, which usually Hitch is detached from the engine and is then taken to some distance before the drill begins, is subsequently removed sufficiently far away before the drill enters the oil-bearing formation, and until the oil and gas are gathered, is used to move the tools in and out of the drill. The boiler frequently supplies the engines of several wells. The engine, which is provided with reversing gear, is of 12 or 15 horse-power and motion is communicated through a belt to the band-wheel, which operates the walking-wheel by means of a crank. The throttle-valve is opened or closed by turning a grooved vertical pulley by means of an endless cord, called the telegraph, passing round another pulley fixed upon the "headache-post," and is thus under the control of four strong uprights or legs placed in position by ties and braces respectively in the engine-house and on the derrick. At one end of the band-wheel is the bell-rope pulley, and upon the other end is a crank having six holes to receive a movable wrist-pin, the length of stroke of the walking-wheel being thus adjusted. The revolution of the bell-wheels is checked by the use of a powerful hand-brake.

The hand-wheel communicates motion to the walking-wheel, which is in progressive through the crank and a connecting-rod known as the pitman; to the bell-wheels, while the tools are being raised, by the bell-rope; and to the sand-pump reel, by a friction pulley, while the sand-pump is being used. The bell-wheels are so arranged that the connections may be rapidly made and broken. The sand-pump reel is in motion by pressing a lever, the reel being then brought into contact with the face of the band-wheel. The sand-pump descends by gravitation, and its fall is checked by pressing back the lever, so as to throw the reel against a post which serves as a brake.

The drilling tools are suspended by an unarrated manila rope, 2 in. in diameter, passing from the bull-wheel shaft over a grooved pulley attached to the derrick. The string of drilling tools consists of two parts separated by an appliance known as the jars. This piece of apparatus was introduced by William Morris in 1851. Instead of well wheels, as previously employed, he inserted a metal plate, or ring, and the sand, which was then free, however, slide freely up and down. It may be compared to a couple of elongated and flattened links of chain. The rings are about 30 in. long and are interposed between the heavy iron auger-drill and the sand, so that the latter is not clogged up. Their principal use is to give a sharp jar to the drill on the up-stroke so that the bit is dislodged if it has become jammed in the formation, and to drive well-boring reamers to enlarge the bore of the well, the winged-substitute which is fitted above the bit to prevent it from glancing off, and above the round reamer to keep it in place, a temper-screw with which it is originally turned in. The jar reamer is also required to remove detritus, water and oil from the bore-hole.

The action of the jars and temper-screw has been described by John F. Carl as follows: Suppose the tools to have been just lowered into the well, and a cap is placed upon them. The men now take hold of the bull-wheels and draw up the slack until the sinker-bar rises, the 'play' of the jars allowing it to come up 15 in., without disturbing the auger-stem. When the jars come together they slack back about 4 in., and the cable is in position to be clamped in the temper-screw. If now the vertical movement of the walking-wheel be 24 in., when it starts on the up-stroke the sinker-bar and reamer are 'screwed' or 'untested' by the barrels. If, on the down-stroke, the auger-stem falls 20 in., while the sinker-bar goes down 24 in. to telescope the jars for the next blow coming up, of course the 4 in. of reamer which has passed the point of the stroke, they are only used to jar down when the tools stick on some obstruction in the well before reaching the bottom, and in fishing operations. An unskilled workman sometimes 'loses the jar' and works for hours without accomplishing anything. The tools may be standing at the bottom while he is playing with the slack of the cable or they may be swinging all the time several feet from the bottom. As the jar works off, or grows more feeble, by reason of the downward advance of the drill, it is 'tempered' to the proper strength by letting down the temper-screw to give the jars more play. The temper-screw forms the connecting link between the walking-wheel and cable, and it is 'let out' gradually to regulate the power of the jars. If the drill-in, therefore, is an upward one, the length is run down, the rope clamps play very near the well-mouth. The tools are then withdrawn, the well is sand-pumped, and preparations are made for the next 'run.'

The ordinary sand-pump or bailer, consists of a plain cylinder of light galvanized iron with a bail at the top and a stem-valve at the bottom. It is usually about 6 ft. in length but is sometimes as much as 15 or 20 ft., and as its valve-stems projects downwards beneath the bottom, it eminently when rested upon the bottom of the waste-trough.

The operation of drilling is frequently interrupted by the occurrence of oil sand which may be encountered in prehistoric or geologically recent formations. If the drilling operation is unsuccessful the well has to be abandoned, often after months of labour, unless it is found possible to drill past the tools which have been lost. In readiness for a fracture of the oil-sands, the tools are placed in the drill, and the necessary fishing tools are provided. These are so numerous and varied in form that a description would be impossible within the scope of this article. The fishing tools are generally attached to the cable, and are used with portions of the ordinary string of tools, but some are fitted to pump-rods or tubing, and others to special rods.

The drilling of a well is commonly carried out under contract, the drilling contractor finding the derrick and the engine while the drilling contractor finds the tools, and is responsible for accidents or failure to complete the well. The drilling crew consists of two drillers, and two or three oil-detectors, passing pairs in two 'tours' (noon to midnight and midnight to noon).

The earlier wells in Pennsylvania consisted of three sections, the first formed of surface clays and gravel, the second of soft rocks containing water, and the third of stratified rocks, including the oil-sands, usually free from water. The conductor, which was a wooden casing of somewhat greater internal diameter than the maximum bore of the well, passed through the section was used to prevent percolation of water into the oil-bearing portion. In later wells the conductor has been replaced with an 8-in. wrought-iron drive-pipe, terminating in a 12-in. collar, and the whole was then tightly fitted in the rocks by a 24-ft. collar, of which the best is drilled below it to the base of the lowest water-bearing stratum. The bore is then reduced to 5½-in., and a bevelled shoulder being made in the rock, a 5½-in. casing, having a collar to fit water-tight the 12-in. collar, was used, and the 12-in. collar should be fitted with a 5½ in. bit. As the water is shut off before the portion of the well below the water-bearing strata is bored the remainder of the drilling is conducted with only sufficient water in the well to
admit of sand-pumping. The drill is thus allowed to fall freely, instead of being partly upheld by the buoyancy of the water, as in earlier wells.

Wells in Pennsylvania now range in depth from 300 ft. to 3700 ft. Four strings of iron casing are usually employed, having the following diameters: 10 in., 8½ in., 6 in. and 5 in., the lengths of tube forming the casing being screwed together. Contractors will often understand that the size of a well is not made by measuring from bottom 8 ft. in diameter and 24 ft. in depth, and lining the sides of this with wood or brick. The initial diameter of the well drilled from the bottom of this pit in some instances as much as 24 ft. and the sides of the well being lined with means to prevent choking, and admit of the use of larger boilers for raising the oil.

The drilling of wells of large sizes requires the use of heavy tools and very strong appliances generally. The system adopted is a modification of the Canadian system already described, the boring rods being, however, of iron instead of wood, but the principle of the same has been already extensively used. For the ordinary 2-in., plain-laid manila cable a wire rope has in some cases been successfully substituted.

Riveted iron casing, made of 1½-in. plate, is employed, and is considered to be far stronger than the earlier wood pipe. To prevent caving. Within recent years, owing to the initiative of Colonel English, a method of raising oil by the agency of compressed air has been introduced into the Balu oil-fields.

In Galicia the Canadian system is nearly exclusively adopted. In some instances under-reaming is found necessary. This consists in the use of an expanding reamer by means of which the well may be drilled to a diameter admitting of the casing, and this obvious difficulty may be accomplished with an ordinary bit introduced through the casing. Of late years the under-reamer has been largely superseded by the eccentric bit.

The Davis calyx drill has also been employed for petroleum drilling. This apparatus may be described as a steel-pointed core-drill. The bit or cutter consists of a cylindrical hollow shell, the inner surface of which is lined with explosive, and in the process of gullotining, into a series of sharp teeth, which are set in and out alternately. The outward set of teeth drill the hole large enough to permit the drilling apparatus to descend freely, and the teeth set inwardly pare down the core to such a diameter as will admit of the body of the cutter passing over it without seizing.

The calyx is a long tube, or a series of connected tubes, situated above the core barrel, to which it is equal in diameter.

The cutting off of the core of drilling for petroleum with which by far the largest amount of work has been, and is being done, are the American or rope comparison system, and the Canadian or rod system. The former is employed in Upper Burma, Java, Rumania and elsewhere. The latter was introduced by Canadians into Galicia and, with certain modifications, has hitherto been found to be the best for that country. A form of the rod system is used in the Russian oil-fields, and owing to the large diameter of the wells the appliances differ from those employed elsewhere.

Drilling from wells. Supplies of natural gas are obtained in the United States and drilled and used in the same manner as the oil wells.

Transport and Storage.—In the early days of the petroleum industry, oil was consigned to the market in barrels and ship manner. Thus, in Upper Burma, it was conveyed in earthenware vessels from the wells to the river bank, where it was poured into the holds of boats. It is interesting to find that a rude pipe-line formerly existed for conveying the crude oil in small pipes under the river; this was made of bamboo, but it is said that the loss by leakage was so great as to lead to its immediate abandonment on completion. In Russia, until 1875, the crude oil was carried in barrels; the common cart known as "arbay." These have two wheels of 8½ ft. in diameter, the body carrying one barrel, while another is slung beneath the axle. In America, crude petroleum was at first transported in iron-hooped barrels, holding from 2 to 2½ Am. gallons. In Canada, 2 Am. gallons were the usual size. The crude oil was conveyed to Oil Creek and the Allegheny River, where they were loaded on boats, these being floated down stream whenever sufficient water was present. This method was not only leading to much loss by collision and grounding. Bulk barges were introduced into use, but the use of these was partially rendered unnecessary by the introduction of railways, when the oil was at first transported in tank-cars, and later was transmitted by rail in the form of consisted of an ordinary truck on which were placed two wrought tin tub-like tanks, each holding about 2000 gallons; they were replaced in 1871 by the modern type of tank-car, constructed with a horizon tubular casing, having an internal radius of 36 m.; but his proposal was never carried into effect. Two years later, however, L. Hutchinson of New York, laid a short line from the Tarr Farm wells to the refinery, which passed over a hill, the oil being moved on the syphon principle, and a year later a constructed another three miles long to the railway. These attempts were, however, unsuccessful, on account of the excessive leakage

The petroleum industry in Canada is mainly concentrated in the districts of Alberta, Ontario, and British Columbia. The latter is the depth of the wells, and the tenacious nature of the principal strata bored through, the Canadian method of drilling differs from the Pennsylvania or American system in the following particulars: 1. The use of slender wooden boring-rods instead of a cable. 2. The employment of a simple auger instead of a spudding-bit. 3. The adoption of a different arrangement for transmitting motion. 4. The use of a lighter set of drilling tools. Although petroleum wells in Russia have not the depth of many of those in the United States, the disturbed character of the strata, with consequent liability to caving, and the occurrence of hard concretions, render drilling a lengthy and expensive business. It is usual to employ a diameter of 8 ft. in diameter and 24 ft. in depth, and lining the sides of this with wood or brick. The initial diameter of the well drilled from the bottom of this pit in some instances as much as 24 ft. and the sides of the well being lined with means to prevent choking, and admit of the use of larger boilers for raising the oil.

Drying in Russia. 

Drying in Galicia.
at the joints of the pipes. With the adoption of carefully fitted screw-joints in 1865 the pipe line gradually came into general use, until in 1891 the lines owned by the various transit companies of Pennsylvania were all that length.

The pumps employed to force the oil through the pipes were at first of the single-cylinder or "donkey" type, but these were found to cause excessive wear—a defect remedied by the use of the "twin-cylinder" which was introduced in 1870. The diameter of the main 6-in. lines are of 600 to 800 h.p., while those on the small-diameter local lines range from 25 to 30 h.p.

Tanks of various types are employed in storing the oil, those at the refinery being usually made of iron, and the rest of steel, and furnished with a capacity of 250 barrels and upwards. Large tanks of boiler-plate are used to receive the oil as it comes through the pipe-lines. Those adopted by the American Oil Company are 90 ft. in diameter and 30 ft. high, with slightly conical bottoms; the capacity is 35,000 barrels, and they are placed upon the carefully levelled ground without any foundation.

In consequence of the various positions of the seaboard in Russia, so many means; specially constructed steel tank barges are used on the waterways of the United States, tank-cars on the railroads, and tank-wagons on the roads. The barrels employed in the transport of petroleum products are of well-seasoned white-oak staves bound by six or eight iron hoops. They are coated internally with glue, and painted in the well-known colours, blue, staves and white heads. The tins largely used for kerosene are made by machinery and contain 16 oz. of oil. They are made in London, and are transferred to barges and thence to Tzaritzin or railway tank-cars. The American type of storage-tank is generally employed, in conjunction with clay-lined reservoirs.

Natural gas is largely used in the United States, and for some time, owing to defective methods of storage, delivery, and consumption, great waste occurred. The improvements introduced in the last years have greatly reduced the consumption, and the general success thus obtained is due to the introduction of the principle of supply by meter, and the adoption of a comprehensive system of regulating the distribution of the gas, as well as to the adoption of a suitable system of regulating the consumption of the different consumers. The success of this system is shown by the fact that the consumption of gas, in recent years, has been reduced to less than half of that of previous years, and the waste is now less than 2 per cent.

Crude petroleum was experimentally distilled in the United States in 1853 by Prof. Silliman (d. 1864), and the refining of petroleum in that country may be said to date from about the year 1855, when Samuel M. Kier fitted up a small refinery with a five-barrel still for the treatment of shale oil obtained from his father's salt works. At this period the supply of raw material was insufficient to admit of any important development in the industry, and the crude crude petroleum was simply distilled, the residue being termed "coal-oil." This term continued to be used by the American oil producers until the introduction of the "oil" process by Ragozin and Tzaritzin at the end of the 19th century, when considerable proportions in the United States. Two large refineries, one on Newtown Creek, Long Island, and another in South Brooklyn, were in successful operation when the abundant production of petroleum, which immediately followed the completion of the refinement of the Drakes well, placed at the disposal of the refiner a material which could be worked more profitably than bituminous shale. The first refining process, which consisted in distilling them for the refining of petroleum; but in the manufacture of burning oil from petroleum the small stills which had been in use in the distillation of shale-oil were at first employed. The earlier refinery stills, which varied from 25 to 80 barrels, usually consisted of a vertical cylinder, constructed of cast- or wrought-iron, with a boiler-plate bottom and a cast-iron dome, on which the "goose-neck" was bolted. The charge was distilled almost to dryness, though the operation was carried far enough to cause the residue to "cok." The operation was, however, completely revolutionized in the United States by the introduction of the "cracking" process, which is characterized by the division of the distillation into two parts, one consisting in the removal of the more volatile constituents of the oil, and the other in the distillation (which is usually conducted in separate stills) of the residue, after the crude oil has been fractionated, for the production of lubricating oils and paraffin.

Various arrangements have been proposed and patented for the continuous distillation of petroleum, in which crude oil is supplied to the stills at one end, and the products are removed from the other. The oil is usually fed into the stills by gas, and it is at the expense of this that the oil is distilled. The stills are usually of the cylindrical type, and in the American stills the distillation is conducted in vertical cylinders, and the charge is fed into the lower part of the cylinder. The stills are usually arranged in parallel lines, and the charge is fed into the lower part of the cylinder. The stills are usually arranged in parallel lines, and the charge is fed into the lower part of the cylinder. The stills are usually arranged in parallel lines, and the charge is fed into the lower part of the cylinder. The stills are usually arranged in parallel lines, and the charge is fed into the lower part of the cylinder.

The "cracking" process, whereby a considerable quantity of the oil which is intermediate between kerosene and lubricating oil is converted into hydrocarbons of lower specific gravity and higher volatility, is of great importance. It is a process of a scientific and technical interest. It is generally understood that the products of fractional distillation, even in the laboratory, are not identical with the hydrocarbons present in the crude oil, but are in part produced by the action of heat upon them. This was plainly stated by Professor Silliman in the earliest stages of development of the American petroleum industry. An important paper bearing on the subject was published in 1871, by T. E. Thorpe, in which he showed how the action of heat under pressure on solid paraffin. They found that the paraffin was thus converted, with the evolution of but little gas, into hydrocarbons which were liquid at ordinary temperatures. In the ordinary partial distillation process of the American Petroleum Refinery (melting point 45° C.) they obtained nearly 4 litres of liquid hydrocarbons, which they subjected to fractional distillation, and on the highest fraction obtained. Further experiments showed that they found it to consist mainly of olefins. The hydrocarbon C3H6, for instance, might be resolved into C3H8 + C4H8, or C3H6 + C5H10, or C3H6 + C5H12, &c., the general equation of the decomposition being:

\[ C_{3n+2} \text{paraffin} = C_{3n} + C_2H_6 + C_2H_4 + \ldots \]

The product actually obtained is a mixture of several paraffins and olefinic hydrocarbons.

The cracking process practically consists in distilling the oils at a temperature higher than the normal boiling point of the compounds which it is desired to decompose. This may be brought about by a distillation under pressure, or by allowing the condensed distillate to fall into the highly heated residue in the still. The result of this treatment is that the comparatively heavy oils
undergo dissociation, as shown by the experiments of Thorpe and Young, is lighter hydrocarbon gases of lower boiling points, and the yield of kerosene from ordinary crude petroleum may thus be greatly increased. A large number of arrangements for carrying out the cracking process have been proposed and patented, probably the most successful being the method devised by Dewar and Young, who in 1865 patented his "Improvements in treating hydrocarbon oils." In this patent, the distillation is described as being conducted in a vessel having a loaded valve or a partially closed top, through which the vapors are led under any desired pressure. Under such conditions, distillation takes place at higher temperatures than the normal boiling-points of the constituent hydrocarbons of the oil, and a partial evaporation of the latter is thus effected by the use of steam, carbon dioxide or other gas, under the required pressure, and the condenser being provided with a regulated outlet for condensed liquid. An objectionable feature of the system of allowing the vapour to escape from the still to the condenser through a loaded valve, viz: the irregularity of the distillation, is thus removed, and the benefits of regular vaporization and condensation under high pressure are obtained. In the American petroleum refineries it is found that sufficient cracking can be produced by slow distillation in stills of which the upper part is sufficiently cooled to allow of the condensation of the vapours of the less volatile hydrocarbons, their condensed liquid thus falling back into the heated body of oil.

In the earlier stages of the development of the manufacture of mineral lubricating oils, the residues were distilled in cast-iron stills, the product being in the form of a paraffin wax, which were injured by overheating. The modern practice is to employ horizontal cylindrical wrought-iron or steel stills, and to introduce steam into the oil. The steam is superheated and may thus be homogeneous and uniform in temperature, the introduction of water-cooling or of a condenser which would be liable to damage the still. The steam operates by carrying the vapours away to the condenser as fast as they are generated, the injury to the products resulting from their remaining in contact with the heated-surface of the still being thus prevented.

In order to separate the distillate into various fractions, and to remove the objection of this method, as it is possible free from condenser troubles, it is now usual to employ condensing apparatus of special form with outlets for running off the different fractions.

The process of distillation of lubricating oils under reduced atmospheric pressure, which is now in common use, consists in obtaining the heavier products. The vapours from the still pass through a condenser into a receiver, which is in communication with the exhauster.

The products obtained by the distillation of petroleum are not in a marketable condition, but require chemical treatment to remove acid and other bodies which impart a dark colour as well as an unpleasant odour to the liquid, and in the case of lamp-oil, reduce the tendency to smoke and to attract flies.

At the inception of the industry kerosene came into the market as a dark-yellow or reddish-coloured liquid, and in the first instance, the object of the process was to effect a separation of the hydrocarbons and a removal of the colour. It was, however, found that after the oil so purified had been burned in a lamp, for a short time, the wick became encrusted, and the oil failed to rise properly. Eicher, of Baku, is ascribed a share of the first to introduce the use of a solution of sulphuric acid, followed by that of soda ash, and his process is in universal use at the present time. The rationale of this treatment is not fully understood, but the action appears to consist in the separation or decomposition of the aromatic hydrocarbons fatty and other acids, phenols, tarry bodies, &c., which lower the quality of the oil, the sulphuric acid removing some, while the caustic soda takes out the remainder, and neutralizes the acid which has been left over. The treated oil is usually subjected to agitation with compressed air. Oils which contain sulphur-compounds are subjected to a special process of refining in which cupric oxide or lightharg is employed as a desulphurizing agent.

**Testing.** A large number of physical and chemical tests are applied both to crude petroleum and to the products manufactured therefrom. A criterion of the oil on this point is the use of a basis of recognized standards of quality, and testing is necessary in the interests of both refiner and consumer, as well as compulsory in connexion with the various statutory and municipal regulations.

The determination of viscosity is a basis of recognized standards of quality, and the test is necessary in the interests of both refiner and consumer. The procedure consists in heating the oil to a temperature of 60°F., and in carrying out at a temperature of 30°F. below the test temperature. The time occupied in the flow of a measured quantity of the oil through a small orifice at a given temperature is measured.

**Uses.** Petroleum has very long been known as a source of light and heat, while the use of crude oil for the treatment of wounds and cutaneous affections, and as a lubricant, was even more general and led to the raw material being an article of commerce at a still earlier date. For pharmaceutical purposes crude petroleum is no longer generally used by civilised races, though the product vaseline is largely employed in this way, and emulsions of petroleum have been administered internally in various pectoral complaints; while the volatile product termed rhizolene has been largely used as a local anaesthetic.

For illuminating purposes, the most extensively-used product is kerosene, but both the more and the less volatile portions of petroleum are employed in suitable lamps. Petroleum is largely utilized as a fuel in the manufacture of (1) the production of "air-gas," (2) the manufacture of oil-gas, and (3) the enrichment of coal-gas. For heating purposes, the stoves employed are practically kerosene lamps of suitable construction, though gasoline is used as a domestic fuel in the United States. The use of petroleum as liquid fuel is dealt with under Fuel, as is the employment of its products in motors, which has greatly
increased the demand for petroleum spirit. Petroleum has largely superseded other oils, and is still gaining ground, as a lubricant for machinery and railway rolling-stock, either alone or in admixture with fixed oils. The more viscous descriptions of mineral oils have also been found suitable for use in the Elmore process of ore-concentration by oil.

Legislation.—Since the inception of the petroleum industry, most civilized countries have prescribed by law a test of flash-point or inflammability in fixed oils primarily to afford a definition of oils for lighting purposes which may be safely stored without the adoption of special precautions. In the United Kingdom the limit has been fixed by the legislature at 73° F., by the adoption of which is established the bulk of the former standard of 100° F. by the "open-test." When the subject of the testing of petroleum for legislative purposes has been under the close scrutiny of British legislative committees of both branches of the legislature, with a view to changes in the law, the standard has never been raised, since such a course would tend to reduce the available supply and thus lead to increase in price or deterioration in quality. Moreover the chief object of the Petroleum Acts passed in the United Kingdom has hitherto been to regulate the sale, conveyance and hawking of petroleum products kept in a flash-point below 73° F., and the Port of London Authority, together with other water-way and harbour authorities in the United Kingdom, have their own by-laws relating to the navigation of vessels carrying such petroleum.

In other countries the flash-point standards differ considerably, as do the storage regulations. In France, the standard is 35° C. (Granier tester, equivalent to 90° F.), and according to their laws a flash-point below 78° C., and the Port of London Authority, together with other water-way and harbour authorities in the United Kingdom, have their own by-laws relating to the navigation of vessels carrying such petroleum.

In other countries the flash-point standards differ considerably, as do the storage regulations. In France, the standard is 35° C. (Granier tester, equivalent to 90° F.), and according to their laws a flash-point below 78° C., and the Port of London Authority, together with other water-way and harbour authorities in the United Kingdom, have their own by-laws relating to the navigation of vessels carrying such petroleum.

The more important local authorities throughout the country have made regulations under the powers conferred upon them by the Petroleum Acts. Among the objects of regulating the "keeping, sale, conveyance and hawking" of petroleum products kept in a flash-point below 73° F., and the Port of London Authority, together with other water-way and harbour authorities in the United Kingdom, have their own by-laws relating to the navigation of vessels carrying such petroleum.

Composition.—Only the common minerals are important as rock formers. Their number is small, not exceeding a hundred in all, and much less than this if we do not reckon the subdivisions into which the commoner species are broken up. The vast majority of the rocks which we see around us every day consist of quartz, felspar, mica, chlorite, kaolin, calcite, epidote, olivine, augite, hornblende, magnetite, haematite, limonite and a few other minerals. Each of these has a recognized position in the economy of nature. A main determining factor is the chemical composition of the mass, for a certain mineral can be formed only when the necessary elements are present in the rock. Calcite is commonest in limestones, as these consist essentially of carbonates of lime; quartz in sandstones and in certain igneous rocks which contain a high percentage of silica. Other factors are of equal importance in determining the natural association or paragenesis of rock-making minerals, principally the mode of origin of the rock and the stages through which it has passed in attaining its present condition. Two rock masses may have very much the same bulk composition and yet consist of entirely different assemblages of minerals. The tendency is always for those compounds to be formed which are stable under the conditions under which the rock mass originated. A granite arises by the consolidation of a molten magma (a fused rock mass; Gr. μεγας, from μολυσα, to knead) at high temperatures and pressures. There are two classes of rocks, and its component minerals are such as are formed in such circumstances. Exposed to moisture, carbonic acid and other subaerial agents at the ordinary temperatures of the earth’s surface, some of these original minerals, such as quartz and white mica are permanent and remain unaffected; others “weather” or decay and are replaced by new combinations. The felspar passes into kaolin, muscovite and quartz, and if any black mica (biotite) has been present it yields chlorite, epidote, rutil and other substances. These changes are accompanied by disintegration, and the rock falls into a loose, incoherent, earthy mass which may be regarded as a sand or soil. The materials thus formed may be washed away and deposited as a sandstone or silt; to these high temperatures and pressures. The structure of the original rock is then replaced by a new one; the mineralogical constitution is profoundly altered; but the bulk chemical composition may not be very different. The sedimentary rock may again undergo a metamorphism. If penetrated by igneous rocks it may be recrystallized or, if subjected to enormous pressures with heat and movement, such as attend the building of folded mountain chains, it may be converted into a gneiss not very different in mineralogical composition though radically different in structure to the granite which was its original state.

Structure.—The two factors above enumerated, namely the chemical and mineral composition of rocks, are scarcely of greater
importance than their structure, or the relations of the parts of which they consist to one another. Regarded from this standpoint rocks may be divided into the crystalline and the fragmental. Inorganic matter, if free to take that physical state in which it is most stable, always tends to crystallize. Crystalline rock masses have conSolidated from solution or from fusion. The vast majority of igneous rocks belong to this group and the degree of perfection in which they have attained the crystalline state depends primarily on the conditions under which they solidified. Such rocks as granite, which have cooled very slowly and under great pressures, have completely crystallized, but many lavas were poured out at the surface and cooled very rapidly; in this latter group a small amount of non-crystalline or glassy matter is frequent. Other crystalline rocks such as rock-salt, gypsum and anhydrite have been deposited from solution in water, mostly owing to evaporation on exposure to the air. Still another group, which includes the marbles, mica-schists and quartzites, are recrystallized, that is to say, they were at first fragmental rocks, like limestone, clay and sandstone and have never been in a molten condition nor entirely in solution. Certain agencies however, acting on them, have effaced their primitive structures, and induced crystallization. This is a kind of metamorphism.

The fragmental structure needs little explanation; wherever rocks disintegrate fragments are produced which are suitable for the formation of new rocks of this group. The original materials may be organic (shells, corals, plants) or vitreous (volcanic glasses) or crystalline (granite, marble, &c.); the pulverizing agent may be frost, rain, running water, or the steam explosions which shatter the lava within a volcanic crater and produce the fragmental rocks known as volcanic ash, tuffs and agglomerates. The materials may be loose and incoherent (sand, clay, gravel) or compacted by pressure and the deposit of cementing substances by percolating water (sandstone, shale, conglomerate). The grains of which fragmental rocks are composed may be coarse or fine, fresh or decayed, uniform or diverse in their composition; the one feature which gives unity to the class is the fact that they are all derived from pre-existing rocks or organisms. Because they are made up of broken pieces these rocks are often said to be "clastic."

Origin of Rocks.—The study of the structure of rocks evidently leads us to another method of regarding them, which is more fundamental than those enumerated above, as the structure depends on the mode of origin. Rocks are divided into three great classes, the Igneous, the Sedimentary and the Metamorphic.

Igneous Rocks. The igneous (Lat. ignis, fire) rocks have all consolidated from a state of fusion. Some of them are crystalline or "massive"; others are fragmental. The massive igneous rocks include a few which are nearly completely vitreous, and still more which contain a small amount of amorphous matter, but the majority are completely crystallized. Among the best known examples are obsidian, pumice, basalt, trachyte, granite, diorite. The fragmental igneous rocks consist of volcanic ashes more or less firmly compacted. The sedimentary rocks form a second group; they have all been laid down as deposits on the earth's surface subject to the conditions of temperature, moisture and pressure which obtain there. They include fragmental and crystalline varieties. The former consist of the debris of pre-existing rocks, accumulated in seas, lakes or dry land and more or less indurated by pressure and cementing substances, sandstone, gravel, sand and clay, conglomerate, sandstone and shale are well-known examples. Many of them are fossiliferous as they contain fragments of organisms. Some are very largely made up of remains of animals or plants, more or less altered by mineralization. These are sometimes placed into a special group as rocks of organic origin; limestone, peat and coal are typical of this class. The crystalline sediments are such as rock-salt and gypsum, deposits of saline lakes or isolated portions of the sea. They were formed under conditions unfavourable to life and hence rarely contain fossils. The metamorphic rocks are known to be almost entirely altered igneous or sedimentary masses. Metamorphism consists in the destruction of the original structures and the development of new minerals. The characteristic composition of the rocks however suffers little change. The rock becomes as a rule more crystalline; but all stages in the process may be found and in a metamorphosed sediment, e.g., a sandstone, remains of the original sand grains and primary fragmental structure may be observed, although extensive recrystallization has taken place. The agencies which produce metamorphism are high temperatures, pressure, interstitial moisture and in many cases movement. The effects of high temperatures are seen best in the rocks surrounding great outcrops of intrusive granite, for they have been baked and crystallized by the heat of the igneous rock (thermo-metamorphism). In folded mountain chains where the strata have been greatly compressed and their particles have been forced to move over one another a different type of metamorphism prevails (regional or dynamic metamorphism).

Methods of Investigation.—The macroscopic (Gr. μάξις, large) characters of rocks, those visible in hand-specimens without the aid of the microscope, are very varied and difficult to describe accurately and fully. The geologist in the field depends principally on them and on a few rough chemical and physical tests; and to the practical engineer, architect and quarry-master they are all-important. Although frequently insufficient in themselves to determine the true nature of a rock, they usually serve for a preliminary classification and often give all the information which is really needed. With a small bottle of acid to test for carbonate of lime, a knife to ascertain the hardness of rocks and minerals, and a pocket lens to magnify their structure, the field geologist is rarely at a loss to what group a rock belongs. The fine grained species are often indefinable in this way, and the minute mineral components of all rocks can usually be ascertained only by microscopic examination. But it is easy to see that a sandstone or grit consists of more or less rounded, water-worn sand-grains and if it contains dull, weathered particles of felspar, shining scales of mica or small crystals of calcite these are rarely escape observation. Shales and clay rocks generally are soft, fine grained, often laminated and not infrequently contain minute organisms or fragments of plants. Limestones are easily marked with a knife-blade, effervesce readily with weak cold acid and often contain entire or broken shells or other fossils. The crystalline nature of a granite or basalt is obvious at a glance, and while the former contains white or pink felspar, clear vitreous quartz and glancing flakes of mica, the other will show yellow-green olivine, black augite and grey striated plagioclase.

But when dealing with unfamiliar types or with rocks so fine grained that their component minerals cannot be determined with the aid of a lens, the geologist is obliged to have recourse to more delicate and searching methods of investigation. With the aid of the blowpipe (to test the fusibility of detached crystals), the goniometer, the magnet, the magnifying glass and the specific gravity balance, the earlier travellers attained surprisingly accurate results. Examples of these may be found in the works of von Buch, Scope, Darwin and many others. About the end of the 18th century, Dolomieu examined crushed rock powders under the microscope and Cordier in 1815 crushed, levigated and investigated the finer ground-mass of igneous rocks. His researches showed that many of these rocks, in some cases, at least, that they consisted essentially of such minerals as felspar, augite, iron ores and volcanic glass, and did not differ in nature from the coarser grained rocks. Nicol, whose name is associated with the discovery of the Nicol's prism, seems to have been the first to prepare thin slices of mineral substances, and his methods were applied by Witham (1831) to the study of plant petrifications. This method, of such far-reaching importance in petrology, was not at once made use of for the systematic
research of investigations, and it was not till 1858 that Sorby pointed out its value. Meanwhile the optical study of sections of crystals had been advanced by Sir David Brewster and other physicists and mineralogists and it only remained to apply their methods to rocks. This was first undertaken by A. W. de Quervain in 1857, who published a paper on the application of the methods to rock sections. Since that time progress has been made and the names of Zirkel, Allport, Vogelsang, Schuster, Rosenbusch, Bertrand, Fouqué and Lévy are among those of the most active pioneers in the new field of research. To such importance have microscopical methods attained that textbooks of petrology at the present time are very largely devoted to a description of the appearances presented by the minerals of rocks as studied in transparent micro-sections.

A good rock-section should be about one-thousandth of an inch in thickness, and of the polished surface of the rock the splinter of the rock, about as large as a halfpenny may be taken; it should be as fresh as possible and free from obvious cracks. By grinding on a plate of plane steel or cast iron with the face of a glass plate as a polishing agent, the surface can be brought to a fine polish. If the rock is not transparent, and when that is accomplished the smooth, dry, warm rock is pressed firmly into contact with the glass plate so that the film of balsam intervening may be as thin as possible and free from air-bubbles. The rock will then be ready to be examined. The reflected light characterizes the mineral, and the rock is mounted down as before, first with carbordum and, when it becomes transparent, with fine emery till the desired thickness is obtained. It is then cleaned, again heated with a little more balsam, and cemented to the plate with India ink. The pressures may be avoided by cutting off a smooth slice with an iron disk armed with crushed diamond powder. A second application of the slitter after the first face is smoothed and cemented to the glass will in expert hands leave a rock-section so thin as to be already transparent. In this way the preparation of a section may require only twenty minutes.

The microscope employed is usually one which is provided with a rotating stage beneath which there is a polarizer, while above the objective or the eyepiece an analyser is mounted; alternatively the stage may be fixed and the polarizing and analysing prisms and plate may be rotated on the axis of the toothed wheels and a connecting-rod. If ordinary light and not polarized light is desired, both prisms may be withdrawn from the axis of the instrument; if the polarizer only is inserted the light transmitted is plane polarized; with both prisms in position the slide is viewed between crossed nicsols. A microscopic rock-section in ordinary light if a suitable magnification (say 30) is employed is seen to consist of grains or crystals varying in colour, size, form, and transparency. Some are transparent and colourless; others have a yellow, green, purple, or grey tint. The same mineral may present a variety of colours, in the same or different rocks, and these colours may be arranged in zones parallel to the surfaces of the crystals. Thus tourmaline may be brown, yellow, pink, blue, green, violet, or grey, but every mineral has one or more characteristic, because most common tints. The shapes of the crystals determine in a general way the outlines of the sections of them presented on the slides. If the mineral has one or more good cleavages the section will be indicated by systems of cracks (see pp. III.). The refractive index is also clearly shown by the appearance of the sections, which are rough, with well-defined borders if they have a much stronger cleavage parallel to the cleavage plane; the members of the cleavage may be broken off cleanly. Some minerals decompose readily and become turbid and semi-transparent (e.g. felspar); others remain always perfectly fresh and clear (e.g. quartz), others yield characteristic secondary products (such as green chlorite after biotite). The inclinations in the crystals are of great interest; one mineral may enclose another, or may contain spaces occupied by glass, by fluids or by gases. The nature of the cleavage planes, the relation of its components to one another, is usually clearly indicated, whether it be fragmental or massive; the presence of glassy matter in contradistinction to a completely crystalline or detrital rock is known what the ‘cement’ of a rock is. Methods of observation may be introduced, such as the measurement of the size of the elements of the rock by the help of micrometers; their relative proportions by means of a glass plate ruled in small squares; the angle between cleavages, or faces seen in section by the use of the rotating graduated stage, and the estimation of the refractive index of the mineral by comparison with those of different minerals.

Further information is obtained by inserting the polarizer and rotating the section. The light vibrates now in one plane, and in passing through doubly refracting crystals in the stage it is divided up into two rays, the ordinary which vibrate at right angles to one another. In many coloured minerals such as biotite, hornblende, tourmaline, chlorite, et al., it is always found that a section consisting of any of these contains any of these minerals is divided into two rays, in all spots which surround minute enclosures of other minerals, such as zircon and epidote; these are known as ‘pleochroic halos.’

If the analyser be now inserted in such a position that it is crossed by the sections, a characteristic coloured film is seen between them or near it sometimes, and the intensity of these colours is often very striking. This property, known as ‘pleochroism’ (Gr. πλευχος, more; χρωμα, colour), is of great value in the determination of minerals as well as their presence in rocks. This is due to the fact that there are no minerals, or where the light passes through isotropic substances such as glass, liquids and cubic crystals. All other crystalline bodies, being doubly refracting, give a birefringent film. The only exception to this rule is provided by sections which are perpendicular to the optic axes of birefringent crystals; these remain dark or nearly dark during whole rotation, and as will be seen later, their investigation is of special importance. The doubly refracting mineral sections, however, will in all cases appear black in certain positions as the stage is rotated. The extinction or angle of the section by this takes place. If we note these positions we may measure the angle between them and any cleavages, faces or other structures of the crystal by means of the rotating stage. These angles may be marked on the stage (or eyepiece) and the whole oriented.

The mineral sections when not extinguished are not only bright but are coloured and the colours they show depend on several factors, the most important of which is the strength of the double refraction. If the sections are very thick or the mineral is not very volatile, of the mineral species itself (see Crystallography). To facilitate measurement of extinction angles various kinds of eyepieces have been devised, some having a stauroscopic calcite or quartz wedge, others a Nicol prism. In all cases these are often found to give more exact results than are obtained by observing merely the position in which the mineral section is most completely dark between crossed nicsols.

the bar of which remain parallel to the wires in the field of the eye-

piece. Sections perpendicular to the same show a dark line.

under these conditions a show a dark line which on rotation becomes curved to a hyperbolic shape. If the section is perpendicu-
lar to a "biscirct" (see CRYSTALLOGRAPHY) a black cross is seen
which on rotation opens out to form two hyperbolas, the apices of
which are turned towards one another. The optic axes emerge at
the apices of the hyperbolas and may be surrounded by coloured
rings, though owing to the thinness of minerals in rock sections
these are often concealed by the double refraction of the oils used.

The distance between the axes as seen in the field of the
microscope depends partly on the axial angle of the crystal and
partly on the numerical aperture of the objective. If it is
inevitable that the embedded mineral is of a particular size the
axial angle of the crystal can be found by a simple calculation. The
quartz wedge, quarter mica plate or selenite plate permit the determination of the positive or negative character of the crystal and
the convexity or concavity of the apices observed in the field. These operations are precisely similar to those employed by the mineralogist in the examination of plates cut from crystals. It is sufficient to point
out that the petrological microscope in its modern development is an optical instrument of great precision, enabling us to determine physical constants of crystallized substances as well as serving to produce magnified images like the ordinary microscope. A great
variety of accessory apparatus has been devised to fit it for these special uses.

The separation of the ingredients of a crushed rock powder
from one to another in order to obtain pure samples suitable
for analysis is also extensively practised. It may be

be effected by means of a powerful electro-magnet in the
strength of which can be regulated as desired. A weak magnetic field will attract magnetite, then haematite,
and other ores, and sulphides. SIllica and magnesia minerals can be
removed in definite order and biotite, enstatite, augite, hornblende,
garnet and similar ferro-magnesian minerals may be success-
ively abstracted; at last only the colourless, non-magnetic
compounds, such as muscovite, calcite, quartz and felspar, will remain.

Chemical methods also are useful. A weak acid will
dissolve calcite from a crushed limestone, leaving only dolomite,
silicates or quartz. Hydrofluoric acid will attack felspar before
quartz, and if employed with great caution will dissolve these
and any glassy material in a rock powder before dissolving
augite or hypersthene. Methods of separation by specific
gravity have a still wider application. The simplest of these
is levigation (Lat. levigare, to make smooth, lede) or treatment
by a current of water; it is extensively employed in the mechanical
analysis of soils and in the treatment of ores, but is not so
successful with rocks, as their components do not as a rule
differ very greatly in specific gravity.

Fluids are used which do not attack the majority of the rock-
making minerals and at the same time have a high specific gravity.
Solutions of potassium mercuric iodide (sp. gr. 3-196), cadmium
bromide (sp. gr. 3-06), methyl bromide (sp. gr. 3-00) or arsenic
form (sp. gr. 2-80), or acetylene bromide (sp. gr. 3-00) are the
principal media employed. They may be diluted (with water, benzene,
&c.) to any desired extent and again concentrated by evaporation.
If the rock be a granite consisting of biotite (sp. gr. 3-1), muscovite
(sp. gr. 2-85), quartz (sp. gr. 2-65), olivine (sp. gr. 2-64) and
orthoclase (sp. gr. 2-56) the crushed minerals will all float in
methylene iodide; on gradual dilution with benzene the less dense
powders may be precipitated in the order given above. Although simple in theory these
methods are tedious in practice, especially as it is common
for one rock-making mineral to enclose another. But expert
handling of suitable table rock powders in the different
purposes may be obtained by this means than by any other.

Although rocks are now studied principally in microscopic
sections the investigation of fine crushed rock powders,
which was the first branch of microscopic petrology to
receive attention, is by no means discontinued.

The modern optical methods are perfectly applicable to
transparent mineral fragments of any kind. Minerals are
always dissolved in the same way as in section, but it is
otherwise with rocks, as the structure or relations of the
components to one another, which is an element of great
importance in the study of the history and classification of rocks,
is almost completely destroyed by grinding them to powder.

In addition to naked-eye and microscopic investigations
chemical methods of research are of the greatest practical
utility to the petrographer. The crushed and separated
powders, obtained by the processes described above, may be
analysed and thus the chemical composition of the minerals
in the rock determined qualitatively or quantitatively. The
chemical testing of microscopic sections and minute
grains by the help of micropipettes is therefore a valuable
and valuable means of discriminating between the
mineral components of fine-grained rocks. Thus the
presence of apatite in rock-sections is established by covering
a bare rock-section with solution of ammonium molybdate;
a turbid yellow precipitate forms over the crystals of the mineral
in question (indicating the presence of phosphates). Many
silicates are insoluble in acids and cannot be tested in this way,
but others are partly dissolved, leaving a film of gelatinous
silica which can be stained with colouring matters such as the
anine dyes (nephrine, analicate, zeolites, &c.).

Complete chemical analyses of rocks are also widely made use of
and are of the fine examination of rocks, but for practical purposes a knowledge of the relative proportions
of silica, alumina, ferrous and ferric oxides, magnesia, lime, potash,
soda and water will carry us a long way in determining the position
of the rock in the series. It is to the determination of these
proportions that a chemical analysis is usually used in
whether the original mass was a sedimentary or of volcanic origin.
The specific gravity of rocks is determined in the usual way by
means of the balance and the pycnometer. It is greatest in those
rocks which contain the same substances, as metals; least in
rocks rich in alkalies, silica and water.

It diminishes with weathering, and generally those rocks
which are highly crystalline have higher specific gravities than those
which are wholly or partly vitreous when both have the same
chemical composition. The specific gravity of the commoner rocks
ranges from about 2-5 to 3-2.

The above methods of investigation, naked eye, physical,
microscopical, chemical, may be grouped together as analytical
in contradistinction to the synthetic investigation
of rocks, which proceeds by experimental work to
reproduce different rock types and in this way to
elucidate their origin and explain their structures.
Many cases no experiment is necessary. Every stage in the origin
of clay, sands and gravels can be seen in process around us,
but where these have been converted into coherent shales, sand-
stones and conglomerates, and still more where they have
experienced some degree of metamorphism, there are many
obscure points about their history upon which experiment may
yet throw light. Up to the present time these investigations
have been almost entirely confined to the attempt to reproduce
igneous rocks by fusion of mixtures of crushed minerals or of
chemicals in specially contrived furnaces. The earliest researches
of this sort are of those of Faujas St Fond and of de Saussure,
but Sir James Hall really laid the foundations of this branch
of petrology. He showed (1798) that the whinstones (dialysis)
of Edinburgh were fusible and if rapidly cooled yielded black
vitreous masses closely resembling natural pitchstones and
obsidians; if cooled more slowly they consolidated as crystalline
rocks not unlike the whinstones themselves and containing
olivine, augite and felspar (the essential minerals of these rocks).
Many years later Daubrée, Delcasse and others carried on similar
experiments, but the first notable advance was made in 1878,
when Fouqué and Lévy began their researches.

They succeeded in producing such rocks as porphyrite, leucite-
phryite, basalt and dolerite, and obtained also various structural
modifications well known in igneous rocks, e.g. the porphyritic
and the doleritic rocks, G., &c., and it was shown that while
many basic rocks (basalts, G., &c.) could be perfectly imitated in
the laboratory, the acid rocks could not, and advanced the explana-
tion that for the crystallization of the latter the gases never absent
in nature, act as indispensable mineralizing agents.

The most notably proved that steam, or such volatile
substances as certain borates, molybdates, chlorides, fluorides, assist
in the formation of orthoclase, quartz and mica (the mineral of
granite). Sir James Hall also made the first contribution to
the experimental study of metamorphic rocks by converting chalk
The rock consists of alternate bands of brown and colourless glass which have been arranged in stripes by the fluxion movement of the viscous mass before solidification. The glass is rendered granular by very minute crystals.

In the centre are crystals of felspar, rather turbid through weathering. The matrix is partly glassy, partly felsitic, and shows the effects of streaming movements with eddies behind the felspar crystals.

This rock has a damascened pattern owing to the irregular mingling of streams of brown and of colourless glass. It is nearly quite free from minute crystals.

The clear glassy base there are rounded yellow spots (spherulites) arranged in fluxion streams.

The round spherulites of this rock are large and sometimes composite; their radiate structure is obvious. This is a devitrified pitchstone, no longer glassy but finely crystalline, and at the centres of the spherulites there are spaces occupied by a secondary deposit of quartz. The ground-mass is partly glassy, partly felsitic, and shows fluxion-banding. The large quartz is a double hexagonal pyramid, but its edges and corners are rounded by corrosion and large irregular areas of glass penetrate to its centre.
A large porphyritic felspar crystal is seen lying in a pale-brown glassy base and containing many glass inclusions of irregular shape. The felspar, in one margin especially, shows corroded outlines.

There are larger porphyritic felspars of the first generation, and smaller ones of later origin composing part of the ground-mass, which also contains a considerable amount of yellow vitreous material.

This rock consists of angular patches of clear quartz scattered through a striated dull matrix of felspar. The different quartz areas have all the same optical orientation, as if they were parts of a single crystal.
into marl by beating it in a closed gun-barrel, which prevented the escape of the gases. At high temperatures, Adams and Nicholson have carried this a stage farther by subjecting marble to great pressure in hydraulic presses and have shown how the foliated structures, frequent in natural marbles, may be produced artificially.

**Rock Classification.**—The three great classes of rocks above enumerated—the igneous, the sedimentary and the metamorphic—are subdivided into many groups which to a small extent resemble the genera and species under which the naturalist classifies the members of the animal kingdom. There are, however, no hard and fast boundaries between allied rocks. By increase or diminution in the proportions of their constituent minerals they pass by every gradation into one another; the distinctive attitudes of one kind of rock may gradually merge into those of another. Hence the definitions adopted in establishing rock nomenclature merely correspond to selected points (more or less arbitrary) in a continuously graduated series. This is frequently urged as a reason for reducing rock classification to its simplest possible terms, and using only a few generalized rock designations. But it is clear that many apparently trivial differences tend regularly to recur, and have a real significance, and so long as any variation can be shown to be of this nature it deserves recognition.

The **Igneous rocks** (crystalline and fragmental) form a well-defined group, differing from all other rocks in that crystals of different varieties may occur in two different ways; the lavas have been poured out at the surface and have consolidated after eruption, under conditions which are fairly well understood; the dikes and sills, and other intrusive rocks, have been injected into the rocks of the earth, in many parts of the world; the intrusive rocks, on the other hand, have been injected from below into cracks and fissures in the strata and have cooled there beneath masses which conceal them from view till exposed by denudation or other agency. The intrusive rocks, in contact with the air, are mostly finely crystalline rocks in which the crystals are of such a size that they can be seen with the naked eye. The fine-grained varieties of igneous rocks have been described as semi-crystalline in which the crystals are only partially developed and in which the aggregate mass may be transparent and not noticeably different from the original glassy or ignebrite. The fine-grained rocks, which are more abundant, have been termed microcrystalline or cryptocrystalline. They may be subdivided into three classes according to the degree of development of the crystals:

1. **Lavas or Effusive Types.**—These lavas are formed at a surface of the earth and contain large crystals (phenocrysts) which when they are cooled sufficiently will form minerals; the mass is then cooled under water, and in these circumstances the crystals are grown upon each other and are more interdependent. The lavas pass into the liquid state, but it is expected, if the magma is held at the liquid state for a long time, that it will cool at the surface. If it is not exposed to the air, it will be cooled by conduction from the ground beneath it. The cooling of the lava is affected by the rate at which it is cooled, which may be very slow or very rapid, depending on the thickness of the strata. The cooling of the lava is affected by the temperature of the air, which may be very high or very low, depending on the season of the year. The cooling of the lava is affected by the amount of water present, which may be very large or very small, depending on the climate. The cooling of the lava is affected by the presence of other materials, which may be very large or very small, depending on the other rocks present. The cooling of the lava is affected by the presence of gases, which may be very large or very small, depending on the other rocks present. The cooling of the lava is affected by the presence of other minerals, which may be very large or very small, depending on the other rocks present. The cooling of the lava is affected by the presence of other substances, which may be very large or very small, depending on the other rocks present. The cooling of the lava is affected by the presence of other rocks, which may be very large or very small, depending on the other rocks present.
The commoner rock constituents are nearly all oxides; chlorine, sulphur and carbon are the only exceptions, excepting in the case of volcanic ashes. In most of their total amount in any rock is usually much less than 1%.

F.W. Clarke has calculated that a little more than 47% of the earth's crust consists of oxygen. It occurs predominantly combined as silicates, of which the chief are silica, alumina, iron oxides, lime, magnesium, potash and soda. The silica functions principally as an acid, forming silicates, and all the commonest minerals of igneous rocks are of this nature. From a chemical and physical standpoint the chief minerals are felspars, presented. pyroxene, biotite or hornblende, which are present in various percentages. These minerals are accompanied by lesser amounts of other silicates, such as micas, amphiboles, feldspars, pyroxenes, and olivines. The character of the igneous rocks is determined by the percentage of these minerals which are present.

The felspars present in the igneous rocks are the orthose, microcline, albite, and the potassic, labradorite, andesine. The orthose and microcline are the commonest felspars; they are often found in combination with each other and with other minerals. The orthose is usually present in much smaller amounts than the microcline.

The pyroxenes, biotite and hornblende, are the principal ferromagnesian minerals present in the igneous rocks. The pyroxenes are found in the form of euhedral crystals, and are often associated with the felspars. The biotite and hornblende are usually present in smaller amounts, but they are important in determining the character of the rocks.

The silica is present in the form of quartz, which is the most common mineral in the igneous rocks. It is usually present in large amounts, and is often found in combination with other minerals.

The alumina is present in the form of felspars, particularly orthose, microcline, and labradorite. It is also present in small amounts in other minerals, such as biotite and hornblende.

The iron oxides are present in the form of magnetite and haematite. They are usually present in small amounts, but they are important in determining the character of the rocks.

The lime is present in the form of calcite. It is usually present in small amounts, but it is important in determining the character of the rocks.

The magnesia is present in the form of olivines. It is usually present in small amounts, but it is important in determining the character of the rocks.

The sodium is present in the form of felspars, particularly orthose, microcline, and labradorite. It is also present in small amounts in other minerals, such as biotite and hornblende.

The potassium is present in the form of felspars, particularly orthose, microcline, and labradorite. It is also present in small amounts in other minerals, such as biotite and hornblende.

The chlorine and sulphur are present in the form of halites and other salts. They are usually present in small amounts, but they are important in determining the character of the rocks.

The carbon is present in the form of graphite and other forms of carbon. It is usually present in small amounts, but it is important in determining the character of the rocks.

The rocks containing felspars and felspathoid minerals are called acid rocks, and those containing pyroxenes, biotite or hornblende are called basic rocks. The rocks containing both felspars and pyroxenes, biotite or hornblende are called intermediate rocks. The rocks containing felspars and pyroxenes, biotite or hornblende, and also magnesium, iron, and silica, are called ultrabasic rocks.

to be unique, turn up with identical features in widely scattered regions, and this, for example, occurs in Norway, Scotland, Montreal, British Columbia, the Urals, the Tatra Mountains, Norway, Brazil, Montana, Portugal, &c. This indicates that underlying all the variations in mineralogical, structural and chemical properties there are definite relationships which tend to repeat themselves, producing the same types whenever the same conditions are present.

Although in former years the view was widely current, especially in Germany, that rocks belonging to different geological epochs should receive different names, it is now admitted on all sides that this cannot be upheld.

In 1902 a group of American petrographers brought forward a new proposal abolishing all existing classifications of rocks and to substitute for them a "quantitative" classification based on chemical analysis. They showed how vague and often unscientific was much of the existing terminology and argued that the rock should be judged by the order of magnitude of the quantities of its mineral constituents and that a mineral characteristic it should be elevated to prime position. Geological occurrence, structure, mineralogical constitution, the lithic, accepted criteria for the determination of rock species were thus relegated. Moreover, the latest work of mineralogists is to find groups distinctly according to the relative proportions of these minerals to one another. There is no need here to describe the many modifications of rock types which have been very clearly in their treatise (Quantitative Classification of Igneous Rocks, Chicago, 1902), and there is no indication that even in the United States it will ever displace the older classifications.

A large number of different rocks belong to one period and a restricted area certain features which distinguish them as a whole more or less completely from other similar assemblages. Such groups are often said to be consanguineous, and to characterize a definite "petrological province." Excellent examples of this are furnished by the Devonian igneous rocks of southern Norway as described by Brøgger, the Tertiary rocks of the Hebrides (Harker), the Italian lavas of Sicily, the Neogene lavas of the Azores. Rocks of this type girdle the Pacific (Andes, Cordillera, Japan, &c.), and those which occur on the volcanic islands of the Atlantic, show the same phenomena. Each of these groups has been presumably formed in a region embracing large portions of the surface of the earth where the magmas have been extruded, a period which while necessarily prolonged was not of vast duration in a geological sense.

On the other hand, each of the great suites of eruptive rocks which constitute such a petrological province embraces a great range of types. Prolonged eruptions have in a few cases a somewhat monotonous character, owing to the persistent appearance of the same kind of magmas, and to the fact that the Hawaiian Islands are mostly basaltic, as are those of Oregon, Washington and the Deccan, all of which form geological masses of enormous magnitude. But it is more usual to find basaltic, andesitic, trachytic, dacitic, and finally rhyolitic, and this succession was repeated a second time. Yet at all times they all must have come from the same focus, or at any rate from a group of foci very closely connected with one another, and we have good reasons to believe that the earlier lavas are of intermediate character and that basic lava and rhyolite alternate during the later stages of the volcanic history.

There are also those cases in which the one type of rock has in consolidation yielded a variety of petrological types often widely divergent. This is best shown by great plutonic bodies which may be regarded as having once been vast subterranean spaces of molten or semi-molten material with a nearly homogeneous liquid magma. Cooling took place gradually from the outer surfaces where the igneous rock was in contact with the surrounding strata. The resultant laccolite (Gr. λακτός, pit, crater, λάκτος, stone), stock or mass, may be so named. In the greater thicknesses of these laccolites, occasionally, the edges being highly acid while the central parts consist of more basic rocks. Sometimes the latter phases penetrate into and vein the earlier; evidently there has been some movement due to temporary increase of pressure when part of the laccolite was solid and part still in a liquid state. This links these phenomena with those above described where successive emissions of different character have proceeded outwards from the focus.

According to modern views two explanations of these facts are possible. Some geologists hold that the different rock facies are the result of differentiation during cooling of the molten magma (\textit{"assimilation"}). Effects of this kind are to be expected, and have been clearly proved in many places. There is, however, a general reluctance to admit that they represent the only or the most important process. Other species do not as a rule show any relation to the sedimentary or other materials which may be supposed to have been dissolved; and with solution known to have gone on the products are of abnormal character and easily distinguishable from the common rock types.

Hence it is generally supposed that differentiation is to be accounted for as a result of the cooling of the magma, splitting up of a magma into dissimilar portions, each of which consolidates as a distinct kind of rock. Two factors can be selected as probably most potent. One important factor is cooling and the other, especially when the magma is somewhat acid, is that least soluble substances will tend to diffuse towards the cooling surfaces (Ludwig—Soret's principle). This is in accordance with the majority of the observed facts and is probably a vera causa of part of the magma that has not crystallized to be a solution of mineral rocks.

A rock solidifies the minerals which crystallize follow one another in a more or less well-defined order, the most basic (according to Rosenbusch's law) being first to separate out. This in a general way is the sequence in which most other minerals have been ascribed to. It also early basic minerals suggests that the sequence of crystallization helps largely in determining the succession (and consequently the time) in which other minerals are precipitated. Gravity also may play a part, for it is proved that in a solution at rest the least soluble components will be concentrated towards the base. This must, however, be of secondary importance as in laccolites the top portions appear to be more basic than the lower parts, and concentric lakcolites are formed, bearing the same characteristic in the centres. This has also been argued that the earliest minerals being heaviest and in any case denser than the fused magma around them, will sink to their own weight and be congregated near the bottom of the mass. Electric currents, magnetic attraction and convection currents have also been called in to account for the phenomena observed. Magmas have also been compared to liquids which, when they cool, split up into portions no longer completely soluble in each other, and it has been pointed out that these magmas may dissolve a portion of the others and as the temperature falls and the conditions change a range of liquids differing in composition may be supposed to arise.

All igneous magmas contain dissolved gases (steam, carbonic acid, sulphuric hydrogen, chlorine, fluorine, boracic acid, &c.). Of these water is the principal, and was formerly believed to have percolated downwards from the earth's surface to the heated rocks below, but is now generally admitted to be an integral part of the magma. Many peculiarities of the structure of the plutonic rocks as contrasted with the lavas may reasonably be accounted for by the general presence and the severity of the physical conditions. These gases often do not enter into the composition of the rock. Their escape is often observed, as for instance in the case of gaseous acid, &c. Hence as crystallization goes on the residual liquid must contain an ever-increasing proportion of volatile constituents. It is conceivable that in the final stages the still uncrystallized part of the magma has not necessarily to be a solution of mineral matter in superheated steam than to a dry igneous fusion. Quartz, for example, is the last mineral to form in a granite. It bears much of the stamp of the quartz which we know has been deposited in its solution in veins. It is at the same time the most insubflusible of all the common minerals of rocks. Its late formation shows that in this case it arose at comparably low temperatures and points clearly to the special importance of the gases of the magma in determining the crystallization of the mineral body.

When solidification is nearly complete the gases can no longer be retained in the rock and make their escape through fissures and veins, and the air and saprolite and the surfaces of the minerals of the rocks which they traverse, and instances of their operation are found in the kaolinization of granites, tourmalinization and formation of greisen, deposit of quartz veins, stanniferous and other mineralization, and the loss of those gases as known as propylitization. These "pneumatolitic" (Gr. πνευμα, spirit, vapour, λάυς, to loose, dissolve) processes are of the first importance in the genesis of many ore deposits. They are a real marking which leads to the formation of a new rock, and constitute the terminal phases of the volcanic sequence.

The complicated succession from basic (or ultrabasic) to acid types exemplified in the history of many magmas is reflected with 1 The term "propylitization" (Gr. πρωπολωσις, a gateway) was given by Richthofen to a volcanic rock which is supposed to have marked a new epoch in volcanic geology (see ANDESITE).
astonishing completeness in the history of individual products. In each class of rock crystallization follows a definite course. The first minerals to separate belong to a group known as plagioclases, augite, hornblende, biotite, micas, etc., as they contain much less silicate lattice material than the other minerals that follow. Many exceptions to this rule are known; the same mineral may crystallize at two different periods; two or more minerals may crystallize simultaneously or the stages in which they form may overlap, although this is less common than it may appear at first sight.

Sequence of Crystallization. In the arrangements of the various materials in the rocks, the various minerals that were present in the magma are laid down in a certain order, and the crystallization of the rock is said to be a function of the composition of the magma. This order is determined by the temperature and pressure of the magma, and the minerals that crystallize are those that can be precipitated from the magma at the highest temperature. The minerals that crystallize first are those that are most stable in the magma, and those that crystallize last are those that are most unstable. The order of crystallization is determined by the solubility of the minerals in the magma, and the minerals that are most soluble in the magma are those that crystallize first.

Poliklit. Many minerals in the early stages of crystallization are known as phenocrystals, and they are often the most abundant minerals in the rock. These minerals can be seen in thin-sections, and they are often the most abundant minerals in the rock. The minerals that are most abundant in the rock are those that are most stable in the magma, and they are the first minerals to crystallize. The minerals that are most unstable in the magma are those that crystallize last. The order of crystallization is determined by the solubility of the minerals in the magma, and the minerals that are most soluble in the magma are those that crystallize first. The minerals that are most insoluble in the magma are those that crystallize last.

Growth of Crystals. The growth of crystals is a function of the composition of the magma. The minerals that crystallize first are those that can be precipitated from the magma at the highest temperature. The minerals that crystallize last are those that can be precipitated from the magma at the lowest temperature. The order of crystallization is determined by the solubility of the minerals in the magma, and the minerals that are most soluble in the magma are those that crystallize first. The minerals that are most insoluble in the magma are those that crystallize last.

Physical Chemistry of Igneous Rocks. The physical chemistry of igneous rocks is a function of the temperature and pressure of the magma. The temperature of the magma is determined by the heat of fusion of the minerals that crystallize from the magma. The pressure of the magma is determined by the depth of the magma. The depth of the magma is determined by the temperature of the magma, and the temperature of the magma is determined by the depth of the magma. The temperature of the magma is determined by the heat of fusion of the minerals that crystallize from the magma. The pressure of the magma is determined by the depth of the magma. The depth of the magma is determined by the temperature of the magma, and the temperature of the magma is determined by the depth of the magma.

Solutions as Components of Minerals. The solutions as components of minerals are a function of the temperature and pressure of the magma. The temperature of the magma is determined by the heat of fusion of the minerals that crystallize from the magma. The pressure of the magma is determined by the depth of the magma. The depth of the magma is determined by the temperature of the magma, and the temperature of the magma is determined by the depth of the magma. The temperature of the magma is determined by the heat of fusion of the minerals that crystallize from the magma. The pressure of the magma is determined by the depth of the magma. The depth of the magma is determined by the temperature of the magma, and the temperature of the magma is determined by the depth of the magma.
the processes involved in the formation of igneous rocks cannot be successfully handled. But every day sees an increase in the amount of data available, and encourages us to believe that sooner or later some of the simpler igneous rocks at any rate will be completely explained.

Rock masses of igneous origin have no sooner consolidated than they begin to change. The gases with which the magma is charged are slowly dissipated, lava-flows often remain hot and may change for many years. These gases attack the components of the rock and deposit new minerals in cavities and fissures. The beautiful zeolites, so well known to collectors of minerals, are largely of this origin. Even before these "post-volcanic" processes have ceased atmospheric decomposition begins. Rain, frost, carbonic acid, oxygen and other agents operate continuously, and do not cease till the whole mass has crumbled down and most of its ingredients have been resolved into new products. The whole process is called allochthonous, but the changes are generally considered unessential; rocks are classified and described as if they were ideally fresh, though this is rarely the case in nature.

Epigenetic change (secondary processes) may be arranged under a number of headings, each of which is typical of a group of rocks or rock-forming minerals, though usually more of these alterations will be found in progress in the same rock. Silicification, the replacement of the minerals by crystalline or cryptocrystalline silica, is most common in acid rocks, such as rhyolite, and is also found in serpentine, &c. Kaolinitization, the transformation of the mica minerals of igneous rocks, into kaolin (along with quartz, muscovite, &c.); it is best shown by granites and syenites. Serpentinitization is the alteration of olivine to serpentine (with magnetite); it is typical of the rocks of volcanic origin in the middle latitudes. Chloritization secondary hornblende replaces augite; this occurs very generally in diabases; chloritization is the alteration of augite (biotite or hornblende) to chlorite, and is seen in many diabases, basaltic lavas, and gabbros. Epidotization occurs also in rocks of this group, and consists in the development of epidote from biotite hornblende, augite or plagioclase felspar.

The sedimentary rocks, which constitute the second great group, have many points in common that distinguish them from the igneous and the metamorphic. They have all originated on the surface of the earth, and at the period of their formation were exposed only to the temperature of the air and to atmospheric pressure (or the pressures which exist at the bottoms of seas and lakes). The minerals in most cases are susceptible to change when exposed to moist air or sea, and many of them are hydrated (chlorite, micas, &c.), or oxidized (iron ores), or contain carbonic acid (calcite, dolomite). The extent, however, to which this is the case depends largely on the rapidity with which they have accumulated; coarse rocks quickly piled up often consist of materials only partly weathered. When crystalline, the sedimentary rocks are usually soluble at low temperatures. The members of this group occur in beds or strata, hence they are often known as the stratified rocks; the upper beds are always of later formation than those which underlie them, except (as may happen when great disturbance has taken place) the whole series is inverted or overturned. Many of the to form these beds have been formed by the moving water (rivers, currents, &c.) and are grouped together as "aqueous" rocks; others have been deposited by the wind in deserts, on sandy beaches, &c. (these are "aeolian" rocks). Others are the remains of animals or of plants, modified by the action of time, pressure and percolating water. Lastly, we find beds of crystalline nature, such as rock-salt and gypsum, which have been formed by the precipitation of saline waters; other crystalline stratified rocks, such as dolomite and many bedded iron-stones, are replacement products due to the introduction of mineral matter in solution, which replaced the original rock mass partially or wholly.

When the rocks exposed at the earth's surface give way before the attack of the agencies of denudation, they crumble down and are carried away. One part (the pebbles and coarse conglomerates, sand, &c.) is acted upon by the water, which may or may not contain organic matter; the other (the clay and bands or clays) is carried away by the running water, and is deposited in various forms; in this latter portion the rocks of organic origin are built up. These may also contain certain ingredients derived from the atmosphere (oxygen, carbon in coals, &c.).

We have thus three types of sediments of distinct origin, which may be named the clastic (or fragmental), the crystalline and the organic.

The clastic materials may accumulate in situ, and then differ chiefly in their disintegrated and weathered state from the parent rock masses on which they rest. The best example of this is the detritus of the cliffs and beaches; this rock often covers large areas. More usually they are transported by wind or water, and become sorted out according to their size and density. The coarsest débris comes first to rest and is least easily transported; the finer materials, such as sand and silt, and consolidates as conglomerates, breccias and pebbly grits. The bedding of these rocks is rudimentary and imperfect, and as each bed is traced along its outcrop it frequently changes its character and is added to in various ways. In this way flats are built up, and the weathering process continues. Thus the material is changed by the action of weathering, and its shape to the size of small and flat objects is the tendency to remain suspended in water for a very long time. Chlorite, white micas and kaolins are the best examples of this class of substances. Wind action is even more effective than water in separating and removing these fine particles. They to a very large extent the material may be derived from the weathering of rocks both on land and sea; some are derived from the disintegration of coarse minerals in deep earthy cavities, and some from the weathering of the sea-floor.

The mechanical sorting of the transporting agencies is usually somewhat incomplete, and mixed types of sediment result, such as gravels containing sand, or clays with coarse arenaceous particles. Moreover, successive layers of deposit may not always be entirely similar, so that alternation of the types may occur, and another in thin laminae e.g. laminae of arenaceous material in beds of clay and shale. Organic matter is frequently mingled with the fine-grained sediments.

Three types have been named the psammithe (or pebbly; Gr. /psóphos, pebble/); psammitic (or sandy; Gr. /ϕύσως, sand/), and pelitic (or muddy: Gr. /πέλας, mud/).

two groups of clastic sediments deserve special treatment. The pyroclastic (Gr. /φυράκη, fire/) and /αγκάθους, broken/ rocks of volcanic origin, consist mostly of broken pieces of lava (bombs, ash, &c.) (Pl. IV, fig. 2), and only accidentally contain other rocks or fossils. These pyroclastics are generally well rounded and roughly inclosed, and are usually less perfectly sorted out, according to their fineness, than the other are known as the conglomerates. These sands and gravels are usually derived from the strata in which they are found, but these strata have been eroded away. They are usually stratified, and are frequently composed of sandstone or siltstone, and are often rich in organic fossils. Many of these sands and gravels are likely to be found in marine or brackish water, and are often in the form of bars or shoals, and are often interbedded with the rocks of the ocean floor. They may be divided into two classes, according to their organic content, into calcareous,
PETROLOGY

carbonate, siliceous, ferruginous, and so on. The calcareous ones are derived principally from corals, brachiopods, molluscs, and bryozoans.

Some kinds of these rocks have a metamorphic origin, and it is often difficult to distinguish the two classes of metamorphic rocks. It is a glauconite sand that have been deposited in the absence of water, and that have subsequently been metamorphosed.

Thermal metamorphism is the term applied to those processes that occur below the surface of the earth, and that are accompanied by a change in the mineral assemblage of the rocks. The most common example of such a process is the formation of metamorphic rocks from sedimentary rocks by the process of recrystallization. This process is characterized by the breakdown of the original minerals, and the formation of new minerals that are stable at the higher temperatures and pressures encountered in the subsurface environment.

Cenomanian. The Cenomanian epoch is a unit of the Cretaceous period, characterized by the deposition of a large amount of limestone, which was later metamorphosed to form marble. The metamorphic rocks of the Cenomanian are characterized by the presence of calcite, dolomite, and quartz, which are derived from the breakdown of the original limestone.

The Cenomanian rocks are commonly used as building materials, and are also a source of natural gas. The marble formed during the Cenomanian is often used as a decorative material, and is prized for its beauty and durability.

Sandstones and limestones are both metamorphic rocks, and are formed by the recrystallization of sediments. Sandstones are formed from the breakdown of grains of sand, while limestones are formed from the breakdown of the shells of marine organisms. The metamorphic rocks formed during the Cenomanian are characterized by the presence of calcite, dolomite, and quartz, which are derived from the breakdown of the original sedimentary rocks.

The Cenomanian rocks are commonly used as building materials, and are also a source of natural gas. The marble formed during the Cenomanian is often used as a decorative material, and is prized for its beauty and durability.
PETROLOGY

FIG. 1.—PHONOLITE, TEPLITZER SCHLOSSBERG, BOHEMIA (x 12).
The large white crystal is felspar, the smaller ones are nepheline having six-sided and four-sided sections. The dark mineral in the ground-mass is aegirine.

FIG. 2.—LEUCITOPHYRE, RIEDEHN, EIFFEL, GERMANY (x 15).
A porphyritic clear crystal of leucite lies near the centre of the field; towards the margins are nosean crystals with clear centres and broad black edges. The black spots are aegirine and aegirine-augite, and in the ground-mass small prisms of white nepheline may be seen.

FIG. 3.—LEUCITE-BASANITE, VESUVIUS (x 8).
The rounded central crystal is leucite, showing zones of inclusions and well-marked cracks; below it is a dark-brown augite, and olivine occurs near the bottom of the field. There are numerous rectangular white sections of plagioclase felspar. The dark ground-mass is partly vitreous.

FIG. 4.—HYPERSTHENE-ANDESITE, ALWYN, CHEVIOTS, ENGLAND (x 10).
A porphyritic rock with phenocrysts of white plagioclase felspar and of pale-brown augite and hypersthene in a fine ground-mass, partly glassy.

FIG. 5.—OLIVINE-BASALT, CRAIGLOCKHART, EDINBURGH, SCOTLAND (x 10).
Two large crystals of augite above and below, and of olivine (right and left) lie in a crystalline ground-mass of plagioclase felspar, augite, and magnetite. The olivine has been altered to fibrous green serpentine, and the pseudomorphs show traces of the original cleavage cracks.

FIG. 6.—OPHITIC OLIVINE-DOLERITE, DUN FION, ARRAN, SCOTLAND.
The white mineral is plagioclase felspar, which penetrates a large dark crystal of augite in ophitic manner. At the bottom of the field there are a few grains of olivine, colourless, but with strongly marked cracks.

FIG. 7.—OLIVINE-GABBRO, VOLPERSDORF, SILESIA (x 10).
Felspar occurs towards the edges of the field and surrounds a cluster of diallage (with strong, dark, parallel lamination) and of olivine (covered with a black network of secondary magnetite).

FIG. 8.—PERIDOTITE, ELBA (x 10).
The rounded crystals are olivine, weathering as usual to magnetite and serpentine along its cracks and borders. The dark interstitial substance is enstatite weathered to bastite.

FIG. 9.—SERPENTINE, COLMONELL, AYRSHIRE, SCOTLAND (x 12).
In this rock the process of serpentinisation, seen in the previous figure, is complete. No olivine remains, but a meshwork of magnetite indicates the position of the cracks in the original crystals. The cloudy, dark streak above the centre is bastite replacing primary enstatite.
The white pebbles are quartz with irregular cracks and streaks of fluid inclusions. The matrix is a dark, semi-opaque mixture of clay and small sand-grains.

A fragmental volcanic rock with small lapilli of basalt; these are vesicular and contain little felspar crystals. Broken felspars also lie scattered through the rock.

The oolitic grains are round or oval, with concentric zoning; in their interior there is sometimes a shell fragment or other nucleus. The interstitial matrix is clear, granular, crystalline calcite. The rock contains fragments of echinoderms, brachiopods, and other fossils.

This well-banded rock was once a crystalline gneiss which has been greatly crushed by earth-movements, and has been ground down into a fine aggregate of quartz, felspar, and mica. The banding is due to internal flow under great pressure.

A clay rock like the preceding one, but more metamorphic and coarsely crystalline. The clear spots are quartz and the bladed mineral between them is brown and white mica (biotite and muscovite).

A clay rock affected by contact metamorphism attended by the production of needles of chialolite, which have in transverse section a diamond-shape with dark enclosures at their centres and a dark cross radiating to their corners.
PETRONEL—PETRONIUŚ

will be visible. In gneisses these alternating folia are thicker and less regular than in schists; they are often lenticular, dying out rapidly. Gneisses also, as a rule, contain more felspar than schists do, and they are tougher and less fissile. Contortion or crumpling (Deflexion) is always present in gneiss, the splitting faces being at a different angle from the general bedding. The classification of the splitting faces is undulate or puckered. The origin of schistosity or foliation is not perfectly understood, but it is clear that in many cases it is due to pressure, acting in a direction perpendicular to the bedding, and causing a mechanical rearrangement of the mineral grains while they are crystallizing.

Rocks which were originally sedimentary and rocks which were undoubtedly igneous are converted into schists and gneisses, and if one inquires into the question whether there is anything characteristic about the sedimentary rocks which distinguishes them from one another if the metamorphism has been great. A quartz-porphyry, for example, and a fine felspathic sandstone, may yield a gneiss of a green or pink mica-schist. Usually, however, we may distinguish between the two classes. Syntectonic schists are more or less isotropic; schists and gneisses. Often the metamorphism is progressive, and if the whole district occupied by these rocks are searched traces of the metamorphism. The derivation of the mica-schists and gneisses may be obtained showing that we are dealing with a group of altered sediments.

In other cases intrusive junctions, chilled edges, contact alteration or porphyry-like structure may prove that in its original condition the rocks, however, are sometimes recrystallized. The appearance of the schists is often to the chemist, for there are certain rock types which occur only as sediments, whereas others are found only among igneous masses, and, however advanced the metamorphism may be, it rarely modifies the composition of the rocks from that which it possessed before the metamorphism. For example, the rocks, for example, as limestones, calc-schists, dolomites, quartzites and aluminous shales have very definite chemical characters which distinguish them even when completely recrystallized.

These quartzose units are classified as quartzites and the minerals they consist of, and this depends principally on their chemical composition. We have, for example, a group of metamorphic limestones and mica-schists. The group of mica-schists includes the dolomites; many of these contain silicates as mica, tremolite, diopside, scapolite, quartz and felspar. They are derived from calcareous sediments of different degrees of purity. Another group is rich in quartz (quartzites, quartz schists and quartzose gneisses), with variable amounts of white and black mica, garnet, felspar, zoisite and hornblende. These were once sandstones and arenaceous rocks. The graphic schists may readily be believed to represent sedimentary rocks, and, dealing with them, it is not surprising that they are also schistose ironstones (haematite-schists), but metamorphic beds of salt or gypsum are exceedingly uncommon. Among schists of igneous origin we may mention the milky calc-schists, the foliated syenites, gabbroic rocks, serpentine rocks, mica-schists, porphyroids and banded halleleliths, which have been derived from rhyolithes, quartz-porphyries and acid tuffs. The majority of mica-schists, however, are altered clays and shales. The least appeal is often to the chemist, for there are certain rock types which occur only as sediments, whereas others are found only among igneous masses, and, however advanced the metamorphism may be, it rarely modifies the composition of the rocks from that which it possessed before the metamorphism.

PETRONEL, a 16th or 17th century fire-arm, defined by R. Barret (Theorie et Practice of Modern Warres, 1598) as a "horsman's piece." It was the fire-arm which developed on the one hand into the pistol and on the other into the carbine. The name (Fr. petrelin for poiirinal) was given to the weapon either because it was fired with the butt resting against the chest (poiirin, Lat. pectus) or because it was carried slung from a belt across the chest.

PETRONIUŚ (G. ?) Petronius Arbiter), Roman writer of the Neronian age. His own work, the Satirae, tells us nothing directly of his fortunes, position, or even century. Some lines of Sidonius Apollinaris refer to him and are often taken to imply that he lived and wrote at Marseilles. If, however, we accept the identification of this author with the Petronius of Tacitus, Nero's courtier, we must suppose either that Marseilles was his birthplace or, as is more likely, that Sidonius refers to the novel itself and that its scene was partly laid at Marseilles. The chief personages of the story are evidently strangers in the towns of southern Italy where they find their ways. Their Greek-sounding names (Encolpius, Asclepios, Giton, &c.) and literary training appear in the character of Sidonius himself, a 1st century A.D. The high position among Latin writers ascribed by Sidonius to Petronius, and the mention of him beside Menander by Macrobius, when compared with the absolute silence of Quintilian, Juvenal and Martial, seem adverse to the opinion that the Satirae was a work of the age of Nero. But Quintilian was concerned with writers who could be turned to use in the

The principal authorities on the analysis and chemical composition of rocks are J. Roth, Beiträge zur Petrographie (Berlin, 1875-1884); A. Orange, Beiträge zur chemischen Petrographie (Stuttgart, 1902); H. S. Washington, Manual of the Chemical Analysis of Rocks (New York, 1904); and Chemical Analyces of Igneous Rocks (Washington, 1904); F. W. Clarke, Analyses of Rocks (Washington, 1904); Max Dittrich, Anleitung zur Gesteinsanalyse (Leipzig, 1905); W. F. Hiller, Handbuch der Petrography (Leipzig, 1907).

The principal French works are E. Jannet tas, Les Roches (3rd ed., Paris, 1900); F. Fouquè and A. Michel Lévy, Mineralogie micrographique (Paris, 1879); A. Michel Lévy and A. Lacroix, Les Minéraux des roches (Paris, 1888); A. Lacroix, Mineralogie de la France (I., II., Paris, 1893); and Les Encauvés des roches éruptives (Macon, 1893).

But the Satirae is not a novel, in the strict sense of the word. Petronius is not an interpreted by reason of the word of the age of Nero. But Quintilian was concerned with writers who could be turned to use in the

1 The MSS. of the Satirae give no praenomen. Tacitus's Petronius is Gaius, though the elder Pliny and Plutarch call him Titus. The name Arbiter, given by later writers, is not an ordinary cognomen, and may have been invented by contemporaries from the fact that Petronius was regarded as the criterion of good taste.
education of an orator. The silence of Juvenal and Martial may be accidental or it is possible that a work so abnormal in form and substance was more highly prized by later generations than by the author’s contemporaries.

A critic may be permitted to say that this book gives us an insight into the character and genius of its author with the elaborate picture of the courtier in Tacitus certainly suggests the identity of the two. Tacitus, it is true, mentions no important work as the composition of his C. Petronius; such a work as the Satyræ he may have regarded as beneath that dignity of history which he so proudly realized. The care he gives to Petronius’s portrait perhaps shows that the man enjoyed greater notoriety than was due merely to the part he played in history. “He spent his days in sleep, his nights in attending to his official duties or in amusement, by his dissolute life he had become as famous as other men by a life of energy, and he was regarded as no ordinary person.” But if such was his reputation, his reckless freedom of speech, being regarded as frankness, procured him popularity. Yet during his provincial governorship, and later when he held the office of consul, he had shown vigour and capacity for affairs. Afterwards returning to his life of vicious indulgence, he became one of the chosen circle of Nero’s intimates, and was looked upon as an absolute authority on questions of taste (arbiter elegantiae) in connexion with the science of luxurious living.”

Tacitus goes on to say that this excited the jealousy of Tigidillus, an accusation followed, and Petronius committed suicide in a way that was in keeping with his life and character. He selected the slow process of opening veins and in doing so bound up again, whilst he conversed on light and trifling topics with his friends. He then dined luxuriously, slept for some time, and, so far from adopting the common practice of flattering Nero or Tigidillus in his will, wrote and sent under seal to Nero a document which professed to give, with the names of his partners, a detailed account of the abominations which that emperor had practised.

A fact confirmatory of the general truth of this graphic portrait is added by the elder Phiny, who mentions that just before his death he destroyed a valuable murrine vase to prevent its falling into the imperial hands. Do the traits of this picture agree with that impression of himself which the author of the Satyræ has left upon us? That we possess therein part of the document sent to Nero is an impossible theory. Our fragments profess to be extracts from the fifteen and sixteenth books of the Satyræ. Petronius could not have composed one-tenth even of what we have in the time in which he is said to have composed his memorial to Nero. We may be sure that the latter was very frank in its language, and treated Nero with far greater severity than the Banquet treats Trimalchio. On the other hand, it is clear that the creator of Trimalchio, Encolpius and Giton had the experience, the inclinations and the literary gifts which would enable him to describe with forcible mockery the debaucheries of Nero. And the impression of his personality does in another respect correspond closely with the Petronius of the Annals—in the union of immoral sensuality with a rich vein of cynical humour and admirable taste.

The style of the work, where it does not purposely reproduce the solecisms and colloquialisms of the vulgar rich, is of the purest Latin of the Silver age. Nor would there be any point in the verses on the capture of Troy and the Civil War at any

1 Ann. xvi. 18.
2 The false taste in literature and expression fostered by the declamationes is condemned by both Persius and Petronius on the same grounds. Cf. too Pers. i. 121, hoc ego apertum, hoc ridere meum, tam mi, nulii tibi uende iibade mit Sat. 52, meum intelligere nulla fuit; non me meum, sed illum meum; qvam, how to express this, praeclare, qvam o sub rastro crept argenti misi seriad Sat. 88, Alius donum promittit, si proximam divum exclamier, alius si thesaurum esserit, et alius si thesaurum esserit et 42, homo animam exhiliat, Pers. iv. 26, orat . . . quantum non meum; with Sat. 37, fandos habet qui me miserebant. Both use the rare word baro. Animam exhiliare occurs in Seneca’s Apocolocyntosis, and the verbal resemblance illustrate perhaps rather the common use by both writers of the vulgar style. Cf. for resemblances to Trimalchio the imitations of Seneca and the date of the work in general, Studer, Rb. Mus. (1843).

other era than that in which Nero’s Troica and Lucan’s Pharsalia were fashionable poems. The reciting poet indeed is a feature of a later age also, as we learn from Martial and Juvenal. But we learn from the Satyræ that Petronius was the first to reproduce C. Tacitus’ portrait of the vulgar Ninius in the Banquet, and the first to reproduce his character in the mediocrity of prose and verse composition. But the string of fictitious narrative by which the medley is held together is something quite new in Roman literature. This careless prodigal was so happily inspired in his devices for amusing himself as to introduce to Rome and thereby transmit to modern times the novel based on the ordinary experience of contemporary life, the pre- and post-cures of such novelists as Gil Blas and Randolph. There is no evidence of the existence of a regular plot in the fragments, but we find one central figure, Encolpius, who professes to narrate his adventures and describe all that he saw and heard, whilst allowing various other personages to exhibit their peculiarities and express their opinions dramatically.

The fragment opens with the appearance of the hero, Encolpius, who seems to be an itinerant lecturer travelling with a companion named Ascylos and a boy Giton, in a portico of a Greek town, where he tells us his career up to the time he first made the acquaintance of Trimalchio, resulting from the prevailing system of education, is replied to by a rival declaimer, Agamenno, who shifts the blame from the teachers to the parents. The central personages of the story next go through a series of incidents which, in the original work, must have involved a charge of robbery. A day or two after they are present at a dinner given by a freedom of enormous wealth, Trimalchio, who entertained with ostentation and grotesque extravagance a number of his own rank but less prominent personages, invited the couple to the ordinary talk of the guests about their neighbours, about the weather, about the hard times, about the public games, about the entertainments, and about the value of their possessions. He at once proceeds to the same kind of vulgarity and pretension which the satirist of all times delights to expose in the litilertate and ostentatious millionaires of the age. Next day Encolpius separates from his companions and, alone, in a sort of study,3 the study where his master, named Circe, a priestess of Priapus, and a certain matron who leaves them her heirs, but attaches a condition to the inheritance which even Encolpius might have shrunk from fulfilling. He can suppose the author of this work to have been stimulated by any other motive than the desire to amuse himself, it might be that of conviving himself that the world in general was as bad as he was himself. Juvenal and Swift are justly regarded as among the very greatest of satirists, and their estimate of human nature is perhaps nearly as unfavourable as that of Petronius; but their attitude towards human degradation is not one of complacent amusement; their repugnance is the realization of disgust, not, like that of Petronius, an enthusiasm of sympathy. Martial does not glory over the vices of which he writes with cynical frankness. He is perfectly aware that they are vices, and that the reproach of them is the worst that can be cast on any one. And, further, Martial with all his faults, is, in his affections, his tastes, his relations to others, essentially human, friendly, generous, true. There is perhaps not a single sentence in Petronius which implies any knowledge of or sympathy with the incapacity of any Christian conscience or honour, or even the most elementary goodness of heart.

3 For the whole question of possible predecessors and Petronius’s relation to the extant Greek romances see W. Schmid, "Der griechische Roman in "Jahrbücher für das klass. Altertum, &c. (1904). One would certainly have expected the realistic tendency which in the New Comedy is the sole object of satirical dislike, not, like that of Petronius, an enthusiasm of sympathy, to have borne this fruit before the first century of our era.—(W. C. St.)

Omnis qui in testamento meo legat habent praepter libertos meos, nec conditionem quaestio meum in partes considerent et astante populio commoderit (141).
The work has reached us in so fragmentary and mutilated a shape that we may of course altogether have missed the key to it; it may have been written during a period of extraordinary excitement and made such a vein of reserved and powerful irony, of the type realized in our modern Jonathan Wild or Barry Lyndon. Otherwise we must admit that, in the entire divorce of intellectual power and insight from any element of real feeling, and Halloway’s work is an exceptional phenomenon in literature. For, as a work of original power, of humorous representation, of literary invention and art, the fragment deserves all the admiration which it has received. We recognize the arbiter elegans in the sense of the remarks scattered through it on education, on art, and poetry and on eloquence. There is a true feeling of nature in the description of a grove of plane-trees, cypresses and pines:

“Has inter ludebat aquis errantium annus Spumus et querulo vexabat rere lapillos.”

And some of the shorter pieces anticipate the terseness and elegance of Martal. The long fragment on the Civil War does not seem to have been written with much of poetry as if of entering into rivalry with the poem of Lucan. In the epigram extemporized by Trimalchio late on in the banquet:

Quod non expectes, ex transverso fit—

It suit non datur, neglo cortat;

Quare da nobis visa Falerna, puer?

we have probably a more deliberate parody of the style of verses produced by the illiterate aspirants to be in the fashion of the day. We might conjecture that the chief gift to which Petronius owed his fame as a writer of the De Rebus Caesaris was the bumptiousness of his style.

In Trimalchio and his various guests, to be in the old poet, in the cultivated, depraved and moody Encolpius, in the Chrysis, Quaesturilla, Polyaeusis, &c., we recognize in living examples the play of those various appetites and loves and hates which satisfy the spirit with abstract qualities. Another gift he possesses in a high degree, which must have availed him in society as well as in literature—the gift of story-telling; and some of the stories which first appear in the Sallust may have come from him, and have contributed to the renown of his name and to the reputation in later times. His style, too, is that of an excellent talker, who could have discussed questions of taste and literature with the most cultivated men of any time as well as amused and delighted society of any time in their most reckless revels. One phrase of his is often quoted by many who have never come upon it in its original context, “Horatii curiosa felicitas.”

And so in conclusion we may say that a large part of the Banquet of Trimalchio, with the other fragments of the work, was known. The best MS. of this type is a Leiden MS., a copy by Scaliger of one which seems to have belonged to Cujacius. Marinus Statilius see, however, Ellis, Journal of Philology, 12, p. 266) discovered at Tras dalmatia a MS. containing the whole Banquet, which was first published at Padua in 1664.

The important editions are (1) with the text of 1611 (Amsterdam, 1743, with Heinaius’s notes), and, of the Cena only, Friedlander (Leipzig, 2nd ed., 1906) and Lowe and Cambridge, 1904; (2) with critical notes: Buccheri (Berlin, 1882, 4th ed., 1904). Translations into German in Friedlander’s edition (1898), into French in the complete (1893) and in Caron’s Bibliotheca into English in Lowe’s edition (Cena only) and Bohn’s complete (complete). Lexicon to Petronius by Seghede and Lommatsch (Leipzig, 1898). Criticism of this edition has been written by Norden, Antike Kunstprosa (1. Leipzig, 1898); Secco, Leben und Politik der Empereor Nero (London, 1903); Dill, Roman Society from Nero to Marcus Aurelius (London, 1905); and the various histories of Roman literature (especially Schanz, §§ 505 seq.).

PETROPAVLOVSK, a town of West Siberia, in the government of Akмолin, on the right bank of the Ishim river, and on the great Siberian highway, 170 m. by rail W. of Omsk. The population, 78,500 in 1865, was 21,700 in 1900, of whom one-third were Mahomedan Kirghiz. The town carries on an active trade in cattle, furs, tea, wool, skins, cottons, woolen stuffs, corn, metals, metallic wares and spirits. The small fort of Petrovsk was founded in 1752, and was the military centre of the Ishim line of fortifications.

Petrovsk is also the name of a Russian seaport in Kamchatka, on the eastern shore of the Bay of Avacha, in 53° N. and 158° 44’ W., near the mouth of the Avacha, in the Bering Sea. It is completely used, and its naval institutions were transferred to Nikolayevsk after the attack of the Anglo-French fleet in 1854.

PETROPAVLOVSK—PETRUCCI

PETROPOLIS, a city of the state of Rio de Janeiro, Brazil, in an elevated valley of the Serra de Estrela, 2534 ft. above sea-level and 27 m. N. of the city of Rio de Janeiro, with which it is connected by a combined railway and steamship line, and also by a longer railway line. Pop. of the municipality (1900), 29,331, a large percentage being summer residents, as the census was taken late in December; (1902, municipal census), 18,372. Petropolis is served by the Principe do Géar Park railway, now a part of the Leopoldina system, which connects with Rio de Janeiro and Niteroy on the coast, and with the station of Entre Rios on the Central Brazil railway. Its altitude gives the city a cool invigorating climate, making it a favourite summer residence for the well-to-do classes of Rio. The rainfall is abundant, and especially so in summer (December to March) when the humidity is extreme. Vegetation is luxuriant and comprises a great variety of tropical and sub-tropical species. The city is built in a large, irregularly shaped basin formed by streams which confluence to form the Piabana river, a tributary of the Parahyba do Sul. Among the public buildings are the old imperial palace, a modern summer residence of the national executive and a municipal hall. Although Petropolis is not a commercial centre, its water-power and cool climate are making it an important manufacturing town. Among the products are cotton fabrics and garments, beer, and Camembert and Brie cheeses.

Petropolis was founded in 1845 by Julius Frederick Köler under the auspices of the emperor of Brazil, Dom Pedro II., on lands purchased by his father, Dom Pedro I., in 1822. The place was previously known as Corrego Seco, which Dr George Gardner described in 1837 as “a small, miserable village.” The first emperor planned to establish there a German colony, but the plan was not realized until 1845, when about 2700 colonists from Germany were located there. Its growth is slow, but the choice of the place by the emperor as a summer residence drew thither many of the wealthy residents of the capital. The Maia railway was opened to the foot of the serras (Raiz da Serra) in 1854, and the amalgamated road up to the town in 1856. The mountain section of the railway, on the Riggenbach (1900), was completed in 1883. Petropolis has since become the summer residence of the diplomatic corps and of the higher officials of the Federal government, and was the capital of the state of Rio de Janeiro from 1893 to 1903.

PETROVSK, a seaport of Russia in Transcassania, on the Caspian Sea, in the province of Daghastan, 180 m. by rail E. of Vladikavkaz, and 235 m. N.W. from Baku. Pop. 9806. The town has become the port of embarkation for Krasnovodsk, the Transcaspian territory, and the Central Asian khantae. There are naphtha wells; and the hot sulphur baths at Ak'gol and Talga, close by, attract many visitors in summer.

PETROVSK, a town of eastern Russia, in the government of Saratow, 125 m. N. by rail from the Don, 60 m. N.W. of the town of Saratow. Pop. (1866), 10,128; (1897), 13,212. It was founded by Peter the Great in 1698 as a defence against the Kuban Tatars. Its industrial establishments include distilleries, tanneries, tallow and brickworks.

PETOZAVODSK, a town and episcopal see of Russia, capital of the government of Olenots, on the west shore of Lake Onega, 190 m. N.E. of St Petersburg. Pop. (1865), 11,027; (1897), 12,521. Two cathedrals, built towards the end of the 18th century, a mining school, an ecclesiastical seminary and a government cannon-foundry are the chief public buildings and institutions. Peter the Great founded ironworks here in 1795, but they continued in operation only twenty-four years. The cannon-foundry was instituted in 1774. Petozavodsk became the capital of the government of Olenots in 1802.

PETRUCCI, PANDOLFO (d. 1542), tyrant of Siena, spent the greater part of his youth in exile, on account of the civil strife by which his native town of Siena was torn; but on the triumph of the party of the Noveschi (those who supported the Council of Nine) in 1487 he was able to return home. On the death of his brother Giacopo, one of the most powerful men in the city, Pandolfo succeeded to all the latter's offices and emoluments (1497), thus becoming in fact if not in name master of Siena. By his marriage with Aurelia, daughter of Nicola Borghese, another very influential citizen, he still further strengthened his authority. But he soon began to abuse his power by selling public offices to
PETRUS AUREOLUS—PETTY

the highest hiders, or conferring them on his followers. A plot was made to murder him, but he discovered the conspiracy in time, and his own father-in-law, who had been leader of the movement, was put to death. In 1498 he prevented the outbreak of war with Florence over the possession of Montepulciano, which had been a bone of contention between the two cities for over a hundred years. His attitude towards Cesare Borgia was exceedingly astute; at first he assisted him, and obtained from him with the favour of the French king the cession of Fiumambre; but having subsequently aroused the suspicions of Borgia, the latter attempted to suppress Petrucci by inviting him to the fatal meeting of Senigallia. The Sieneese tyrant, however, did not fall into the trap, and although Borgia in 1502 obliged him to quit Siena, he returned two months later, more powerful than before. Petrucci supported Pisa in the war against Florence, but eventually, through the intervention of the pope and of the king of Spain, he made peace with the latter city, to which he gave back Montepulciano in 1512. As a reward for this action Pope Julius II. created his nephew cardinal. During his last days Petrucci abdicated his authority in favour of his son Borghese. He died at San Quirico di Ossena on the 21st of May 1512.

See Pecell, Memorie storico-critiche di Siena (Siena, 1755); U. G. Merryon, F. Petrucci signore di Siena (Siena, 1899).

PETRUS AUREOLUS (Oxot), scholastic philosopher and monk of the Franciscan order, lived in the latter half of the 13th century, and died in Paris in 1321 just after his appointment as archbishop of Aix. He was one of the first to attack the realist doctrines of Duns Scotus, and is interesting mainly as the precursor of William of Occam in his revival of Nominalism. His ability earned for him the titles of Doctor Facundus and Doctor Abundans.

PETTENKOFEN, AUGUST VON (1821–1889), Austrian painter, born in Vienna, was brought up on his father's estate in Galicia. Having decided to give up the military career on which he had started, he devoted himself to painting. For taking for his subjects the simple scenes of the life on the dreary Puszta. His paintings are treasured for their fine qualities of colour, and for the sincerity with which the artist sets before us the uneventful melancholy life of Hungarian peasants and gipsies—without any theatrical pathos or forced humour. He was the inventor of the Pettenkofen box, an appliance for dissolving and redistributing cracked or discoloured varnish without friction or the dangerous use of chemicals. He died in Vienna in 1889.

PETTENKOFER, MAX JOSEPH VON (1818–1901), Bavarian chemist and hygienist, was born on the 3rd of December 1818 at Lichtenhein, near Neuburg. He was a nephew of Franz Xavier Pettenkofen (1783–1850), who from 1823 was surgeon and alchemist at the Bavarian court and was the author of some chemical investigations on the vegetable alkaloids. He studied pharmacy and medicine at Munich, where he graduated M.D. in 1843, and after working under Liebig at Giessen was appointed chemist to the Munich mint in 1845. Two years later he was chosen extraordinary professor of chemistry in the medical faculty, in 1853 he received the ordinary professorship, and in 1865 he became also professor of hygiene. In 1894 he retired from active work, and on the 10th of February 1901 he shot himself in a fit of depression at his home on the Sarnberger See, near Munich. In his earlier years he devoted himself to chemistry, both theoretical and applied, publishing papers on the preparation of gold and platinum, numerical relations between the atomic weights of analogous elements, the formation of aurantium glass, the manufacture of illuminating gas from wood, the preservation of oil-paintings, &c. The reaction known by his name for the detection of bile acids was published in 1844. In his widely used method for the quantitative determination of carbonic acid the gaseous mixture is shaken up with baryta or lime water of known strength and the change in alkalinity ascertained by means of oxalic acid. But his name is most familiar in connection with his work in practical hygiene, as an apostle of good water, fresh air and proper sewage disposal. His attention was drawn to this subject about 1850 by the unhealthy condition of Munich.

Pettenkofen gave vigorous expression to his views on hygiene and disease in numerous books and papers; he was an editor of the Zeitschrift für Biologie from 1865 to 1882, and of the Archiv für Hygiene from 1875 to 1895.

PETTICOAT, an underskirt, as part of a woman's dress. The petticoat, i.e. "petty-coat" or small coat, was originally a short garment for the upper part of the body worn under an outer dress; in the Promontorium parvulum the Latin equivalent is tunicula. It was both a man's and a woman's garment, and was in the first case worn as a small coat under the doublet, and by women apparently as a kind of chemise. It was, however, early applied to the skirt worn by women hanging from the waist, whether as the principal lower garment or as an underskirt. In the middle of the 17th century the wide breeches with hanging embroidered "petticoat breeches," now known as "petticoat breeches," a term also applied to the loose canvas or oilskin overalls worn by fishermen.

PETTIE, JOHN (1839–1883), Scottish painter, was born in Edinburgh on the 15th of March 1839, the son of Alexander and Alison Pettie. In 1852 the family removed to East Linton, Haddingtonshire, and a portrait by the lad of the village carrier and his donkey overcame his father's objections to art as a career for his son. When sixteen he entered the Trustees' Academy in Edinburgh, working under Robert Scott Lauder with W. Q. Orchardson, J. MacWhirter, W. M'Taggart, Peter Graham, Tom Graham and G. P. Chalmers. His first exhibition at the Royal Scottish Academy were "A Scene from the Fortunes of Nigel"—one of the many subjects for which he sought inspiration in the novels of Sir Walter Scott—and two portraits in 1858, followed in 1859 by "The Prison Pet." To the Royal Academy in 1860 he sent "The Armourers" and the success of this work and of "What d'ye Lack, Madam?" in the following year, encouraged him to settle in London (1862), where he joined Orchardson. In 1866 he was elected an Associate of the Royal Academy, and in 1874 received full academical honours in succession to Sir Edwin Landseer. His diploma picture was "Jacobites, 1745." Pettie was a fast and rapid worker, and, in his best days, a colourist of a high order and a brilliant executant. In his early days he produced a certain amount of book illustration. His connexion with Good Words began in 1861, and was continued till 1864. With J. MacWhirter he illustrated The Postman's Bag (Strahan, 1862), and Wordsworth's Poetry for the Young (Strahan, 1863). His principal paintings, in addition to those already mentioned, are "Cromwell's Saints" (1862); "The Trio" (1863); "George Fox refusing to take the Oath" (1864); "A Drumhead Court-martial" (1865); "The Arrest for Witchcraft" (1866); "Treason" (1867, now in the Mappin Art Gallery, Sheffield); "Tussle with a Highland Smuggler" (1868); "The oily dog" (1870); "The Dance of the Bensigners" (1871); "The Dance of the Truce" (1873); "Ho! Ho! Old Noll! of "A State Secret" (1874); "A Sword and Dagger Fight" (1875); "The Death Warrant" (1875); "Monmouth and James II." (1876); "The Vigil" (1884, in the Chantrey Collection, National Gallery of British Art); "Challenged" (1885); "The Chiefain's Candlesticks" (1886); "Two Strings to Her Bow" (1887): "The Traitor" and "Sir Charles Wyndham as David Garrick" (1888); and "The Ultimatum" and "Bonnie Prince Charlie" (1892). Pettie died at Hastings on the 21st of February 1893. In 1894 a selection of his work was included in the Winter Exhibition of the Royal Academy. His portrait by himself is in the Tate Gallery. The portrait of John Pettie, R.A. (Loggian, 1908), by his nephew Martin Hardie, gives the story of his life, a catalogue of his pictures, and fifty reproductions in colours.

PETTY, SIR WILLIAM (1632–1687), English statistician and political economist, born on the 26th of May 1632, was the son of a clothier at Romsey in Hampshire, and received his early education at the grammar school there. About the age of fifteen he went to Caen (Normandy), taking with him a little stock of merchandise, on which he traded, and so maintained himself. His chief leading was in French, improving himself in Latin and Greek, and studying mathematics and other sciences. On his return to England he seems to have had for a short time a place
PETWORTH—PETWORTH

in the royal navy. He went abroad again in 1643, and remained for three years in France and the Netherlands, pursuing his studies. In Paris he read Vesalius with Hobbes, who was then preparing his Tractus opiticas, and it is said that Petty drew the diagrams for him. In 1647 Petty obtained a patent for the invention of double writing, i.e. a copying machine. In politics he espoused the side of the parliament. His first publication was a letter to Samuel Hartlib in 1648, entitled Advice for the Advancement of some Particular Parts of Learning, the object of which was to recommend such a change in education as would give it a more practical character. In the same year he took up his residence at Oxford, where he was made deputy professor of anatomy, and where he gave instruction in that science and in chemistry. In 1649 he obtained the degree of doctor of physic, and was soon after elected a fellow of Brasenose College. He gained some notoriety in 1650 by restoring to life a woman who had been hanged for infanticide. In 1651 he was made professor of anatomy at Oxford, and also became professor of music at Gresham College. In 1652 he went to Ireland, having been appointed physician to the army in that country. In 1654, observing that the admeasurement and division of the lands forfeited in 1641 and granted to the soldiers had been “much inefficiently and absurdly managed,” he entered into a contract to execute a fresh survey, which he completed in thirteen months.1 By this he gained £6,000, and part of the money he invested profitably in the purchase of soldiers’ debentures. He thus became possessed of so large a domain in the county of Kerry that, according to John Aubrey, he could behold from Mt Mangerton the plains of his own land. He set up ironworks in that neighbourhood, opened lead-mines and quarries, established a pilchard fishery, and commenced a trade in timber. Besides the office of commissioner of distribution of the lands he had surveyed, he held that of secretary to the lord-lieutenant, Henry Cromwell, and was also during two years clerk of the council. In January 1658 he was elected to Richard Cromwell’s parliament as member for West Looe in Cornwall. After the Restoration he returned to England and was favourably received and knighted by Charles II., who “was much pleased with his ingenuous discourses, and who, it is said, intended to create him earl of Kilmore. He obtained from the king a new patent constituting him surveyor-general of Ireland. In 1663 he attracted much notice by the success of his invention of a double-bottomed ship, which twice made the passage between Dublin and Holyhead, but was afterwards lost in a violent storm. He was one of the first members of the Royal Society, and sat on its council. He died in London on the 16th of December 1687, and was buried in the church of his native place. His will, a curious and characteristic document, is printed in Chalmers’s Biographical Dictionary.

His widow, Elizabeth (d. 1708), daughter of Sir Hardress Waller (1604-1666), the Irish Cromwellian soldier and regicide, was created Baroness Shelburne by James II. in 1668; and her two sons were successively created earls of Shelburne, but on their death without issue the Petty estates passed to their sister, Anne, and after her marriage to the 1st earl of Kerry the Shelburne title was revived in her son’s favour (see under Lansdowne, 1st Marquess).

Petty’s Irish survey was based on a collection of social data which entitles him to be considered a real pioneer in the science of comparative statistics. He was also one of the first in whom we find a tendency to a view of industrial phenomena which was at variance with the then dominant mercantilist ideas, and he exhibits a statesmanlike sense of the elements in which the strength of a nation really consists. Roscher names him as having, along with Locke and Dudley North, raised the English school to the highest point it attained before the time of Hume.

I. The survey executed by Petty was, somewhat whimsically, called “his Dorking.” It was made between 1665 and 1670, and it is called by that name in Petty’s will. He left in MS. a full account of the proceedings in connexion with it, which was edited by Sir Thomas A. Larcom for the Irish Archaeological Society in 1851. The maps, some of which were injured by a fire in 1711, are preserved in the Public Record Office, Dublin.

His Treatise of Taxes and Contributions contains a clear statement of the doctrine that price depends on the labour necessary for production. Petty is much concerned to discover a fixed unit of value, and he thinks he has found it in the necessary sustenance of a man for a day. He understands the cheapening of money due to the depreciation of natural values, and he establishes the idea of “natural and true” rent as the remainder of the produce of land after payment of the cost of production; but he seems to have no idea of the “law of diminishing returns.” He has much that is just on the subject of money: he sees that there may be an excess of it as well as a deficiency, and regards the prohibition of its exportation as contrary to sound policy. But he errs in attributing the fall of the rate of interest which takes place in the progress of industry to the increase in the quantity of money. He protested against the fetters imposed on the trade of Ireland, and advocated a union of that country with Great Britain. Whilst the general tendency in his day was to represent England as in a state of progressive decline—an opinion put forward particularly in the tract entitled Britannia languens—Petty declared her resources and prospects to be not inferior to those of France.

A complete list of his works is given in the Athenae oxfordienses. The most important are: the Treatise of Taxes and Contributions (1662, 1667 and 1668); Political Arithmetic, presented in MS. to Charles II., but, because it was contrary to the interests of England, kept unpublished till 1691, when it was edited by Petty’s son Charles; Quaestiones Quinque, or a Tract concerning Money (1682); Petty’s Remonstrance against the Bill of Mortality in 1687 and the State of that City (1688); Essay concerning the Multiplication of mankind (1686); Political Anatomy of Ireland (1691). Several papers appeared in the Philosophical Transactions. See Economic Writings of Sir William Petty, ed. C. H. Hull (2 vols. 1890).

PETWORTH, the title in the name of a large number of minor (fr. petit, small) officers, of less than commissioned or warrant rank—such as the master-at-arms, sailmaker, caulkier, armourer, cook, &c. They were originally named, and removable, by the captain.

PETUNIA, in botany, a genus of plants belonging to the natural order Solanaceae and containing about 16 species, chiefly South American (southern Brazil and Argentina). The garden forms are derived from the white-flowered P. nyctaginiflora and the violet- or purple-flowered P. violacea. The varieties of petunia, especially the double forms, make admirable specimens for pot culture.

Named or specially fine varieties are propagated by cuttings taken from the stock plants; shoots from the top, pricked through the winter, are potted into small boxes in a warm shelf, and moved into a brisk moist heat in early spring; the young shoots are planted in pans or pots filled with sandy soil, and, aided by a brisk bottom heat, strike root in a few days. They are then potted singly into the thumb-pots, and, when once rooted, are gradually hardened off, and afterwards repotted as required. The shoots should be toped to make bushy plants, and their tops may be utilized as cuttings. The single varieties are raised from seeds sown in light sandy soil in hot, in the early spring, and very slightly covered. The plants need to be pricked out or potted off as soon as large enough to handle. Good strains of seeds supply plants suitable for bedding; but, as they do not reproduce themselves exactly, any sorts particularly required must be propagated, like the double ones, from cuttings.

PETWORTH, a market town in the Horsham parliamentary division of Sussex, England, 55 m. S.S.W. from London by the London, Brighton & South Coast railway. Pop. (1901), 253. The church of St Mary is Perpendicular, and contains numerous memorials of members of the Percy family and others. Petworth House, situated in a beautiful park, dates from the 18th century, and contains a magnificent collection of pictures. At Bignor in the neighbourhood are remains of an important and splendidly adorned Roman villa.

The first mention of Petworth (Peartingawrth, Petteorde, Petewerd, Pedewurde, Putteword, Ptteworde, Petteworth) occurs as a grant by Eardwulf, king of Northumbria, to St Peter’s Church, about 791. In the time of Edward the Confessor Petworth was an alodial manor held by his queen Edith, and in 1086 Robert Fitz-Tevold held it of Roger Montgomery, earl of Shrewsbury. It then included a church and a mill, and was rated at nine hides. Through Queen Adelis, Petworth came first into the hands of
Somerset, the village member doubtful, Desjardins. The term, whole 1682, the medieval generally 1424 non-parishioner. Montpelier 27-8 tin decline at shows a by Berthuald rise considered with 468. London, who certainly framing, his parish oak (Eng. PEWENSEY, Tafel and PEUTINGER, see Map), a map of the military roads of the western Roman Empire, which was discovered by Konrad Celtce, who handed it over to Peutinger for publication. Peutinger also edited the Historia Geographorum of Jordanes, and the Historia gentis Langobardorum of Paulus Diaconus.

The Tabula peutingeriana was first published as a whole by F. de Scheyb (1753); later editions by E. Desjardins (1869–1874) and C. Miller (1888); see also E. Paulus, Erklärung der Peutinger Tafel (1862). The Peutinger table is a map of the military roads of the Roman Empire, which was discovered by Konrad Celtce, who handed it over to Peutinger for publication. Peutinger also edited the Historia Geographorum of Jordanes, and the Historia gentis Langobardorum of Paulus Diaconus.

PEVENSEY, a village in the Eastbourne parliamentary division of Sussex, England, 65 m. S.S.E. from London by the London, Brighton & South Coast railway. Pop. (1901), 468. The village is a member of the Cinque Ports, but the sea has receded a mile from it in historic times. The outer wall, with solid towers, of the celebrated castle, is of Roman construction, and originally enclosed a complete oval; it is generally considered to have enclosed the strong town of Anderida. Within the fine ruins, principally of the 13th century, but in part Norman, of the castle proper, with a keep and four massive round towers. The church of St Nicholas, close to the castle, shows beautiful Early English work. It has been supposed that Pevensey was the scene of the landing of Caesar in 55 B.C., but the question is disputed.

The name of Pevensey (Peaveniseld, Penesel, Penvenes, Pemsey) first occurs in a grant of land there by the south Saxon Duke Berthweld to the abbey of St Denis in 705. In later Saxon times, at least by the reign of Edward the Confessor, it was a royal borough and had a harbour and a market. Its early importance was due to its fertile port. It was the landing place of William the Conqueror in his way to conquer, and was the caput of the Rape of Pevensey, which was granted by William to the earl of Mortain and subsequently became the Honour of the Eagle. Some time before the reign of Edward I. the town of Pevensey was made a member of Hastings and shared the liberties of the Cinque Ports, but apart from them it possesses no charter. It was governed by a bailiff and twelve jurats, elected annually, until by an act of 1833 it ceased to exist as a borough. Its seal dates apparently from the reign of Henry III. The gradual decline of Pevensey was complete in the 19th century and was caused by the recession of the sea and consequent loss of the harbour.

PEW (Mid. Eng. pwew, through O. Fr. pueu, pu, mod. pu, in the sense of hill, cf. appuyer, to lean against; from Lat. podium, a high place, balcony; Gr. θόκος, pedestal, πόδος, foot), a term, in its usual meaning, for a fixed seat in a church, usually enclosed, slightly raised from the floors, and composed of wood framing, mostly with ornamented ends. Some bench ends are certainly of Decorated character, and some have been considered to be of the Early English period. They are sometimes of plain oak board, 2½ to 3 in. thick, chamfered, and with a necking and finial generally called a poppy head; others are plainly panelled with bold cappings; in others the panels are ornamented with tracery or with the linen pattern, and sometimes with running tracery. The pew ends, often in the enclosures, curtains, &c., known familiarly as "horse-boxes," and common in English parish churches during the 18th and early part of the 19th centuries, have nearly all been cleared away. The parish church of Whitby, in Yorkshire, is perhaps the best surviving example of an unaltered interior.

The Latin word podium was particularly applied to a balcony or parapet next to the arena in the Roman theatre where the emperor and his suite sat during a performance. According to Justinus (Glossarium, s.v. podium), it is found in medieval Latin for a bench (subsellium) for the minor canons at a church in Lyons (1343), and also for a kneelers stool in a monastic church. The word "pew" in English was often used for a stall for the minister, for a reading desk, or for a pulpit. The floor space of the nave and transepts of medieval churches was usually open, mats being sometimes used for kneeling and if any fines were provided these would be for the patrons of the church or for distinguished people. Some enclosed seats, however, seem to have been reserved for women, as is seen in Pieris Plowman, ch. vii. 144, "Among wyves and wodwes I saw ane lyttel by mynne in puyes." They did not come into general use till the middle of the 15th or beginning of the 16th century (see Gasquet, Parish Life in Medieval England, 1906, pp. 62 and 133). Over the few seats thus allotted dispute arose and attempts were made to appropriate them. Thus the constitutions for the synod of Exeter, drawn up by Bishop Peter Quivel in 1287, forbid any one "to claim any sitting in the church as his own... Whoever first comes to pray, let him take what place he wishes in which to pray."

At common law all seats in a parish church are for the common use of all the parishioners, and every parishioner has a right to a seat without paying for it. The disposition of the seats is in the discretion of the churchwardens acting for the ordinary for the purpose of orderly arrangement (as to the exercise of this discretion see Reynolds v. Monckton, 1841, 2 M. & R. 384), and this can be exercised in cases where all the seats are free (Asher v. Calerft, 1887, 18 Q.B.D. 607). The right to a seat does not belong to a non-parishioner. As against the assignment and disposition of seats by the ordinary, acting through the churchwardens, two kinds of appropriation can be set up (a) by the provision of a faculty by the ordinary; and (b) by prescription, based on the presumption of a lost faculty. Such faculties are rarely granted now; they were formerly common; the grant was to a man and his family "so long as they remain inhabitants of a certain house in the parish"; the words "of a certain house" are now usually omitted. The claim to a pew by prescription must be in respect of a house in the parish; the right is subject to the burden of repairing the pew; it is not an easement, nor does the Prescription Act 1832 apply to it (see for the whole subject of a claim by prescription Phillips v. Halliday, 1831, A.C. 228). The letting of pews in parish churches became common in the 17th century, but there are some earlier instances of the use, for example 1345 (Rec. Eccles. No. 614) and 1475 (Rec. Eccles. No. 1355). Sir J. Maclean, Trans. Bristol and Gloucester Archaeol. Assoc., vol. xv., 1800–1801). The taking of pew rents in parish churches is illegal (Lord Stowell, in Walter v. Gunner, 1798, 3 Harg. Consist. 872); but under the various Church Building Acts seats may be let and rents charged to pay the salary of the minister, &c.

See A. Heales, History and Law of Church Seats and Pews (1872); Phillimore, Eccles. Law (1896), ii. 1424 seq.

PEWTER, a general name used to denote a number of alloys of various metals in diverse proportions, the sole common feature of which lies in the fact that tin is always the chief constituent. The etymology of the word is doubtful, but it is probably an English adaptation of the German pewter, which was adopted with more or less technical modification by the continental European nations. The early pewterers, at an early period were eager purchasers of the ware, becoming peaster in Dutch, peure, peauetre or plasiter in French, peltro in Italian and peltre in Spanish. Roman pewter, the oldest known, which has been disinterred at various places in England and elsewhere, was composed of tin and lead alone, for the occasional traces of iron are believed to be accidental, in proportions which, though varying considerably, group themselves around two definite formulae, one containing 71-5 parts of tin to 27-8 of lead, the other 78-6 of tin to 21-7 of lead, or one libra of tin to 42 and 3 unicae of lead respectively. On the European continent in the middle ages, some ten centuries later than the supposed date of the Roman pewter found in Britain, we first get definite records of the composition of pewter, lead remained the chief, if not the only secondary ingredient. In 1437 the pewterers of Montpelier added 4 parts of lead to 66 of tin,
when making dishes and porringer 10 parts of lead to 90 of tin for salt-cellars and ewers; those of Limoges used 4 parts of lead to 100 of tin; at Nuremberg in 1576 it was ordained that not more than 1 lb of lead should be mixed with every 10 lb of tin; in France during the 18th century a limit of 15% of lead was imposed, while at the present time 16-5% with a margin of 1-5 for errors is regarded as safe for the storage of wine and consequently legal.

In England the earliest known ordinances for the regulation of the craft were drawn up in 1548 and received the approval of the mayor and alderman in 1549. From them we learn that for rounded vessels lead might be mixed with the tin in the proportion of 26 lb to each hundredweight, though this quantity appears to have been found excessive, since in 1551 a pewterer was punished because his alloy contained more than 16 lb to the hundredweight, unless this be a clerical error in the contemporary records of the Pewterers’ Company. Articles made of this material were to be known as “vessels of tyn for ever” but the alloy soon came to be known as “ley.” Another formula, however, authorized in the same document, would appear to have been at that time an exclusively English secret, by which was presumably due the universal recognition of the superiority of the island wastes which is so notable a fact in the history of pewter. It was known as “fyne peauer” and used for dishes, saucers, platters, chargers, and for all “things that they make square,” such as cruets, chisimatories, &c., which owing either to the rough usage they would be submitted to, or to the sharpness of their angles, called for greater toughness in the material. The recipe for this alloy as originally propounded was as much brass to the tin “as it wol receve of his nature,” but the lack of precision in this perhaps renders it difficult to distinguish accidental variations from deliberate adulteration, and in 1474-1475 it was resolved that 26 lb of brass must be mixed with every hundredweight of tin. The penalties for infringement of the rules were severe and frequently enforced, but in spite of them alterations and improvements crept in. The chief and perhaps the earliest of these was the addition of a certain proportion of bismuth, or as it was then called “tin glass.” When this was first used is not recorded, but by 1561 it was accepted as a matter of course; in 1630 a maker “was found in fault for not sufficiently tempering his metal with tin glass”; and in 1653 it was ordered that 3 lb weight of tin glass at least must be mixed with every 1000 lb of tin. Antimony was subsequently introduced—though there is no mention of it in the records of the Pewterers’ Company—sometimes alone in 1584 or in combination with bismuth. It seems that the amount of antimony found to be satisfactory was from 8 to 83 of tin, sometimes with other metals as in hard metal (96 parts of tin, 8 of antimony and 2 of copper), a mixture very closely resembling that still used under the name of “Britannia metal,” and in plate pewter (100 parts of tin, 8 of antimony, 4 of copper and 4 of bismuth). The wares were originally fashioned in two ways, by hammering or by casting, and the workers in the early were strictly differentiated, the former, who worked in flat pewter, being known as Sadware men, the latter who used “ley” as Hollow-ware men. A third class, known as Trillers, from the alloy they were limited to, probably at first only manufactured such small articles of domestic use or ornament as did not definitely fall under either of the other headings (bismuth and antimony). The alloy for this class was drawn up by a committee of Trillers in 1612; it is clear that the barrier between them and the Hollow-wares men had been largely broken down. Another method of working pewter which seems to have been introduced later, and never followed to any great extent, was spinning, by which the vessel was shaped in a mould on a wheel by the mere pressure of a blunt tool, the softness of the metal allowing of its flowing sufficiently for this purpose.

Pewter first appears in history in 1774, when a synod at Rouen permitted its use as a substitute for gold or silver in church vessels, a concession accepted also at Winchester two years later, again withdrawn in 1775, but once more tacitly adopted some twenty years after. The records of its domestic use commence with the caldrons employed for boiling the meat at the coronation of Edward I. in 1274, though we gather that the trade was even then flourishing in Paris and Bruges, whence during the following century it extended to Augsburg, Nuremberg, Poitiers, Mons and other continental centres. Confined at first to the more wealthy classes, we can trace as time goes on its extension lower and lower in the social scale, until at the end of the 17th century its use was almost universal. Thenceforward its vogue steadily declined. The growing cheapness of glass and chinaware and the invention of more showy metals brought upon it by degrees the fate of the fad in any country, but for a very few exceptions its manufacture entirely ceased.

Artistically, pewter was at its best when its makers were least conscious of the art revealed in it, thinking more of the durability and appropriateness to purpose of their wares than of their decorative qualities. Though intentionally ornamental vessels may be found earlier, it was not until the 18th century that the pewterers set themselves to slavishly copying the designs and methods of the silversmiths, whether suitable to their material or not, and thereby undoubtedly hastened their own downfall.

Of recent years pewter has taken its place among the articles sought after by collectors, and its cost has so materially and rapidly increased that the manufacture of vessels, guaranteed of course genuinely antique, bids fair to become once more a paying industry. Unfortunately the various engravings compelling each maker to stamp his ware with a definite touchmark seem at all times to have been very generally evaded or ignored, and experience alone is therefore the only safe guide to distinguishing new from old.

PÉZENAS, a town of southern France, in the department of Hérault 33 m. W.S.W. of Montpellier on the southern railway. Pop. (1906), 6432. The commerce in cognac, spirits and wines is so important that the prices current for these at the weekly sales are registered throughout the wine marts of France and Europe. There is a handsome monument to Molière, who lived at Pézenas several years and produced his first plays there in 1655 and 1656. The university was founded in 1589, and in the 17th century and early of the 18th century it was partially suppressed by the Jesuits. In the 17th and 18th centuries are of interest.

Pézenas (Piscenae) was founded by the Gauls. In the 10th century it became the capital of a countship subsequently held by important families including those of Montmorency, Condé and Conti. In the 17th century the town was on several occasions the meeting place of the estates of Languedoc.

PFÄFF, JOHANN FRIEDRICH (1765-1825), German mathematician, was born on the 22nd of December 1765 at Stuttgart. He received his early education at the Carlsruhe, where he met F. Schiller, his lifelong friend. His mathematical capacity was early noticed; he pursued his studies at Göttingen under Abraham Gotthelf Kästner, and in 1787 he went to Berlin and studied practical astronomy under J. E. Bode. In 1788 Pfaff became professor of mathematics in Helmstedt, and so continued until that university was abolished in 1810. From that time till his death on the 21st of April 1825 he held the chair of mathematics at Halle. Pfaff’s researches bore chiefly on the theory of series, to which he applied the methods of the so-called combinatorial school of German mathematicians, and on the solution of differential equations. His two principal works are Disquisitiones analyticae maxime ad calculum integralen et doctrinam serierum pertinientes (14o, vol. i., Helmstedt, 1797) and "Methodus generalis, acqualiones differentiarum particularum, nemon acqualiones differentiale vulgares, utrasque etiam multorum aliorum quantitatum variables, complete integrandi" in "Abb. d. Brl. Acad. (1814-1815). The former work contains Pfaff’s discussion
PFALZBURG—PFORTA

of a certain differential equation which generally bears his name, but which had originally been treated in a less complete manner by L. Euler (see Differential Equations). The latter work contains an important addition to the theory of partial differential equations as it had been left by J. L. Lagrange.

His brother, JOHANN WILHELM ANDREAS PFAF (1774–1835), was professor of pure and applied mathematics successively at Dorpat, Nuremberg, Würzburg and Erlangen. Another brother, CHRISTIAN HEINRICH PFAF (1773–1852), graduated in medicine at Stuttgart in 1793, and from 1801 till his death was professor of medicine, physics and chemistry at the university of Kiel.

PFZLZBURG, a town of Germany, in the imperial province of Alsace-Lorraine, lies high on the west bank of the Voges, 25 m. N.W. of Strassburg by rail. Pop. (1805), 74. It contains an Evangelical and a Roman Catholic church, a synagogue and a teachers’ seminary. Its industries include the manufacture of gloves, straw hats and liqueurs, and also quarrying.

The principality of Pfalzburg, of which this town was the capital, originally a part of Luxemburg, afterwards belonged in turn to the bishop of Metz, the bishop of Strassburg and the duke of Lorraine, and passed into the possession of France in 1661. The town was of importance as commanding the passes of the Voges, and was strongly fortified by Vauban in 1680. The French held the town from 1814 to 1815, and the Germans, for four months in 1879, but they were taken on the 12th of December of that year. They have since been razed.

PFIEFFER, FRANZ (1851–1868), German scholar, was born at Bettlach near Solure on the 27th of February 1815. After studying at the university of Munich he went to Stuttgart, where in 1846 he became librarian to the royal library. In 1856 Pfeiffer founded the Germania, a quarterly periodical devoted to German antiquarian research. In 1857, having established his name as one of the foremost authorities on German medieval literature and philology, he was appointed professor of these subjects at the university of Vienna, and in 1866 was made a member of the Imperial Academy of Science. He died at Vienna on the 29th of May 1868.

Among the many writings edited by him may be mentioned the Barlaam und Josaphat of Rudolf von Ems (1843), the Edelstein of Ulrich Boner (1844), Die deutschen Mystiker des 14. Jahrhunderts (1845–1857; new ed., 1860), the Buch der Natar of Konrad von Megenberg, a 14th-century writer (1861), Die Predigten des Berthold von Regensburg (1862), and the poems of Walther von der Vogelweide (1864; 6th ed. by K. Bartsch, 1880). Of his independent writings the following may mention here: Übergriechische Litteraturgeschichte, über Wesen und Bildung der höfischen Sprache in mittelhochdeutscher Zeit, Der Dichter desNibelungenliedes, Forschung und Kritik auf dem Gebiete des deutschen Altertums, and Altdönsches Übungsbuch. A biography of the famous Karl Friedrich von Haffken in two volumes, with Prehehren von Lossberg, edited by Franz Pfeiffer (1870).

PFIEFFER, IDA LAURA (1792–1858), Austrian traveller, daughter of a merchant named Reyner, was born at Vienna on the 14th of October 1797. In 1820 she married Dr Pfeiffer, a lawyer of Lemberg, who subsequently incurred official persecution and was reduced to poverty. In her later life Mme Pfeiffer devoted her limited means to travel. In 1842 she visited Palestine and Egypt, and published an account of her journey in Reise einer Wienerin in das Heilige Land (Vienna, 1843). In 1845 she set out to Scandinavia and Iceland, describing her tour in two volumes, Reise nach dem skandinavischen Norden und der Island (Pesth, 1846). In 1846 she started on a journey round the world, visiting Brazil, Chile and other countries of South America, Tahiti, China, India, Persia, Asia Minor and Greece, and reaching home in 1848. The results were published in Eine Frauenfahrt um die Welt (Vienna, 1850). In 1851 she went to England and thence to South Africa, intending to penetrate into the interior; this proved impracticable, but she proceeded to the Malay Archipelago, spending eighteen months in the Sunda Islands and the Moluccas. After a visit to Australia, Madame Pfeiffer proceeded to California, Oregon, Peru, Ecuador, New Granada, the Missions Territory, and north again to the Great Lakes, reaching home in 1854. Her narrative, Meine zweite Weltreise, was published at Vienna in 1856. In May of the same year she set out to explore Madagascar, where at first she was cordially received by the queen. But she unwittingly allowed herself to be involved in a plot to overthrow the government, and was expelled the country. She died at Vienna on the 27th of October 1858.

The Reise nach Madagascar was issued in 1861 (Vienna), with a biography by her son.

PFLEIDERER, OTTO (1839–1908), German Protestant theologian, was born at Stetten near Cannstatt in Württemberg on the 1st of September 1839. From 1857 to 1861 he studied at Tübingen under F. C. Baur; and afterwards in England and Scotland. He then entered the ministry, became respondent at Tübingen, and for a short time held a pastorate at Heilbronn (1868). In 1870 he became chief pastor and superintendent at Jena and soon afterwards professor ordinarius of theology, but in 1875 he was called to the chair of systematic theology at Berlin, having made his name by a series of articles on New Testament criticism and Johannine and Pauline theology, which appeared in Adolf Hilgenfeld’s Zeitschrift für wissenschaftliche Theologie, and by his Der Paulinismus, published in 1873 (2nd ed., 1890; Eng. trans., Paulinism: a Contribution to the History of Primitive Christian Theology, 2 vols., 1873, &c.). Das Urschriftentum, seine Schriften und Lehren, in geschichtlichem Zusammenhang beschrieben was published in 1878 and considerably enlarged for a second edition in 1903 (Eng. trans., 1906). In 1890 appeared The Development of Theology since Kant, and its Progress in Great Britain since 1825, which was written for publication in England. A more elaborate work was his Religionsphilosophie auf geschichtlichen Grundlage (1878; 2nd ed., enlarged, 1883–1884; Eng. trans., from 2nd German ed., The Philosophy of Religion on the Basis of its History, 4 vols., 1886–1888). “The Influence of the Apostle Paul on the Development of Christianity” was the title of a course of Hibbert Lectures given in London in 1885. In 1894 he delivered the Gifford Lectures at Edinburgh, the subject being “The Philosophy and Development of Religion.” His later publications included: The Early Christian Conception of Christ (1905), Die Entstehung des Christentums (1905; Eng. trans., 1906), Religion und Religionen (1906; Eng. trans., 1907), and Die Entwicklung des Christentums (1907). He died on the 18th of July 1908, at Gross Lichterfelde, near Berlin. In New Testament criticism Pfeiffer belonged to the critical school which grew out of the impulse given by F. C. Baur. But, like other modern German theologians, he showed a greater disposition to compromise. All his work shows a judicial tone of mind, and is remarkable for the charm of its style.

Pfeiferer’s younger brother EDMUND (1842–1902) distinguished himself both in philosophy and theology. He too entered the ministry (1864) and during the Franco-German War served as army chaplain, an experience described in his Erlebnisse eines Feldgeistlichen (1890). He was afterwards appointed professor ordinarius of philosophy at Kiel (1873), and in 1878 he was elected to the philosophical chair at Tübingen. He published works on Leibnitz, empiricism and scepticism in Hume’s philosophy, modern pessimism, Kantian criticism, English philosophy, Heraclitus of Ephesus and many other subjects.

PFORTA, or SCHULPFORTA, formerly a Cistertian monastery dating from 1140, and now a celebrated German public school. It is in the Prussian province of Saxony, on the Saale, 2 m. S.W. of Naumburg. The remains of the monastery include the 13th century Gothic church, recently restored, the Romanesque chapel (12th century) and other buildings now used as dormitories, lecture rooms, &c. There is also the Fürstenhaus, built in 1573. Schulpforta was one of the three Fürstenschulen founded in 1543 by Maurice duke, and later elector, of Saxony, the two others being at Grimma and at Meissen. The property of the dissolved monastery provided a good revenue for the new educational foundation, which now amounts to about £15,000 a year. Free education is provided for 140 boys, the total number of pupils being 185. After being in the possession of Saxony, Pforta passed to Prussia in 1815, and since this date the school has been entirely reorganized.
PFORZHEIM—PHAEDRUS

PFORZHEIM, a town of Germany, in the grand duchy of Baden, at the confluence of the Nagold and the Enz, on the northern margin of the Black Forest, 19 m. S.E. of Karlsruhe by rail, and at the junction of lines to Wildbad and Ettingen. Pop. (1895), 33,345; (1905), 59,395, most of whom are Protestants. Its most interesting buildings are the old palace of the margraves of Baden, and the Schlosskirche, the latter an edifice of the 12th-15th centuries, containing the tombs and monuments of the margraves. Pförzheim is the chief centre in Germany for the manufacture of gold and silver ornaments and jewelry, an industry which gives employment to about 22,000 hands, besides which there are iron and copper works, and manufactures of chemicals, paper, leather, machinery, &c. A brisk trade is maintained in timber, cattle, and agricultural produce. Pförzheim (Porta Hercynica) is of Roman origin. From about 1300 to 1565 it was the seat of the margraves of Baden. It was taken by the troops of the Catholic League in 1624, and was destroyed by the French in 1689. The story of the 400 citizens of Pförzheim who sacrificed themselves for their prince after the battle of Wimpfen in May 1622 has been belated by modern historical research to the domain of legend.

PHAEDO. Greek philosopher, founder of the Elian school, was a native of Elis, born in the last years of the 5th century B.C. In the war of 401-400 between Sparta and Elis he was taken prisoner and became a slave in Athens, where his beauty brought him notoriety. He became a pupil of Socrates, who conceived a warm affection for him. It appears that he was intimate with Cebes and Plato, and he gave his name to one of Plato's dialogues.

Athenaeus relates, however, that he resolutely declined responsibility for any of the views with which Plato credits him, and that the relations between him and Plato were the reverse of friendly. See Coste, Die 400 Pförzheims (1879); Brombacher, Der Tod der 400 Pförzheims (Pforzheim, 1886); Stolz, Geschichte der Stadt Pförzheim (Pforzheim, 1901).

PHAEON. See PHEAON.

PHAEON, in Greek legend, daughter of Minos and Pasiphaë. With her sister Ariadne she was carried off by Theseus to Athens, and became his wife. On the way to Eleusis she met Hippolytus, son of Theseus by a former wife (Hippolyte, queen of the Amazons, or her sister Antiope), and fell in love with him. Finding her advances rejected, she hanged herself, leaving behind a letter in which she accused Hippolytus of having done her dishonourable plague. The same story, in the main, is told of Belerofon and Antea. It formed the subject of tragedies by Sophocles, Euripides (two, one of which is extant), Seneca and Racine.

PHAEON, Roman fabulist, was by birth a Macedonian and lived in the reigns of Augustus, Tiberius, Gaius and Claudius. According to his own statement (prologue to book iii.), not perhaps to be taken too literally, he was born on the Pician Mountain, but he seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief MS. he was a slave and was freed by Augustus. He incurred the displeasure of Sejanus, the powerful minister of Tiberius, by some supposed allusion in a piece of verse, and was brought to trial and punished. We learn this from the prologue to the third book, which is dedicated to Eutychus, who has been identified with the famous charioteer and favourite of Gaius. The fourth book is dedicated to Particulo, who seems to have dabbled in literature. The dates of their publication are unknown, but Seneca, writing between a.d. 41 and 43 (Consol. ad Polyb. 27), knows nothing of Phaedrus, and it is probable that he had published nothing then. His work shows little or no originality; he simply versified in iambic trimeters the fables current in his day under the name of "Aesop," interspersing them with anecdotes drawn from daily life, history and the classics. Of what is left, however, he is very remarkable businesslike directness and simplicity; his language is terse and clear, but thoroughly prosaic, though it occasionally attains a dignity bordering on eloquence. His Latin is correct, and, except for an excessive and peculiar use of abstract words, shows hardly anything that might not have been written in the Augustan age. From a literary point of view Phaedrus is inferior to Babrūs, and to his own imitator, La Fontaine; he lacks the quiet picturesqueness and pathos of the former, and the exuberant vivacity and humour of the latter. Though he frequently refers to the envy and detraction which pursued him, Phaedrus seems to have attracted little attention in antiquity. He is mentioned by Martial (vii. 50, 5), who imitated freely from his verses, and by Avianus. Prudentius must have read him, for he imitates one of his lines (Prud. Cath. vii. 115; cf. Phaedrus, iv. 6, 10).

The first edition of the five books of Phaedrus was published by Pithou at Troyes in 1596 from a manuscript now in the possession of the Bibliothèque Nationale at Paris. The identity of the Phaedrus, to whom there was attributed by Diodorus Siculus (vii. 22) a copy of the fables, was nullified by Coste in 1626, when it was learned from Wildbad (now Wettenberg) that a MS. of an edition of Phaedrus by E. Coste there existed which contained 64 fables of Phaedrus, which some thirty were new. These new fables were first published at Parma (1544), and at Venice (1553), and were translated into French by Jannelli in 1609. A Latin edition (Venetiis, 1610) and a French version were published the same year by Senesii, of whom there are a few extant fables. In the middle ages Phaedrus exercised a considerable influence through the prose versions of his fables which were current, though his own works and even his name were forgotten. Of these prose versions the oldest existing seems to be that known as the "Anonymus Nilanti," so-called because first edited by Nilant at Leiden in 1599 from a MS. of the 13th century. It approaches the text of Phaedrus so closely that it was, for many years, considered to be a fourteenth century work, in which it contains thirty are derived from lost fables of Phaedrus. But the largest and most influential of the prose versions of Phaedrus is that which bears the name of Romulus. It contains 300 fables, and seems to have been based on a still earlier prose version, which, under the name of "Aesop," and addressed to one Rufus, may have been made in the Carolingian period or even earlier. Among the versions of Romulsus is a work in MS. in the Weissenburg (now Wolfenbüttel) MS. is based on the same version as Romulus. These three prose versions contain in all one hundred distinct fables, of which fifty-six are derived from the existing and the remaining forty-four presumably from lost fables of Phaedrus. Some scholars, as Burmann, Dresler and L. Müller, have tried to restore these lost fables by versifying the prose versions.

The collection bearing the name of Romulus became the source from which all the rest, during the next three centuries, all the collections of Latin fables in prose and verse were wholly or partially drawn. A 12th-century version of the first three books of Romulus in elegiac verse enjoyed a wide popularity, even into the 16th century. The first printed edition was published by Neveleti in 1610 as the "Anonymus Neveleti" and was long unknown, but Hervieux has shown grounds for identifying him with Walther of England, chaplain to Henry II. and afterwards archbishop of Paris.

Another version of Romulus in Latin elegics was made by Alexander Neckam, born at St Albans in 1157. Amongst the collections partly derived from Romulus the most important is that in verse by Marie de France. About 1200 a collection of fables in Latin prose, based partly on Romulus, was made by the Cistercian monk Od. de Sherrington; they have a strong medieval and clerical tinge. In 1570 Gerard of Minden wrote a poetical version of Romulus in English.

Since Pithou's edition in 1596 Phaedrus has been often edited and translated; among the editions may be mentioned those of Burmann (1718 and 1727), Bentley (1776), Schlegel (1806), and their followers: they are many, but the most of them are said by Beechey to be "useless and without value." Since 1886, however, a new edition has been prepared by the Prussian Academy of Sciences, and this is the most accurate and complete edition to date.
PHAER—PHAGOCYTOSIS

medieval versions of Phaedrus and their derivatives see L. Roth, in Phaed, i. 523 sq.; E. Grosse, in Jahrb. f. class. Philol., cv. (1872); and especially the learned work of Hervieux, Les Fabulistes latins depuis le siècle d’Auguste jusqu’a la fin du moyen age (Paris, 1884), who gives the Latin texts of all the medieval imitators (direct and indirect) of Phaedrus, some of them being published for the first time.

PHAER (or PHAYER), THOMAS (1510?-1560), English translator of Virgil, was educated at Oxford and at Lincoln’s Inn. He published in 1535 Natura brevium, and in 1543 Newe Boke of Presidents. He says on the title-page of his version of the Aeneid that he was “solicitor to the king and queen’s majesties, attending their honourable council in the marches of Wales.” He settled at Kilgarran in Pembroke-shire, and combined for some years his legal and literary practice. He wrote on several medical works, and was admitted M.D. of Oxford in 1559. He contributed to Sackville’s Mirror for Magistrates, “Howe Owen Glendower, being seduced by false prophecies, toke upon him to be Prince of Wales.” In 1558 appeared The Seven First Bookes of the Eneidos of Virgil converted into English Meter. He had completed two more books in April 1560 and had begun the tenth, but he died in the autumn of that year, leaving his task incomplete. The translation was finished by Thomas Twyne in 1584. Phaer’s translation, which was in rhymed fourteen-syllabled lines, was greatly admired by his contemporaries, and he was more successful as the first to attempt a complete version, the earlier renderings of Surrey and Gawen Douglas being fragmentary although of greater poetic value.

PHAETHON (Gr. φαέθων, shining, radiant), in Greek mythology, the son of Helios the sun-god, and the nymph Clymena. He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it. To save the world from utter destruction Zeus killed Phaethon with a thunderbolt. He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters, the Hellades, were transformed into poplars and their tears into amber. This part of the legend points to the mouth of the Oder or Vistula, where amber abounds. Phaethon was the subject of a drama of the same name by Euripides, of which some fragments remain, and of a lost tragedy of Aeschylus (Heciade); the story is most fully told in the Metamorphoses of Ovid (i. 790–ii. 366 and Nonnus, Dionysiaca, xxxvii). Phaethon has been identified with the sun himself and with the morning star (Phosphorus). In the former case the legend is supposed to represent the sun sinking in the west in a blaze of light. His identification with the morning star is supported by Hyginus (Astron. ii. 43), where it is stated that the morning (and evening) star was the son of Ceos and Eurydice; the name Phaethon is also alluded to in Hesiod, Theog. 984–986). The fall of Phaethon is a favourite subject, especially on sarcophagus reliefs, as indicating the transitoriness of human life.

PHAGOCYTOSIS (Gr. φαγεῖν, to eat, devour, and κύτος, cell). Many cells of the body possess the property of engulfing particles, a character to be associated with their power of performing amoeboid movement. This property is termed phagocytosis. Primarily this phagocytic power was simply the means by which the cell took within its cell body food particles which were ultimately digested and assimilated. In the higher organisms, however, this property has been developed for different purposes, and in pathology at the present day a meaning wider than that above given is often included in the term. The particle having been taken into the cell, one of three things may happen: (1) The particle may consist of digestible material, in which case the cell secretes a digestive fluid, a food vacuole is formed, the particle is gradually dissolved by the secretion and the products absorbed into the cell substance. (2) The particle may be indigestible, in which case it is retained within the cell body for a time and ultimately discharged. The particle engulfed may comprise almost any material, but if it is to serve as a food it must be of animal or vegetable origin. At the time of ingestion it may be dead or living. In the case in which it is living the organism is first killed and then digested, or (3) the organism may prove resistant, in which case it may multiply and finally destroy the cell, when a number of organisms are set free. This is one of the means by which, in the higher organisms, a local infection may become distributed through the organism. The digestion effected within a cell is fermentative in character. Thus a proteolytic ferment has been prepared from the bodies of amoebae to the ferment possessing fairly active properties both in acid, neutral or alkaline media, but especially in the latter.

In studying the process of phagocytosis generally much information may be gained as to its general characters by the study of the processes of intracellular digestion in the simpler Invertebrates, a study largely extended by Metchnikoff and his co-workers in the elaboration of Metchnikoff’s view of the nature of immunity. Thus, to take an instance from the sponges. Food substances, in the form of minute organisms, which have penetrated the pores of the sponge are seized by the ciliated or amoeboid cells lining those spaces, and are then killed and digested. In this case also the process of digestion is proved to be fermentative. It is readily understandable that we should find such cells on the external surface of an organism or on the surface lining the alimentary tract, particularly in the latter position. But in addition there are many cells within the body in which phagocytic power is retained and markedly developed. Such cells may be fixed or wandering cells. They are employed for removing foreign material or debris which may occur within a tissue. For instance, as the result of an injury, inflammatory process, &c., cells and other structures of a tissue may be destroyed. One of the processes of repair consists in the removal of the resulting debris, which is effected by phagocytes. A similar process is seen with red blood corpuscles which may have escaped into a tissue through rupture of capillaries. Foreign particles accidentally gaining admission to a tissue are in many cases removed in a similar manner, e.g. soot particles which have passed through the respiratory surface are then largely removed by phagocytes and carried to the bronchial lymphatic glands. Very commonly living organisms effect an entrance through wound surfaces, the alimentary surface, &c., and one of the processes employed for their destruction and removal is that of phagocytosis.

As an illustration of the removal of foreign red blood corpuscles we may take the experiments of Metchnikoff in which a small drop of defibrinated blood of the goat was injected under the skin of a snail. The corpuscles quickly spread through the haemolymph of the snail without amelioration of any kind, and effects no change in them. At the end of several hours examination shows that the leucocytes of the snail have engulfed a large number of the red corpuscles. The following day intact corpuscles can still be found in the haemolymph, but the major number have already been devoured by the leucocytes. When taken up by a phagocyte the red corpuscle becomes round and its wall permeable. A vacuole is formed around the corpuscle, in which dissolved haemoglobin can be seen; a part of this haemoglobin also passes into the nucleus of the red corpuscle, proving that it too has been profoundly altered. Many of the nuclei are discharged. After some time the only parts of the corpuscle remaining are pieces of the nucleus and the peripheral layer of the corpuscle. Frequently the phagocytes, after having devoured one or several red corpuscles, themselves become a prey to their fellows. Analogous changes are observed in the tissues of a mammal when blood which has been extravasated is being removed, e.g. after a bruise. The first effect of the haemorrhage is an exudative inflammation, during which leucocytes arrive in large numbers and engulf the corpuscles. In the process of digestion which follows the haemoglobin is altered and new pigments formed from it. In mammals this pigment is dark red or brownish, in the pigeon it is green. Finally the corpuscles are completely digested. Analogous phenomena may be observed
in connexion with the removal of cell débris resulting from any injury. Numbers of phagocytes may be found at work in this direction, for instance in the pus formed within an aseptic abscess. Hence we may regard the phagocytes as acting as the scavengers of the tissues.

In the instances we have been dealing with the phagocytes are chiefly of the class of wandering cells and are brought to the seat of their activity by the blood. In examining any tissue where the process is going on it is seen that the phagocytes have accumulated there in large numbers. They have been attracted to the damaged area. The mechanism which effects this attraction is a chemical one—chemotaxis. At the seat of the change chemical substances are produced which act upon the phagocytes, causing them to migrate towards the source—positive chemotaxis. Apparently the material dissolving from cell débris can act in this manner. Thus if a capillary tube filled with a tissue extract be inserted under the skin of an animal, within a short time it will be found to be surrounded with numbers of leucocytes, which may also have encroached into the tube itself. As in other instances of chemotaxis the same chemical stimulus in a higher concentration may repel the cells—negative chemotaxis. Instances of this are especially frequent in relation to micro-organisms and phagocytes, to which we may now turn.

That phagocytes can paralyse, kill and digest many micro-organisms is the main fact in Metchnikoff’s theory of the nature of immunity. The reaction may be readily studied by injecting a small quantity of a fluid culture of some mildly pathogenic organism into the peritoneal cavity of an animal, and in the course of an hour or so examining a smear from the surface of the omentum, when an abundance of phagocytes enclosing the organism in different stages of digestion will be found. Or we may adopt Leishman’s method, in which a few drops of human blood are diluted with saline solution and centrifuged. The layer of white corpuscles is pipetted off, suspended in serum, and a minute drop of a suspension of a pathogenic organism is added. The preparation is then incubated at 37° C. for a quarter of an hour. Upon examining a drop of this mixture a number of bacteria are found within the phagocytes. Thus this attack and destruction of bacteria by phagocytes may take place within the body or by cells removed from the body. Whether or no a phagocyte can engulf bacteria is dependent upon a number of factors—partly specific properties of the phagocyte, partly factors varying with the constitution of the body serum. Thus Wright and Douglas, employing Leishman’s method, have proved that leucocytes do not take up bacteria freely unless the serum in which they are suspended contains opsonins. They found, for example, that leucocytes taken from a patient suffering from a pyococci infection if suspended in normal human serum take up the cocci abundantly, whereas if the same leucocytes are suspended under similar conditions in the patient’s own serum the reaction may be almost absent. Further, leucocytes taken from a normal individual and suspended in the patient’s serum are practically inactive, while the same phagocytes in normal serum are very active. Exactly how the substance in the serum acts is undecided, but it has been proved that there are in serum substances which become fixed to bacteria and which render them an easier prey to the phagocytes. This specific opsonin is used up when the bacteria are added to the serum, so that if the bacteria are subsequently removed the serum is no longer active. There is evidence too that there is a multiplicity of opsonins. As to the origin of the opsonins we have no certain evidence. It is suggested that they are a secretion from the leucocytes themselves and that it is an evidence of another and preliminary mode of attack possessed by the leucocyte, viz. the discharge of a secretion from the cell which is to damage or paralyse the bacterium and thus enable the phagocyte to engulf it.

The mechanism of destruction of a bacterium once it has been taken up by a phagocyte is probably, just as in the instance of dead cellular material, one of intracellular digestion. The bacterium before being engulfed is probably inert in most instances, though it may yet prove too strong for the phagocyte. The next stage we can trace is the formation of a vacuole around the organism, or, if the latter be large, around a part of the organism, and the part thus surrounded quickly shows signs of destruction. For instance, its staining reactions become weaker. When a part only of the organism is surrounded by a vacuole the part thus surrounded soon ceases to stain, while the remaining part stains normally, and we thus have a marked contrast evidencing the two stages.

In the next place we must ask which are the cells possessing phagocytic powers? Leaving apart the cells lining the alimentary tract (because we know practically nothing of their power in this respect) a number of free cells possess amoeboid properties as well as also a number of fixed cells. These latter are attached to certain spots of a tissue, but are capable of throwing out processes which can seize upon particles of foreign matter or even upon certain elements of the same organism. Of this category Metchnikoff distinguishes the nerve cells, the large cells of the spleen pulp and of lymph glands, certain endothelial cells, the neuroglia cells, and perhaps certain cells of connective tissues. All these elements can under certain conditions act as phagocytes, and with the exception of the nerve cells all are of mesoblastic origin. Those of greater importance on account of their greater activity in this respect are the large splenic and lymph cells, the neuroglia cells and certain endothelial cells. With regard to the wandering cells Metchnikoff considers that some are certainly non-phagocytic, for instance the lymphocytes. According to Metchnikoff it is only when these cells become older and have developed a nucleus rich in chromatin and an abundant cell body that these cells develop phagocytic properties. This is the large hyaline leucocyte. The polymorphonuclear and the eosinophil leucocyte are both phagocytes. Metchnikoff therefore divides the phagocytes into two classes—the microphages, comprising the polymorphonuclear and the eosinophil cell, and the macrophages, containing the large hyaline cell, the cell of the spleen pulp, the endothelial cell and the neuroglia cell. From further observation of these cells he concludes that the microphages are chiefly concerned in opposing the micro-organisms of acute infections, whereas the macrophages are chiefly concerned in combating chronic infections. It is the macrophage also which is concerned in removing cell débris, e.g. red corpuscles from a haemorrhage or the red corpuscles of another animal which may have been introduced experimentally.

Metchnikoff and his co-workers have shown that the two principal groups of leucocytes are generally spread throughout the vertebrates. Thus instances of each kind are found even in the lamprey, though here their staining properties are feebler; also in the lungfish. There are but small differences from the amoeboid cells of mammals are found in the alligators. (T. G. B.)
always ⌗, the lower one very large and inclined forwards, and the canines normally ⌘, of which the inferior is always minute, and in one genus generally absent. The molars number either ⎦ or ⌘. All the species here discussed are included in the sub-family Phalangeridae, of which the distinctive features, as well as those of the family Phalangeridae, are referred to under Marsupialia.

The most generalized representatives of the group appear to be the ring-tailed phalangers, constituting the genus *Pseudochirus*, which is common to Australia, Tasmania and New Guinea, and hairied ears. There are six pairs of cheek-teeth, of which the last three are small and rounded, with blunted cusps, while the anterior teeth are sharp and of insectivorous type. The pimpy flying-phalanger feeds on honey from flowers and insects.

In so far as is known the primitive carcinoid relations between *Acrobates* and *Petaurus*, although without a parachute, are the beautiful little dormouse-phalangers, as typified by *Dromicia nana*, which range from Western Australia and Tasmania to New Guinea. They appear to be a generalized type, which has died out without ever having come into competition with the more specialized forms. Although unable to fly they are exceedingly active, and take long leaps from bough to bough; externally they are characterized by their dormouse-

Fig. 1.—Skull of Grey Cuscus (*Phalanger orientalis*).

includes at least half a score of species. The dentition is generally i. 3, 4, 5, 3, 2, +m. 3, but one upper incisor and the canine may be wanting. The crowns of the molars show a crescentic structure, but they are said to retain the three primitive cusps, which are fused in the other genera. The prenasal tusk has its tip nacked for a short distance, and the whole of the terminal third and the under surface of the remainder short-haired, the tip being generally white. The hair is thick and woolly, and generally yellowish-olive in colour. These phalangers are the ring-tailed oppossums of the Australians. From this genus is apparently derived the taguan flying-squirrel, or flying-phalanger (*Petauroides volans*), which ranges from Queensland to Victoria, and is the largest of the flying ground-phalangers, of dentition is essentially similar to that of *P. orientalis*, although there is one pair less of cheek-teeth, and the bushy tail is nacked and prehensile at the tip. Reverting to the non-flying species, we have *Gymnobelideus teudaberi*, a small animal from Victoria representing a genus by itself, with the same dental formula as *Pseudochirus*, but cheek-teeth of a different type, the ears nacked (instead of hairy) behind, glands on the chest and between the ears, and the tail long and evenly bushy to the tip. From this are evidently derived the flying-phalangers—flying-squirrels—of the genus *Petaurus*, which differ merely in the possession of a parachute, and are represented by several species, ranging from Australia (the Moluccas) to the Aru Islands, New Guinea, New Zealand, and New Ireland. Of the yellow-bellied species, *P. australis*, the habits are described by J. Gould as follows: "This animal is common in all the bushes of New South Wales, particularly those which stretch along the coast from Port Phillip to Moreton Bay. In these vast forests trees of one kind or another are perpetually flowering, and thus afford a never-failing supply of the blossoms upon which it feeds; the flowers of the various kinds of gums, some of which are of great magnitude, are the principal favourites. Like the rest of the genus, it is nocturnal in its habits, dwelling in holes and in the spouts of the larger branches during the day, and displaying the greatest activity at night while running over the small leafy branches, frequently even to their extreme extremities, in search of insects and the honey of the newly opened blossoms. Its structure being ill adapted for terrestrial habits, it seldom descends to the ground except for the purpose of passing to a tree too distant to be attainable by springing from the one it wishes to leave. The tops of the trees are traversed by this animal with as much ease as the most level ground is by such as are destined for terra firma. If charged on foot to flight it ascends to the highest branch and performs the most enormous leaps, sweeping from tree to tree with wonderful address; a slight elevation gives its body an impetus which with the expansion of its membrane enables it to pass to a considerable distance; as it alights at the extremity of the leap; by this ascent the animal is prevented from receiving the shock which it would otherwise sustain."

A second species, *P. scierus*, in some ways one of the most beautiful of all mammals, is shown in Fig. 2.

Precisely similar relationship exists between the tiny feather-tailed phalanger, *Distoechurus pennatus*, of New Guinea, and the equally minute pimpy flying-phalanger or flying-mouse, *Acrobates pygmaeus*, of Queensland, New South Wales and Victoria; both being characterized by the hairs of the tail forming a vane on each side, as well as by tufts of long hairs at the base of the thinly-

Fig. 2.—Squirrel Flying-Phalanger (*Petaurus scierus*), like form, large, thin, and nearly naked ears, without tufts inside or at the base, sharp and rudimentary front claws and long sharp hind ones, and mouse-like tail, which is furry at the base, then scaly, and naked and prehensile at the tip. There may be either six or seven pairs of cheek-teeth, of which the hinder carry four or five small smooth cusps, and the first upper incisor is much longer than the other two. The striped phalangers (*Dactylotos*) are larger animals, of the approximate size of a squirrel, easily recognized by the longitudinal yellow and black striping of the fur, and the slender and elongated fourth front toe. The typical *D. trivirgata* is common to north Australia and New Guinea, but *D. palpator*, which has the fourth toe still more elongated, is exclusively Papuan. They have seven pairs of cheek-teeth, of which the four last are oblong and four-cusped; and the first lower incisor is longer than in any other phalanger. They apparently feed on both leaves and grubs, probably extracting the latter from crannies with the elongated toe. The tail is more or less bare on the under side of the tip.

The last group of the sub-family is represented firstly by the cuscuses, or cuscuses (*Phalanger*), which are arboreal animals of the approximate size of cats, and range from the Solomon Islands through New Guinea and the Moluccas to Celebes, being, in fact, the only Old World marsupials found westwards of New Guinea. Externally they are characterized by their thick woolly fur, short or medium ears, which are hairy outside, and sometimes inside as well, by the naked and striated soles of the feet, and the long and markedly prehensile tail, of which the basal half is furred like the body, and the terminal half entirely naked. The number of cheek-teeth varies, owing to the frequent absence of some of the front ones, but there are generally seven pairs, of which the last four carry crescents internally and cusps externally. About ten species are known, of which the grey cuscus (*P. orientalis*) of Ambonay and Timor was discovered about 300 years ago, and was thus the first known Old World marsupial. In the spotted cuscus (*P. maculatus*) the males are marked with orange and white, while the females are uniformly greyish. Cuscuses are sleepy animals, feeding mainly on leaves, but also devouring birds and small mammals.

Nearly allied to the cuscuses are the typical Australian phalangers, or oppossums, forming the genus *Trichosurus*. They differ from the cuscuses, among other features, by the thick and non-tapering tail being covered with bushy hair up to the extreme tip, which is naked, as is a narrow line along the middle of the terminal third
PHALANX—PHALTAN

(or rather more) of the lower surface, by the presence of a gland on the chest, and by the soles of the hind feet being hairy. In the skull the upper canine is separated from the outermost incisor, instead of close to it as in the cucususes (fig. 1). The best-known species described, phalanger (Phalanger, T. vulpecula, of Australia, an animal of the size of a small fox, represented in Tasmania by the brown phalanger (T. vulpecula fuliginosus). The short-eared phalanger (T. canina) represents the group of bush-phalangers, of which 'comb' or 'bundle' is a synonym. The coat formula in both is t. c., p. d., m., m. These animals are wholly arboreal and mainly nocturnal in their habits; and it is these which form the chief game in "opossum-shooting" among the gum-trees by moonlight.

The long-nosed phalanger is referred to under Marsupialia.

(R. L.*)

PHALANX (Gr. φάλανξ, of unknown origin), the name, in Greek history of the arrangement of heavy-armed infantry in a single close mass of spearmen (see ARMY: History). In anatomy, the Latin plural phalanges is the term applied to the bones of the finger and toe, and in botany to a group of united stamen clusters. The term "phalax," was adopted by F. C. M. Fourier (p.v) as the name of the socialistic community living in a "phalanstery.

PHALARIS, tyrant of Acragas (Agrigentum) in Sicily, c. 570–554 B.C. He was entrusted with the building of the temple of Zeus Atabury in the citadel, and took advantage of his position to make himself despot (Aristotle, Politics, v. 10). Under his rule Agrigentum seems to have attained considerable prosperity. He supplied the city with water, adorned it with fine buildings, and strengthened it with walls. On the northern coast of the island the people of Himera elected him general with absolute power, in spite of the warnings of the prophet Telemachus (see Stesichorus, Acharnians, Rhesus, etc.), and he succeeded in making himself master of the whole of the island. He was at last overthrown in a general rising headed by Thermus, the ancestor of Theron (tyrant c. 438-472), and burned in his brazen bull.

After ages have held up Phalaris to infamy for his excessive cruelty. In his brazen bull, invented, it is said, by Perillus of Athens, the tyrant's victims were shut up and, a fire being kindled beneath, were roasted alive, while their shrieks represented the bellowing of the bull. Perillus himself is said to have been the first victim. There is hardly room to doubt that we have here a tradition of human sacrifice in connexion with the worship of the Phoenician Baal (Zeus Atabury) such as prevailed at Rhodes; when misfortune threatened Rhodes the brazen bulls in his temple bellowed. The Rhodians brought this worship to Gela, which they founded colonially in the 6th century (see also Gela and Thera), and from there it passed to the mainland. Human sacrifices to Baal were common, and, though in Phoenicia proper there is no proof that the victims were burned alive, the Carthaginians had a brazen image of Baal, from whose down-turning eyes the children slid into a pit of fire; and the Phocaeans of Minos had a brazen man who pressed people to his glowing breast points to similar rites in Crete, where the child-devouring Minotaur must certainly be connected with Baal and the favourite sacrifice of the island.

The story of the bull cannot be dismissed as pure invention. Pindar (Pythia, i. 185), who lived less than a century afterwards, expressly associates this instrument of torture with the name of the tyrant. There was certainly a brazen bull at Agrigentum, which was carried off by the Carthaginians to Carthage, whence it was again taken by Scipio and restored to Agrigentum. In later times it became a popular excursion. Its preservation at the present time is due to the fact that all the figures of Phalaris were destroyed with his person on the occasion of the defeat of the Carthaginians, and that the bull, which was restored to Agrigentum in 1883, is the only one in existence. Phalaris may thus have been one of those men who combine justice and even humanity with religious fanaticism (Suidas, s.v.; Diod. Sic. ix. 30; Pliny, H. N. xiii. 115; Theopom. De Officiis, ii. 7, iii. 6).

The letters bearing the name of Phalaris (148 in number) are now chiefly remembered for the crushing exposure they received at the hands of the writer of the Secret History. Bentley's Discovery in 1695 of the writings of Bentley: Dissertation on Phalaris, which he published an edition of them in 1695. The first edition of Bentley's Dissertation on Phalaris appeared in 1697, and the second edition, replying to the criticism which he published the following year. To the first edition of the work published in 1696. In the first edition of the book in 1696. In the second edition in 1697. In the third edition in 1698. In the fourth edition in 1699. In the fifth edition in 1700. In the sixth edition in 1701. The name is not mentioned in the letters of Phalaris, and the names of the phalanges, from the imitations of authors (Herodotus, Demosthenes, Euripides, Callimachus) who wrote long after he was dead, from the reference to tragedies, though tragedy was not yet invented in the lifetime of Phalaris, from the dialect, which is not Dorian but Attic, Nag. or Late Attic, as well as from absurdities in the matter, and the entire absence of any reference to Phalaris by any writer before Stobaeus (c. A.D. 500), Bentley sufficiently proved that the letters were written by a sophist or rhetorician (possibly Marcus Cato, who died c. A.D. 120) nearly two centuries before the death of Phalaris. Suidas admired the letters, which were written, and in modern times, before their exposure by Bentley, they were thought highly of by some (e.g. Sir William Temple in his Essay on Ancient and Modern Learning), though others, as Politianus and Erasmus, perceived that they were not by Phalaris. The latest edition of the Epistles is by R. Hercher, in Epistolographi graeci (1873), and of Bentley's Dissertation by W. Wagner (with Introduction and notes, 1853); see especially R. C. Jebb, Life of Bentley (1882).

PHALLICISM, or PHALLOS (from Gr. φάλλος), an anthropological term applied to that form of nature worship in which adoration is paid to the generative function symbolized by the phallus, the male organ. It is common among primitive peoples, and has been prominent also among more advanced peoples, e.g. the Egyptians and the Greeks. In its most elementary form it is associated with frank orgiastic rites. This aspect remains in more advanced forms, but gradually it tends to give place to the joyous recognition of the principle of natural reproduction. In Greece for example, where phallicism was the essence of the Dionysiac worship and a phallic revel was the origin of comedy (see also Hermes), the purely material and the symbolic aspects no doubt existed side by side; the Orphic mysteries had to the intellectual Greeks a significance wholly different from that which they had to the common people. Phallic worship is specially important as marking the end of the Stone Age, as a form of adoration manifesting the fertilizing effect of sun and rain, the savage source to promote the growth of vegetation in the spring by means of symbolic sexual indulgence. Such were the rites which shocked Jewish writers in connexion with the worship of Baal and Astathor (see Baal, and cf. Atargates, Ishhtar). The same principle is at the root of the widespread nature worship of Asia Minor, whose chief deity, the Great Mother of the Gods (g.v.), is the personification of the earth's fertility; similarly in India worship is paid to divine mothers. Generally it should be observed that phallic worship is not specially or primarily paid to male deities, though commonly the more important deity is accompanied by a companion of the other sex, or is itself androgynous, the two symbols being found together.

In the Dionysiac rites the emblem was carried at the head of the processions and was immediately followed by a body of men dressed as women (the ithyphallii). In Rome the phallicus was the most common amulet worn by children to avert the evil eye: the Latin word was fascinum (cf. Phiny, Nat. Hist. xix. 50, satyricos signa; Varro, Ling. Lat. vii. 97, ed. Müller). Pollux says that such emblems were placed by smiths before their forges. Before the temple of Aphrodite at Hierapolis (g.v.) were two huge phalli (180 ft. high), and other similar objects existed in all parts of the ancient world both in statuary and in painting. Among the Hindus (see Hinduism) the phallicus is called linga or lingas, with the female counterpart called yoni: the linga symbolizes the generative power of Siva, and is a charm against sterility. The rites classed together as Sakta puja represent the adoration of the female principle. In Mexico, Central America, Peru and other parts of America phallic emblems are found. The tendency, however, to identify all obelisk-like stones and truncks, together with rites like circumcision, as remains of phallic worship, has met with much criticism (e.g. Robertson Smith, Religion of the Semites, 2nd ed., pp. 456 sqq.).

For authorities see works quoted under Religion: §§ A and B.

PHALTAN, a native state of India, in the central division of Bombay, ranking as one of the Satara jagirs. Area, 397 sq. m.; pop. (1901), 457,739, showing a decrease of 31% in the decade. The estimated revenue is £13,000, and the tribute £640. The chief, whose title is nimbalkar, is a Mahatta, tracing his descent to a grantee from a Delhi emperor in the 14th century. The town of Phaltan is 37 m. north-east of Satara; pop. (1901), 9512.
PHANARIOTES—PHARISEES

PHANARIOTES, a name derived from Phanar, the chief Greek quarter at Stamboul, where the eccenomical patriarchate is situated, and applied to those members of families resident in the Phanar quarter who between the years 1771 and 1821 were appointed hospodars of the Danubian principalities; that period of Moldo-Wallachian history is also usually termed the Phanariote epoch. It is not to be understood as marking the introduction into the principalities of the Greek element, which had already established itself firmly in both provinces, to both of which Greek princes had been appointed before the 18th century. But whereas the Greek families of earlier introduction gradually became merged in their country of adoption, the later immigrants retained their separate nationality and grew to be powerful agents for furthering the spread of Graecism in the principalities. The person raised to the princedly dignity was usually the chief dragoon of the Sublime Porte, and was consequently well versed in contemporary politics and the statecraft of the Ottoman government. The new prince, who was compelled to purchase his elevation with a heavy bribe, proceeded to the country which he was selected to govern, and of the language of which he was in nearly every case totally ignorant, accompanied by a horde of needy hangers-on; he and his acolytes counted on recouping themselves in as short a time as possible for their initial outlay in laying by a sufficiency to live on after the termination of the prince's brief authority. It was the interest of the Porte to change the princes as often as possible, as the accession donation thus became due more frequently. When, owing to the numerous cases of treachery among the princes, the choice became limited to a few families the plan was hit upon of frequently shifting the prince from one province to the other: the prince of Wallachia, the richer of the two principalities, was always ready to pay a handsome douceur to avert his transfer to Yassy; the prince of Moldavia was equally ready to bribe his supporters at Constantinople to secure his appointment to Wallachia. To raise funds to satisfy the rapacity of the Porte the princes became past masters in the art of spoliation, and the inhabitants, liable to every species of tax which the ingenuity of their Greek rulers could devise, were reduced to the last stage of destitution. The active part taken by the Greek princes in the revolt of 1820—21 induced the Porte to revert to the appointment of native princes.

PHANIAS, of Eresus in Lesbos, Greek philosopher, important as an immediate follower of and commentator on Aristotle, came to Athens about 332 B.C., and joined his compatriot, Theophrastus, in the Peripatetic school. He wrote works entitled Analytica, Categorica and De Interpretatione, which were either paraphrases or critical commentaries, and seem to have added little to Aristotle's own writings. Alexander of Aphrodisias refers to a work πρὸς Διδωρυκαν, and Athenaeus quotes from another treatise, Against the Sophists. Outside philosophy, he and Theophrastus carried on the physical investigations of Aristotle; Athenaeus frequently quotes from a work on botany which manifests great care in definitions and accuracy of observation. From Plutarch (Life of Themistocles) we learn that he was regarded as an historian of importance. The chief of his historical works is the Pryianeis Eresii, which was either a history of his native place or a general history of Greece arranged according to the period of the Eresian magistracy. He wrote also works on the Tyrants of Sicily and on tyranny in general. The value of these books is attested by the frequency with which they are quoted on questions of chronology (e.g. by Plutarch, Suidas, Athenaeus). To the history of Greek literature he contributed works on the poets and on the Socratres, both of which are quoted.

He must be distinguished from another Phanias, a Stoic philosopher, disciple of Posidonius. Diogenes Laërtius mentions a work of his which he compares Posidonius with, arguing from physical principles.

PHANOCLES, Greek elegiac poet, probably flourished about the time of Alexander the Great. His extant fragments show resemblances in style and language to Philetas, Callimachus and Hermesianax. He was the author of a poem on paederasty. A lengthy fragment in Stobaeus (Florilegium, 64) describes the love of Orpheus for the youthful Calais, son of Boreas, and his subsequent death at the hands of the Thracian women. It is one of the best extant specimens of Greek elegiac poetry.

See N. Bach, Philoletae, Hermesianicis et Phanoclesi relicisque (1825); L. Preller, Ausgewählte Aufsätze aus dem Gebiete der klassischen Alterthumswissenschaft (1864).

PHANTASMAGORIA, a name invented by a certain Philipstal in 1802 (from Gr, φαντασμαγορα, phantasm, apparition; and ἀγών, assembly) for a show or exhibition of optical illusions produced by means of the projecting lantern (q.v.). The word has since been applied to any rapidly or strikingly changing scene, especially to a disordered or fantastic scene or picture of the imagination.

PHARAOH (Par'oh), the Hebraized title of the king of Egypt (q.v.), in Egyptian Per'-o'; Phoron in Herodotus represents the same. Its combination with the name of the king, as in Pharaoh-Necho, Pharaoh-Hophra, is in accordance with contemporary native usage: the name of the earlier Pharaoh Shishak (Sheshonk) is rightly given without the title. In hieroglyphic a king bears several names preceded by distinctive titles. In the IVth Dynasty there might be four of the latter: (1) identifying him with the royal god Horus; the name is commonly written in a frame representing the façade of a building, perhaps a palace or tomb, on which the falcon stands. (2) connecting him with the vulture and uraeus goddesses, Nekhab and Buto of the south and north. (3) a hawk on the symbol of gold, signifying the victorious Horus. (4) the old titles of the rulers of the separate kingdoms of Upper and Lower Egypt, to be read sti, "butcher(?)" and byti, "bekeeper(?)"). The personal name of the king followed (4), and was enclosed in a cartouche apparently symbolizing the circuit of the sun which alone bounded the king's rule. Before the IVth Dynasty the cartouche is seldom found: the usual title is (1), and (3) does not occur. In the Vth Dynasty the custom began of giving the king at his accession a special name connecting him with the sun: this was placed in the cartouche after (4), and a fifth title was added: (5) Si-rê, "son of the Sun-god," to precede a cartouche containing the personal name. The king was briefly spoken of by his title sti (see 4), or hum-f, "his service," or Hiy, "liege-lord." These titles were preserved in the sacred writing down to the latest age. An old term for the royal palace establishment and estate was Per-o, "the Great House," and this gradually became the personal designation of Pharaoh (cf. the Grand Porte), displacing all others in the popular language.

PHARI, a town of Tibet. It is supposed to be the highest and coolest town in the world, being 15,000 ft. above the sea. As it commands the road between the Chumbi Valley and Lhasa and also one of the chief passes into Bhutan, Phari is of considerable military importance, and is defended by a large fort or Jong, which was occupied by the British expedition of 1904. Phari Jong is supposed to have been built about 1500 A.D., and was enlarged or rebuilt in 1792, under Chinese advice, as a defence against the British. It has the appearance of a medieval castle, and seems to have been built in imitation of the European style.

PHARISEES, a sect of the Jews first mentioned by Josephus, in his account (Ant. xiii. 5, 9) of the reign of Jonathan, the brother and successor of Judas Maccabaeus. The name, which may be translated "Separatists," indicates their devotion to the ideal, enforced by Ezra and Nehemiah upon the reluctant Jews, of a nation separate from all other nations in virtue of its
PHARMACOLOGY

peculiar relation to Yahweh (Neh. ix.). This ideal nation consisted of all who were prepared to obey the Law of Moses, irrespective of their natural descent. Consequently the Pharisees, who seem to have been an order of religious teachers, were concerned to make converts (proselytes), and some of their greatest teachers were of non-Jewish parentage. They were also concerned to insist upon the strict observance of the Law, so far as it was compatible with the exigencies of ordinary life, and to train disciples who should set a proper example to the mass of the people.

The ideal of separation descended from the Great Synagogue (Assembly) of the time of Ezra to the Synagogue of the Hasidaeans (Assidheans), who allied themselves with Judas Maccabaeus. The Pharisees decided upon the observance of the Sabbath, in order that the true Jews might be discerned from idolaters; and thus were able to keep the Law as a whole. This action of the Hasidaeans is clearly the practical outcome of the principle which Josephus describes in the language of philosophy as the characteristic of the Pharisees—"some things and not all are the work of Fate" (Ant. xiii. 5, 9). Fate is the Stoic term for God; and these forerunners of the Pharisees judged that the time had come for them to take action rather than to wait passively on God. But then and always the prime concern of the Pharisees was the extension of God's sovereignty (the Kingdom of God) throughout the world. God's will, which all men should obey, was revealed in the Law, and He himself appointed governors over them. He remained their King, and noextérieur who was not a prophet—God's mere mouthpiece—could command their unquestioning obedience. When Judas reconquered Jerusalem and re-dedicated the desecrated Temple, his work, from the Pharisees' point of view, was done. The Temple-worship was part and parcel of the Divine plan, and a legitimate High Priest was necessary. Alanius was, therefore, welcomed by the Hasidaeans, and only his treacherous murder of sixty of their number taught them that any Syrian nominee was their enemy. Later they acquiesced in the election of Simon to the high-priesthood with the condition "until there should arise a faithful prophet"; but some of them renounced the combination of the sacred office with the position of political ruler in the person of John Hyrcanus as contrary to the precedent set by Moses at his death. When Alexander came to the throne the Pharisees were the real rulers and imposed upon the people the deductions from the written Law which formed the growing body of their oral tradition. Their reign was long enough to establish this tradition in respect of ritual, and even when this golden age—as it seemed to later Scribes—was over they exercised a paramount influence upon the common people.

They had learned to read God's will in the events of history, and deduced (for example) the doctrine of the resurrection of the dead from the death of the martyrs under Antiochus Epiphanes and Alcimus. And what they learned from current history and from the ancient history of the nation recorded in Scripture they taught in the synagogues, which corresponded not merely to the parish churches but also to the schools—day schools and Sunday schools—of to-day. Apart from their control of public education, their power was enhanced by their efforts to better the position of women, and by their notorious leniency in the matter of punishments. Everything—the repeated statements of Josephus and the facts of Jewish history after a.d. 70—goes to show that the Pharisees moulded the religion of the people. Attempts have been made in modern times to represent the Apocalyptists as opposed to the Pharisees and as occupying the position in popular estimation which Josephus ascribes to the Pharisees. But for such representations there is no solid ground. Superficially the language of apocalypses differs from that of rabbinic decisions, and where the seer takes a comprehensive view of the ages the rabbi legislates for particular cases. But even in the Talmud the reign of Alexander is described in apocalyptic language such as is commonly applied to the future age, and if allowance be made for the symbolism proper to revelations it is clear that essentially the scribe and the seer have the same purpose and even the same doctrines. The Pharisees were occupied with the piecemeal realization of the dreams of their supposed opponents, which gain a vague glory from their being far off.

The Greeks generally have left upon the minds of men an impression unfavourable to the Pharisees, due to the denunciations attributed to our Lord and assigned—with obvious injustice in some cases—to the scribes of this sect. It is to be remembered that the Pharisees were the only sect of the Jews who survived in Christian times and that the Pharisees were never a homogeneous body possessed of a definite policy or body of doctrine. Moreover it is clear that our Lord denounced not all the Pharisees but the hypocrites only, as did the rabbis whose sayings are reported in the Talmud and other Jewish books. Again the third gospel in particular betrays relations between the Pharisees and Jesus very different from those of the rabbinic view, which conjures up an impossible picture of an absolute breach between the Prophet of Nazareth and the whole corporation of the Pharisees as a result of a quarrel with certain members of that dissident sect of independent thinkers. Gamaliel and his pupil St Paul are better representatives of the non-hypocritical Pharisee; and the Pauline Epistles or the writings of Philo are the best extant examples of the manner and matter of their teaching. As for the denunciations, apart from the charge of insincerity, it appears that the scribes in question are pilloried for the defects—or the excesses—of their qualities. Indeed they are corroborative evidence for the reverence with which the Pharisees were regarded by the people generally, and for the conjuring with which they strove to fulfil God's will as contained in the Law and elucidated by the Tradition.

(J. H. A. II.)

PHARMACOLOGY. Systematic writers on the subject differ considerably in the exact meaning which they attach to the term pharmacology (φάρμακον, a drug; λόγος, a discourse), some making it much more comprehensive than others. Binz, for instance, defines it as treating of the origin, nature, chemical and physical qualities, physiological actions, and therapeutic uses of drugs; in France and in Italy it is restricted to the mere description of medicines and their preparations, the action and uses of which are described in the term therapeutics. In English-speaking countries, and by the majority of German writers, the meaning is now restricted to the study of the action of chemical substances (as apart from foods) on all kinds of animals, from bacteria up to man; it is, in fact, a comparative study of the action of chemical bodies on invertebrate and vertebrate animals. One of its practical aims is to obtain a wide and accurate knowledge of remedial substances in relation to their application in the treatment of disease, while another is to discover new or improved remedies. This meaning of the word has now become fixed in the English language by use and wont. The term pharmaco-dynamics (φάρμακον, δύναμις, power), which is etymologically more correct, is often used as its equivalent, but it has never become widely adopted. The study of pharmacological actions was at first almost entirely confined to those of remedial agents, and especially to the remedies in the different national pharmacopœias, but in many cases it has now been extended to substances which are not used for curative purposes. The introduction into practical use of many medicines, such as paraldehyde, phenazonia and strophanthus, has followed the study of their actions on animals, and this tends to be more and more the case. Pharmacology is a branch of biology; it is also closely connected with pathology and bacteriology, for certain drugs produce structural as well as functional changes in the tissues, and in germ diseases the peculiar symptoms are caused by foreign substances (toxins) formed by the infective organisms present in the body. The effects of many of these toxins bear a close resemblance to the action of certain well-known drugs, as in the case of tetanus toxin and streptolysin, and are studied by the same methods of observation and research. It is impossible also to dissociate pharmacology from clinical therapeutics; the former investigates the agents which are used in the treatment of disease, the latter is concerned with their remedial powers and the conditions under which they are to be used. Hence the word "pharmaco-therapy" has come into
use, and most of the newer standard textbooks combine together the consideration of pharmacology and therapeutics. Pharmacology is also related to toxicology, as many remedial and other agents are more or less poisonous when given in large doses, but it does not include the detection, tests, and the other strictly medical methods of poisoning.

Pharmacology proper began as the result of the application of strictly experimental methods to physiology. The discovery (early in the 19th century) that plants owe their remedial and poisonous qualities to small quantities of definite active principles, such as alkaloids and neutral bodies, which can be extracted in a chemically pure condition, had also a very important effect on its development. We meet first with experiments made by investigators who perceived that observations on man and animals might lead to a better understanding of the action of drugs. In 1766 Wepfer and Conrad Brunner demonstrated on dogs the tetanizing action of nux vomica, and similar rough experiments were repeated from time to time with other substances by later investigators. In 1755 Menghini published an elaborate study of the action of camphor on a great variety of different kinds of animals. Albert von Haller (b. 1708) sought to elucidate the action of remedies by observations on healthy men, and in 1767 William Alexander made experiments on himself with drugs, which were, however, brought to an abrupt termination by his nearly killing himself. In 1776 Daries, by observations on himself and on cats, established the mydriatic action of belladonna and other atropoaceous plants. Hitherto no attempt had been made to determine what particular parts of the body were especially affected by drugs, but Fontana showed, in his great work (Florence, 1765) on the venom of the viper and on other poisons, that the general symptoms were brought about by an action on particular organs. He performed more than six thousand experiments, more than four thousand of which were on animals, and he determined the effects on the heart and other important structures. These analytical methods of research were well known to the second Monro in Edinburgh, and to his pupils, one of whom, William Alexander, wrote a thesis in 1790 entitled "De partibus corporis animalis quae viribus opii parent." His methods were doubtless known also to the French physiologist Magendie, who improved upon them, and who in 1809 published a research on the Uapas Touéf and other strychnine-containing plants, in which he showed that their effects were due to an action on the spinal cord. The researches of his pupil, Claude Bernard, on curare, were equally exact and logical, and have served as the model for many subsequent investigations. In consequence, from the time of Magendie pharmacology may be said to have been put on a more exact basis. By the middle of the 19th century there were many workers on the subject, and the actions of such drugs as digitalis, morphine, alcohol, and many others had been frequently and minutely investigated. About this time Buchheim, professor of materia medica in Dorpat from 1846 to 1879, founded the first pharmacological laboratory on modern lines in Europe, and he introduced a more rational classification of drugs than had hitherto been in use, arranging them in groups according to their pharmacological actions. In the herbs and older treatises on materia medica and therapeutics no explanation is usually offered of the action of medicines, and in such works as that of Cullen (1789) only a few of the more obvious actions are occasionally explained according to the current theories of physiology and pathology. In works such as Pareira's Elements of Materia Medica and Therapeutics (1842), the physiological effects of medicines are usually described, but very briefly as compared with the materia medica. At the present day most textbooks dealing with medicinal agents and treatment devote a large part of their space to pharmacology, and a corresponding change has taken place in the teaching of the subject in universities and medical schools. Since Magendie's time numerous papers dealing with pharmacological subjects have appeared in the Journal of Anatomy and Physiology, the Journal of Physiology, Virchow's Archiv, and the principal medical periodicals of all countries. In 1873 the Archiv für experimentelle Pathologie und Pharmakologie first appeared, in 1893 the Archives Internationales de Pharmacodynamie, and in 1900 The Journal of Pharmacology and Therapeutics (published at Baltimore, U.S.A.), all of which are chiefly or entirely devoted to pharmacology.

Methods of research are essentially those employed by physiologists, the action of substances being studied in the usual way on bacteria, leucocytes, frogs, rabbits and other animals. Not only are the general symptoms investigated, but it is necessary to carry out observations on the nerves, muscles, circulation, secretions, &c., so as to get a more exact knowledge of the reasons of the general action. It is true that many of these animals react somewhat differently to drugs, both as regards each other and as regards man, but for the most part the differences are quantitative rather than qualitative. After carrying out a series of observations on animals, the drug can be assigned to its special group, and a good idea can be obtained of its possible practical value or the reverse; hence there is a saving of time and an avoidance of the necessity of testing its effects on man. The action of a drug may be called direct when it acts on any part to which it is immediately applied, or which it may reach through the blood; and indirect when one organ is affected secondarily to another, as, for instance, in strychnine poisoning when the muscles are violently contracted as the result of the action of the alkalioid upon the spinal cord. In a few cases the action is merely physical, but most frequently it is chemical in its nature, and is exerted on the living cell, the activity of which is either stimulated or depressed. In some cases the substances actually enter into a chemical combination with the protoplasm, which may be temporary or (much less frequently) permanent; in other cases they seem simply to modify or disturb the usual chemical activity of the cells. Prolonged or excessive stimulation invariably leads to depression or paralysis, the tissues becoming fatigued, and from this condition they may recover or they may not. When we come to consider more in detail the results of these actions we find that the various secretions of the body, such as the sweat, gastric juice, bile, milk, urine, &c., may be increased or diminished; that the heart may have its muscular or nervous apparatus stimulated or depressed; that the nerve-centres in the brain, medulla and spinal cord may be rendered more sensitive or the reverse; and that the general metabolism of the body may be altered in various ways. In addition, the fluid constituents, such as the lymph and blood, may have their composition and bulk considerably altered, while the special senses, the temperature, and, in short, every function and tissue, may be more or less affected.

Some drugs given in excess are poisons to all forms of protoplasm, but when given in doses much short of the lethal they usually exhibit a distinct tendency to affect specially, and at an early period, certain organs or tissues, and hence result differences in action; others may act only on certain organs, leaving the others practically untouched. It is often possible by appropriate dosage to contrive that these special parts or organs may be affected and the rest of the body left practically intact, and it is by taking advantage of these selective actions that remedial or therapeutical effects are usually obtained. Some substances have a very wide range of action, and involve a great variety of structures, while others, such as purgatives, have a very limited sphere. The action of drugs is often modified by circumstances peculiar to the individuals or animals to whom they are administered. In man the most important of these circumstances is age, but speaking broadly this is really a question of bulk, the child being affected like the adult, but by smaller doses. There are exceptions to this, however, as children are more affected in proportion by opium and some other substances, and less by arsenic or mercury and arsenic. In old age also the nervous system and the tissues generally do not react so readily as in youth. Habit, race, personal temperament, emotional conditions, disease, the time and circumstances of administration, and other accidental causes may also modify the action in man. Some species of animals are much more susceptible to the action of certain drugs than others, a condition which depends on obvious
or unknown structural or metabolic differences. In the same way, some individuals show a special tendency to poisoning by doses of certain drugs which are harmless to the great majority of mankind, and hence we get unexpected or unusual results, these arising from special susceptibility on the part of certain organs. These idiosyncrasies are not confined to drugs, but are seen with a few articles of food, such as eggs and shellfish. It is well known that the habitual consumption of certain drugs, such as tobacco, Indian hemp, opium, arsenic, alcohol and many others, gradually induces a condition of tolerance to their effects, so that large doses can be taken without causing symptoms of poisoning. In all cases, however, there is a limit, and after it is reached the ordinary effects of these substances are seen. When, however, it is overcome, and show poisonous effects on each repetition of the dose. The degree of tolerance often differs in individuals at different times and in different circumstances, and may become lost by breaking off the habit for a short time. The explanation generally given is that the nerve and other cells become accustomed to the drug, so that they cease to react, or that an antitoxin is formed which antagonizes the poison, or that the poison is rapidly destroyed in the body. Recent research on arsenic and atropine, however, points to the leucocytes as playing an important part in the production of tolerance, as these gradually become capable of ingesting large amounts of the foreign substances, and thus render them more or less harmless to the tissues, until they are gradually excreted from the body. When the amount is too large to be dealt with by the leucocytes, poisoning seems to occur even in the most habituated. Tolerance is therefore analogous to, but not identical with, the immunity which takes place with the toxins of infectious diseases and snake poison. Certain substances, notably digitals, lead, mercury and strychnine, exhibit what is called a cumulative action—that is to say, when small quantities have been taken over a period of time, poisoning or an excessive action suddenly ensues. The explanation in these cases is that the drug is absorbed more rapidly than it is excreted, hence there is a tendency to accumulation in the body until a point is reached when the amount becomes poisonous.

Bodies which have a close resemblance in their chemical constitution exhibit a similar resemblance in their pharmacological action, and as the constitution of the substance becomes modified chemically so does its action pharmacologically. Numerous researches have demonstrated these points with regard to individual groups of substances, but hitherto it has not been possible to formulate any fixed laws regarding the relationship between chemical constitution and physiological action.

When drugs are swallowed no absorption may take place from the alimentary canal; but, as a rule, they pass from there into the blood. Absorption may also take place from the skin, from the rectum, from the respiratory passages, or from wounds, and from direct injection into the subcutaneous tissue or into a blood vessel. Very rarely, as in the case of silver salts, excretion does not take place; but usually the drug is got rid of by the ordinary channels of elimination. Just as drugs act upon the tissues, so they themselves are in many cases reacted upon, and broken up or altered. While in the alimentary canal they are subjected to the action of the digestive fluids and the varied contents of the stomach and intestines, and after absorption they come under the influence of the constituents of the blood and lymph, and of the chemical action of the tissue cells. Inorganic bodies, such as metals, may enter into albuminous combinations which may greatly modify their effects, and organic substances may be split up into simpler compounds by oxidation or reduction, or may be rendered more complex by synthesis.

The antagonism between certain drugs has been much studied in relation to their use as antidotes in poisoning, the aim being to counteract the effects rather than to obtain a direct physiological antagonistic action. Substances which directly antagonize each other by acting on the same tissue are few in number, but there are numerous instances in which the effects or symptoms may be obviated by acting on another tissue. Thus curare may stop strychnine convulsions, and chloroform may exercise the same effect by abolishing the irritability of the spinal cord. If two poisons act on the same tissue, one stimulating and the other paralysing it, the paralysing substance removes the action of the alimentant substance, not by bringing the tissue back to its normal state, but by abolishing its excitability; hence, although life may be saved by such an action, yet it can only be so within certain limits of dosage, because the antagonism is never complete at every point.

Speaking in the widest sense, every substance has an action on the body, whether poisonous or innocent; pharmacological substances have come to be limited to those which are used as drugs, or which have a distinct action upon the animal organism. Such substances are derived from (1) the chemical elements and their compounds; (2) plants; and (3) animals. The first class includes such substances as iodine, mercury, iron, carbon, and their various compounds, and such bodies as alcohol, chloroform and chloral, all of which are found in nature or can be prepared by ordinary chemical processes of manufacture. From plants many substances are obtained which at the present time we are unable to make in the chemical laboratory, and of the constitution or composition of which we are in many cases ignorant. Some of these, such as resins, gums, vegetable oils and fats, are readily obtained as natural exudations or by very simple manipulations, while others, such as the alkaloids, glucosides and vegetable acids, often require to be extracted by very complex processes. Substances obtained from animals include gland secretions, pepsin and other ferments, musk, cod-liver oil, &c., and to these may be added various antitoxins. The classification of substances having pharmacological actions presents so many difficulties that no satisfactory or universally adopted method has yet been proposed. Our knowledge presents so many gaps, and the mode of action of many remedies is so obscure and imperfectly understood, that any arrangement adopted must be more or less tentative in character. The close alliance between pharmacology, therapeutics and clinical medicine has induced many authors to treat the subject from a clinical point of view, while its relationships to chemistry and physiology have been utilized to elaborate a chemical and physiological classification respectively as the basis for systematic description. Certain writers in despair have adopted an alphabetical arrangement of the subject, while others have divided it up into organic, vegetable and animal substances. These last-mentioned methods are far behind our present state of knowledge, and need not be discussed here. The objection to a strictly chemical classification is, that while many substances closely allied chemically have a somewhat similar action in certain respects, yet in others they differ very widely—a striking example of which is given in the case of sodium and potassium. A physiological classification according to an action on the brain, heart, kidney or other important organ becomes still more bewildering, as many substances produce the same effects by different agencies, as, for instance, the kidneys may be acted upon directly or through the circulation, while the heart may be affected either through its muscular substance or its nervous apparatus. A clinical or therapeutic classification into such divisions as anaesthetics, expectorants, bitter, and so on, according to their practical applications, also leads to difficulties, as many drugs are employed for numerous purposes. The ideal method of grouping pharmacological substances would be in reference to their chemical action on living protoplasm, but as yet our knowledge is too scanty for this. At the present time the method adopted by Buchheim, or some modification of it, is the most scientific. As the result of painstaking investigations he grouped together all those substances having similar actions, giving to each group the name of its best-known or most thoroughly investigated member. Once the groups were more or less fixed any new substance could, when
PHARMACOLOGY

its action was determined, be referred to its own group, and thus be placed or classified. As few substances are absolutely identical in action, but only broadly similar, it is often difficult to divide sharply one group from another. In a résumé it is manifest, when pass in review many very pharmacological substances, and we shall therefore confine ourselves to those groups which are of practical importance. Many individual drugs are described under their own headings.

Group I. Acids.—This includes sulphuric, hydrochloric, nitric, phosphoric, tartaric, citric, ascorbic, and lactic acids, all of which give the action to their acidity. Many of the other acids, such as carbolic and salicylic, have specific effects which have no relationship to their acid reaction. The concentrated acids have an intense local action, the effects being limited to the part of the body in contact with them, with little or no increase of the effects when given by the mouth. When iron is injected directly into a vein it depresses the heart's action, the blood pressure and the nervous system, and during its excretion greatly irritates the bowel and the kidneys. When taken by the mouth, however, no injurious effects are produced. The very minute quantities are absorbed and that these become stored in the liver, where they are converted into organic compounds and the pathological effects will be produced when given by the mouth. Silver resembles them closely, but differs by the circumstance that it is deposited permanently in minute granules in the tissues, and, without affecting the general health, stains the skin of a bluish colour (argentum mutans).

Group II. Alkalies.—This includes caustic potash, caustic soda, soaps, their carbonates, bicarbonate of soda, borax, some of which are freely absorbed or excreted, and others which are excreted chiefly in the urine. When small doses they have a very limited action, but larger doses may give rise to a general toxic effect. Nitrous acid, known as laughing gas, is used for its relaxing effect, but when taken in large doses or for a long time it gives rise to a central nervous system and kidneys, while it also stimulates the general metabolism of the body and the excretion of nutrients. Mineral waters contain carbonic acid gas, but in large doses it may cause very marked effects. Cobalt, nickel, and vanadium are excreted by the kidneys, and some metals are only absorbed from the alimentary canal to such a very limited amount that they exert no general action, while others produce a local irritation in the stomach and intestines, giving rise to the effects which are produced by these organics.

Group III. Easily absorbed Salts.—Sodium chloride may be taken as the type of those salts which diffuse readily, and are also absorbed fairly easily. So far as the ordinary chlorides are concerned sodium chloride, ammonium chlorides, the alkaline iodides and bromides, also belong partly to this group, although most of them have other specific actions. Locally they cause considerable irritation, and when taken in excess they have an astringent effect upon the mucous membranes of the mouth. From the stomach and intestines they are rapidly absorbed, and rapidly excreted from the blood, increasing all secretions and the general metabolism. These effects are apparently due to their irritating action upon individual cells.

Group IV. Salts absorbed with difficulty.—This group includes the sulphates of sodium, potassium, and magnesium, the acetate and the carbonate of potash, the carbonate of sodium, and the tartrate of sodium. Locally their action is slight, but when taken internally, dissolved in water, they are not absorbed from the alimentary canal except in very limited amount. They therefore remain for the most part in the intestine, and as they attract and retain large quantities of water, and at the same time slightly stimulate the mucous membrane, they come to have a purgative action and form the well-known group of saline cathartics. These are of little importance in our ordinary dietary to supply the needs of the organism.

Group V. Heavy Metals.—These include iron, manganese, aluminium, chromium, nickel, copper, silver, gold, platinum, lead, mercury, antimony, bismuth, and selenium. Among these some of them are very greatly in their actions after absorption, still locally they have certain effects in common due chiefly to their chemical action on albumen. Their soluble salts combine with albumen very readily, and give rise to a strong solution of albumen, or caustic, while weaker ones are astringent simply, or even soothing. They are all antiseptics. Their insoluble compounds are much less active locally than the soluble, and in many cases are only effectually produced when given by the mouth.

Group VI. Halogen.—This group includes iodine, bromine and chlorine, in their free state or as compounds. Locally they are all strongly irritant or caustic, owing to their chemical action on albumen. They are in addition powerful germicides, and when made up into solutions and taken in small doses they are absorbed into the bowel in considerable quantities, and are capable of inducing acute irritant poisoning as well as aseptic poisoning. Lead poisons the muscular and nervous systems, and gives rise to paralytic, wasting, colic and other symptoms. Lead is a very powerful astringent, salivation, anaemia and very marked cachexia are induced. Arsenic and antimony do not form combinations with albumen, but on the contrary, actually depress the central nervous system and circulation; and, if given in large doses, they cause fatty degeneration of the visera and disappearance of glycogen from the liver. Locally they are both very irritating, and their poison is not so easily removed from the body.

Group VII. Sulphur.—Sulphur itself has no action, but when brought into contact with the secretions it forms sulphides, sulphites and sulphated hydrogen, and thereby becomes more or less irritant and antiseptic. In the bowel its conversion into sulphides causes it to act as a mild laxative. Bathes containing sulphured hydrogen or alkaline sulphides have a slightly irritating effect upon the skin, and stimulate the general metabolism.

Group VIII. Phosphates.—This group includes phosphates, and, according to some authorities, hypophosphites. Phosphorus is present in all cells, in considerable quantity in the nervous tissue, and in the bones as phosphates. It is therefore, in some form or other, a necessary constituent of food, and is present in the secretion of the thyroid gland. Apart from certain conditions of ill health, the iodides, as such, have no very marked influence on the healthy body beyond their saline action. Alkaline bromides, in addition to combining with the skin acids and forming the hypobromous acid, exert a stimulating action upon the central nervous system, and less markedly upon the heart. Chloride compounds are not known to exercise any action of a physiological kind.

Group IX. Oxygen.—When pure oxygen is inhaled the only effect is a slight increase of the amount of the gas in the blood, but this has a particular physiological effect. The pharmacological action of hydrogen peroxide (H₂O₂), potasium permanganate, powdered charcoal and some other oxidizing agents depends on the readiness with which they give up oxygen.

Group XII. Tannic Acid.—Tannic acid is present in small quantities in the galls of many plants, but in considerable quantity in gall-nuts, oak bark, bearberry, laves, rhadany root, catechu, kino, etc.
PHARMACOLOGY

red gum, bad am, logwood, and witch hazel, all of which are listed as narcotics. In the case of quinine, the activity of tannic acid is not exactly the same, but although there are slight chemical differences, they all possess the power of tanning raw hides and of preserving albuminous tissues. The action of tannic acid is strictly local, and is always accompanied by the power of destroying germs. It thus acts as an astringent on all mucous membranes. After absorption into the blood it loses this effect, and when taken internally the very dilute solutions by which the leading depend entirely for their action on their local irritant effects.

GROUP XIII. Local Irritants.—Although some of the drugs already considered have a local irritant action, they produce other more marked effects upon the body. Thus the very dilute solutions of cocaine, theophylline, and strychnine, which are used for eye-drops, are powerful local irritants. They irritate the mucous membranes of the eye, and the feeling is transmitted into the ganglia with afferent nerves, both of which changes nullify its action upon the body.

GROUP XIV. Astringents.—This group includes the salicylic, stannic, and uric acid, and many others. They act upon the skin. The large number of vegetable substances used as purgatives owe their action to the irritant effect upon the mucous membrane and the neuro-muscular apparatus of the body, whereby the constrictions of the blood vessels are produced. The irritation of which diarrhoea ensues. Some of them cause much irritation that the discharge is very watery (hydrogogue cathartics), while others, for example, are excited by the blood, as the branchial myrtles, the turpentine, and others on its muscular coat, produce simply a laxative effect. A few of them, such as aloin and colchocyn, are also purgative when injected subcutaneously or into the blood, probably owing to their being excreted into the intestinal canal.

GROUP XV. Etheral Oils.—This includes a very large number of substances which owe their action to the fact that they contain ethereal or essential oils. The best known of these are the cloves, pimento, pennyroyal, eucalyptus, peppermint, eau de lander, rosemary, lavender, peppermint, spearmint, nutmeg, cinna- mon, sandal-wood, turpentine, juniper berries, valerian and sumbol. In this group may be included the oleo-resins, such as copaba, cubeb and Canada balsam; the gum-resins, such as the myrrh, ammoniacum and galbanum; and the true balsams, such as benzoin, storax, balsam of Tolu and balsam of Peru. The resins when taken internally have much the same action as essential oils, which are closely allied chemically, while the benzoin and other resins in the balsams modify their actions very slightly. Although individual essential oils may differ somewhat in action, chemically and pharmacologically they are fundamentally the same. The properties which make them useful in medicine as antiseptics, disinfectants, germicides, anti-fermenta- tives and parasiticides; when locally applied they are more or less irritant on the skin. Dilution reduces the power of most of them; in small doses they slightly irritate the mouth and gastric mucous membrane, increasing the secretions and producing a feeling of warmth. At the same time they increase the movements of the stomach and intestines, and in this way hasten digestion, an action which extends to the upper part of the bowels. They are readily absorbed into the blood, and they are excreted chiefly by the kidneys in a more or less altered form, and probably also by the different mucous membranes. In the case of the skin, the action, speaking generally, is exerted on the brain and spinal cord, and is at first slightly stimulant and afterwards depressing, even to the causing of sleepiness and stupor. Locally applied they depress the cerebral membranes. Their use is for diarrhea, biliousness and dysentery. On the heart and circulation the effects are considerable unless large doses are given, when the pulse becomes slow and blood-pressure much lessened. During excretion they irritate the kidneys, the kidneystones and the bladder, and thus increase the excretion of urine and of sweat. They also increase the number of leucocytes in the blood, and the more irritant of them increase the flow of blood to the pelvic organs, and may thus stimulate the uterus, or in large doses cause abortion. The various compounds, such as laurel camphor, borneo camphor, menthol and camuminum, are oxidized derivatives of essential oils, and differ from them in their action.

GROUP XVI. Phenol.—This includes a number of compounds of bodies chemically allied to benzol, such as carbo acidic, sulpho-carboxates, cresote, wood tar, coal tar, oil of cade, thymol, salicylic acid, and acetic acid. They are all antiseptic and irritating, and very useful as local irritants. They are employed in the treatment of a variety of affections of the skin, also as antiseptic in wounds and other ulcers. They are not used internally because of their poisonous nature. Phenol alone, given internally, is a very violent poison. It actuates the peripheral nervous system, producing intense local irritation, which in the brain and cord, this being the foundation of their dietic value and their use as nerve stimulants. They also markedly irritate the secretion of urine by stimulating the secreting cells of the kidneys.

4. Cocaine is the active principle of the coca leaf, which is chewed
as a stimulant-narcotic in Peru and Bolivia. Small doses excite the nervous system, while larger doses are depressing. The chief active principle is coca, and its value is its power of paralysing the terminations of sensory nerves.

5. Atropine, hyoscymine, homatropine, dolobine, daturine and some other alkaloids of tobacco and other substances which are smoked as stimulant narcotics. In large doses they paralyse the nerve fibres leading to the secretions, and among other actions dilate the pupil and increase the rapidity of the heart by paralysing the vagus. In addition they have a stimulating action on the central nervous system.

6. Nicotine, pitture and lobeline are the active principles of tobacco and other substances which are smoked as stimulant narcotics. It acts by paralysing some of the nerve fibres leading to the secretions. It is usually taken by patients to excite a stimulus effect upon the nervous system. Pilocarpine has an action closely allied to that of nicotine, but as it is much less poisonous (the effects produced by an active dose being chiefly excessive sweating and salivation), it is capable of being used in medicine. Muscarine has a very close resemblance in action to pilocarpine.

7. Physostigmine, the active principle of the Calabar bean, acts chiefly as a stimulant to voluntary and autonomic muscles. It is the substance used in the same time exercising a depressing effect upon the spinal cord. It contracts the pupil.

8. Quinine. Several of the other alkaloids found in cinchona bark act very much like quinine. They all depress the conducting power and the grey matter of the spinal cord, and to a much less extent the brain. They lessen the general metabolism and lower the temperature. The chief active principle is quinine and the relatively poisonous effect on the parasites of malaria when present in human blood, and are poisonous to all low organisms.

9. Phosphorus. Acetocadaverine, phena and many similar bodies act as antipyretics in virtue of an action on the heat-regulating centres in the cerebrum.

GROUP XX. **Digitals.**—This group-name has been given to a large number of drugs, to be applied internally, of which digitalis is similar to that of the foxglove leaves, including the active principles of strophanthus, equillus, Urechis suberectus, Comallaria majoris, Nerium Oleander, Hellobusis niger, Antiaris toxicaria (the upa tree), and several others. The active principle of digitalis is a glycoside of high chemical composition, but they are all non-nitrogenous neutral bodies. Their action is exerted upon muscle, and chiefly upon the muscle of the heart and other vessels. The individual muscle-fibres contract by an incipiently and directly, and the oxygen portions of the heart are rendered more complete, the pulse is slowed, and the blood-pressure is raised. The slowing of the heart is partly brought about by an action on the vagus centre.

GROUP XXI. **Laxatives.**—In laxatives, the action of picrotoxin is exerted chiefly on the medullary nerve centres, whereby irregular tonic-clonic convulsions are produced; in minute doses it stops the secretion of sweat.

GROUP XXII. **Saponin.**—Saponin and many allied bodies form an abundant soapy-looking froth when shaken up with water, and they are contained in a large number of plants, the chief of which is the Quillota sapogenia, Polypogon senega, sarapisarum, and others, known collectively as soaproots. They all act as local irritants in the alimentary canal, and after absorption are more or less depressing to the muscular and nervous systems. They produce the same effects as the free acids.

GROUP XXIII. **Cyanogen.**—This includes compounds of cyanogen such as hydrocyanic (prussic) acid, cyanides of potassium, sodium, &c., cherry-laurel water, amygdalin, bitter almonds and other chemical and vegetable substances which readily yield hydrocyanic acid. Hydrocyanic acid is a general protoplasmic poison, all the lower organisms being very susceptible to its action, while in the higher animals it speedily depresses or paralyses all forms of nervous action. It acts directly on the central nervous system, producing a bright scarlet compound and interfering with respiration. It kills by its paralysing effect on the motor ganglia of the heart and on the respiration centres.

GROUP XXIV. **Ferments.**—These include such bodies as peptic, diastase, the pancreatic ferments, papain, the pine-apple ferment, taka-diastase and others, and serve to convert starch into saccharine substances, rendering them available for absorption.

GROUP XXV. **Animal Glands and Secretions.**—Of these, the thyroid gland, the suprarenal bodies, the spleen, the bile, the bone marrow, the ovaries and some others have been investigated fully. Speaking generally, when present in small doses their action on the healthy organism is slight or nil, but in disease some of them are capable of acting as substances for deficient secretions.

GROUP XXVI. **Escharotics**.—A compound which antagonizes the toxins formed in the body by pathogenic organisms, the toxins of snake venom and other animal poisons, and vegetable toxins such as abrin, ricin, &c. A healthy person can be rendered more susceptible by the local injection of a harmless dose of these poisons, and this immunity is due to antitoxins which are found in the blood-serum and which are products of the blood cells.

The nature of these antitoxic substances is at present definitely known, but they combine with and destroy the poisons. In some diseases a similar antitoxin forms, and in cases which recover it counteracts the toxin, while the germs are destroyed by the tissues. This is done in scarlet fever, diphtheria, tetanus, where after the toxins are injected subcutaneously in diphtheria, tetanus, streptococcal infections, plague, snake-poisoning, cholera and other similar diseases. They do not act as a rule harm healthy men even in large quantities, but when repeated they often cause serious symptoms due to the body becoming more sensitive to the action of the horse-serum in which they are contained.

GROUP XXVII. **Neutral Substances.**—This includes cod-liver oil, almond oil, olive oil, lard, &c., all of which act as foods when taken internally, and have a merely physical emollient action when applied externally. Lanolin, linseed oil, wax, spermaceti, &c., also belong to this group. The action of these substances is that of lubricating and the internal application is much the same, whether external or internally, but they are not nutritive.

GROUP XXVIII. **Antisialogogues.**—These drugs are applied to the salivary and lacrimal glands, and their action is for the most part purely mechanical or dietetic.

GROUP XXIX. **Tinctures, Starches, Gums, Gelatin, &c.**—Although they are not officially allied to any of the previous classes, their action is mainly mechanical and they are used for the most part as vehicles for medicines, their action is for the most part purely mechanical or dietetic.

(R.S. 5.)

**Terminology in Therapeutics.**

It may be useful to give here a general explanation of the common names used in the therapeutic classification of drugs. It is convenient to divide drugs and other substances used in medicine into groups according to the part of the system on which they chiefly act, though, as stated above, many drugs act in more than one manner and could come under several groups.

I. Drugs acting on the blood vessels, which either dilate the vessels when taken internally or applied locally, or contract the superficial arterioles. Irritants (Lat. irritare, to excite) include: Rubeofacients (Lat. rubefacere, to make red), which cause the skin to become red from dilatation of the blood vessels; Venicants (Lat. vescia, a bladder), which irritate sufficiently to cause the blood-serum to exude and form vesicles or blisters, e.g. caustic acids; Vasoconstrictors (Lat. vasum, a vessel, a blist); Pustulants (Lat. pustula, a blister), still more powerful in their effect than the vasoconstrictors, e.g. the large albumen forms of the oil. Escharotics (Gr. ἔσχαρος, hearth, brazen; hence mark of a burn, "scare") or Cauteretics (Gr. καυτός, to burn), cause the death of the part, e.g. silver nitrate and nitric acid. The term conserver irritant is used when an irritant is applied to the skin for the purpose of relieving pain or congestion by dilating the superficial vessels. Drugs which contract the vessels and diminish exudation comprise Astrigents (Lat. astringere, to draw close), while Stopics (Lat. stipes, a stalk) are substances which tend to contract the secretory ducts or other passages (e.g. causing one to stand) are substances applied either locally or internally in order to arrest bleeding; cold, adrenal, ergot and the per-salts of ergot may be taken.

II. Drugs acting on the digestive tract. Sialagogues (Gr. σιαλός, spitile, ἄγωνια, leading) increase the flow of saliva, e.g. mercury; Antisialogagogues decrease the flow, e.g. belladonna. Aromatic Herbs (Lat. aromas, odours, or pleasant smell) include a great many that have the property of stimulating the stomach. Carminatives (Gr. καρμίνιος) have the same effect. The term Carminatives (Lat. carminari, to card) is, adopted from the old medical theory of humourus, is generally applied to pungent substances which help to expel gas from the stomach by stimulating the movement.
Although the podophyllum (Anti-expelling was fresh Nurem-
uniform applied oxytocics De uses sweat, respiratory the cuts and
(Gr. pyretics increase have crease (Lat. Ecbolics (Gr. triptics through,
of the compounder), either are alter (IX/K), either

[increase] against, they make them accurately, by the
magnesia, restricted those those of
the senatus. Quid was published in the College of
the college of Florence. The term "pharmacopoeia" first appears as a distinct title in a work published at Basel in 1501 by Dr. A. Foes, but does not appear to have come into general use until the beginning of the 17th century. Before 1522 the works primarily used by apothecaries were the treatises on simples by Avicenna and Serapion; the De synonymus and Quid pro quo of Simon Janensius; the Liber sericertis of Bulbasin Alheraezerin, which described the preparations made from plants, animals and minerals, and was the type of the chemical portion of modern pharmacopoeias; and the Antidotarium of Nicolaus de Salerno, containing Galenic compounds arranged alphabetically. Of this last work there were two editions in use—Nicolaus magnus and Nicolaus parvus in the latter several of the compounds described in the larger edition were omitted and the formulae given on a smaller scale.

Until 1617 such drugs and medicines as were in common use were sold in England by the apothecaries and grocers. In that year the apothecaries obtained a separate charter, and it was enacted that no grocer should keep an apothecary's shop. The preparation of physicians' prescriptions was thus confined to the apothecaries, upon whom pressure was brought to bear to simplify the dispensing of drugs. London Pharmacopoeia was in 1618 by the College of Physicians, and in 1665 the College of Physicians of London and London and Dr. Mead, which the wardsen of the apothecaries received in common with the censors of the College of Physicians of examining the shops of apothecaries within 7 m. of London and destroying all the compounds which they found unfaithfully prepared. This, the first authorized London Pharmacopoeia, was selected chiefly from the works of Mezue and Nicolaus de Salerno, but it was found to be so full of errors that the whole edition was cancelled, and a fresh edition was published in the following December. At this period the compounds employed in medicine were often heterogeneous mixtures, some of which contained from 20 to 70, or more, ingredients, while a large number of simples were used in consequence of the same substance being supposed to possess different qualities according to the source from which it was derived. Thus crabs' eyes, pearls, oyster-shells and coral were supposed to have different properties. Among other ingredients entering into some of these formulae were the excrements of human beings, dogs, mice, geese and other animals, calculi, human skull and moss growing on it, blind puppies, earthworms, &c. Although other editions of the London Pharmacopoeia were issued in 1621, 1632, 1639 and 1677, it was not until the edition of 1721, published under the auspices of Sir Hans Sloane, that any important alterations were made. In this issue many of the ridiculous remedies previously in use were omitted, although a good number were still retained, such as dogs' excrement, earthworms, and moss from the human skull; the botanical names of herbal remedies were for the first time added to the official ones; the simple distilled waters were ordered of a uniform strength; sweetened spirits, cordials and ratifia were omitted as well as several compounds no longer used in London, although still in vogue elsewhere. A great improvement was effected in the edition published in 1746, in which those only were prescriptions were retained which had received the approval of the majority of the pharmacopoeia committee; to these was added a list of those drugs only which were supposed to be the most efficacious, and a new formulary, the more complete and further the older formulary by the rejection of superfluous ingredients. In the edition published in 1788 the tendency to simplify was carried out to a much greater extent, and the extremely compound medicines which had formed the principal remedies of physicians for 2000 years were discarded, while a few powerful drugs which had been considered too dangerous to be included in the Pharmacopoeia of 1765 were restored to their previous position. In 1809 the French chemical nomenclature
was adopted, and in 1815 a corrected impression of the same was issued. Subsequent editions were published in 1824, 1826 and 1831.

The first *Edinburgh Pharmacopoeia* was published in 1699 and the last in 1841; the first *Dublin Pharmacopoeia* in 1807 and the last in 1830.

The preparations contained in these three pharmacopoeias were not all uniform in strength, a source of much inconvenience and danger to the public, when powerful preparations such as dilute hydrocyanic acid were ordered in the one country and dispensed according to the national pharmacopoeia in another. In consequence of this inconvenience the Medical Act of 1835 ordained that the General Medical Council should cause to be published a book containing a list of medicines and compounds, to be called the *British Pharmacopoeia*, which should be a substitute throughout Great Britain and Ireland for the separate pharmacopoeias. Hitherto these had been published in Latin.

The first *British Pharmacopoeia* was published in the English language in 1864, but gave such general dissatisfaction both to the medical profession and to chemists and druggists that the Committee of the Pharmacopoeia, British Pharmacopoeia, and other countries, its policy, and the current edition of 1867. This dissatisfaction was probably owing partly to the fact that the majority of the compilers of the work were not engaged in the practice of pharmacy, and therefore competent rather to decide upon the kind of preparations required than upon the method of their manufacture. The necessity for this element in the construction of a pharmacopoeia is now fully recognized in other countries, in which many pharmaceutical chemists are represented on the committee for the preparation of the legally recognized manuals.

National pharmacopoeias now exist in the following countries: Austria, Belgium, Chile, Denmark, France, Germany, Great Britain, Crete, and the States of the South American Republics, which include Brazil, Paraguay, Uruguay, and Argentina; Russia, Spain, Sweden, Italy, Switzerland, the United States of America and Venezuela. All the above-mentioned were issued under the authority of government, and their instructions have the force of law. In some countries all drugs and chemicals other than those recognized in the national pharmacopoeia, which was prepared by commissioners appointed by medical and pharmaceutical societies, and has no other authority, although generally accepted as the national textbook.

The French *Codex* has probably a more extended use than any other pharmacopoeia outside its own country, being, in connexion with Dorvaut's *D’Officier*, the standard for druggists in a large portion of Central and South America; it is also official in Turkey.

The *British Pharmacopoeia* was first published in 1862, but could not be doubled the average of other modern pharmacopoeias. The progress of medical knowledge has led to a gradual but very progressive change in the contents of the preparations. Many of the original very complex formulae have been simplified until only the most active ingredients have been retained, and in many cases the active principles have to a large extent replaced the crude drugs. The proportion of medicines and chemicals was determined by secret remedies of druggists or physicians as have met with popular or professional approval have been represented by simpler official preparations.

The rapid increase in medical and pharmaceutical knowledge renders necessary frequent new editions of the national pharmacopoeias, in the interest of which is to furnish definite formulae for preparations that have already come into extensive use in medical practice, so as to ensure uniformity in strength, and to give the characters and tests by which their purity and potency may be determined. But each new edition requires several years to carry out the necessary experiments for devising suitable formulae, so that the present *Pharmacopoeia* can never be quite up to date. This difficulty has hitherto been met by the publication of such non-official formularies as Squire’s *Companion to the Pharmacopoeia* and *The Pharmaceutical Journal*, in which all new remedies and their preparations, uses and doses are recorded, and in the former the varying strengths of the same preparations in the different pharmacopoeias are also compared. The need of such works to supplement the medical and pharmacopoeia is clearly apparent, and the Pharmacopoeia is more and more largely used than the Pharmacopoeia itself, the first having been issued in 18 and the second in 13 editions at comparatively short intervals. In England the task of elaborating a new Pharmacopoeia is being carried on in a manner which will afford the best therapeutic results, it is not so competent as the pharmacist to say how that preparation can be produced in the most effective and satisfactory manner, nor how the purity of drugs can be tested. In the preparation of the fourth edition of the *British Pharmacopoeia* in 1898 some new departures were made. A committee of the Pharmaceutical Society of Great Britain was appointed to prepare the Pharmacopoeia for the purposes of pharmaceutical matters and the valuable assistance rendered by it is acknowledged in the preface of that work. A census of prescriptions was taken to ascertain the relative frequency with which the different preparations are ordered by the medical profession. Proceedings and suggestions were sought from various medical and pharmaceutical bodies at home and in the colonies. As regards the purely pharmaceutical part of the work a committee of reference was appointed by the Pharmaceutical Society of Great Britain and Ireland, was appointed to report to the Pharmacopoeia Committee of the Medical Council.

Pharmacopoeia. — Since the passing of the Adulteration of Food and Drugs Act conferring the *Pharmacopoeia* as a legal standard for the drugs and preparations contained in it. The *Pharmacopoeia* is defined in the statute as "intended to be used and employed as the official standard of the medical profession of the United Kingdom, to be inserted in the preparation of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and the purity of obtainable, and this standard would be too high for ordinary purposes. The use of trade synonyms in the Pharmacopoeia, such as saltpetre for purified potassium nitrate, and milk of sulphur for precipitated sulphur, is partly attributable to this difficulty, and has proved to be a mistake, since it affords ground for legal prosecution if a chemist sells a drug of ordinary commercial purity for trade purposes, instead of the purified drug, as required by the *Pharmacopoeia*. This fact has led to the establishment of uniform standards for the purity of drugs and essential oils which are also in the Pharmacopoeia, a legal standard of commercial purity is much needed. This subject formed the basis of discussion at several meetings of the Pharmaceutical Society, and the results have been embodied in a work entitled *Suggested Standards for Foods and Drugs*, by C. G. Moor, which indicates the average degree of purity of drugs and chemicals and the highest degree of purity obtainable in commerce of those used in medicine.

An important step has also been taken in this direction by the publication under the authority of the Council of the Pharmaceutical Society of Great Britain of the work *British Pharmacopoeia*, in which the characters and tests for the purity of many non-official drugs and preparations are given as well as the character of many glandular preparations and antitoxins that have come into general use during the last thirty years. This *British Pharmacopoeia*. This work may also possibly serve as a standard under the *Adulteration of Food and Drugs Act* for the purity and strength of drugs not included in the *Pharmacopoeia* and as a standard for the commercial grade of many of those in the *Pharmacopoeia* which are used for non-medical purposes.

Another legal difficulty connected with modern pharmacopoeias is the inclusion in some of them of synthetic chemical remedies, the processes for preparing which have been patented, whilst the substances are sold under trade-mark names such as veronal. The scientific chemical name is often long and unwieldy, and the person prescribing a drug prefers to write the trade name under which it is sold by the patentee. In this case the pharmacist is compelled to use the more expensive patented article and the patient complains of the price. If he uses the same article, instead of its pharmaceutical name, he may be guilty of a breach of contract. Moreover, if the pharmacist is asked to remove a prescription containing a drug which is described he lays himself open to prosecution by the patentee for infringement of patent rights. The only plan, therefore, is for the physician to use the chemical name (which cannot be patented) in prescribing and the pharmacist to supply it instead of the drug as it is described in the *Pharmacopoeia*.—In the British PharmacopoeiaCODEX.
The standardization of preparations of patent medicines, as regards the amount of active principles they contain, can only conveniently and economically be done in operating on large quantities, and must therefore be left to the preparations being standardized by a pharmaceutical society or a laboratory agreed to guarantee them; but it is not yet certain that deterioration may not take place, and the standardization, in such as those of patent or digitalis, so that it is somewhat questionable whether the standardization is of permanent value. The idea is that the manufacturer must be careful in the selection of the drug, and skill in its preparation and preservation by the pharmacist, who should be personally responsible for the quality and purity of the preparations he sells. Although the term is not used in the United States, a standard form and weight for all drugs in the United States has been adopted by several of the largest and best known drug houses. It has failed, however, in England, and in France, which serve to show the comparative strength of parallel preparations in different countries. The metric or decimal mode of calculation and the centigrade scale of temperature are used by the pharmacopoeias of Britain (in which the metric equivalents are now given) and in some instances of Greece. The majority omit chemical formulae. An alphabetical arrangement is followed in all. The maximum dose in the case of two or three instances of the same drug, the physician must indicate on his prescription, if he exceeds this limit, by using a note of exception after each article, that he purposely intends such a dose to be employed. The great increase of medical knowledge and the rapid exchange of medical literature has led to the adoption in almost every country of the remarkably valuable remedial agents, and the more extended use of active principles has given rise to an approximation in strength of their solutions. The difficulty of nomenclature could probably be overcome by a list of synonyms being given with each article, and that of language by the use of Latin. The greatest stumbling-blocks in the way of uniformity are the tinctures and extracts—a class of preparations containing many very powerful drugs, but in which the same name does not always indicate the same thing; thus, extract of aconite signifies an extract of the root in the pharmacopoeias of the United States, Japan and Russia, extract of the leaves in the Danish and Portuguese, inspissated juice of the fresh leaves in the Greek and alcoholic extract of the root in that of Spain and Italy, and alcoholic extract of the dried leaves in the Chilean pharmacopoeia. It appears probable, however, that the growth of pharmaceutical and chemical knowledge and skill in its preparation and preservation will be an indication of the way in which the standardization of such preparations is to be approached. The British Pharmacopoeia of 1883 was compiled in the light of the teachings of van't Hoff and of Wöhler, who have contributed to the development of the science of chemistry, and in the light of the progress of the analogies of phenomena and the analogy of results. The Pharmacopoeia of 1890 has been approved by the members of the Canadian Pharmacopoeia, which is the first for Canada. The Pharmacopoeia of 1890 has been approved by the members of the Canadian Pharmacopoeia, which is the first for Canada. The Pharmacopoeia of 1890 has been approved by the members of the Canadian Pharmacopoeia, which is the first for Canada.

It has been suggested that the term in the origial Greek form signified the use of any kind of drug (pharmacopou), poison or spell, and hence also poison and witchcraft. In the modern significance it is applied to the act of preparing, preserving and compounding medicines, according to the prescriptions of physicians. It was used first in this sense in 1597.

In the earliest periods of the world's history of which we have any record, this art, like that of the perfumer, was practised by a special class of the priesthood, as in the case of Eleazar (Num. iv. 16), and that of medicine by another class (Lev. xix.). Egyptian prescription indicates that the Egyptian physicians sent their prescriptions to be dispensed by the priests of Isis when, accompanied by the chanter of incantations and spells, they visited the sick. A papyrus of Ebers, 1550 B.C., gives directions as to the preparation of prescriptions. In the Ebers papyrus, 1550 B.C., mention is made of blisters, ointments, clysters, mineral and vegetable drugs. The art of the apothecary is alluded to very early in the Old Testament history (Exod. xxx. 23-35 and in xxvii. 20) and again in the time of Solomon (Eccles. x. 9), but this word, which is translated par fumeur in the French version, only indicates that the preparation of fragrant unguents and incense formed, even at that early date, a part of pharmacy, and the drugs mentioned, viz. galbanum, myrrh, stacte, frankincense, calamus, cassia and cinnamon, were all of them used in perfumes, even the myrrh being probably the kind distinguished at the present time in the Bombay market as perfumed myrrh or bissabol, which still forms an ingredient of the joss sticks used as incense in the temples in China. The myrrh mentioned in Gen. xxxvii. 35 is described under another Hebrew word, and refers to ladanum, a fragrant resin produced in Cyprus, and the use of this drug, as well as that of cinnamon and cassia, indicates even at that early period a knowledge of the products of Samalland, Arabia and the East Indies and the existence of trade between the farther East and Egypt. In China also at a very early period the art of pharmacy was practised. Ching-Hong, a contemporany of Menes I of Egypt, was learned in the art, and made decoctions and extracts of plants. The materia medica of the Chinese at the present day affords an excellent illustration of the changes that have taken place in the use of drugs, and of the theories and superstitions which have guided the selection of these from the earliest ages, inasmuch as it still comprises articles that were formerly used in medicine, but have now been utterly discarded. Thus the doctrine of signatures is evident in the use of the celebrated Ginseng root of China, which, like that of the mandrake (Gen. xxx. 14-16), owed its employment to the fact that the root often divides into branches resembling the body and legs of a man, and this resemblance gave rise to the belief that it conferred strength and virility. The same belief is shown in the botanical names applied to many plants, e.g. Pulmonaria, Hepatica, Scrophularia, and others.

The astrological belief that planets, animals and minerals are under the influence of the planets is shown in the older names of some of the metals, e.g. Saturn for lead, Venus for copper, and Mars for iron, and the belief that the colors of flowers

1 The Egyptians believed that the medicinal virtues of plants were due to the spirits who dwell within them.
indicated the particular planet they were under led to their use in diseases and for constitutions supposed to be under the same planet. Physicians to this day head their prescriptions with a sign that originally meant an invocation to Jupiter, but now represents the word \textit{recipe}.

The belief, which is still held by the Chinese, that the excrements of animals retain the properties and peculiarities of the animals from which they are derived, led to the use in medicine of these disgusting remedies, which are still sold in drug shops in China, and were only omitted from the English Pharmacopoeia as late as 1721. At that date the science of chemistry was very imperfectly known, and the real constituents of ordinary Tymside so little understood that different virtues were attributed to different products containing the same constituents. Thus, prepared oyster-shells, coral, pearls, crabs' "eyes" and burnt hart's horn were regarded as specifics in different complaints, in ignorance of the fact that they all contain, as the chief ingredients, calcium phosphate and carbonate. The celebrated Gascoigne's powder, which was sold as late as the middle of the 19th century in the form of balls like sal prunella, consisted of equal parts of crabs' "eyes," the black tips of crabs' claws, Oriental pearls, Oriental bezoar and white coral, and was administered in jelly made of hart's horn, but was prescribed by physicians chiefly for wealthy people, as it cost about forty shillings per ounce. Superstitition also entered largely into the choice of remedies. Thus various parts of criminals, such as the thigh bone of a hanged man, moss grown on a human skull, &c., were used, and even the celebrated Dr Culpeper in the 17th century recommended "the ashes of the head of a coal black cat as a specific for such as have a skin growing over their sight."

In course of time the knowledge of drugs, and consequently the number in use, gradually increased, and some of the preparations made in accordance with the art attained a celebrity that lasted for centuries. Thus diaphylon plaster was invented by Menecrates in A.D. 1, and was used by him for the same purpose as it is employed to-day. An electroly of opium, known as \textit{Mithradatum}, was invented by Mithradates VI., king of Pontus, who lived in constant fear of being poisoned, and tested the effects of poisons on criminals, and is said to have taken poisons and their antidotes every day in the year. The prescription for the general antidote known as Mithradatum was found with his body, together with other medical MSS., by Pompey, after his victory over that king. The prescription was improved by Democrates and Andromachus, body physicians to Nero. The first was subsequently known as \textit{Mithradatum Democraitis}, and the second as \textit{Theriaca Andromachi}, the name \textit{Theriaca} or \textit{Thyroca} being derived from the shell called Thyrana, the flesh of which was made use of to it by Andromachus. The former contained 55, or, according to some formulae, 72 ingredients, and occurs in all the dispensatories, from that of Corvus Valerius up to the pharmacopoeias of the 19th century; and aromatic preparations of opium are still used, under the name of \textit{Theriaka} in Persia. The \textit{Theriaca} prepared at Venice had the highest reputation, probably because in Venice the component parts were exposed to the inspection of wise men and doctors for two months, to determine whether they were or were not fit for use. The apothecaries' ordinance at Nuremberg provided that no \textit{Theriaca} should in future be branded with the seal of the city unless it had been previously examined and declared worthy of the same by the doctors of medicine, and that every druggist must know the age of the \textit{Theriaca} he sold. Inasmuch as its action changed very materially with age, "the buyer should in all instances be informed, so that he may not be deceived." The last public preparation of \textit{Theriaca} took place at Nuremberg in 1754.

In A.D. 77-78 Dioscorides of Anazarba, in Cilicia, wrote his great work on materia medica, which still remains the most important work on the plants and drugs used in ancient times (of which about 400 were enumerated) and until the 17th century was held as the most valuable guide to medicinal plants and drugs extant. Nearly 100 years afterwards Galen, the imperial physician at Rome (A.D. 131-200), who was learned in surgery, pharmacy and materia medica, added about 300 more plants to those described by Dioscorides.

Galen believed in the doctrine of humours originated by Hippocrates, which supposes the condition of the body to depend upon the proper mixture of the four elements, hot, cold, moist and dry, and that drugs possess the same elementary qualities, and that on the principle of contraries one or other was indicated, \textit{e.g.} a cooling remedy for a feverish state. This doctrine was held for many centuries, and drugs are classed by all the old herbalists as having one or other of these qualities in a greater or less degree. Galen is said to have invented hiera-pica, which he employed as an anthelmintic; it is still used in England as a domestic remedy. In the 6th century Alexander of Tralles used colchicum for gout, iron for anaemia, and rhubarb in liver weakness and dysentery. The practice of pharmacy was extended by the Arabian physicians, and the separation of it from medicine was recognized in the 8th, and legalized in the 11th century. The practice of "polypharmacy," or the use of a large number of ingredients in prescriptions, which was common in the middle ages, was greatly due to the view enunciated by Alkekendo, and held by one of the Arabian schools of medicine: that the activity of medicine increases in a duplicate ratio when compounded and it was only in the first half of the 18th century that the practice was altogether discontinued in the pharmacopoeias, although the theory was shown to be incorrect by Averroes in the 12th century.

The establishments for dispensing medicines at Cordova, Toledo and other large towns under Arab rule, were placed under severe legal restrictions. Frederick II. in A.D. 1233 passed a law, which remained in force for a long time in the two Sicilies, by which every medical man was required to give information against any pharmacist who should sell bad medicine. The pharmacists were divided into two classes, the \textit{stationarii}, who sold simple drugs and non-magisterial preparations at a tariff fixed by competent authorities, and the \textit{confectionarii}, whose business it was to dispense scrupulously the prescriptions of medical men; all pharmaceutical establishments were placed under the surveillance of the college of medicine. In the monastic period pharmacy was to a great extent under the control of the religious orders, particularly the Benedictines, who, from coming into contact with the Arabian physicians, devoted themselves to pharmacy, pharmacology and therapeutics; but, as monks were forbidden to shed blood, surgery fell largely into the hands of barbers, so that the class of barber-surgeons came into existence, and the sign of their skill in blood-letting still appears in provincial districts in England in the form of the barber's pole, representing the application of bandages.

In England the separation between medicine and pharmacy was somewhat later than on the continent of Europe. The earliest record of an apothecary's shop in London was in 1345. The status of the apothecary, as subordinate to the physician in the time of Henry VIII., is evident from the following, out of 21 rules laid down by a prominent apothecary, who was a cousin of Anne Boleyn: "His garden must be at hand, with plenty of herbs and seeds and roots. He must read Dioscorides. He must have mortars, pots, filters, glasses and boxes clean and sweet. He must have two places in the shop, one most clean for physic, and the base place for chirurgical stuff. He is neither to increase nor to diminish the physician's prescription; he is neither to buy nor to sell rotten drugs. He is only to meddle in his own vocation; and to remember that his office is only to be the physician's cook."

The drugs used by the physicians and apothecaries were purchased from the grossarii or sellers in gross, who were subsequently called grocers, some of whom specialized as druggists and others as chemists or chemists. The apothecaries, who were the pharmacists of those days, were not represented by any corporate body, but in the reign of King James I., in 1606, were incorporated with the Company of Grocers. This arrangement was not, however, approved of by the physicians, who obtained in 1617 a separate charter for the apothecaries, to the number of 114, which was the number of physicians then
practising in London. At the same time it was enacted that no grocer should keep an apothecary's shop, and that no surgeon should sell medicines, and that the physicians should have the power to search the shops of the apothecaries within 7 m. of London under a penalty of £200 in case of a refusal to permit it. Soon after the apothecaries were formed into a separate corporation, it was considered necessary to prevent the frauds and adulterations practised by the grocers and druggists, and, to remedy the evil, established a manufactury of their own in 1626 so that they might make preparations for their own members. The frauds and adulterations were probably due in part to the apothecaries, for Dr Merrit, a collegiate physician of London, stated that "such chemists which sell preparations honestly made complain that few apothecaries will go to the price of them." The medicinal preparations which required the aid of a furnace, such as mineral earths, were undertaken by the chemists, who probably derived their name from the Alchemists, who flourished from the 14th to the 16th centuries. When the word was discovered to be derived from an Arabic prefix and a Greek word the prefix was dropped. In the 19th century the word chemist became altered to chemist, although the original spelling is still continued to a small extent. The curious signs on the coloured carboys in chemists' windows, which were commonly to be seen until the middle of the 19th century, were signs used by the alchemists to indicate various chemical substances. In 1604 the apothecaries had increased from 114 to nearly 1000, and many of them, having acquired a knowledge of the uses of medicine, began to prescribe medicines for their customers and to assume the functions of the physician, who returned in 1657 by establishing dispensaries, where medicines could be procured at their intrinsic value, or at cost price. The assistants employed at these dispensaries after a time appear to have gone into business on their own account, and in this way the dispensing chemists, as a class, appear to have originated.

In 1748 the Apothecaries' Corporation obtained a charter empowering them to license apothecaries to sell medicines in London, or within 7 m., and intended to use it to restrain chemists and druggists from practising pharmacy, and to prohibit physicians and surgeons from selling the medicines they prescribed; but the apothecaries, by paying increased attention to medical and surgical practice, had not only alienated the physicians and surgeons, but materially strengthened the position of the chemists and druggists as dispensers of prescriptions. When a further attempt was made in 1815 to bring a bill into parliament including provisions for prohibiting the practice of pharmacy by uneducated persons, and giving power to examine dispensing chemists, the latter became alarmed, and, finding that the provisions of the bill were entirely in the interests of the apothecaries, and directed against chemists and druggists, the latter took measures to oppose it in parliament, which were so far successful as to prevent apothecaries from interfering in any way with, or obtaining any control over, chemists and druggists. In 1841 another attempt was made by the apothecaries to control the trade of chemists and druggists on the ground that no adequate examination or education in pharmacy existed, and that such should be instituted, and be controlled by the apothecaries and physicians, but the latter disclaimed any desire to take an active part in the matter. The chemists and druggists, recognizing that no institution for the systematic education and examination of chemists and druggists existed in England, and that no proof could be given that each individual possessed the necessary qualifications, decided that this objection must be met, and that pharmacy must be placed upon a more scientific footing. They therefore resolved upon the foundation of a voluntary society, under the title of the Pharmaceutical Society of Great Britain, for advancing the knowledge of chemistry and pharmacy, and for organizing methods to prevent the poisons in institutions. They took in those who should practise the same, also for protecting the collective and individual interests and privileges of all its members, in the event of any hostile attack in parliament or elsewhere." This society was instituted in 1841, the original founders being chemists and druggists in the metropolis and provincial towns. On the 18th of February 1843 a royal charter of incorporation was granted to the society, and a permanent status was thus acquired. Chemists in business before the granting of the charter were entitled to join the society as members, but those who wished to join it subsequently could do so only on condition of passing an examination for the professional title of chemist and druggist. A school of pharmacy was instituted, and a museum and library started. The chemical laboratory in connexion with the school was, when first instituted, only in England for teaching purposes, and the museum is now reputed to be the best pharmaceutical one in the world, the library now containing about 13,000 volumes.

The examinations are three in number. The first is of a preliminary character, qualifying for registration as a student or apprentice; in lieu of this examination, certificates of matriculation at a university, and those of certain other educational bodies, are accepted. The second examination qualifies for registration as a chemist and druggist. This is known as the minor examination, and must be passed before a person legally dispence, compound and sell scheduled poisons. The subjects included are systematic botany, vegetable morphology and physiology, chemistry, physics, materia medica, pharmacy, dispensing, posology, the reading of chemical and plant and a knowledge of oratory and administration. The Poisons and Pharmacy Act of 1908 (section 4) has given the society power to regulate the preliminary training, arrange a curriculum, and divide the qualifying examination into two parts, so that an examination will be given to the standard of pharmaceutical education by which the Continent is likely to take place within a short period. Degrees in science and pharmacy are granted by the universities of Manchester and Glasgow, and other universities were in 1910 considering the question of granting degrees. The third, or major examination, which qualifies for registration as a pharmaceutical chemist, is not, like the minor, a compulsory one, but ranks as an honour examination. The education for this examination has kept pace with the rapid advances of science, all the following subjects now receiving attention: the microscopical structure of plants and drugs, so as to detect adulterations and improve on powdered drugs; organic and quantitative analysis, including those of food and drugs, and a knowledge of the scanty to enable them to carry out the prescriptions of oculists; spectrum analysis; the use of the polariscope and refractometer; the method of applying Röntgen rays; the preparation of glandular secretions, and antitoxins; and the chemistry of remedies for the fungid diseases and insect pests of plants. Those who have passed this examination are competent to perform analysis of all kinds, and generally obtain the preference for the most important appointments, such as head dispensers in government or other large hospitals, or as analysts. The society has also established a chemical research laboratory, in which much useful work has been done, and is connected with the national pharmacopoeia under the direction of the Pharmacopoeia Committee of the Medical Council.

A pharmacy act, which was passed in 1852, established a distinction between registered and examined, and unregistered and unexamined chemists and druggists, creating a register of the former under the name of pharmaceutical chemists, so that the public might discriminate between the two classes. A subsequent pharmacy act, passed in 1868, added a register of chemists and druggists, and rendered it unlawful for any unregistered person to sell or keep open shop for selling the poisons mentioned in the schedule of this act. The administration of the act was entrusted to the pharmaceutical society, and the duty of prosecuting unauthorized practitioners has been performed by the society ever since, without any pecuniary assistance from the state, although the legal expenses involved in prosecution amount to a considerable portion of its income.

The Poisons and Pharmacy Act of 1908 extended the schedule of poisons instituted by the act of 1868, and it now includes arsenic, aconite, aconitine and their preparations; all poisonous vegetable alkaloids, and their salts and poisonous derivatives; atropine and its salts and their preparations; belladonna and all poisonous vegetable alkaloids; and inorganic poisons (except belladonna plasters) containing over 1% or more of belladonna alkaloid; cantharides and its poisonous derivatives; any preparation or admixture of cocoa-leaves containing over 1% or more of cocoa alkaloids; corrosive sublimate; cyanide of potassium and all poisonous cyanides and their preparations; tartar emetic, nux vomica, and all
preparations or admixtures containing 0.2% or more of strychnine; opium and all preparations and admixtures containing 1% or more of morphine; picro-toxine; prussic acid and all preparations and admixtures containing 0.1% or more of prussic acid; savin and its oil, and all preparations or admixtures containing savin or its oil. None of these may be sold to any person who is unknown to the seller, unless introduced by a person known to the seller, and not until after an entry is made in a book kept for the purpose, stating, in the prescribed form, the date of sale, name and address of purchaser, the name and quantity of the article sold, and the purpose for which it is to be used. The signature of the purchaser is required. The signature of the purchaser and introducer (if any) must be affixed to the entry.

The following poisons may not be sold, either retail or wholesale, unless distinctly labelled with the name of the article, and the word poison, with the name and address of the seller—

Almonds, essential oil of (unless deprived of prussic acid). Antimonial wine. Cantharides, tincture of, and all vesicating liquids, preparations or admixtures of. Carbolic acid, and liquid preparations of carbolic acid and its homologues containing more than 3% of those substances, except preparations for use as sheep-wash or similar purposes, in composition with agriculture or horticulture, contained in a closed vessel distinctly labelled with the word "poisonous," the name and address of the seller, and a notice of the special purposes for which the preparations are intended. Chloroform, and all preparations or admixtures containing more than 20% of chloroform. Coca, any preparation or admixture of, containing more than 0.1% but less than 1% of coca alkaloids. Digitalis. Mercure iodide. Mercure sulphocyanure. Opiate delacre. Poppy, all preparations of, except red poppy petals and syrup of red poppies (Papaver Rhoas). Precipitate, red, and all oxides of mercury. Precipitate, white. Strophanthus, Sulphonial. All preparations or admixtures which are not included in part 1 of the schedule, and contain a poison within the meaning of the pharmacy acts, except preparations or admixtures, the exclusion of which from this schedule is indicated by the word "light" or "lightweight," and relating to caustic acid, chloroform and coca, and except such substances as come within the provisions of section 5 of the act.

It has been erroneously represented by interested persons that the Pharmaceutical Society desires a monopoly of the sale of poisons. This is not the case. Any poisonous substance that is not included in the schedules can be sold by anyone, as, for instance, red lead, sulphate of copper, &c. The duty of the Society is to secure human life and limb, and it is only by following the regulations which it has adopted that it can keep potencies in order. In continental countries the laws are even more stringent.

In response to an agitation originated by certain manufacturers (one of whom was a member of parliament), who were prosecuted for the sale of poisons, and secured the withdrawal of the Bill as required by the Pharmacy Act of 1868, a new act was passed in 1908, by which persons, without any training in toxicology, and being neither pharmaceutical chemists, nor chemists and druggists, may be granted licences by local authorities to sell poisonous substances used exclusively in agriculture or horticulture, for the destruction of insects, fungi or bacteria, or as sheep dips or weed-killers, but which are poisonous by reason of containing the scheduled poisons, arsenic or nicotine, &c. One condition concerning the granting of such licences has been, it is said, deliberately ignored in many towns, viz., that the local authority, before granting a licence, shall be satisfied that the person applying is in a position, in the public interest, to follow such a business. Thus, it may be seen that the reasonable requirements of the public are satisfied with regard to the purchase of poisonous substances, and also any objections they may receive from the chief officer of police, or from any existing vendors of the substance to which the applications relate.

It is left to the Pharmaceutical Society to take legal action against any infringement of the law, although it is obvious that this should be carried out at the government expense, since it is the crime and its prevention of which the members of the Pharmaceutical Society. Moreover, the present act nullifies the object of the previous act of 1868, which was to reduce the facilities for obtaining poisons. The fact that the provision with respect to legal suits must be stopped, local councils, without government support, seems likely to render this provision of the act of 1908 a dead letter.

As one result of the legislation of 1908, the Pharmacopoeial associations did not come under consideration, and no provision was made concerning them as regards the title of chemist, or as to any action such associations might take to evade the law. It has been decided in the law courts that a limited liability company is not a person in the eye of the law, and therefore does not come under the operation of the act of 1868. The result of this decision was that any chemist who failed to pass the qualifying examination could constitute himself with a few others, even if ignorant of pharmacy, into a limited liability company, which would have been outside the powers of the act, and not subject to its provisions. This false position was remedied by the act of 1908, which brings companies into line with individuals.

On the continent of Europe the dispensing of prescriptions is confined to pharmacists (pharmacien and apothekers). They are not allowed to prescribe, nor the manufacturers to dispense, except under special licence, and then only in small villages, where the pharmacist could not make a living. The principle of "one man one shop" is general; a pharmacist may not own more than one shop in the same town. In Holland he may not enter into any agreement, direct or indirect, with a medical man with regard to the supply of medicines. In Austria, Germany, Italy, Rumania and Russia the number of pharmacies is limited according to the population. In France, Switzerland, Belgium and Holland the number is not limited, and every qualified pharmacist has the right to open a shop or buy a pharmacy. Where the number of pharmacies is limited by law prescriptions may only be dispensed at the pharmacy. In some countries it is required that the pharmacist for either three or ten years, according to the country, and a certified copy given by him, written on white paper if for internal use, or on coloured paper (usually orange yellow) if for external use. The price of the drugs and the tariff for dispensing prescriptions is fixed by government authority.

In Russia a prescription containing any of the poisons indicated in the schedules A and B in the Russian pharmacopoeia may not be repeated, except by order of the doctor. The use of pharmacopoeia preparations made by manufacturers is allowed, but the seller is held responsible for their purity and strength. The prices charged for dispensing anywhere in countries where the number of pharmacies is limited by law, the larger returns enabling the profit to be lessened.

The educational course adopted in different countries varies as to the details of the subjects taught. The preliminary, or classical examination, is usually that of university matriculation, or its equivalent. The period of study is eighteen months in Denmark or Norway, and two in Austria, Finland, Germany, Portugal, Russia, Sweden and Switzerland, three in Belgium, France, Greece and Italy, four to six in Holland, and five in Spain. In Great Britain the period of study is voluntary, and usually occupies only one year. Two or three years of apprenticeship is required in many countries, including Great Britain, but none in Belgium, Greece, Italy or Spain.

The subject of patent medicines is but little understood by the general public. Any medicine, the composition of which is kept secret, but which is advertised on the label for the cure of diseases, must in Great Britain bear a patent medicine stamp equal to about one-ninth of its face value. The British Medical Association published in 1907 a work on Secret Remedies; what they cost and what they contain. The analyses published in this work show that nearly all the widely advertised secret remedies contain only well-known and inexpensive drugs. The Pharmaceutical Society on the other hand has published a Pharmaceutical Journal Formula, including several hundred formulae of proprietary medicines sold by pharmacists, so that it is now possible for any medical man to ascertain what they contain. The government accepts all the therein published formulae as "known, admitted and approved" remedies, and therefore not requiring a patent medicine stamp. In this way widely advertised secret remedies can be replaced by medicines of known composition and accepted value in any part of the world. Most continental countries have issued stringent laws against the sale of secret remedies, and these have been lately strengthened in Germany, France and Italy. In Switzerland secret remedies cannot be advertised without submitting the formula and a sample of the remedy to the board of health.
PHARNAZABUS—PHARYNX

PHARNAZABUS, Persian soldier and statesman, the son of Pharcaes, belonged to a family which from 475 governed the satrapy of Phrygia on the Hellespont, from its headquarters at Dascylion, and, according to a discovery by Th. Nöldeke, was descended from Oanes, one of the associates of Darius in the murder of Smerdis. Pharnazabus first appears as satrap of this province in 413 B.C., when the Persian government sent in the outstanding tribute of the Greek cities on the coast, he, like Tissaphernes of Caria, entered into negotiations with Sparta and began war with Athens. The conduct of the war was much hindered by the rivalry between the two satraps, of whom Pharnazabus was by far the more energetic and upright. After the war he came into conflict with Lysander (q.v.: see also PeloPENNISIAN War), who tried to keep the Greek cities under his own dominion, and became one of the causes of his overthrow, by a letter which he sent to the ephors at Sparta (Plut. Lyg. 15; Nepos, Lys. 4; Polyacen. vi. 19). He received Alcibiades at his court and promised him means to go up to the king to reveal the intrigues of Cyrus, but when the Spartans insisted on his death he yielded to their demand for his assassination (Plut. Alcib. 37 sqq.; Dio. xiv. 11). When in 399 the war with Sparta broke out again he tried to conduct it strenuously. With the help of Conon and Evagoras of Salamis he organized the Persian fleet, and while he was hard pressed on land by Agesilus he prepared the decisive sea-battle, which was fought in August 394 at Cnidus under his and Conon's command, and completely destroyed the Spartan fleet. He sent support to the allies in Greece, by which the walls of the Peiraeus were rebuilt. But in the war on land he struggled in vain against the lethargy and disorganization of the Persian Empire; and when at last, in 387, in consequence of the embassy of Antalcladas to Susa, the king decided to conclude peace with Sparta and to enter again into close alliance with her, Pharnazabus, the principal opponent of Sparta, was recalled from his command in high honours, to marry Apame, a daughter of the king (Plut. Artax. 27). In 385 he was one of the generals sent against Egypt, and in 377 he was ordered to prepare a new expedition against the valley of the Nile. The gathering of the army took years, and when in 373 all was ready, his attempt to force the passage of the Nile failed. A conflict with Iphicrates, the leader of the Greek mercenaries, increased the difficulties; at last Pharnazabus led the army back to Asia. From these campaigns date the first names of Pharnazabus in Aramaic writing, when he died is not known.

In the time of Alexander we meet with a Persian general Pharna-zabus, son of Artabazus (Arrian ii. 1 seq.), who probably was the grandson of the older Pharnazabus.

Pharnazabus was also borne by a king of Iberia (Georgian on the Caucasus, where the dynasty seems to have been of Persian origin, defeated by a general of Marcus Antonius (Mark Antony) in 36 B.C. (Dio Cass. xlix. 24). In the Georgian dynasty the name occurs as late as the 19th century. (Ed. M.)

PHARYNGITIS. The pharynx, or upper portion of the gut (seen to a large extent on looking at the back of the mouth) is frequently the seat of a chronic inflammatory condition, usually associated with debility of the digestive organs, or with syphilis or gout; sometimes it is due to much speaking or to excessive tobacco-smoking—especially of cigarettes. On inspection, the inflamed mucous membrane is seen unduly red and glazed, and dotted over with enlarged follicles. The condition produces considerable irritation and "dryness," with cough and discomfort, which may eventually become chronic. Treatment consists in removing all sources of irritation, in rectifying gastric disturbance, and in the application of the electric current, of astringent lotions or of mild caustic solutions. The pain may be relieved by spraying with certain anodyne solutions. In the case of adenoid growths (see ADENOID) there is seen an asymmetrical granular appearance, and other pathological features in the minute glands of the mucous membrane. The inflamed pharynx of the orator ("clergyman's sore—throat") may be put right by lessons in elocution or by complete rest for a time. The gouty throat may call for a change of diet, or for a stay at one of the watering-places where early rising, moderate food, regular exercise and the drinking of laxative waters join in restoring health. (E. O.*.)

PHARYNX (Gr. φαράγγις, throat), in anatomy, the cavity into which both the nose and mouth lead, which is prolonged into the oesophagus or gullet below, and from which the larynx or air tube comes off below and in front; it therefore serves as a passage for food and the free edition of the throat. Dorsally the sack turned upside down and narrowing toward its mouth. The back and sides of the sack are formed by the three constrictor muscles of the pharynx, each of which overlie the outer surface of the one above it, and these are lined internally by thick mucous membrane. The upturned bottom of the sac is attached firmly to the base of the skull and the internal pterygioid plates, so that this part cannot collapse, but below the anterior and posterior walls are in contact, and a transverse section of the pharynx is a mere slit.

From the front wall, on a level with the floor of the nose and roof of the mouth, a slanting shelf of muscular and glandular tissue, covered with mucous membrane, projects downward and backward into the cavity, and divides it into an upper part or naso-pharynx and a lower or oral pharynx (see fig.). This shell is the soft palate, and from the middle of its free border hangs a worm-like projection, a modification of the posterior part of the palate. The whole length of the floor of the nasso-pharynx is wanting, and here the cavity opens into the nose through the posterior nasal apertures (see olfactory System). On each side of the nasso- pharynx there is a small posterior part, which is overlapped by one large triangular opening of the Eustachian tube through which air passes to the tympanum (see Ears). Behind this opening, and reaching up to the line of the naso-pharynx, the nasso-pharynx is most in children, known as the pharyngeal tonsil. This tissue, when it hypertrophies, causes the disease known as "adenoid." From the mid-line of the roof of the pharynx a small pouch, the bursa pharyngea, best seen in childhood, projects upward, while on each side, above and behind the opening of the Eustachian tube, is a depression known as the lateral recess of the pharynx. The oral pharynx communicates with the nasso-pharynx by the pharyngeal orifice, which is the edge of the gullet (see Oesophagus), and in front it is continuous with the cavity of the mouth, and the demarcation between the two is a ridge of mucous membrane on each side running from the soft palate to the side of the tongue, and formed by the posterior wall of the naso-pharynx. This is known as the anterior pillar of the faucæ or anterior palatine arch. About half an inch behind this ridge is another, made by the palato-pharyngeal muscle, which gradually fades away in the side of the pharynx below. This is the posterior pillar of the faucæ or posterior palatine arch, and between it and the anterior is the fossa (tonsillar sinus) in which the tonsil lies.

The constrictor muscle is an oblong muscle, bordered above by mucous membrane which dips in to form mucous crypts; externally its position nearly corresponds to that of the angle of the jaw. It is very vascular, deriving its blood from five neighbouring arteries. Behind it is bounded by the edge of a flat bone, the hyoid bone, which is divided in the middle by a transverse line, and in front it is continuous with the cavity of the mouth, and the demarcation between the two is a ridge of mucous membrane on each side running from the soft palate to the side of the tongue, and formed by the posterior wall of the naso-pharynx. This is known as the anterior pillar of the faucæ or anterior palatine arch. About half an inch behind this ridge is another, made by the palato-pharyngeal muscle, which gradually fades away in the side of the pharynx below. This is the posterior pillar of the faucæ or posterior palatine arch, and between it and the anterior is the fossa (tonsillar sinus) in which the tonsil lies.

The mucous membrane of the nasso-pharynx, like that of the rest of the respiratory tract, is lined by ciliated columnar epithelium, but the nasal portion is epithelium of a different type, with ciliated pillar cells, and the oral portion with a lining of squamous epithelium. Numerous mucous glands are present (see epithelial Tissues), as well as patches of lymphoid tissue especially in children. The orifice of the naso-pharynx is the naso-pharyngeal constrictor muscles is the pharyngeal aperionysus, which blends above with the periosteum of the base of the skull. Embryology.—The pharynx is partly formed from the ectoderm under the stomodeum (see Stomodeum) and partly from the fore gut, which is the cephalic part of the endodermal mesoderm. Up to the fifteenth day (see mouth), the bucco-pharyngeal membrane separates these structures, and, though it is supposed that removal of this membrane will result in the naso-pharynx is stomatodaeal while the rest is mesodermal. The five visceral arches with their intervening clefts or pouches surround the pharynx, and the Eustachian tube is a remnant of the second arch. These are lined alternately by the mucous membrane of the pharynx and the branchial sinus, and until lately the lateral recess of the pharynx was looked upon as part of the same, but it has now been shown to be an independent diverticulum. The sinus pharyngis probably represents that part of the pharynx from which the lateral lobes of the thyroid body are derived.
PHEASANT

The Bursa pharyngea was at one time looked upon as the place whence the putative body had been derived from the roof of the pharynx, but this is now disproved and its meaning is unknown. The tonsils is formed in the second branchial cleft or rather pouch, for the clefts are largely incomplete in man, about the fourth month; its lymphoid tissue, as well as that elsewhere in the pharynx, is formed from lymphocytes in the subjacent mesenchyme (see Embryology), though whether these wander in from the blood or are derived from original mesenchyme cells is still doubtful. The

these form the simplest type of true internal gills. In the larval lamprey (Ammocoetes) there are eight gill slits opening from the pharynx, but in the adult (Petromyzon) they are reduced to seven, and a septum grows forward separating the ventral or branchial part of the pharynx (or branchial arch) into two parts. Both these tubes, however, communicate near the mouth.

In fishes there are usually five pairs of gill slits, though a rudimentary one in front of these is often present and is called the first. Occasionally, as in the archiaci, there may be six or seven slits, and the evidence of comparative anatomy is that fishes formerly had a larger number of gill slits than at present.

In the Teleostomi, which include the bony fishes, there is an external gill cover or operculum, as well.

In the Dipnoi or mud fish the work of the gills is shared by that of the lungs, and in the African form, Proteus, external gills, developed from the ectodermal parts of the gill slits, first appear. In the tadled Amphibians (Urodelta) the first and fifth gill clefts are never perforated and are therefore in the same condition as all the gill clefts of the human embryo, while in the gilled salamanders (Necturus and Proteus) only two gill clefts remain patent. The gills in all of Amphibia are external and of ectodermal origin, but in the Anura (frogs and toads) these are succeeded before the metamorphoses from the tadpole stage by internal gills, which, unlike those of fish, are said to be derived from the endoderm.

In the embryos of the Sauropsida (reptiles and birds) five gill clefts are evident; though the posterior two are seldom at any time perforated, while in the Mammalia the rudiments of the fifth cleft are no longer found in the embryo, and in man, at all events, none of them are normally perforated except that part of the first which forms the Eustachian tube. It will thus be seen that in the process of phylogeny there is a gradual suppression of the gill clefts beginning at the more posterior ones.

The soft palate is first found in crocodilians as a membranous structure, and it becomes muscular in mammals. The bursa pharyngea and pharyngeal tonsil are found in several of the lower mammals. In the sheep the latter is particularly large.

For literature and further details, see R. Wiedersheim's Comparative Anatomy of Vertebrates, translated by W. N. Parker (London, 1907); also Parker and Haswell's Zoology (London, 1897).

PHEASANT (Mid. Eng. faisant and fessant; Ger. fasan and anciently fasant; Fr. faisant—all from the Lat. phasianus or phasiana, sc. avis), the bird brought from the banks of the river Phasis, now the Kloni, in Colchis, where it is still abundant, and introduced, according to legend, by the Argonauts into Europe. Judging from the recognition of the remains of several species referred to the genus Phasianus both in Greece and France, it seems impossible that the ordinary pheasant, P. colchicus of ornithologists, may have been indigenous to this quarter of the globe. If it was introduced into England, it must almost certainly have been brought by the Romans; for, setting aside several earlier records of doubtful authority, Stubbs has shown that by the regulations of King Harold in 1059 unus phasianus is prescribed as the

1 These are P. archaci from Pikermi, P. altus and P. medius from the lacustrine beds of Sansan, and P. desayersii from Touraine, see A. Milne Edwards, Recherches de la faune de la France (Paris, 1843), pp. 367, 368, whereas (from) the Indo-Australian region, R. Argonauts in the fourth month; it becomes abundant in the seventh, and is present in the adult.

2 Undoubted remains have been found in excavations at Silchester.

3 Among these perhaps the worthy of most attention is in Probert's translation of The Ancient Laws of Cambria (ed. 1823, pp. 367, 368), whereas (from) the Indo-Australian region, R. Argonauts in the fourth month; it becomes abundant in the seventh, and is present in the adult.

5 Among these perhaps the worthy of most attention is in Probert's translation of The Ancient Laws of Cambria (ed. 1823, pp. 367, 368), whereas (from) the Indo-Australian region, R. Argonauts in the fourth month; it becomes abundant in the seventh, and is present in the adult.

6 Among these perhaps the worthy of most attention is in Probert's translation of The Ancient Laws of Cambria (ed. 1823, pp. 367, 368), whereas (from) the Indo-Australian region, R. Argonauts in the fourth month; it becomes abundant in the seventh, and is present in the adult.
alternative of two partridges or other birds among the "pitaniae" (rations or commons, as we might now say) of the canons of Waltham Abbey, and, as W. B. Dawkins has remarked (Ibis, 1860, p. 358), neither Anglo-Saxons nor Danes were likely to have introduced it into England. It seems to have been early under legal protection, for, according to Dugdale, a licence was granted in the reign of Henry I. to the abbot of Amesbury to kill hares and pheasants, and from the price at which the latter are reckoned in 1149 with the same measure as by hay (Symonds, math. animalium, pp. 213, 214) on the authority of Liwyd or Lloyd, though there is no mention of it in Wotton and Clarke's Leges Waliae (1730). A charter (Kemble, Cod. Diplom. i, 230), professedly of Edward the Confessor, granting the wardenship of certain forests in Essex to Ralph Peperking, speaks of "feasant hen" and "feasant cocke," but is now known to be spurious.

Following Linné's De studio militari (see Bronte, 1854) he states (p. 195) that the pheasant was brought from the East by "Palladius anticorista."

3Quoted by the writer (Broderip?) of the article "Spanish" in the Penny Cyclopaedia. The terms "wheezing cockerel" on the asserted Welsh practice mentioned in the form of bird are correctly "piffling cockerel.

361 to the Zeus of grow thus him. A much rarer variety is sometimes seen; this is known as the Bohemian pheasant, not that there is the least reason to suppose it has any right to such an epithet, for it appears, as it were, accidentally among a stock of the pure P. colchicus, and offers an example analogous to that of the Japan peacock (see Peacock), being, like that breed, capable of perpetuation by selection. Two other species of pheasant have been introduced to the coverts of England—P. reevestis from China, remarkable for its very long tail, white with black bars, and the copper pheasant, P. semmerringii, from Japan. The well-known gold and silver pheasants, P. pictus and P. nyctheerus, each the type of a distinct section or subgenus, are both from China and have long been introduced into Europe, but are only fitted for the aviary. To the former is allied the still more beautiful P. amherstiae, and to the latter about a dozen more species, most of them known to Indian sportsmen by the general name of "kalege." The comparatively plain pucras pheasants, Psarias, the magnificent monalus, Lophophorus, and the fine snow-pheasants, Crossoptilum of each of which genera there are several species, may also be mentioned.

All the species known at the time are beautifully figured from drawings by J. Wolf in D. G. Elliot's Monograph of the Phasianidae (2 vols., fol., 1870–1872)—the last term being used in a somewhat general sense. With a more precise scope W. B. Tegelmeier's Pheasants: their Natural History and Practical Management (4th ed., 1904) is to be commended as a very useful work. (A. N.)

PHIEDIAS, son of Charmides, universally regarded as the greatest of Greek sculptors, was born at Athens about 500 B.C. We have varying accounts of his training. Hegias of Athens, Ageladas of Argos, and the Thasian painter Polynotus, have all been credited as his teachers. In favour of Ageladas it may be said that the influence of the many early Persian schools is certainly to be traced in some of his work. Of his life we know little apart from his works. Of his death we have two discrepant accounts. According to Plutarch he was made an object of attack by the political enemies of Pericles, and died in prison at Athens. According to Philochorus, as quoted by a scholarist on Aristophanes, he fled to Elis, where he made the great statue of Zeus for the Eleans, and was afterwards put, to death by them. For several reasons the first of these tales is preferable.

Plutarch gives in his life of Pericles a charming account of the vast artistic activity which went on at Athens while that statesman was in power. He tells us that the city the money furnished by the Athenian allies for defence against Persia: it is very fortunate that after the time of Xerxes Persia made no deliberate attempt against Greece. "In all these works," says Plutarch, "Phiedias was the adviser and overseer of Pericles." Phiedias introduced his own portrait and that of Pericles on the shield of his Parthenon statue. And it was through Phiedias that the political enemies of Pericles struck at him. It thus abundantly appears that Phiedias was closely connected with Pericles, and a ruling spirit in the Athenian art of the period. But it is not easy to go beyond this general assertion into details. It is certain that the sculptor gave to the famous name of Phiedias upon the sculptures of the Parthenon we proceed with little evidence. No ancient writer ascribes them to him, and he seldom, if ever, executed works in marble. What he was celebrated
for in antiquity was his statues in bronze or gold and ivory. If Plutarch tells us that he superintended the great works of Pericles on the Acropolis, this phrase is very vague. On the other hand, inscriptions prove that the marble blocks intended for the pedimental statues of the Parthenon were not brought to Athens until 434 B.C., which was probably after the death of Pheidias. And there is a marked contrast in style between these statues and the certain works of Pheidias. It is therefore probable that most if not all of the sculptural decoration of the Parthenon was the work of pupils of Pheidias, such as Alcamenes and Agarcritus, rather than his own.

The earliest of the great works of Pheidias were dedications in memory of Marathon, from the spoils of the victory. At Delphi he erected a great group in bronze including the figures of Apollo and Athena, several Attic heroes, and Mitaiades the general. On the Acropolis of Athens he set up a colossal bronze image of Athena, which was visible far out at sea. At Pellene in Achaea, and at Plataea he made two other statues of Athena, also a statue of Aphrodite in ivory and gold for the people of Eilis. But among the Greeks themselves the two works of Pheidias which far outshine all others, and were the basis of his fame, were the colossal figures in gold and ivory of Zeus at Olympia and of Athena Parthenos at Athens, both of which belong to about the middle of the 5th century. Of the Zeus we have unfortunately lost all trace save small copies on coins of Eilis, which give us but a general notion of the pose, and the character of the head. The god was seated on a throne, every part of which was used as a ground for sculptural decoration. His body was of ivory, his robe of gold. His head was of somewhat archaic type: the Otricoli mask which used to be regarded as a copy of the head of the Olympian statue is certainly more than a century later in style. Of the Athena Parthenos two small copies in marble have been found at Athens (see Greek Art, fig. 38) which have no excellence of workmanship, but have a certain evidential value as to the treatment of their original.

We shall see how very small is our actual knowledge of the works of Pheidias. There are many stately figures in the Roman and other museums which clearly belong to the same school as the Parthenos; but they are copies of the Roman age, and not to be trusted in point of style. A. Furtwängler proposes to find in a statue of which the head is at Bologna, and the body at Dresden, a copy of the Lemnian Athena of Pheidias; but his arguments (Masterpieces, at the beginning) are anything but conclusive. Much more satisfactory as evidence are some 5th century torsos of Athena found at Athens. The very fine torso of Athena in the École des Beaux Arts at Paris, which has unfortunately lost its head, may perhaps best serve to help our imagination in reconstructing a Pheidian original.

As regards the decorative sculptures of the Parthenon, which the Greeks rated far below their colossal in ivory and gold, see the article PARTHENON.

Ancient critics take a very high view of the merits of Pheidias. What they especially praise is the ethos or permanent moral level of his works as compared with those of the later "pathetic" school. Demetrius calls his statues sublime, and at the same time precise. That he rode on the crest of a splendid wave of art is not to be questioned: but it is to be regretted that we have no morsel of work extant for which we can definitely hold him responsible.

(P. G.)

PHEIDON (8th or 7th century B.C.), king of Argos, generally, though wrongly, called "tirant." According to tradition he flourished during the first half of the 8th century B.C. He was a vigorous and energetic ruler and greatly increased the power of Argos. He gradually regained sway over the various cities of the Argive confederacy, the members of which had become practically independent, and (in the words of Ephorus) "re-united the broken fragments of the inheritance of Temenus." His object was to secure predominance for Argos in the north of Peloponnesus. According to Plutarch, he attempted to break the power of Corinth, by requesting the Corinthians to send him 1000 of their picked youths, ostensibly to aid him in war, his real intention being to put them to death; but the plot was revealed. Pheidon assisted the Pisatans to expel the Elean superintendents of the Olympic games and presided at the festival himself. The Eleans, however, refused to recognize the Olympiad or to include it in the register, and shortly afterwards, with the aid of the Spartans, who are said to have looked upon Pheidon as having ousted them from the headship of Greece, defeated Pheidon and were reinstated in the possession of Pisat and their former privileges. Pheidon is said to have lost his life in a faction fight at Corinth, where the monarchy had recently been overthrown. The affair of the games has an important bearing on his date. Pausanias (vi. 22, 2) definitely states that Pheidon presided at the festival in the 8th Olympiad (i.e. 768 B.C.), but in the 7th century. Lycias, daughter of Cleithenes of Sicyon, given by Herodotus, Plato and others, is the name of Leocedes (Lacedaemon), son of Pheidon of Argos. According to this, Pheidon must have flourished during the early part of the 6th century. It has therefore been assumed that Herodotus confused two Pheidons, both kings of Argos. The suggested substitution in the text of Pausanias of the 28th for the 8th Olympiad (i.e. 668 instead of 748) would not bring it into agreement with Herodotus, for even then Pheidon's son could not have been a suitor in 570 for the hand of Agrist of. But the story of Agriste's wooing resembles romance and has slight chronological value. On the whole, modern authorities assign the two Pheidons to the 8th century. Herodotus further states that Pheidon established a system of weights and measures throughout Peloponnesus, to which Ephorus and the Ptolemaic Chronicle adds that he was the first to coin silver money, and that his mint was at Aegina. But according to the better authority of Herodotus (i. 94) and Xenophanes of Colophon, the Lydians were the first coiners of money at the beginning of the 7th century, and, further, the oldest known Aeginetan coins are of later date than Pheidon. Hence, unless a later Pheidon is assumed, the statement of Ephorus must be considered unhistorical. No such difficulty occurs in regard to the weights and measures; it is generally agreed that a system was already in existence in the time of Pheidon, into which he introduced certain changes. A passage in the Aristotelian Constitution of Athens (s. 2) states that the measures used before the Solonian period of reform were called "Pheidonian."

See Herodotus vi. 127; Ephorus in Strabo viii. 358, 376; Plutarch, Amatoriae narrationes, 2; Marmor parium, ep. 30; Pollux ix. 83; Nicolaus Damascenus, frag. 41 (in C. W. Müller's Frag. histi. graec., iii.); G. Grote, History of Greece, pt. ii. ch. 41 B. V. Head, History of the Peloponnesian War (1887); F. Hultsch, griechische und römische Metrologie (1882); G. Rawlinson's Herodotus, appendix, bk. i., note 8. On the question of Pheidon's date, see J. B. Bury, History of Greece, 868 (1907); J. F. Macaulay, Problems in Greek History, ch. 3 (1892); J. G. Frazer's note on Pausanias vii. 22; and especially G. Busolt, Griechische Geschichte (2nd ed., 1893), ch. iii. 12. C. Triebel, Pheidon von Argos (Hanover, 1880), and J. Beloch, in Rheinisches Museum, xiv. 595 (1890), favour a later date, about 580.

PHPELS, AUSTIN (1820-1890), American Congregational minister and educationalist, was born on the 7th of January 1820 at West Brookfield, Massachusetts, son of Eliakim Phelps,1 a clergyman, who, during the boyhood of his son was principal of a girls' school in Pittsfield, Massachusetts, and later pastor of a Presbyterian church in Geneva, New York. The son studied at Hobart College in 1833-1835, then at Amherst for a year, and in 1837 graduated at the university of Pennsylvania. He studied theology at Union Theological Seminary, at the Yale Divinity School, and at Andover, and was licensed to preach in 1840 by the Third Presbytery of Philadelphia. He was pastor of the Pine Street (Congregational) Church in Boston in 1842-1845, and in 1845-1859 was pastor of sacred rhetoric Pheidon-literaries at Andover. Of the educational Seminary, of which he was president from 1860 to 1870, when his failing health forced him to resign. He died on the 13th of October 1890 at Bar Harbor, Maine. His Theory of Preaching (1881) and English

1 Eliakim Phelps afterwards lived in Stratford, Herkimer county, New York, where his house was "possessed" and was long a place of curious interest to students of "spiritualism."
PHelps, E. J.—Phenacetin

PHelps, Edward John (1822–1900), American lawyer and diplomat, was born on the 11th of July 1822 at Middlebury, Vermont. He graduated from Middlebury College in 1840, was a schoolmaster for a year in Virginia, and was admitted to the bar in 1843. He began practice at Middlebury, but in 1849 moved to Burlington, Vermont. From 1851 to 1853 he was second comptroller of the United States Treasury, and then practiced law in New York City until 1857, when he returned to Burlington. Becoming a Democrat after the Whig party had ceased to exist, he was debarred from a political career in his own state, where his party was in the minority, but he served in the state constitutional convention in 1870, and in 1880 was the Democratic candidate for governor of his state. He was one of the founders of the American Bar Association, and was its president in 1880–1881. From 1881 until his death he was Kent Professor of Law in Yale University. He was a superb advocate. His pupils were the leading lawyers of the state, and it was remarked that after his death the state lost its best orator.

Phelps, Samuel (1804–1878), English actor and manager, was born at Devonport on the 13th of February 1804. He was early thrown upon his own resources, and worked in various newspaper offices. Shortly after his marriage in 1826 to Sarah Cooper (d. 1867), he accepted a theatrical engagement in the York circuit at eighteen shillings a week, and afterwards appeared in south of England towns in prominent tragic roles, attracting sufficient attention to be spoken of as a rival to Kean. He made his first London appearance on the 28th of August 1837 as Shylock at the Haymarket. After a short season at the Comedy Theatre, he joined Madame Vestris at Drury Lane, and six years later, at Covent Garden, the Haymarket and Drury Lane successively. In 1844 he became co-lessee of Sadler's Wells Theatre with Thomas L. Greenwood and Mrs Mary Amelia Warner (1804–1854). Greenwood supplied the business capacity, Phelps was the theatrical manager, and Mrs Warner leading lady. In this position Phelps remained for twenty years, during which time he raised the Sadler's Wells house to an important position, and himself appeared in a very extensive and varied repertory. Thirty-four of Shakespeare's plays were presented there under his direction, with great educational effect, both on public and players. In 1861 Greenwood retired from the partnership, and Phelps, with 1854, took the business. After fifteen years he acted under various managements, achieving considerable success in some of Halliday's dramatic versions of Scott's novels, such as The Fortunes of Nigel and Ivanhoe. His last appearance was in 1878 as Wolsey in Henry VIII., and he died on the 6th of November 1878. He was a sound and capable actor, rather than one of any marked genius; and, in spite of his predilection for tragedy, was most successful in such characters of comedy as called for dry humour. Perhaps Sir Pertinax Macscypont in Charles Macklin's The Man of the World was his finest impersonation. He published an annotated edition of Shakespeare's plays (2 vols., 1852–1854).

Phelypeaux, a French family of Blésois. Its two principal branches were those of the seigneurs of Herbeaut, La Vrillière and Saint Florentin, and of the counts of Pontchartrain and Maurepas. Raimond Phelypeaux, seigneur of Herbeaut and La Vrillière (d. 1629), was treasurer of the Épargne in 1599, and became secretary of state in 1621. His son Louis succeeded him in this latter office, and died in 1651. Balthazar Phelypeaux, marquis de Châteauneuf (d. 1700), and Louis, marquis de La Vrillière (d. 1725), respectively son and grandson of Louis, were also secretaries of state. Louis Phelypeaux (1705–1777), count of Saint Florentin and afterwards duke of La Vrillière (1770), succeeded his father as secretary of state; became minister of the king's household in 1749, a minister of state in 1751, and discharged the functions of minister of foreign affairs on the disgrace of Choiseul (1770). He incurred great unpopularity by his abuse of lettres de cachet, and had to resign in 1775. Raimond Balthazar Phelypeaux, seigneur du Verger, a member of the La Vrillière branch, was sent as ambassador to Savoy in 1700, where he discovered the intrigues of the duke of Savoy, Victor Amadeus II., against France; and when war was declared he was kept a close prisoner by the duke (1793–1794). At the time of his death (1793) he was governor-general in the West Indies. The branch of Pontchartrain-Maurepas was founded by Paul Phelypeaux (1683–1761), brother of the first-mentioned Raimond; he became secretary of state in 1760.

Phenacetin, C₉H₆O₂C₄H₄-NHCOCH₃ (para-acetamino-phenetidin), a drug prepared by acetylation of para-phenetidin, or by heating para-acetylaminophenol and potassium ethyl sulphate with alcoholic soda to 150° C. Para-phenetidin is prepared by treating the sodium salt of para-nitrophenol with ethyl iodide, and reducing the nitrophenol to para-phenetidin or aminophenol. The yield may be doubled by diazotizing para-phenetidin, coupling with phenol, ethylating and reducing: EtO-C₆H₄-NH₂ → EtO-C₆H₄-NHOH → EtO-C₆H₄-NH₂-HOEt → EtO-C₆H₄-NH₂-OEt → EtO-C₆H₄-NH₂.

It crystallizes from water in colourless plates, melting at 135° C. It is soluble in about 20 parts of hot and in about 400 parts of cold water.

Several compounds related to phenacetin have been introduced into medicine. Trifenphen is propylphenetidin; lactophenin is lactophenidin; pyrantin is para-ethoxyphenyl succinimide, EtO-C₆H₄-N(CO-CH₃); salophen or salphenin is salicylphenetidin; amylyphenin is mandelylphenetidin. In addition, several other derivatives have been suggested which have a greater solubility than phenacetin, e.g. phenin, which is the sodium salt of phenacin sulphonic acid, apolin and citrinphenin (both with Methylphenidin), which are citric acid derivatives of para-phenetidin, &c.

Phenacetin is contained in both the British and United States pharmacopoeia, in the latter under the name of acetophenetidin. The dose is 5 to 10 grs. given in cachets or in suspension. When the drug is carelessly made it may contain impurities, producing considerable irritation of the kidneys. The physiological action of phenacetin consists in a sedative action on the sensory tracts of the spinal cord, and a depressant action on the heart, where it
tends to paralyse the action of the cardiac muscle. Upon the bodily heat it exercises a marked effect, decreasing the action of the heat-producing centre as well as increasing the dissipation of heat, and thus causing a marked fall in temperature; and doses the blood becomes dark and blackish from the formation of methaemoglobin, and the urine is changed in colour from the passage of altered blood. The chief therapeutic use of phenacetin is as an antineuraltic, and it is of service in migraine, rheumatism of the sub-acute type, intercostal neuralgia and locomotor ataxia.

PHENACITE is a mineral consisting of beryllium orthosilicate, Be$_3$SiO$_4$, occasionally used as a gem-stone. It occurs as isolated crystals, which are rhombohedral with parallel-faced hemimorphite and are either lenticular or prismatic in habit; the lenticular habit is determined by the development of faces of several obtuse rhombohedra and the absence of prism faces (the accompanying figure is a plan of such a crystal viewed along the triad, or principal, axis). There is no cleavage, and the fracture is conchoidal. The hardness is high, being 7–8; the specific gravity is 2.98. The crystals are sometimes perfectly colourless and transparent, but more often they are greyish or yellowish and only translucent; occasionally they are pale rose-red. In general appearance the mineral is not unlike quartz, for which indeed it had been mistaken; on this account it was named, by N. Nordensköld in 1833, from Gr. φωσαλη (a deceiver).

Phenacite has long been known from the emerald and chrysoberyl mine on the Takovaya stream, near Katunburg in the Urals, where large crystals occur in mica-schists. It is also found with topaz and amazonstone in the granite of the frontline mountains in the southern Urals and of the Pike's Peak Region in Colorado. Large crystals of prismatic habit have more recently been found in a felspar quarry at Kragerø in Norway. Framont near Schirmeck in Alsace is another well-known locality. Still larger crystals, measuring 12 in. in diameter and weighing 28 lb, have been found at Greenwood in Maine, but these are pseudomorphs of quartz after phenacite.

For gem purposes the stone is cut in the brilliant form, of which there are two fine examples, weighing 43 and 34 carats, in the British Museum. The indices of refraction ($n_1=1.6540$, $n_2=1.6527$) are higher than those of quartz, beryl or topaz; a faceted phenacite is consequently rather brilliant, and may sometimes be mistaken for diamond.

PHENACODUS, one of the earliest and most primitive of the ungulate mammals, typifying the family Phenacodontidae and the sub-order Condylarthra. The typical Phenacodus primaeus, of the Lower or Wasatch Eocene of North America, was a relatively small ungulate, of slight build, with straight limbs each terminating in five complete toes, and walking in the digitigrade fashion of the modern tapir. The middle toe was the largest, and the weight of the body was mainly supported on this and the two adjoining digits, which appear to have been encased in hoofs, thus foreshadowing the triadactyle type common in perissodactyle and certain extinct groups of ungulates. The skull was small, with proportionately minute brain; and the arched back, strong lumbar vertebrae, long and powerful tail, and comparatively feeble fore-quarters all proclaim kinship with the primitive creodont Carnivora (see CREODONTA), from which Phenacodus and its allies, and through them the more typical Ungulata, are probably derived. All the bones of the limbs are separate, and those of the carpus and tarsus do not alternate; that is to say, each one in the upper row is placed immediately above the corresponding one in the row below. The full series of forty-four teeth was developed; and the upper molars were short-crowned, or brachydont, with six low cones, two internal, two intermediate and two external, so that they were of the typical primitive bunodont structure. In habits the animal was cursorial and herbivorous, or possibly carnivorous.

In the Puero, or Lowest Eocene of North America the place of the above species was taken by Euprotognathus cuernoensis, an animal only half the size of Phenacodus primaeus, with the terminal joints of the limbs intermediate between hoofs and claws, and the first and fifth toes taking their full share in the support of the weight of the body. These two genera may be regarded as forming the earliest stages in the evolution of the horse, coming below Hyracotherium (see EQUIDAE).

As ancestors of the Artiodactyle section of the Ungulata, we may look for forms more closely related to the North American Lower Eocene genera Miochaenus and Panolodontes, respectively typifying the families Miochaenidae and Pantoideidae. These were five-toed, bunodont Condylarthra, with a decided approximation to the perissodactyle type in the structure of the feet. A third type of Condylarthra from the North American Lower Eocene is represented by the family Menisotheriidae, including the genera Menisotherium and Hyracops. These, it is suggested, may have been related to the ancestral Hyracoidae. Teeth and jaws probably referable to the Condylarthra have been obtained in European early Tertiary formations. All Ungulata probably originated from Condylarthra.

See H. F. Osborn, Sketch of Phenacodus primaeus; comparison with Euprotognathus, Bull. Amer. Mus. x. 150.

PHENANTHRENE, C$_{14}$H$_{10}$, a hydrocarbon isomeric with anthracene, with which it occurs in the fraction of the coal tar distillate boiling between 270°-400° C. It may be separated from the anthracene oil by repeated fractional distillation, followed by fractional crystallization from alcohol (anthracene being the less soluble), and finally purified by oxidizing any residual anthracene with potassium bichromate and sulphuric acid (R. Ansutz and G. Schultz, Ann., 1879, 196, p. 33); or the two hydrocarbons may be separated by carbon bisulphide, in which anthracene is insoluble. It is formed when the vapours of toluene, stilbene, dibenzyl, ortho-dityl, or coumarone and benzene are passed through a red-hot tube; by distilling morphine with zinc dust; and, with anthracene, by the action of sodium on ortho-benzylbenzyl bromide (C. L. Jackson and J. F. White, Amer. Chem. Jour., 1880, 2, p. 391). It crystallizes in colourless plates or needles, which melt at 99° C. Its solutions in alcohol and ether have a faint blue fluorescence. When heated to 250° C. with red phosphorus and hydriodic acid it gives a hydride, C$_{14}$H$_{14}$. It is nitrated by nitric acid and sulphonated by sulphuric acid. With picric acid it forms a sparingly soluble picrate, which melts at 145° C. On the condition of phenanthrene in alcoholic solution see R. Behrend, Zeit. phs. Chem., 1879, 9, p. 409; 10, p. 260. Chomatic acid oxides phenanthrene, and its dihydro derivative, to dihydroquinone, and then to diphenic acid, H$_2$O.C$_7$H$_4$.C$_7$H$_9$.CO.H.

Phenanthrene-quinone, [CH$_4$.H$_2$.CO].H, crystallizes in orange needles which melt at 198° C. It possesses the characteristic properties of a diketone, forming crystalline derivatives with sodium bisulphite and a dioxide with hydroxylamine. It is non-volatile in steam, and is odourless. Sulphuric acid reduces it to the corresponding dihydroxy compound. It combines with ortho-diamines, in the presence of acetic acid, to form phenazines.

On the constitution of phenanthrene see CHEMISTRY: § Organic.

PHENAZINE (Azophenylene), C$_{14}$H$_{10}$N$_2$, in organic chemistry, the parent substance of many dyestuffs, e.g. the eurhodines, toluylene red, indulines and safranines. It is a dibenzopara- diazine having the formula given below. It may be obtained by distilling barium azobenzene (A. Claus, Ber., 1873, 6, p. 723); by passing aniline vapour over lead oxide, or by the oxidation of dihydrophenazine, which is prepared by heating pyrocatech in with orthophenylene diamine (C. Ris, Ber., 1886, 19, p. 226). It is also formed when ortho-aminodiphenylamine is distilled over lead peroxide (O. Fischer and E. Hepp). It crystallizes in yellow needles which melt at 171° C, and are only sparingly soluble in alcohol. Sulphuric acid dissolves it, forming a deep-red solution. The more complex phenazines, such as the naphthophenazines, naphthazines and naphthotolazines, may be prepared by condensing ortho-diamines with ortho-quinones (O. Hilsberg, Ann., 1887, 237, p. 348); by the oxidation of an ortho-diamine in the presence of a-naphthol (O. Witt, and by
PHENOLPHTHALEIN—PHERECYDES OF SYROS

the decomposition of ortho-anilino-(toluidido- &c.-)azo compounds with dilute acids. If alkyl or aryl-ortho-diamines are used azonium bases are obtained. The azines are mostly yellow in colour, distil unchanged and are stable to oxidants. They add on alkyl iodides readily, forming alkyl azonium salts.

By the extraction of amino or hydroxy groups into the molecule dyestuffs are formed. The mono-amine derivatives or eucroides are obtained when the arylmonamines are condensed with ortho-aminoazo compounds; by condensing quinone dichlorides or para-nitrodiametly aniline with monamines containing a free para position, or by oxidizing ortho-hydroxydiamino diphenylamines (R. Nietzki, Ber., 1893, 28, p. 2976; O. Fischer, ibid., 1896, 29, p. 1874). They are yellowish-red solids, which behave as weak bases, their salts undergoing hydrolytic dissociation in aqueous solution. When heated with concentrated hydrochloric acid the amino group is replaced by the hydroxyl group and the phenolic ethylenediamines are produced.

The symmetrical diamino phenazine is the parent substance of the important dyestuff toluidine red or dimethylaminotoluidophenazine. It is obtained by the oxidation of orthophenylenediamine with ferric chloride; when a mixture of para-aminodimethylaniline and meta-toluylenediamine is oxidized in the cold, toluylene blue, an indamine, being formed as an intermediate product and passing into the red when boiled, and also by the oxidation of dimethyl-paraaminophenylamine with metatoluylene diamine. It crystallizes in orange-red needles and its alcoholic solution fluoresces strongly. It dyes silk and mordanted cotton a fine scarlet. It is known commercially as neutral red. For the phenazonium salts see SAFRANINE.

Phenazine is an isomer of phenazone, with which it bears the same relation that phanethrene bears to anthracene. It is formed by reducing dicyano-phenazone with magnesium amalgam in alcohol, or by heating diphenylene-ortho-dihydrazine with hydrochloric acid to 150°C. It crystallizes in needles which melt at 156°C. Potassium permanganate oxidizes it to pyridazine tetracarboxylic acid.

PHENOLPHTHALEIN, in organic chemistry, a compound derived from phthalophenone, or diphenyl phthalide (formula I), the anhydride of triphenyl-carbonil-ortho-carboxylic acid, which is obtained by condensing phthalic anhydride with benzene in the presence of aluminium chloride. The phthalic anhydrides are formed from this anhydride by the extraction of hydroxyl or amino groups into the two phenyl residues, and are prepared by condensing phenols with phthalic anhydride, phenol itself giving rise to phenolphthalein (formula II) together with a small quantity of fluorone (formula III), whilst resorcin under similar conditions yields fluorescein (p.a.). The phthalic anhydrides on reduction yield phthalides, which are derivatives of triphenylmethylene carboxylic acid; these reduction products are colourless and are obtained as the lower compounds of the phthalides, thus phenolphthalein itself gives phenolphthalein (formula IV). Dehydrating agents usually convert the phthalophenolines into anthraquinone derivatives.

I. Diphenyolphthalein, II. Phenolphthalein, III. Fluorone.

Phenolphthalein is obtained when phenol and phthalic anhydride are heated with concentrated sulphuric acid. It crystallizes in colourless crystals and is nearly insoluble in water, but dissolves in dilute solutions of the caustic alkalies with a fine red colour, being precipitated from these solutions by the addition of mineral acid. It dissolves in concentrated caustic alkalies at a colourless solution which probably contains salts of a non-quinonoid character. This 'difference in behaviour has led to considerable discussion (see H. Meyer, Monats., 1899, 20, p. 337; R. Meyer, Ber., 1903, 36, p. 2949; A. G. Pfitzner, Green, Jour. Chem. Soc., 1904, p. 390). On heating with caustic alkali, phenolphthalein yields benzoic acid and para-dihydroxybenzophenone, which shows that in the original condensation the phthalic acid residue has taken the para position to the hydroxy groups of the phenol.

Fluorone is a product of the condensation of the phthalic acid residue in the ortho position to the hydroxyl groups of the phenol, anhydride formation also taking place between these hydroxyl groups. It dissolves in concentrated sulphuric acid with a yellowish-green fluorescence. The rhodamines, which are closely related to the phthalic anhydrides, are formed by the condensation of the alkyl metanaphthalimines with phthalic anhydride in the presence of sulphuric acid. Their salts are fine red dyes.

PHENOMENON (Gr. φαινόμενον, a thing seen, from φαίνειν, to appear), in ordinary language a thing, process, event, &c., observed by the senses. Thus the rising of the sun, a thunderstorm, an earthquake are natural "phenomena." From this springs the incorrect colloquial sense, something out of the common, an event which especially strikes the attention; hence such phrases as "phenomenal" activity. In Greek philosophy phenomena are the changing objects of the senses as opposed to essences (αὐτά δέρσα) which are one and permanent, and are therefore regarded as being more real, the objects of reason rather than of senses which are "bad witnesses." In modern philosophy the phenomenon is neither the "thing-in-itself" nor the noumenon (p.a.) or object of pure thought, but the thing-in-itself as it appears to the mind in sensation (see especially KANT and METAPHYSICS).

In this sense the subjective character is of prime importance. Among derivative terms are "Phenomenalism" and "Phenomenology." Phenomenalism is either (1) the doctrine that there can be no knowledge except by phenomena, i.e. sense-given data, or (2) the doctrine that all known things are phenomena, i.e. that there are no "things-in-themselves." "Phenomenology" is the science of phenomena: every special science has a special section in which its particular phenomena are dealt with. The term was first coined in Europe in the 3rd edition of the Ency. Brit. in the article "Philosophy" by J. Robison. Kant has a special use of the term for that part of the Metaphysics of Nature which considers motion and rest as predicates of a judgment about things.

PHERECRATES, Greek poet of the Old Attic Comedy, was a contemporary of Cratinus, Crates and Aristophanes. At first an actor, he seems to have gained a prize for a play in 438 B.C. The only other ascertained date in his life is 420, when he produced his play The Wild Men. Like Crates, whom he imitated, he abandoned personal satire for more general themes, although in some of the fragments of his plays we find him attacking Alcibiades and others. He was especially famed for his inventive imagination, and the elegance and purity of his diction are attested by the epithet ἀρωματώρος (most Attic) applied to him by Athenaeus and the sophist Phrynichus. He was the inventor of a new metre, called after him Pherecratean, which frequently occurs in the choruses of Greek tragedies and in Horace.

A considerable number of fragments from his 16 (or 15) plays has been preserved, collected in T. Kock, Comitiorum Atticorum Fragments, i. (1880), and A. Meinecke, Poetarum Comitiorum Graecorum Fragments (1885).

PHERECYDES OF LEROS, Greek mythographer, b. c. 454 B.C. He is probably identical with Pherecydes of Athens, although the two are distinguished by Suidas (also by I. Lipsius, Quaestiones logographiae, 1886). He seems to have been born in the island of Leros, and to have been called an Athenian because he spent the greater part of his life and wrote his great work there. Of his treatises, On Leros, On Iphigenia, On the Festivals of Dionysus, nothing remains; but numerous fragments of his genealogies of the gods and heroes, variously called Ἰωρραία, Πειραιοί, Πειραιάδες, in ten books, written in the Ionic dialect, have been preserved (see C. W. Müller's Frag. hist, graec, vol. i. pp. xxxiv., 70). He modified the legends, not with a view to rationalizing them, but rather to adjust them to popular beliefs. He cannot, therefore, be classed with Hecataeus, whose method was far more scientific.

See C. Lütke, Pheredyda (diss. Göttingen, 1893); W. Christ, Geschichte der griechischen Literatur (1898); and specially H. Bertsch, Pheredydische Studien (1898).

PHERECYDES OF SYROS, Greek philosopher (or rather philosophical theologian), flourished during the 6th century B.C. He was sometimes reckoned one of the Seven Wise Men, and is said to have been the teacher of Pythagoras. With the possible
exception of Cadmus (q.v.) of Miletus, he was the first Greek prose-writer. He belonged to the circle of Peisistratus at Athens, and was the founder of an Orphic community. He is characterized as “one of the earliest representatives of a half-critical, half-credolectic eclecticism” (Gomperz). He was credited with having originated the doctrine of metempsychosis (q.v.), while Cicero and Augustine asserted that he was the first to teach the immortality of the soul. Of his astronomical studies he left a proof in the "heliotropium," a cave at Syros which served to determine the annual turning-point of the sun, like the grove of Paros (Posilippo, Posilippo) at Naples, and was on the silt of the island.

In his cosmogonic treatise on nature and the gods, called Περιγένεσις (Peller's correction of Suidas, who has περιγένεσις, a five original or elementary principles (ether, fire, air, water, earth; Gomperz substitutes smoke and darkness for aether and earth), he enunciated a system in which science, allegory and mythology were blended. In the beginning were Chronos, the principle of time; Zeus (Zas), the principle of life; and Chthoné, the earth goddess. Chronos begat fire, air and water, and from these three sprang numerous other gods. Smoke and darkness appear in a later tradition. A fragment of this Codex of Chthoné, a large roll of papyrus found on an Egyptian papyrus at the end of the 19th century.

See H. Diels, Fragmente der Vorsokratiker (1903); also O. Kern, Οrfei, Εpimēnides, Πהροδύς θεογονίας (1888); S. Speliotopoulos, Περί Θεόκρατης τοῦ Σωκράτη (1890); T. Gomperz, Greek Thinkers (1893); R. S. Lattimore, Peisistratid Art in Greece (1937). W. H. Wiel, Études sur l'antiquité grecque (1900).

PHIGALIA, or PHIGALIA (Φιγάλια or Φιγαλία; mod. Polilista), an ancient Greek city in the south-west angle of Arcadia, situated on an elevated rocky site, among some of the highest mountains in the Peloponnesus—the most conspicuous being Mt Cotylium and Mt Elasum; the identification of the latter is uncertain.

In 659 B.C. Phigalia was taken by the Laconians, but soon after recovered its independence by the help of the Orasthians. During the struggle between Achaeans and Aetolians in 221 B.C. it was held by Dorimachus, who left it on the approach of Philip V of Macedon. In common with the other cities of Arcadia, it appears from Strabo to have fallen into utter decay under the Roman rule. Several curious cults were preserved near Phigalia, including that of the fish-tailed goddess Eurynome and the Black Deometer with a horse's head, whose image was renewed by Onatas. Notices of it in Greek history are rare and scanty. Though its existing ruins and the description of Pausanias show it to have been a place of considerable strength and importance, no autonomous coins of Phigalia are known. Nothing remains above ground of the temples of Artemis or Dionysus and the numerous statues and other works of art which existed at the time of Pausanias's visit, about A.D. 170. A great part of the city wall, built in fine Hellenic masonry, partly polygonal and partly isodomeous, and a large square central fortress with a circular projecting tower, are the only remains now traceable—at least without the aid of excavation. The walls, once nearly 2 m. in circuit, are strongly placed on rocks, which slope down to the little river Neda.

One very important monument still exists in a fairly perfect state; this is a temple dedicated to Apollo Epicurius (the Pre-server), built, not at Phigalia itself, but at Bassae, 5 or 6 m. away, on the slope of Mt Cotylium; it commemorates the aid rendered by Apollo in stopping a plague which in the 5th century B.C. was devastating Phigalia. This temple is mentioned by Pausanias (viii. 41) as being next to that of Tegése the finest in the Peloponnesus, and he speaks of its marble as the summit of its proportions.” It was designed by Iktinos, who with Callicrates, was joint architect of the Parthenon at Athens. Though visited by Chandler, Dodwell, Gell, and other English travellers, the temple was never explored nor measured till 1811-1812, when C. R. Cockerell and some other archaeologists spent several months in making excavations there. After nearly fifty years' delay, Professor Cockerell published the results of these labours, as well as of his previous work at Aegina, in Temples of Aegina and Bassae (1860), one of the most careful and beautifully illustrated archaeological works produced. The labours of Cockerell and his companions were richly rewarded; not only were sufficient remains of the architectural features discovered to show clearly the whole design, but the internal sculptured frieze of the cela was found almost perfect. This and other fragments of its sculpture are now in the British Museum. The colonnade of the temple has been recently restored by the Greek authorities.

Plan of the Temple at Bassae.
PHILADELPHIA

two favourite subjects in Greek plastic art of the best period. They are described with wonderful fertility of invention, and life-like representations are the established rule. Their artistic position is so arranged as to form a series of diagonal lines or ziggatas at right angles, and is pleasing to the unbroken horizontal lines of the cornice and architrave. The various groups are skillfully united together by some dominant link of connection, so that the whole subject forms one unbroken composition.

The relief is very high, more than 3½ in. in the most sallent parts, and the whole treatment is quite opposite to that of the Parthenon frieze, a very inferior work of art that at 6½ in. of the limbs are quite detached from the ground; the drill has been largely used to emphasize certain shadows, and in many places, for want of due calculation, the sculptor has had to cut into the flat background behind the figures. From this it would appear that a finished clay-model was prepared, but that the relief was sculptured with only the help of a drawing. The point of sight, more than 20 ft. below those of the Parthenon frieze, and the direction in which the light fell on it have evidently been carefully considered. Many parts invisible from below, are left comparatively rough. The workmanship throughout is unequal, and the hands of several sculptors can be detected. On the whole, the execution is not equal to the beauty of the design, and the whole frieze is somewhat marred by an evident desire to produce the maximum of effect with the least possible amount of labour—very different from the almost gem-like finish of the Parthenon frieze. Even the design is inferior to the Athenian one; most of the figures are ungracefully short in their proportions, and there is a great want of refined beauty in many of the female hands and faces. It is in the fire of its varied action and its variety of pose that this sculpture excels. The noble movements of the heroic Greeks form a striking contrast to the feminine weakness of the wounded Amazons, or the struggles with naked and hoofs of the brutal centaurs. The group of Apollo and Artemis in their chariot is full of grace and dispensed power. The marble in which this frieze is sculptured is somewhat coarse and crystalline; the slabs appear not to have been built into their place but fixed afterwards, with the aid of two bronze bolts driven through the face of each. Of the metopes, which were 2 ft. 8 in. square, only one exists nearly complete, with eleven fragments; the one almost perfect has a relief of a nude warrior, with floating drapery, overcoating a long-haired bearded man, who sinks vanquished at his feet. The relief of these is rather less than that of the frieze figures, and the work is nobler in character and superior in execution.

Several excursions from Philadelphia, see Leake, Morea (i. 400 and ii. 319; Curtius, Peloponnesos. l. 319; Ross, Reisen in Peloponnesos; Hackelberg, Der Apollo-Tempel zu Bassae (1826); Lapicque, Bas-reliefs du Parthenon et de Phigale (1834); and Histories of Sculpture mentioned under GREEK ART.

PHILADELPHIA, the Greek name (i) of a city in Palestine in the land of Ammon (see AMMONITES), and (2) of a city so-called in honour of Attalus II. of Pergamum, the modern Ale-Shera (q.v.)

PHILADELPHIA, the third city in population in the United States, the chief city of Pennsylvania, and a port of entry, co-extensive with Philadelphia, Selma, and Port Deposit, Delaware river beyond the Schuylkill River, and from below the confluence of the Delaware and Schuylkill rivers N.E. 23 m. along the Delaware river and Poquez Creek. Independence Hall, which is a few squares east by south of the city hall, is in 39° 46' 57" N. and 75° 8' 54" W. The port is about 102 m. from the Atlantic Ocean, and the city hall is 90 m. by rail S.S.W. of New York and 135 m. N.E. of Washington. The city has an area of 132-7 sq. m. At the southern extremity are lowlands protected by dikes from the tide; the business centre between the rivers is about 40 ft. higher but level; the district west of the Schuylkill is generally rolling; and in the upper district the surface rises from the Delaware toward the north-west until in the extreme north-west is a picturesque district overlooking Wissahickon Creek from hills exceeding 400 ft. in height.

Population.—When the first United States census was taken, in 1790, Philadelphia was the second largest city in the Union, and had a population of 28,322. It held this rank until 1830, when it was exceeded in size by Baltimore as well as by New York. In 1890 it was smaller also than Boston; but in 1894 the Consolidation Act extended its boundaries so as to include all Philadelphia county and in 1880 the city had risen again to second rank. This rank it held until 1890 when, although its population had grown to 1,266,964, it was 50,000 less than that of Chicago. In 1900, with a population of 1,393,679, it was still farther behind both New York and Chicago. In 1900, of the total population, 998,357, or 77-18% were native-born, as against only 63% native-born in New York and 65-43% native-born in Chicago. Of Philadelphia's native-born white population, however, 414,003, or 44·24%, were of foreign-born parentage. The foreign-born population included 98,427 born in Ireland, 71,319 born in Germany, 36,752 born in England, 28,951 born in Russia (largely Hebrews), 17,830 born in Italy, 8479 born in Scotland and 3754 born in Austria; and the coloured consisted of 62,613 negroes, 1165 Chinese, 234 Indians and 12 Japanese. In 1900 the population was 1,549,008.

Streets.—With the exception of a limited number of diagonal thoroughfares and of streets laid out in outlying districts in conformity with the natural contour of the ground the plan of the city is regular. Market Street—which Penn called High Street—is the principal thoroughfare east and west, Broad Street the principal thoroughfare north and south, and these streets intersect at right angles at City Hall Square in the business centre. The streets parallel with Broad are numbered from First or Front Street west from the Delaware River to Sixth-Thirty-third Street, taking the prefix "N. " north of Market Street and the prefix "S. " south of it; the streets parallel with Market are named mainly from trees and from the governors and counties of Pennsylvania.

The wholesale district is centred at the east end of Market Street near the Delaware river. The best retail shops are farther west on the south side of Chestnut Street and on Market and Arch streets. Most of the leading banks and trust companies are on Market Street and on Third Street between Chestnut and Walnut streets. Several of the larger office buildings and the stations of the Pennsylvania and the Philadelphia & Reading railways are in the vicinity of the city hall; here too, are the Baldwin Locomotive Works. The large textile mills, the great coal wharves and the Cramp Ship-Yards are to the north-east along the Delaware and in districts west of these are the leading many factories of iron and steel. There are large sugar refineries in the south-eastern part of the city. Rittenhouse Square, a short distance-south-west of the city hall, is the centre of the old aristocratic residential district, and the south side of Walnut Street between Fourteenth and Nineteenth streets is a fashionable parade. There are fine residences on North Broad street and on some of the streets crossing it, and many beautiful villas in the picturesque suburbs of the north-west. The most congested tenements, occupied largely by Italians, Hebrews and negroes, are along the alleys between the rivers and south of Market Street, often in the rear of some of the best of the older residences including the town.

The principal structure is the city hall (or "Public Buildings") one of the largest buildings in the world in ground space (44 acres). It rises 54 ft. to the top of a colossal bronze statue (37 ft. high) of William Penn (by Alexander Calder) surmounting the tower. It accommodates the state and county courts as well as the municipal and county offices. The foundation stone was laid in August 1872. On its first floor is Joseph A. Bailly's statue of Washington, which was erected in front of Independence Hall in 1869. About the Public Buildings are statues of Generals McClellan and Reynolds, President McKinley, and Joseph Leidy and St. Gaudens's "Pilgrim." On all sides are great buildings: on the north the Masonic temple (1868-1873); on the south the state Capitol; and on the west the enormous Broad street station of the Pennsylvania railway. The Pennsylvania Academy of Fine Arts and the Oddfellows' Temple are among other notable buildings in the vicinity. The post office, facing Ninth Street and extending from Market to Chestnut Street, was opened in 1884; in front is a seated statue of Benjamin Franklin, by John J. Boyle. The mint is at the corner of Sixteenth and Spring Garden streets. The custom-house, on Chestnut Street, was designed by William Strickland (1797-1854), in his day the leading American architect. It was modelled after the Parthenon of Athens, was built for the Second United States Bank, was completed in 1824, and was put to its present use in 1845. Other prominent buildings of
which Strickland was the architect are the stock exchange, St Paul's Protestant Episcopal Church, St Stephen's Church, the almshouse and the United States Naval Asylum. The main building of Girard College (on Girard Avenue, between North 10th and North 25th streets), of which Thomas Ustick Walter (1804–1889), a pupil of Strickland's, was the architect, is one of the finest specimens of pure Greek architecture in America. Near the Schuylkill River, in West Philadelphia, are the buildings of the university of Pennsylvania. Its free museum of science and art, at South 23rd and Spruce, on the opposite side of the river, was built from the designs of Walter Cope, Frank Miles Day and Wilson Eyre, and its north-western part was first opened in 1890. Tall steel-frame structures, of which the Betz Building, completed in 1893, was the first, have become numerous. The Roman Catholic Cathedral of St Peter and St Paul, east of Logan Square, was begun in 1846 and was eighteen years in building. The Arch Street Methodist Episcopal Church is one of the most handsome churches in the city. The South Memorial Church of the Advocate (1897), on North 18th and Diamond streets, is a reproduction on a smaller scale of Amiens Cathedral.

Perhaps the most famous historical monument in the United States is Independence Hall, on Chestnut Street between Fifth and Sixth streets, designed for the state house by Andrew Hamilton (c. 1676–1741), speaker of the assembly, and was used for that purpose until 1799. The foundations were laid in 1731 and the main building was ready for occupancy in 1735, although the entire building was not completed until 1751. The steeple was taken down in 1774 but was restored by Strickland in 1828, and further restorations of the building to its original condition were effected later. In the east room on the first floor of this building the second Continental Congress met on the 10th of May 1775, George Washington was chosen commander-in-chief of the Continental army on the 15th of June 1775, and the Declaration of Independence was adopted on the 4th of July 1776. The room contains much of the furniture of those days, and on its walls are portraits of forty-five of the fifty-six signers of the Declaration and a portrait of Washington by Peale. At the head of the stairway is the famous Liberty bell, which bears the inscription, "Proclaim liberty through all the land unto all the inhabitants thereof" and is supposed (without adequate evidence) to have been the first bell to announce the adoption of the Declaration of Independence. It was cast in 1752, was recast soon after it was brought to America, was recast with more copper in Philadelphia, and was cracked again in 1835 while being tolled in memory of Chief Justice John Marshall, and on the 22nd of February 1843 this crack was so increased as nearly to destroy its sound. On the second floor is the original of the charter which William Penn granted to the city in 1701 and the painting of Penn's treaty with the Indians by Benjamin West. The building has been set apart by the city, which purchased it from the state in 1816, as a museum of historical relics. On the north-west corner of Independence Square is old Congress hall, in which Congress sat from 1790 to 1800, and in which Washington was inaugurated in 1789. At 1760, a few feet east of the old city-hall, on the second floor of which the Supreme Court of the United States sat from 1791 to 1890. A short distance east of Independence Square in Carpenters' Hall, in which the first continental congress assembled on the 5th of September 1774 and in which the national convention in 1787 framed the present constitution of the United States; the building was also the headquarters of the Pennsylvania committee of correspondence, the basement was used as a magazine for ammunition during the War of Independence, and from 1791 to 1797 the whole of it was occupied by the First United States Bank. The Carpenters' Company (established in 1724) erected the building in 1770, and since 1857 has preserved it wholly for its historic associations. On 12th Street near the Delaware is preserved as a national monument the house in which Betsy Ross, in 1777, made what has been called the first United States flag, in accordance with the resolution of Congress of the 14th of June. Not far from this house is Christ Church (Protestant Episcopal), a fine colonial edifice designed mainly by Dr Johnearsley (1684–1772). The corner stone was laid in 1727, but the steeple, in part designed by Benjamin Franklin and containing a famous chime of eight bells, was not completed until 1754. The interior was restored to its ancient character in 1884, the pew on which Benjamin Franklin and Benjamin Rush sat during the commision plate presented to the church by Queen Anne in 1708 is used on great occasions. In the churchyard are the graves of Benjamin Franklin, Robert Morris, Brigadier-General John Forbes, John Penn, Peyton Randolph, Francis Hopkinson and Benjamin Rush. St Peter's, the second Protestant Episcopal church in the city, has a massive tower and a simple spire; within are the original pews. In the south-east part of the city near the Delaware is the ivy-clad Old Swedes' Church, built of brick in 1696–1700. The house which William Penn built about 1683 for his daughter Letitia was removed to Fairmount Park and rebuilt in 1859. In Germantown (q.v.), a suburb which was annexed in 1854, are several other historic buildings.

The dominant feature of the domestic architecture is the long rows, in street after street, of plain two-storey or three-storey dwellings of red brick ("Philadelphia") pressed brick with white marble steps and trimmings, and with white or green shutters, each intended for one family.

Parks.—Fairmount Park extends along both banks of the Schuylkill for about 5 m. and from the confluence of the Schuylkill and Wissahiccon Creek it continues up the latter stream through a romantic Glen for 6 m. its area is about 3418 acres. Five acres of an estate belonging to Robert Morris during the War of Independence and known as "Fair Mount," or "The Hills," were purchased by the municipality for "a city waterworks and for park purposes," in 1812, and from this beginning the park grew to its present dimension. Various public buildings have been erected within the park; are: the McPherson mansion, once the property of Benedict Arnold and in October 1780 confiscated by the committee of safety; the Peters (or Belmont) Mansion, built in 1745 and much frequented by the Adams family during the Revolution, which is now the birth-place of David Rittenhouse, the astronomer, and a monastery of the German pietists, both on the banks of Wissahickon; and memorial hall and horticultural hall, both survivals of the centennial exhibition of 1876. On Lemon Hill, near the south end of the park, stands the Robert Morris mansion; in the vicinity is the cabin which was General U. S. Grant's headquarters at City Point, Virginia, during the winter of 1864–1865. Near the Columbia Turnpike is the property of the Lebanon Club. East of the children's playground and playground is the residence of Mr. and Mrs. E. J. Marshall. The residence of Mr. and Mrs. J. R. Rodgers; an equestrian statue of Grant by Daniel Chester French and Edward C. Potter; an equestrian statue of Major-General James Gordon Meade by Alexander Milne Calder; and other parks is the gift of the Pennsylvania Turnpike Company. An heroic bust of James A. Garfield by Augustus St Gaudens; statues of Columbus, Humboldt, Schiller and Goethe; a 'Tam O' Shanter group of four figures in red sandstone by James Thom; John J. Boyle's "Stone Age in America"; Cyrus Edwin Dallin's "Medicine Man"; and "Wilhelm Wolff's "Wounded Lioness" (at the entrance to the Zoological Gardens); Albert Wolff's "Lion Fighter"; Auguste Nicolas Cain's "Lions bringing a Wild Beast to Table"; and Emil Adolphus Anderson's "Hudson River" (a bronze statue of "Frederick Remington's "Cow Boy"; and several artistic fountains, and a Japanese temple-gate. In the downtown district, Franklin, Washington, Rittenhouse and Logan squares, are laid out from the public square, formerly the site of the market; in Rittenhouse Square is the bronze "Lion and Serpent" of A. L. Barye. In Clarence H. Clark Park, West Philadelphia, is Frank Edwin Dorn's "Dionysus", a bronze statue of the god of wine. Garden streets opposite the Baldwin Locomotive Works is Herbert Adams's statue of Matthias William Baldwin (1793–1866), founder of the works. Close to the bank of the Delaware, some distance from the city, is the memorial estate of the city, an octagonal monument to mark the site of the great elm tree under which Penn, according to tradition, negotiated his treaty with the Indians in 1683. In the south-west part of the city, along the Schuylkill, is Bartlam's botanical garden (57 acres). This garden was occupied by a number of buildings.
Franklin entitled, *A Proposal for Promoting Useful Knowledge among the British Plantations in America*. In 1769 it united with (and officially took the name of) "The American Society held at Philadelphia for Promoting Useful Knowledge." Among its early projects was the *Transactions of the American Philosophical Society*, published in Philadelphia in 1786. It was the first society in the United States to publish a scientific journal, and its proceedings have been published regularly since then. In 1866, the collection of the society was transferred to the American Philosophical Society, and its library was housed in the building now occupied by the Franklin Institute. The society has continued to publish its *Transactions* and *Proceedings* since that time, and its library is now located in the Philadelphia Museum of Art.

**The American Philosophical Society**

The American Philosophical Society is one of the oldest and most prestigious scientific institutions in the United States. It was founded in 1783 by Benjamin Franklin, who served as its first president. The society's mission is "to promote useful knowledge among the American colonies" and it has played a significant role in the development of American science and education. The society's library is one of the oldest and largest in the United States, and it houses a valuable collection of rare books, manuscripts, and other materials related to the history of science. The society's publications include the *Transactions of the American Philosophical Society*, which is one of the oldest scientific journals in the world, and the *Proceedings of the American Philosophical Society*, which is published regularly and contains peer-reviewed research in a variety of scientific disciplines. The society's headquarters are located in Philadelphia, and it continues to play an important role in the advancement of science and education in the United States.
PHILADELPHIA

households, science and library economy departments; a School of industrial arts; two manual training schools; about one hundred night schools; the Mennonite Girls' Industrial School, chiefly for habitual truants or insubordinate and disorderly children; and a number of vacation schools and playgrounds for the summer season. In 1909 district high schools were planned as a part of the public school system. The city has also many private high schools and academies.

Besides the university of Pennsylvania and the Central High School for boys the collegiate institutions are La Salle College (Roman Catholic, diocesan seminary; chartered in 1828 as Temple College after four years of teaching; in 1891 received the power to confer degrees); which is desolate; the Curtis Institute of Music, founded in 1884 by Russell Hermann Conwell (b. 1842), a lawyer and journalist, who entered the Baptist ministry in 1879, was pastor of the Grace Baptist Church of Philadelphia in 1881-1891, became pastor of other churches, and in the second half of the century the Universal Instructor in all Arts and Sciences and Pennsylvania Gazette. It was established in 1728 by Samuel Keimer, but less than a year afterwards it became the property of Benjamin Franklin. The Universal Instructor was continued by Hugh M' Alley, who was also the first editor of the Pennsylvania Gazette. The only one of the newspapers established during the colonial era which survived the 19th century was the Pennsylvania Packet or General Advertiser, which was started in 1717 at the printing house of John Dunlap and was published weekly. The first semi-weekly, with occasional "postscripts" of important news, in 1839 it was absorbed by the North American (1829), with which it was united in 1847 and which is still published as the North American and Philadelphia Advertiser, established in 1790 by Benjamin Franklin Bache (1790-1798), a grandson of Franklin, was a notorious anti-Federalist organ in its time.

A prolific variety of other newspapers, the Public Ledger, founded in 1836, and in 1864 purchased by George William Childs. Other prominent daily papers now published are the Inquirer (Republican; 1829), the Press (Republican; 1857), the Record (Independent Democrat; 1870), the Democratic (1838), the Evening Bulletin (Republican; established in 1815 as the American Sentinel), the Evening Telegraph (Independent Republican; 1864), and the Tageblatt (Labour; German; 1877) which was published in Philadelphia; among them were the American Magazine (1757-1758 and 1769), Thomas Paine's Pennsylvania Magazine (1775-1776), the Columbian Magazine (1796-1799; called the Journal of Commerce, founded in 1796; it was issued by A. J. Dallas, the excellent American Museum (1789-1792 and 1798), with which Carey was connected, the Port Folio (1801-1827; edited until 1812 by Joseph Dennie) and the Alacrite (1802-1812) which succeeded Select Reviews and Spirit of the Times (1809), of which Washington Irving was editor in 1813-1814, and to which Paulding and Verplanck contributed, and the American Edifice (1812-1837). Among others were: Gosnell's Lady's Book (1803-1827), for which Paulding and Verplanck wrote; and Graham's Lady's and Gentleman's Magazine (1820-1859), with the contributors just named and Cooper, John G. Whipple, and others (1836-1859). The Monthly Magazine published monthly, best known for its fiction. The Saturday Evening Post, which has the largest circulation of the weekly publications, and the Ladies' Home Journal (1883), the semi-monthly with the largest circulation in the country. The Form Journal (1877) is a well-known agricultural monthly.

Trusts, Charities, Etc.—Girard College and thirty-eight other charities are maintained out of the proceeds of as many trusts, which are placed in the hands of trustees appointed by the courts of common pleas, and the mayor, president of the select council, and president of the common council as ex-officio members. In 1907 the invested capital of the Girard Trust alone amounted to $25,000,000, the income from it was $1,988,054. The total capital of all the minor trusts in the same year was $1,583,026 and the income from this was $56,730. Among the minor trust funds are: Wills Hospital (established in 1852); the Franklin Fund (1887), a fund for the support of the Franklin Institute, administered by Thomas D. Grover Fund (1849) for providing the poor with fuel and food; Mary Shields Almshouse Fund (1886); and the John Scott Fund (1816) for bestowing medals upon young inventors. The Franklin Institute is largely supported by the Pennsylvania hospital, the first hospital in the United States, which was projected in 1731 and is one of the foremost of nearly one hundred such institutions in the city. The Episcopal hospital and the hospitals for the indigent and the insane are maintained by the municipality, but most of the other institutions for the sick are maintained by medical schools and religious sects. Municipal corporation has control of the water works, gas works, public health and charities. Philadelphia is the seat of the state peniten- tiary for the eastern district, in which, in 1829, was inaugurated the "individual" system, i.e. the separate imprisonment and discriminating treatment of criminals with a view to effecting their reform.

Transportation and Commerce.—Nearly every street in the business centre and about one-third of the streets throughout the
built-up portion of the city have a single track of electric railway (overhead trolley), and most of the wider ones, except Broad Street, which has none, have a double track. A subway line has been opened for a short distance under Market Street, and another subway line has been projected. The electric system, embracing in 1900 a total of 624,21 ft., is operated by the Philadelphia Rapid Transit Company. Several interurban electric lines afford cheap service to neighbouring towns and cities. The electrification of the Pennsylvania, the Brooklyn, the Atlantic & Great Western, and the Delaware & Hudson railways together with the Baltimore & Ohio railroad affords transportation facilities north to New York, south to Baltimore, Washington, and the south west, and to the famous coalfields of Pennsylvania, the grain fields of the Middle West, and to Cleveland, Cincinnati and Chicago. The Philadelphia & Reading railway connects the city with the great anthracite coal region, and the Philadelphia & Reading, the Reading and the anthracite line to Atlantic City. The Schuylkill is navigable for small craft to the "Fall line," about 72 ft. above its mouth and for vessels drawing 2 ft. to the oil refineries at Point Breeze, 3 m. from the mouth, and it is served by a number of locks. The channel depth varies from 14 to 22 ft. The Delaware river is navigable to Trenton, New Jersey, about 30 m. above the upper end of the port of Philadelphia, and although in its natural condition this river was only 17 ft. deep at low water in shallow reaches, the channel depth was increased between 1836 and 1899 to 26 ft. (except in three shallow stretches), and a project of the Federal government for improvement with locks to a depth of 30 ft. and the width to 600 ft. In 1905 the city of Philadelphia and the Pennsylvania appropriated $750,000 for the improvement of the river between the city and the southern boundary of the state.1 Steamers ply between Philadelphia and several points on the Delaware, there are minor harbour facilities on the Schuylkill. The natural facilities, together with the improvements that have been made, were long offset by an inefficient port administration under an antiquated law, under which the wharves passed largely into private control; but in 1907 the old board of port warders was abolished and in its place was created a municipal department of what is called the "Bureaus." Until the opening of the Erie Canal, in 1825, Philadelphia was the emporium of the United States; it was then displaced by New York. Some years later Philadelphia lost its lucrative China trade, and as a consequence, its commercial supremacy. In 1842, when the value of its imports amounted to only $52,811,042, the value of its exports to only $8,662,434, and the city was outranked in foreign trade by New York, Boston, San Francisco and New Orleans. By 1900, however, the value of its imports had risen to $49,191,236 and the value of its exports to $81,327,704; in 1909 the value of the imports was $78,903,464, an amount less than one-eleventh that of New York, but exceeded only by New York. In 1900 the value of the exports was $81,346,578, an amount less than one-eighth that of New York, but exceeded only by New York, Galveston and New Orleans. The principal imports are sugar, drugs and chemicals, goatskins, wool, tobacco, and many foodstuffs. The iron goods, machinery, hardware, hides and bananas; the principal exports are iron (manufactured), steel, petroleum, wheat, flour, lard, cattle and meat products. The proximity of the city to New York, whence many of its products are shipped, makes the statistics of its direct imports and exports no true index of its commercial importance.

Manufactures.—Philadelphia has always been one of the foremost manufacturing centres in the United States, and in 1900 it was surpassed only by New York and Chicago.2 The total value of its factory product was $519,981,812 in 1900, and $591,388,078 in 1905. Measured by the value of the products, Philadelphia ranked first among all cities in the United States ($37,182,504; 13.4% of the total of the country), and in the manufacture of carpets and rugs ($25,232,510; 41 of the total of the country), leather ($5,956,293; 9.5% of the total of the country), hosiery and knit goods ($15,770,873; 11.5% of the total of the country), woolen goods ($12,239,881; 8.6% of the total of the country), and felt hats ($5,847,771; 16% of the total of the country); second in the manufacture of worsted goods ($26,994,533; 16% of the total of the country); third in the manufacture of cotton goods ($25,131,882; 5% of the total of the country) and silk goods ($5,079,193; 3% of the total of the country); fourth in the manufacture of machinery and machine-shop products, cotton goods, malt liquors, iron and steel, chemicals, cigars and cigarettes, soap, confectionery, furniture, paints, boots and shoes, electrical apparatus, and ordnance and twisted iron and steel, chemicals, cigars and cigarettes, soap, confectionery, furniture, paints, boots and shoes, electrical apparatus, and ordnance and twisted 1 The city had previously expended $1,555,000 on the improvement of the Delaware and Schuylkill rivers. 2 The census assumes that excluding slaughter-house and sweat-shop products the value of Philadelphia's manufactured products is greater than that of any other city in the country. 3 A document purporting to be a charter, bearing the date of the 20th of May 1691, and signed by Thomas Lloyd, deputy-governor, was discovered in 1887, but the great seal is missing and there is no evidence that it ever was the original. 4 A meeting of the Council held at Philadelphia on the third day of Sixth Month 1691 mention Humphrey Morrey the present Mayor of the city of Philadelphia; and this would seem to show that there was a charter of incorporation for Philadelphia: Its Founding and Seals: Report of the Committee to determine the Year of the Physical and Legal Founding of the City of Philadelphia: 5 In 1905 the state legislature took the appointment of these officers from the mayor and vested it in the councils, but this legislation was repealed in 1906.
are: public safety, public works, receiver of taxes, city treasurer, city controller, law, education, charities and corrections, supplies, public buildings and public works. For these purposes the financial commission and sinking fund commission (provided by the mayor and controller and a commissioner elected by a majority vote of the city council) are elected. The members of the city council are elected for three years, and the mayor for two years—one half each year; and the receiver of taxes, the city treasurer, the city controller, and the city solicitor, who is the head of the department of law, for a term of three years. The police and the new filter department and the water works, the superintendent of which is a superintendent appointed by the director of the department with the approval of the select council. The departments of education and the bureau of public charities are now under the direction of a board of education appointed by the central board appointed (at large) by the judges of the courts of common pleas.

The assessed value of taxable property in the city increased from $1,873,738 in 1856 to $33,699,248 in 1880, to $80,935,265 in 1900 by the end of 1900. During the last twenty years, the assessed value has increased from $5,170,686 in 1880 to $14,640,479 in 1880, to $30,628,246 in 1900, and to $48,012,630 in 1900. The principal items of expenditure in 1900 were: for public schools $8,242,218; for the bureau of water, $2,827,200; for streets and highways, $4,210,260; for police, $3,810,535; and for protection against fire, $1,873,720. The receipts for the same year were $4,372,927, of which $18,851,442 were from the property tax (municipal and state), and $4,376,124 were from the water tax. The city's indebtedness increased rapidly for a period of twenty-five years following consolidation. At the beginning of 1886 the funded debt was $42,401,933, being $30,658,114 from the water fund, which had grown to $42,401,933, and by the beginning of 1886 to $70,970,041. By the beginning of 1886, under the new state constitution adopted in 1873 no municipality is permitted to create a debt exceeding 7% of the assessed value of its taxable property, in the case of the city state, if the said total be passed by the council by a two-thirds vote, provided the city is living beyond its income, and as a consequence of these restrictions the funded debt, less loans held by the sinking fund, was reduced by the beginning of 1895 to $33,139,605. The gross expense of installing the new filter plant and filter system, and making other improvements has, however, caused it to grow again; at the beginning of 1910 the total funded debt was $95,483,820 and the net funded debt was $84,901,620.

History.—The patent granted to William Penn for the territory embraced within the present commonwealth of Pennsylvania was dated 20th March, 1681, and on 4th of March 1681 and 9th of 1682, Penn and his associates agreed that "a quantity of land or grant of plat should be laid out for a large town or city in the most convenient place upon the river for health and navigation," and that every purchaser of 50 acres in the country shall be allowed a lot of 10 acres in the town or city, "if the place will allow it." In September 1681 Penn appointed William Crispin, Nathaniel Allen and John Bezan a commission to proceed to the new province and lay out the city, directing them to select a site on the Delaware where "it is most navigable, high, dry, and healthy; that is where most ships can best ride, of deepest draught of water, if possible to load or unload at the bank or key slide without baulking or being liable to be driven up." It seems the prior, died on the voyage out, but William Heage had named a fourth commissioner some time after the appointment of the others and the three survivors arrived in the province toward the close of the year. They had been preceded by Penn's cousin, Captain William Markham, as deputy-governor, and were soon followed by the Surveyor-General, Thomas Holme. Although the Swedes had established a settlement at the mouth of the Schuylkill not later than 1643 and the site now selected by the commissioners was held by three brothers of the Swedish family, these brothers agreed to take in exchange land in what is now known as Northern Liberties, and as early as July 1682, Holme, according to tradition, visited an autumn from the Delaware for making the lots smaller than originally intended, laid out the city extending from the Delaware river on the east to the Schuylkill river on the west, a distance of about 2 m., and from Vine Street on the north to Cedar (now South) Street on the south, a distance of about 1 m. Penn landed at New Castle on the Delaware on the 27th of October 1682 and two days later came up as far as Upland, now Chester, 13 m. south of Philadelphia, but when he came to his newly founded city is not known. He is known, however, to have presided at a meeting of the provincial council held here on the 10th of March 1683, and from that time Philadelphia was the capital of Pennsylvania until 1799, when Lancaster became the capital. During nearly the whole of this period it was also the most important city commercially, politically and socially in the colonies. Quaker influence remained strong in the city, especially up to the beginning of the 19th century; and it was predominant in Philadelphia long after it had given way before the Scotch-Irish in the rest of Pennsylvania. But even in Philadelphia the academy (later the university of Pennsylvania) soon came under the control of the Protestant Episcopal Church. The first Continental Congress met in Carpenters' Hall on the 5th of September 1774; the second in the old state house (Independence Hall) on the 10th of May 1775; and throughout the War of Independence, except from the 26th of September 1777 to the 18th of July 1778, when it was in possession of the British. Philadelphia was the virtual capital of the colonies; it was a brilliant social city, especially during the British possession.

The national convention which framed the present constitution of the United States sat in Philadelphia in 1787, and from 1790 to 1800 the city was the national capital. Here Benjamin Franklin and David Rittenhouse made their great contributions to science, and here Washington delivered his farewell address to the people of the United States. Here, in July 1879, clerical and lay delegates from the Protestant Episcopal Churches in the United States met and formally organized the Protestant Episcopal Church in the United States. Here the first bank in the colonies—the Bank of North America—was opened in 1781, and here the first mint for the coinage of the money of the United States was established in 1792. The city was visited during the epidemic of yellow fever in 1793 and again in 1798; and in 1832 nearly 1000 inhabitants died of Asiatic cholera.

The original boundaries remained unchanged for 172 years, but the adjoining territory as it became populated was erected into the corporate districts in the following order: Southwark (1762), Northern Liberties (1773), Moyamensing (1812), Spring Garden (1813), Kensington (1820), Penn (1846), Richmond (1847), West Philadelphia (1851) and Belmont (1853). In 1854 all these districts, together with the boroughs of Germantown, Frankford, Manayunk, White Hall, Bridesburg and Aramingo, and the townships of Passyunk, Blockley, Kingsessing, Roxborough, Germantown, Bristol, Oxford, Lower Dublin, Moreland, Byberry, Delaware and Penn was abolished and the boundaries of Philadelphia were extended to the county lines by a single act of the state legislature. The consolidation was in part the outcome of a demand for efficiency in preserving order. There had been a number of occasions, especially the period of the 17th of May, 1838 an anti-abolition mob had burned Pennsylvania Hall, which had been dedicated three days before the discussion of abolition, temperance and equality; in May 1844 anti-Catholic rioters had burned St Michael's and St Augustine's churches, and minor riots had occurred in 1835, 1842 and 1843. Philadelphia was from the first strongly anti-slavery in sentiment, and it was here in December 1833 that the American Anti-Slavery Society was organized, and in 1836, on the anniversary of the battle of Bunker Hill, that the first national convention of the Republican party met. During the Civil War the arsenal and the Southwark navy yard were busy manufacturing material for the Federal forces, and Philadelphia furnished men, women, and soldiers, and here in 1864 was held the great sanitary fair for the benefit of the United States sanitary commission, an organization for the relief and care of wounded and sick soldiers. In 1876, the centennial year of American independence, a great exhibition of the industries of all nations was held in Fairmount Park from the 10th of May to the 10th of November, and about fifty buildings were erected for the purpose. In October 1882 the city celebrated the bi-centennial of the landing of William Penn, and in October 1908 the 225th anniversary of its foundation.

1. Lord Howe, who had been in command of the British fleet, embarked for England on the 24th of May, and on the 18th of this month was held for his farewell entertainment the famous Mischiana, a feast of gaiety with a tournament somewhat like those common in the age of chivalry, which was in large part planned by Captain John Andrè.
PHILADELPHIANS—PHILARET

Philadelphians, a sect of religious mystics, founded in London in the latter part of the 17th century. In 1652 Dr John Pordage (1607-1681), rector of Bradford, Berkshire, gathered together a few followers of Jakob Boehme, the chief of whom was Jane Lead or Leadle (née Ward; 1623-1704). Pordage was ejected from his living by the Tiers in 1655, but was restored in 1660. Mrs Leadle had been from girlhood of a mystical temperament, and experienced phantasmagoria which she recorded in a diary entitled A Fountain of Gardens, beginning in 1670, in which year the Philadelphia society was definitely organized. She drew up for it "The Laws of Paradise," which show that the enterprise was designed "to advance the Kingdom of God by means of the truth, including the doctrine of doing the duty of universal brotherhood, peace and love." Its members had a strong faith in what they called the "Divine Secrets," the wonders of God and nature, the profound spiritual experiences of regeneration and soul-resurrection, and the second Advent. In 1693 some of Mrs Leadle's writings were translated into Dutch, and by this means and her acquaintance with Francis Lee (1661-1719), an Oxford scholar who studied medicine at Leiden and became her son-in-law, a connection was opened up with Germany and Holland. In 1703 the Philadelphians drew up their confession, but they made no further progress and soon declined. The Holland branch of this society, and the English government forbade the society to meet. For many years, however, a considerable number of people regarded Mrs Leadle's visions, which were published in a long series of writings, as proofs of her divine calling. In later years she had a severe struggle with poverty, which was relieved by a pension granted by Baron Kniphausen.

PHILAE, an islet in the Nile above the First Cataract, of great beauty and interest, but since the completion of the Assuan dam in 1902 submerged except for a few months yearly during High Nile (July to October), when the water is allowed to run freely through the sluices of the Assuan dam. Philae is the nearest island to the point where the ancient desert road from Assuan meets the river south of the cataract. It marks also the end of the cataract region. Below it the channel is broad and straight with rocky granite islands to the west. The name in Egyptian was Philak, "the angle (?) island?"; the Arabs call it Anas el Wagad, after the hero of a romantic tale in the Arabian Nights. Ancient graffiti abound in all this district, and on Bighch, a larger island adjoining Philae, there was a temple as early as the reign of Tethmosis III. The name of Amasis II. (570-553 B.C.) is said to have been found at Philae, and it is possible that there were still older buildings which have been swallowed up in later constructions. About 350 B.C., Nekhtnef, the last of the native kings of Egypt, built a temple to Isis, most of which was destroyed by floods. Ptolemy Philadelphus reconstructed some of this work and began a large temple which Ptolemy Euergetes I. completed, but the decoration, carried on under later Ptolemies and Caesars, was never finished. The temple of Isis was the chief sanctuary of the Dodecaschoenus, the portion of Lower Nubia generally held by the Ptolemies and Romans. The little island won great favour as a religious resort, not only for the Egyptians and the Ethiopians and others who frequented the border district and the market of Assuan, but also for Greek and Roman visitors. One temple or chapel after another sprang up upon it dedicated to various gods, including the Nubian Mandulis. Ergamenes (Arkamane), king of Ethiopia, shared with the Ptolemies in the building. Besides the temple of Isis with its birth-temple in the first court, there were smaller temples or shrines of Arsinoephis, Mandalis, Imubes, Hathor, Harenodotes (a form of Horus) and Augustus (in the Roman style), besides unnamed ones. There were also monumental gateways, and the island was protected by a stone quay all round with the necessary staircases, &c., and a Nilometer. The most beautiful of all the buildings is an unfinished kiosque inscribed by Trajan, well known under the name of "Pharaoh's Bed." Graffiti of pilgrims to the shrine of Isis are dated as late as the end of the 5th century A.D. The decree of Theodosius (A.D. 378) which suppressed pagan worship in the empire was of little effect in the extreme south. In A.D. 455 Maximinus, the Theodosian general, after massacring the inhabitants of the small island, resorted to the Bakchis and Blemmyes who were settled in Lower Nubia, and thence raided Upper Egypt, made peace on terms which included permission for these heathen tribes to visit the temple and even to borrow the image of Isis on certain occasions. It was not till the reign of Justinian, A.D. 527-555, that the temple of Philae was finally closed, and the idols taken to Constantinople. Remains of Christian churches were disclosed by the thorough exploration carried out in 1850-1866 in view of the Barrage scheme, under the direction of Captain Lyons. The accumulations of rubbish on the island were cleared away and the walls of the ancien buildings levelled. The buildings that were strengthened before the dam was completed. The annual flooding now appears to be actually beneficial to the stonework, by removing the disintegrating salts and incrustations. The tops of most of the buildings and the whole nucleus of the temple of Isis to the floor remained all the year round above the water level until the dam was raised another 26 ft.—a work begun in 1907—when the temples were entirely submerged except during July-October. But the beauty of the island and its ruins and palm trees, the joy of travellers and artists, is almost gone.

St. H. G. Lyons, A Report on the Island and Temples of Philae (Cairo, 1896), with numerous plans and photographs; a second report, A Report on the Temples of Philae (1908), deals with the condition of the ruins as affected by the immersions occasioned by the filling of the Assuan dam; Baedeker's Egypt; and on the effects of the submersion, &c., reports in Annales du service des antiquites, vol. v. (P. Ll. G.)

PHILARET [Theodore Nikitich Romanov] (1755-1763), patriarch of Moscow, was the second son of the boyar Nikita Romanovich. During the reign of his first cousin Theodore I. (1584-1598), Theodore Romanov distinguished himself both as a soldier and a diplomat, fighting against the Swedes in 1590, and conducting negotiations with the ambassadors of the emperor Rudolph II. in 1593-1594. On the death of the emperor, 1593, he was the strongest candidate for the imperial throne; but he acquiesced in the election of Boris Godunov, and shared the disgrace of his too-powerful family three years later, when Boris compelled both him and his wife, Xenia Chestovaya, to take monastic vows under the names of Philaret and Martha respectively. Philaret was kept in the strictest confinement in the Antoniev monastery, where he was exposed to every conceivable indignity; but when the pseudo-Demetrius overthrew the Godunovs he released Philaret and made him metropolitan of Rostov (1605). In 1609 Philaret fell into the hands of pseudo-Demetrius II., who named him patriarch of all Russia, though his jurisdiction only extended over the territory which acknowledged the impostor. From 1610 to 1618 he was a prisoner in the hands of the Polish king, Sigismund III., whom he refused to acknowledge as tsar of Muscovy on being sent on an embassy to the Polish camp in 1610. He was released on the conclusion of the truce of Deulino (Feb. 13, 1619), and on the end of June was canonically enthroned patriarch of Moscow. Henceforth, till his death, the established government of Muscovy was a diarchy. From 1619 to 1633 there were two actual sovereigns, Tsar Michael and his father, the most holy Patriarch Philaret. Theoretically they were co-regents, but Philaret frequently transacted affairs of state without consulting the tsar. He replenished the treasury by a more equitable and rational system of assessing and collecting the taxes. His most important
PHILATELY—PHILEMON

374

domestic measure was the chaining of the peasantry to the soil, a measure directed against the ever increasing migration of the down-and-out tenant farmers to the towns, where they became free-bombers instead of tax-payers. The taxation of the tsar's dvyatkhne lyudi, or military tenants, was a first step towards the proportional taxation of the hitherto privileged classes. Philaret's zeal for the purity of orthodoxy sometimes led him into excesses; but he encouraged the publication of theological works, formed the nucleus of the subsequently famous Patriarchal Library, and commanded that every archbishop should establish a seminary for the clergy, himself setting the example.

Another great service rendered by Philaret to his country was the reorganization of the Muscovite army with the help of foreign officers. His death in October 1863 put an end to the first Polish War (1832–33), withdrawing the strongest prop from the executive feeble even when supported by all the weight of his authority.

PHILATELY (Gr. φιλάτες, loving, and ἀρετής, free of tax), the study and collection of postage-stamps and other marks of prepayment issued by post-offices. The fancy for collecting postage-stamps began a short time after the issue of the first British penny and two-penny stamps in 1840 (see Post and Postal Services). Dr Gray, an official of the British Museum, began collecting them soon after their appearance, and an advertisement in an issue of The Times of 1841 asks for gifts of cancelled stamps for a young lady. In 1842 the new hobby was ridiculed in Punch. It was not until about 1860, however, that stamp collecting began to be systematically carried on with full regard to such minutaie as the different kinds of paper, water-marks, perforation, shade of colour and distinctive outline. About 1862 a teacher in Paris directed that foreign stamps should be collected and pasted upon the pages of his pupils' atlases and geographical countries according to this method may have been the first form of the systematic classification of stamps in a collection. Of existing collections the oldest were begun between 1853 and 1866, by which year French collectors had assumed especial prominence. Professional dealers now made their appearance, and in 1861 philatelic literature, now of vast extent, was inaugurated by the publication in Strasbourg of a catalogue of stamps issued up to that time. The Paris collectors were the first to classify stamps, measure them by the gauge, note the water-marks and separate the distinct issues of each country. Collecting with due regard to the relationship of different issues is called plating. The first English catalogue was issued in 1862, followed in December of the same year by The Stamp Collector's Review and Monthly Advertiser, published in Liverpool, the first philatelic periodical, the second, The Stamp Collector's Magazine, appearing in 1863. In 1863 also appeared Le Timbre-Postal, a Brussels journal. Up to 1910 over 800 philatelic periodicals had appeared.

Although small bodies of enthusiasts had banded together in England, France and the United States for the study and collection of postage-stamps as early as 1865, it was not until 1869 that the first great club, the Philatelic Society of London, still the most important in the world, was founded. Other societies in Great Britain are the Junior Philatelic of London, and those of Birmingham, Manchester, Edinburgh and Leith. The leading society in America is the American Philatelic Association; in France the Société française de timbres-poste; in Germany the International Philatelisten-Verein. More than 400 such organizations are now in existence, the majority of them in the United States and Germany. At a philatelic congress, held in London in 1910, the formation of a universal union of philatelic societies "to discourage unnecessary or speculative issues" was considered.

Not only the stamps themselves were collected, but "entires," i.e. postcards, envelopes with the stamps still adhering, &c. Marks of prepayment at last became so numerous that, about 1880, specialists began to appear, who restricted their collections to the stamps of some particular country or continent, or to postcards or newspaper-wrappers alone. The most extensive and valuable stamp collection in the world, that of Baron P. von Ferrary of Paris, was begun about 1865. This collection, which cost its owner at least £250,000, contains a cancelled and an uncancelled specimen of each stamp. The next greatest collection is that bequeathed to the British nation in 1891 by T. K. Tapling, M.P., now in the British Museum. Among other important collections may be mentioned those in the German Postal Museum in Berlin, of King George V. of England, W. B. Avery, H. J. Duveen and the earl of Crawford. The largest sum realized for an entire collection was £27,500, which was paid for that of M. P. Castle, consisting of European stamps only. The buying of a stamp depends largely upon the value of the stamps of the country and the number of collectors, and is more upon its rarity, which again is dependent upon the number of the particular stamps originally issued. Most stamps have a quoted value, but some possess a conventional value only, such as those of which only one or two specimens are known to exist; for instance, the one-cent stamp of the 1856 issue of British Guiana (one known copy); the Italian 15 centesimi stamp of 1805 converted by an overprint into 20 centesimi (one copy); the Cape of Good Hope triangular, printed by mistake on paper intended for stamps of other colonies (four copies); and the 2 cent stamps of the earliest issue of British Guiana (ten copies). The best known of the very rare stamps are the 1d. and 2d. "Postage due" Mauritius (1847); every one of these mail stamps on another, although 23 copies are known to exist out of the 1000 issued. For a fine specimen of these Mauritius stamps £2000 has been offered. Two of them have been sold for £4000. Philatelic exhibitions such as those held in London in 1890 and 1897 and in Manchester in 1909 have proved popular. Reprints are reprints, taken from the original plates,_of obsolete stamps, and have a much smaller value than specimens of the original issue. Forgery of the rarer stamps are common but are easily detected. Modern postage-stamp albums are often beautiful specimens of the printer's art, reproductions of every known stamp being given in the original colours.

PHILEMON (c. 361–263 n.c.), Greek poet of the New Comedy, was born at Soli in Cilicia, or at Syracuse. He settled at Athens early in life, and his first play was produced in 330. He was a contemporary and rival of Menander, whom he frequently vanquished in poetical contests. Posteriorly reversed the verdict and attributed Philemon's successes to unfair influence. He made a journey to the east, and resided at the court of Ptolemy, king of Egypt, for some time. Plutarch (De Cohabentia Ira, 9) relates that on his journey he was driven by a storm to Cyrene, and fell into the hands of its king Magas, whom he had formerly satirized. Magas treated him with contempt, and finally dismissed him with a present of toys. Various accounts of his death are given; a violent outburst of laughter, excess of joy at a tragic victory, or a peaceful end where the Augustus, who had patronized his last work (Apuleius, Florida, 16; Lucian, Macrob. 25; Plutarch, An Seni, p. 725). Of the ninety-seven plays which he is said to have composed, the titles of fifty-seven and considerable fragments have been preserved. Some of these may have been the work of his son, the younger Philemon, who is said to have composed fifty-four comedies. The Merchant and The Treasure of Philemon were the originals respectively of The Mercator and Trinummus of Plautus. The fragments preserved by Stobaeus, Athenaeus and other writers contain much wit and good sense. Quintilian (Instit. x. 1, 72).
PHILEMON, EPSILITE TO - PHILETAS

375

PHILEMON and BAUCIS, the hero and heroine of a beautiful story told by Ovid (Metam. viii. 610–715), the scene of which is laid in Phrygia. Zeus, accompanied by Hermes, visited earth in human form; tired and weary, they sought shelter for the night, but all shut their doors against them except an aged couple living in a humble cottage, who afforded them hospitality. Before their departure the gods revealed themselves, and bade their hosts follow them to the top of a mountain, to escape the punishment destined to fall on the rest of the inhabitants. The country was overwhelmed by a flood; the cottage, which alone remained standing, was changed into a magnificent temple. The gods appointed Philemon and Baucis priest and priestess, and granted their prayer that they might die together. After many years they were changed into trees—Philemon into an oak, Baucis into a lime. The story, which emphasizes the sacred duty of hospitality, is probably of local Phrygian origin, put together from two widely circulated legends of the visits of gods to men, and of the preservation of certain individuals from the flood as the reward of piety. It lingers in the account (Acts xiv.) of the healing of the lame man by Paul at Lystra, the inhabitants of which identified Paul and Barnabas with Zeus and Hermes, "come down in the likeness of men."

Similar stories are given in J. Grimm, Deutsche Mythologie (Eng. trans., 1883, ii. 580–581, 380–381).

MANUEL (c. 1775–1349), of Ephesus, Byzantine poet. At an early age he removed to Constantinople, where he was the pupil of Georgius Pachymeres, in whose honour he composed a memorial poem. Philes appears to have travelled extensively, and his writings contain much information concerning the imperial court and distinguished Byzantines. Having offended one of the emperors by indiscreet remarks published in a chronography, he was thrown into prison and only released after an abject apology. Philes is the counterpart of Theodorus Prodromus in the time of the Comment; his character, as shown in his poems, is that of a begging poet, always pleading poverty, and ready to descend to the grossest flattery to obtain the favourable notice of the great. With one unimportant exception, his productions are in verse, the greater part in dediaesyllabic dactylic verse, the remainder in the fifteen-syllable poetic measure.

Philes was the author of poems on a great variety of subjects: on the characteristics of animals, chiefly based upon Aelian and Oppian, a didactic poem of some 2000 lines, dedicated to Michael Palaeologus; on the elephant; on plants; a nomenclature poem, probably written on the death of one of the sons of the emperor; and a panegyric on John Cantacuzene, in the form of a dialogue; a conversation between a man and his soul; on ecclesiastical subjects, such as church festivals, Christian beliefs, the saints and fathers of the church; on censures and changed lapses—from Philemon to Colossae, from Archippus to Ephesus, a letter on the eunuch to Paul, an apology to Paul, and a letter to the author by the emperor Justinian. He published another apology, in which he explains his circumstances for their bearing on Byzantine iconography, since the writer had before him the works he describes, and also the most successful from a literary point of view; occasional poems, many of which simply bear the title of a piece for their bear on Byzantine iconography, since the writer had before him the works he describes, and also the most successful from a literary point of view; occasional poems, many of which simply bear the title of a piece for their bearing on Byzantine iconography. He published another apology in which he explains his circumstances for their bearing on Byzantine iconography, since the writer had before him the works he describes, and also the most successful from a literary point of view; occasional poems, many of which simply bear the title of a piece for their bearing on Byzantine iconography.

Martini (1800); Manueli Phileae Carmina ed. E. Koller (1850); Manueli Phileae Carmina ed. C. Krummbach, Geschichte der Byzantinischen Litteratur (1897).

PHILETAS of Cos, Alexandrian poet and critic, flourished in the second half of the 4th century B.C. He was tutor of the young Ptolemy I of Egypt, and also taught Theocritus and the grammarian Zenodotus. His thinness made him an object of ridicule; according to the comic poets, he carried lead in his shoes to keep himself from being blown away. Over-study of Megarian dialectic subtleties is said to have shortened his life. His elegies, chiefly of an amatory nature and singing the praises of his mistress Battis (or Bittis), were much admired by the Romans. He is frequently mentioned by Ovid and Propertius, the latter of whom imitated him and preferred him to his rival Callimachus, whose superior mythological lore was more to the taste of the Alexandrian critics. Philetas was also the author of a vocabulary called Ἀραξα, explaining the meanings of rare

PHILIDOR—PHILIP (KINGS OF MACEDONIA)

and obscure words, including words peculiar to certain dialects; and of notes on Homer, severely criticized by Aristarchus. Fragments edited by N. Bach (1828), and T. Bergk, Poetae lyrici Graeci; see also E. W. Maass, De tribus Philaei carnibus (1895).

PHILIDOR, FRANCOIS ANDRE DANIAC (1726-1795), French composer and chess-player, was born at Dreux, on the 7th of September 1726, of a musical family. The family name was Danican, but that of Philidor; added in the middle of the 18th century, eventually supplanted the older name. François André received a musical education as a member of the corps of pages attached to the orchestra of the king; and subsequently he earned his living by giving lessons and copying music. Much of his time was, however, devoted to chess, at which he soon became an expert. He spent many years in travelling on the Continent and in England, meeting and defeating the most noted players of the time, and is regarded as the strongest player and greatest theoretical of the 18th century. Returning to France in 1754, he resolved to devote himself seriously to musical composition, and after producing several works of minor importance brought out at Paris, in the year 1759, his successful light opera, Blaise le Serdier, which was followed by a number of others, notably Le Soldat magicien (1760), Le Jardinier et son seigneur (1761), Le Sorcier (1762), and Tom Jones (1764). He died in London on the 31st of August 1795.

PHILIP (Gr. Φιλίππος, fond of horses, from φιλέω, to love, and πός, horse; Lat. Philippus, whence e.g. M. H. Ger. Philippus, Dutch Philips, and, with dropping of the final s, It. Filippo, Fr. Philippe, Ger. Philipp, Sp. Felipe), a masculine proper name, popularized among the Christian nations as having been that of one of the apostles of Christ. Notices of distinguished men who have borne this name are arranged below in the following order: (1) Biblical; (2) Kings of Macedonia, France, Germany and Spain; (3) Other rulers.

PHILIP, one of the twelve apostles, mentioned fifth in all the lists (Matt. x. 3; Mark iii. 18; Luke vi. 14; Acts i. 13). He is a mere name in the Synoptists, but a figure of some prominence in the Fourth Gospel. There he is said to have been "of Bethsaida, the city of Andrew and Peter," and to have received his call to follow Jesus at Bethany, having previously been, it would seem, a disciple of the Baptist (John i. 43, 44; cf. 28). Philip was at that time the means of bringing Nathanael to Jesus (John i. 49), and at a later date he, along with Andrew, carried the request of the inquiring Greeks to the Master (John xii. 22). Philip is also mentioned by name in connexion with the feeding of the five thousand (John vi. 7, 7), and Philip is also one of the few interlocutors in John xiv. Slight though these references are, all agree in presenting Philip as of an inquiring and calculating character, slow to take the initiative, but, when convinced of the path of duty, thoroughly loyal in following it. After the resurrection he was present at the election of Matthias as successor to Judas, but he does not again appear in the New Testament history; it is, however, implied that he still continued in Jerusalem after the outbreak of the first persecution.

Little reliance can be placed on the traditional accounts of Philip, owing to the evident confusion that had arisen between him and the evangelist of the same name, who appears in the book of Acts (see below). According to Polycrates, bishop of Ephesus, in his controversial letter written to Victor of Rome towards the end of the 2nd century (ap. Euseb. H. E., iii. 31, v. 24), the graves of Philip "of the twelve apostles," and of his two aged virgin daughters were in (the Phrygian) Hierapolis; a third daughter, "who had lived in the Holy Ghost," was buried at Ephesus. With this may be compared the testimony of Clement of Alexandria, who incidentally (Strom. iii. 6) speaks of "Philip the Apostle" as having begotten children and as having given daughters in marriage. On the other hand, Proclus, one of the interlocutors in the "Dialogue of Calus," a writing of somewhat later date than the letter of Polycrates, mentions (ap. Euseb. H. E., iii. 31) "four prophetesses, the daughters of Philip at Hierapolis in Asia, whose tomb and that of their father are to be seen there," where the mention of the daughters prophesying identifies the person meant with the Philip of Acts (cf. Acts xxi. 8). The reasons for setting aside this latter identification, and for holding that the Philip who lived at Hierapolis was the Apostle are clearly stated by Lightfoot, Colossians (2) note 3, p. 45 seq., and fresh confirmation of his view has recently been afforded by the discovery of an inscription at Hierapolis, showing that the church there was dedicated to the "of the holy and glorious apostle and theologian Philip" (Ramsay, Cities and Bishops of Phrygia, vol. i., pt. ii. p. 552).

See also Corssen, "Die Töchter des Philippus" in the Zeitschrift für die neutestamentliche Wissenschaft (1901), p. 289 seq. The other view, that the Philip of Hierapolis is the Philip of Acts, is taken by Zahn, Forschungen zur Geschichte des neutestamentlichen Kanons (1900), vol. i. 158 seq.

A later stage of the tradition regarding Philip appears in various late apocryphal writings which have been edited by Tischendorf in his Acta apostolorum apocrypha, and in his Apocalypses apocryphae. According to the Acta Philippi, a work belonging at the earliest to the close of the 4th century (see Zahn, op. cit. p. 18 sqq.), Philip, with Bartholomeus and his own sister Mariamne, exercised a widespread missionary activity, preaching not only throughout Asia Minor, but also in Hellas the city of the Athenians, in Scythia, and in Gaul, &c. According to one account he died a natural death; according to another he was hanged or crucified, head downwards. An apocryphal gospel, which describes the progress of the soul through the next world, bears his name (Hennecke, Neutestamentliche Apokryphen, 1904, p. 40 seq.).

Since the 6th century Philip has been commemorated in the West, along with St James the Less, on the 31st of May, their relics being deposited in the same church in Rome; in the Eastern Church Philip's day is the 14th of November, and that of James the Less the 23rd of October.

PHILIP, "the evangelist," is first mentioned in the Acts (vi. 5) as one of "the seven," who were chosen to attend certain temporal affairs of the church in Jerusalem in consequence of the murmurgings of the Hellenists against the Hebrews. After the martyrdom of Stephen he went to "the city of Samaria," where he preached with much success, Simon Magus being one of his converts. He afterwards instructed and baptized the Ethiopian eunuch on the road between Jerusalem and Gaza; next he was "caught away by the Spirit and found at Azotos" (Acts, viii. 9), whence "passing through he preached in all the cities of Libya and entered into Egypt" (Acts viii.). Here some years afterwards, according to Acts xxi. 8, 9, where he is described as "the evangelist" (a term found again in the New Testament only in Eph. iv. 11; 2 Tim. iv. 5), he entertained Paul and his companion on their way to Jerusalem; at that time "he had four daughters which did prophesy." At a very early period he came to be confounded with the apostle Philip (see above); the confusion was all the more easy because, as an esteemed member of the apostolic company, he may readily have been described as an apostle in the wider sense of that word (see further Salmon, Introd. to the New Testament, 7th ed., p. 513 sqq.). A late tradition describes him as settling at Taphes in Asia Minor, where he became the teacher of the church. "The Philip the deacon" is commemorated on the 6th of June.

PHILIP I., king of Macedonia, a semi-legendary prince, son of Artabazus, was, according to Herodotus (viii. 137-139) and Thucydides (ii. 100), the third of the Macedonian kings. In the texts of Dexippus and Eusebius he ranks sixth, Caranus, Coenus and Thurimus (or Turimbas) being there regarded as the predecessors of Perdiccas I., whom Herodotus and Thucydides regard as the first king of Macedonia. Eusebius and Dexippus assign to Philip I. a reign of 38 and 35 years respectively. There is, however, no real evidence for his existence.

PHILIP II. (382-336 B.C.), king of Macedonia, the son of Amyntas and the Lycastrian Eurydice, reigned 359-336. At his birth the Macedonian kingdom, including the turbulent peoples of the hill-country behind, was very imperfectly consolidated. In 370 Amyntas died, and the troubled reign of
such a position Philip had determined to secure: the Macedonian agents continued to work throughout the Greek states, and in the Peloponnesus Sparta soon found herself isolated. Euoebs, too, submitted to Macedonian influence, and even received some garrisons. But more work had to be done in the Balkan highlands. In 344, or one of the following years, the Macedonian arms were carried across Epirus to the Adriatic. In 342 Philip led a great expedition north “comparable to nothing in antiquity since Darius’ famous march to Scythia.” In 341 his army was still campaigning in eastern Thrace, when Philip felt compelled to show his presence in Thessaly. During these years, although Athens had not overtly broken the peace of 346, there had been numerous Macedonian incursions and hostile intrigues between the two powers (cf. the Philippics of Demosthenes). Athens had even sent emissaries to the Persian court to give warning of the proposed national crusade. She now egged on the cities of the Propontis (Byzantium, Perinthus, Selymbria), who felt themselves threatened by Philip’s Thracian conquests, to declare against him. The sieges of Perinthus and Byzantium (340, 339) ended in Philip’s meeting with a signal check, due in some measure to the help afforded the besieged cities by Athens and her allies. Philip’s influence all over Greece was compromised. But before marching south he led another expedition across the Balkans into the country now called Bulgaria, and returned to Pella with much spoil but severely wounded in the thigh. In 338 he once more crossed into central Greece. The pretext was the conumity shown by the Locrian town Amphissa to the rulings of the Amphictyonic Council. Philip’s fortification of Elatea filled Athens with alarm. Thebes was induced to join Athens; so were some of the minor Peloponnesian states, and the allies took the field against Philip. This opposition was crushed by the epoch-making battle of Chaeronea, which left Greece at Philip’s feet. In the following year (337) Philip was in the Peloponnesus, and a congress of the Greek states at the Isthmus (from which, however, Sparta held sullenly aloof) recognized Philip as captain-general for the war against Persia. Philip returned to Macedonia to complete his preparations; an advanced force was sent into Asia in the spring of 336. But Philip’s plans were suddenly blasted by his assassination in the same year during the marriage festival of his daughter at Aegae, the old capital of Macedonia. He left, however, in the Macedonian army a splendid instrument which enabled his son within ten years to change the face of the world.

Philip stands high among the makers of kingdoms. Restless energy, determination, a faculty for animating and organizing a strong people, went with unscrupulous duplicity and a full-blooded vehemence in the pleasures of sense. Yet Philip was not untouched by ideal considerations, as is proved by the respect with which he treated the spirit of Hellenic culture, by his forbearance and deference with which he treated Athens, the sacred city of that culture and his mortal foe. A special interest belongs to the Macedonian kingdom as it was shaped by Philip, since it fastens a system which was not to find the time ripe for it in European history till many centuries later—the national kingdom quickened with the culture developed by the ancient city-states. The national kingdoms founded by the Northern races, after the fall of the Roman Empire, under the influence of the classical tradition, are the beginnings of the modern European system; Philip of Macedon foreshadowed Theodoric, Charlemagne and William the Conqueror. But this first national kingdom within the sphere of Greek culture could not ultimately live between the surge of the Northern barbarians and the Roman power.

See the authorities under GREECE: History. A vivid and masterly sketch of Philip’s personality and work is given in D. G. Hogarth’s Philip and Alexander (1897).

PHILIP III. [ARRHIDAEUS], king of Macedonia, was the feeble-minded son of Philip II. of Macedonia by a Thessalian wife. He was chosen by the Macedonian army at Babylon in 323 to be nominal king conjointly with the Infant Alexander, and was killed in Macedonia by order of Olympias (317). (See Macedonian Empire.)

PHILIP (KINGS OF MACEDONIA) 377
Philip IV, king of Macedonia, was the son of Cassander, king of Macedonia: he reigned only one year (297–296).

Philip V, king of Macedonia, son of Demetrius II and Chryseis, was an infant at his father's death in 295–294 B.C. His cousin, Antigonus Doson, administered the kingdom as regent till his death in 221–220, when Philip was eighteen years old. Philip now ascended the throne and reigned till 79. His reign was occupied in the vain struggle to maintain the old Macedonian supremacy in the Balkan Peninsula, which became hopeless after the intervention of Rome and the decisive battle of Cynoscephalae (197). See Rome: History, § II. "The Republic" (period B, § b). (E. R. B.)

PHILIP I. (1052–1108), king of France, eldest son of Henry I. of France and Anne, daughter of Jaroslav I. (d. 1054), grand duke of Kiev, came to the throne, when a child of eight, by the death of his father on the 4th of August 1066. He had been crowned at Reims, in the presence of a number of magnates, on the 23rd of May 1059. Philip passed most of his early years in and around Paris, where the castles of lawless barons, such as that of Montlhéry, threatened even his personal safety. His minority came to an end in 1066. In the long reign that followed he showed no great ability or energy, and a looseness of morals which embroiled him with the Church. Before he was fifty years of age he became "fond of nothing but good cheer and sleep." But he increased the lands of his house around Paris, maintained order in them, and held his own against William I. and William II. of England, whose power in France far exceeded his own. This he accomplished for the most part by taking advantage of the quarrels among his vassals. When Baldwin VI. of Flanders died, in 1070, his son Baldwin was attacked by his uncle Robert the Frisian, count of Holland. Philip interfered, at the prayer of Arnulf's mother, Richildis; but the allies were defeated near Cassel on the 22nd of February 1071 and Arnulf slain. After a second war peace was sealed, apparently, by the marriage of Philip to Robert's step-daughter Bertha, daughter of Gertrude of Saxony and Florence, count of Holland. In 1074 a new rupture led to Philip seizing Corbie, part of the dower of his aunt Adele, who had married Baldwin IV. of Flanders. By this he secured a sort of outpost in the direction of Flanders. The other main episodes of his reign were the quarrel over the Angevin inheritance and his wars with the dukes of Normandy. In the struggle between Fulk Rechin and his brother Geoffrey, the former was deprived of the inheritance of their uncle, Geoffrey Martel (d. 1060), count of Anjou. Philip received from Fulk in 1069, as the price of his neutrality, Château Landon and the Gatinais. This acquisition linked the county of Sens, acquired in 1055, with the rest of the domain round Paris, Melun and Orleans. War with William I. was chronic but intermittent. In 1076 Philip forced him to raise the siege of Dol in Brittany. Peace was made in 1077, and in December 1079 they together besieged Robert Curthose in the castle of Gerberoy. On the 8th of May 1080 the siege was raised and peace made. War with William began again in 1081 over the county of Vexin, which Philip had seized on the retirement of its count, Simon of Valois, to a monastery in 1076. William demanded the return of the territory, and on the cession of Pontoise, Chaumont-en-Vexin and Mantes, but died after sacking Mantes in the same year. In 1098 there was war between Philip and William Rufus in both Maine and the Vexin. William came in person from Maine to lead the attack in the Vexin in September, and crossed the Seine, penetrating to within 30 m. of Paris on the west; but the campaign brought no results. In his last years Philip left the duty of repelling the attacks of his Norman and other enemies to his son Louis, associating him with himself, as "king-designate," some time between the 24th of May 1098 and the 25th of September 1100.

It was his second marriage which was the cause of Philip's greatest difficulties. On the 15th of May 1092 he carried off Bertrada, daughter of Simon, baron de Montfort, wife of Fulk Rechin, and prepared to marry her, though his wife Bertha was still living. The bishops, headed by Yvo, bishop of Chartres, refused to attend the ceremony of marriage, but one was found to perform it. Philip's open simony had long been a cause of friction with the papacy. When he added bigamy and adultery, Urban II. excommunicated him. The bishop of Chartres, in consequence, refused to bring his vassals to help Philip's ally, Robert, duke of Normandy, against his brother William in 1094. Bertha died in that year, but Fulk was still living, and the sentence was renewed at the council of Autun on the 15th of October. Philip replied by summoning the bishops to Paris to try Ivo of Chartres for treason. He gained a respite from the papal sentence by promises of submission, but the sentence was renewed by Urban at the council of Clermont in 1095, in 1096, and in 1097, and at Poitiers in 1101, despite the protest of William IX., count of Poitiers, who entered the church with his knights to prevent his suzerain from being excommunicated on his lands. Philip was reconciled with the Church in 1104, and took an oath not to have any converse or society with Bertrada except in the presence of "non-suspect" persons. But they seem to have gone on living together, and even visited Fulk Rechin (Bertrada's husband) in company on the 15th of October 1106. Philip died at the end of July 1108.

His reign is chiefly remarkable for the steady growth of the royal domain. In addition to the gains mentioned, he bought in 1101 a large slice of territory, including Bourges and Dun-le-Roi, from Eudes Arpin, viscount of Bourges, who was going on the crusade; and toward the end of his reign took Montlhéry, whose lord best the southern approach to Paris. By his first queen he had four children: Louis VI., who succeeded him; Henry, who died young; Charles; and Constance, who married Hugh I., count of Anjou, grandson of William, called the Lion, in 1104.

By Bertrada de Montfort he had three children: Philip, called of Montes; Fleurie or Florus, who married the heiress of Nangis; and Cecilia, who married, first Tancred, prince of Galilee and Antioch, and secondly Pons de Saint Gilles, count of Tripoli.

The materials for the reign of Philip I. are in the Recueil des historiens des Gaules et de la France, vols. xi. to xvi. See especially the critical examination by Dom Bréal of the historians who have spoken of Philip I. at the beginning of vol. xvi Consult also A. Freeman, "Notre Dame de Paris et l'Eglise religieuse de Paris jusqu'a l'année 1220," p. 285-302; A. Luchaire, Louis le Gros (Paris, 1890), and "Les Premiers Capetiens" in E. Lavisse's Histoire de France (II. ii., pp. 168-175). More recent is the Recueil des actes de Philippe I., edited by M. Pron (1906), and B. Monod's "Essai sur les rapports de Plantagenet I. avec Philippe I." (Paris, 1907). For notices of the principal chronicles of the time see A. Molinié, Les Sources de l'Histoire de France (II, esp. p. 307 et seq.).

PHILIP II. (1155–1223), known as PHILIP AUGUSTUS, king of France, son of Louis VII. and Adela, daughter of Theobald II., count of Champagne, was born on the 21st of August 1165. On the 1st of November 1179 he was associated with his father as king by being crowned at Reims, and at once his father's illness threw the responsibility of government on him, the death of Louis on the 15th of September 1180 leaving him sole king.

The boy-king found himself and his kingdom in a difficult and humiliating position. His long strip of royal domain was hemmed in by the Angevin Empire on the west and by the kingdom of Arles on the south-east. Henry II. of England was feudal lord of the greater part of France, practically all west of a line from Paris to Poitiers at Le Mans, and his power was more than half-way across to the Mediterranean, while at one point it nearly touched the Rhone. Philip's predecessors had consolidated the Capetian power within these narrow limits, but he himself was overshadowed by the power of his uncles, William, archbishop of Reims; Henry I., count of Champagne; and Theobald V., count of Blois and Chartres. He secured an ally against them, and an addition to the royal domain, by marrying, on the 28th of April 1180, Isabella or Elizabeth, daughter of Baldwin V., count of Hainaut, and of Marguerite, sister of Philip ofAlsace, the reigning count of Flanders, who ceded Arns, St Omer, Aire and Hesdin, and their districts, as Isabella's dowry, a district extending from the Somme to the French coast. In 1183 he concluded a treaty with Henry II. at Gisors, and his reign thus opened auspiciously. But from 1183 to 1189 he had to struggle against a feudal league of his Champagne and other great
PHILIP II. (FRANCE)

379

barons, whose most active member was Stephen I., count of Sancerre (1152-1191). Though attacked from both north and south, the king's activity enabled him to compel the count of Sancerre to implore peace in 1185. On the death of Isabel of Avis, the widowed Count Philip of Flanders, in 1189, he claimed Vermandois and seized Chauné and St. Quentin, and forced his father-in-law, Baldwin of Hainaut, to support him by threatening to divorce Queen Isabel. The count of Flanders was obliged to sign the treaty of Boves in July 1185, which gave the king, in addition to the expectation of Artois, his wife's dower, sixty-five castles in Vermandois and the town of Amiens. By 1186 Hugh, duke of Burgundy, the only member of the coalition not yet subdued, was forced to submit. Then, secure at home, the king turned against Henry II., and by the truce of Châteauroux in June 1187, gained Issoudun and the seigniory of Fretval in the Vendômois. Though the truce was not renewed, Philip assembled an army in 1188 to invade Normandy, desiringgisors and the conclusion of the marriage which had been arranged between his sister Alice and Richard of England, who had meanwhile deserted his father. But the news came that Saladin had taken Jerusalem and Richard took the cross. Shortly afterwards Philip took advantage of a rising against his quondam friend Richard, who was duke of Aquitaine, to seize the county of Berry. At a conference at Bonnoulines on the 18th of November Richard again abandoned his father, and after a second conference at La Ferté Bernard, Philip invaded Maine and forced Henry II. to conclude the treaty of Azay on the 4th of July 1189, by which the English king did homage and gave the territories of Gracy and Issoudun. Henry died two days later. Pledges of mutual good faith and fellowship were renewed between Philip and Richard of England on the 30th of December 1189, and they both prepared to go on the crusade.

Before setting out Philip arranged for the government of France during his absence by his famous testament of 1190, by which he proposed to rule France as far as possible from Palestine. The power of the regents, Adela, the queen-mother, and William, archbishop of Reims, was restricted by a council composed mostly of clerks who had the king's confidence. An annual report on the state of the kingdom was to be sent him. On the way to Palestine the two kings quarrelled. At the siege of Acre Philip fell ill, and on the 22nd of July, nine days after its fall, he announced his intention of returning home. He reached Paris at Christmas 1191, having concluded on his way an alliance with the emperor Henry VI. against Richard, despite his pledges not to molest his lands. When Leopold I., duke of Austria, took Richard prisoner and delivered him to the emperor, Philip did his utmost by offers of money to prolong his captivity, and, allied with the English king's brother John, attacked Richard's domains, but upon Richard's return the Normans rallied enthusiastically to his aid. Philip was defeated at Fretéval on the 3rd of July 1194, but he continued the war, generally with ill success, for the next five years. Again a formidable coalition was formed against him, including Baldwin IX., count of Flanders and Hainaut, Renaud of Dammartin, count of Boulogne, Louis, count of Blois, and Raymond VI., count of Toulouse. In Germany, Otto of Brunswick, afterwards the emperor Otto IV., allied himself with Richard, while Philip was supported by Otto's rival, Philip of Swabia.

Richard's death, in April 1199, removed his archenemy, and Richard's successor, John, concluded the treaty of Le Goulet with Philip on the 22nd of May 1200, ceding to him the county of Evreux, Gracy and Issoudun, and the suzerainty of Berry and Auvergne. John renounced his suzerainty over Brittany and the guardianship of his nephew, Arthur; he engaged not to aid the count of Flanders for Otto IV. without Philip's consent, paid him a relief of 20,000 marks, and recognized himself as his vassal for his continental fiefs. Philip's son Louis, afterwards Louis VIII., married Blanche of Castile, John's niece. But in 1202 the war was renewed, John having seized some castles from the family of Lusignan, whose head was the count of La Marche, and taken for his queen a prospective bride, Isabelle Tilsolle, from Hugh, son of Hugh IX., count of La Marche. At an interview at Le Goulet on the 25th of March, Philip demanded the cession of Anjou, Poitou and Normandy to his ward, Arthur. John refused; he was summoned to Paris before the royal judges, and failing to appear was sentenced at the end of April 1202 to lose all his fiefs. Brittany, Aquitaine and Anjou were conferred on Arthur. Philip invaded Normandy, took Lyons-la-Forêt and Eu, and, establishing himself in Gournay, besieged Arques. But John, joined by William des Roches and other lords of Maine and Poitou, jealous at the increase of Philip's power, defeated and took Arthur prisoner at Mirebeau. Philip abandoned the siege of Arques in a fit of fury, marched to the Loire, burning everywhere, and then returned to Paris. But John soon alienated the Poitevin barons, and William des Roches signed a treaty with Philip on the 22nd of March 1203. Then Philip continued his great task, the conquest of Normandy, capturing the towns around the fortress of Château-Gaillard which Richard had fortified on the valley of the Seine. Pope Innocent III. tried to bring a peace at Philip January 1204, and after murdering Arthur of Brittany John took refuge in England in December 1203. The fall of Château-Gaillard, after a siege which lasted from September 1203 to April 1204, decided the fate of Normandy. Rouen, bound by ties of trade to England, resisted for forty days; but it surrendered on the 24th of June 1204. The conquest of Maine, Touraine, Anjou and Poitou in 1204 and 1205 was little more than a military promenade, though the castles of Loches and Chinon held out for a year. Philip secured his conquest by lavishing privileges on the convents and towns. He left the great lords, such as William des Roches, in full possession of their feudal power. In 1206 Philip marched through Brittany and divided it amongst his adherents. A truce for two years was made on the 26th of October 1206 by which John renounced all claims in Normandy, Maine, Brittany, Touraine and Anjou, but it did not last six months. Then Poitou was thoroughly subdued, and another truce was made in 1208, little more than southern Saintonge and Gascony being left in the hands of John. Philip had reduced toa mere remnant the formidable continental empire of the Angevins, which had threatened the existence of the Capetian monarchy.

Philip then undertook to invade England. In the assembly of Soissons on the 8th of April 1213 he made every preparation for carrying out the sentence of deposition pronounced by the pope against John. He had collected 1500 vessels and summoned all his barons when Innocent III., having sufficiently frightened John, sent Pandulf with the terms of submission, which John accepted on the 13th of May.

Disappointed of his hopes of England, Philip turned his arms against Ferdinand, count of Flanders. Ferdinand, son of Sancho I., king of Portugal, owed his county to Philip, who, hoping to find him a docile protégé, had married him to Jeanne, heiress of Flanders, daughter of Count Baldwin IX., who became emperor of the East, using the weak Philip of Namur, her guardian, to accomplish that end. They were married on January 1213. On the marriage of the marriage Louis, afterwards Louis VIII., seized Aire and St. Omer in right of his mother, Isabella, and on this account Ferdinand refused his feudal duty in the English expedition. Moreover, the trade interests of his subjects, who got their raw wool from England, drew him to an alliance with England. Philip's attack brought about this on the 22nd of May 1213. He invaded Flanders and took the chief towns within a week; but he had part of his fleet burned by the English at Damme, and had to burn the rest to save it from falling into their hands. He returned to Paris, and Ferdinand retook most of the towns which had been taken by the king. A war of fire and pillage began, in which Philip and his son Louis burned their way through Flanders, and Ferdinand did the same through Artois.

In 1214 came the great crisis of Philip's life. All the forces against which he had been struggling united to overwhelm him. Paris was to be attacked from Flanders and Guînême at the same time. A league including his rebel vassals, Renaud of Dammartin, count of Boulogne, and Ferdinand, count of Flanders, with the emperor Otto IV. and a number of German princes of the Rhine region, had been formed in the north-east, while John of England...
PHILIP II. (FRANCE)

made one more attempt to recover his heritage at the head of an army of mercenaries aided by the fierce baronage of Poitou. John landed at La Rochelle on the 16th of February 1224, and was at first successful. On the 19th of June he laid siege to La Rochelle-aux-Moines, the fortress which defended Angers and commanded the Loire valley; but on the approach of a royal army under Prince Louis on the 2nd of July his Poitou mercenaries refused to risk a pitched battle, and he fled hastily to La Rochelle. The Angevin Empire in France was lost. Meanwhile Philip himself won his greatest victory at the bridge of Bouvines, among the morasses of Flanders. At first taken by surprise, he turned the abortive attack into a complete rout. Renaud and Ferdinand were taken prisoner, and Otto IV, fled from the battlefield. The army of the allies was utterly destroyed (July 27, 1214). Nothing shows the progress of the Capetian monarchy more than the enthusiasm and joy of the people of France, as described by William le Breton, over this crowning victory. The battle of Bouvines, a decisive battle for the history of Germany as well as for France and England, sealed the work of Philip Augustus. The expedition of his son Louis to conquer England can hardly be considered as an incident of his reign, though he was careful to safeguard the rights of the French Crown. More important was the Albigensian crusade, in which he allowed Louis to take part, though he himself, preoccupied with the king of England, had refused time after time to do anything. He treated Simon de Montfort as if he were a royal baili; but it was not in virtue of any deep-laid scheme of his that in the end Amaury de Montfort, Simon's son, resigned himself to leave his lands to the Crown of France, and gave the Crown a power it had never before possessed in Aquitaine.

Even more than by his conquests Philip II. marks an epoch in French history by his work as an organizer and statesman. He surrounded himself with clerks and legists of more or less humble origin, who gave him counsel and acted as his agents. His bailis, who at first rather resembled the itinerant justices of Henry II. of England, were sent into the royal domain to supervise the conduct of the prévôts and hear complaints, while in the newly acquired lands in the south local feudal magnates were given similar powers with the title of sénéchal. Feudal service was more and more compounded for by a money payment, while additional taxes were raised, all going to pay the mercenary bands that followed him on his expeditions. The Crown took over the exaction of the system of saquegarde, by which abbots, towns or lay vassals put themselves under the special protection of the king, and that of pariage, by which the sovereign surrender half the interest in his estate to the king in return for protection or some further grant, increased the royal power. The small barons were completely reduced to submission, whilst the greater feudatories could often appoint a castellan to their own castles only after he had taken an oath to the king. Philip supported the clergy against the feudal lords, and in many cases against the burgesses of the towns, but rigidly exacted from them the performance of their secular duties, ironically promising to aid the clergy of Reims, who had failed to do so, "with his prayers only" against the violence of the lords of Rethel and Roucy. He clung to his right of regale, or enjoyment of the revenues of bishops during their vacancy, though it was at times commuted for a fixed payment. The attempt to raise a tithe for the crusade in 1189 failed, however, before a general resistance owing to an unfair assessment.

It has been said with some justice that Philip II. was the first king of France to take the bourgeoisie into partnership. He favoured the great merchants, granting them trade privileges and monopolies. The Jews he protected and plundered by turns, as the chroniclers of medieval kings. Amongst the subject towns administered by prévôts a great extension of the "custom of Lorrès" took place during his reign. But it is as the ally and protector of the communes that he takes his almost unique place in French history. Before him they were resisted and often crushed; after him they were exploited, oppressed, and finally destroyed. In the case of Sensis he extended the jurisdiction of the commune to all crimes committed in the district. It is true that he suppressed some communes in the newly conquered fiefs, such as Normandy, where John had been prodigal of privileges, but he erected new communes in his own private domain, quite contrary to the custom of other kings. He seems to have regarded them as a kind of garrison against feudal unruliness, while the rents they furnished increased his financial resources. His code of law, the Vieilles consignes, does not touch the commune, however, except Peronne, which received a maximum of political independence, the twenty-four electors, who named the jurats and other officers, being elected by the corps de métier.

The newly organized powers of the Crown were in evidence everywhere, interfering in the family affairs of the great feudatories and taking advantage of minorities, such as that of Theobald IV. of Champagne. The great feudatories accepted his legislation on dower in 1214 and 1219 and the établissement of 1209 making co-heirs of fiefs hold direct from the king and not from one of their number. The Tournois was substituted for the Angevin money in Normandy after 1204. The army which safeguarded this active monarchy consisted chiefly of mercenaries. The old feudal estat was but rarely convoked. The communes, though they appear as taking part in the battle of Bouvines, compounded for their service by a money payment as early as 1194. Philip's policy of building up a strong monarchy was pursued with a steadiness of aim which excluded both enthusiasm and scruple. But he seems to have prided himself on a certain humanity, or even generosity of temper, which led him to avoid putting his enemies to death, though he did not scruple to condemn Renaud of Dammartin to the most inhuman of imprisonments. He was impulsive and could display extraordinary activity at times, but he could also show a very characteristic caution. He shrank from any trickery in carrying out his ends, and had no room for pity. He could not even trust his own son with any power, and was brutal in his relations with his queen, Ingeborg. He is described by Païen Gâtineau as "a well-knit, handsome man, bald (from his illness at Acre), of agreeable face and ruddy complexion, loving good cheer, wine and women. Generous to his friends, he was miserly to those who displeased him; very skilled in the art of the engineer, Catholic in his faith, far-seeing, obstinate in his resolution. His judgment was sound and quick. He was also quick in his anger, but easily appeased." As the result of his steadiness of aim and patient sagacity, at the end of his reign he was able to give his own succession a absolutely plain of feudal nobility and the royal domain extended to the frontier, the Duchy of Burgundy and Savoy being ruled along with royal authority. Artois, the Amienois, Valois, Vermandois, the greater part of the Beauvaisis, Normandy, Maine, Anjou, Touraine, and an important part of Poitou and Saintonge, were added to the domain during his reign. The number of prévôts was increased from thirty-eight to ninety-four, and the royal revenue increased from 19,000 livres a month to 12,000 livres a day.

Philip Augustus died on the 14th of July 1223. He was thrice married. His first wife, Isabella, by whom he had one son, Louis, died in 1189 or 1190. After her death he married Ingibjorg or Ingeborg (q.v.), daughter of Valdemar I. of Denmark. This unlucky marriage was negotiated, it is said, chiefly to acquire the old claims of Denmark over England, to be used as a weapon against Richard I. However that may be, he soon repudiated this Danish princess, for whom he seems to have conceived an unconquerable aversion on the very morrow of his marriage to her, and in 1196, in defiance of the pope, who had refused to nullify his union with Ingeborg, married Agnes, daughter of Bertold IV., duke of Meran. This led to his excommunication and brought the interdict upon France, and did more to weaken him than any other act of his. In 1200 he was forced to put away Agnes and to recognize Ingeborg as his lawful wife, but he kept her in prison until 1223. By Agnes (d. 1201) he had a son Philip, called "le Téméraire" child of Clermont, a daughter Mary, who married Philip, count of Namur (d. 1213), and then Henry II., duke of Brabant. Ingeborg lived until 1236.

A. Molinier, Les Sources de l'histoire de France (tome iii, pp. 1-38), gives a complete bibliography of the sources for Philip's reign, including the history of the Third Crusade.

PHILIP III. (1245-1285), surnamed "the Bold" (le Hardi), king of France, son of Louis IX. and Margaret, daughter of Raymond-Bérenger IV., count of Provence, was born on the 3rd of April 1245. His funeral monument at St Denis depicts a man with beardless, square-cut features, but lacking character and animation. The authenticity of this effigy is fairly well borne out by what is known of him from other sources. He had many of the virtues of St Louis, but neither decision of character nor devotion to duty. He was pious, charitable, of unimpeachable morality, quick-tempered but placable, no great scholar, and only energetic as a hunter. The absence in him of the qualities that fit a man to rule made his court the arena of intriguing factions, which in reality ruled France during his reign of fifteen years. Matthew of Vendôme, abbot of St Denis, an old servant of Louis IX., acted as Philip's counsellor, so the chroniclers state, throughout the reign; but he is only a shadowy figure, and it is difficult to reconcile the statement that "everything was done according to his will" with the knowledge that his father II. was probably with administration, and not policy, that Matthew was chiefly concerned. In one instance at least his advice was openly flouted. Coming to the throne by the death of his father on the 25th of August 1270, Philip began his reign by falling entirely under the influence of Pierre de la Brosse, who had been surgeon and valet-de-chambre to his father, upon whom he lavished lands and honours, making him lord (seigneur) of Langeais, Chartillon-sur-Indre and Damville. Even Edward I. of England and William Dampierre, count of Flanders, strove to win his favour by gifts. But his fall was assured when Philip, who in 1271 lost his first wife, Isabella, daughter of James I., king of Aragon, married in 1274 Marie, daughter of Henry III., duke of Brabant. She was young and beautiful, and supplied a centre round which those who wished the downfall of the favourite grouped themselves. In June 1278 he was charged with various crimes, including one of poisoning the king's eldest son, and hanged at Montfaucon. His death left the parties of Marie, the queen, and Margaret, the queen-mother, to struggle for the mastery. The first subject of dispute was the inheritance of the count of Provence, Raymond-Bérenger IV., father of Margaret and of Eleanor, wife of Henry III. of England. Upon his death, in 1245, his youngest daughter, Beatrice, wife of Charles of Anjou, the king's nephew, married his living eldest elder sisters, who claimed some portion of them for themselves. In 1251 war nearly broke out on this question. Margaret and her friends formed the league of Mâcon against Charles of Anjou, but the king managed to keep them at peace. The settlement of the claims of the king of England in Aquitaine by the treaty of Amiens in 1270 was a victory for the party of Margaret. Agenais and southern Saintonge, which fell to the Crown by the death of Alfonse of Poitiers in 1276, as part of his vast possessions in Aquitaine and Languedoc, were ceded to Edward I. of England in accordance with the treaty of Paris 1259. Another portion of the heritage of Alfonse, the Vexin, was ceded to the king. The death of Jeanne, the heir of Jeanne of Navarre and Champagne, along with the guardianship of the king of Navarre during the minority of Jeanne. But early in 1276 Jeanne's mother, Blanche, the widow of Henry III. of Navarre and Champagne, married Edmund, first earl of Lancaster, brother of Edward I.; and she and her English husband kept Champagne until, in 1284, Jeanne came of age.

An expedition of Philip against Castile in aid of the children of his sister, Blanche, proved abortive. Regardless of this warning, he was induced in 1284 to take up the quarrel of his uncle Charles in Sicily, after the Sicilian Vespers in 1282. Two assemblies of barons and prelates were held at Bourges in November 1283 and February 1284 to deliberate on the question. This was a mere matter of form; Marie of Brabant and her party had decided the matter beforehand, and the crown of Aragon, which the French pope Martin IV. had declared forfeited by Peter, was accepted for Charles of Valois, Philip's third son. The project was strongly opposed by Matthew of Vendôme, who was in correspondence with the king of England on the subject. It was the first time that a prince of France undertook the house of Capet outside France. It proved a disastrous failure. The French army laid siege to Gerona on the 26th of June 1285. The town surrendered on the 7th of September, but disease and the defeat of the fleet by the Aragonese navy at Las Farmiguan Islands led to a retreat, during which, on the 5th of October, the king died. In the same month the garrison placed at Gerona surrendered. It is typical of Philip's character and career that he should die thus, in an expedition undertaken against the interests of his kingdom, at the instigation of his ambitious uncle.

Philip was twice married. On the 28th of May 1262 he married Isabella, daughter of James I., king of Aragon, who died in 1273. By her he had two sons: Louis, who died in 1276; Philip, born in 1268; Charles of Valois, born on the 12th of March 1270; and Robert, who died young. By his second wife, Marie (d. 1322), daughter of Henry III. of Brabant, whom he married in 1274, he had three children: Louis, count of Evreux; Margaret, who married in 1290 Edward I., king of England; and Blanche, who married Rudolph III., duke of Austria.

PHILIP IV. (1268-1314), called "le Bel" or "the Fair," king of France, was the son of Philip III. and his wife, Isabella of Aragon. His reign, which began in October 1285, is one of the most momentous in the history of medieval Europe, yet it belongs rather to the history of France and to that of the papacy than to the biography of the king. Little is known of the personal part played by Philip in the events associated with his name, and later historians have been divided between the view which regards him as a bystander in the complex picture of the reign, which paints him as a master of statecraft who, under a veil of phlegmatic indifference and pious sentiment, masked an inflexible purpose, of which his ministers were but the spokesmen and executors. The first view seems to be borne out by the language of contemporary chroniclers. To his enemy, Bernard Saisset, he was neither man nor beast, but a statue, "the handsomest man in the world, but unable to do anything but stare fixedly at people without saying a word." Guillaume de Nogaret, his minister, draws a far more flattering picture, enlarging on his charm, his amiability, his modesty, his charity to all men, and his piety; and the traits of this over-coloured portrait are more or less repeated by Yves de Villeneuve, his historian. Yet, without a word of any qualities of will or initiative. All of which suggests a personality mentally and physically phlegmatic, a suggestion strengthened by the fact that Bartholomaeus de Neocastro (quoted by Wencz) describes him as corpulent in 1290.

Yet this was the king who with equal implacability brought the papacy under his yoke, carried out the destruction of the powerful order of the Temple, and laid the foundations of the national monarchy of France. In this last achievement Professor Finke finds the solution of a problem which Langlois had declared to be insoluble. In 1302, in the midst of a hostile assembly, Philip cursed his sons should they consent to hold the Crown of England, which God in 1290 had consecrated to Philip, but he sees the key to his character. "Philip was not a man of violent initiative, the planner of daring and fraught operations; otherwise there

1 Wencz, p. 49.
PHILIP V. (FRANCE)

would have been some signs of it. His personality was that of a well-instructed, outwardly cold, because cool and calculating man, essentially receptive, averse for only one idea: the highest possible development of the French monarchy, internally and externally, as against both the secular powers and the Church. His merit was that he carried through this idea in spite of dangers to himself and to the state. A resolution once arrived at he carried out with iron obstinacy. 1 Certainly he was no roi fainéant. His courage at the battle of Mons-en-Pévèle was the admiration of friend and foe alike. It was against the advice of his tutor, Aegidius Colonna, that on coming to the throne he chose as his counsellors men of the legal class, and the names of his great ministers—Guillaume de Nogaret, Enguerrand de Marigny, Pierre Flotte (d. 1302)—attest the excellent quality of his judgment. He was, too, one of the few monarchs who have left to their successors reasoned programmes of reform for the state.

The new materials from the Aragonese archives, published by Finke, give the same general impression of "uncanny" reticence on Philip's part; when other contemporary kings would have spoken he keeps silence, allowing his ministers to speak for him. Isolated passages in some of the Aragonese letters included in the collection, however, throw a new light on contemporary estimate of his character, describing him as all-powerful, as "pope and king and emperor in one person." 2

The reign of Philip IV. is of peculiar interest, because of the intrusion of economic problems into the spheres of national politics and even of religion. The increased cost of government and the growing wealth of the middle class, rather than the avarice of the king and the genius of his ministers, were responsible for the genesis and direction of the new order. The greatest event of the reign was the struggle with Pope Boniface VIII. (q.v.). The pope, in his opposition to the imposition of royal taxation upon the clergy, went so far in the bull Clerics laicos of 1296 as to forbid any lay authority to demand taxes from the clergy without his consent. When Philip retaliated by a decree forbidding the exportation of any coin from France, Boniface gave way to save the papal dues, and the bulls issued by him in 1307 were a decided victory for the French king. Peace between the two potentates followed until 1311. After the arrest, by Philip's orders, of Bernard Saisset (q.v.), bishop of Pamiers, in that year, the quarrel flamed up again; other causes of difference existed, and in 1302 the pope issued the bull Unam sanctam, one of the most extravagant of all statements of papal claims. To ensure the support of his people the king had called an assembly of the three estates of his kingdom at Paris in April 1302; then in the following year Guillaume de Nogaret seized the person of the pope at Anagni, an event immortalized by Dante. Boniface escaped from his captors only to die (October 11), and the short pontificate of his sainly successor, Benedict XI., was occupied in a vain effort to restore harmony to the Church. The concave that met at Perugia on his death was divided between the partisans of the irremediable policy of Boniface VIII. and those of a policy of compromise with the new state theories represented by France. The election was ultimately determined by the diplomacy and the gold of Philip's agents, and the new pope, Clement V., was the weak-willed creature of the French king, to whom he owed the tiara. When in 1305 the pope installed himself at Avignon, the new relation of the papacy and the French monarchy was patent to the world. It was the beginning of the long " Babylonian captivity " of the popes. The most notable of its first-fruits was the hideous persecution of the Templars (q.v.), which began with the sudden arrest of the members of the order in France in 1307, and ended with the suppression of the order by Pope Clement at the council of Vienne in 1313.

It is now tolerably clear that Philip's motives in this sinister proceeding were lack of money, and probably the deliberate wish to destroy a body which, with its privileged position and international financial and military organization, constituted a possible menace to the state. He had already persecuted and plundered the Jews and the Lombard bankers, and repeated recourse to the debasing of the coinage had led to frequent small risings. But under his rule something was done towards systematizing the royal taxes, and, as in England, the financial needs of the king led to the association of the people in the work of government.

In 1304 Philip IV. attacked Edward I. of England, then busied with the Scottish War, and seized Guienne. Edward won over the counts of Bar and of Flanders, but they were defeated and he was obliged to make peace in 1297. Then the Flemish cities rose against the French royal officers, and utterly defeated the French army at Courtin in 1302. The reign closed with the French position unimproved in Flanders, except for the transfer to Philip by Count Robert of Lille, Douai and Béthune, and their dependencies. Philip died on the 29th of November 1314. His wife was Jeanne, queen of Navarre (d. 1304), through whom that country passed under the rule of Philip on his marriage in 1284; three of his sons, Louis X., Philip V. and Charles IV., succeeded in turn to the throne of France, and a daughter, Isabella, married Edward II. of England.

See the Chronique de Geoffrey of Paris, edited by M. Bouquet, in vol. xxiii. of the Recueil des historiens des Gaules et de la France. Of the works of Philip the Rhätin, see especially: Philippe le Bel (1861); G. Digard, Philippe le Bel et le Saint-Siège (1900); C. V. Langlois in E. Lavisse's Histoire de France, vol. iii. (1901); K. Wenck, Philippe de Schanft (Marburg, 1905); H. Finke, Papsttum und Untergang des Templerordens, 2 vols. (Münster i. W. 1907), esp. i. ch. ii.

PHILIP V. (c. 1294-1322), "the Tall," king of France, second son of Philip the Fair and Jeanne of Navarre, received the county of Poitiers as an appanage, and was anfrayed when a year old to Jeanne, daughter and heiress of Otto IV., count of Burgundy. The marriage took place in 1307 when he was thirteen years of age. When his elder brother, Louis X., died, on the 5th of July 1316, leaving his second wife, Clementine of Hungary, with child, Philip was appointed regent for eighteen years by the parlement of Paris, even in the event of a male heir being born. Clementine's son, born on the 15th of November, lived only four days, and Philip immediately proclaimed himself king, though several of the great barons declared that the rights of Jeanne, daughter of Louis X. by his first wife, Margaret of Burgundy, ought to be examined before anything else was done. The coronation at Reims, on the 9th of January 1317, took place with the gates of the city closed for fear of a surprise. The state-general of the 2nd of February 1317, consisting of the nobles, prelates, and the burgesses of Paris, approved the coronation of Philip, swore to obey him, and declared that women did not succeed to the Crown of France. The university of Paris approved this declaration, but its members did not take the oath. The Salic law was not involved, and it was later that the lawyers of the 14th century tried to connect this principle to an article of the Salic law, which accords inheritance in land (i.e. property) to males. In the Frankish law the article refers to private property, not to public law. The death of Philip's son Louis, in 1317, disarmed the opposition of Charles, count of La Marche, who now hoped to succeed to the Crown himself. Odo or Eudes IV., duke of Burgundy, was married to Jeanne, Philip's daughter, and received the county of Burgundy as her dowry. The barons all did homage except Edward II. of England, and Philip's position was secured. The war with Flanders, which had begun under Philip IV. the Fair, was brought to an end on the 2nd of June 1320. The revolt of the Pastoureaux who assembled at Paris in 1320 to go on a pilgrimage to the church of the seneschal of Carcassonne, whether they marched. One of the special objects of their hatred, the Jews, were also mutilated heavily by Philip, who extorted 150,000 livres from those of Paris alone. He died at Longchamp on the night of the 2nd of January 1322.

Philip was a lover of poetry, surrounded himself with Provengal poets and even wrote in Provengal himself, but he was also one of the most hard-working kings of the house of Capet. The

1 Finke, ii. no. 78, p. 122. Anon. to the commanderies of Gardeyne and Ascho. "Pus el es rey et papa et emperador! Car tot lo mon sap, quel papa no es engn et que el fa tot goques vol del papa et de la eglaz."
insecurity of his position made him seek the support of national assemblies and of provincial estates. His reign in some ways resembled that of Edward I. of England. He published a series of ordinances organizing the royal household and affecting the financial administration, the "parlement" and the royal forests. He abolished all garrisons in the towns except those on the frontier and provided for public order by allowing the inhabitants of his towns to arm themselves under the command of captains. He tried hard to procure a unification of coinage and weights and measures, but failed owing to the opposition of the estates, who were afraid of the new taxation necessary to meet the loss involved in raising the standard of the coinage, and who held to their local measures and currency partly from conservatism, partly as a relic of local liberty. Philip as a reformer was in many ways before his time, but his people failed to understand him, and he died under the reproach of extortion.

See P. Lehugeur, Histoire de Philippe le Long (Paris, 1897); E. Lavisse, Histoire de France (Tome III, 2); and sources indicated in A. Molinier, Répertoire des sources de l'histoire de France (Paris, 1903).

PHILIP (1193-1250), king of France, was the son of Charles of Valois, third son of Philip III, the Bold, and of Margaret of Sicily, and was thus the nephew of Philip IV, the Fair, whose sons, Louis X., Philip V. and Charles IV., died successively without leaving male heirs. He succeeded to the throne on the death of his cousin, Charles IV., in 1328. Before his accession Philip had enjoyed considerable influence, for he was count of Valois, Anjou, Maine, Chartres and Alençon. He had married in 1313 Jeanne (d. 1348), daughter of Robert II. of Burgundy, a determined woman who was long known as the real ruler of France. An expedition to Italy in 1319-20 against Galéas Visconti brought him little glory; he was more successful in small expeditions, undertaken against a revolted vassal who was supported by the English.

When Charles IV. died, in February 1328, his wife was enceinte, and it became necessary to appoint a regency until the birth of the child, who would, if a son, succeed to the throne. At the assembly of barons called to choose a regent, Edward III. of England, the nephew and nearest male relation of Charles IV., put in a claim. Edward III., however, descended from the royal house of France by his mother Isabel, and the barons, probably actuated by an objection to the regency of an English king, decided that neither a woman, "nor by consequence her son, could succeed to the kingdom of France," and Philip of Valois, in spite of his belonging to a junior branch of the family, was elected regent. On the birth of a girl to the queen widow the regency naturally led to the throne of France, and Philip was crowned at Reims on the 20th of May 1328. Navarre had not accepted the regency, that kingdom being claimed by her husband for Jeanne, countess of Evreux, the eldest daughter of Louis X., the count of Evreux himself being, like Philip of Valois, a grandson of Philip the Bold. The new king secured the friendship of the count by allowing Jeanne's claim to Navarre, in return for a renunciation of any right to Champagne. Edward III. of England, after more than one citation, tendered verbal homage for part of Guienne at Amiens in 1320, but he declined to place his hand on the shoulder of Philip formally to acknowledge him as his liege lord. Two years later, however, he forwarded the acknowledgment by letters patent. Meanwhile Philip VI. had won a victory, which he turned into a masterpiece, at Cassel (August 23, 1328) over Bruges and the other towns of West Flanders, which under the leadership of Jakob van Artevelde had thrown off the authority of their count, Louis of Nevers. The count of Flanders was reinstated, and maintained his authority by a reign of terror.

Much harm was done to Philip VI.'s authority by the scandal arising out of the prosecution of Robert of Artois, count of Beaumont, who was the king's brother-in-law. The count had presented to the parlement of Paris forged deeds in support of his claim to the county of Artois, held by his aunt, Mahaut, countess of Burgundy. The sudden death of Mahaut, and of her daughter and heiress, Jeanne, widow of Philip V., lent colour to other suspicions, and Robert was driven from France and his goods confiscated. He found refuge, first in Brabant and then at the English court, where he was received as a relative and a victim of false accusations.

Philip VI. enjoyed powerful alliances. In Italy he was allied with his uncle, Robert of Anjou, king of Sicily, and with his former enemy, Galéas Visconti; in the north with the duke of Brabant and the princes of the Netherlands; and on the east with the reigning princes of Lorraine and Savoy; with the king of Bohemia and with Pope John XXII. at Avignon, and his successor, Benedict XII. In 1336 it seemed that the Crusade, for which Philip VI. had long been preparing, would at last start; but the relations with Edward III. of England, which had always been strained, became worse, and within a year France was embarked on the struggle of the Hundred Years' War. The causes which led to war, the conflict for commercial supremacy in Flanders, disputed rights in Guienne, the help given by France to the Scots, and the unnatural situation of an English king who was also a vassal of the French Crown are dealt with elsewhere (see France: History). The immediate rupture in Flanders was due chiefly to the tyranny of the count of Flanders, Louis of Nevers, whom Philip VI. had reinstated. Edward III. had won over most of Philip's German and Flemish allies, and the English naval victory at Sluys (June 24, 1340), in which the French fleet was annihilated, effectually restored English preponderance in Flanders. A truce followed, but this was disturbed after a short duration by the disputed succession to the duchy of Brittany. Edward III. supported John of Montfort; Philip IV. his own nephew, Charles of Blois. A truce made at Malestroit in 1345 at the invitation of the pope, was rudely broken by Philip's violence. Olivier de Clisson, who with fourteen other Breton gentlemen, was suspected of intrigue with Edward III., was invited to a great tournament in Paris. On their arrival they were seized by Philip's orders, and without form of trial beheaded. Then followed Edward III.'s invasion of Normandy and the campaign of Crecy (q.v.). Philip's army was destroyed; he himself was wounded and fled from the field. He sought in vain to divert Edward from the siege of Calais by supporting the Scots in their invasion of England; but eventually a truce was arranged, which lasted until 1351.

Philip VI. died at Nogent-le-Roi on the 12th of August 1350.

Philip VI. met his necessities by the imposition of the hated gabelle or salt tax, which was invented by his legal advisers. The value of the coinage fluctuated continuously, to the great benefit of traders, and although at a meeting of the States-General it was asserted that the king could levy no extraordinary taxes without the consent of the estates, he obtained heavy subsidies from the various provinces. Towards the close of his reign he acquired from Humbert II., comte de Vienne, the province of Dauphiné, and Montpellier from the king of Majorca. These acquisitions made the ultimate annexion of Provence a certainty. Philip married a second wife, Blanche of Navarre. By his first wife he left two sons—his successor, John II., and Philip of Orleans, count of Valois.

PHILIP (6. 1177-1208), German king and duke of Swabia, the rival of the emperor Otto IV., was the fifth and youngest son of the emperor Frederick I. and Beatrice, daughter of Renaud II., count of Upper Burgundy, and consequently brother of the emperor VI. He entered the church, was made provost of Aix-la-Chapelle, and in 1190 or 1191 was chosen bishop of Würzburg. Having accompanied his brother Henry to Italy in 1191, Philip forsook his ecclesiastical calling, and, travelling again to Italy, was made duke of Tuscany in 1195 and received
an extensive grant of lands. In 1196 he became duke of Swabia, on the death of his brother Conrad; and in May 1197 he married Irene, daughter of the eastern emperor, Isaac Angelus, and widow of Roger II., king of Sicily, a lady who is described by Walther von der Vogelweide as "the rose without a thorn, the dove without guile." Philip enjoyed his brother's confidence to a very great extent, and appears to have been designated as guardian of the young Frederick, afterwards the emperor Frederick II., in case of his father's early death. In 1197 he had set out to fetch Frederick from Sicily for his coronation when he heard of the emperor's death and returned at once to Germany. He appears to have desired to protect the interests of his nephew and to quell the disorder which arose on Henry's death, but events were too strong for him. The hostility to the kingship of a child was growing, and after Philip had been chosen as defender of the empire during Frederick's minority he consented to his own election. He was elected German king at Mühlhausen on the 8th of March 1198, and crowned at Mainz on the 8th of September following. Meanwhile a number of princes hostile to Philip, under the leadership of Adolph, archbishop of Cologne, had elected an anti-king in the person of Otto, second son of Henry the Lion, duke of Saxony. In the war that followed, Philip, who drew his principal support from south Germany, met with considerable success. In 1199 he received further accessions to his party and carried the war into his opponent's territory, although unable to obtain the support of Pope Innocent III., and only feebly assisted by his ally Philip Augustus, king of France. The following year was less favourable to his arms; and in March 1201 Innocent took the decisive step of placing Philip and his associates under the ban, and began to work energetically in favour of Otto. The two succeeding years were still more unfavourable to Philip. Otto, aided by Ottakar I., king of Bohemia, and Hermann I., landgrave of Thuringia, drove him from north Germany, thus compelling him to seek by abject concessions, but without success, reconciliation with Innocent. The submission to Philip of Hermann of Thuringia in 1204 marks the turning-point of his fortunes, and he was soon joined by Adolph of Cologne and Henry I., duke of Brabant. On the 6th of January 1205 he was crowned again with great ceremony by Adolph at Aix-la-Chapelle, though it was not till 1207 that his entry into Cologne practically brought the war to a close. A month or two later Philip was loosed from the papal ban, and in March 1208 it seems probable that a treaty was concluded by which a nephew of the pope was to marry one of Philip's daughters and to receive the disputed dukedom of Tuscany. Philip was preparing to crush the last flicker of the rebellion in Brunswick when he was murdered at Bamberg, on the 21st of June 1208, by Otto of Wittelsbach, count palatine in Bavaria, to whom he had refused the hand of one of his daughters. He left no sons, but four daughters; one of whom, Beatrix, afterwards married his rival, the emperor Otto IV. Philip was a brave and handsome man, and contemporary writers, among whom was Walther von der Vogelweide, praise his mildness and generosity.

See W. von Giesebrecht, Geschichte der deutschen Kaiserzeit, Bd. V. (Leipzig, 1888); E. Winkelmann, Philipp von Schwaben und Otto IV. von Braunschweig (Leipzig, 1873-1878); O. Abel, König Philipp der Hohenstaufen (Berlin, 1852); Regesta imperii, ed. by J. Schwalbach (Berlin, 1855); Giesebrecht, Historischer Überblick über das Herzogtum Braunschweig, und die deutsche Kirche während des Thronstreits von 1196-1208 (Strassburg, 1882); and R. Riant, Innocent III., Philippe de Souabe, et Boniface de Montferrat (Paris, 1873).

PHILIP I., the Handsome (1478-1506), king of Spain, son of the emperor Maximilian I., and husband of Joanna the Mad, daughter of Ferdinand and Isabella, was the founder of the Habsburg line in Spain, and was born in Graz on the 22nd of July 1478. In 1482 he succeeded to the Burgundian possessions of his mother Mary, daughter of Charles the Bold, under the guardianship of his father. In 1496 he married Joanna. The marriage was one of a set of family alliances with Austria and Portugal designed to strengthen Spain against France. The death of John, the only son of Ferdinand and Isabella, opened the succession to the Spanish Crown to Joanna. In 1502 she and her husband received the homage of the cortes of Castile and of Aragon as heirs. Philip returned to Flanders before the close of the year. His life with Joanna was rendered extremely unhappy by his infidelity and by her jealousy, which, working on a nervous temperament predisposed to her insanity. The princess gave way to paroxysms of rage, in which she was guilty of acts of atrocious violence. Before her mother's death, in 1504, she was unquestionably quite insane, and husband and wife lived apart. When Isabella died, Ferdinand endeavoured to lay hands on the regency of Castile, but the nobles, who disliked and feared him, forced him to withdraw. Philip was summoned to Spain, where he was recognized as king. He landed, with his wife, at Corunna on the 28th of April 1506, accompanied by a body of German mercenaries. Father and son-in-law had interviews at Renedo, and at Reno, the only result of which was an ineffectual family quarrel, in which Ferdinand professed to defend the interests of his daughter, who he said was imprisoned by her husband. A civil war would probably have broken out between them; but Philip, who had only been in Spain long enough to prove his incapacity, died suddenly at Burgos, apparently of typhoid fever, on the 25th of September 1506. His wife refused for long to allow his body to be buried or to part from it. Philip was the father of the emperors Charles V. and Ferdinand I.

PHILIP II. (1527-1558) king of Spain, was born at Valladolid on the 21st of May 1527. He was the son of the emperor Charles V., and of his wife Isabella of Portugal, who were first cousins. Philip received his education in Spain. His tutor, Dr Juan Martinez Pedernales, who initiated his name to Spanish and who was also his confessor, does not appear to have done his duty very thoroughly. The prince, though he had a good command of Latin, never equalled his father as a linguist. Don Juan de Zuñiga, who was appointed to teach him the use of arms, was more conscientious; but he had a very poor pupil. From his earliest years Philip showed himself more addicted to the desk than the saddle and to the pen than to the sword. The emperor, who spent his life moving from one part of his wide dominions to another and in the camps of his armies, watched his heir's education from afar. The trend of his letters was to impress on the boy a profound sense of the high destinies to which he was born, the necessity for keeping his nobles apart from all share in the conduct of the internal government of his kingdom, and the wisdom of distrustful counsellors, who would be sure to wish to influence him for their own ends. Philip grew up grave, self-possessed and distrustful. He was beloved by his Spanish subjects, but utterly without the power of attracting men of other races. Though accused of extreme licentiousness in his relations with women, and though he lived for years in adultery with Doña María de Osorio, Philip was probably less immoral than most kings of his time, including his father, and was rigidly abstemious in eating and drinking. His power of work was unbounded, and he had an absolute love of reading, annotating and drafting despatches. If he had not become sovereign of the Low Countries, as heir of Mary of Burgundy through his father, Philip would in all probability have devoted himself to warfare with the Turks in the Mediterranean, and to the conquest of northern Africa. Unhappily for Spain, Charles, after some hesitation, decided to transmit the Netherlands to his son, and not to allow them to go with the empire. Philip was summoned in 1548 to Flanders, where he went unwillingly, and was ill regarded. In 1551 he was back in Spain, and intrenched with its government. In 1543 he had been married to his cousin Mary of Portugal, who bore him a son, the unhappy Don Carlos, and who died in 1554. In 1551, when Charles was working on his successor's dynastic legitimacy, the position of his son was so alarming that Philip was summoned to Flanders again, and arranged the marriage with Mary, queen of England, who was the daughter of his sister Catherine, in order to form a union of Spain, the Netherlands and England, before which France would be powerless. The marriage proved barren. The abdication of his father on the 16th of January 1556 constituted Philip sovereign of Spain with its American possessions, of the Aragonese inheritance
in Italy, Naples and Sicily, of the Burgundian inheritance—the Netherlands and Franche Comté, and of the duchy of Milan, which his father separated from the empire for his benefit. It was a legacy of immense responsibilities and perils, for France was bound in common prudence to evade to ruin a power which encircled her on every side save the sea and threatened her independence. France was for a time beaten at the battles of St Quentin and Gravelines, and forced to make the Peace of Cateau Cambresis (April 2, 1559). But the death of Mary of England on the 17th of November 1558 had deprived Philip of English support. The establishment of Elizabeth on the English throne put on the flank of his scattered dominions another power, forced no less than France by unavoidable political necessities to be his enemy. The early difficulties of Elizabeth’s reign secured him a deceitful peace on that side for a time. His marriage with Elizabeth of Valois on the 22nd of June 1559, and the approach of the wars of religion, gave him a temporary security from France. But the religious agitation was affecting his own Flemish possessions, and when Philip went back to Spain, in August 1559, he was committed to a life-long struggle in which he could not prove victorious except by the conquest of France and England.

If Philip II. had deserved his name of the Prudent he would have made haste, so soon as his father, who continued to intervene in the government from his retreat at Yuste in Estremadura, was dead, to relieve himself of the ruinous inheritance of the Low Countries. It was perhaps impossible for him to renounce his rights, and his education, co-operating with his natural disposition, made it morally impossible for him to believe that he could be in the wrong. Like the rest of his generation, he was convinced that unity of religion was indispensable to the maintenance of the authority of the State and of good order. Family pride, also, was carried by him to its highest possible pitch. Thus external and internal influences alike drove him into conflict with the Netherlands, France and England; with the first because political and religious discontent combined to bring about revolt, which he felt bound in duty to crush; with the second and third because they helped the Flemings and the Hollanders. The conflict assumed the character of a struggle between Protestantism and Roman Catholicism, in which Philip appeared as the champion of the Church. It was a part he rejoiced to play. He became, and could not but become, a persecutor in and out of Spain; and his persecutions not only hardened the obstinacy of the Dutch, and helped to exasperate the English, but they provoked a revolt of the Moriscos, which impoverished his kingdom. No experience of the failure of his policy could shake his belief in its essential excellence. That whatever else he did for God, that his every failure depended on the inscrutable will of the Almighty and not on himself, was his guiding convictions, which he transmitted to his successors. The “service of God and his majesty” was the formula which expressed the belief of the sovereign and his subjects. Philip must therefore be held primarily responsible for the insane policy which brought Spain to ruin. He had a high ideal of his duty as a king to his own people, and had no natural preference for violent courses. The strong measures he took against disorderly elements in Aragon in 1591 were provoked by extreme misconduct on the part of a faction. When he enforced his claim to the crown of Portugal (1579-1581) he preferred to placate his new subjects by paying attention to their feelings and their privileges. He even made dangerous political concessions to secure the support of the gentry. It is true that he was ready to make use of assassination for political purposes; but he had been taught by his lawyers that he was “the prince,” the embodied state, and as such had a right to act for the public good, legibus solutus. This was but in accordance with the temper of the times. Coligny, Lord Burghley and William the Silent also entered into murder plots. In his private life he was orderly and affectionate to his family and servants. He was slow to withdraw the confidence he had once given. In the painful episode of the imprisonment and death of his firstborn son, Don Carlos, Philip behaved honourably. He bore the acute agony of the disease which killed him with manly patience, and he died piously at the Escorial on the 13th of September 1598.

As an administrator Philip had all the vices of his type, that of the laborious, self-righteous man, who thinks he can supervise everything, is capable of endless toil, and jealous of his authority, and who therefore will let none of his servants act without his instructions. He set the example of the unending discussions in committee and boundless minute writing which finally choked the Spanish administration.

The Histoire de Philippe II. of M. H. Forneron (Paris, 1881), contains many references to authorities and is exhaustive, but the author has some violent prejudices. Philip II., by Martin Hume (London, 1897), is more just in its treatment of Philip’s personal character, and gives a useful bibliography. The main sources for the history of his reign are his embassies and a large correspondence (ed. by R. Falck, vol. i., ii., iii., viii., xv., xxv., xl., xxvi., cl., cxx., cxi., cxii., cxiii., and others; L. P. Gachard, Actes des états généraux des Pays Bas, 1576-1830, Bruxelles, 1861-1866) and the Calendars of State Papers, Foreign Series, Elizabeth (London, 1869-1901). See also Martin Hume, Two English Queens and Philip (1898).

PHILIP III. (1578-1621), king of Spain, son of Philip II. and his fourth wife, Anne, daughter of the emperor Maximilian II., was born at Madrid on the 14th of April 1578. He inherited the beliefs of his father, but no share of his industry. The old king had by his compromise with the religion of the Netherlands, which had been capable of governing his vast dominions, and had foreseen that Philip III. would be led by his servants. This calculation was exactly fulfilled. The new king put the direction of his government entirely into the hands of his favourite, the duke of Lerma, and when he fell under the influence of Lerma’s son, the duke of Uceda, in 1581, he trusted himself and his states to the new favourite. The king’s own life was passed amid court festivities, on which enormous sums of money were wasted, or in the practice of childish piety. It was said that he was so virtuous as hardly to have committed a venial sin. He cannot be justly blamed for not having been born to rule a despotic monarchy, without even the capacity which would have qualified him to manage a small estate. He died at Madrid on the 31st of March 1621. The story told in the memoirs of the French ambassador Bassompierre, that he was killed by the heat of a brasero (a pan of hot charcoal), because the proper official to take it away was not at hand, is a humorous exaggeration of the formal etiquette of the court.

R. Watson and W. Thompson, History of Philip III. (1786), give the most available general account of his reign; see also the continuation of Mariana’s History of Spain by Miliana (Madrid, 1823).
king’s life. When, in 1643, the disasters falling on the monarchy on all sides led to the dismissal of Olivares, Philip had lost the power to devote himself to hard work. After a brief struggle with the task of directing the administration of the most extensive and the worst organized monarchy in Europe, he sank back into his pleasures and was governed by other favourites. His political opinions were those he had inherited from his father and grandfather. He thought it his duty to support the German Habsburgs and the cause of the Roman Catholic Church against the Protestants, to assert his sovereignty over Holland, and to extend the dominions of his house. The utter exhaustion of his people in the course of a hopeless struggle with Holland, France, and England was seen by him with sympathy, but he considered it an unavoidable misfortune and not the result of his own errors, since he could not be expected to renounce his rights or to desert the cause of God and the Church. In public he maintained a bearing of rigid solemnity, and was seen to laugh only three times in the course of his life. But in private he indulged in horseplay and very coarse immorality. His court was grossly vicious. The early death of his eldest son, Baltasar Carlos, was unquestionably due to debauchery encouraged by the gentlemen entrusted by the king with his education. The lesson shocked the king, but its effect soon wore off. Philip IV. died broken-hearted on the 17th of September 1665, expressing the hope that his surviving son, Carlos, would be more fortunate than himself.

The best accounts of Philip IV. will be found in the Estudios del reinado de Felipe IV., by Don A. Canovas del Castillo (Madrid, 1889), and in the introduction, by Don F. Silvela, to his edition of the Cartas de Sor Maria de Agreda y del rey Felipe IV. (Madrid, 1885-1896).

PHILIP V. (1663-1746), king of Spain, founder of the present Bourbon dynasty, was the son of the Dauphin Louis and his wife, Maria Anna, daughter of Ferdinand Maria, elector of Bavaria. He was born at Versailles on the 10th of December 1683. On the extinction of the male line of the house of Habsburg in Spain he was named heir by the will of Charles II. He had shared in the careful education given to his elder brother, Louis, duke of Burgundy, by Fénélon, and was himself known as duke of Anjou. Philip was by nature dull and phlegmatic. He had learnt morality from Fénélon’s teaching, and showed himself throughout his life strongly adverse to the moral laxity of the great court and most of the princes of his time. But his very domestic regularity caused him to be entirely under the influence of his two wives, Maria Louisa of Savoy, whom he married in 1702, and who died in February 1714, and Elizabeth Farnese of Parma, whom he married in December of the same year, and who survived him. He showed courage on the field of battle, both in Italy and Spain, during the War of the Spanish Succession, and was flattered by his courtiers with the title of El Animoso, or the spirited. But he had no taste for military adventure. If he had a strong passion, it was to provide for his succession to the throne of France, if his nephew, Louis XV., should die, and he indulged in many intrigues against the house of Orleans, whose right to the succession was supposed to be secured by Philip’s solemn renunciation of all claim to the French throne, when he became king of Spain. It was in pursuit of one of these intrigues that he abdicated in 1724 in favour of his son Louis. But Louis died in a few months, and Philip returned to the throne. At a later period he tried to abdicate again, and his wife had to keep him in a species of disguised confinement. Throughout his life, but particularly in the later part of it, he was subject to prolonged fits of melancholia, during which he would not even speak. He died of apoplexy on the 9th of July 1746.

The best account of Philip’s character and reign is still that given by Coke in his Memoirs of the Kings of Spain of the House of Bourbon (London, 1815).

PHILIP THE BOLD (1342-1404), duke of Burgundy, fourth son of John II. of France and Bonne of Luxemburg, was born on the 15th of January 1342. He earned his surname by his bravery while fighting by his father’s side on the field of Poitiers. After the defeat of King John he accompanied him into captivity in England. In 1360 he received the title of duke of Touraine, and in June 1363 was entrusted with the government of Burgundy, which John had united to the crown at the death of the last duke of the Capetian family, Philip of Rouvre, in 1361. In September 1363 John bestowed on Philip the title of Duke of Burgundy, together with that of first peer of France. John was anxious not to displease the Burgundians, who were accustomed to their independence; and, moreover, with Philip as duke of Burgundy he was in a better posture to resist the king of Navarre, Charles the Bad, who laid claim to the duchy. The donation, which was at first kept secret in spite of a request made in 1363 for its confirmation by the emperor Charles IV., was ratified at the accession of Charles V. of France; but in consequence of Philip’s preoccupation with the Grand Companies, which had invaded France, it was not until November 1364 that he definitely took possession of the duchy. Charles continued to show favour to his brother, appointing him (in 1366) his lieutenant in Champagne and marrying him to Margaret, daughter and heiress of Louis of Mâle, count of Flanders, and widow of Philip of Rouvre. Edward III. of England was negotiating for the marriage of this princess with his son Edmund, earl of Cambridge; but Charles prevailed upon Pope Urban V. to refuse the dispensation necessary on grounds of kinship, and even consented to give up Lille, Douai and Orchies to Flanders on condition that Margaret should marry his brother. Philip eventually won the day, thanks to the support of the late count’s mother, and the marriage took place with high revel at Ghent on the 19th of June 1366.

During the succeeding years Philip proved a faithful ally to Charles. He took part in the almost bloodless campaign against the duke of Lancaster, who had landed at Calais; in 1377 he took several towns in French Flanders from the English; and in 1379 relieved Troyes, which had been besieged by the English. On Charles’s death Philip found himself, with his brothers, the dukes of Anjou and Berry, in charge of the government of France in the name of Charles VI., who was a minor; and in the absence of the duke of Anjou, who left France in 1382 to conquer the kingdom of Naples, Philip occupied the most powerful position in the realm. He persuaded the young king to intervene in Flanders, where the citizens of Ghent, whose rebellious spirit had necessitated Philip’s intervention in 1379, had again revolted under Philip van Artevelde and had expelled Louis of Mâle. On the 27th of November 1382 the Franco-Burgundian chivalry crushed the rebels at Roosebecke, and on his return the duke of Burgundy took part in repressing the popular movements which had broken out in Paris and other French towns. In 1383 an insurrection in Flanders supported by England gave rise to another French expedition; but in January 1384 the death of Louis of Mâle made Philip master of the countships of Flanders, Artois, Rethel and Nevers; and in the following year the citizens of Ghent decided to submit. At this period Philip sought to ingratiate himself with the emperor, who was a near neighbour, and of whom he held a part of his dominions, by giving two of his daughters in marriage to two princes of the house of Bavaria; he also took an important part in bringing about the marriage of a princess of the same family, Isabel, to King Charles VI.
Hostilities, however, were renewed between France and England. A formidable expedition was prepared under the direction of the duke of Burgundy, and a fleet of 1400 sail assembled at Sluys; but the enterprise failed owing to the dilatoriness of the duke of Berry. The fatiguing and inglorious expedition in the Netherlands, into which the duke dragged Charles for the purpose of supporting his kinswoman, Joan of Brabant, against his rival, the duke of Burgundy, came back with Philip’s credit with his nephew, who on his return declared himself and confided the government to the ancient councillors of his father, the “Marmousets.” The king’s madness (1392) restored his uncle’s power, and particularly Philip, who after assuring peace by treating with the duke of Brittany and by concluding a truce of twenty-eight years with England, made strenuous efforts to put an end to the Great Schism, visiting Pope Benedict XIII.
at Avignon in 1305 in the hope of obtaining a voluntary resignation from him. But the growing influence of the king’s younger sons, Louis, Philip, and Charles, who were the terms of great intimacy with Queen Isabel and was accused of being her lover, was a serious obstruction. Discord broke out in the council, and but for the intervention of the dukes of Berry and Bourbon the two princes would have come to an open struggle. For a brief period Philip was dispossessed of authority, but he regained it in 1402 and kept it till his death, which took place on the 27th of April 1404. The cathedral of St Bénézet at Dijon contains his remains, and his tomb (formerly in the Chartreuse of Dijon) is now in the museum in the Hôtel-de-ville.

Although he had to curb the independent spirit of the seigneurs of Franche-Comté, and in spite of frequent collisions with his vassals in Flanders and with the Somme (who in 1386 extracted from him a promise to respect their privileges), Philip appears to have governed his territories with sagacity and a certain moderation, and he was particularly successful in employing the resources of France in the interests of Burgundy. He granted numerous privileges to the inhabitants of Dijon, and created in 1386 two chambres des comptes, one at Dijon and the other at Lille. He was, in the phrase of a contemporary, “kindly and amiable to high and low and those of middle rank, liberal as an Alexander, noble and pontifical, in court and state magnificent.” But his liberality and his love of display involved him in enormous expense, and he left so many debts that his widow was compelled to renounce her personal estate to avoid the responsibility of discharging them. By his wife Margaret (d. 1405) he had a numerous family: John the Fearless, who succeeded him; Charles and Louis, who both died in infancy; Anthony, count of Rethel, and Philip, count of Nevers, both killed at Agincourt; Margaret, who married William of Bavaria, count of Ostrevant; Catherine, wife of Leopold, duke of Austria; Mary, wife of Amadeus VIII. of Savoy; and Bonne, who was betrothed to John of Bourbon and died young.

(R. Fo.)

PHILIP THE GOOD (1396–1467), duke of Burgundy, son of John the Fearless, duke of Burgundy, and Margaret of Bavaria, was born at Dijon on the 13th of June 1396, and succeeded his father on the 16th of September 1419. The natural outcome of the assassination of John the Fearless (q.v.) was to drive his successor to the English side. In 1419 Philip signed with Henry V. of England the treaty of Arras, by which he recognized Henry as regent and future heir of the kingdom of France, and in 1420 gave his adherence to the treaty of Troyes. Early in December 1420 Philip entered Paris with the king of England, and subsequently took part in the defeat of the French at Mon-s-en-Vimeu. By a treaty concluded by Philip at Amiens in April 1423 with the dukes of Brittany and Bedford, John, duke of Bedford, married Philip’s sister Anne, and Arthur of Brittany, earl of Richmond, became the husband of Philip’s sister Margaret. A few years later discord arose among the allies. When the duke of Bedford besieged Orleans the inhabitants offered to surrender, but to the duke of Burgundy; whereupon Bedford retorted that “he did not beat the bushes for others to take the birds.” When this speech reached Philip’s ears he withdrew his troops in dudgeon, and concluded a truce with France (1429). Bedford, however, succeeded in conciliating him by promises and presents, and in 1430 Philip took part in the campaign against Complége.

But another conflict arose between the duke of Burgundy and the English. Jacqueline, countess of Hainaut, the divorced wife of the duke of Brabant and the heiress of Holland and Zealand, had married the duke of Gloucester, who attempted to take forcible possession of his wife’s territories. Philip, however, himself claimed Brabant as having been bequeathed to him by his cousin Philip, the late duke, with the result that the Burgundians repulsed the troops of the duke of Gloucester, and Jacqueline was forced to recognize the duke of Burgundy as her lieutenant and heir. Moreover, the duchess of Bedford had died in 1433. Charles VII., who in spite of the efforts of the cardinal of Ste-Croix and the conferences held by him at Auxerre and Semur had hitherto refused to return to France, finally decided to take part in the conferences which were opened at St Vaast d’Arras on the 6th of August 1435, and to which the whole of Christendom was invited. On the 20th of December 1435, all the princes of Europe and the pope and the council of Basel being represented. Philip consented to a reconciliation with the king of France, and agreed to recognize him as his legitimate sovereign on condition that he should not be required to pay him homage during his lifetime. Charles, on his part, solemnly craved pardon for the murder of John the Fearless through the mouth of the dean of the church in Paris, and handed over to the duke the counties of Mâcon, Auxerre, Bar-sur-Seine and Pontlieu, and the towns on and near the Somme (Roye, Montdidier, Péronne), reserving the option of recovering them at a future day. The latter agreed to prove a faithful ally of the king, aiding him in re-entering Paris and preparing an expedition against Calais, which, however, failed through the ill-will of his Flemish subjects (1436). In 1440 he paid the ransom of Charles of Orleans (the son of his father’s old enemy), who had been a prisoner in England since the battle of Agincourt; received him with great honour at Gravelines; and married him to Mary of Cleves, upon whom he bestowed a handsome dowry. In 1442 Philip entered into a conspiracy to give the duke of Orleans a larger share in the affairs of the kingdom. To René of Anjou, the duke of Loraine, he showed himself less generous, setting up another claimant to the duchy of Loraine in the person of Anthony of Vaudemont, and taking René prisoner in 1431; it was not until 1436 that he consented definitively to release René on condition that he should abandon several strong places and pay an enormous ransom. In 1445, at the conferences of Châlons-sur-Marne, the duchess of Burgundy renounced these claims in her husband’s name in order to assure the execution of the treaty of Arras.

Philip was frequently disturbed by the insubordination of the Flemish communes. He had to quell seditions at Liége (1430), Ghent (1432) and Antwerp (1435). In 1438 he was in conflict with the duchess out of Bruges by the revoluted citizens, a revolt which he repressed with great severity. In 1448 the citizens of Ghent rose in rebellion, but, disappointed of French support, they were defeated at Rupelmonde and in 1453 were overwhelmed at the battle of Gavre, where they left 20,000 dead on the field. At a banquet shortly afterwards Philip vowed that he would lead a crusade against the Turks, who had seized Constantinople, and the knights of his court swore to follow his example. The expedition, however, did not take place, and was but a pretext for levying subsidies and for knightly entertainments. In 1459 Philip sent an embassy under the duke of Cleves into Italy to take part in the conferences preparatory to a fresh expedition against the Turks, but this enterprise likewise fell to the ground. In 1456 the duke of Burgundy had given an asylum to the Dauphin Louis (afterwards Louis XI.), who had quarrelled with his father and had been forced to leave France. The “fox who would rob his host’s hen-roost,” as the old king called Louis, repaid his protector by attempting to sow discord in the ducal family of Burgundy, and then retired to the castle of Genappe in Brabant. At Charles VII.’s death, however, Philip was one of the first to recognize the new king, and accompanied him to Paris. During the journey Louis won over the seigneurs of Croy, the principal counsellors of the duke of Burgundy, and persuaded Philip to allow him to redeem the Somme towns for the sum stipulated in the treaty of Arras. This proceeding infuriated Philip’s son Charles, count of Charolais, who prevailed upon his father to break his pledge and declare war on the king of France. On the 12th of April 1465 Philip handed over to his son the entire administration of his

1 This was the singular vow known as “the vow of the pheasant,” from the fact that Philip placed his hand solemnly on a pheasant, which had been brought to him by his herald, and vowed that he would fight the Turks and challenge their sultan to single combat.
PHILIP (OF HESSE)

PHILIP, LANDGRAVE OF HESSE (1504-1567), son of the landgrave William II., was born at Marburg on the 13th of November 1504. He became landgrave on his father's death in 1509, and having been declared of age in 1518, was married in 1523 to Christina, daughter of George, duke of Saxony (d. 1539). In 1522 and 1523 he assisted to quell the rising of Franz von Sickingen (q.v.), who had raided Hesse five years previously, and in 1525 he took a leading part in crushing the rebellion of the peasants in north Germany, being mainly responsible for their defeat at Frankenhausen. About this time Philip adopted the reformed faith, of which he was afterwards the zealous and daring defender. Indifferent to theological, or even to patriotic, considerations, his plans to protect the reformers rested upon two main principles—unity among the Protestants at home and military aid from abroad. The schemes he put forward as one of the heads of the league of Schmalkalden, aimed primarily at overthrowing the house of Habsburg; to this end aid was sought from foreigner and native, from Protestant and Catholic alike. Envoy's were sent repeatedly to France, England and Denmark; Turkey and Venice were looked to for assistance; the jealousy felt towards the Habsburgs by the Bavarian Wittelsbachs was skillfully fostered. The German princes united to the extent that attack was the best, nay the only, means of defence. Before the formation of the league of Schmalkalden Philip was very intimate with Zwingli, and up to the time of the reformer's death, in 1531, he hoped that material aid would be forthcoming from his followers. In 1526 he had aided John the Constant, elector of Saxony, to form an alliance of reformatory princes; and in 1529 he called together the abortive conference at Marburg, hoping thus to close the breach between Lutherans and Zwinglians. More aggressive was his action in 1528. Deceived by the forgeries of Otto von Pack (q.v.), he believed in the existence of a conspiracy to crush the reformers, and was only restrained from attacking his enemies by the influence of John of Saxony and Luther. He succeeded, however, in compelling the archbishop of Mainz and the bishops of Würzburg and Bamberg to contribute to the cost of his mobilization. Philip was freely accused of having employed Pack to concoct the forgery; and, although this charge is doubtful false, his eager acceptance of Pack's unproved statements aroused considerable ill-feeling among the Catholics, which he was not slow to return. In 1530 the landgrave signed the "protest," which was presented to the diet at Spires, being thus one of the original "Protestants." In 1530 he was among the subscribers to the confession of Augsburg; and the formation of the league of Schmalkalden in the same year was largely due to his energy.

His next important undertaking, the restoration of Ulrich, duke of Württemberg (q.v.), to his duchy, was attended with conspicuous success. Württemberg had passed into the possession of the Habsburgs, but after Philip's brief and victorious campaign in 1534 the humiliation of Charles V. and his brother, the German king, Ferdinand I., was so complete that it was said the landgrave had done more for Protestantism by this enterprise than a thousand of Luther's books would do. After this victory Philip entertained the idea of coming to terms with Charles V. on the basis of extensive concessions to the Protestants; but he quickly returned to his former plans for leading a general attack on the Habsburgs. The Concord of Wittenberg, made in 1536, was favourable for these schemes, but after five years spent in anxious preparation war was prevented by the serious illness of the landgrave and the lukewarmness of his allies. Recovering from his malady, he had returned to his intrigues when an event happened which materially affected the fortunes of the Reformation. His union with Christina was not a happy one, and having fixed his affections upon Margaret von der Saal (d. 1560), he obtained an opinion from Protestant theologians that bigamy was not forbidden by Holy Writ. Luther and Melancthon at length consented to the marriage, but stipulated that it should be kept secret, and it was celebrated in March 1540. The marriage, however, became known, and a great outcry arose against Philip, whose friends quickly deserted him. He objected to Luther's counsel to deny the existence of a second marriage; abused John Frederick, elector of Saxony, for not coming to support him; and caused bigamy to be publicly defended. Alarmed, however, by the strength of his enemies, and by their evident determination to punish him as a bigamist, he in June 1541 made a treaty with Charles V. at Regensburg. In return for a general pardon he undertook to break off relations with France and England and loyally to support the emperor.

During these years Philip had been forwarding the progress of the Reformation in Hesse. This was begun about 1526, when an important synod was held at Homburg; the university of Marburg was founded in the interests of the reformers in 1527; and after the diet of Spires in 1529 the work was conducted with renewed vigour. The Catholic worship was suppressed, and the secularized church revenues supplied an endowment of the new university.

The peace between the emperor and the landgrave was soon broken. In 1542 Philip persuaded the league of Schmalkalden to attack Henry II., duke of Brunswick-Wolfenbüttel, ostensibly in the interests of the Protestant towns of Brunswick and Goslar. The duchy was quickly overrun, and Henry—a Catholic prince—crushed. But the good understanding between the emperor and the landgrave was destroyed, and the relations between Protestants and Catholics became worse than before. Nor was the fissure in the Protestant ranks closed, and Charles took advantage of this disunion to conquer Gelderland and to mature his preparations for overthrowing the league of Schmalkalden. Unlike John Frederick of Saxony, Philip divined, or partly divined, the emperor's intentions, and urged repeatedly that the forces of the league should be put in order. This advice passed unheeded, and when Charles suddenly showed his hand, and in July 1546 issued the imperial ban against the landgrave and the elector, it was seen that the two princes were almost isolated.企业的能量。
PHILIP, J.—PHILIP, K.

Charles V. at the hands of Maurice in 1525; and after the conclusion of the peace of Passau in this year he returned to Hesse. Although less active than formerly, the landgrave did not cease to intrigue on behalf of the Protestants while continuing the work of reforming and organizing the Church in Hesse. In 1562 he aided the Hugenots with troops, and he was frequently in communication with the Insurgents in the Netherlands; but his efforts to foster a union of the Protestants were fruitless. Philip, who had sometimes called the Magdeburger, died at Cassel, 31st of March 1567. By Christina he had four sons and five daughters, and according to his directions the landgrave was partitioned at his death between his sons. He had also by Margaret von der Saal seven sons, who were called Counts of Dietz, and one daughter.

PHILIP, JOHN (1775–1851). British missionary in South Africa, was born on the 14th of April 1775, at Kirkcaldy, Fife, the son of a schoolmaster in that town. After having been apprenticed to a linen draper, and for three years a clerk in a Dundee business house, he entered the Hoxton (Congregational) Theological College, and in 1804 was appointed to a Congregational chapel in Aberdeen. In 1818 he joined the Rev. John Campbell in his second journey to South Africa to inspect the stations of the London Missionary Society, and reported that the conduct of the Cape Colonists towards the natives was deserving of strong reprobation. In 1822 the London Missionary Society appointed him superintendent of their South African stations. He made his headquarters at Cape Town, where he also established and undertook the management of a school for the education of the Hottentots and Kaffirs (by a minority of the colonists), and he set himself to remedy their grievances; but his zeal was greater than his knowledge. He misjudged the character both of the colonists and of the natives, his cardinal mistake being in regarding the African as little removed from the European in intellect and capacity. It was the period of the agitation for the abolition of slavery in England, where Philip's charges against the colonists and the colonial government found powerful support. His influence was seen in the ordinance of 1828 granting all free coloured persons at the Cape every right to which any other British subjects were entitled. While Philip was in England, and in the last-named year he published Researches in South Africa, containing his views on the native question. His recommendations were adopted by the House of Commons, but his unpopularity in South Africa was great, and in 1830 he was convicted of libelling a Cape official. The British government, however, caused the Cape government to conform to the views of Philip, who for over twenty years exercised a powerful, and in many respects unfavourable, influence over the destinies of the country. One of Philip's ideals was the curbing of colonial "aggression" by the creation of a belt of native states around Cape Colony. In Sir Benjamin D'Urban, Philip found a governor anxious to promote the interests of the natives and Grossmütigen (Cassel, 1905). At the close of the Kaffir War of 1834–35 D'Urban annexed the country up to the Kei River, Philip's hostility was aroused. He came to England in 1836, in company with a Kaffir convert and a Hottentot convert, and aroused public opinion against the Cape government. His views triumphed, D'Urban was dismissed, and Philip returned to the Cape as unofficial adviser to the government on all matters affecting the natives. For a time his plan of buffer states was carried out, but in 1846 another Kaffir rising convinced him of the futility of his schemes. The Kaffir chief who had accompanied him to England joined the enemy; and many of his converts showed that his efforts on their behalf had effected no change in their character. This was a blow from which he did not recover. The annexation of the Orange River Sovereignty in 1848 followed, finally destroying his hope of maintaining independent native states. In 1849 he severed his connexion with politics and retired to the mission station at Hankey, Cape Colony, where he died on the 27th of August 1851.

PHILIP, KING (c. 1639–1670), chief sachem of the Wampanoag Indians in America, and the son of Massasoit (d. 1662), as the English, mistaking this title (great chief) for a proper name, called Woosamequin (Yellow Feather)—who for forty years was the friend and ally of the English colonists at Plymouth. To Massasoit's two sons, Wamsutta and Metacom, the English gave the names respectively of Alexander and Philip. Alexander succeeded his father as sachem, and in the same year, while in Marshfield, whither he had gone to explain certain alleged unfriendly acts towards the English, was taken ill; he died on his way home. Philip, who succeeded Alexander, suspected the English of poisoning his brother. The English had grown stronger and more numerous, and had begun to meddle in the internal affairs of the Indians. In 1667 one of Philip's Indians accused him to the English of attempting to betray them to the French or Dutch, but this charge was not proved. In 1671 the Plymouth authorities demanded that the Wampanoags should surrender their arms; Philip consented, but his followers failed to comply, and measures were taken to enforce the promise. Philip thereupon went before the general court, agreed to pay an annual tribute, and not to sell lands or engage in war with other Indians without the consent of the Plymouth government. In 1674, when three Wampanoags were executed at Plymouth for the alleged murder of Sassamon, an Indian convert who had played the part of informer to the English, Philip could no longer hold his followers in check. There were outbreaks in the middle of the year 1675, when many Wampanoags and whites began. There was no concerted movement of the various tribes and the war had not been previously planned. The Nipmuck Indians rose in July; the tribes along the Connecticut river in August; those in the present states of Maine and New Hampshire in September and October, and the Narragansets in December, when (on the 10th) they were attacked and seriously crippled, in what is now the township of South Kingstown, Rhode Island, by the English (under Governor Josiah Winslow of Plymouth), who suspected their loyalty.

The colony of Connecticut took quick measures of defence, guarded its front, maintained its alliance with the Mohicans, and suffered little injury. Massachusetts and Plymouth were slower in acting and suffered great loss. Rhode Island raised no troops, and suffered severely. Early in the autumn Philip went nearly as far west as Albany in an unsuccessful attempt to get aid from the French and the Mohawks and supplies from the Dutch traders. At Deerfield on the 18th of September about 60 English were killed and the settlement was abandoned. In the spring of 1676 it became evident that the Indian power was waning. The warriors had been unable to plant their crops; they were weaker numerically and more poorly armed than the English, and the latter had also made an alliance with the friendly Naticks and the Narragansets. On the 1st of August 1676 Philip's wife and nine-year-old son were captured, and on the 11th of August an Indian tradition was received that the sachem's hiding place was in a swamp at the foot of Mount Hope (in what is now the township of Bristol, Rhode Island), where early the next morning he was surprised, and while trying to escape was killed by an Indian. The head of Philip was sent to Plymouth and set
PHILIPPA OF HAINAUT—PHILIPPANS

on a pole in a public place, where it remained for a quarter of a century; his right hand was given to his slayer, who preserved it in rum and won many pennies by exhibiting it in the New England towns. The struggle was now over in some parts of England, but it continued along the north-eastern frontier till the spring of 1378, and nearly every settlement below the Piscataqua was destroyed. In the colonies of Plymouth, Massachusetts, Rhode Island and Connecticut six hundred men (or about 9% of the fighting population), besides many women and children, had been killed; thirteen settlements had been completely destroyed, and about forty others were partly burned. Plymouth had incurred a debt greater than the value of the personal property of her people. The Indians suffered even worse: in addition to the large number of men, women and children slain, great numbers, among them the wife and son of Philip, were sold into slavery in the Spanish Indies and the Bermudas. Many others migrated from New England to New York; and the few remaining Indians, feeble and dispirited, were no longer a power to be reckoned with. Philip was an Indian patriot and statesman, not a warrior; he united the tribes in their resistance to the colonists, but was not a great leader in battle.

See George M. Bodges, Soldiers in King Philip's War (Loo-
minster, Mass., 1896); John Gorham Palfrey, History of New
England, vol. iii. (Boston, 1864); and especially George W. Ellis
and C. Peirce Goodwin, The Story of King Philip's New York
War, also Entertaining Passages Relating to King Philip's War. (Boston,
1716; new edition, edited with notes by H. M. Dexter, Boston,
1865), the account by Colonel Benjamin Church (1639-1719),
the principal leaders of the English, of the warfare in south-eastern
New England, in which he took part; it is one of the most famous
and realistic accounts of early Indian warfare.

PHILIPPA OF HAINAUT (c. 1314-1360), queen of the English
king Edward III., was the daughter of William the Good, count
of Holland and Hainaut, and his wife Jeanne de Valois, grand-
daughter of Philip III. of France. Edward visited the court of
Count William in 1326 with his mother Isabella, who immediately
arranged a marriage between him and Philippa. After a dispen-
sation had been obtained for the marriage of the cousins (they
were both descendants of Philip III.) Philippa was married by
proxy at Valenciennes in October 1327, and landed in England
in December. She joined Edward at York, where she was
married on the 30th of January 1328. Her marriage dower had
been seized by the queen dowager Isabella to pay a body of
Hainauters, with whose help she had compassed her husband's
deposition. The alliance ensured for Edward in his French wars
the support of Philippa's influential kindred; and before starting
on his French campaign he secured troops from William the
Good, as well as from the count of Gelderland, the count of
Jutland, and the emperor Louis the Bavarian. Her mother
Jeanne de Valois, visited her in 1331 and further cemented the
community of interests between England and Flanders. Before
1335 Philippa had established a small colony of Flemish weavers
at Norwich, and she showed an active interest in the weaving
trade by repeated visits to the town. She also encouraged coal-
mining on her estates in Tynedale. Her eldest son, Edward the
Black Prince, was born in 1330, and she subsequently bore six
sons and five daughters. In November 1342 she became guardian
of John of Gaunt and her younger children, with their lands.
Her agents are said to have shown great harshness in collecting
the feudal dues with which to supply her large household.
The anecdotes of her piety and generosity which have been preserved
are proof, however, of her popularity. She interceded in 1331
with the king for some carpenters whose careless work on a
platform caused an accident to herself and her ladies, and on
a more famous occasion her prayers saved the citizens of Calais
from Edward's vengeance. There is a generally accepted story,
based on the chronicles of Jehan le Bel and Froissart, that she
summoned the English forces to meet the Scottish invasion of
1346, and harangued the troops before the battle of Neville's
Cross. She certainly exercised considerable influence over her
husband, whom she constantly accompanied on his campaigns;
and her death on the 15th of August 1369 was a misfortune for
the kingdom at large, since Edward from that time came under
the domination of the rapacious Alice Perrers. Philippa was the
patron and friend of Froissart, who was her secretary from 1361
to 1377. Queen Catherine of Lancaster, was made, as is stated in
Skerton's version of her epitaph, founded by her, but by her
chaplain, Robert of Eglesfield. Her chief benefactions
were made to the hospital of St Katharine's by the Tower, London.

See Agnes Strickland, Lives of the Queens of England, vol. i.
In addition to the account given in his Chroniques, Froissart wrote
a formal eulogy of her, which has been lost.

PHILIPPEVILLE, a seaport of Algeria, chief town of an
arrondissement in the department of Constantine, and 54 m. N. by E. of that city, on the Bay of Stora, in 36° 53' N. 6° 54' E.
It is connected by railway with Constantine, Batna and Biskra.
The town derives its importance from being the port of
Constantine. The harbour works, with every vessel in port, having
been destroyed by a storm in 1878, a more commodious harbour
was built, at a cost of about £1,200,000. From Cape Skikda, on
the east a mole or breakwater projects 4,092 ft. to the W.N.W.,
while from Château Vert on the west another mole runs out
1,312 ft. to the north, leaving an entrance to the port about 650 ft.
wide. The protected area comprises an outer and an inner
basin. The depth of water at the entrance is about 33 ft., along-
side the quays about 20 ft. The quays are faced with blocks
of white marble brought from the quarries at Filila, 16 m. distant.
Pop. (1906), of the town 16,539, of the commune 26,050, of
the arrondissement, which includes 12 communes, 147,607.
Phildipeville occupies the site of successive Phoenician and
Roman cities. By the Romans, under whom it attained a high
state of prosperity, it was named Ruscica. In the middle ages
the town ceased to be inhabited. The site was purchased from
the Arabs by Marshal Valére in 1838 for £6. Some parts of
the Roman theatre remain, but the stones of the amphitheatre,
which stood without the walls of the modern town, and which
the French found in an almost perfect state of preservation,
were used by them for building purposes, and the railway was
cut through the site. On a hill above the town are the Roman
reservoirs, which have been restored and still supply the town
with water. They are fed by a canal from the Wadi Beni Melekh.
The Roman baths, in the centre of the modern town, serve as
cellars for military stores.

PHILIPPI (Turk. Filibeğî), a city of ancient Macedonia, on
a steep hill near the river Gangites (mod. Angiûsa), overlooking
an extensive plain and at no great distance from the coast of the
Aegean, on the highway between Neapolis (Kavalla) and Thessa-
lonica. Originally called Crenides (Fountains), it took its
later name from Philip II. of Macedon, who made himself master
of the neighbouring gold mines of the Hill of Dionysus, and
fortified the city as one of his frontier-towns. In 42 B.C., after
the victory gained over the senatorial party by Octavius and
Antony, it became a Roman colony, Colonia Julia Philippensis,
which was probably increased after the battle of Actium (Col.
Ang. Julia Phil.). The inhabitants received the Jus Italicum,
and Philippa was one of the specially designated "first cities"
(Acts xvi. 12; see Marquardt, Röm. Staatsverwaltung, i. 187).
The city was twice visited by St Paul, whose Epistle to the
Philippians was addressed to his converts here. The site,
now uninhabited, is marked by ruins—the substructions of an
amphitheatre, parts of a great temple—which have furnished
interesting inscriptions. A little to the east is the huge stone
monument of C. Vilius, known to the Turks as Dikeltashlar and
to the Greeks as the Manger of Bucphalus.

and other authorities in bibliography of MACEDONIA; Corp. Inter.
Lat. iii. i. (J. D. B.)

PHILIPPINS, EPISTLE TO THE, a book of the New Testa-
ment. Communications had already passed between the Chris-
tians of Philip and Paul, not only when he was at Thessalonica
(iv. 15-16), but at some subsequent period (iv. 18), when Epaph-
roditus had brought him a present of money from them. It is
possible that this gift was accompanied by a letter. At any rate
the extant epistle is the answer to one received from the Philippine
Christians, who had evidently desired information about the
Paul's health and prospects (i. 12), assured him of their prayers (i. 10), and wondered whether he, their pride and glory (καθώς ταύτα), would return to them (i. 25 seq.).

After a brief greeting (i. 1, 2), Paul assures them of his loving interest in their present attainments and future progress in the faith of the gospel (i. 3—11); then, relieving their anxiety about his own prospects, he expresses the confident hope that he will be released and thus be able to return to them (i. 12—26). Meantime they were to avoid any pride or factiousness which might break their unity as a church (i. 17—ii. 18), and they are promised a visit from two of Paul's catechumens, who are well known to them (ii. 19—30). At this point the letter suddenly swerves into a passionate warning against some errors of Judaism (iii. 1—iv. 1), after which the appeal of the Apostle is reiterated (iv. 2—9), and the epistle closes with some personal details (iv. 10—23).

Paul is a prisoner when he writes, and the place of composition may therefore be Caesarea or Rome (Acts xxviii. 16, 30—31). The evidence upon the whole seems to point to the latter. The phrase οἶκος Καίσαρος (iv. 22) suits Rome better than Caesarea, and, while παράδοχοι (i. 13) does not necessarily imply the capital, it is most naturally understood of Rome. But the whole tone of the epistle suggests that Paul expected a speedy end to his case. Now at Caesarea this was out of the question. His appeal to Caesar involved a protracted process, and it is very unlikely that the Philippian epistles, as e.g. of ii. 23, were written under such a situation. The critical outlook of Philippians does not correspond with the position of the apostle at Caesarea, nor can the latter town be said to have been a centre of vigorous Christian propaganda (i. 17). Finally, the contention that no visit of Timothy to Rome is known is an argument from silence which is of little more weight than the plea of Spitta that the caputiy of Felix (Acts xxiv. 26) was excited by the arrival of the money from Philippi (Phil. iv. 16).

A further examination of the epistle shows that it must have been written towards the close of the διήκον of Acts xxviii. 30, not in the earlier part of the Roman captivity. Paul is on the point of passing into the Roman residence, and his present position lies a period during which considerable progress has been made in the local preaching and extension of the gospel, nor does the language of the apostle suggest that this fresh departure in the propaganda was stimulated by the mere novelty of his arrival. Furthermore, the relations between the Philippians and himself presuppose, on any fair estimate, an interval of time which cannot be crushed into a few months. News of his arrival must have reached them; money was collected (ii. 25, iv. 18) and then forwarded by Epaphroditus, who fell sick after he reached the capital; news of this again floated back to Philippi, and subsequently Paul heard of the Philippians' concern (ii. 26). Not till then was the letter written.

Philippians is thus the last extant letter we possess from Paul, unless some of the notes embedded in the pastoral epistles are to be dated subsequent to its composition. It unites the close of his career in Rome with the beginning of his mission work in Europe (iv. 15; cf. Acts xvi. 12), and illustrates not merely the situation of the apostle at Rome, but the terms of exceptional affection which existed from first to last between him and the church.

For the strong Christian consciousness of solidarity, presupposed in the Philippians, see Von Dobschütz's Christian Life in the Primitive Church, pp. 40—45. The appeal of Paul in this epistle is not, however, to the whole church, but to a number of individuals, and this is shown by the reference to the particular Epaphroditus, who was the object of special concern in the Philippians, and who was the first to reach Rome with the money for the church (iv. 18). The prayer of heart and desire is that Epaphroditus may be restored to them (iv. 10). But the appeal of the epistle is very much broader than this. It is aimed at the whole church, as is shown by the exhortation, "if you have heard the ripple of the waves at the meeting of the two streams which have their source in Zion and the Parthenon." (Drummond).

The epistle is addressed to "the household of faith" (Phil. i. 2). The expression meant (a) of the praefecti praetorio or officials charged with the care of prisoners under trial, i.e. the supreme imperial court, or (b) the praeatorian guard, or (c) their barracks, this would almost follow. But conceivably it might mean the palace, i.e. of Herod (Acts xxiii. 35). The balance of probabilities falls, however, in favour of the court hypothesis. Macedonian churches. The main argument for putting it earlier is derived from the admitted affinities between it and Romans, the Colossian and Ephesian epistles containing, it is held, a more advanced christology (so Lightfoot especially, and Hort, Judaistic Christianity, pp. 115—119). But such considerations are not decisive. Paul wrote from time to time, not in the execution of a literary plan, but as different objects or interests called out his powers. The Philippians did not require, and therefore did not receive, the same elaborate warnings as the Asiatic churches. Hence on the one hand it is unreal to lay stress on coincidences with Rom. as if these necessarily implied that both epistles must have been composed shortly after one another, while on the other the further stage of thought on Christ and the Church, which is evident in Colossians, does not prove that the latter must have followed the former. Upon the whole, the internal evidence of the epistle strongly favours its position as the last of the captivity epistles.

The attempts made during the 19th century to disprove the Pauline authorship now possess merely an historic interest, nor have the various hypotheses of more or less extensive interpolation won any serious support. More significance attaches to the view that the epistle is made up of two separate notes, or, more probably, of different sections of the fusion of the two is found in the abrupt hiatus of iii. 1, and evidence is led from supposed inconsistencies between the earlier and the latter parts of the epistle. But the flexibility of a letter-writer, under different moods of feeling, which would naturally lead to rapid transitions, may be adduced as some explanation of the latter phenomena. The exegesis does not absolutely necessitate a partition of the epistle, which (so Heinrichs and Paulus) would make iii.—iv. 20 a special letter addressed to some inner circle of the apostle's friends (in spite of iv. 16 seq.), or take iii.—iv. (Hausrath, History of N. T. Times, iv. 162 seq. and Bacon, Story of St Paul, pp. 398 seq.) as earlier than i.—ii. Besides, as Pfeiffer points out, "the whole section of iv. 1—18 is a parenthesis which is shipwrecked on the difficulty of the literal meaning of the words.

"each of the epistles had but one essential part: the first, in particular, lacking an expression of thanks for the gift from the Philippians, which must nevertheless, according to ii. 25, have already taken place." In his letter to the Philippians (iii. 2) Polycarp indeed observes that Paul wrote ἐπιστολάς to them; but, even if the plural could not be taken as equivalent to a single dispatch, it would not necessarily support the partition theory of the canonical Philippians. Polycarp may have known of more than one Pauline note to Philippi, no longer extant, or he may be referring loosely to 2 Thessalonians, which was addressed to neighbours of the Macedonians. The exegetical arguments are, in short, the final court of appeal, and their verdict tells rather in favour of the epistle's integrity. The simplest account of iii. 1 is to suppose that Paul started afresh to complete or supplement what he had already written, possibly because some fresh tidings from Philippi had reached him in the interval. Psychologically the change from iii. 19 seq., with its note of farewell, to the impassioned outburst of iii. 2 seq., is incredible in an informal letter from a man like Paul. The hiatus is striking, but it cannot be held to necessitate an editoral dovetailing of two separate epistles. It is doubtful, therefore, if the ingenious attempts to analyse Philippians have proved much more convincing than the similar movement of literary criticism upon the first Philippi of Demosthenes, where research has swung back in the main to a conservative position (cf. A. Barin in Wiener Studien, 1884, 175—205).

The first clear echoes of the epistle are heard in Polycarp, though it was probably known to Clement of Rome and Ignatius (cf. the evidence tabulated in The New Testament in the Apostolic Church). To the details furnished in the present writer's Historical New Testament (2nd ed., 1901, pp. 634—635) may be added references to Völker's Paulus ii, seine Briefe (1905), pp. 386—393, Beller's Einleitung in der N. T. (2nd ed., 1905), pp. 555 seq., and Schmiedel's paragraphs in Ency. Bib. (314—3148). Pléiderer (Primitive Christianity, i. 254 seq.) now hesitates on ii. 6 seq. alone, like Brückner and Schmiedel. The objections to Paul's authorship on the score of style and grammar are finally set aside by the philologist Nagel in Der Wortschatz des Apostes Paulus (1905), pp. 80—82.
PHILIPPINES—PHILIPPINE ISLANDS

PHILIPPINES, or the Philippines, an archipelago belonging to the United States of America, situated about 900 m. off the S.E. coast of Asia between 4° 40’ and 28° 20’ N., between 116° 40’ and 126° 34’ E. It is bounded W. and N. by the China Sea, E. by the Pacific Ocean, and S. by the Celebes Sea and the coastal waters of Borneo. Of the large islands, Luzon (40,669 sq. m.) is the most northerly, and Mindanao (36,292 sq. m.), the most southerly. Between Luzon and Mindanao are Samar (5031 sq. m.), Negros (4881 sq. m.), Panay (4611 sq. m.), Mindoro (3851 sq. m.), Leyte (2722 sq. m.), Cebu (1762 sq. m.), Bohol (1441 sq. m.) and Masbate (1256 sq. m.). Farther west and separated from the southern portion of this chain is the long narrow island of Palawan or Paragua (4027 sq. m.). The total land area of the Philippines is 315,926 sq. m., and 92% of these twenty others, which have an area ranging from 106 sq. m. to 682 sq. m., and the total number of islands enumerated within the archipelago is 3141; of these 2775 contain less than 1 sq. m. each.

Physical Features.—The islands are mainly of volcanic origin, and their surface is much broken by hills, isolated volcanoes and mountain ranges, and many of the islands are cut through by deep canyons 3.6 m. east, or north-east and south-west. Extending for 350 m. along the east coast of central and northern Luzon is the Sierra Madre range, which in occasional places rises to more than 4500 ft., and seldom less than 3500 ft. On the west coast of Luzon and on the south-eastern coast of Mindanao north from the Gulf of Lingayen and the Zambales southward from that gulf to Manila Bay, the Caraballac Occidentales range is very low; in fact, the coastal plains cut off from it, but it rises in Mt. Dadá to 7366 ft., and numerously extends west from it. Much of the Zambales range has an average height of 4000 ft. or more, and several peaks are more than 5000 ft. high. Between the Sierra Madre and Caraballac Occidentales is the valley of the Cagayan river, about 50 m. wide, and east of the Zambales range is a lowland basin, about 150 m. long and 50 m. wide, and not more than 100 ft. above the sea except near its centre, where the river rises from 2500 ft. The eastern part of southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. Mt. Mayon (7916 ft.), near the south-eastern extremity, is an active volcano with an almost perpendicular side of 11,000 ft. high. Other active volcanoes are Mt. Isarog (6634 ft.) and Mt. Masaraga (5244 ft.). The island of Mindanao is traversed north to south by mountain ranges, which rise in their summits to heights exceeding 4000 ft. That along the north coast is the longest and least broken, and between it and the next range inland is the level valley of the Agusan river, from 40 to 50 m. wide. Farther west and south-west is the valley of the Rio Grande de Mindanao, which is the widest river on the island, and between the lower course of this river and the Caraballac Occidentales range with a north-west and south-east trend. On the east border of the south portion of the basin of the Rio Grande is Mt. Manibot (2973 ft.), an extinct volcano and the highest elevation in the archipelago.

Each of the larger islands between Luzon and Mindanao, except Samar and Bohol, is traversed longitudinally by a single mountain range with occasional spurs. In Luzon, apart from isolated volcanic cones, two of which, in the north part, exceed 4500 ft. In Mindoro the range is broad, extending from coast to coast, and it culminates in Mt. Halcon (about 8800 ft.). In Negros is Mt. Canlion (8192 ft.), a volcano, and several summits exceeding 4000 ft. In Panay is Mt. Madiáás (7264 ft.) and several other peaks exceeding 4000 ft. The highest peaks in Masbate are about 2500 ft. high, and in Cebú not much more than 2000 ft. In Samar there are many islands with masses over 500 ft. but the outer portion of theBasques, the natural inhabitants to revolt, and on the destruction of the Spanish at once assumed the purple. Among his first acts were the deposition of Cyprian, the orthodox patriarch of Carthage, and the punishment of two Christian converts, in favour of John, a member of his own sect, and the summoning of the Council of Carthage, which abolished the canons of the sixth general council. Marcus Terbolis, king of the Bulgarians, plundered up to the walls of Constantinople, and shortly afterwards the Saracen's made similar forays from the Asiatic side. The reign of Phéllipicus was brought to a close through a conspiracy headed by two of his generals, who caused him to be blinded.

Agno rises in the mountains on the north border, flows south, south-west and north-west, and discharges through several channels into the Gulf of Lingayén. Each of these has a great number of small tributaries, and along the coast of this lowland basin are many lakes formed by the tides. The Mamit and Mindanao are locally important tributaries. Two estuaries on the western coast have an especially important stream connecting Laguna de Bay with Manila Bay. The Rio Bicol, which rises in Lake Bato and flows N.N.W. into San Miguel Bay, is the principal river of south Luzon. Samar, Panay, Negros and Mindanao have several large rivers, but few of those in Samar, Panay and Negros are of considerable size.

In the lowland basin of central Luzon, 6 m. inland from Manila Bay, is Laguna de Bay, the largest body of fresh water in the Philippines. It is long from north-west to south-east and its coast-line, broken on the north by two hilly peninsulas, is 108 m. long. Lake Taal, a few miles south-west of Laguna de Bay, occupies the crater of a great volcano. It is 173 m. long and 121 m. wide, and is girt by a wall of 120 m. high and 60 ft. thick. A small island near its centre is the active volcano of Taal, 1050 ft. high. In north Luzon is Lake Cagayan. In Mindanao there are lakes Lamas in regiona, the Philippines are renowned for their diversity. lakes Mainit, Pinaya, Dagun, Saducun and Limao in the valley of the Agusan. There are small lakes in some of the other islands.

Geology.—The Philippines appear to be the remnants of a somewhat complex system of mountain arcs, which from their similarity in form and direction seem to be in some way connected with the mountain ranges of Annam. The oldest rocks exposed are gneiss, talc-schist and serpentinite, with intrusive masses of gabbro and diorite. These rocks are overlain by a low, and a very much lower, a series of bedded shales and sandstones, forming a series of sandstones with coal seams. The age of these beds is unknown. In some of the islands nummulitic limestone (Eocene) occurs. Coral limestones, probably of Middle Tertiary age, are also found. Sandstones and conglomerates of a very late geological period occur near the coast and in the low-lying depressions. Volcanic rocks of modern date cover extensive areas, especially in the northern part of Luzon and in Mindanao. Lakes, trachytic tuffs are sometimes interbedded with nummulitic limestone, thus showing that the eruptions had already begun in the Eocene period.

Volcanoes and Earthquakes.—There are twelve active volcanoes in the archipelago. They are Babyúna Claro, Camiguín de Babuyanes and Dídacas in the Babuyanes Islands off the north coast of Luzon; Cagura or Cuaa in north Luzon; Taal, Mayon and Bulusan in south Luzon; Mayon and Sabtang in Negros and Negros Oriental; the island of Camiguín, off the north coast of Mindanao; and Apo and Calayo in Mindanao. Only a few eruptions have been recorded of any of these, however, except Mayon and Taal, and there have been eruptions of the last two times since 1780. But there are no eruptions of Mayon in the 19th century, and those of 1815 and 1816 were of great violence. That of 1897 began practically without warning on the 23rd of June, became alarming on the 24th and destructive on the 25th, and ceased on the 30th. Streams of lava completely destroyed several villages and injured others, as well as the town of San Fernando. The lava flow extended more than 7 m. from the crater and covered an area of 150 sq. km. The destruction of Lears Cave was caused by about 60 strong earthquakes; 16 of these, in ten different regions, occurred in the decade from 1890 to 1900. There were 8 in the year 1897 alone, and one of these ruined the town of Zamboanga in west Mindanao and caused considerable loss of life by falling boulders and by sea waves. A new island appeared at this time off the coast of Borneo, near Labuan. The principal centres of disturbance are in the valley of the Agusan, in the region of Mayon volcano, in the province of Quezon, which borders on Masbate, and on the south-western shore of Luzon. The islands of Cebú, Bohol, Negros and Palawan are rarely shaken.

Fauna.—The Philippines, politically speaking, and the Philippines, zoologically speaking, are not identical areas; Balabac, Palawan and the Calamianes being characterized by the occurrence of numerous Bornean forms which are conspicuously absent from the islands of Luzon and Mindanao. It is held to form a extension of the Indo-Malayan sub-region, there is a large amount of specialization in the fauna of the islands eastward of the Palawan group. Mammals are scarce. No marsupials occur. The bird species (Manis sp.) of the Palawan group. In the seas are found the dolphin, cęhalot and dugong. Wild pigs of at least two species occur. The beautiful axis deer of Sulú has apparently been brought through the sea, and the level depression of the sea at these points has probably contributed to the development of the sea. The young are forced to dig their way out and shift for themselves. The eggs are highly prized by the natives. The jungle fowl abounds. There are 35 species of pigeons and doves, many of them most beautifully coloured and all, black plover, turnstones and other shore birds are abundant during
the cool season, and herons, bitterns and ducks at all times. The birds of prey, 45 species, of which 22 are peculiar to the group, vary in size from a tiny falcon not larger than a sparrow to the hieron (Milvus lineatus, Grant), which is strong enough to seize monkeys as they leap from tree to tree. There are 21 species of kingfishers, 15 being land species. Of the 175 birds of the group, 132 are found outside of the Philippines. Frog-moths, bee-birds, night-hawks and swifts are found in considerable variety. One of the last (Collocalia troglodytes, Gray) constructs the edible nests so highly prized in China. The best are those which occur on the island of Negros. The eggs are prized by the natives, and the flesh of one species, known as ibit or peluid, is highly esteemed. Crocodiles are extremely numerous in many of the streams, and are occasionally found in the coastal waters. They cannot be obtained, however, in 18 ft. in length. Land turtles of small size are common. Very large sea turtles are often captured by the fishermen, and their flesh is highly appreciated by them. Dragon flies are very numerous, and many are of great beauty. Sun-birds, and 23 flower-peckers, titymics, shrikes, swallow-shrikes, tailor-birds, thrushes, fruit-thrushes, fairy blue-birds, fire-birds, 42 fly-catchers, 4 swallows, and 5 species of swallows are also very common, as well as a large number of birds for which English names cannot be readily supplied.

Reptiles and batrachians are abundant, but have been little studied. Pythons occur throughout the group, and sometimes attain enormous size. There are numerous venomous serpents, but the mortality from snake-bite is low. Geckoes may be seen on the walls and ceilings of any house. Flying lizards abound in the mountains. The largest lizards are Tropidurus. Their eggs are prized by the natives, and the flesh of one species, known as ibit or peluid, is highly esteemed. Crocodiles are extremely numerous in many of the streams, and are occasionally found in the coastal waters. They cannot be obtained, however, in 18 ft. in length. Land turtles of small size are common. Very large sea turtles are often captured by the fishermen, and their flesh is highly appreciated by them. Dragon flies are very numerous, and many are of great beauty. Sun-birds, and 23 flower-peckers, titymics, shrikes, swallow-shrikes, tailor-birds, thrushes, fruit-thrushes, fairy blue-birds, fire-birds, 42 fly-catchers, 4 swallows, and 5 species of swallows are also very common, as well as a large number of birds for which English names cannot be readily supplied.

The Philippines are famous for the variety, beauty and abundance of their land mollusces. Fresh-water and marine mollusces and also bivalves are very abundant. While most of the species are of interest chiefly to the conchologist, there are a number of edible forms. The shells of Pachisa plana, L., split into thin flat plates and, cut into small pieces, are used like glass in place of glass. The valves of the giant clam (Tridacna) sometimes attain a length of 5 ft. and weigh hundreds of pounds. Pearl oysters are abundant in the southern waters of the archipelago. Plaques of locusts occasionally, during a drought, run growing crops; in damp wet weather these insects are destroyed by a fungus growth (Empusa grilae) within their bodies. Land-leeches swarm in the damp lowland forests. The coral beetle, Clymene Sultana, and the Malayan oyster, Gyrida, are also seen. Beetles, beauty, and Guimaras, Cebú and Siquijor are completely covered with a thick cap of coral limestone.

Flora.—The rich and varied flora of the Philippines is essentially Malayan, imbibed with Chinese and Australian elements, but with sufficient individuality to constitute a sub-region, there being at least 769 species peculiar to the archipelago. More than two- thirds of the flora are composed of tree plants. In the lowlands and on the lower mountain slopes the forests are of the following kinds: hard-wooded, broad-leaved trees, common among which are the bamboo, the coco and other palms, and the banyan tree; but on the higher mountains the broad-leaved trees are mostly replaced by a density of commercial or local value, among them are woods well suited for structural purposes, inside finishing, cabinet work and carriage making. Plants valuable for their fibre number among these the bamboo, which is in demand for matting, and the leaves of which Manila hemp is made. There are gatta-percha, india-rubber and other trees and plants yielding gums, the banana, mango, and many other trees and plants yielding fruits; and various trees and plants yielding nuts, spices, oils and medicines.

Climate.—A uniformly high temperature, excessive humidity, heavy rainsfalls and violent tropical storms, known as typhoons or hurricaines, are the characteristics of the climate. The mean annual temperature is about 80° F., the range of mean monthly temperature 6-38°, from 77° in January to 83-48° in May; and the range of extremes (during the period from 1881 to 1900) 74-10° F. The dry season extends from October to December. The general and the monthly variations in temperature at Manila the year is divided into three seasons: temperate (November, December, January and February), hot (April, May and June) and rainy (July, August and September). The mean annual temperature of the archipelago the mean annual temperature varies much more with the altitude than with the latitude, but the range in mean temperature extends from 11-4 in 17° south latitude to 4° 31' in 7° north latitude. In 17° north latitude. In December. At Manila the monthly average of relative humidity ranges from 70-7° in April to 85-5° in September, and the annual average is 79-4°. The mean annual rainfall in this city is about 110 in., occurring in 120 days. About three-fourths of the year's rain falls from April to September. Except in the lowland of Luzon, the months of June, July and August are the drier. The same months are the wettest in the lowland of Luzon. The Philippines are visited on the average by twenty or more typhoons annually. About one-fifth of them occur in September. During January, February, March and April they are rare; in May, June, July and August they are increasing in number, which reaches its maximum in September, gradually decreasing in October, November and December. The damage from the typhoons is less in the interior than in the lowland of Luzon, from which they pass over Manila, an immense amount of damage was done in the city. Two thousand persons lost their lives in Samar and Leyte during the great storm of 1897.

Agriculture.—Agriculture is the principal industry. In 1903 about 40% of the working population were engaged in agricultural pursuits. The people are farmers. The native farmers are lazy and slow to appreciate the advantages of the methods recommended by the Americans. Only 9-5 % of the land in the archipelago was in "farms" in 1903, as against 64% in the United States. It is estimated that only a small part of the land in the province of Bulacan, Pampanga, La Laguna, was, the only province in which more than 50% of the land was included in "farms," and Cebú the only island in which more than 25% of the land was included in farms; in the province of Mindanao, about 60% of the land is considered as "farms," whereas in Mindoro only 3-0%. There were 815,453 "farms" or individual holdings, but more than one-fifth of these were small parcels or gardens containing less than an acre each; about one-half contained less than a quarter each, and the average size was 0-57 acres. More than four-fifths of them were worked by owners, and the remainder chiefly by share tenants. The principal crops are hemp (abacá), sugar, tobacco, coco-nuts and rice. Most of the hemp (535,600 acres in 1902) is grown in south Luzon and in Samar and Leyte, but smaller crops are produced in Cebú, Mindanao, Marinduque, north Mindanao and south Negros; the crop became of commercial importance only about 1885; it is of value to the government in amount of 71,000 tons to 112,895 tons. About two-thirds of the sugar is produced in Negros, but it is an important crop in the provinces of Pampanga and Tarlac, within the lowland basin of Luzon, also in the province of Batangas on the south coast of Luzon, in the south and east of Panay, and in Cebú. The production increased from about 6000 tons in 1855 to 3000 tons in 1893, and for many years prior to 1887 it was a more important crop than hemp, but since the American administration hemp has taken its place. The sugar output in 1899 was 177,620 acres, and in 1907 the yield for export was 118,395 tons. Approximately one-half of the tobacco, 77,632 acres yielding 37,485 lb. in 1902, is grown for the local market, the remainder, which is of inferior quality, in the neighbouring provinces of Union, Ilocos Norte and Abra, and in Panay, Cebú, Masbate and Negros. The natives chew betel nuts and betel leaves freely. The produced of cocoa, 1,337 acres yielding 12,000 lbs., is being increased by the extension of plantations. The rich soil of the lowlands of the province of Laguna is especially well adapted to the culture of the coco-nut palm, and since the American occupation considerable land in this province that had formerly been devoted to sugar has been returned to coco-nut culture.
has been planted with these trees. They thrive well also in most low districts along the coasts; in 1902 about 375,000 acres of them were devoted to the culture of the seed.

Rice is the staple food of the natives. When the Philippines were annexed in 1898, the exportation of rice was the only crop which was of importance, and until the 19th century it was the chief article of export, but as the culture of the more profitable crops of hemp, sugar, and tobacco was extended it became an article of import.

As late as 1902, however, a land commission stated that the demand for rice was only 1,000,000 bushels, which is barely sufficient to meet the demand. In 1904 it was reported that the rice production was 254,470 bushels. For several years prior to 1891, coffee, grown principally in the provinces of Caviite, Batangas, and Lepanto-Bontoc, Luzon, was nearly as important a crop as tobacco, but between 1891 and 1898 most of the coffee plantations were destroyed by insects and disease. A small quantity of coffee is grown in the province of Benguet, Luzon, and is of superior quality. Cotton, the cultivation of which was discouraged by the Spanish government as a means of increasing the cultivation of tobacco, is a very small crop, except in the provinces of Ilocos Norte, and Ilocos Sur on the west coast of North Luzon; in 1902 the total area of the cultivated land was 5,000 acres, and the crop was estimated at 1,000,000 bushels. The principal tropical fruits grow wild but their quality is inferior; those cultivated most extensively are mangoes and bananas. Grapes, blackberries, figs and strawberries have been introduced from the United States, and the cultivation of the first two has increased considerably.

The natives care little for the garden vegetables common to Europe and America, but in the vicinity of Manila and other large centers of population the Chinese grow many of these for consumption by the European and American population.

With the exception of the water-buffalo, which is indispensable for agricultural purposes, the domestic animals are very inferior in quality and few in numbers. The horses, which are of Mexican, Spanish and Chinese origin, are small and poorly cared for; some American horses have been introduced for the purpose of improving the breed. The cattle, which are of Australian and Indian origin, are in poor condition. The sheep and goats number about nine-tenths of them were destroyed by the rinderpest and the war at the close of the 19th century.

Swine are numerous but they are of a kind known in the United States as "rooket." The sheep, goats, and cattle near Manila duck-raising is of considerable importance; but the principal branch of the poultry industry consists in the raising of game-cocks for cock-fighting, which is the national sport.

Mineral Resources.—Numerous mineral deposits have been discovered, but little has been determined with respect to their value. The principal one is with the exception of the water-buffalo, which is indispensable for agricultural purposes, the domestic animals are very inferior in quality and few in numbers. Negros. They are very short of stature, 4 ft. 10 in. being about the average height of a full-grown man, and the women are shorter. Their colour is black, their skull decidedly round, their hair thick and frizzly, their legs thin and almost without calves, and their toes so prehensile that they can use them nearly as well as their fingers. They tattoo themselves and wear very little clothing; usually only a gestic. They have no fixed abode but roam about in groups of a few families. They are skilful with the bow and in throwing stones, and they can easily kindle a fire, even in the wet season, by rubbing together two pieces of dry bamboo. Their food consists principally of game, roots and wild fruits. The women, who do all the work, collect wax and honey, which are their principal staples in trade. Few Negritos live to be fifty years of age. The brown race, which came from the south in successive waves of immigration beginning in prehistoric times, is composed of twenty-three distinct tribes varying widely in culture, language and appearance; their languages however belong to one common stock and there is a general resemblance in physical features and in quality of mind. The great bulk of the population, approximately 90% is included in seven Christian tribes as follows: Visayan, 3,210,030; Tagalog, 1,460,605; Ilocano, 803,942; Bicol, 566,355; Pangasinan, 343,586; Pampangan, 280,984; and Cagayan, 159,648. The Visayans are the principal inhabitants of the islands in the central part of the archipelago (Panay, Cebu, Negros, Leyte, Bohol, Samar, Masbate and Paragua) and on the north and east coasts of Mindanao; they were perhaps the most civilized people in the archipelago when discovered by the Spaniards, by whom they were originally called Pintados because they were in the habit of painting their bodies; but since then their progress has been less rapid than that of the Tagalogs—who constitute the bulk of the population of Manila and central Luzon and the majority of the population of Mindanao—who are now the most cultured of the brown races in the Philippines. Most of the Ilocanos are in the western half of north Luzon; most of the Bicolos in south Luzon; most of the Pangasinans in the province of Pangasinan, which borders on the Gulf of Lingayen; most of the Pampangans in the province of Pampanga, which borders the north shore of Manila Bay; and most of the Cagayan in the valley of the Cagayan river. More than three-fourths of the wild population is included in the Moro, Igorot and Negrito tribes. The Igorots (197,938 wild and 13,400 civilized) are a vigorous, industrious, thrifty race, who have been the most active of all the tribes in the immigration to the archipelago. They are the principal inhabitants of the provinces of Lepanto-Bontoc and Benguet in north Luzon and are numerous in the mountain districts of neighboring provinces. Among the wildest of them head-hunting is still a common practice; but the majority are industrious farmers laying out their fields on artificial terraces and constructing irrigation canals with remarkable skill. The Moros (275,224 wild and 2325 civilized) were the last of the Malays to migrate to the islands; they came after their conversion to the Mahomedan religion, and their migration continued until the Spanish conquest. More than one-half of them are in Mindanao and they are the principal inhabitants of the small islands of Jolo, Basilan, Siassi and Tawi Tawi south-west of Mindanao. Slavery is common among them. They are generally miserably poor, cruel and haughty. Nearly three-fourths of the foreign-born and 97.5% of the representatives of the yellow race come from China. The mixture of the races is principally that of the Chinese with the Malays or the Spaniards with the Malays. More than half the representatives of the white race (1903) were Americans. Most of the inhabitants live in groups of villages. In 1903 there were 13,400 villages and nearly three-fourths of them contained fewer than 600 inhabitants each. Laon in north Luzon with a population of 19,696, Hilo in Panay with a population of 19,954, Cebu with a population of 18,330, and Nueva Caceres in south Luzon (10,201), were the only towns with a population exceeding 10,000; and Manila (219,028) was the only city. After the 1903 census many towns were enlarged by annexation of suburbs.

Government.—At the beginning of the American occupation, in August 1898, a purely military government was established; but in May 1899 the military authorities began the re-establishment of civil courts, and in July of the same year they began the organization of civil municipal governments. To continue the work of organizing and establishing civil government the president of the United States appointed in February 1900 a Philippine Commission of five members, with William H. Taft as chairman. On the 1st of September 1900 this body assumed the legislative functions of the central government at Manila; on the 14th of July 1901 the executive authority was, by order of the president, transferred from the military governor to Judge Taft, whom he had appointed civil governor; on the 6th of September 1901 the Philippine Commission, by authority of the president, established the four executive departments, of interior, commerce and police, finance and justice, and public instruction; and on the 29th of October 1901 the president appointed a vice-governor. The Congress of the United States, in an act approved on the 1st of July 1902, ratified and confirmed the government as thus established, but required that future appointments by the president of the governor, vice-governor, members of the commission and heads of the executive departments should be made with the consent of the Senate. The organic act contained a bill of rights, provided for the establishment of a popular assembly two years after the completion of a census of the Philippines, and more definitely provided for the organization of the judiciary. The first popular assembly, of 80 members, was opened at Manila on the 16th of October 1907, and since then the legislature has been composed of two branches, the Philippine Commission (five Americans and four, formerly three, Filipinos), and the Philippine Assembly. The members of the Assembly are elected by districts (the population of which is approximately equal) for a term of two years. A voter must be twenty-three years of age, must have been a resident of the municipality for six months, must not be a citizen or subject of any foreign country, and must possess at least one of the following qualifications: have been an office-holder under Spanish rule, own real estate worth 500 pesos, pay taxes amounting annually to 30 pesos, or be able to speak, read and write either Spanish or English. The legislature meets annually; a regular session is limited to 90 days, and a special session to 30 days.

Justice is administered principally by a supreme court, courts of first instance, and courts of justices of the peace. The supreme court consists of seven members, four Americans and three Filipinos; and the chief justice and associate justices of the supreme court are appointed by the president of the United States with the consent of the Senate. The judges of the courts of first instance are appointed by the governor with the consent of the Philippine Commission. A judgment of the supreme court of the Philippines which affects any statute, treaty, title, right or privilege of the United States may be reversed, modified or affirmed by the Supreme Court of the United States; an appeal to the Supreme Court of the United States may also be had in any cause in which the value in controversy exceeds $25,000. The most common form of provincial government is that by a governor, who is elected biennially by the municipal councillors in convention, and a secretary, a treasurer, a supervisor, and a fiscal or prosecuting attorney, who are appointed by the Philippine Commission. Each municipality is governed by a president, a vice-president, and a municipal council, all of whom are elected biennially by the qualified electors of the municipality. The Philippine "municipality" is an administrative area, often sparsely settled, is often called a town, and may be compared to a New England township; the municipalities are the units into which the provinces are divided. Each municipality is made up of barrios or small villages (about 13,400 in the entire archipelago) and of one, or more, more thickly populated areas, each called a poblacion, and resembling the township "centre" of New England.

Education.—The establishment of an efficient system of elementary education has been an important feature of Philippine administration. Under Spanish rule the Church established colleges and seminaries for training priests, but the Spanish system of secular schools for elementary instruction, established in 1865, accomplished little; the schools were taught by unqualified native teachers and the supervision of them was very lax. The American
system, established by the Philippine Commission in 1901, provides a course of instruction (in the English language) for 11 years: 4 primary, 3 intermediate and 4 secondary. In the intermediate and secondary departments there is a choice of six courses: general, teaching, farming, mining, business, and housekeeping. The administrative head of the system is the director of education, who is appointed by the commission, and who arranges the course of study, approves the plans for school houses, determines in what towns secondary schools shall be established and in what towns American teachers shall teach, divides the archipelago into school divisions and appoints a division superintendent in each, and superintends all examinations of teachers and the application of their school funds. Each division is an association, besides which is an association also appointed by the commission. In each school division, of which there were 35 in 1908, the division superintendent apportions the money appropriated for school purposes in certain counties to the cost of school expenses, and approves all expenditures from the division school funds. In each municipality there is a school board consisting of the president of the municipality and from four to six other members as the division superintendent shall determine: one-half of them are elected by the municipal council and one-half are appointed by the division superintendent. In 1902 there were 928 American teachers employed in the Philippine schools; the employment of American teachers is only a temporary policy, however, and by 1908 the number has been reduced to 705. In 1910 there were more than 6000 Filipino teachers who were teaching English to more than 900,000 pupils. The total number of children of school age in the Philippines probably reaches 2,000,000. The insular government also makes annual appropriations for the maintenance of Filipino students at educational institutions in the United States and provides funds for war orphans. Besides the elementary schools there are at Manila the Philippine Naval School, the Philippine School of Arts and Trades, the Philippine School of Commerce and the school for the instruction of the deaf and blind. Since 1885 the national legislature has passed an act for the establishment of a university of the Philippines. Finance.—Revenue is derived largely from customs duties and internal revenue taxes. In 1909 the receipts were $29,739,000, the expenditure $25,337,000, and the total bonded debt $16,000,000. (N. D. M.)

History.—The Philippine Islands were discovered by Magellan in March 1521. The first island on which he landed was Malabug, between Samar and Dinagat. Then sailing south he touched at Mindanao, from which he sailed north-west, past Bohol to Cebu. Here he found a good harbour in the bay on which the city of Cebu now stands. He made an alliance with the natives, who undertook to supply him with provisions. With his new allies he crossed to the little island of Mactan, where he was killed in a skirmish. A Portuguese by birth, he had been sailing in the employ of King Charles I. of Spain (the emperor Charles V.), with the object of proving that the Moluccas lay within that part of the world which Pope Alexander VI. and the treaty of Tordesillas (June 7, 1494) had given to Spain and not to Portugal. Magellan named his discovery the Archipelago of San Lazarus. The Spaniards, however, called the group the Islas de Poniente (Western Islands). The Portuguese called them the Islas de Oriente. The distinction was not accidental. To the Portuguese they constituted the eastern boundary of their world. From the Spanish point of view the islands were on the extreme western verge of the national domain. In 1529, by the treaty of Zaragoza, Spain relinquished to Portugal all claims to the Moluccas and agreed that no Spaniard should trade or sail west of a meridian drawn 297 leagues east of the Moluccas. This was a plain renunciation of any rights over the Philippines, which lie several degrees west of the Moluccas. This fact, however, was ignored and in 1542 an attempt to conquer the Philippines was made by Ruy Lopez de Villalobos (c. 1500-1544). Villalobos chose to honour the heraldic symbol of the Spanish throne by naming some of the islands which he discovered, west and north of Magellan's discovery, the Islas Filipinas. After the accession of Philip II. (1555-1598) a much more important expedition was fitted out on the orders of the king and the viceroy of the Philippines. Under the command of the conquistador, Miguel Lopez de Legaspi (1542-1572). In the sailing directions, issued in 1561, for the use of this expedition the phrase "las Islas Filipinas" was used as applying to the entire archipelago. Starting on the 2nd of November 1564, from Navidad, with four ships built and equipped on the spot, Legaspi began an enterprise which entitles him to a place among the greatest of colonial pioneers. He was accompanied by five Augustinian friars and four hundred men. In 1565 he founded, on the island of Cebu, San Miguel, the first permanent Spanish settlement in the islands, destined to become the Villa de Sanlino Nome de Jesus, later the city of Cebu. In 1571 the city of Manila, the capital, was founded, and considerable improvements in the local administration were made. The conquest of the islands was facilitated by the fact that there were no established native states, but rather a congeries of small clan-like groups, the headship of which was hereditary. Legaspi was reinforced from time to time by small contingents of troops and frics. Although he encountered enormous obstacles, including famine and mutiny, the hostility and treachery of the natives and of foreigners, and the neglect of the home government, he laid a sure foundation for permanent Spanish occupation. By a combination of tact, courage and resourcefulness he won the hearts of the natives, repelled the Portuguese and, notwithstanding the great distance from Spain, established a new colony on a practical basis. Before his death in 1572 he had explored and pacified a large part of the island territory, had established trade, and had arrested the progress of Mahomedanism.

The conquest of the Philippines was essentially a missionary conquest. Inspired by apostolic zeal the friars braved the terrors of life in the remote villages, raised the natives from barbarianism and taught them the forms of the Christianity. As a result of their labours the Chris- tun Filipinos stand unique as the only large mass of Asiatics converted to Christianity in modern times. The friars promoted the social and economic advancement of the islands, cultivated the soil to an extent unprecedented in Philippine agriculture and imported Indian corn and cacao from America. Tobacco was introduced by the government.

The colonial government was patterned on that of Spain. The powers of the governor-general were limited only by the audiencia or supreme court, of which he was president, and by the residencia or official investigation at the expiration of his term. The islands were subdivided into provinces under alcaldes mayores who exercised both executive and judicial functions. The vassalism and corruption that honeycombed the civil service of Spain frequently resulted in placing in responsible positions persons who were entirely unfit. Hairdressers were made into alcaldes, and sailors were transformed into gobernadores by the miraculous grace of royal decrees. The provinces were subdivided into pueblos, each under a native gobernadorcillo, elected annually. The permanent offices could be bought, sold and inherited. The mistake was made of paying very low salaries to the officials, who took this as a justification for illegal exactions. The difficulty of securing proper officials gradually resulted in the more important civil functions being handed over to the friars, who frequently exercised a benevolent despotism. In more than half of the twelve hundred villages there was no other Spaniard besides the priest. The Spanish language was practically unknown. It was far easier for the monks to learn the native dialects than to teach their parishioners Spanish. For two centuries and a half after the conquest there is little narrative history worth recording. There were border wars with rebellious savage tribes, attacks made by Chinese pirates seeking plunder or refuge, volcanic eruptions, earthquakes, tornadoes and the periodical visits of marauders from the southern islands.

In 1762, however, as an incident of the war between Spain and England, a British fleet of thirteen ships, under the command of Admiral Samuel Cornish (d. 1770) and Brigadier—British General William Draper (1721-1757), was sent to the occupation of the Philippines. The available Spanish army con sisted of about 600 men, while the attacking force numbered 700. In July the British force landed, and in a bloody battle of the 5th of October the British entered the city. By the terms of the capitulation the whole of the archipelago was surrendered to the British and an indemnity of 4,000,000 pesos was to be paid. As there was no governor-general at the time, the British were obliged to treat with the acting-governor, the Archbishop Manuel Antonio Rojo; but his authority was set aside by a war-party which rallied around Simon Anda y Salazer, a member of the audiencia. Anda proclaimed himself governor-general and practically
succeeded in confining the British to Manila. At the close of the war the Philippines were returned to Spain. Manila was evacuated in March 1764.

For the first quarter of a century after the Spanish conquest the islands were allowed free trade. Then came the familiar economic restrictions, limiting commerce to a fixed amount annually, and effectively checking economic development. In 1591 direct trade between the Philippines and South America was prohibited. In 1593 trade between the Philippines and Mexico, the only route open between the colony and Spain, was limited to two native annually, the ships to carry 500 tons burden. The result was that the command of the Acapulco galleon was rarely worth less than $50,000. The passenger fare from Manila to Acapulco, at the end of the 18th century, was $1,000. This monopoly lasted until the Mexican War of Independence forced the Spanish government to regard the Philippines as being in the East instead of the West. Spain's colonial policy was not based on an exaltation of the commercial ideal. However much the administrators may have fallen short in actual practice, the Spanish ideal was to preserve and civilize the native races, rather than to establish lucrative trading posts where they could be easily be ejected. In Spanish law, which provided elaborate safeguards for the protection of the Indians, were to a large degree, nullified by the lust for gold and silver and the consequent demand for labourers in the mines.

In the Philippines the humane policy of the home government had no such powerful obstacles to contend with. Business was not developed. The natives were allowed to live the indolent life of the tropics. Compared with the results of English or Dutch colonization the conversion and civilization of the Filipinos is a most remarkable achievement. Notwithstanding the undeniable vices, follies and absurd illiberalities of the Spanish colonial régime, the Filipinos were the only group in the East Indies that improved in civilization in the three centuries following their discovery. The chief defect in the Spanish Philippine policy was that while it made converts it did not make citizens. Self-reliance, free-thought and mental growth were not encouraged. Progress in scientific knowledge was effectively blocked by the friars. Their presses confined their activities to the production of catechisms, martyrologies and handbooks in the native languages after the fashion of the presses of Mexico. Five hundred such works were printed and distributed in Manila alone before 1800. To reach the masses, unfamiliar with Spanish, manuals of devotion and outlines of Christian doctrine were translated into the various native languages. The friars, for themselves, put no part was translated or published. A knowledge of reading and writing was generally diffused throughout the group.

The era of discontent may be said to have begun in 1825 when the loss of her colonies on the mainland of America caused Spain to take a more immediate interest in the Philippines, and increased emigration to the islands. Between 1840 and 1872 thirty newspapers were founded. The introduction of secular books and papers, more or less surreptitiously, helped to spread the seeds of sedition. In 1852 the Spanish Filipino Bank was established. In 1856 foreign trade, hitherto cut off from Manila, was permitted to enter the port of Iloilo, and foreign traders were allowed to open branch houses outside of the capital. The change in Spain's economic policy, including an attempt to exploit the coalfields and to encourage both agriculture and commerce, helped to awaken hitherto dormant elements. In 1860 the Jesuits had opened a college in Manila for the education of Spanish youth. In 1768 they had been expelled. In 1850 they were permitted to return on the understanding that they would devote themselves to education.

The Spanish Revolution of 1868 caused a further influx of Spaniards and also the introduction of the pernicious "spoils system." With every change of party a new lot of hungry politicians anxious to fill even the more humble colonial offices. The opening of the Suez Canal in 1869, followed by the establishment of direct steam communication between Spain and the Philippines, sounded the death knell of the peaceful missionary era and brought about the definite entry of the islands into the world of commerce and progress.

The friars, by perpetuating medieval conditions in a country that was now being opened to contact with the civilized world, increased the feeling of discontent. The natural result was a violent conflict. The more advanced Filipinos desired the fulfilment of the decrees of the Council of Trent whereby the incumencies in Christianized towns and villages should be held by regular clergy and not by friars. Filipinos had for generations been ordained into priesthood although not received into "ecstatic orders. This measure was really aimed at the political and economic supremacy of the Spanish-born friars, who had by this time acquired 400,000 acres of agricultural land, more than half of it in the vicinity of Manila. The agrarian question added to the growing discontent. All the revolutions began in the province of Cavité, where the friars owned 125,000 acres. In 1857 the secret agents of the friars induced the native garrison at Cavité to mutiny and thus give the friars an excuse to press for vigorous action. The mutiny was not successful, but Father Burgos, the leader of the reform party, was publicly garrotted by the other native priests; and the native clergy were declared to be incompetent to have the care of souls. Several of the richest and best educated Filipinos were convicted of treason and banished.

With the increased facilities for European travel Filipinos began to visit Europe and return with new and broader notions of life. The most distinguished of the travellers was José Rizal (1861-1896). Born in Calahin, in the province of Luzon, of pure Tagalog parentage, he attended the newly reopened Jesuit university in Manila. He was then sent to Europe to complete his studies, first in Madrid, where he became a doctor of medicine, and later in Germany, where he received the degree of Ph.D. He came into touch with advanced methods of scientific research, acquired great ability as a writer, and keen perception of truth and an unflinching realization of the defects of his own people, and the unpleasant but essential fact that to have better government they must first deserve it. His propaganda, aimed at the small body of Filipinos who had sufficient education to appreciate political satire, was very effective. His most famous novel, Noli me tangere, was published in 1886. In this he drew a masterly picture, not only of the life and immorality of the friars but also of the insolent Filipino chiefs or caciques, subservient to the powers above, tyrannical to those below, superfluous, unprogressive and grasping. Caciquism or "high-brow" government by local aristocrats, was the prime feature of village life in the islands during the entire period of Spanish rule and existed long before their arrival.

The campaign of Rizal, Marcelo del Pilar, Graciano Lopez Jaena and Apolinario Mabini, the leaders in the "Young Filipino Party," was a protest against both the domination of the friars and economic and administrative caciquism. To escape the vengeance of the friars, Rizal was obliged to flee to Europe. In 1892 he returned to the islands on the assurance of the governor, Eulogio Despujol y Dusay, that he might live there in peace. His enemies, however, succeeded in having him arrested on a charge of treason. Meantime Mabini had organized the reform party under the title of Liga Filipina. Its object had been to procure, by pacific means, several reforms in the government of the islands, the chief of which were the expulsion of the friars, and the withdrawal of the governor-general's arbitrary power to deport Filipinos. The friars importuned Despujols for Rizal's life but he persistently refused their demand, and met the case half-way by banishing Rizal to Mindanao. Incensed by the failure of their plot, the friars obtained the recall of Despujols.

The new governor, Ramón Blanco, was like Despujols and many of his predecessors, humane at heart, but he could do little more than hold in check the tyrannical schemes of the clergy. The banishment of Rizal combined the reform party that peaceful endeavour was futile. A secret organization, the Katipunan, was therefore started to secure reforms by force of arms. It was founded by Andrés
Bonifacio, a schoolmaster of Cavite. In 1895–1896 the friars acting as spies for the government, obtained the banishment of the majority, and many of those who remained were imprisoned.

On the day after the Katipunan conspiracy had been brought prematurely to light by a traitor, three hundred prominent Filipinos were lodged in prison. This precipitated the revolt. The insurrectos attacked the civil guard outside the city, but were unsuccessful. A week later some hundreds of insurgents attacked the powder magazine at San Juan del Monte, but were completely routed. Four of their chiefs were taken prisoners and executed in Manila. Ten days after the plot was discovered Manila and five other provinces were officially proclaimed in a state of siege. The insurrectos concentrated upon Cavite and Manila. Several villages fell into their hands. The insurgent commander-in-chief was Emilio Aguilardo. He was born in 1869 in Cavite, son of a native farmer of considerable ability, and of a half-caste mother whose father was a Chinaman. After attending the Tagalog school at Cavite he entered the Jesuit College in Manila but did not graduate. In 1891 he became municipal alcalde of Cavite, and later joined the Katipunan.

The government was in a difficult position. General Blanco had extremely few European troops at his disposal, and it was doubtful how far native troops could be trusted. Reinforcements were on the way from Spain, but the demands of Cuba had already depleted the Peninsula of the best fighting material. Blanco, blamed for not acting at once, was recalled. In December 1896 General Camilo García de Polavieja (b. 1838) arrived as his successor, with General José Lachambre (b. 1846) as chief of staff. Before Blanco left he had released Rizal and allowed him to go to Spain, but the friars caused his arrest and he was sent back to Manila, where he was executed by Polavieja’s orders in December 1896.

Lachambre took the field in Cavite with energy and succeeded in quelling the rebellion in that province. He was then despatched north. Numerous small battles were fought with Aguilardo and the insurgents, who were repeatedly defeated only to reappear in other places. Polavieja’s demand for more troops having been refused, he resigned, and was succeeded in the spring of 1897 by General Fernando Primo de Rivera. Hostilities continued, but the wet season set in, making operations extremely difficult. Before Primo de Rivera could make much headway against the insurgents affairs in Cuba became so serious that the Spanish government cabled him that pacification was most urgently desired. As a result he suspended operations and signed the armistice of Bicábató (Dec. 12, 1897), by which Aguilardo and thirty-five of his chief followers were allowed to retire to Hongkong with a cash indemnity of 400,000 pesos. The Madrid government refused to confirm the terms of peace, and the peace rejoicings in Manila were followed by the persecution of all those who were known to have sympathized with the movement.

On the 15th of February 1898 in Havana harbour, the U.S.S. "Maine" was blown up. On the 15th of March Primo de Rivera, learning that the American Commodore George Dewey was mobilizing his fleet in the harbour of Hongkong, called a council at which the Spanish Admiral Patricio Montoyo (b. 1839) stated that, in the event of a conflict, his own fleet would be inevitably defeated. Primo de Rivera was now recalled and General Basilio Augusti (b. 1840) took his place. With a new governor-general all plans had to be reconsidered. Before suitable defences could be made, word came from Hongkong that Dewey had started for Manila and Montoyo hurriedly sailed from Subig Bay to Cavite, barely in time to anchor before Dewey arrived. Few among his crew understood handling a gun properly, and owing to the poor care which his vessels had received they were actually inferior to the individual vessels of the American squadron. Commodore Dewey arrived in the Bay of Manila on the 1st of May, and totally destroyed or disabled the Spanish fleet. The surrender of the city was refused. The Americans occupied Cavite. The battle of Manila Bay and the defeat of the Spanish fleet destroyed the prestige of Spain throughout the islands. Insurrections began in nearly every province. Aguinaldo and his friends were allowed to come to Cavite in an American transport. With the arrival of Commodore Dewey, who allowed arms to be supplied him, Aguinaldo successfully renewed his campaign against the Spaniards until practically all Luzon, except the city of Manila and suburbs, was in his control. Reinforcements arrived, and on the 13th of August Manila was taken by the Americans, under General Wesley Merritt (b. 1836).

The refusal of General Merritt to permit Aguinaldo’s troops to enter Manila created resentment on the part of the Filipinos. A so-called constitutional convention was held at Malolos, and a constitution was adopted. At the same time the Visayan Republic was organized, and it professed allegiance to Aguinaldo. The successive governments of the Visayan government was able to maintain order, and the whole country was subject to the looting of rubber bands. The treaty of peace between the United States and Spain, by which the Philippine Islands passed into the hands of the former, was signed in Paris on the 10th of December 1898, but it was not confirmed by the Senate until the 6th of February 1899. During this period the Filipino army remained unter arms. On the 4th of February hostilities broke out between the Americans and the Filipinos. The latter were defeated on the 9th, at Paco, with heavy loss. The American troops, now under General E. S. Otis (b. 1838), following up the enemy, drove them out of Malolos and then withdrew to Manila to await reinforcements, which brought the total American force up to about 60,000 men. It is unnecessary to trace in detail the gradual conquest of the islands, or the hundreds of engagements, often small, between the rebels and the Americans. Owing to the nature of the country, and the hope of securing independence from a possible overthrow of the Republican party in the United States, the war was prolonged for two or three years. With the capture of Aguinaldo on the 23rd of March 1901, the resistance became little more than that of guerrillas.

Civil government was introduced as fast as possible. During 1899 the Schurman commission, headed by Dr Jacob G. Schurman of Cornell University, was sent by President McKinley to report on the state of affairs. In February 1900 a second and more powerful commission was appointed, consisting of Judge W. H. Taft, Professor D. C. Worcester (b. 1866), General L. E. Wright (b. 1846), Mr H. C. Ide (b. 1844), and Professor Bernard Moses (b. 1846). Under the presidency of Mr Taft it began to exercise a legislative jurisdiction in September 1900. Its first act was to appropriate $1,000,000 for the construction and improvement of roads. It next provided for the improvement of Manila harbour, which involved an expenditure of $3,000,000. The fifth act extended to the islands the benefits of a civil service based on merit. In 1901 a general school law was passed under which 1000 American school teachers were introduced. They were scattered among 500 towns, to teach 2500 Filipino teachers English and modern methods of school teaching. Other legislation provided for the organization of a judiciary, a supreme court, the enactment of a code of civil procedure, the establishment of a bureau of forestry, a health department, and an agricultural bureau and a bureau of consular, made up of native soldiers officered by white men. Ladorism was very widely distributed under Spanish rule, and the old guardia civil committed outrages almost equal to those of the brigands themselves. The new constabulary has been eminently successful in maintaining law and order. Great progress has been made in the scientific mapping of the islands.

On the 4th of July 1901 the office of military governor was abolished, the military forces being largely recalled, and the part remaining being made henceforth subordinate to the civil authorities. Mr Taft became governor-general. A general amnesty was granted to all rebels and political prisoners who would take the oath of allegiance to the United States. On the 1st of July 1902 President
PHILIPPOLIS—PHILIPSBURG

PHILIPPOPOLIS (Bulgarian, Plovdiv; Turkish, Felibe), the capital of Eastern Rumelia, and of the department of Philippopolis, Bulgaria; situated in the midst of picturesque granite eminences on the right bank of the river Maritsa, 66 m. E.E. of Sofia and 97 m. W.N.W. of Adrianople. Pop. (1906) 45,572, of whom a large majority are Bulgarians, and the remainder chiefly Turks, Greeks, Jews, Armenians or gypsies. Philippopolis is on the main railway from Vienna to Constantinople, via Belgrade and Sofia. The Maritsa is navigable up to this point, and as the city has communication by rail both with the port of Dédéagatch on the Mediterranean and that of Burgas on the Black Sea, and is situated in a remarkably fertile country, it has become the chief commercial centre of southern Bulgaria, and is the seat of both Greek and Bulgarian archbishops. The residences of the richer Greeks and Bulgarians occupy the slopes of the largest eminence, the Jambaz-tepé, in the centre of the city; between it and the Nobet-tepé, from the summit of which there is a magnificent view of the city, is the Armenian quarter; near the bridge over the Maritsa is the poorer Turkish quarter; and south-west of the Jambaz-tepé there is a suburb of villages. On the Burgas road a monument has been erected by the Russians in commemoration of the war of 1877, and near this is the new palace of the king of Bulgaria. The Saba-tepé is crowned by a clock-tower. Not far from it are the beautiful Exhibition Park laid out in 1892 and the fine Journalski Mosque. Near the Maritsa are the remains of the ancient konak (palace) of the Turkish pashas, the public park formed by the Russians in 1877, the gymnasium, and the new Greek cathedral. The city has a large commerce in rice, attic of roses, and cocoons; other exports being wheat, wine, tobacco, alcohol and hides.

PHILIPPSBURG, a Thracian town, was captured by Philip of Macedon and made one of his frontier posts; hence its name of Philippopolis, or "Philip's City." In the 1st century the Romans Philippopolis or Trimitricium became the capital of Thrace; and, even after its capture by the Goths, when 100,000 persons are said to have been slain, it continued to be a flourishing city till it was again sacked by the Bulgarians in 1205. It passed under Turkish rule in 1363; in 1818 it was destroyed by an earthquake; and in 1846 it suffered from a severe conflagration. During the war of 1877–78 the city was occupied by the Russians (see also BULGARIA: History).

PHILIPSBURG, a town of Germany, in the grand duchy of Baden, situated on a sluggish arm of the Rhine, 15 m. N. of Karlsruhe, on the railway Bruchsal–Germersheim. Pop. (1905) 2625. It has manufactures of tobacco and cigars, and some trade in cattle and hops. Philipsburg, formerly an imperial fortress, originally belonged to the ecclesiastical principality of Spires, and was named Udenheim. In 1338 it was surrounded with walls by bishop Gerhard. A later bishop of Spire, Philipp Christoph von Sötter, made the place his residence early in the 17th century, strengthened the fortifications, and renamed it Philippsburg after himself. At the peace of Westphalia in 1648 the French remained in possession of the town, but in 1670 it was restored to Germany, and though again captured by the French in 1688 it was once more restored in 1697. In 1734 the Gallican clergy fell an easy prey to the French under Marshal Berwick, but never lost his life beneath its walls. It was restored to Germany in 1735, and was again besieged by the French in 1799. The town was assigned to Baden in 1863.

See Nopp, Geschichte der Stiid Philippsburg (Philippsburg, 1881).
PHILIPPIUS, MARCUS JULIUS, Roman emperor A.D. 244 to 249, often called "Philip the Arab," was a native of Bostra in Arabia Trachonitis. Having entered the Roman army, he rose to be praetorian prefect in the Persian campaign of Gordian III, and, incurring the soldiers' enmity, the young emperor was raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248, when Rome was supposed to have reached the thousandth year of her existence. A rebellion broke out among the legions of Moesia, and Decius, who was sent to quell it, was forced by the troops to put himself at their head and march upon Italy. Philip was defeated and slain in a battle near Verona. According to Christian writers, he was a convert to Christianity.

Seneca: Aurelius Victor, Cæsares, 28; Eutropius, ix. 3; Zonaras, xii. 19.

PHILIPPS, AMBROSE (c. 1675-1740), English poet, born in Shropshire of a Leicestershire family. He was educated at Shrewsbury school and St John's College, Cambridge, of which he became a fellow in 1709. He seems to have lived chiefly at Cambridge until he resigned his fellowship in 1708, and his pastorals probably belong to this period. He worked for Jacob Tonson the bookseller, and his Pastoral has opened the 6th volume of Tonson's Miscellanea (1709), which also contained the pastorals of Philips and Wogan. As a stage writer, he was a friend of Steele and Addison. In Nos. 22, 23, 30 and 32 (1713) of the Guardian he was injudiciously praised as the only worthy successor of Spenser. The writer of the papers, who is supposed to have been Thomas Tickell, pointedly ignored Philips's pastorals. In the Spectator Addison applauded him for his simplicity, and for having written English eclogues unencumbered by the machinery of classical mythology. Pope's jealousy was roused, and he sent an anonymous contribution to the Guardian (No. 40) in which he drew an ironical comparison between his own and Philip's pastorals, censuring himself and praising Philips's worst passages. Philips is said to have threatened to have Pope with a rod he kept up at his cottage at Button's coffee-house for the purpose. It was at Pope's request that Gay burlesqued Philips's pastorals in his Shepherd's Week, but the parody pleased by the very quality of simplicity which it was intended to ridicule. Samuel Johnson describes the relations between Pope and Philips as a "perpetual reciprocation of malvolence." Pope lost no opportunity of scoffing at Philips, who figured in the Bathos and the Dunciad, as Maier in the Characters; and in the "Instructions to a Porter how to find Mr. Curl's authors" he is a "Pindaric writer in red stockings." In 1718 he started a Whig paper, The Freethinker, in conjunction with Hugh Boulter, then vicar of St Olave's, Southwark. He had been made judge of the police at Westminster, and was commissioner for the lottery, and when Boulter was made archbishop of Armagh, Philips accompanied him as secretary. He sat in the Irish parliament for Co. Armagh, was secretary to the lord chancellor in 1726, and in 1733 became a judge of the prerogative court. His patron died in 1742, and six years later Philips returned to London, where he died on the 18th of June 1749.

His contemporary reputation rested on his pastorals and epistles, particularly the description of winter addressed by him from Copenhagen (1700) to the earl of Dorset. In T. H. Ward's English Poets, however, he is represented by two of the simple and charming pieces addressed to the infant children of Lord Carteret and of Daniel Defoe. These were抄袭ed by Swift as "little flams on Miss Carteret," and earned for Philips from Henry Carey the nickname of "Namby-Pamby." Philips's works are an abridgment of Bishop Hacket's Life of John Williams (1700); The Thousand and One Days; Persian Tales . . . . (1722), from the French of P. Téles de la Croix; three pastorals-The Harlot and the Knave (1712), an adaptation of Racine's Andromaque; The Briton (1722); Humphrey, duke of Gloucester (1723). Many of his poems, which included some translations from Sappho, Anacreon and Pindar, were published separately, and a collected edition appeared in 1748.

PHILIPPS, JOHN (1676-1708), English poet and man of letters, son of Dr Stephen Philips, archdeacon of Shropshire, was born at his father's vicarage at Bampton, Oxfordshire, on the 30th of December 1676. He was educated at Winchester and Christ Church, Oxford. He was a careful reader of Virgil and of Milton. In 1701 his poem, The Splendid Shilling, was published without his consent, and a second unauthorized version in 1705 induced him to print a correct edition in that year. The Splendid Shilling, which Addison in The Tatler called "the finest burlesque poem in the British language," recites in Miltonian blank verse the miseries consequent on the want of that piece of money. Its success introduced Philips to the notice of Robert Harley and Henry St John, who commissioned him to write a Tory counterblast to Joseph Addison's Campaign. Philips was happier in burlesquing his favourite author than in genuine imitation of a heroic theme. His Marlborough is modelled on the warriors of Homer and Virgil; he rides precipitate over heaps of fallen horses, changing the fortune of the battle by his own right arm. Cyder (1708) is modelled on the Georgics of Virgil. Cerises, as early as the writing of Mining and Metallurgy, which bears his name, may safely be ascribed to him. In all his poems except Blankheim he found an opportunity to insert a eulogy of tobacco. Philips died at Hereford on the 15th of February 1708/9. There is an inscription to his memory in Westminster Abbey.

See The Whole Works of . . . John Philips . . . To which is prefixed his life, by Mr (G.) Sewell (3rd ed., 1720); Johnson, Lives of the Poets; and Biographia Britannica.

PHILIPS, KATHARINE (1631-1664), English poet, daughter of John Fowler, a merchant of Bucklersbury, London, was born on the 1st of January 1631. Her father was a Presbyterian, and Katharine is said to have read the Bible through before she was five years old. On arriving at years of discretion she entered with Presbyterian traditions in both religion and politics, became an ardent admirer of the king and his church policy, and in 1647 married James Philips, a Welsh royalist. Her home at the Priory, Cardigan, became the centre of a "society of friendship," the members of which were known to one another by fantastic names, Mrs Philips being "Orinda," her husband "Antenor," Sir Charles Cotterel "Policarchus." The "matchless" Orinda, as her admirers called her, posed as the apostle of female friendship. That there was much solid worth under her affectations is proved by the respect and friendship she inspired. Jeremy Taylor in 1659 dedicated to her his Discourse on the Nature, Offices and Measures of Friendship, and Cowley, Henry Vaughan the Silurist, the earl of Roscommon and the earl of Cork and Orrery all celebrated her talent. In 1663 she went to Dublin to pursue her husband's claim to certain Irish estates, and there she completed a translation of Cornelle's Poumè, produced with great success in 1663 in the Smock Alley Theatre, and printed in the same year both in Dublin and London. She went to London in March 1664 with a nearly completed translation of Cornelle's Horace, but died of smallpox on the 22nd of June. The literary atmosphere of her circle is preserved in the excellent Letters of Orinda to Policarchus, published by Bernard Libert in 1705 and 1709. "Policarchus" (Sir Charles Cotterel) was master of the ceremonies at the court of the Restoration, and afterwards translated the romances of La Calprenède. Mrs Philips had two children, one of whom, Katharine, became the wife of Lewis Wogan of Boulston, Pembrokeshire. According to Mr Gosse, this lady may have been "Joan Philips," the author of a volume of Female Poems . . . written by Ephelia, which are in the style of Orinda, and display genuine feeling with very little reserve.

PHILISTINES,1 the general name for the people of Philistia (Ass. Palašu, Pilišu; Eg. P-r-s-l), a district embracing the rich lowlands on the Mediterranean coast from the neighbourhood

1 "Philistine," as a term of contempt, hostility or reproach, appears first in English, in a sense equivalent to "the enemy," as early as the beginning of the 17th century, and later as a long term for a bailiff or a sheriff's officer, or merely for drunken or vicious people generally. In German universities the townsfolk
of Jaffa (Joppa) to the Egyptian desert south of Gaza (on the subsequent extension of the name in its Greek form Palaestina, see PALESTINE).

1. **Egyptian Evidence.**—The name is derived from the Purasati, one of a great confederation from north Syria, Asia Minor and the Levant, which threatened Egypt in the XXth Dynasty. They are not among the hordes enumerated by Ramessess II, Mentuhotep, Horemheb, Year of Ramsess III (c. 1200-1190) the Purasati hold a prominent place in a widespread movement on land and sea. The Syrian states were overwhelmed and the advance upon Egypt seemed irresistible. Ramesseus, however, collected a large fleet and an army of native troops and mercenaries and claimed decisive victories. The Egyptian monuments depict the flight of the enemy, the heavy ox-carts with their women and children, and the confusion of their ships. But the sequel of the events is not certain. Even if the increasing weakness of the Egyptian Empire did not invite a repetition of the incursion, it could have allowed the survivors to settle down, and about a century later one of the peoples formerly closely allied with the Purasati is found strongly entrenched at Dor, and together with the more northerly port of Byblos treats with scant respect the traditional suzerainty of Egypt.†

That some definite political changes ensued in this age have been inferred on other grounds, and the identification of the Purasati with the Philistines may permit the assumption that the latter succeeded in occupying the district with which they have always been associated.

The Egyptian monuments represent the Purasati with a very distinctive feather head-dress resembling that of the Lydians and Mycenaens. Their general physiognomy is hardly Cilician or Hittite, but European. Their arms comprise two short swords, a longer spear, a round shield, and they sometimes wear a coat of mail; a curious feature is their tactics of fighting in a circle of protecting shields. The chariotis resemble the Hittite with two crossed receptacles for the weapons, but obviously these were not used by the Purasati alone. On archaeological grounds the Purasati have been connected with the people of Keftu, i.e. Mycenaens of Crete, although a wider application of this term is not to be excluded.

2. **History.**—Biblical tradition, too, has recognized the Philistines as immigrants from Caphtor (Amos ix. 7). They appear in the pre-Mosaic age (Gen. xxi. 32, 34, xxvi.), at the Exodus of the Israelites (Ex. xii. 17, xv. 14), and the invasion of Palestine. They are represented as a confederation of five cities (Ashdod, Ascalon [Ashkelon], Ekron, Gath and Gaza) which remained unconquered (Joshua xii. 2 sqq.; Judges iii. 5; compare Joshua xv. 45-47, xix. 43). The institution of the Hebrew monarchy (c. 1000 B.C.) followed upon periods of Philistine oppression (Judges iii. 31, x. 7, xi. xiii. 1-5; see SAMSON; ELIJAH; SAMUEL; SAUL; DAVID). The subjugation of them is ascribed to the ancient peoples of the Philistia; they were "outsiders," the enemy of the chosen people. It is supposed that this use arose in 1693 in Jena after a "town and gown" row in which a student had been killed and a sermon preached on the text "the Philistines be nevereh the Lord's people" (see Quarterly Review April 1899, 435, quoted in the New English Dictionary). "Philistine" thus became the name of contempt applied by the cultured to those whom they considered as thick-skinned in intellect and taste, and was first so used in English by Carlyle, and Matthew Arnold (Essays in Criticism; "Heinrich Heine," 1865) gave the word its vogue and its final connotation, as signifying "inaccessible to and impatient of instruction."

1 So the Papyrus first published by W. Golénischeff (Rec. de travaux, xxi. 74 sqq.), on which see A. Erman, Zeit. f. egypt. Sprache, pp. 1-14 (1900); W. M. Müller, Mittell, d. vordeutschen, Gezel, pp. 14 sqq. (1900); J. H. Breasted, *Hist. of Egyp*, pp. 513 sqq.; Historical Records, i. 274 sqq.; H. W. Hogg, in the Theolog. Series i. of the publications of university of Manchester, p. 90 sqq.

2 See G. A. Smith, *Dict. of the Holy Land*, chs. ix. seq.; and M. A. Meyer, *History of the City of Gaza* (New York, 1907). For the traditions associating Gaza with Crete, see the latter, Index, 9 B. Minos: the resemblance between the Minoans of South Albania and Cretan Philistines "is too striking to be dismissed for all kinds of speculations, ancient (Plinei vi. 157) and modern."

3 Between the central Judaean plateau and the latter lay the *Iaphetians* (Šophēphāl), a district open equally to Judeans and Philistines alike.

4 Cf. Gaza and Edom against Judah in Amos i. 6, and, for the part played by Damascus, the latter vicissitudes under the Nabataeans (Josephus, *Ant.* xi. 3-5). It is difficult to date the alliance of Syria and Philistia against Israel in Isa. ix. 11 seq. (on the text, see the commentaries).
of the coast and, descending from Sidon, took Jaffa, Beth-dagon, Benebalak, Ekron and Timnah (all in the district ascribed to the southern Dan). At Eltekeh (also in Dan) the allies were defeated. Farther south came the turn of Ascalon, Lachish, Lihnah. Judah under Hezekiah suffered severely, and its western cities were transferred to the faithful vassals of Ekron, Ashdod and Gaza. The immediate subsequent events are obscure (see further HEZEKIAH). In the 7th century Gaza, Ascalon, Ashdod and Ekron were Assyrian vassals, together with Judah, Moab and Edom—in all, twenty-two kings of the "Hittites"—and the discovery of Assyrian contract-tablets at Gezer (c. 650) may indicate the presence of Assyrian garrisons. But as the Assyrian power declined Egyptian monarchs formed plans of aggrandizement. Herodotus mentions the Assyrian invasion and sacking the temple of Aphrodite Urania (Astarte) at Ascalon, also the pre-empted siege of Ashdod and Lachish by Pharaoh Pharaoh Psamtik I (wpty, 3), after the occupation of Kadytos (7 Gaza) by Necho (i. 105, ii. 157 seq., iii. 5). But the Babylonian Empire followed upon traditional lines and thrust back Egypt, and Nabonidus (553 B.C.) claims his vassals as far as Gaza. The Persians took over the realm of their predecessors, and Gaza grew in importance as a seat of international commerce. Nehemiah speaks not of Philistines, but of Ashdodites (iv. 7), speaking an "Ashdoide" dialect (xii. 24); just as Strabo regards the Jews, the Idumaeans, the Gazans and the Ashdodites as four cognate peoples having the common characteristic of combining agriculture with commerce. In southern Philistia at least, Arabian immigration became more pronounced. In the time of Cambyses Arabs were settled at Jenyos south of Gaza (Herod. iii. 5), and when Alexander marched upon Egypt, Gaza with its army of Arabs and Persians offered a strenuous resistance. Recent discoveries near Tell Sandahannah (or Marashah) have revealed the presence of North Arabian (Edomite) names about the 2nd century B.C.1 On the history of the district see further JEWS; MACCABEES.

3. Philistine Traditions. The interdependence of the south Palestinian peoples follows from geographical conditions which are unchangeable, and the fuller light thrown upon the last decades of the 8th century B.C. illuminates the more fragmentary evidence elsewhere.2 Hence the two sieges of the Philistine Gibbethon by the Israelites (above) obviously have some significance for Judaean history, but the Judaean annals unfortunately afford no help (see AS). Again, the Aramaean attack upon Israel by Hazael of Damascus leads to the capture of Gath (2 Kings xii. 17), and this, together with the statement that he took "the Philistines" from Jehoshah of Israel (ibid. xiii. 22, Lucian's recension), bears upon Judah, but the statements are isolated. Somewhat later, the Assyrian king Adad-nirari IV claimed tribute from Edom, Philistia and Beth-Omri (the Israelite kingdom); the curious omission of Judah has suggested that it was then included with the second or third of these (see JEWS, § 12). The Philistines naturally had a prominent place in popular tradition, and the story of Isaac and the Philistine Abimelech (Gen. xxvii., cf. xxi. 32) is of great interest for its unbiased representation of intercourse, enmity, alliance and covenant. But it is important to notice that a parallel story (xx.) is without this distinctive Philistine background, and this variation is significant. One account of the Israelite invasion conceived a conquest of earlier giant inhabitants (Anâkmim) who survived in Gaza, Gath and Ashdod (Joshua xii. 21 seq., contrast xiii. 3), but were driven out from Hebron by Caleb (Joshua xv. 14, cf. Num. xiii. 22, 28). The Philistines themselves are called the remnant of the Anâkmim (Jer. xvii. 5; so the Septuagint), or as Caphtorim replace the earlier Avvim (Deut. ii. 23, see Joshua xiii. 3). Samuel's great defeat of the Philistines leads to "peace between Israel and the Amorites" (1 Sam. vii. 14); and the migration of the Danites is placed after the conflict with the Philistines (Judges xiv. 19 seq.), perhaps as due to the pressure of Amorites (i. 34). Even in David's fights with the Philistines in Judah, Jerusalem is Jебusite, neighbouring non-Israelite cities are Hivite or Amorite (Joshua ix. 7, 2 Sam. xxi. 2), and his strange adversaries find a close parallel in the semi-mythical sons of Anak (2 Sam. xxi. 16, 18, 20, 22). This fluctuation, due partly to the different circles in which the biblical narratives took shape, and partly to desiring reshaping of the traditions of the past, seriously complicates all attempts to combine the early history of Israel with the external evidence. The history of the Philistine district goes back long before the time of the Purasati (c. 1200 B.C.), and if the references to conflict with the Philistines (Nehemiah xiii. 21 seq.) are not as anachronisms, those which can be applied to the 12th-11th century do not at once acquire a historical value.3 The references of the time of the Exodus, the Invasion and the "Judges"—whatever chronological scheme be adopted—must be taken in connexion with a careful examination of all the evidence. It is inherently not improbable that a recollection has been preserved of Philistine oppressions in the 11th century, but it is extremely difficult to sketch any adequate sequence of events, and among the conflicting traditions are situations equally applicable to later periods of hostility. Biblical history has presented its own views of the Israelite and Philistine relations, and its emphasis on the continuing power of Judah and the Philistines, who, while building up their independent kingdom, were the representatives of the north and south, respectively. As such they came into conflict with the Judaeans in the days of Samuel and later, even in his reign, made an expedition, not against the Purasati, but into North Syria, and, as appears from the Papyrus Harris, restored Egyptian supremacy over Palestine and Syria. Upon the (incomplete) external evidence and upon a careful criticism of the biblical history of this period, and not upon any promiscuous combination of the two sources, must depend the value of the plausible though broad reconstructions which have been proposed.4

Considerable stress is often laid upon Goliath's armour of bronze and his iron weapon, but even David himself has helmet, sword and coat-of-mail at his disposal (1 Sam. xviii.), and suits of armour had already been taken from Mesopotamia by Tethys II. Chariots of iron are ascribed to the Canaanites (Joshua xvii. 16, 18, Judges i. 19, iv. 3); but if early references to iron are treated as unhistorical (Gen. iv. 22, Num. xxxii. 22, xxvii. 16, Deut. iv. 20, viii. 9, xix. 5, xxvii. 5, xxviii. 48, xxxii. 25, Joshua vi. 19, 24) Goliath's iron spear-head must be judged together with the whole narrative in the light of a consistent historical criticism.5

1 The inhabitants of Ascalon besieged by Rameses II, are represented as Hittites. For an attempt to treat the pre-Mosaic references as historical, see A. Alt, Israel u. Aegypten, pp. 10-36 (Leipzig, 1909). It would be unsafe to infer much from the Eng. reference to the "passenger (empty, meaning ambiguous)" of Canaan and Philistia (Bull. Mus. Cairo, i. 98).
4. Conclusions.—The Philistines appear in the Old Testament as a Semitic or at least a thoroughly Semitized people. Their proper names show that before and even during the Persian age their languages differed only dialectically from Hebrew. Among the exceptions must be reckoned Achish (Sept. εἰκος), with which has been compared Ikaua, a king of Ekron (7th century) and the “Keltian” name Akhasso of the XIXth Egyptian dynasty. Names in -atḥ (Goliath, Ahazuth, Gen. xxvi.) are not restricted to Philistines, and Philo (ibid.) is too obscure to serve as evidence. The religion is not novel. The male god Dagon has his partner Astarte (qq.v.), and Baal-zebub, a famous oracle of Ekron (2 Kings i) finds a parallel in the local “baals” of Palestine. Even when the region seems to be completely Hellenized after the Persian age, it is not so certain that Greek culture pervaded all classes (see G. F. Moore, Ency. Bib. col. 3526), although a certain amount of foreign influence probably made itself felt upon the coast-towns at all times. The use of the term ἀλαβάστρον in Maccabean and later writings (cf. the contemptuous hatred of Ben Sira, Ecclesiasticus i. 26, and the author of Jubilees xxiv. 30 sqq.) correctly expresses the conditions of the Greek age and the Maccabean wars, and naturally any allusion to the situations of many centuries previously is quite unnecessary. Similarly, the biblical evidence represents the traditions in the form which they had reached in the writer’s time, the true date of which is often uncertain. Antagonism between Philistines and Israelites was not a persisting feature, and, although the former are styled “uncircumcised” (chiefly in the stories in the book of Samuel), the term gained new force when the expulsion of uncircumcised aliens from the sanctuary of Jerusalem was proclaimed in the writings ascribed to Ezekiel (ch. xliv.).

In fact the question arises whether the history of the Philistines is not that of a territorial designation, rather than that of the lineal descendants of the Purasati, who, if one of the peoples who took part in the events of the XXth Dynasty, may well have bequeathed their name. The Mediterranean coast-land was always exposed to incursions of aliens, and when Carians appear as royal and temple guards at Jerusalem (2 Kings xi. 4), it is sufficient to recall old Greek traditions of a Carian sea-power and relations between Philistia and Greek lands.² Even the presence of Carians and Ionians in the time of Psammetichus I. may be accounted for by these incursions. It is noteworthy that this is also closely associated with a Jewish colony (viz. Taanahes, Jer. xxxii. seq.). Although the Purasati appear after the 15th-14th centuries, now illuminated by the Amarna tablets, their own history is perhaps earlier.¹ But there is no reason at present to believe that their entrance caused any break in the archaeological history. The apparently “Aegean” influence which enters into the general “Amarna” period seems to begin before the age of the Amarna tablets (at Lachish), and it passes gradually into later phases contemporary with the

See further, F. Schwally, Zett. Wiss. Theol. xxxiv. 103–108. A few Hebrew words have been regarded as Philistine loan-words, so notably pilgelsh, “concubine” (παλαβάστρον, παλαβάστρωτος, Lat. pelluc), and seren (σέρον) the title applied to the five lords of the Philistine confederacy in Phil. xxxv. 24, and may have been metaphorically linked with the Arab. kāptar (W. R. Smith, Biblical proper names, p. 108), another word, a common origin in Asia Minor is also possible for these words.

¹ In the prophetical writings the Philistines are denominated (with Ammon, Moab and Edom) for their vengeance upon Judah (Ezek. xxv. 15–17). With Tyre and Sidon they are condemned for plundering Judah, and for kidnapping its children to sell to the Greeks (Ezek. xxvi. 1 ff., 19 sqq.; 30 sqq.), and a remnant of the Philistines may become worshippers of Yahweh (Zech. ix. 7). The historical backgrounds of these passages are disputed. See L. Myres, Journal of Hellenistic Studies, xxxvi. 84 sqq. (1906); especially 197 sqq.

² This is suggested by the recent discovery at Phæastes in Crete of a disk with evidence for a native script; see A. J. Evans, Scripta Minoea (Oxford, 1909), pp. 22 seq.; E. Meyer, Jahresberichte of the Berlin Academy for the 214 of October 1909.

Israelite monarchy. There is a fairly continuous intercourse with external culture (Cyproite, early and late Greek), and, if Gath be identified with Tel eš-Săhā, Blas and Macalister, who excavated it, found no trace of any interruption in its history. Only at Gezer—perhaps Philistia, 2 Sam. v. 25—has there been found evidence for a strange race with several distinctive features. The brick signs, not discovered on sites within the country, but in unusually fine character and comprised slive, alabaster and even iron. The culture appears to find Carian and Lydian parallels, and has been ascribed provisionally to the 13th–14th centuries. So far, however, of the cities lying within or immediately exposed to Philistine influence, the discoveries at Gezer are unique.³ According to the biblical traditions the Philistines are the remnant of Caphtor (Jer. xi. vii. 4, Amos ix. 7), and the Capḥōrīm took up the Avva from Gaza and district, as the Horites and Rephaim were displaced by Edom and Ammon (Deut. ii. 23). These Capḥōrīm, together with Ludim (Lydians) and other petty peoples, apparently of the Delta, are once reckoned to Egypt (Gen. x. 14).⁴ By Capḥor the Septuagint sometimes understood Cappadocia, which indeed may be valid for its age, but the name is to be identified with the Egyptian K(a)ptar, which in later Ptolemaic times seems to mean Phoenicia, although ḫēṭīnu had had another connotation. The Cherethites, associated with the Philistine district (1 Sam. xxx. 14, 16, Ezek. xxv. 16, Zeph. ii. 5 seq.), are sometimes recognized by the Septuagint as Cretans, and, with the Pelethites (often taken to be a rhyming form of Philistines), they form part of the royal body-guard of Judaean kings (2 Sam. viii. 18, xv. 22, xv. 7, 1 Kings i. 38, 44; in 2 Sam. xx. 23 the Hebrew text has Carites). However adequate these identifications may seem, the persistence of an independent clan or tribe of Cherethites-Cretans to the close of the 7th century would imply an unbroken chain of nearly six hundred years, unless, as is inherently more probable, later immigrations had occurred within the interval. But upon the ethological relations either of the south Palestinian coast or of the Delta it would be unsafe to dogmatize. So far as can be ascertained, then, the first mention of the Philistines belongs to an age of disturbance and change in connexion with movements in Asia Minor. Archaeological evidence for their influence has indeed been adduced, but it is certain that some agents were at work in the interval by land from North Syria and Asia Minor. The influences, whether from the Levant or from the north, were not confined to the age of Rameses III. alone, and the biblical evidence, especially, while possibly preserving some recollection of the invasion of the Purasati, is in every case late and may be shaped by later historical vicissitudes. It is impossible that Palestine should have remained untouched by the external movements in connexion with the Delta, the Levant and Asia Minor, and it is possible that the course of internal history in the age immediately before and after 1000 B.C. ran upon lines different from the detailed popular religious traditions which the biblical historians have employed. See further Palestine: History.

For older studies, see F. Hitzig, Urgeschichte der Philister (1845), with the theory of the Peloponnesian origin of the Philistines; K. Stark, Gasa u. d. philist. Käste (1852), and with special reference to earlier theories W. Robertson Smith’s art. in Encyc. Brit., 9th ed. (S. A. C.)

PHILISTUS, Greek historian of Sicily, was born at Syracuse about the beginning of the Peloponnesian War (432 B.C.?). He was a faithful supporter of the elder Dionysius, and commander

⁴ Also wo. may be a secondary notion “written from specially intimate acquaintance with the (later?) Egyptian geography” (J. Skinner, Genesis, p. 214).

⁵ See D. G. Hogarth, Ionia and the East, pp. 28 seq. (Oxford, 1909); Evans, Scripta Minoea, pp. 77 seq.
of the citadel. In 386 he excited the jealousy of the tyrant by secretly marrying his niece, and was sent into banishment. He settled at Thrull, but afterwards returned to Adria, where he remained until the death of Dionysus (366). He was then recalled by the younger Dionysus, whom he persuaded to dismiss Plato and Dion. When Dion set sail from Zacynthus with the object of liberating Syracuse from the tyrannis, Philistus was entrusted with the command of the fleet, but he was defeated and put to death (356). During his stay at Adria, Philistus occupied himself with the composition of his Σκαλακά, a history of Sicily in eleven books. The first part (bk. i.-vii.) comprised the history of the island from the earliest times to the capture of Agrigentum by the Carthaginians (406); the second, the history of the elder and the younger Agesilaus (till 363). From this point the work was carried on by Philistus's fellow-countryman Athanas. Cicero (ad. Q. Fr. ii. 13), who had a high opinion of his work, calls him the miniature Thucydidies " (πειστίλιον Θυκειδίδης). He was admitted by the Alexandrian critics into the canon of historiographers, and his work was highly valued by Alexander the Great.

Müller, Fragmenta historiorum graecorum, vol. i. (1841); C. Wachsmuth, Einleitung in das Studium der alten Geschichte (1845); E. A. Freeman, History of Sicily (1861-1865); John Phillips, Sicilius (1870-1876).

PHILLIP, a town of British India, in Jullundur district, Panjab, on the north bank of the river Sutlej, 8 m. N. of Ludhiana. Pop. (1901), 6,065. Founded by the Mogul emperor Shah Jahan, it was long of importance as commanding the crossing of the Sutlej. At the Mutiny in 1857 the fort contained the siege train, which was sent safely to Delhi; but the sepoys regiment in the cantonment shortly afterwards mutinied and escaped. The fort is now occupied by the police training school and the central bureau of the criminal identification department.

PHILLIMORE, SIR ROBERT JOSEPH (1816-1885), English judge, third son of a well-known ecclesiastical lawyer, Dr Joseph Phillimore, was born at Whitcliff on the 3rd of November 1816. Educated at Westminster and Christ Church, Oxford, where he had the lasting friendship with W. E. Gladstone began, his first appointment was to a clerkship in the board of control, where he remained from 1832 to 1835. Admitted as an advocate at Doctors' Commons in 1839, he was called to the bar at the Middle Temple in 1841, and rose very rapidly in his profession. He was engaged as counsel in almost every case of importance that came before the admiralty, probate or divorce courts, and became successively master of faculties, comissary of the deans and chapters of Middlesex and Westminster, official of the archdeacons of Middlesex and London, and chancellor of the dioceses of Chichester and Salisbury. In 1833 he entered parliament as member for Tavistock. A moderate in politics, his energies were devoted to non-party measures, and in 1854 he introduced the bill for allowing viva voce evidence in the ecclesiastical courts. He sat for Tavistock until 1857, when he offered himself as a candidate for Coventry, but was defeated. He was appointed judge of the Cinque Ports in 1855, Queen's Counsel in 1858, and advocate-general in admiralty in 1862, and succeeded Dr Stephen Lushington (1782-1875) as judge of the court of arches five years later. Here his care, patience and courtesy, combined with unusual lucidity of expression, won general respect. In 1875, in accordance with the Public Worship Regulation Act, he resigned, and was succeeded by Lord Penzance. When the Judicature Act came into force the powers of the admiralty court were transferred to the High Court of Justice, and Sir Robert Phillimore was therefore the last judge of the admiralty court of the lord high admiral of England. He continued to sit as judge for the new admiralty, probate and divorce division until 1883, when he resigned. He wrote Ecclesiastical Law of the Church of England, a book which still holds its ground, Commentaries on International Law, and a translation of Lessing's Laocoon. He married, in 1844, Charlotte Anne, daughter of John Denison of Ossington Hall, Newark. He was knighted in 1862, and created a baronet in 1881. He died at Shiplake, near Henley-on-Thames, on the 4th of February 1885. His eldest son, Sir Walter G. F. Phillimore (b. 1845), also distinguished as an authority on ecclesiastical law and admiralty law, became in 1897 a judge of the high court.

PHILLIP, JOHN (1817-1867), Scottish painter, was born at Aberdeen, Scotland, on the 10th of April 1817. His father, an old soldier, was in humble circumstances, and the son became an errand-boy to a tinsmith, and was then apprenticed to a painter and glazier. Having received some technical instruction from a local artist named William Mercer, he began, at the age of about fifteen, to paint portraits. In 1834 he made a very brief visit to London. About this time he became assistant to James Forbes, an Aberdeen portrait-painter. He had already gained a valuable patron. Having been sent to repair a window in the church of Mauthen, painted by C. F. Barlow, an art in the house attracted the attention of their owner. Gordon brought the young artist under the notice of Lord Panmure, who in 1836 sent him to London, promising to bear the cost of his art education. At first Phillip was placed under T. M. Joy, but he soon entered the schools of the Royal Academy. In 1839 he figured for the first time in the royal academy exhibition with a portrait and a landscape, and in the following year he was represented by a more ambitious figure-picture of "Tasso in Disguise relating his Persecutions to his Sister." For the next ten years he supported himself mainly by portraiture and by painting subjects of national incident, such as "The Scottish Catechizing," "Bannockburn," "Scotland's全国ische Gesange," and the "Vespasian." His productions at this period, as well as his earlier subject-pictures, are reminiscent of the practice and methods of Wilkie and the Scottish genre-painters of his time. In 1851 his health showed signs of delicacy, and he went to Spain in search of a warmer climate. He was brought face to face for the first time with the brilliant sunshine and the splendid colour of the south, and it was in coping with these that he first manifested his artistic individuality and finally displayed his full powers. In the "Letter-writer of Seville" (1854), commissioned by Queen Victoria at the suggestion of Sir Edwin Landseer, the artist is struggling with new difficulties in the portrayal of unpolished splendours of colour and light. In 1857 Phillip was elected an associate of the Royal Academy, and in 1859 a full member. In 1855 and in 1860 further visits to Spain were made, and in each case the painter returned with fresh materials to be embodied with increasing power and subtlety in the long series of works which won for him the title of "Spanish Phillip." His highest point of execution is probably reached in "La Gloria" (1864) and a smaller single-figure painting of the same period entitled "El Cigarillo." These Spanish subjects were varied in 1860 by a rendering of the marriage of the princess royal with the crown prince of Prussia, executed by command of the queen, and in 1865 by a picture of the House of Commons. During his last visit to Spain Phillip occupied himself in a careful study of the art of Velazquez, and the copies which he made fetched large prices after his death, examples having been secured by the royal and the royal Scottish academies. The year before his death he visited Italy and devoted attention to the works of Titian. The results of this study of the old masters are visible in such works as "La Loteria Nacional," "left uncompleted at his death. During this period he resided much in the Highlands, and seemed to be returning to his first love for Scottish subjects, painting several national scenes, and planning others that were never completed. He died in London on the 27th of February 1867.

His works were collected in the International Exhibition of 1873, and many of them are engraved by T. Oldham Barlow. In addition to the paintings already specified the following are among the more important: "Life among the Gipsies of Seville" (1843); "El Paseo" (1855); "Collection of the Officery in a Scotch Kirk" (1855); "A Gipsy Water-carrier in Seville" (1856). "The Prayer of Faith shall save the Sick" (1856); "The Dying Contrabandist" (1856); "The Prison Window" (1857); "A Huff" (1859); "Early Career of Murillo" (1865); "A Chat round the Braser" (1866).

PHILLIPS, ADELAIDE (1833-1882), American contralto singer, was born at Stratford-on-Avon, England, her family emigrating to America in 1840. Her mother taught dancing,
PHILLIPS, E. — PHILLIPS, S.

and Adelaide began a career on the Boston stage at ten years old. But in 1850 her talent for singing became evident, and through Jenny Lind and others she was sent to London and to Italy to study. In 1855 she returned to America an accomplished vocalist; and for many years she was the leading American contralto, equally successful in oratorio and on the concert platform. She died at Carlshad on the 3rd of October 1883.

PHILLIPS, EDWARD (1630-1696), English author, son of Edward Phillips of the crown office in chancery, and his wife Anne, only sister of John Milton, the poet, was born in August 1630 in the Strand, London. His father died in 1631, and Anne Phillips eventually married her husband's successor in the crown office, Thomas Agar. Edward Phillips and his younger brother, John, were educated by Milton. Edward entered Magdalen Hall, Oxford, in November 1650, but left the university in 1651 to be a bookseller's clerk in London. Although he entirely differed from Milton in his religious and political views, and seems, to judge from the free character of his Mysteries of Love and Eloquence (1658), to have undergone a certain revulsion from his Puritan upbringing, he remained on affectionate terms with his uncle to the end. He was tutor to the son of John Evelyn, the diarist, from 1663 to 1672 at Sayes Court, near Deptford, and in 1677-1679 in the family of Henry Bennet, earl of Arlington. The date of his death is unknown, but his last book is dated 1696.

His most important work is Theatrum poëtarum (1659), a list of the English poets and their countries, but especially of the English poets, with short critical notes and a prefatory Discourse of the Poets and Poetry, which has usually been traced to Milton's hand. He also wrote A New World in Words, or a General Dictionary (1658), which went through many editions; a new edition of Baker's Chronicle, of which the section on the period from 1650 to 1658 was written by himself from the royalist standpoint; a supplement (1676) to John Speed's Theatre of Great Britain; and in 1664 Enchiridion linguæ latinæ, said to have been taken chiefly from notes prepared by Milton. Aubrey states that all Milton's papers came into Phillips's hands, and in 1694 he published a translation of the poetarum edition of 1718.

His brother, John Phillips (1631-1706), in 1652 published a Latin reply to the anonymous attack on Milton entitled Pro Rege et populo anglicano. He appears to have acted as unofficial secretary to Milton, but, disappointed of regular political employment, and chafing against the discipline he was under, he published in 1655 a bitter attack on Puritanism entitled a Satyr against Hypocrity (1655). In 1656 he was summoned before the privy council for his share in a book of licentious poems, Sportive Wit, which was suppressed by the authorities but almost immediately replaced by a similar collection, Wit and Drollery. In Montesquieu (1660) he ridiculed the astrological almanacs of William Lilly. Two other skits of this name, in 1665 and 1666, also full of course royalist wit, were probably by another hand. In 1678 he supported the agitation of Titus Oates, writing on his behalf, says Wood, "many lies and villanies." Dr Oates's Narrative of the Popish Plot indicated was the first of these tracts. He began a monthly historical review in 1688 entitled Modern History or a Monthly Account of all considerable Occurrences, Civil, Ecclesiastical and Military, followed in 1690 by The Present State of Europe, or a Historical and Political Mercury, which was supplemented by a preliminary volume giving a history of events from 1668. He executed many translations from the French, and a version (1687) of Don Quixote.

An extended, but by no means friendly, account of the brothers is given by Wood, Athen. axon. (ed. Bliss, iv. 764 seq.), where a long list of their works is dealt with. This formed the basis of William Godwin's Lives of Edward and John Phillips (1819), with which is reprinted Edward Phillips's Life of John Milton.

PHILLIPS, JOHN (1680-1784), English geologist, was born on the 7th of August 1680 at Marden in Wiltshire. His father belonged to an old Wiltshire family, but settled in England as an officer of excise and married the sister of William Smith, the "Father of English Geology." Both parents dying when he was a child, Phillips came under the charge of his uncle; and after being educated at various schools, he accompanied Smith on his wanderings in connexion with his geological maps. In the spring of 1824 Smith went to York to deliver a course of lectures on geology, and his nephew accompanied him. Phillips accepted engagements in the principal Yorkshire towns to arrange their museums and give courses of lectures on the collections contained therein. York became his residence, where he obtained, in 1825, the situation of keeper of the Yorkshire museum and of the York Philosophical Society. In 1824 he opened his own museum in a room which he extended his operations to towns beyond the county; and in 1831 he included University College, London, in the sphere of his activity. In that year the British Association for the Advancement of Science was founded at York, and Phillips was one of the active minds who organized its machinery. He became in 1832 the first assistant secretary, a post which he held until 1850. In 1834 he accepted the professorship of geology at King's College, London, but retained his post at York. In 1834 he was elected F.R.S.; in later years he received hon. degrees of LL.D. from Dublin and Cambridge, and D.C.L. from Oxford; while in 1843 he was awarded the Wollaston Medal by the Geological Society of London. In 1840 he resigned his charge of the York museum and was appointed on the staff of the geological survey of Great Britain under De la Beche. He spent some time in studying the Palaeozoic fossils of Devon, Cornwall and West Somerset, of which he published a descriptive memoir (1841); and he made a detailed survey of the region of the Malvern Hills, of which he prepared the elaborate account that appears in vol. ii. of the Memoirs of the Survey (1848). In 1844 he became professor of geology in the university of Oxford. Nine years later, on the death of H. E. Strickland, who had acted as substitute for Dean Buckland in the readership of geology in the university of Oxford, Phillips succeeded to the post of deputy, and in 1854 became himself reader, a post which he held to the time of his death. During his residence in Oxford he took a leading part in the foundation and arrangement of the new museum erected in 1859 (see his Notices of Rocks and Fossils in the University Museum, 1863; and The Oxford Museum, by H. W. Acland and J. Ruskin, 1859, reprinted with additions 1893). Phillips was also keeper of the Ashmolean museum from 1854-1870. In 1859-1860 he was president of the Geological Society of London, and in 1865 president of the British Association. He dined at All Souls College on the 23rd of April 1874, but on leaving he slipped and fell down a flight of stone stairs, and died on the following day.

From the time he wrote his first paper "On the Direction of the Double Doms" in 1828 (Phil. Trans. 1829), events in the later years of his life, Phillips continued a constant contributor to the literature of science. The pages of the Philosophical Magazine, the Journal of the Geological Society, the Geological Magazine and other publications testify to the valuable contributions of numerous separate works, which were of great benefit in extending a sound knowledge of geology. Among these may be specially mentioned: Illustrations of the Geology of Yorkshire (in two parts, 1829 and 1836; 2nd ed. of pt. i. in 1835, 3rd ed., edited by R. Etheridge, in 1875); A Treatise on Geology (1837-1839); Memoirs of William Smith (1844); The Rivers, Mountains and Sea-Coast of Yorkshire (1856); Manual of Geology, Practical and Theoretical (1855); Life on the Earth: Its Origin and Succession (1860); Vestiges (1869); Geology of Oxford and the Valley of the Thames (1871). To these should be added his Monograph of British Blemnitesidae (1866), founded on a monograph of the Geological Society, and his geological map of the British Isles (1847).

See Biographical Memoir, with portrait, in Geol. Mag. (July 1870).
PHILLIPS, S.—PHILLIPS, WENDELL

407

conferred upon him the honorary degree of LL.D. He died at Brighton on the 14th of October 1834.

PHILLIPS, STEPHEN (1806—1887), British poet and dramatist, was born on 21st July 1806, at Stourton near Oxford, the son of the Rev. Stephen Phillips, precentor of Peterborough Cathedral. He was educated at Stratford and Peterborough Grammar Schools, and entered Queen's College, Cambridge; but during his first term at Cambridge, when F. R. Benson's dramatic company visited the town, he joined it, and for six years played various small parts. In 1830 a slender volume of verse was published at Oxford with the title Primaveræ, which contained contributions by him and by his cousin Laurence Binyon and others. In 1835 he published Eremus, a long poem of loose structure in blank verse of a philosophically complexion. In 1836 appeared Christ in Hades, forming with a few other verses one of the slim paper-covered volumes of Elin Mathew's "Shilling Garland." This poem arrested the attention of watchful critics of poetry, and when it was followed by a collection of Poems in 1837 the writer's position as a new poet of exceptional gifts was generally recognized. This volume contained a new edition of "Christ in Hades," together with "Marpessa," "The Woman with the Dead Soul," "The Wife," and shorter pieces, including the fine lines "To Milton, Blind." The volume won the prize of £100 offered by the Academy newspaper for the best new book of its year, run through half a dozen editions in two years, and established Mr Phillips's rank as poet, which was sustained by the publication in the Nineteenth Century in 1898 of his poem "Endymion." George Alexander, the actor-manager, moved perhaps by a certain clamour among the critics for a literary drama, then commissioned Mr Phillips to write him a play, the result being Paolo and Francesca (1900), a drama founded on Dante's famous episode. Encouraged by the great success of the drama in its literary form, Mr Alexander produced the piece at the St James's Theatre in the course of 1901. In the meantime, Mr Phillips's next play, Iphed: a Tragedy, had been produced by Beerbohm Tree on the 31st of October 1900, and was published as a book in 1901; Ulysses, also produced by Beerbohm Tree, was published in 1902; The Sin of David, a drama on the story of David and Bathsheba, translated into the times and terms of Cromwellian England, was published in 1904; and Nero, produced by Beerbohm Tree, was published in 1906. In these plays the poet's avowed aim was, instead of attempting to revive the method of Shakespeare and the Elizabethans, to revitalize the method of Greek drama. Paolo and Francesca (which admitted certainly one scene on an Elizabethan model) was the most successful, the subject being best adapted to the lyrical cast of Mr Phillips's poetical temperament; but all contained fine poetry, skilfully stage-managed by a writer who had practical experience of stage craft.

See the section on Stephen Phillips in Poets of the Younger Generation, by William Archer (1900); also the articles on "Tragedy and Mr Stephen Phillips," by William Watson, in the Fortnightly Review (March 1898); "The Poetry of Mr Stephen Phillips," in the Edinburgh Review (January 1900); "Mr Stephen Phillips," in the Century (January 1901), by Edmund Gosse; and "Mr Stephen Phillips," in the Quarterly Review (April 1902), by Arthur Symons. For bibliography up to July 1903, see English Illustrated Magazine new series, vol. xxix. p. 442.

PHILLIPS, THOMAS (1770—1843), English portrait and subject painter, was born at Dudley in Warwickshire on the 18th of October 1770. Having acquired the art of glass-painting at Birmingham he visited London in 1790 with an introduction to Benjamin West, who found him employment on the windows in St George's Chapel at Windsor Castle. In 1792 Phillips succeeded to the position of Windsor Castle, and in the next two years he exhibited the "Death of Talbot, Earl of Shrewsbury, at the Battle of Castillon," "Ruth and Naomi," "Elijah restoring the Widow's Son," "Cupid disarmed by Euphrosyne," and other pictures. After 1796, however, he mainly confined himself to portrait-painting. It was not long before he became the chosen painter of men of genius and talent, notwithstanding the rivalry of Hoppner, Owen, Jackson and Lawrence; and he left behind portraits of nearly all the illustrious characters of his day. In 1804 he was elected associate and in 1808 member of the Royal Academy. In 1824 Phillips succeeded Fuseli as professor of painting to the Royal Academy, and would have continued in that position but for the publication of ten Lectures on the History and Principles of Painting, which were published in 1833. He died on the 20th of April 1845.

PHILLIPS, WENDELL (1811—1884), American orator and reformer, was born in Boston on the 29th of November 1811. His father, John Phillips (1770—1823), a man of wealth and influence, graduated at Harvard College in 1788, and became successively "town advocate and public prosecutor," and in 1822 first mayor of Boston, then recently made into a city. Wendell Phillips himself attended the public Latin school, entered Harvard College before he was sixteen, and graduated in 1831 in the same class with the historian John Lothrop Motley. He graduated at the Harvard law school in 1834, and was admitted to the bar in Boston. He soon came under the influence of the anti-slavery movement, witnessing in 1835 the mobbing, in Boston, of William Lloyd Garrison. On the 5th of December 1837 a meeting was held at Faneuil Hall to express the sentiments of the people on the murder of Elijah P. Lovejoy, at Alton, Illinois, for defending his press from a pro-slavery mob. In the course of the meeting a speech was made in opposition to its general current by James T. Austin (1784—1870), attorney-general of the state, who said that Lovejoy had died "as the fool dieth," and compared his murderers to the men who threw the tea into Boston harbour just before the War of Independence. The speech seemed likely to divide the audience, when Wendell Phillips took the platform. "When I heard," he said, "the gentleman lay down principles which placed the murderers of Alton side by side with Otis and Hancock, with Quincy and Adams, I thought these pictured lips (pointing to their portraits) would have broken into voice to rebuke the recreant American, the slanderer of the dead." This appeal not merely determined the sentiment of the meeting, it gave Wendell Phillips his first fame and determined his career. Although loving his profession, and thus especially for the opening it gave in the direction of public life, he practically stepped outside the sphere dearer to young Americans, and lived henceforth the life of an agitator, or, like his father, that of a "public prosecutor." Accepting unhesitatingly the leadership of Garrison, and becoming like him gradually a disunionist, he lived essentially a platform life, interested in a variety of subjects, but first and chiefly an abolitionist. In 1865, however, after the Civil War, he broke with Garrison over the question of discontinuing the Anti-Slavery Society, and from that date until the society was disbanded in 1870 he, instead of Garrison, was its president. He was not, moreover, like his great leader, a non-resistant, nor was he, on the other hand, like John Brown, borne on by irresistible necessity to overt action. Nor did he find, like his fellow-worker, Theodore Parker, the leisure to keep up his scholarship and lead in part the life of a student. Early study and travel had indeed furnished him with abundant material for rhetorical illustration; and he was also a great reader of newspapers, but he used to say that he knew in his whole life but one thing thoroughly, namely, the history of the English Civil War, and there were few occasions when he could not draw from it the needful illustration. His style of eloquence was direct and brilliant, but eminently self-controlled. He often surprised his hearers by the quietness of his beginnings, and there were very often the speeches which turned out most brilliant and most irresistible are the close. He may be said to have introduced the direct and colloquial manner upon the American public platform, as distinct from the highly elaborated and often ornate style which had been established by Edward Everett; nor has there ever been a reversion since his day to the more artificial method. He was capable at times, nevertheless, of highly sonorous periods with superb climaxæ; yet his favourite style was the conversational. His logic, while never obtruded, was rarely at fault; but he loved the flash of the rapier, and
was never happier than when he had to face down a mob and uncertainly foil it by sheer superiority in fencing. The two volumes of his speeches, as edited by James Redpath, were fortunately made from verbatim reports, and they wisely enclose in parenthess those indications of favour or dissent from the audience which transformed so many of his speeches into exhibitions of gladiatorial skill. He was a tribute of the people, associated unflinchingly not merely with the unpopular but with the unpolished; always carrying about him not merely a certain Roman look, but a patrician air. After slavery had fallen Phillips associated himself freely with reformers occupied in other paths, herein separating himself from the other patrician of the movement, Edmund Quincy, who always frankly said that after slavery was abolished there was nothing else worth fighting for. Among other things, Phillips contended, during his later years, for prohibition, woman suffrage and various penal and administrative reforms. He was not always the best judge of character, and was sometimes allied in these movements with men who were little more than demagogues. But the proof he gave by his transfer of energies that the work of reform was never quite finished—this was something of peculiar value, and worth the risk of some indiscretions. The life of a reformer did not in itself make him thoroughly happy; he chafed more and more under its fatigues, and he always felt that his natural place would have been among senators or ambassadors; but he belonged essentially to the heroic type, and it may well have been of him that Emerson was thinking when he wrote those fine words: "What forests of laurel we bring and the tears of mankind to him who stands firm against the opinion of his contemporaries." His domestic life was most happy, though his wife was a confirmed invalid, seldom quitting her room. She was a woman of heroic nature and very strong convictions. Her husband used to say that she first made him an abolitionist. They had no children, but adopted an orphaned daughter of Mrs Eliza Garnaut, a friend, and this young girl (afterwards the wife of George W. Smalley), brought much light and joy into the household. Their worldly circumstances were easy, though they were always ready to impoverish themselves for the sake of others. Wendell Phillips died in Boston on the 2nd of February 1884.

PHILLIPS, WILLIAM (1775-1838), British mineralogist and geologist, son of James Phillips, printer and bookseller in London, was born on the 10th of May 1775. He early became interested in mineralogy and geology, and was one of the founders of the Geological Society of London (1807). His Outlines of Mineralogy and Geology (1815) and Elementary Introduction to the Knowledge of Mineralogy (1816) became standard textbooks. His digest of English geology, A selection of Facts from the Best Authorities, arranged so as to form an Outline of the Geology of England and Wales (1818), formed the foundation of the later work undertaken by Phillips in conjunction with W. D. Conybeare, of which only the first part was published, entitled Outlines of the Geology of England and Wales (1824). This volume was one in a series of works on geology of great observation, judicious compilation, of succinct description and of luminous arrangement it has been of the utmost service in the development of geology in Britain. In this work Phillips reprinted his admirable description of the chalk cliffs of Dover and other parts of East Kent, published in 1819 in Trans. Geol. Soc. vol. v. Phillips was a member of the Society of Friends. He was elected a Fellow of the Royal Society in 1827. He died on the 2nd of April 1838.

His brother, Richard Phillips (1778-1851), was distinguished as a chemist, and became F.R.S. in 1822. He was also acting as a practitioner. His Practical Chemistry (afterwards Practical Geology), then situated in Craig's Court (1839). He was the author of papers published in the Annals of Philosophy and Philosophical Magazine. In 1796 the two brothers, together with William Allen and Luke Howard, took part in forming the Askean Society.

PHILLIPSBURG, a town of Warren county, New Jersey, U.S.A., on the Delaware river, opposite Easton, Pennsylvania, and about 51 m. N.N.W. of Trenton, N.J. Pop. (1900) 10,052, of whom 990 were foreign-born; (1910 U.S. census) 13,903. Served by the Central of New Jersey and other railways, the town is situated in the river bottom and on a bluff which commands beautiful views. The river is spanned here by several bridges. The town has railway shops and various manufactures. In 1905 the value of the factory products was $6,084,173 (45.8% more than in 1900). Phillipsburg was settled about 1750. It was only a straggling village when the Morris Banking and Canal Company was chartered in 1824, but its growth was accelerated by the canal (no longer used), by the establishment in 1848 of an iron furnace, and by the completion of the Central Railroad of New Jersey to this point in 1825; the town was incorporated in 1861.

PHILLIPSITE, a mineral of the zeolite group; a hydrated potassium, calcium and aluminium silicate, approximating to (K₅₆, Ca₈₆)(SiO₃)₄₄H₂O. It varies somewhat in composition, and a variety ("phillipsite") containing rather less silica has the formula (K₃₆, Ca₈₆)₄H₂O. Crystals are monoclinal, but only complex cruciform twins are known, these being exactly like twins of harrmoute (q.v.). Crystals of phillipsite are, however, usually smaller and more transparent and glassy than those of harrmoute. Spherical groups with a radially fibrous structure and bristled with crystals on the surface are not uncommon. The hardness is 4 ½, and the specific gravity 2 2. The species was established by A. Lévy in 1825 and named after William Phillips. French authors use the name christianite (after Christian VIII. of Denmark), given by A. De Clozeaux in 1847.

Phillipsite is a mineral of secondary origin, and occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks: e.g. in the basalt of the Giant's Causeway in County Antrim, and near Melbourne in Victoria; and in lenticular near Rome. Small crystals of recent formation have been observed in the masonry of the hot baths at Plombières and Bourbionnes-Bains, in France. Minute spherical aggregates embedded in red clay were dredged by the "Challenger" from the bottom of the Central Pacific, where they had been formed by the decomposition of lava.

(L. J. S.)

PHILLIPSTONS, HENRY (1778-1859), English bishop, was born at Bridgwater on the 6th of May 1778, and was educated at Gloucester College, Oxford, where he was called to the ministry. He became a fellow of Magdalen College, Oxford, in 1795, took orders in 1802, and was select university preacher in 1804. In 1805 he received the living of Stanton-le-Street, Durham, and in addition was appointed to Bishop Middleham, Durham, in the succeeding year. For twenty years he was chaplain to Shute Barrington, bishop of Durham. He was appointed vicar of Gateshead in 1808, prebendary of Durham in 1809, and vicar of St Margaret, Durham, in 1810. After holding the rich living of Stanhope, Durham from 1820, and the deanery of Chester from 1828, he was consecrated bishop of Exeter in 1831, holding with the see a residuary canonry at Durham. His visitation tour of Exeter was an epoch in the history of the county, including those connected with his well-known Roman Catholic controversy with Charles Butler (1750-1832). He was an energetic supporter of the Tory party, even when it acted contrary to his views in passing the Roman Catholic Emancipation Act of 1829. He died on the 18th of September 1869.

"Henry of Exeter," as he was commonly called, was one of the most striking figures in the English Church of the 18th century. His intellect was strong rather than broad, his position being that of the traditional High Churchman, with little sympathy either with the Evangelicals or with the Tractarians. On the one hand the famous Gorham judgment was the outcome of his thought, and in his battle of 1833 for the clerical title of George Cornelius Gorham (1787-1857), who had openly denounced his belief in baptismal regeneration; on the other he denounced the equally famous Tract XC. In his episcopal charge of 1843. As bishop he was a strict disciplinarian, and
did much to restore order in a diocese of which the clergy had become extraordinarily demoralized. Though accused of avarice and pluralism, Philoptothos was generous in his gifts to the church, founding the theological college at Exeter and spending large sums on the restoration of the cathedral.

PHILEO, Jewish Hellenist, and author of an epic poem in Greek hexameters on the history of Jerusalem. Alexander Polyhistor (c. 105–35 B.C.) quotes several passages of the poem, and is the source of the extracts in Eusebius (Praeparatio evangelica, ix. 20, 24, 37). This is probably the Philo who is mentioned by Clemens Alexandrinus (Strom. i. 21, 141) and by Josephus (Contra Apionem, i. 23), who calls him "the elder." See M. Philippon's work on the Jewish poets Ezechiel and Philo (Bibl., 1850).

PHILEO, often called PHILO JUDAENS, Jewish philosopher, appears to have spent his whole life at Alexandria, where he was probably born c. 20–10 B.C. His father Alexander was a alabarch or arabarch (that is, probably, chief farmer of taxes) on the Arabic side of the Nile, from which it may be concluded that the family was influential and wealthy (Jos. Ant. xviii. 8, 1). Jerome's statement (De vir. ill. 11) that he was of priestly race is confirmed by no older authority. The only event of his life which can be actually dated belongs to A.D. 40, when Philo, then a man of advanced years, went from Alexandria to Rome, at the head of a Jewish embassy, to persuade the emperor Gaius to abstain from claiming divine honour of the Jews. Of this embassy Philo has left a full and vivid account (De legatione ad Gaium). Various fathers and theologians of the Church state that in the time of Claudius he met St Peter in Rome; but this legend has no historic value, and probably arose because the book De vita contemplativa, ascribed to Philo, in which Eusebius already recognized a glorification of Christian monasticism, seemed to indicate a disposition towards Christianity.

Thouglw we know so little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe and of life, and his religious and scientific aims, and so enable us adequately to estimate his position and importance in the history of thought. He is quite the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism was and aimed at. The development of Judaism in the diaspora (q.v.) differed in important points from that in Palestine, where, since the successful opposition of the Maccabean age to the Hellenization which Antiochus Epiphanes had sought to carry through by force, the attitude of the nation to Greek culture had been essentially negative. In the diaspora, on the other hand, the Jews had been deeply influenced by the Greeks; they soon more or less forgot their Semitic mother-tongue, and with the language of Hellas they appropriated much of Hellenic culture. They were deeply impressed by that irresistible force which was blending all races and nations into one great cosmopolitan unity, and so the Jews too on their dispersion became in speech and nationality Greeks, or rather "Hellenists." Now the distinguishing characteristic of Hellenism is not the absolute disappearance of the Oriental civilizations before that of Greece but the combination of the two with a preponderance of the Greek element. So it was with the Jews, but in their case the old religion had much more persistence than in other Hellenistic circles, though in other respects they too yielded to the superior force of Greek civilization. This we must hold to have been the case not only in Alexandria but throughout the diaspora from the commencement of the Hellenistic era. Philo's works (Strom. ii. 22 to the last) are the last effort of the Jews to resist this influence. It is after all only ancient civilisation gave way before the barbarian immigrations and the rising force of Christianity that rabbinism became supreme even among the Jews of the diaspora. This Hellenistic-Judaic phase of culture is sometimes called "Alexandrian," and the expression is justifiable if it only means that in Alexandria it attained its highest development and flourished most. For

1 Euseb., H. E. ii. 17, 1; Jer. ut supra; Phot. Bibl. Cod. 105; Suid. s.v. "Φωλιο".

2 The fathers of the Church have specially noticed his Platonism and Pythagoreanism; an old proverb even says, with some exaggeration, "He was a Philo of Pythagoras."

3 See the list of these in Vallarsi's edition of Jerome (ii. 731–734) and compare Siegfried, "Philosophische Studien," in Merz's Archiv. ii. 143–163 (1872).

4 See Siegfried, Philo, pp. 142–159.
decisive and normative authority is to him the "holy laws" of Moses, and this not only in the sense that everything they contain is true but that all truth is contained in them. Everything that is right and good in the doctrines of the Greek philosophers had already been quite as well, or even better, taught by Moses. Thus, since Philo had been deeply influenced by the teachings of Greek philosophy he actually finds in the Pentateuch everything which he had learned from the Greeks. From these premises he assumes as requiring no proof that the Greek philosophers must in some way have drawn from Moses, a view indeed which is already expressed by Aristobulus.

To carry out these presuppositions called for an exegetical method which seems very strange to us, that, namely, of the allegorical interpretation of Scripture. The allegorical method had been practised before Philo's date in the rabbinical schools of Palestine, and he himself expressly refers to its use by his predecessors, nor does he feel that any further justification is requisite. With its aid he discovers indications of the profoundest doctrines of philosophy in the simplest stories of the Pentateuch.

The merely formal principle of the absolute authority of Moses is really the one point in which Philo still holds to genuinely Jewish conceptions. In the whole substance of his philosophy the Jewish point of view is more or less completely modified—sometimes almost extinguished—by what he has learned from the Greeks. Comparatively speaking, he is most truly a Jew in his conception of God. The doctrine of monotheism, the stress laid on the absolute majesty and sovereignty of God above the world, the principle that He is to be worshipped without images, are all points in which Philo justly feels his superiority as a Jew over popular heathenism. But only over popular heathenism, for the Greek philosophers had long since arrived at least at a theoretical monotheism, and their influence on Philo is nowhere more strongly seen than in the detailed development of his doctrine of God. The specifically Jewish (i.e., particularistic) conception of the election of Israel, the obligation of the Mosaic law, the future glory of the chosen nation, have almost disappeared; he is really a cosmopolitan and praises the Mosaic law just because he deems it cosmopolitan. The true sage who follows the law of Moses is the citizen not of a particular state but of the world. A certain attachment which Philo still manifests to the particularistic conceptions of his race is meant only "in maiorum Judaeorum gloriam." The Jewish people have a right to exist as a people independent of God, as evidence that it has the most virtuous ancestry and is itself distinguished for virtue. The Mosaic law is binding, but only because it is the most righteous, humane and rational of laws, and even its outward ceremonies always disclose rational ideas and aims. And lastly, outward prosperity is promised to the pious, even on earth, but the promise belongs to all who turn from idols to the true God. Thus, in the whole substance of his view of the universe, Philo occupies the standpoint of Greek philosophy rather than of national Judaism, and his philosophy of the world and of life can be completely set forth without any reference to conceptions specifically Jewish.

His doctrine of God starts from the idea that God is a Being absolutely bare of quality. All quality in finite beings has limitation, and no limitation can be predicated of God, who is eternal, unchangeable, simple substance, free, self-sufficient, better than the good and the beautiful. To predicate any quality (σωμάτως) of God would be to reduce Him to the sphere of finite existence. Of Him we can say only that He is, not what He is, and such purely negative predications as to His being appear to Philo, as to the later Pythagoreans and the Neoplatonists, the only way of securing His absolute elevation above the world. At bottom, no doubt, the meaning of these negative predications is that God is the most perfect being; and so, conversely, we are told that God contains all perfection, that He fills and encompasses all things with His being.

A consistent application of Philo's abstract conception of God would exclude the possibility of any active relation of God to the world, and therefore of religion, for a Being absolutely without quality and movement cannot be conceived as actively concerned with the multiplicity of individual things. And so in fact Philo does teach that the absolute perfection, purity and loftiness of God would be violated by direct contact with imperfect, impure and finite things. But the possibility of a connexion between God and the world is reached through a distinction which forms the most important point in his theology and cosmology; the proper Being of God is distinguished from the infinite multiplicity of divine Ideas or Forces: God himself is without quality, but He disposes of an infinite variety of divine Forces through whose mediation an active relation of God to the world is brought about. In the details of his teaching as to these mediating entities Philo is guided partly by Plato and partly by the Stoics, but at the same time he makes use of the concrete religious conceptions of heathenism and Judaism. Following Plato, he first calls them Ideas or ideal patterns of all things; they are thoughts of God, yet possess a real existence, and were produced before the creation of the sensible world, of which they are the types. But, in distinction from Plato, Philo's ideas are at the same time efficient causes or Forces (δύναμες), which bring uniformed matter into order conformably to the patterns within themselves, and are in fact the media of all God's activity in the world. This modification of the Platonic Ideas is due to Stoic influence, which appears also when Philo gives to the λόγος or δύναμες the name of λόγος, i.e., operative ideas—parts, as it were, of the operative Reason. For, when Philo calls his mediating entities λόγος, the sense designed is analogous to that of the Stoics when they call God the Logos, i.e., the Reason which operates in the world. But at the same time Philo maintains that the divine Forces are identical with the "daemones" of the Greeks, and the "angels" of the Jews, i.e., servants and messengers of God by means of which He communicates with the finite world. All this shows how uncertain was Philo's conception of the nature of these mediating Forces. On the one hand they are nothing else than Ideas of individual things conceived in the mind of God, and as such ought to have no other reality than that of immanent existence in God, and so Philo says expressly that the totality of Ideas, the κόσμος τοπος, is simply the Reason of God as Creator (θεος λόγος ὅθεν κοσμοποιωτός). Yet, on the other hand, they are represented as hypostases distinct from God, individual entities which are creations of God, and by which God creates. However, as Zeller and other recent writers have justly remarked, it is necessarily involved in Philo's premises, for, on the one hand, it is God who works in the world through His Ideas, and therefore they must be identical with God; but, on the other hand, God is not to come into direct contact with the world, and therefore the Forces through which He works must be distinct from Him. The same inevitable amphiboly dominates in what is taught as to the supreme Idea or Logos. Philo regards all individual Ideas as comprehended in one highest and most general Idea or Force—the unity of the individual Ideas—which he calls the Logos or Reason of God, and which is again regarded as operative Force, or, as the Logos, as the world. For Philo God and the world, the firstborn son of God, the archangel who is the vehicle of all revelation, and the high priest who stands before God on behalf of the world. Through him the world was created, and so he is identified with the creative Word of God in Genesis (the Greek λόγος meaning both "reason" and "word"). Here again, we see, the philosopher is unable to escape from the difficulty that the Logos is at once the immanent Reason of God, and yet also an hypostasis standing between God and the world. The whole doctrine of this mediatorial hypostasis is a strange intertwining of very dissimilar threads; on one side the way was prepared for it by the older Jewish interpreters of the Pentateuch, on the other by the Stoics, some of which we find the beginnings even in the Old Testament (Job xxi. 12 seq.; Prov. viii. 14 seq.), and the fuller development in the books of Ecclesiasticus and Wisdom, the latter of which comes very near to Philo's ideas if we substitute for the term "wisdom"
that of (divine) "Reason." In Greek philosophy, again, Philo, as we have seen, chiefly follows the Platonic doctrines of Ideas and the Soul of the World, and the Stoic doctrine of God as the Mover or Reason operating in them (cf. especially, e.g., Iren. ii. 32). But the latter doctrine was pantheistic, but Philo could adapt it to his purpose simply by drawing a sharper distinction between the Logos and the world.

Like his doctrine of God, Philo's doctrine of the world and creation rests on the presupposition of an absolute metaphysical contrast between God and the world. The world can be ascribed to God only in so far as it is a cosmos or orderly world; its material substratum is not even indirectly referable to God. Matter (ὕλη, or, as the Stoics said, οὐσία) is a second principle, but in itself an empty one, its essence being a mere negation of all truth and order and a lifeless, shapeless mass, out of which God formed the actual world by means of the Logos and divine Forces. Strictly speaking, the world is only formed, not created, since matter did not originate with God.

Philo's doctrine of man is also strictly dualistic, and is mainly derived from Plato. Man is a twofold being, with a higher and a lower origin. Of the pure souls which fill airy space, those nearest the earth are attracted by the sensible and descend into sensible bodies; these souls are the Godward side of man. But on his other side man is a creature of sense, and has in him a fountain of sin and all evil. The body, therefore, is a prison, a cell, or a grave for the soul which seeks to rise again to God. Philo's attempt to apply the principles of Philo's ethics are derived, its highest maxim necessarily being deliverance from the world of sense and the mortification of all the impulses of sense. In carrying out this thought, as in many other details of his ethical teaching, Philo closely follows the Stoics. But he is separated from Stoical ethics by his strong religious interests, which carry him to very different views of the means and aim of ethical development. The Stoics cast man upon his own resources; Philo points him to the assistance of God, without whom man, a captive to sense, could never raise himself to walk in the ways of true wisdom and virtue. And as moral effort cannot be a fruit only with God's help, so too God Himself is the goal of that effort. Even in this life the truly wise and virtuous is lifted above his sensible existence, and enjoys in ecstasy the vision of God, his own consciousness sinking and disappearing in the divine light. Beyond this ecstasy there lies but one further step, viz. entire liberation from the body of sense and the return of the soul to its original condition; it came from God and must rise to Him again. But natural death brings this consummation only to those who, while they lived on earth, kept themselves free from attachment to the things of sense; all others must at death pass into another body; transmigration of souls is in fact the necessary consequence of Philo's premises, though he seldom speaks of it expressly.

Philo's literary labours have a twofold object, being directed either to expound the true sense of the Mosaic law, i.e., the philosophy which we have just described, to his Jewish brethren, or to convince heathen readers of the excellence, the supreme purity and truth, of the Jewish religion, whose holy records contain the deepest and most perfect philosophy, the best and most humane legislation. Thus as a literary figure Philo, in conformity with his education and views, adopted the objects of that Greek science wherewith he was not in sympathy. He sought to gain the Jews for Hellenism and the Greeks for Judaism, yet always taking it for granted that his standpoint really is Jewish, and just on that account truly philosophical and cosmopolitan.

The time of the appearance of Philo present at first sight a most confusing multiplicity. More than three-fourths of them, however, are really mere items of a small number of larger works. Three such great works on the Pentateuch can be distinguished.

1. The smallest of these is the Προεόμενα καὶ λόγια (Quaestiones et solutiones), a short exposition of Genesis and Exodus, in the form of question and answer. The work is cited under this title by Euseb. H. E. ii. 18, 1; Porph. adv. Err. vii. 12, 15; and the later writers, but the Greek text is now almost wholly lost, only and about one-half preserved in an Armenian translation. Genesis seems to have occupied six books. Euseb tells us that Exodus filled five books. In the Armenian translation, first published by the learned Mechiarchit, J. Bapt. Aucher, in 1826, are preserved four books on Genesis and two on Exodus, but with lacunae. A Latin translation of this work is said to have been made by Irenaeus (Contra Haereses, iv. 30). See Opp. ed., Mangey, ii. 648-650; Mai, op. cit., vii. pt. i. 97. [It is proposed to publish a Latin fragment on the cheringon, Exod. xxv. 18, has been published by Mai, op. cit., ii. 14, 15. See also, γεγος, by Grossman (1856) and by Tischendorf (p. 144 seq.).]
legislation was conformed to the will of nature, and that therefore those who followed it were true cosmopolitans; (b) the Biographies of the Virtuous—being, so to say, the most ideal of the biographies of the virtuous—will be referred to throughout this treatise and the rubrics of the decalogue, arranged under the headings of certain cardinal virtues.

The treatises which belong to this work are the following: (1) Περὶ τῶν ἔθνων (Vita Moysi, ii. 1-108) (2) Περὶ τῶν ἐνθυμίων καὶ ἐνθυμεῖσθαι (De consolatione, i. 1-83). This work does not fall within the number of the allegorical commentaries. On the other hand, the introduction to the treatise De Abrahamo makes its clear connection with the De mundi origine. This paper of the Eusebian, and the head of the second commandments, which is at present usual in the editions, seems indeed to go back to a very early date, for even Eusebius cites a passage from it within his own De legibus. The De legibus and the De incipitibus are four titles which are connected, in the grossest manner, and even to persecute them to the shedding of blood. In the second he tells how the Jews had been subjected to still greater sufferings through the command of Caligula that five years of their years should be proclaimed as the years of the Jews of Alexandria in vain sought relief by a mission to Rome which was headed by Philo. But both together were only parts of a larger work, in five books, of which the first two and the last have been preserved. For it is evident that the Eusebian Flaccus that it had been preceded by another book in which the Jewish persecutions by Sejanus, under the reign of Tiberius, were spoken of, and the Chronicon of Eusebius (ed. Schoene, i. 153) informs us of these persecutions. The book which was related to the second book of the work now under discussion. But from the conclusion of the Legatio ad Gaium, which we still possess, we learn that it was an account of the expulsions of the Jews from the polity, or change of Jewish fortunes for the better. Thus we make out five books in all—the number actually given by Eusebius (H.E. ii. 18, 7; Præp. Ev. vii. 20 fn., viii. 13 fn., ed. Gasior). The Armenian text gives two books, but of these the first, if genuine at all, in any case appears only in an abridged and somewhat revised state; Eusebius (Præp. Ev. viii. 14) quotes from the second book to an extent that amounts to a series of excerpts from the whole. The latter passage is in Præp. Ev. i. 18, 6. This also now exists only in an Armenian translation, which has been edited by Aucher. Two small Greek fragments occur in the Florilegium of Eusebius and John of Jerusalem (Mai. Scr. rerum. coll. viii. p. 1006, 1a). (7) Τοποθέτησις, a writing now known to us only through fragments preserved in Eusebius, Præp. Ev. viii. 6, 7. The title, by Bernard 2 has shown, means "Counsels," Recommendations, the reference being to the laws of Greek and Jewish writers, especially to the Jewish readers. (8) Περὶ ἱστολογίας, a title met with in Eusebius, H.E. ii. 18, 6. The writing is no doubt the same as Περὶ ἱστολογίας ἀποκολούθουσα, from which a quotation is given in Eusebius, Præp. Ev. viii. 11. To this class belongs, which is concerned with the respect of the sacred books, of that of true that of noble wisdom in which the Jewish people 3 also is not wanting.

1. The two doubtful treatises: (a) Περὶ βιβλίων ἐνθυμεῖσθαι (on the use of the vita communitas) (b) Περὶ βιβλίων ἐνθυμεῖσθαι (on the vita comunitas). This contains the sole original account of an ascetic community known as the Therapeutae (q.v.) having their home on the shores of Lake Mareotis. These were held by Eusebius and many other Christian writers to be the earliest Christian monks, which of course could not be the case, it was a genuine work of Philo. On this account, amongst others, it was held to be spurious by Graetz and P. E. Lucius; and this view gradually the ascent of most modern scholars. Lastly, however, L. F. M. Beloch has shown with great thoroughness that in language and thought alike it is essentially Philonic, and the genuineness of the book has indeed been affirmed by P. Wendland, who first published it (F. Wendland, "Die Bücher der Berenike, oder die "Incorruptibili mundi," declared unauthentic by Z. Frankel and J. Bernays, has been successfully defended by F. Cumont. (3) Περὶ κόσμου (De mundo). It is generally agreed that, in L. Cohn's words, this is "nothing but a collection into a single whole of the portions of the περὶ ἀθάνατος κόσμου and other Philonic works." (4) Two discourses, De Sampsono and De Iona, exist only in Armenian, and certain writings of the same kind. These appear only to have been introduced into the manuscripts by chirographers. They claim to be his work. (5) Περὶ τῶν πάνω στοιχείων εἶναι διάθεσις (Quod omnis probus liber sit) has been questioned by Z. Frankel and R. Ansfeld; but their arguments would rather point to its being an imitation of work of Philo which P. Wendland believes to be the case. (6) Περὶ προφανείας (We possess this as a whole

3 This conjecture is Dähne's, Theol. Stud. u. Krit. (1833), pp. 990, 1037.
only in an Armenian version, consists of two books, the first of which appears to be in a Christian recension, but there is no reason for deeming its Philonic origin.

Editions.—Till recent days the best edition was that of Manegy (2 vols., London, 1851); the handling of the Holzze duodecimo (Leipzig, 1851). Both are still very useful, but for scholars they will be superseded by the enlarged and critical edition of Leopold Cohn and Paul Wendland (Berlin, 1896-1902). See also papers by Cohn in Hermes, xxxviii. (1903) and xliii. (1908). There is an English translation of the old text by C. D. Yonge (4 vols., London, 1854).

(Edward.).

PHILO OF BYZANTIUM.—PHILODEMSUS

PHILO OF BYZANTIUM, writer on mechanics, flourished during the latter half of the 2nd century B.C. (according to some, a century earlier). He was the author of a large work Ἐκ λύσεως ὁρών (of which the fourth and (in part) sixth books are later) the compilation consisting of a discussion of the four elements, fortresses, provisioning, attack and defence (ed. R. Schörk, 1893, with German translation in H. Köchly's Griechische Kriegsschriftsteller, vol. i. 1853; E. A. Rochas d'Aiglun, Poliorcetique des Grecs, 1872). Another portion of the work, on pneumatic engines, has been preserved in the form of a Latin translation (De ingenii spiritualibus) made from an Arabic version (ed. W. Schmidt, with German translation, in the works of Heron of Alexandria, vol. i, in "Teubner Series," 1895; with French translation by Rochas, La Science des philosophes dans l'antiquité, 1882).

PHILO DE LARISSA, Greek philosopher of the first half of the 1st century B.C. During the Mithradatik wars he left Athens and took up his residence in Rome. He was a pupil of Chrysippus, whom he succeeded as head of the Third or New Academy. He is best known as a commentator and treatise writer, and there are eighty-five of his works extant, from Cicero's De Nat. Deor. (53 B.C.) to his De vulg. Litter. (25 B.C.). His commentaries on Plato, however, are of more importance. He was the first to give a comprehensive account of the Academy, but other writers refuse to admit the separate existence of more than three academies (see Academy, Greek). In Rome he lectured on rhetoric and philosophy, and collected around him many eminent students, amongst whom Cicero was the most famous and the most enthusiastic. None of his works is extant; our knowledge of his views is derived from Cicero, Sextus Empiricus and Cicer. In general, his philosophy was a reaction against the sceptic or agnostic position of the Middle and New Academy in favour of the dogmatism of Plato.

See Gysbers, Die Academy der Philo und Antiochus (1889); Hermann, De Philone Larissae (Göttingen, 1851 and 1852).

PHILO, HERENNIIUS, of Byblus, Greek grammarian, was born, according to Suidas, in a.D. 42. He lived in the reign of Hadrian, of which he wrote a history, now lost. He was the author of various works: On the Acquisition and Choice of Books; On Cities and their Famous Men, epitomized by the grammarians Aelius Severus, and one of the chief authorities used by Hesychius and Stephanus of Byzantium; On Synonyms, of which there is extant an epitome by Ammonius Grammaticus. But he is chiefly known for his translation of the Phoenician history of Sanchuniathon, who was said to have lived before the Trojan war. Of this work considerable fragments have been preserved, chiefly by Eusebius in the Praeparatio evangelica (i. 9, 10; iv. 19). They contain a comprehensive iconography of Phoenician theology and mythology, which is represented as translated from the original Phoenician. Sanchuniathon is probably an imaginary personage, whose name is formed from that of the Phoenician god Sanchon.
settled in Rome in the time of Cicero. He was a friend of Calpurnius Fiso, and was implicated in his profligacy by Cicero (in Pisonem, 29), who, however, praises him warmly for his philosophic views and for the elegans lascivia of his poems (cf. Horace, Satires, i. 2. 120). The Greek anthology contains thirty-four of his epigrams. From the excavations of the villa at Herculaneum (or) there have been recovered thirty-six treatises attributed to Philodemus, and it has been suggested that the villa was actually owned by him; but this is generally denied. These works deal with music, rhetoric, ethics, signs, virtues and vices, and defend the Epicurean standpoint against the Stoics and the Peripatetics.

The Rhetoric has been edited by Sudhaus (1892-1895); the De Ira and the De Pietae by Gomperz (1864 to 1865); the De Musica by Kempke (1864); De Vitiis by Usong (1868); De Morie by Meckler (Philolaus was the first to profess the death of Socrates, 1824 and 1861); Mayor on Cicero's De Natura deorum (1871).

PHILOLAUS (b. c. 480), Greek philosopher of the Pythagorean school, was born at Tarentum or at Crotona (so Diog. Laërt. viii. 84). He was said to have been intimate with Democritus, and was probably one of his teachers. After the death of Pythagoras great dissensions prevailed in the cities of lower Italy. According to some accounts, Philolaus, obliged to flee, took refuge first in Lucania and then at Thebes, where he had as pupils Simmias and Ceboes, subsequently, being still young men (oratores), were present at the death of Socrates. Before this Philolaus had returned to Italy, where he was the teacher of Archytas. He entered deeply into the distinctively Pythagorean number theory, particularly dwelling on the properties inherent in the decad—the sum of the first four numbers, consequently the fourth triangular number, the tetractys (see Vit. Pythag. ap. Phot. Bibl. p. 712)—which he called great, all-powerful, and all-producing. The great Pythagorean oath was taken by the sacred tetractys. The discovery of the regular solids is attributed to Pythagoras by Eudemus, and Empedocles is stated to have been the first who maintained that there are four elements. Philolaus, connecting these ideas, held that the earth, water, air, and fire were the four elements, and assigned the tetrahedron to fire, the octahedron to the air, the icosahedron to water, and the cube to earth; the dodecahedron he assigned to a fifth element, aether, or, as some think, to the universe (see Plut. de Pl. Ph. ii. 6, εκ δε του δωδεκαεδρου την του πατων σφαεων και Stob. Ed. Phys. i. 10, δ τας σφαεων δεκαυ). This theory, however superficial from the standpoint of observation, indicates considerable knowledge of geometry and gave a great impulse to the study of the science. Following Parmenides, Philolaus regarded the soul as a "mixture and harmony of the bodily parts; he also assumed a substantial soul, whose existence in the body is an estate on account of sin.

Philolaus, in the nature of the motion of the earth; some attribute this doctrine to Pythagoras, but there is no evidence in support of their view. Philolaus supposed that the sphere of the fixed stars, the five planets, the sun, moon and earth, all moved round the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods (see Stob. Ed. Phys. i. 488); but as these made up only nine revolving bodies he conceived, in accordance with his number theory, a tenth, which he called counter-earth, ἀντιγηρα. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of 29½ days, the lunar year of 354, and the solar year of 365½ days. He was the first who published a book on the Pythagorean doctrines, a treatise of which Plato made use in the composition of his Timaeus. This work of the Pythagoreans, to which the mystical name Bάχχα is sometimes given, seems to have consisted of three books: (1) Περί κόσμου, containing a general account of the origin and arrangement of the universe; (2) Περί φύσεως, an exposition of the nature of numbers; (3) Περί ψωτης, on the nature of the soul.

Heidelberg, 1853); Zeller, History of Greek Philosophy; Chaignet, Pythagore et la philosophie pythagoricienne, contenant les fragments de Philolaus et d'Archias (1873); Th. Gompers, Greek Thinkers (Eng. trans. 1893), §§ 53-54, and authorities there quoted; also art. PYTHAGORAS. For fragments see Ritter and Preller, Hist. Philosop. ch. ii.

PHILOLOGY, the generally accepted comprehensive name for the study of the word (Gr. λόγος), or languages; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man. Philology has two principal divisions, corresponding to the two uses of "word" or "speech," as signifying either what is said or the language in which it is said; as either the thought expressed—which, when recorded, takes the form of literature—or the instrumentality of its expression: these divisions are the literary and the linguistic. Not all study of literature, indeed, is philological: as when, for example, the records of the ancient Chinese are ransacked for notices of astronomical or meteorological phenomena, or the principles of geometry are learned from the textbook of a Greek sage; while, on the other hand, to study Ptolemy and Euclid for the history of the sciences represented by them is philological more than scientific. Again, the study of language itself has its literary side: as when the vocabulary of a community (say of the ancient Indo-European or Aryans) is taken as a document from which to infer the range and grade of knowledge of its speakers, their circumstances and their institutions. The two divisions thus do not admit of absolute distinction and separation, though for some time past tending toward greater independence. The literary is the older of the two; it even occupied until recently the whole field, since the scientific study of language itself has arisen only within the 19th century. Till then, literary philology included linguistic, as a merely subordinate and auxiliary part, the knowledge of a language being the necessary key to a knowledge of the literature written in that language. When, therefore, instead of studying each language by itself for the sake of its own literature men began to compare one language with another, in order to bring to light their relationships, their structures, their histories, the name "comparative philology" naturally enough suggested itself and came into use for the new method; and this name, awkward and trivial though it may be, has become so firmly fixed in English usage that it can be only slowly, if at all, displaced. European usage (especially German) tends more strongly than English to restrict the name philology to its older office, and to employ for the recent branch of knowledge a specific term, like those that have gained more or less currency with us also; as glotto, glossology, linguistics, linguistic science, science of languages, the like. It is not a question of absolute propriety or correctness, since the word philology is in its nature wide enough to imply all language-study of whatever kind; it is one, rather, of the convenient distinction of methods that have grown too independent and important to be any longer well included under a common name.

I.—The Science of Language in general.

Philology, in all its departments, began and grew as a branch of the classical; the history of our civilization made the study of Greek and Latin the exclusive, still longer the predominant and regulating, occupation of secular scholarship. The Hebrew and its literature were held apart, as something of a different order, as sacred. It was not imagined that any tongue to which culture and literature did not lend importance was worthy of serious attention from scholars. The first essays in comparison, likewise, were made upon the classical tongues, and were as erroneous in method and fertile in false conclusions as was to be expected, considering the narrowness of view and the controlling prejudices of those who did them; and when "comparison" of Hebrew to the comparison only added to the confusion. The change which the past century has seen has been a part of the general scientific movement of the age, which has brought about the establishment
of so many new branches of knowledge, both historical and physical, by the abandonment of shackling prejudices, the freedom of inquiry, the recognition of the dignity of all knowledge, the wide-reaching assimilation of whatever is useful and true, and the resulting constant improvement of method. Literary philology has had its full share of advantage from this movement; but linguistic philology has been actually created by it out of the crude observations and wild deductions of earlier times, as truly as chemistry out of alchemy, or geology out of diluvianism. It is unnecessary here to follow out the details of the development; but we may well refer to the decisive influence of one discovery, the decisive action of one scholar. It was the discovery of the special relationship of the Aryan or Indo-European languages, depending in great measure upon the introduction of the Sanskrit as a term in their comparison, and demonstrated and worked out by the German scholar Bopp, that founded the science of linguistic philology. While there is abundant room for further improvement, it yet appears that the grand features of philologic study, in all its departments, are now so distinctly drawn that no revolution of its methods, but only their modification in minor respects, is henceforth probable. How and for what purposes to investigate the literature of any people (philology in the more proper sense), combining the knowledge thus obtained with that derived from other sources; how to study and set forth the material and structure and combinations of a language (grammar), or of a body of related languages (comparative grammar); how to co-ordinate and interpret the general phenomena of language, as variously illustrated in the infinitely varying facts of different tongues, so as to exhibit its nature as a factor in human history and its methods of life and growth (linguistic science)—these are what philology teaches.

The study of language is a division of the general science of ethnology (q.v.), and is akin to all the rest in respect to its objects and its methods. Man as we now see him is a twofold being: in part the child of nature, as to his capacities and desires, his endowments of mind and body; in part the creature of education, by training in the knowledge, the arts, the social conduct, of which his predecessors have gained possession. And the problem of anthropologic is this: how natural man has become cultivated man; how a being endowed by nature should have begun and carried on the processes of acquisition which have brought him to his present state. The results of his predecessors' labours are not transmuted for his benefit into natural instincts, in language or in anything else. The child of the most civilized race, if isolated and left wholly to his own resources, aided by neither the example nor the instruction of his fellows, would no more speak the speech of his ancestors than he would build their houses, fashion their clothes, practise any of their arts, inherit their knowledge or wealth. In fact, he would possess no language, no arts, no wealth, but would have to go to work to acquire them, by the same processes which began to win them for the first human beings. One advantage he would doubtless enjoy: the descendant of a cultivated race has an enhanced aptitude for the reception of cultivation; he is more cultivable; and this is an element that has to be allowed for in comparing present conditions with past, as influencing the rate of progress, but nothing more. In all other respects it is man with the endowments which we now find him possessed of, but destitute of the gradually accumulated results of the exercise of his faculties, whose progress we have to explain. And it is, as a matter of necessity, by studying records of the earliest stages of acquisition, and transferring those, with due allowance for different circumstances, to more primitive periods, that the question of first acquisition or origin is to be solved, for language as for tools, for arts, for family and social organization, and the rest. There is just as much and just as little reason for assuming miraculous interference and aid in one of these departments as in another. If men have been left to themselves to make and improve instruments, to form and perfect modes of social organization, by implanted powers directed by natural desires, and under the pressure of circumstances, then also to make and change the signs that constitute their speech. All expressions, as all instruments, are formed and changed by the men who use them; the same will have been the case in the unknown or prehistoric past. And we command now enough of the history of language, with the processes of its life and growth, to determine with confidence its mode of origin—within certain limits, as will appear below.

It is beyond all question, in the first place, that the desire of communication was the only force directly impelling men to the production of language. Man's sociability, his disposition to hand together with his fellows, is the reason; and for sympathy, is one of his most fundamental characteristics. To understand those about one and to be understood by them is now, and must have been from the very beginning, a prime necessity of human existence; we cannot conceive of man, even in his most undeveloped state, without the recognition of it. Communication is still the universally recognized office of speech, and to the immense majority of speakers the only one; the common man knows no other, and can only with difficulty and imperfectly be brought to see that there is any other; of the added distinctness and reach of mental action which the possession of such an instrumentality gives him he is wholly unconscious: and it is obvious that what the comparatively cultivated of to-day can hardly be made to realize they have never acted upon the first men as a motive to action. It may perhaps be made a question which of the two uses of speech, communication or the facilitation of thought is the higher; there can be no question, at any rate, that the former is the broader and the more fundamental. That the kind and degree of thinking which we do nowadays would be impossible without language-signs is true enough; but so also it would be impossible without written signs. That there was a time when men had to do what mental work they could without the help of writing, as an art not yet devised, we have no difficulty in realizing, because the art is of comparatively recent device, and there are still communities enough that are working without it; it is much harder to realize that there was a time when speaking also was an art not yet attained, and that men had to carry on their rude and rudimentary thinking without it. Writing too was devised for conscious purposes of communication only; its esoteric uses, like those of speech, were at first unsuspected, and incapable of acting as an inducement; they were not noticed until made experience of, and then only by those who look beneath the surface of things. There is no analogy closer and more instructive than this between speech and writing. But analogies are abundant elsewhere in the history of human development. Everywhere it is the lower and more obvious inducements that are first effective, and that lead gradually to the possession of what serves and stimulates higher wants. All the arts and industries have grown out of men's effort to get enough to eat and protection against cold and heat—just as language, with all its uses, out of men's effort to communicate with their fellows. As a solitary man now would never form even the beginnings of speech, as one separated from society unlearns his speech by disuse and becomes virtually dumb, so early man, with all his powers, would never have acquired speech, save as to those powers was added sociability with the needs it brought. We might conceive of a solitary man as housing and dressing himself, devising rude tools, and thus lifting himself a step from wildness toward culture; but he could not conceive of talking. Recognization of the impulse to communication as the efficient cause of language-making is an element of primary importance in the theory of the origin of language. No one who either leaves it out of account or denies it will, however ingenious and entertaining his speculations, cast any real light on the earliest history of speech. To inquire under what peculiar circumstances, in connexion with what mode of individual or combined action, a first outburst of oral expression may have taken place, is, on
the other hand, quite futile. The needed circumstances were always present when human beings were in one another's society; there was an incessant drawing-on to attempts at mutual understanding which met with occasional, and then ever more frequent and complete success. There inheres in most reasoning upon this subject the rooted assumption, governing opinion even when not openly upheld or consciously made, that conception have real natural names, and that in a state of nature these will somehow break forth and reveal themselves under favouring circumstances. The falsity of such a view is shown by our whole further discussion.

The character of the motive force to speech determined the character of the beginnings of speech. That was first signified, as judged by any standard which we can apply to it, in or first in order of conceptional development. All attempts to determine the first spoken signs by asking what should have most impressed the mind of primitive man and must be failures. It was the exigencies and possibilities of practical life, in conditions quite out of reach of our distinct conception, that prescribed the earliest signs of communication. So, by a true and instructive analogy, the beginnings of writing are rude depictions of visible objects; it is now thoroughly recognized that no alphabet, of whatever present character, can have originated in any other way; everything else is gradually arrived at from that—as, indeed, in the ingenuously shaping hands of man, from any central body of signs, though but of small extent, all else is attainable by processes of analogy and adaptation and transfer. Now what is it that is directly signifiable in the world about us? Evidently the separate acts and qualities of sensible objects, and nothing else. In writing, or signification to the eye, the first element is the rude depiction of the outline of an object, or of that one of the sum of its characteristic qualities which the eye takes note of and the hand is capable of intelligibly reproducing; from that the mind understands the whole complex object itself, and then whatever further may in the circumstances of its use be suggested by it. So, for example, the picture of a tree signifies primarily a tree, then perhaps wood, something made of wood, and so on; that of a pair of outstretched wings signifies secondarily flight, then soaring, height, and whatever else these may lead to. No complete act of writing has been called for in itself; the whole is a facile analysis of its constituent qualities and a selection of the one which is both sufficiently characteristic in itself and capable of being called up by a sign before the mind addressed.

And what quality shall be selected depends in great measure upon the instrumentality used for its signification. Of such instrumentali- ties men possess a considerable variety. We must leave out of account that of depiction, as instrumentali-

The earliest human language may be said to have been a language of gesture-signs; indeed, there exist at the present day such gesture-languages as those in use between roving tribes of different speech that from time to time meet one another (the most noted example is that of the gesture-language, of a very considerable degree of development, of the prairie tribes of the North American Indians) these languages may have next best if of those who by deafness are cut off from ordinary spoken intercourse with their fellows. Yet there never can have been a stage or period in which all the three instrumentalities were not put to use together. In fact, they are still all used together; that is even now an ineffectual speaking to which grimace and gesture ("action," as Demosthenes called them) are not added as enforcers; and the lower the grade of development and culture of a language, the more important, even for intelligibility, is their addition. But voice has won to itself the chief and almost exclusive part in communication, inasmuch that we call all communication "language" (i.e. "longuiness") just as a race of mute might call it "handiness" and talk (by gesture) of a handiness of grimace. This is not in the least because of any closer connexion of the thinking apparatus with the muscles that act to produce audible sounds than with those that act to produce visible motions; not because there are natural uttered names for conceptions any more than natural gestured names. It is simply a case of "survival of the fittest," or analogous to the process by which iron has become the exclusive material of swords, and gold and silver of money: because, namely, experience has shown this to be the material best adapted to this special use. The advantages of voice are numerous and obvious. There is first its economy, as employing a mechanism that is available for little else, and leaving free for other purposes those indispensable instruments the hands. Then there is its superior perceptibleness: its nice differences impress themselves upon the sense at a distance at which visible motions become indistinct; they are not hidden by intervening objects; they allow the eyes of the listener as well as the hands of the speaker to be employed in other useful work; they are as plain in the dark as in the light; and they are able to catch and command the attention of one who is not to be reached in any other way. We might add as the third advantage a superior capability of variation and combination on the part of spoken sounds; but this is not to be insisted on, inasmuch as we hardly know what the gestures show in this respect. Ingenuity in expression had been expended through all time upon its elaboration; and the superiority, however real, can hardly have been obvious enough to serve as a motive: certainly, there are spoken languages now existing whose abundance of resources falls short of what is attainable by gesture. Oral utterance is the form which expression has inevitably taken, the sum of man's endowments being what it is; but it would be a mistake to suppose that a necessity of any other kind is involved in their relation. The fundamental conditions of speech are man's grade of intellectual power and his social instinct; these being given, his expression follows, availing itself of what means it finds best suited to its purpose; if voice had been wanting it might have been taken in its place. So, in certain well-known cases, a marked artistic gift on the part of individuals deprived of the use of hands has found means of exercise in the feet instead. But men in general have hands, instruments of exquisite tact and power, to serve the needs of their intellect; and so voice also, to provide and use the tools of thought; there is no error in maintaining that the voice is given us for speech, if only we do not proceed to draw from such a dictum false conclusions as to the relation between thought and utterance. Man is created with bodily instruments suited to do the work prescribed by his mental capacities; therein lies the harmony of his endowment. Through imitation, and in all signification becomes directly suggestive. The first written signs are (as already noticed) the depictions of visible objects, and could be nothing else; and, by the same necessity, the first uttered signs were the imitations of audible sounds. To reproduce
any sound of which the originating cause or the circumstances of production are known, brings up of course before the conception that sound, along with the originator, or circumstances of origination, or whatever else may be naturally associated with it. There are two special directions in which this mode of sign-making is fruitful: imitation of the sounds of external nature (as the cries of animals and the noises of inanimate objects when in motion or acted on by other objects) and imitation of human sounds. The two are essentially one in principle, although by some held apart, or even opposed to each other, as respectively the imitative or onomatopoetic and the exclamatory or interjectional beginnings of speech; they differ only in their spheres of significance, the one being especially suggestive of external objects, the other of inward feelings. There are natural human tones, indicative of feeling, as there are natural gestures, poses, modes of facial expression, which either are immediately intelligible to us (as is the warning cry of the hen to the day-old chicken), or have their value taught us by our earliest experiences. If we hear a cry of joy or a shriek of pain, a laugh or a groan, we need no explanation in words to tell us what it signifies any more than when we see a sad face or a drooping attitude. So also the characteristic cry or act of anything outside ourselves, if even rudely imitated, is to us an effective reminder and awakener of conception. We have no reason to question that such were the suggestions of the beginnings of uttered expression. The same means have made their contributions to language even down to our own day; we call words so produced "onomatopoetic" (i.e. "name-making"), after the example of the Greeks, who could not conceive that actually new additions to language should be made in any other way. What and how wide the range of the imitative principle, and what amount of language-signs it was capable of yielding, is a subject for more detailed investigation—rather, of speculation, since anything like exact knowledge in regard to it will never be attained; and the matter is one of altogether secondary consequence; it is sufficient for our purpose that enough could certainly be won in this way to serve as the effective germs of speech.

All the natural means of expression are still at our command, and are put to more or less use by us, and their products are as intelligible to us as they have been to any generation of our ancestors, back to the very first. They are analogous also to the means of communication of the lower animals; this, so far as we know, consists in observing and interpreting one another's movements and natural sounds (where there are such). But language is a step beyond this, and different from it. To make language, the intent to signify must be present. A cry wrung out by pain, or a laugh of amusement, though intelligible, is not language; either of them, if consciously produced in order to signify to another pain or pleasure, is language. So a cough within hearing of any one attracts his attention; but to cough, or to produce any other sound, articulate or inarticulate, for the purpose of attracting another's attention, is to commit an act of language-making, such as in human history preceded in abundance the establishment of definite linguistic sign-signs and language-forms, and therefore, in the domain of human language and all brute expression; since we do not know that any animal but man ever definitely took this step. It would be highly interesting to find out just how near any come to it; and to this point ought to be especially directed the attention of those who are investigating the communication of the lower animals in its relation to human communication. Among the animals of highest intelligence that associate with man and learn something of his ways, a certain amount of sign-making expressly for communication is not to be denied; the dog that barks at a door because he knows that somebody will come and let him in is an instance of it; perhaps, in wild life, the thriving out of certain cries becomes a speech. But that warnin cry shall advertise their fellows of the threat of danger is as near an approach to it as is anywhere made.

But the actual permanent beginnings of speech are only reached when the natural basis is still further abandoned, and signs begin to be used, not because their natural suggestiveness is seen in them, but by imitation, from the example of others who have been observed to use the same sign for the same purpose. Then for the first time the means of communication becomes something to be handed down, rather than made anew by each individual; it takes on that traditional character which is the essential character of all human institutions, which appears not less in the forms of social organization, the details of religious ceremonial, the methods of art and the arts, than in language. That all existing speech, and all known recorded speech, is purely traditional, cannot at all be questioned. It is proved even by the single fact that for any given conception there are as many different spoken signs as there are languages—say a thousand (this number is rather far within than beyond the truth), each of them intelligible to him who has learned to use it and to associate it with the conception to which it belongs, but unintelligible to the users of the nine hundred and ninety-nine other signs, as these are all unintelligible to him; unless, indeed, he learns a few of them also, by observation, and learns the one that he calls his own. What single sign, and what set of signs any individual shall use, depends upon the community into the midst of which he is cast, by birth or other circumstances, during his first years. That it does not depend upon his race is demonstrated by facts the most numerous and various; the African whose purity of descent is attested by every feature is found all over the world speaking just that language, or jargon, into the midst of which the fates of present or former slavery have brought his parents; every civilized community contains elements of various lineage, combined into one by unity of speech, and instances are frequent enough where whole nations speak a tongue of which their ancestors knew nothing. For example, the Celtic Gauls and the Germanic Normans of France speak the dialect of a geographically insignificant district in central Italy, while we ourselves can hardly utter a sentence or write a line without bringing in more or less of that same dialect. There is not an item of any tongue of which we know anything that is "natural" expression, or to the possession of which its speaker is brought by birth instead of by education; there is even very little that is traceably founded on such natural expression; everywhere θέωs or human attribution reigns supreme, and the original φῶς or natural significance has disappeared, to be found only in the name of an object (as we have found it above). It seems to some as if a name like cucuoo (one of the most striking available cases of onomatopoia) were a "natural" one; but there is just as much θέωs in it as in any other name; it implies the observation of an aggregate of qualities in a certain bird, and the selection of one among them as the convenient basis of a mutual understanding when the bird is in question; every animal consciousness to us must have its designation, won in one way or another; and in this case to imitate the characteristic cry is the most available way. If anything but convenience and availability were involved, all our names for animals would have to be and to remain imitations of the sounds they make. That the name of cucuoo is applied also to the female and young, and at other than the singing season, and then to related species which do not make the same sound—all helps to show the essentially conventional character of even this name. An analogous process of elimination of original meaning, and reduction to the value of conventional designation merely, is to be seen in every part of language throughout its whole history. Since men ceased to derive their names from signs having a natural suggestiveness, and began to make them from other names already in use with an understood value, every new name has had its etymology and its historical occasion—as, for example, the name quarantime from the Italian quarante giorni, or the word volume from its use in Latin for "a roll up," or book from a beech-wood staff or roller, or copper from Cyprus, or lunacy from a fancied influence of the moon, or priest from being an older (πρεσβύτερος) person, or butterfly from the butter-yellow colour of a certain...
common species: every part of our language, as of every other, is full of such examples—but, when once the name is applied, it belongs to that to which it is applied, and no longer to its relatives by etymology; its origin is neglected, and its form may be gradually changed beyond recognition, or its meaning so far altered that comparison with the original shall seem a joke or an absurdity. This is a regular and essential part of the process of name-making in all human speech, and from the very beginning of the history of speech; in fact (as pointed out above), the latter can only be said to have begun when this process was successfully initiated, when uttered signs began to be, what they have ever since continued to be, conventional, or dependent only on a mutual understanding. Thus alone did language gain the capacity of unlimited growth and development. The sphere and scope of natural expression are narrowly bounded; but there is no end to the resources of conventional sign-making. It is the essential characteristic of all the lower animals. The two are not of the same kind, any more than human society in its variety of organization is of the same kind with the instinctive herding of wild cattle or swarming of insects, any more than human architecture with the instinctive burrowing of the fox by a step-building of the bird, any more than human industry and accumulation of capital with the instinctive hoarding of bees and beavers. In all these cases alike the action of men is a result of the adaptation of means at hand to the satisfaction of felt needs, or of purposes dimly perceived at first, but growing clearer with gradually acquired experience. Man is the only being that has established institutions—gradually accumulated and perfected results of the exercise of powers analogous in kind to, but greatly differing in degree from, those of the lower animals. The difference in degree of endowment does not constitute the difference in language, it only leads to it. There was a time when all existing human beings were as destitute of language as the dog; and that time would come again for any number of human beings who should be cut off (if that were practicable) from all instruction by their fellows: only they would at once proceed to recreate language, society and arts by the same steps by which their own remote ancestors created those which we now possess; while the dog would remain what he and his ancestors have always been, a creature of very superior intelligence, indeed, as compared with most, of infinite intelligence as compared with many, yet incapable of rising by the acquisition of culture through the formation and development of traditional institutions. There is just the same salt in the difference between man's conventional speech and the natural communication of the lower races as in that between men's forms of society and the instinctive associations of the lower races; but it is no greater and no other; it is neither more absolute and characteristic nor more difficult to explain. Hence those who put forward language as the distinction between man and the lower animals, and those who look upon our language as the same in kind with the means of communication of the lower animals, only much more complete and perfect, fail alike to comprehend the true nature of language, and are alike wrong in their arguments and conclusions. No addition to or multiplication of brute speech would make anything like speech; the two are separated by a step which no animal below man has ever taken; and, on the other hand, language is only the most conspicuous among those institutions the development of which has constituted human progress, while their possession constitutes human culture.

With the question of the origin of man, whether or not developed out of lower animal forms, intermediate to the anthropoid apes, language has nothing to do, nor can its study ever be made to contribute anything to the solution of that question. If there once existed creatures above the apes and below man, who were extirpated by primitive man as his especial rivals in the struggle for existence, or became extinct in any other way, there is no difficulty in supposing them to have possessed the same forms of imperfectly imperfect speech. At any rate, all existing human speech is one in the essential characteristics which we have thus far noted or shall hereafter have to consider, even as humanity is one in its distinction from the lower animals; the differences are in non-essentials. All speech is one in the sense that every human being, of whatever race he may be, is capable of acquiring any existing tongue, and of using it for the same purposes for which its present possessors use it, with such power and effect as his individual capacity allows, and without any essential change in the mental operations carried on by means of speech—even as he may acquire any other of the items of culture belonging to a race not his own. The difference between employing one language and another is like that between employing one instrument and another in mechanical arts; one instrument may be better than another, and may enable its user to turn out better work, but the human ingenuity behind both is the same, and works in the same way. Nor has the making of language anything whatever to do with making man what he is, as an animal species having a certain physical form and intellectual endowment. Being what he is by nature, man has by the development of language and other institutions become what he is by culture. His acquired culture is the means means of realizing the native endowment, not the contrary. The acquisition of the first stumbling beginnings of a superior means of communication had no more influence to raise him from a simian to a human being than the present high culture and perfected speech of certain races has to lift them up to something more than human and specifically different from the races of inferior culture. It cannot be too absolutely laid down that differences of language, down to the possession of language at all, are differences only in respect to education and culture.

How long man, after he came into such being as he now is, physically and intellectually, continued to communicate with imitative signs of direct significance, when the production of traditional signs began, how rapidly they were accumulated, and how long any traces of their imitative origin clung to them—these and the question, it is at present idle to try to answer even concretely: just as it is to seek to determine when the first instruments were used, how soon they were shaped instead of being left crude, at what epoch fire was reduced to service, and so on. The stages of development and their succession are clear enough; to fix their chronology will doubtless never be found practicable. There is much reason for holding, as some do, that the very first items of culture were hardest to win and cost most time, the rate of accumulation as in the case of capital increasing with the amount accumulated. Beyond all reasonable question, however, there was a positively long period of purely imitative signs, and a longer one of mixed imitative and traditional ones, the latter gradually gaining upon the former, before the present condition of things was reached, when the production of new signs by imitation is only sporadic and of the utmost rarity, and all language-signs besides are traditional, their increase in any community being solely by variation and combination, and by borrowing from other communities.

Of what nature, in various respects, this earliest language-material was is sufficiently clear. The signs, in the first place, were of the sort that we call "roots". By this is meant only that they were integral signs, significant in their entirety, not divisible into parts, of which one signified one thing and another another thing, or of which one gave the main significance, while another was an added sign of kind or relation. In a language of developed structure like our own, we arrive at such "roots" mainly by an artificial stripping-off of the signs of relation which almost every word still has, or can be shown to have once had. In un-cost-li-ness, for example, cost is the centrally significant element; so far as English is
concerned it is a root, about which cluster a whole body of forms and derivatives; if we could follow its history no farther it would be to us an ultimate root, as much so as bind or sing or mean. But we can follow it up, to the Latin compound con-sta, a root sta with a prefixed formative element con. Then sta, which in slightly varied forms we find in a whole body of related tongues called "Indo-European," having in them all the same significance "stand," is an Indo-European root, and to us an ultimate one, because we can follow its history no farther; but there always remains the possibility that it is as far from being actually original as is the English root cost: that is to say, it is not within our power ever to get back to the really primitive elements of speech and to demonstrate their character by positive evidence. The reason for accepting a primitive root-stage of language is in great part theoretical: because nothing else is reconcilable with any acceptable view of the origin of language. The law of the simplicity of beginnings is an absolute one for every thing of the nature of an institution, for every gradually developed product of the exercise of human faculties. That an original speech-sign should be of double character, one part of it meaning this and another part that, or one part radical and the other formative, is as inconceivable as that the first instruments should have had handles, or a front room and a back one. But this theoretical reason finds all the historical support which it needs in the fact that, through all the observable periods of language-history we see formative elements coming from words originally independent, and not from any thing else. Thus, in the example just taken, the -li-of costliness is a suffix of so recent growth that its whole history is distinctly traceable; it is simply our adjective like, worn down in both form and meaning to a subordinate value in combination with certain words to which it was appended, and then added freely as a suffix to any word from which it was desired to make a derivative adjective—or, later but more often, a derivative adverb. The ness is much older (though only Germanic), and its history obscure; it contains, in fact, two parts, neither of them of demonstrable origin; but there are equivalent later suffixes, as ship in hardship and dom in wisdom, whose derivation from independent words (shape, deem) is beyond question. The un- of uncostliness is still more ancient (being Indo-European), and its probably pronominal origin hardly available as an illustration; but the comparatively modern prefix be-, of become, belte, &c., comes from the independent preposition by, by the same process as -ly or -li from like. And the con which has contributed its part to the making of the quasi-root cost is also in origin identical with the Latin preposition cum, "with." By all the known facts of later language-growth we are driven to the conclusion that a great part of them go back to some previously existing independent word; and hence that in analysing our present words we are retracing the steps of an earlier synthesis, or following up the history of our formed words toward the uniformed roots out of which they have grown. The doctrine of the historical growth of language-structure leads by a logical necessity to that of a root-stage in the history of all language; the only means of avoiding the latter is the assumption of a miraculous element in the former.

Of what phonetic form were the earliest traditional speech-signs, is, so far as essentials are concerned, to be inferred with reasonable certainty. They were doubtless articulated: that is to say, composed of alternating consonant and vowel sounds, like our present speech; and they probably contained a part of the same sounds which we now use. All human language is of this character; there are no sounds in any tongue which are not learned and reproduced as easily by children of one race as of another; all dialects admit a like phonetic analysis, and are representable by alphabetic signs; and the leading sounds, consonant and vowel, are even practically the same in all; though every dialect has its own (for the most part, readily definable and imitable) niceties of their pronunciation, while certain sounds are rare, or even met with only in a single group of languages or in a single language. Articulate sounds are such as are capable of being combined with others into that succession of distinct yet connectable syllables which is the characteristic of human speech-utterance. The name "articulate" belongs to this utterance, as distinguished from inarticulate human sounds and cries and from the sounds made by the lower animals. The word itself is Latin, by translation from the Greek, and, though very widely misunderstood, and even deliberately misapplied in some languages to designate all sound, of whatever kind, uttered by any living creature, is a most happily chosen and truly descriptive term. It signifies 'jointed,' or broken up into successive parts, like a limb or stem; the joints are the syllables; and the syllable structure is mainly effected by the alternation of close or consonant sounds with opener or vowel sounds. The simplest syllabic combination (as the facts of language show) is that of a single consonant with a following vowel; and there are languages even now existing which reject any other. Hence there is much plausibility in the view that the first speech-signs will have had this phonetic form and been monosyllabic, or dissyllabic only by repetition (reduplication) of one syllable, such as the speech of very young children shows to have a peculiar ease and naturalness. The point, however, is one of only secondary importance, and may be left to the further progress of science if study to settle, if it can; the root-theory, in any rate, is bound to any definite form or extent of root, but only denies that there can have been any grammatical structure in language except by development in connexion with experience in the use of language. What particular sounds, and how many, made up the first spoken alphabet is also a matter of conjecture merely; they are likely to have been the closest consonants and the openest vowels, medial utterances being of later development.

As regards their significant value, the first language-signs must have denoted those physical acts and qualities which are directly apprehensible by the senses; both because these don't are directly significable, and because it was only they that untrained human beings had as yet been able to use, and the power to deal with or the occasion to use. Such signs would then be applied to more intellectual uses as fast as there was occasion for it. The whole history of language, down to our own day, is full of examples of the reduction of physical terms and phrases to the expression of non-physical conceptions and relations; we can hardly write a line without giving illustrations of this kind of linguistic growth. So pervading is it, that we never regard ourselves as having read the history—of any intellectual or moral term till we have traced it back to a physical origin. And we are still all the time drawing figurative comparisons between material and moral things and processes, and calling the latter by names which go back to the physical stages of the former.

Earliest Phonetic Forms.

PHILOLOGY
Such a language is far below ours in explicitness; but it would suffice for a great deal of successful communication; indeed (as will be shown farther on) there are many languages even now in existence where we have to apply the same kind of dialectical or disputatious, a gesture of becokning or repulsion, a grunt of assent or inquiry, as is significant as a sentence, means a sentence, is translatable into a sentence, and hence may even in a certain way be called a sentence; and in the same way, but only so, the original roots of language may be said to have been sentences. In point of fact, between the holophrastic gesture or uttered sign and the sentence which we can now substitute for it—for example between the sign of becokning and the equivalent sentence, "I want you to come here"—lies the whole history of development of indicative speech.

What has been this history of development, how the first scanty and formless signs have been changed into the immense variety and fullness of existing speech, it is of course impossible to point out in detail, or by demonstration of facts, because nearly the whole process is hidden in the darkness of an impenetrable past. The only way to cast any light upon it is by careful induction from the change and growth which are seen to have been going on in the recent periods for which we have recorded evidence, or which are going on at the present time. Of some groups of related languages we can read the life for three or four thousand years back, and by comparison can infer it much farther; and the knowledge thus won is what we have to apply to the explanation of periods and languages otherwise unknown. Nothing has a right to be admitted as a factor in language-growth of which the action is not demonstrable in recorded language. Our own family of languages is the one of whose development most is known, by observation and well-warranted inference; and it may be well here to sketch the most important features of its history, by way of general illustration.

Apparently the earliest class-distinction traceable in Indo-European speech is that of pronominal roots, or signs of position, from the more general mass of roots. It is not a formal distinction, marked by a structural difference, but, so far as can be seen, is founded only on the assignment by usage of certain elements to certain offices. Formal distinction began with combination, the addition of one element to another, their fusion into a single word, and the reduction of the one part to a subordinate value, as sign of a certain modification of meaning of the other. Thus, doubtless by endings of pronominal origin, were made the first verb-forms, or words used only when predication was intended (since that is all that makes a verb), conveying at first a distinction of persons only, then of persons and numbers, while the further distinctions of tense and mode were by degrees added. To the nouns, which became nouns by the setting up of the separate and special class of verbs, were added in like manner distinctions of case, of number, and of gender. With the separation of noun and verb, and the establishment of their respective inflexion, the creative work of language-making is virtually done; the rest is a matter of differentiation of uses. For the noun (noun substantive) and the adjective (noun adjective) become two parts of speech only by a gradually deepened separation of use; there is no original or formal distinction between them; the pronouns as a rule merely add the noun-inflexion to a special set of stems; adverbs are a part of the same formation as noun-cases; prepositions are adverbs with a specialized construction, of secondary growth; conjunctions are the products of a like specialization; articles, where found at all, are merely weakened demonstratives and numerals.

To the process of form-making, as exhibited in this history, belong two parts: the one external, consisting in the addition of one existing element of speech to another and their combination into a single word; the other internal, consisting in the adaptation of the compound to its special use and involving the subordination of one element to the other. Both parts appear also abundantly in other departments of language-change, and throughout the whole history of our languages; nothing has to be assumed for the earliest formations which is not plainly illustrated in the latest. For example, the last important addition to the formative apparatus of English is the common adverb-forming suffix -ly, coming, as already pointed out, from the independent adjective like. There was nothing at first to distinguish a compound like godly (godlike) from one like storm-tossed, save that the former was more adaptable than the other to wider uses; resemblance is an idea easily generalized into apperance and the like, and the conversion of godlike to godly is a simple result of the processes of phonetic change described farther on. The extension of the same element to combination with adjectives instead of nouns, and its conversion to adverb-making value, is a much more striking case of adaptation, and is nearly limited to English among the Germanic languages that have turned like into a suffix. A similar striking case of combination and adaptation is seen in the Romanic adverb-making suffix mente or ment, coming from the Latin ablative mente, "with mind." So, to make a Romanic future like donnerai, "I shall give," there was needed in the first place the pre-existing elements, donner, "to give," and ai, "I have," and their combination; but this is only a part; the other indispensable part is the gradual adaptation of a phrase meaning "I have [something before me] for giving" to the expression of simple futurity, donnons. So far as the adaption is concerned the case is quite parallel to that of j'ai donné, "I have given," &c. (equivalent phrases or combinations are found in many languages), where the expression of possession of something that is acted on has been in like manner modified into the expression of past action. Parallel in both combination and adaptation is the past tense loved, according to a widely accepted theory, from love-did, while we have again the same adaptation without combination in the equivalent phrase did love.

That these are examples of the process by which the whole indicative structure of Indo-European language was built up admits of no reasonable question. Our belief that it is so rests upon the solid foundation that we can demonstrate no other process, and that this one is sufficient. It is true that we can prove such an origin for our formative elements in only a small minority of instances; but this is just what was to be expected, considering what we know of the disguising processes of language-growth. No one would guess in the mere y of ably (for able-ly) the presence of the adjective like, any more than in the altered final of sent and the shortened vowel of led the effect of a did once added to send and lead. The true history of these forms can be shown, because there happen to be other facts left in existence to show it; where such facts are not within reach we are left to infer by analogy from the known to the unknown. The validity of our inference can only be shaken by showing that there are forms incapable of having been made in this way, or that there are and have been other ways of making forms. Of the former there is evidently but small chance; if a noun-form meaning, "with mind," can become the means of conversion of all the adjectives of a language into adverbs, and a verb meaning "have," (and, yet earlier, "seize") of signifying both future and past time, there is obviously nothing that is impossible of attainment by such means. As regards the latter, no one appears to have even attempted to demonstrate the genesis of formative elements in any other way during the historical periods of language; it is simply assumed that the early methods of language-making will have been something different from and superior in spontaneity and fruitfulness to the later ones; that certain forms, or forms at certain periods, were made out-and-out, as forms; that sign of form-making is found in the cases; that original words were many-ventriloquized and that a formative value settled in some member of them—and the like. Such doctrines are purely fanciful, and so opposed to the teachings both of observation and of sound theory that the epithet absurd is hardly too strong to apply to them. If the later races, of developed intelligence, and trained in the methods of a fuller expression, can only win a new form by a long and gradual process of combination and adaptation, why should the earlier and comparatively untrained generations have been able to do any
better? The advantage ought to be, if anywhere, on our side. The progress of language in every department, accompanying and representing the advance of the race, on the whole, in the art of speaking as in other arts, is from the grosser to the more refined, from the physical to the moral and intellectual, from the material to the formal. The conversion of composition to form-words, or reduction of one of their elements to formative value, is a part of the general process which also creates auxiliaries and form-words and connectives, all the vocabulary of mind, and all the figurative phraseology that gives life and vigour to our speech. If a copula, expressive of the grammatical relation of predication, could be won only by attenuation of the meaning of verbs signifying "grow," "breathe," "stand," and the like; if our auxiliaries of tense and mode all go traceably back to words of physical meaning (as have to "seize," may to "be great or strong," shall to "be under penalty," and so on); if of comes from the comparatively physical off, and for from "before," forward; if relative pronouns are specialized demonstratives and interrogatives; if right means etymologically "straight," and wrong means "twisted"; if spirit is "blowing," and intellect a "picking out among," and understanding a "getting beneath," and development an "unfolding"; if an event takes place or comes to pass, and then drops out of mind and is forgotten (opposite of gotten)—then it is of no avail to object to the grossness of any of the processes by which, in earlier language or in later, the expression of formal relations is won. The mental sense of the relation expressed is entirely superior to and independent of the means of its expression. He who, to express the plural of man, says what is equivalent to man-man or heap-man (devices which are met with in not a few languages) has just as good a sense of plurality as he who says men or homines; that sense is no more degraded in him by the coarseness of the phrase he uses to signify it than is our own sense of eventuality and of pastness by the undisguised coarseness of take place and have been. In short, it is to be laid down with the utmost distinctness and confidence, as a law of language-growth, that there is nothing formal anywhere in language which was not once material; that the formal is made out of the material, by processes which began in the earliest history of language and are still in action. We have dropped here the restriction to our own or Indo-European language, which we had, because it is evident that it is true of this family of speech, one of the rest—must be true of them, unless some valid evidence be found to the contrary. The unity of human nature makes human speech alike in the character of its beginnings and in the general features of its after-history. Everywhere among men a certain store of expression, body of traditional signs of thought, being given, as used by a certain community, it is capable of increase on certain accordant lines, and only on them. In some languages, and under peculiar circumstances, borrowing is a great means of increase; but it is the most external and least organically important of all. Out-and-out invention (which, so far as we can see, must be of the kind called by us onomatopoetic) is found to play only a very insignificant part in the historical periods of language—clearly because there are other and easier modes of gaining new expression for what needs to be expressed. In the course of phonetic change a word sometimes varies into two (or more) forms, and makes so many words, which are differently turned to account. Everything beyond this must be the product of combination; there is no other way, so far as concerns the externals of speech. Then, partly as accompanying and aiding this external growth, partly as separate from and supplementing it, there is in all language an internal growth, making no appearance in the audible part of speech, consisting in multiplication of meanings, internal modification in the way of precision to the moral and intellectual, the restriction of words to certain uses, and so on. Along with these, too, a constant change of phonetic form constitutes an inseparable part of the life of language. Speech is no more stable with respect to the sounds of which it is composed than with respect to its grammatical forms, its vocabulary, or the body of conceptions signified by it. Even nearly related languages differ as much in their spoken alphabets and the combinations of sounds they admit, and in their uttered forms of words historically the same, as in any other part; and the same is true of local dialects and of class dialects within the same community. Phonetic change is not only a real but the structural development of language, and are the product of wholly independent tendencies. Sometimes, in fact, they chance to coincide, as in the distinction of minute "small," and minute "moment"; but it is only by chance, as the spoken accordance of second in its two meanings ("next" and "sixtieth of a minute") shows; words that maintain their identity of value most obstinately, like the numerals, are liable to vary indefinitely in form (so four, dòtor, quatuor, τέσσαρες, etc., from an original kwetwov: πεντε, πέντε, cóic, etc., from pentwv—while, on the other hand, two and three show as striking an accordance of form as of meaning through all the same languages); what is far the most common is that the word becomes very unlike its former self in both respects, like priest from the Greek πρεσβύτερος (presbyter), literally "older man." Human convenience is, to be sure, the governing motive in both changes; but it is convenience of two different kinds: the one mental, depending on the fact (pointed out above) that a name when once applied belongs to the thing to which it is applied, to the disregard of its etymological connexions, does not need to be changed when the thing changes, and is ready for new application to anything that can be brought into one class with the latter; and the other physical, depending on the organs of speech and their successive movements, by which the sounds that make up the word are produced. Phonetic convenience is economy of effort on the part of those organs; and to no other law than that of economy of utterance have any of the phenomena of phonetic change been found traceable (though it is also to be noted that some phenomena have not hitherto been successfully brought under it, and that the way of effecting this is still unclear). "Euphony," which used to be appealed to as explanation, is a false principle, except so far as the term may be made an idealized synonym of economy. The ear finds that agreeable which the organs of utterance find facile. Economy in utterance is no isolated tendency; it is the same that plays its part in all other kinds of human action, and in language appears equally in the abbreviation of the sentence by leaving out parts that can be spared without loss of intelligibility. It is that ubiquitous tendency, always lying in wait, like gravitation, to pull down what is not sufficiently held up—the holding-up force in language being the faithfulness of tradition, or accurate reproduction by the learner and user of the signs which he has acquired. No generation of men has any intention to speak otherwise than as its predecessor has spoken, or any consciousness that it is doing so; and yet, from generation to generation, words are shortened, sounds are assimilated to one another, and one element passes out of use while a new one is introduced. Abbreviation and assimilation are the most conspicuous departments of phonetic change, and those in which the nature of the governing tendency is most plainly seen. Taken by itself, one sound is as easy to another to the person who has accustomed himself to it from childhood; and those which the young child most easily acquires are not those which in the history of speech are least liable to alteration; it is especially in the combinations and transitions of rapid speaking that the tongue, as it were, finds out for itself easier ways of performing its task, by dropping and slurring and adapting. To trace out the infinitely varied items of this change, to co-ordinate and compare them and discover their reasons, constitutes a special department of language-study, which is treated under the head of Phonetics. It only needs to be pointed out here that phonetic change plays an arbitrary part in the structural development of language, by integrating compound words through fusion and loss of identity of their component parts, and, what is of yet more importance, by converting them into forms, through disguise of identity of one of the parts and its phonetic subordination to the other part. It is this that turns, for example, the compound god-like into PHILOLOGY
the derivative godly, the compound love-did into the verbal form loved. And yet one further result sometimes follows: an internal change is wrought by phonetic influence in the body of a word, which change then may in the further history of the word be left as the sole means of distinction between one form and another. It is thus that, in the most recent period, the distinction of led from lead and met from meet and so on has been made; the added auxiliary which originally made these pretences induced a shortening of the root-vowel, and this was left behind when the auxiliary disappeared by the usual process of abbreviation. It is in the same way that the distinctions of men from man, of were from was, of set from sit, with all their analogues, were brought about: by a modification of vowel-sound (Ger. *Umlaut*) occasioned by the presence in the following syllable of an i-vowel, which in the older stages of the language is still to be seen there. And the distinctions of sing, sang, sung and song, of bind, bound, band and bond, are certainly of the same kind, though they go back so far in the history of our family of languages that their beginnings are not yet clearly demonstrable; they were in their origin phonetic accidents, inorganic, mere accompanying and results of-external combination and not the office of distinction of meaning and were sufficient to it; in some of our languages they have been disregarded and effaced, in others they have risen to prominent importance. To regard these internal changes as primary and organic is parallel with assuming the primariness of the formative apparatus of language in general; like this, it ignores the positive evidence we have of the secondary production of such differences; they are, like everything else in linguistic structure, the outcome of combination and adaptation. Borrowing, or the taking-in of material out of another language, has been more than once referred to above as sometimes an important element in language-history, though less, of course, deep-reaching and organic than the rest. There is nothing anomalous about borrowing; it is rather in essential accordance with the whole process of language-acquisition. All our names were adopted by us because they were already in use by others; and a community is in the same way capable of taking a new name from a community with which it comes in contact as an individual from individuals. Not that it seeks or admits in this way new names for old things; but it accepts new things along with the names that seem to belong to them. Hence any degree of intercourse between one community and another, leading to exchange of products or of knowledge, is sure to lead also to some borrowing of names; and there is hardly a language in the world, except of races and communities so peculiarly isolated positions, that does not contain a certain amount of foreign material thus won, even as our English has elements in its vocabulary from half the other tongues in the world. The scale of borrowing is greatly increased when one people becomes the pupil of another in respect of its civilization: hence the abundant classical elements in all the European tongues, even the non-Romanic; hence the Arabic material in Persian and Turkish and Malay; hence the Chinese in Japanese and Corean; and, as a further result, even dead languages, like the Greek and Latin and the Sanskrit, become stores to be drawn upon in that learned and conscious quest of new expression which is the shape of culture in the various races; the measure replaces the unconscious growth of natural speech. So, in mixture of communities, which is a highly-intensified form of contact and intercourse, there follows such mixture of speech as the conditions of the case determine; yet not a mixture on equal terms, through all the departments of vocabulary and grammar; the resulting speech (just as when two individuals learn to speak alike) is essentially that of the one constituent of the new community, with more or less material borrowed from that of the other. What is most easily taken in out of another language is the names of concrete things; every degree of removal from this involves additional difficulty—names of abstract things, or the names of different forms. Indeed, the laying of forms in the highest sense, or forms of inflexion, is well-nigh or quite impossible; no example of it has been demonstrated in any of the historical periods of language, though it is sometimes adventurously assumed as a part of prehistoric growth. How nearly it may be approached is instanced by the presence in English of such learned plurals as *phenomena* and *straits*. This extreme resistance to mixture in the department of inflexion is the ground on which some deny the possibility of mixture in language, and hence the existence of such a thing as a mixed language. The difference is mainly a verbal one; but it would seem strange to reason and thereby deny that a region is inundated so long as the tops of its highest mountains are above water. According to the simple and natural meaning of the term, nearly all languages are mixed, in varying degree and within varying limits, which the circumstances of each case must explain. These are the leading processes of change seen at work in all present speech and in all known past speech, and hence to be regarded as having worked through the whole history of speech. By their operation every existing tongue has been developed out of its rudimentary radical condition to that in which we now see it. The variety of existing languages is well-nigh infinite, not only in their material but in their degree of development and the kind of resulting structure. Just as the earlier stages in the history of the use of tools are exemplified even at the present day by races which have never advanced beyond them, so is it in regard to language also—and, of course, in the latter case as in the former, this state of things strengthens and establishes the theory of a gradual development. There is not an element of linguistic structure possessed by some languages which is not wanting in others; and there are even tongues which have no formal structure, and which cannot be shown ever to have advanced out of the radical stage. The most noted example of such a rudimentary tongue is the Chinese, in which the present condition lacks all formal distinction of the parts of speech, all inflexion, all derivation; each of its words (all of them monosyllables) is an integral sign, not divisible into parts of separate significance; and each in general is usable wherever the radical idea is wanted, with the value of one part of speech or another, as determined by the connexion in which it stands; a condition parallel with that in which Indo-European speech may be regarded as existing prior to the beginnings of its career of formal development briefly sketched above. And there are other tongues, related and unrelated to Chinese, of which the same description, or one nearly like it, might be given. To call such languages radical is by no means to maintain that they exhibit the primal roots of human speech unchanged or in any way unmodified. The recognition of the fact that they have known nothing of the combination of element with element. Of some of them the roots are in greater or less part disyllabic; and we do not yet know that all disyllabism, and even that all complexity of syllable beyond a single consonant with following vowel, is not the result of combination or reduplication. But all combination is not form-making; it needs a whole class of combinations, with a recognized common element in them producing a recognized common modification of meaning, to make a form. The same elements which (in Latin, and even to some extent in English also) are of formal value in *con-sist* and *pre-dict* lack that character in the case of *cost* and *preach*; and there is no sign either of *earl*-y or of *right*-y which is present without such any value in *such* and *which* (from *so*-like and *who*-like); *cost* and *preach*, and *such* and *which*, are as purely radical in English as other words of which we do not happen to be able to demonstrate the composite character. And so a Chinese monosyllable or an Egyptian or Polynesian disyllable is radical, unless there can be demonstrated in some part of it a formative value; and a language wholly composed of such words is a root-language. Recent investigation goes to show that Chinese had at some period of its history a formal development, since extinguished by the same processes of phonetic decay which in English have been seen to mark signs of formal structure. Indeed, what has so considerable a part of the vocabulary to monosyllabism. In languages thus constituted the only possible external alteration is phonetic change to which all human speech, from the
Every beginning of its traditional life, is liable; the only growth is internal, by that multiplication and adaptation and improvement of meanings which is equally an inseparable part of all language-history. This may include the reduction of certain elements to the value of auxiliaries, particles, form-words, such as play an important part in analytical tongues like English, and are perhaps also instanced in prehistoric Indo-European speech by the class of pronominal roots. Phrases take the place of compounds and of inflexions, and the same element may have an auxiliary value in certain connexions while retaining its full force in others, like, for instance, our own have. It is not easy to define the distinction between such phrase-collocations and the beginnings of agglutination; yet the distinction itself is in general clearly enough to be drawn (like that in French between donnerai and ai donné) when the whole habit of the language is well understood.

Such languages, constituting the small minority of human tongues, are wont to be called "isolating." i.e. using each element by itself, in its integral form. All besides are "agglutinative" or more or less compounded ones.

Agglutinative Language.

Agglutinative Language

into words containing a formal part, an indicator of class-value. Here the differences, in kind and degree, are very great; the variety ranges from a scantiness hardly superior to Chinese isolation up to an intricacy compared with which Indo-European structure is hardly fuller than Chinese. Some brief characterization of the various families of language in this respect will be given farther on, in connexion with their classification. The attempt is also made to classify the great mass of agglutinating tongues under different heads: those are ranked as simply "agglutinative" in which there is a general conservation of the separate identity of root or stem on the one hand, and of formative element, suffix or prefix, on the other; while the name "inflective," used in a higher and pregnant sense, is given to those that admit a superior fusion and integration of the two parts, to the disguise and loss of separate identity, and, yet more, with the development of an internal change as auxiliary to or as substitute for the original agglutination. But there is no term in linguistic science so uncertain of meaning, so arbitrary of application, so dependent on the idiosyncrasy of its user, as the term "inflective." Any language ought to have the right to be called inflective that has inflexion: that is, that not merely distinguishes parts of speech by root and stem, but also makes the properties of those parts, as also the properties of roots and stems, visible by certain rules of formation, and by the use of certain terms, which, while they sometimes act as suffixes, and sometimes as prefixes, and sometimes as both, but also conjugates its verbs and declines its nouns; and the name is sometimes so used. If, again, it be strictly limited to signify the possession of inner flexion of roots and stems (as if simply agglutinated forms could be called "ective"), it marks only a difference of degree of agglutination, and should be carefully used as so doing. As describing the fundamental and predominant character of language-structure, it belongs to only one family of languages, the Semitic, where most of the work of grammatical distinction is done by internal changes of vowel, the origin of which thus far eludes all attempts at explanation. By perhaps the majority of students of language it is, as a generally descriptive title, restricted to that family and one other. All things considered, the final classification of such languages is not to be approved, for, in respect to this characteristic, Indo-European speech ranks not with Semitic but with the great body of agglutinative tongues. To few of these can the name be altogether denied, since there is hardly a body of related dialects in existence that does not exhibit some items of "inflective" structure; the Aryan is only the one among them that has most to show. Outside the Semitic, at any rate, one should not speak of inflective and non-inflective languages, but only of languages more inflective and less inflective.

Value of Structure.

Value of Structure

To account for the great and striking differences of structure among human languages is beyond the power of the linguist. It is only possible to assert that the growth of the body of language is a slow process, and that in all languages we find tongues of every grade, up to a high one, or to the highest. This shows clearly enough that mental power is not measured by language-structure. But any other linguistic test would prove equally insufficient. On the whole, the value and rank of a language are determined by what its users have made it do. The reflex action of its speech on the mind and culture of a people is a theme of high interest, but of extreme difficulty, and apt to lead its investigators away into empty declamation; taking everything together, its amount, as is shown by the instances already referred to, is but small. The question is simply one of the facilitation of work by the use of one set of tools rather than another; and a poor tool in skillful hands can do vastly better work than the best tool in unskilful hands—ever as the ancient Egyptians, without steel or steam, turned out products which, both for colossal grandeur and for exquisite finish, are the despair of modern engineers and artists. In such a history of development as that of human speech a fortunate turn may lead to results of unforeseen value; the earlier steps determine the later in a degree quite beyond their own intrinsic importance. Everything in language depends upon habit and analogy; and the formation of habit is a slow process, while the habit once formed exercises a constraining as well as a guiding influence. Hence the persistency of language-structure: when a certain sum and kind of expression is produced, and made to answer the purposes of expression, it remains the same by inertia; a shift of direction becomes of extreme difficulty. No other reason can at present be given why in historical time there has been no marked development out of one grade of structure into another; but the fact no more shames the linguistic scholar's belief in the growth of structure than the absence of new animal species worked out under his eyes shames the confidence of the believer in animal development. The modifying causes and their modes of action are clearly seen, and yet the results of their action except what is imposed by circumstances.

It is in vain to attempt to use dates in language-history, to say when this or that step in development was taken, and how long a period it cost, especially now that the changed views as to the antiquity of man are making it probable that only a small part of the whole history is brought within the reach even of our deductions from the most ancient recorded dialects. At any rate, for aught that we know or have reason to believe, all existing dialects are equally old; every one alike has the whole immeasurable past of language-life behind it, has reached its present condition by advance along its own line of growth and from its own plan. Hence, however much we may differ in the particular parts of these separate lines we clearly see to converge and unite, as we follow them back into the past; but whether they all ultimately converge to one point is a question quite beyond our power to answer. If in this immensity of time many languages have won so little, if everywhere language-growth has been so slow, then we can only differ as to whether it is reasonably certain, or probable, or only possible, that there should have been a considerable first period of human existence without traditional speech, and a yet more considerable one before the fixation of so much as should leave abiding traces in its descendants, and that meanwhile the race should have multiplied and scattered mankind. The mere difference in the rates is considerable; but it is not enough to exclude all dogmatic assertion of the unity of origin of human speech, even assuming unity of origin of the human race. For to prove that identity by the still existing facts of language is utterly out of the question;
PHILOLOGY

the metamorphosing effect of constant change has been too great to allow it. In point of fact, taking languages as they now exist, only those have been shown related which possess a common structure, or have together grown out of the more primitive radical stage, since structure proves itself a more constant and reliable evidence than material. And this is likely ever to be the case; at any rate, to trace all the world's languages so far back toward their beginnings as to find in them evidences of identity is beyond the wildest hope. We must be content with demonstrating for those beginnings a unity of kind as alike a body of formless roots. But, on the other hand, since this unity is really demonstrated, since all structure is the result of growth, and no degree of difference of structures can any more than of differences of muscles or functions as the result of discordant growth from identical beginnings, it is equally inadmissible to claim that the diversities of language prove it to have had different beginnings. That is to say, the question of the unity of speech, and yet more that of the unity of the race, is beyond the reach of the student of language; the best view he can attain is the hypothetical one, that, if the race is one, the beginnings of speech were perhaps one—but probably not, even then. This negative conclusion is so clearly established as to leave no excuse for the still oft-repeated attempts to press language into service on either side of the controversy respecting human unity of race.

That making and changing of language is by the act of its speakers is too obvious to call for discussion. No other force capable of acting and of producing effects is either demonstrable or conceivable as concerned in the work. The doctrine that language is an organism, growing by its own inherent powers, exempt from the interference of those who use it, is simply an indefensible paradox. Every word that is uttered is so by an act of human will, at first in imitation of others, then more and more by a formed and controlling habit; it is accessible to no change except by influences working in the speaker's mind and leading him to make it otherwise. Not that he is aware of this, or directs his action knowingly to that end. The whole process is unconscious. If any implication of reflective or intended action can be shown to inher in any doctrine of linguistic science, it vitiates that doctrine. The attitude of the ordinary speaker towards his language is that of unreasonable acceptance; it seems to him that his names for things are their real names, and all others unintelligible nicknames; he thinks himself to possess his speech by the same tenure as his sight or hearing; it is "natural" to him (or, if he reasons about it, he attributes it to a divine origin, as races beginning to philosophy assign to their various social institutions to their gods); he knows nothing of its structure and relations; it never occurs to him to find fault with it, or to deem it insufficient and add to or change it; he is wholly unaware that it does change. He simply satisfies his social needs of communication by means of it; and if he has anything to express that is different from what has been expressed before, he takes the shortest way to a provision for the need; while any relaxation of the energy of utterance tends to a variation in the uttered combinations; and thus changes come by his act, though without his knowledge. His sole object is, on the basis of what language he has, to make known his thought in the most convenient way to his fellow; everything else follows with and from that. Human nature and circumstances being what they are, what follows actually is, as already shown, inconsistent growth and change. For it we have not to seek special disturbing causes in the history of the speakers, although such may come in to heighten and quicken the change; we know that even in a small community, on a narrow islet, cut off from all intercourse with other communities, the speech would grow different—as certainly, if not as rapidly, as anywhere in the world—and only by the action of its speakers: not that the speakers of a language act in unison and simultaneously to produce a given change. This must begin in an individual, or more or less accordantly in a limited number of individuals, and spread from such example through the community. Initiation by one or a few, acceptance and adoption by the rest—such is the necessary method of all linguistic change, and to be read as plainly in the facts of change now going on among ourselves as in those of former language. The doctrine of the inaccessibility of language to other action than that of its speakers does not imply a power in the individual speaker to create or alter anything in the common speech, any more than it implies his desire to do so. What he suggests by his example must be approved by the imitation of his fellows, in order to become language. The common speech is the common property, and no one person has any more power over it than another. If there are, for example, a thousand speakers of a certain dialect, each one wields in general a thousandth part of the force required to change it—With just so much more as may belong to his excess of influence over his fellows, due to recognized superiority of any kind on his part. His action is limited only by their assent; but this is in effect a very narrow limitation, ensuring the adoption of nothing that is not in near accordance with the already existing; though it also is to be noted that he is as little apt to strike off into startling change as they to allow it; since the governing power of already formed habits of speech is as strong in him as in them. That change to which the existing habits naturally lead is easy to bring about; any other is practically impossible. It is this tendency on the part of the collective speakers of a language to approve or reject a proposed change according to its conformity with their already subsisting usages that we are accustomed to call by the fanciful name "the genius of a language."

On the relation of the part played in language-change by the individual to that by the community, in combination with the inevitableness of change, rests the explanation of the dialectic variation of language. If language were stable there would of course be no disputation; but since it is always varying, and by items of difference that proceed from individuals and become general by diffusion, there can be uniformity of change only so far as diffusion goes or as the influences of communication extend. Within the limits of a single community, small or large, whatever change arises spreads gradually to all, and so becomes part of the general speech; but let that community become divided into two (or more) parts, and then the changes arising in either part do not spread to the other, and there begins to appear a difference in linguistic usage between them. It is at first slight, even to insignificance; not greater than exists between the dialects of different localities or ranks or occupations in the same community, without detriment to the general unity of speech. This unity, namely, rests solely on mutual intelligibility, and is compatible with no small amount of individual and class difference, in vocabulary, in grammar and in pronunciation; indeed, in the strictest sense, each individual has a dialect of his own, different from that of every other, even as he has a handwriting, a countenance, a character of his own. And every item of change, as it takes place, must have its season of existence as a local or class or trade peculiarity, before it gains universal currency; some of them linger longer in that condition, or never emerge from it. All these differences in the speech of different sub-communities within the same community are essentially dialectic; they differ not in kind, but only in degree, from those which separate the best-marked dialects; they are kept down by general communication within the limit of general mutual intelligibility. Where that restraining influence ceases the limit is gradually but surely overpassed, and real dialects are the result. From what we know of the life of language we can say positively that continued uniformity of speech without continued community is not practicable. If it were possible to divide artificially, by an impassable chasm or wall, a people one for ages, and continuing to occupy the same seats, the language of the divided parts would at once begin to be dialectically different; and after sufficient time had elapsed each would have become unintelligible to the other. That is to say, whenever a community of uniform speech breaks up, its speech breaks.
up also; nor do we know of any other cause of dialectic diversity.

In applying this explanation of dialectic growth we have to allow for modifying circumstances of various nature, which alter not indeed the fact but the rate and kind of divarication. Some languages grow and change much more rapidly than others, with a corresponding effect upon divarication, since this is but a result of discordant growth. Usually, when there is division of a community, the parts get into different external circumstances, come in contact or mingle with different neighbouring communities, and the like; and this quickens and increases their divergence of speech. But the modifying factor of by far the highest importance here, as elsewhere in the history of language, is civilization. Civilization in its higher forms so multiplies the forces of communication as to render it possible that the widely-divided parts of one people, living in circumstances and under institutions of very different character, should yet maintain a substantial oneness of speech; of this there is no more striking example than the two great divisions of the English-speaking people on opposite sides of the Atlantic. On the other hand, a savage people cannot maintain a line without dialectic disunity; there are abundant examples to be met with now of mutually unintelligible speech between the smallest subdivisions of a race of obviously kindred tongue—as the different clusters of huts on the same coral islet. It is with linguistic unity precisely as it is with political unity, and for the same reasons. Before the attainment of civilization the human race, whether proceeding from one centre of dispersion or from several, was spread over the earth in a state of utter disintegration; but every centre of civilization becomes also a centre of integration; its influences make for unity of speech as of all other social institutions. Since culture has dealt surely to the dominant power in human history, the unifying forces in language have also been stronger than the diversifying; and with culture at its full height, and spread equally to every land and race, one universal language, like one universal community, is not an absurdity or theoretic impossibility, but only a Utopian or millennial dream.

Dialectic variation is thus simply a consequence of the movements of population. As the original human race or races, so the divisions or communities of later formation, from point to point through the whole life of man on the earth, have spread and separated, but jostled and interfered, have conquered and exterminated or mingled and absorbed; and their speech has been so affected by circumstance as something of these movements can be read in the present condition of languages, as in a faithful though obscure record—more, doubtless, than can be read in any other way, however little it may be when viewed absolutely. Dialectic resemblances point inevitably back to an earlier unity of speech, and hence of community; from what we know of the history of speech, they are not to be accounted for in any other way. The longer the separation that has produced the diversity, the greater its degree. With every generation the amount of accordance decreases and that of discordance increases the common origin of the dialects is at first palpable, then evident on examination, then to be made out by skilled research, then pinnings no longer demonstrable at all; for there is plainly no limit to the possible divergence. So long, now, as any evidence of original unity is discoverable we call the languages "related dialects," and combine them into a "family." The term "family" simply signifies a group of languages which the evidence thus far at command, as estimated by us, leads us to regard as descended by the ordinary processes of dialectic divarication from one original tongue. That it does not imply a denial of the possibility of wider relationship is obvious from what has been said above. That there is abundant room for error in the classification represented by it is also clear, since we may, take purely accidental resemblances, or the results of borrowing, for evidence of common descent, or may overlook or wrongly estimate real evidences, which more study and improved method will bring to light.

Grouping into families is nothing more than the best classification attainable at a given stage in the progress of linguistic science; it is in no small part provisional only, and is always held liable to modification, even sweeping, by the results of further research. Of some families we can follow the history by external evidences a great way back into the past; their structure is so highly developed as to be traced with confidence everywhere; and their territory is well within our reach: such we regard with the highest degree of confidence, hardly allowing for more than the possibility that some other dialect, or group, or now-accepted family even, may sometime prove its right to be added on. But these are the rare exceptions; in the great majority of cases we have only the languages as they now exist, and in more or less scanty collections, of every degree of trustworthiness; and even their first grouping is tentative and incomplete, and involves an adjournment of deeper questions to the day of more light. To complete and perfect the work of classification by relationship, or the establishment of families and their sub-divisions, is the first object of the comparative study of languages. No other classification has as base the least comparable with it; that by grade of structure is a mere recreation, leading to nothing; that by absolute worth is of no account whatever, at any rate in the present state of our knowledge. On genetic relationship, in the first place, is founded all investigation of the historical development of languages; since it is in the main the comparison of related dialects, even in the case of families having a long recorded history, and elsewhere only that, that gives us knowledge of their earlier condition and enables us to trace the lines of change. In the second place, and yet more obviously, with this classification is connected all that language has to teach us as to the affinities of human races; whatever ad linguiscc science renders to ethology rests upon the proved relationships of human tongues.

That a classification of languages, to which we have now to proceed, is not equivalent to a classification of races, and why this is so, is evident enough from the principles which have been brought out by our whole discussion of languages, and which, in their bearing upon this particular point, may well be recapitulated here. No language is a race-characteristic, determined by the special endowments of a race; all languages are of the nature of institutions, parallel products of powers common to all mankind—the powers, namely, involved in the application of the fittest available means to the end of communication. Hence they are indefinitely transferable, like other institutions—like religions, arts, forms of social organization, and so on—under the constraining force of circumstances. As an individual can learn any language, foreign as well as ancestral, if it be put in his way, so also a community, which in respect to such a matter is only an aggregate of individuals. Accordingly, as individuals of very various race are often found in one community, speaking together one tongue, and utterly ignorant of any other, so there are found great communities of various descent, speaking the dialects of one common tongue, which at some period historical circumstances have frozen in them. Now, the common origin that comes into every one's mind when this subject is discussed, is that of the Romanic countries of southern Europe, all using dialects of the same language which, 2500 years ago, was itself the insignificant dialect of a small district in central Italy; but this is only the most important and striking of a whole class of similar facts. Such are the results of the contact and mixture of races and languages. If language-history were limited to growth and divarication, and race-history to spread and dispersion, it would be a comparatively easy task to trace both backward toward their origin; as the case is, the confusion is inextricable and hopeless. Mixture of race and mixture of speech are coincident and connected processes; the latter never takes place without something of the former; but the one is not at all a measure of the other, because circumstances may give to the speech of the one element of population a greatly disproportionate
PHILOLOGY makes community; these are strongly their special problem. Some of the peculiarities of the Germanic system alluded to above; in the monotony and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflection" in the special sense of that term) for the purposes of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with the Indo-European. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relation; but, though the fact is a striking one, and of no small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety of such, distributed among the multitude of human tongues. Many others compare the Semitic and Indo-European "roots" with one another, and believe themselves to find there numerous indications of identity of material and signification; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as underlie Indo-European structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are stringently against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one.

3. Hamitic Family.—The prominent importance of this family (see Hamitic LANGUAGES) is due to a single one of its members, the Egyptian. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward to beyond the equator. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the more modern Coptic (itself now for some centuries extinct; see Egyptian, Copts); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position, especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the later stages of Hamitic speech are, as Semitic and Egyptian; and by many believed to be found; but the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler
PHILOLOGY

427

elements. It has no derivative apparatus by which noun-stems are made from roots; the root is the stem likewise; there is nothing that can be properly called either declension or conjugation; and the same pronominal particles or suffixes have now a subjective value, indicating use as a verb, and now a possessive, indicating use as a noun. There is no method known to linguistic science by which the relationship of such a tongue as this with the highly and peculiarly inflective Semitic can be shown, short of a thorough working out of the history of development of each family taken by itself, and a retracing in some measure of the steps by which each should have arrived at its present position from a common starting-point; and this has by no means been done. In short, the problem of the relation of Semitic with Hamitic, not less than with Indo-European, depends upon that of Semitic growth, and the two must be solved together. There are striking correspondences between the pronouns of the two families, such as, if supported by evidences from other parts of their material, would be taken as signs of relationship; but, in the absence of such support, they are not to be relied upon, not till it can be shown to be possible that two languages could grow to be so different in all other respects as are Egyptian and Hebrew, and yet retain by inheritance corresponding pronouns. And the possession of grammatical gender by Indo-European, Semitic and Hamitic speech, and by them almost alone, among all human languages, though an extremely noteworthy fact, is (as was pointed out above) in the present condition of linguistic science quite too weak a basis for a belief in the original identity of the three families.

Egyptian is limited to the delta and valley of the Nile, and is the only Hamitic language which has ancient records; of the others the existing forms alone are known.

The Libyan or Berber division of the family occupies the inhabitable part of northern Africa, so far as it has not been displaced by intrusive tongues of other connexion—in later times the Arabic, which since the Mahommedan conquest has been the cultivated tongue of the Mediterranean coast, while the earlier Vandal, Latin and Punic have disappeared, except in the traces they may have left in Berber dialectic speech. The principal dialects are the Kabyle, the Shilha and the Tuarek or Tamashek, corresponding nearly to the ancient Numidian, Mauretanian and Gaetulan respectively.

The third or Ethiopic division includes as its chief members the Beja or Bishārīn, the Sahi, the Dankali, the Somali, and the more inland Galla; the first two lying along the Red Sea north of Semitic Abyssinia, the others south of it, to the equator. By some authorities (Lepsius, Bleek) there is added to the Hamitic family a fourth, the Bantu, from extreme southern Africa, the Hottentot and Bushman languages. The ground of this classification is the possession by the Hottentot of the distinction of grammatical gender, and even its designation by signs closely corresponding to those used in the Ethiopic division. Others deny the sufficiency of this evidence, and rank the Hottentot as a separate group of African dialects, adding to it provisionally the Bushman, until better knowledge of the latter shall show whether it is or is not a group by itself. If the Hottentot be Hamitic, we shall have to suppose it cut off at a very remote period from the rest of the family, and forced gradually southward, while all the time suffering mixture both of speech and of blood with the negro races, until the physical constitution of its speakers has become completely metamorphosed, and of its original speech no signs are left save those referred to above; and while such exceptional phonetic peculiarities have been worked out as the use of the clicks or clucking sounds: and this must be regarded as at least extremely difficult.

4. Monosyllabic or South-eastern Asiatic Family.—This body of languages may well enough be the next taken up; and here again (as was the case with the preceding family) on account of the prominent importance of one of its dialects and of the people speaking it—the Chinese people and language. The territory of the family includes the whole south-eastern corner of Asia: China on the north-east, Farther India in the south, and the high plateau of Tibet, with the neighbouring Himalayan regions, to the westward. The ultimate unity of all these languages rests chiefly upon the evidence of their form, as being all alike essentially monosyllabic and isolating, or destitute of formal structure; the material correspondences among them, of accordant words, are not sufficient to prove them related. The Chinese itself can be followed up, in contemporary records, to a period probably not far from 2000 B.C., and the language, the people, and their institutions, are then already in the main what they have ever since continued to be (see China); the other leading tongues come into view much later, as they receive their historic connexion from China on the one hand (the Annamites), or from India on the other (the Tibetans, Burmese, Siamese); and the territory includes great numbers of wild tribes unknown until our own times, whose race-relations and language-relations are as yet very obscure. Current opinion tends to regard the Annamites, Peguans and Cambodians (the Mon-Khmer group) as forming a more nearly related group or division, and as having been the earlier population of Farther India, in part dispossessed and driven forward by the later intrusion from the north of Siamese and Burmese, of whom the former are more nearly related to the Chinese and the latter to the Tibetans. The Mon-Khmer group is itself more nearly related to the Kolarian and Malay-Polynesian.

The character of the languages of this family, especially as instanced by its most important member, the Chinese, has been pretty fully set forth in the general discussions above. They are languages of roots: that is to say, there is not demonstrable in any of their words a formative part, limiting the word, along with others similarly characterized, to a certain office or set of offices in the formation of the sentence. That the words are ultimate roots, come down from the first period of language-making, we have no reason whatever to believe; and they may possibly have passed through processes of growth which equipped them with some scanty supply of forms, but no evidence to that effect has yet been produced. The indications relied on to show an earlier polysyllabism in the family (though already in Chinese reduced to monosyllabism before the earliest historical appearance of the language, some 4000 years ago) are the comparatively recent loss of certain final mutes in Chinese words, and the presence on a considerable scale in Tibetan spelling of added initial and final consonants, now silent in the literary dialect, but claimed to be still uttered in some parts of the country. If the theory connecting these phenomena be established, the Tibetan will approve itself to be by far the most primitive of the dialects of the family, and have reason to the least developed.

For further details regarding the various tongues of the monosyllabic family, the articles on the different divisions of its territory (Burma; China; Siam; Tibet, &c.) may be consulted. The languages all alike show an addition to the resources of distinction possessed by languages in general, in the use of tones: that is to say, words of which the alphabetic elements are the same differ in meaning according as they are uttered in a higher or a lower tone, with the rising or the falling inflexion, and so on. By this means, for example, the monosyllabic elements of the literary Chinese, numbering but 500 as we should write them, are raised to the number of about 1500 words.

5. Ural-Altaic (Scythian, Turanian) Family.—China and Tibet are bordered on the north and west by the eastern branches of another immense family, which stretches through central and northern Asia into Europe, overlapping the European border in Turkey, and reaching across it in Russia and Scandinavia to the very shore of the Atlantic. Usage has not so definitely determined as in the case of most other families by what name it shall be called; Turanian is perhaps the commonest appellation, but also the most objectionable. Five principal branches are generally reckoned as composing the family. The two easternmost are the Tungusian, with the Manchu for its principal division, and the Mongol (see Mongols)
Of these two the language is exceedingly simple in structure, being raised but little above the formlessness of the Chinese. The Tungusian, however, some authorities would couple with Japanese as a separate branch. The three others are: the Turkish or Tartar, the dialects of which reach from the mouth of the Lena (Yenat) to Turkey in Europe; the Samoyed, from the Altai down to the arctic shore of Asia, and along this to the White Sea—an important congeries of barbarous tribes; and the Finno-Hungarian, including the tongues of the two cultivated peoples from which it takes its name, and also those of a great part of the population of northern and central Russia, to beyond the Ural Mountains, and finally the Lappish, of northern Scandinavian. The nearer relation of the Samoyed is with the Finno-Hungarian. The Turkish is a type of a well-developed language of purely agglutinative structure: that is, lacking that higher degree of integration which issues in internal change. Whether this degree is wholly wanting in Finnish and Hungarian is made a question; at any rate, the languages named have no reason to envy the tongues technically called "inflexive." Of a value not inferior to that of inflective characteristics is one that belongs to all the Ural-Altaic tongues, in varying measure and form, and helps to bind them together into a single family—the harmonic sequence of vowels, namely, as between root and endings, or a modification of the vowels of the endings to agree with that of the root or its final syllable.

While the physical race-characteristics known as Mongolian are wanting in the speakers of the western dialects of this family, they are conspicuously present in the people of Japan and Korea; and hence the tendency of scholars to endeavour to connect the languages of the two latter countries, since they also are of agglutinative structure (see Japan and Korea) with the family now under treatment, as also with one another.

Other languages of north-eastern Asia, too little known to group, and too unimportant to treat as separate families, may be mentioned here by way of appendix to their neighbours of the most diversified and widespread Asiatic family. They are the Aino, of Yezo and the Kurile Islands with part of the neighbouring coast; the Kamchatkan; and the Yukagir and Tchuktchi of the extreme north-east. These are sometimes combined with the Eskimo under the title of the Arctic or Hyperborean languages.

The opinion has been held by many scholars that the agglutinative dialects—Sumerian, Accadian, &c.—of the presumptive founders of Mesopotamian culture and teachers of the Assyrian Semites (see BABYLONIA) belonged to the Ural-Altaic family, and specifically to its Finno-Ugrian branch; but the data for this view are still very uncertain. The mere possession of an agglutinative structure cannot be taken as proving anything in the way of relationship.

6. Dravidian or South Indian Family.—This is an important body of nearly and closely related tongues, spoken by about 50,000,000 people, doubtless representing the main population of all India at the time when the intrusive Indo-European tribes broke in from the north-west, and still filling most of the southern peninsula, the Deccan, together with part of Ceylon. They are languages of a high grade of structure, and of great power and euphony; and the principal ones have enjoyed a long cultivation, founded on that of the Sanskrit. As they obviously have no Indo-European affinities, the attempt has been made to connect them also with the Ural-Altaic or Turanian family, but altogether without success, although there is nothing in their style of structure that should make such connexion impossible.

7. Malay-Polynesian Family.—Not all the tribes that make up the Malayo-Polynesian family were doubtless Malayan speakers of much more widespread, but has now everywhere else lost its separate identity; as such it is of extreme interest to the ethnologist (see BASQUES). The Basque language appears to be unrelated to any other on earth. It is of a very highly agglutinative structure, being equalled in intricacy of combination only by a part of the American dialects. Limited as it is in territory, it falls into a number of well-marked dialects, so that it also may not be refused the name of a "family."

The only other case of the kind worth noting is that of the Kolars on the mainland and the Nicobar Islanders. The principal one among them is the great Malay-Polynesian family. It falls into two principal divisions, Malayan and Polynesian. The Malayan includes, besides the Malay proper (see MALAYS), which occupies the Malaccan peninsula (yet doubtless not as original home of the division, but by immigration from the islands), the languages also of Sumatra, Java, Borneo, &c., of the Philippine Islands, of part of Formosa, and of Madagascar, together with the coasts of Celebes and other islands occupied in the interior by Papuans. The Polynesian division includes most of the tongues of the remaining scattered groups of islands, and that of New Zealand. Probably to these are to be added, as a third division, the Melanesian dialects of the Melanesian Archipelago, of which both the physical and the linguistic peculiarities would in that case be ascribed to mixture with the black Papuan races. All these languages are extremely simple in phonetic form, and of a low grade of structure, the Polynesian branch being in both respects the lowest, and some of the Malayan dialects having reached a development considerably more advanced. The radical elements are much oftener of two syllables than of one, and reduplication plays an important part in their extension and variation. Malay literature goes back as far as to the 12th century, and there are Javan records even from the early centuries of our era, the result of religion and culture introduced into that island from Brahmanic India. In recent years more active investigation has been carried on with a view to tracing out the special laws of historical development prevailing in the family.

8. Other Oceanic Families.—At least two other families, unconnected with the preceding and with one another, are found among the Pacific Islands, and only there. The continental island of Australia, with its dependency Tasmania (where, however, the native tongue has now become extinct), has its own body of probably related dialects, as its own physical type. They have been but imperfectly investigated, their importance, except to the professed student of language, being nothing; but they are not destitute of a rude agglutinative structure of their own. Still less known are the Papuan or Negrito languages, belonging to the black race with frizzled hair inhabiting most of New Guinea, and found also in the interior of some of the other islands, having been driven from the coasts by superior intruders of the Malay race.

9. Caucasian Languages.—Of the existing languages of Asia there remain to be mentioned only those of the Caucasian mountains and highlands, between the Black and Caspian seas, pressed upon the north by Slavonians and Turks, upon the south by Armenians and Kurds and Turks. Its situation makes of the Caucasus a natural eddy in all movements of emigration between Asia and Europe; and its linguistic condition is as if remnants of many families otherwise extinct had been stranded and preserved there. The dialects north of the principal range—Circassian, Mtsjestjegian, Lesghian, &c.—have not been proved to be connected either to one another or to those of the south. Among the latter, the Georgian is much the most widespread and important (see GEORGIA) and, alone among them all, possesses a literature. The Caucasian dialects present many exceptional and difficult features, and are in great part of so high a grade of structure as to have been allowed the epithet inflexive by those who attach special importance to the distinction thus expressed.

10. Remnants of Families in Europe.—The Basque people of the western Pyrenees, at the angle of the Bay of Biscay, are shown by their speech to be an isolated remnant of some race which occupied a large space of Europe south of a much more widespread, but has now everywhere else lost its separate identity; as such it is of extreme interest to the ethnologist (see BASQUES). The Basque language appears to be unrelated to any other on earth. It is of a very highly agglutinative structure, being equalled in intricacy of combination only by a part of the American dialects. Limited as it is in territory, it falls into a number of well-marked dialects, so that it also may not be refused the name of a "family."

The only other case of the kind worth noting is that of the

PHILOLOGY
Etruscan language of northern central Italy, which long ago became extinct, in consequence of the conquest and absorption of Etruria by Rome, but which still exists in numerous brief inscriptions (see ETRUSCI). Many attempts have been made to connect the language with other families, and it has even recently been pronounced Aryan or Indo-European, of the Italic branch, by scholars of high rank. But its supposed Indo-European relationship was at once shown to be erroneous when, in 1892, a small book which had been used to pack a mummy was discovered in the museum at Agram, and published. The probability of relationship with the ancient Lydian, as was the opinion held in ancient times, has been increased by recent research, and is likely soon to be verified or disproved by the discovery of Lydian records.

In order to complete this review of the languages of the Old World it only remains to notice those of Africa which have not been already mentioned. They are grouped under two heads: the languages of the south and those of the centre of the continent.

11. South African or Bantu Family.—This is a very extensive and distinctly marked family (see BANTU LANGUAGES), occupying (except the Hotentot and Bushman territory) the whole southern peninsula of the continent from some degrees north of the equator. It is held apart from all other known families of language by a single prominent characteristic—the extent to which it makes use of prefixes instead of suffixes as the apparatus of grammatical distinction; its inflexion, both declensional and conjugal, is by appended elements which precede the stem or root. The most conspicuous part of the vocabulary is the number of prefixes, different in singular and plural, by which the various classes or genders (not founded on sex; the ground of classification is generally obscure) of nouns are distinguished; these then reappear in the other members of the sentence, as adjectives and verbs and pronouns, which are determined by the noun, thus producing an alliterative concord that runs through the sentence. The pronominal determinants of the verb, both subject and object, also come before it; but the determinants of mode of action, as causative, &c., are mostly suffixed. The language in general is rich in the means of formal distinction. Those dialects which border on the Hottentot have, apparently by derivation from the latter, the clicks or clucking-sounds which form a conspicuous part of the Hottentot spoken alphabet.

12. Central African Languages.—The remaining languages of Africa form a broad band across the centre of the continent, between the Bantu on the south and the Hamitic on the east and north. The Bantu group, extending from north of the equator to the Cape of Good Hope, with a vast variety of dialects, is the most important of all African languages. To it belongs Swahili, the language of Zanzibar, only less valuable as a means of communication and trade than the Hausa of the Sudan, the most important of the dialects under the influence of the Hamitic languages. The African languages are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportioned to the importance of African speech in the general scale of human language. There is no small variety of speech type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher endowment, certain races are set off and made a separate division of; such is the Nubian or Nilotic. It is a subject to which the late regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present an hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies are quotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South African or Bantu family may be secondary, due to the great expansion under favouring circumstances of a race once having no more importance than belongs now to many of the Central African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere. One group in the east (Oigor, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity; things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of gender-distinction like that in our own Indo-European languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen. Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

13. American Languages.—With these the case is closely the same as with the Central African languages; there is an immense number of dialects, of greatly varied structure (see INDIANS, NORTH AMERICAN). Even among neighbouring families like the Algonquin, Iroquois and Dakota, whose agreement is marked by the use of a distinctive preposition or particle, and with the accordant race-type of their speakers, forbids us to regard them as ultimately different, no material correspondence, agreement in words and meanings, is to be traced; and there are in America all the degrees of polysynthesis, down to the lowest, and even to its entire absence. Such being the case, it ought to be evident to every one accustomed to deal with this class of subjects that all attempts to connect American languages as a body with languages of the Old World are and must be fruitless.

Literature.—Many of the theoretic points discussed above are treated by the writer with more fulness in his Language and the Study of Language (1867) and Life and Growth of Language (1875). Other English works to consult are M. Müller's Lectures on the Science of Language; Farrar's Chapters on Language; Wedgwood's Origin of Language (all more or less antiquated); Sayce's Principles of Philology and Introduction to the Science of Language, &c.; Sweet, The History of Language (1900). In German, see Paul's Principien der Sprachgeschichte (Halle, 1880); Delbrück's Einleitung in das Sprachstudium (Leipzig, 1880; 4th ed., 1905; 5th ed., 1910; there is also an English version); Brugmann and Delbrück's Grundriss der vergleichenden Grammatik der indogermanischen Sprachen (1880-1900); a second edition of the first volume was published in 1897, two parts of vol. ii., including the stem-formation and declension of the noun and pronoun appeared in 1906 and 1909); also the works of W. von Humboldt and of H. Steinthal, the most important of whose linguistic works, Charakteristik der hauptsächlichsten Typen des Sprachbaues (1861), was recast and brought up to date under the same title by F. Misteli (1893). See also handy summaries covering the same ground, but without bibliography, in F. N. Finck's Die Sprachstämme des Erdbreiches (1900) and Die Haupttypen des Sprachbaus (1910). Many of the languages of India and Farther India have been treated in the Linguistic Survey of India, edited by De G. E. Ferguson (a government publication still in progress). A short popular account of the subject is given in Porzczinski's Einleitung in die Sprachwissenschaft (1910), a German translation of a Russian original. The Bantu languages have been treated by Black, Torrond, and most recently by Meinhof, whose Lautlehre der Bantu Sprachen (1910) is the most complete handling of the subject. As to the classification and relationships of languages, see Hovelacque's La Linguistique (Paris, 1876) and F. Müller's Grundriß der Sprachwissenschaft (Vienna, 3 vols.; a fourth was left incomplete at the author's
PHILOLOGY

death). Both works are already somewhat antiquated. As to the history of the study, see Lersch's Sprachphilosophie der Alter (1840); Steinthal's Geschichte der Sprachwissenschaft bei den Griechen und Römern (1856); Benfey's Geschichte der Sprachwissenschaft und Orientalischen Philologie in Deutschland (1860); Sandy's History of Classical Scholarship (3 vols., 1905-1905); Vilh. Thomsen's Sprogavenskaliens Historien (Kopenhagen 1902).

(W.D.W.)

II.—Comparative Philology of the Indo-European Languages.

The study of Indo-European comparative philology has from its outset necessarily been in close connexion with the study of Sanskrit, a language unparalleled amongst its cognates in antiquity and distinctness of structure, and consequently the natural basis of comparison in this field. It is therefore not to be wondered at that we find no clear views of the mutual relationship of the Indo-European family or their position with regard to other languages until Sanskrit began to attract the attention of European philologists, or that the introduction of Sanskrit as an object of study was closely followed by the discovery of the original community of a vast range of languages and dialects hitherto not brought into connexion at all, or only made the objects of baseless speculations. We meet with the first clear conception of this idea of an Indo-European community of languages in the distinguished English scholar Sir William Jones, who, as early as 1786, expressed himself as follows: "The Sanskrit language, whatever may be its antiquity, is of a wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could have been produced by accident; so strong that no philologer could examine all the three without believing them to have sprung from some common source which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a different idiom, had the same origin with the Sanskrit." 1 But neither Sir William Jones nor any of his older contemporaries who had arrived at similar conclusions ever raised this important discovery from a brilliant apérmâ into a valid scientific theory through a detailed and systematic comparison of the languages in question. To have achieved this is the undoubted merit of the German, Franz Bopp (q.v.), the founder of scientific philology of the Indo-European languages, and subsequently through this example also the founder of comparative philology in general. Next to him Jacob Grimm (q.v.) must be mentioned here as the father of historical grammar.

The first part of his famous Deutsche Grammatik appeared in 1819, three years after Bopp had published his first epoch-making book, Uber das Conjugationsystem der Sanskrit-Esprache. Bopp's results were here at once utilized, yet Grimm's whole system was entirely independent of that of Bopp, and had no doubt been worked out before Grimm knew of his illustrious predecessor. In fact, their scientific aims and methods were totally different. Bopp's interest was not concentrated in comparison as such, but chiefly inclined towards the explanation of the origin of grammatical forms, and comparison to him was only a means of approaching that end.

In this more or less speculative turn of his interest Bopp showed himself the true son of a philosophical period when general linguistics received its characteristic stamp from the labours and endeavours of men like the two Schlegels and Wilhelm von Humboldt. Jacob Grimm's aims were of a less lofty character than those of Bopp, whose work, to his own mind, was crowned by his theory of the origin of inflexion through agglutination. In confessing his task to a more limited range than the vast field of Indo-European languages embraced in Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research. Grimm's discovery of the so-called "Lautverschiebung," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not always derive the benefit from Bopp's works which they might have afforded him) is clearly traceable in the work of Bopp's successors, amongst whom Friedrich August Pott (1802—1885) is universally judged to hold the foremost rank. In his great work, Etymologische Forschungen auf dem Gebiete der indogermanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Littauischen, und Gothicen (Lemgo, 1833-1836), we find Indo-European etymology for the first time based on a scientific investigation of general Indo-European phonology. Amongst Pott's contemporaries Theodor Benfey deserves mention on account of his Griechisches Wurdlexicon (Berlin, 1850), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

A third period in the history of Indo-European philology is marked by the name of August Schleicher, whoseCompendium der vergleichenden Grammatik der indogermanischen Sprachen first appeared in 1861. In the period subsequent to the appearance of Pott's Etymologische Forschungen, a number of distinguished scholars, too large to be recorded here individually, 2 had devoted their labours to the different branches of Indo-European philology, especially assisted and promoted in their work by the rapidly progressing Vedic (and Avestic) studies that had been inaugurated by Roes, Rothenberg, Westendorf, and others. Moreover, new foundations had been laid for the study of the Slavonic languages by Miklosich and Schleicher, of Lithuanian by Kurschat and Schleicher, of Celtic by Zeuss. Of the classical languages Greek had found a most distinguished representative in Curtius, while Corssen, Mommsen, Aufrecht, Kirchhoff, &c., had collected most valuable materials towards

---

footnote: 1 For this quotation and the following historical sketch in general see Th. Benfey, Geschichte der Sprachwissenschaft, p. 438 (Munch., 1865), and especially B. Delbrück, Introduction to the Study of Languages, p. 1 (Leipzig, 1882; a fifth German edition appeared in 1909).

footnote: 2 The extensive progress made in this period is best illustrated by the foundation of two periodicals especially devoted to Indo-European comparative philology, Kuhn's Zeitschrift für vergleichende Sprachforschung (now 27 vols., Berlin, from 1851), and Kuhn's Beiträge zur vergleichenden Sprachforschung (8 vols., Berlin, from 1858). Benfey's school is more especially represented by the contributors to Benfey's Oriential Occident (3 vols., Göttingen, from 1852) and subsequently Rask's Handbuch der indogermanischen Sprachen (30 vols., Göttingen, from 1877); this journal has now been amalgamated with Kuhn's Zeitschrift. The views of the New Grammarians—Leskien, Brugmann, Osthoff and their schools—are represented in Indogermanische Forschungen (27 vols., since 1890). The Göttingen school has a further representative in Gtter, now (1910) in its third volume. The history of the meaning of words has a special period for itself, Words and Sacken. Besides the works mentioned there are many journals, publications of academies, &c., in Belgium, Sweden, Denmark, Italy, &c., which no serious student of comparative philology can ignore. French philologists and critics of the same kind, the Revue de Linguistique (Paris, from 1868) and the Mémoires de la Société de Linguistique de Paris (also from 1868), while England is represented by the Proceedings and Transactions of the Philological Society of London, and, of the Classical Review (23 vols., since 1887), and the Classical Quarterly (4 vols., since 1907), and America by the Transactions of the American Philological Association (from 1868), the American Journal of Philology (30 vols., from 1860), Classical Philology (5 vols., from 1906), and other more specialist organs.
the elucidation of Latin and the cognate Italic idioms. In his *Compendium* Schleicher undertook and solved the difficult task of sifting down the countless details amassed since the days of Bopp and Grimm, and thus making the individual languages stand out clearly on their common background, while Bopp's attention had been especially occupied with what was common to all Indo-European tongues. There are two prominent features which characterize this part of Schleicher's work—his assumption and partial reconstruction of a pre-historic parent speech, from which the separate Indo-European languages were supposed to have sprung, and the establishment of a long series of phonetic laws, regulating the changes by which that development of the individual idioms had taken place. On Schleicher's views of and contributions towards an active philology, of which he erroneously proposed to consider as a branch of natural science we need not enter here. (See *Evolution and the Science of Language in Darwin and Modern Science*, 1909, pp. 536 sqq.)

For some time after Schleicher's premature death (in 1868) Indo-European philology continued in paths indicated by him and Curtius, with the exception, perhaps, of the school founded by Benfey, who had always stood on independent ground. The difference between the two schools, however, was less strikingly marked in their writings, because it chiefly concerns general views of language and the Indo-European languages in particular, although the characteristic task of the period alluded to was that of working out the more minute details of comparison; but behind all this the general interest still clung to Bopp's old glottogonic problems. In 1876, however, a new movement, inspired in the first instance by the works of W. D. Whitney, began, and a younger school of linguists has sprung up who are united in their opposition to many theories of the older generation, yet often differ materially both with regard to method and the solution of individual problems. In its present state this younger school (often branded with the name of Neo-Grammarians, *Junggrammatiker,* by its opponents real and imaginary) is marked by certain distinct tendencies. In the first place, they are inclined more or less, and the older members of the school perhaps more than the younger, to abandon glottogonic problems as insoluble, if not for ever, yet for the present and with the scanty means that Indo-European philology alone can furnish for this purpose. In this they are in opposition to the whole of the older school. In the second place, they object to the use of all misleading metaphorical comparisons of processes in the history of language with processes of organic development—comparisons used at all times, but especially cherished by Schleicher. In the third place—and this has been of the greatest practical importance—it is evident that our general views of language and our methods of comparison should be formed after a careful study of the living languages, because these alone are fully controllable in every minute detail, and can therefore alone give us a clear insight into the working of the different motive forces which shape and modify language, and that the history of earlier periods of language, consequently, can only be duly illustrated by tracing out the share which each of these forces has had in every individual case of change. Of these forces two are found to be especially prominent—phonetic variation and formation by analogy. They generally work in turns and often in opposition to one another, the former frequently tending to differentiation of earlier unities, the latter to abolition of earlier differences, especially to restoration of conformity disturbed by phonetic change. There are, however, other important differences in the action of the two forces. Phonetic change affects exclusively the pronunciation of a language by substituting one sound or sound-group for another. From this simple fact it is self-evident that phonetic changes as such admit of no exceptions. Pronunciation—that is, the use of certain sounds in certain combinations—is perfectly unconscious in natural unstudied speech, and every speaker or generation of speakers has only one way of uttering for individual sounds or their combinations. If, therefore, a given sound was once changed into another under given circumstances, the new sound must necessarily and unceasingly replace its predecessor in every word that falls under the same rules, because the older sound ceases to be practised and therefore disappears from the language. Thus, for instance, the sound of the short so-called Italian *a* in English has become exchanged for the peculiarly English sound in *man, hat,* &c., which is so exclusively used and practised now by English speakers that they feel great difficulty in pronouncing the Italian sound, which at an earlier period was almost as frequent in English as in any other language that has preserved the Italian sound up to the present day. Again, the sound of the so-called long English *a* in *make, paper,* &c., although once a monophthong, is now pronounced as a diphthong, combining the sounds of the English short *e* and *i;* no trace of the old monophthong is left, except where it was followed by *r,* as in *hare,* *mare* (also *air, their, where,* &c.), where the *a* has a broader sound somewhat approaching that of the short *a* in *hat.* This last instance may at the same time serve to illustrate the restrictions made above as to sounds changing their pronunciation in certain groups or combinations, or under given circumstances only. We may learn from it that phonetic change need not always affect the same original sound in the same way in all its combinations, but that neighbouring sounds often influence the special direction in which the sound is modified. The different sounds of English *hare,* *hare,* *hara,* *hara* are both equivalents of the same Old English sound ð (=the Italian short *a*) in *macian,* *hara.* The latter sound has been split in two, but this process again has taken place with perfect regularity, the one sound appearing before *r,* the other before all other consonants. It is easy to see that the common practice of comprising the history of the Old English *a* in the one rule—that it was changed into the sound of the ð in *make* except when followed by an *r*—can only be defended on the practical ground that this rule is convenient to remember, because the words exhibiting the former change are more numerous than the instances of the latter; apart from this there is nothing to justify the assumption that one of these changes is the rule and the other the exception. The fact is, that we have two independent cases of change, which ought to be stated in two distinct and independent rules according to the different positions in which the original ð stood before the splitting began. It is also easy to observe that the variety of modifying influences may be much more manifold than in the present instance of *make* and *hare,* and that the number of special phonetic rules in such cases must be increased in proportion to the progress made in the investigation of the said modifying powers.

In truth, however, the study of phonetic laws falls into several different stages, and the meaning attached to the phrase *phonetic law* has varied at each of these stages. Moreover, the sweeping nature of the original generalizations has become so hedged in and contracted by limitations that a recent writer has been compelled once more to formulate the question whether phonetic laws actually exist. It must be admitted in the first place that the word *law* has been ill chosen for use in this connexion. In phonetic laws there is no element which can be identified as coming under the definition of a law as propounded by a jurist like John Austin. There is no authority which enunciates the law, there is no penalty for the breach of it. But the philologists who first used the term were not thinking of law in its strict signification, but of its use in such metaphorical expressions as scientific laws, for, as already mentioned, Schleicher and his followers in the middle of the 19th century had taken a keen interest in the development of the natural sciences, and had to some extent assimilated their terminology to that employed in those sciences. It was, however, soon recognized that the laws of language and those of natural science were not really alike or akin. A scientific "law" is only a brief method of expressing the fact that universal experience shows that certain causes universally produce certain effects. In chemistry two atoms of
hydrogen and one of oxygen will make water, and they will make nothing else at any time or at any place the world over. Phonetic laws, however, do not hold true universally. They are often curiously limited in the area to which they apply. In ancient Greek, for example, the sound -s- between two vowels, which had been handed down from the original language whence Greek and the sister languages are derived, regularly disappears; in Latin, on the other hand, it changes into -r-. Thus an original genitive of a neuter substantially identical without the known γίνων, a form which comparison with other languages shows to be traceable to an earlier γενεων, preceding the separation of the languages, while the same original stem with a different vowel in the ending appears in Latin as generis. Similarly an early *euso appears in Greek as ευω, in Latin as ero. This disappearance of original intervocalic s pervades all Greek dialects—the apparent exceptions come under the heading of analogical change; with a very few exceptions similarly explicable Latin intervocalic s has become r. But Latin was originally limited to a very small part even of Italy, and the next neighbours of the Latins on the east and south—the Sabines, Campanians, and Samnites—retained this intervocalic s without changing it into r. On the other hand, the neighbours to the north-east—the Umbrians in and beyond the Appennines—shared in this rhotacism. Yet the Celts, who bordered on the Umbrians along the Po, and who spoke a language in many respects very closely akin to the dialects of Italy, in this regard agree rather with Greek than with the Italic languages. In Latin, again, the period of action of the law which changed intervocalic s into r did not in all probability exceed the century from 450 B.C. to 350 B.C. So unlike, indeed, are phonetic laws to the laws of natural science in universality that an opponent of the dogma which declares that phonetic laws have no exceptions has compared them with the laws of fashion. The comparison is not so outrageous as it may seem at first sight. For in language there are two kinds of sound change, that which is unconscious, universal at a given time and within a given area, and, on the other hand, that which belongs only to a particular class or clique, deviates consciously from the pronunciation of the majority, is therefore not universal, and exercises no permanent influence on the language. The second kind of sound change corresponds exactly to the laws of fashion; it is in fact one of them. Such sound changes are the pronunciation of the English ending -ing as -in{ }', which was fashionable in the middle of the 19th century, and the sound of the English th in though. Knowledge of those who used it, an historical justification in the earlier forms from which most of the English words now ending in -ing are descended, and which survive in numerous local dialects. A similar conventional mispronunciation was the lisp affected by some would-be artistic persons at a somewhat later period. Belonging to an entirely different social stratum, and now equally obsolete, was the London pronunciation of the first half of the 19th century typified in Tony and Sam Weller's treatment of s and w in the Pickwick Papers. This, however, made a much nearer approach to being a genuine dialect peculiarity. It undoubtedly pervaded the pronunciation of the lower classes in London at that time, and it is quite possible it may have spread over a wider and wider area until it embraced the whole population of England. A later change, that of the diphthong ai into ei (so that day, daily are pronounced dy, dyly), has spread from Essex and the East End of London over a large part of London and of the adjacent counties, and is still widening its range both geographically and socially. The history of these sound changes has not yet been investigated in detail with the thoroughness which it deserves.

There is, then, a part of sound change which is a matter of fashion and which is conscious. This sound change appears frequently in the pronunciation of individuals who have migrated from parts of England to parts of Scotland, for example, the prepositions with and of appearing to vary to them in accents forms. In the conscious attempts to pronounce them as they appear in literary English, the educated Scotsman, if he remains in his native place, as a rule pronounces them as with (with the final sound unvoiced as it appears in the Scottish legal preposition osworth) and as of, the final sound here also being unvoiced. If he migrates to England or to Australia he will probably in course of time adopt the pronunciation with a voiced final sound. In the course of years habit will become second nature, and in this respect the speaker's pronunciation will be that of his dialect. It is clear, however, that changes of this nature cannot take place on a large scale. If a large number of persons migrate in a body and continue to live in close intercourse with one another and but little in contact with the outside world, changes such as take place in the pronunciation of the individual emigrant do not occur. There can be no imitation of alien sounds, for there are none; no greater effort to be intelligible is required, for the audience has not changed. Hence it has been often remarked that a population which history shows to have remained undisturbed for very long periods in the same geographical situation manifests but little change in its language. Thus in Arabia and Lithuania the population has remained practically unaltered in the same habitat for thousands of years, with the result that the languages spoken there remain at the present day the most archaic members of the linguistic families to which they respectively belong.

From what has been said it will be obvious that a phonetic law is only an observed uniformity in the treatment of a sound or a combination of sounds within a linguistic area at a given time. In the definition the term linguistic area is a very variable quantity. Thus it is a phonetic law that a sound of the original Indo-European language, the precise pronunciation of which cannot be determined, but which was at any rate a palatal sound (\( \ddot{e} \)), appears in the Indo-European group (Sanskrit, Zend, Old Persian, with their descendants), in Armenian, in Balto-Slavonic and Albanian, in the form of a sibilant, while in Greek, the Italic dialects, Germanic and Celtic, it appears as a k-sound (See Indo-European Languages). Here the linguistic area is extremely wide, and it is clear that the difference between the two groups of languages must be dated back to a very early period. Again, it is a phonetic law of Greek that the original combination st- at the beginning of words is retained in Greek. How then are we to explain the existence side by side of στιγος and τεγος? The former apparently complies with the law, the latter does not. The former has by its side the verb στιγο, while τεγο is supported only by the rare τεγη. Yet the forms of the verb and substantive found in the Indo-European languages leave no doubt that the forms without s- represent an earlier old form, for the English thatch could not have changed its original t- into th- if it had been preceded by s-, the law being as strict for English as for Greek that initial st- remains unchanged. On the other hand, a phonetic law may be limited to a very small area. Thus in the dialect of Etruria, and nowhere else within the area of the Ionic dialect of ancient Greek, do we find the change of the sound which appears elsewhere in Greek as -\( \alpha \)- between vowels into -\( \omega \)-, στιγος for στιγος (acc. sing.), \( \ddot{a}ραβαλιωνος\) for \( \ddot{a}ραβαλιωνο\) (3rd pl. subjunctive). Why this change should take place here and nowhere else we do not know, although it may be conjectured that the cause was a mixture of the older imitative and the later linguistic which ancient tradition supported. Undoubtedly such mixtures are the chief conditions of phonetic change, the effect of which is universal. The manner in which the change takes place is that the basis of articulation, the method in which the sound is produced, becomes changed. Thus along the "Highland line" in Scotland, where the English and Gaelic-speaking populations had their linguistic frontier for centuries, the wh- of English, the Anglo-Saxon hw-, becomes universally f-, wha? becoming fo? white, file, &c., f being the sound which it was most easy to substitute for the difficult hw-.

The history of Spanish in the different communities of South America excellently illustrates this point. It marks the difference between the Spaniards in Mexico and the Spaniards in Chile, who ultimately, and chiefly by intermarriage, incorporated amongst them a considerable element from amongst the native Araucanian Indians. The result has been
that the language of Chile is Spanish, pronounced not with the
genuine sounds of Spanish, but with the sounds of the Araucanian
language substituted for them. Elsewhere in Spanish America
the language of the conquerors remained comparatively pure,
because the Spaniards were much fewer in number, and had
therefore to make themselves a captive apart. For the same
reason Latin has split up into the numerous forms which we
now know as the Romance languages. The particular line of
development which, e.g. French followed as compared with
Spanish or with the language of the Rhaetian Alps was condi-
tioned by the nature of the sounds in the language which pre-
ceded it in the same area, and which was spoken by the ancient
Gauls who adopted Latin. The difficulty found in all of these
cases is precisely of the same kind as that which an adult at the
present day speaking one language finds in attempting to learn
the pronunciation of another language.
On the one hand, it is
only with the greatest difficulty that muscles for many years
accustomed to perform one set of movements can be forced into
performing another set which are very similar but yet not
identical; on the other hand, to an untrained ear the difference
between the two sounds may remain unappreciated. The result
is that the new language is pronounced with the sounds of the
speaker's original language. If the new language is adopted by
a whole people to whom it was originally foreign, the children
naturally learn it from their parents with the sounds of the old
language which has now become obsolete. Thus the basis of
articulation is changed, and if, as was the case with Latin, this
process be frequently repeated among peoples speaking languages
with articulation widely differing one from another, it is clear
that a series of different dialects of the adopted language has
been created. This kind of change is immediate and universal
throughout the whole area where linguistic change has taken
place.

Analogical change, on the other hand, does not affect the
pronunciation of a language as a whole in the way that phonetic
change does, but is confined to the formation, inflexion, syntax
and meaning of single words or groups of words, and therefore
is very apt to bear an entirely arbitrary and irregular character.
A few instances will be sufficient to illustrate this and also to
show how the apparently irregular phenomena of analogy may
be classified. (6) In Old English a certain number of substantives
formed their plurals by mutation of the root vowels, as ðæt, þæt,
or þís, þís. In Modern English this system of inflexion has been
preserved in some cases, as in foot, feet, and altered in others, as
book, books. Now, while foot, feet and book are the regular
modern phonetic equivalents of the old ðæt, þæt, þís, the plural
books can in no way be phonetically traced back to the old þís,
the phonetical equivalent of which in Modern English would be
*bëech. The only possible explanation of a form like books is that
the older þís was at some date given up and replaced by an
entirely new formation, shaped after the analogy of the numerous
words with a plural in -s without modification of the root-vowel.
Such changes, which are very numerous, exemplify the first kind
of analogy, which is generally termed formal analogy. Other
examples are the almost entire disappearance from the language
of the forms in er and en, which were earlier used as plurals in
English. That they were originally stem and not case suffixes
does not affect the point. In Middle English, as in Modern English,
ære was spelt as a plural; earæ survives, but ear, except in
such dialect forms as the Scotch e'en, has been replaced by the
form in -es: eyes. Similarly in Middle English the suffix -er
existed in many words which had been originally of the neuter
gender. Thus the plural ofchild was children, of calf was calves,
traces of which, besides the survival in dialect ofchilder and of
calver (becoming the 16th century in northern Scotch, cair—
pronounced as cair—which is still in common use), are to be
found in the place, and hence personal, names Childe-lie and
Calver-lie. The old plural ofbrother was brither, where the
suffix, however, contained an original -r, not -s changed into -r,
as did childer and calver. In Old English, alongside the form for
child making a plural childer, there had been a masculine form
making its plural in -s. It would not have been surprising there-
fore if in Modern English the plural of child had been children. But
in spite of the common tendency to make the plural of all nouns
in -s, child has gone in the opposite direction and has not
only maintained its -r, but has added to it the -en of stems like
oxen and even. In Wick we find a similar plural to calf, calveren,
but here calver has long replaced in the literary language both
the old and new forms.

(8) Let us now take another instance from the English verb.
In Old English the different persons of the preterite indicative
in the so-called strong (irregular) verbs were generally distin-
guished by different root-vowels: ridan, "to ride," and bindan,
"to bind," for instance, form their preteritess thus: ic ræd, làu ræde,
he ræde, wæt, gæ, hire ridan, and ic bænde, làu bænde, he bænde, wæt,
ge, hire bundan. In modern English this difference in the root-
vowels has been abandoned, and rode, bound now stand for all
persons, rode being the modern phonetic equivalent of the 1st
and 3rd sing. ræd, while bound represents the u-form of bindan.
When one form or set of forms ousted other varying forms from
the same paradigm, the change is described variously as
material or logical analogy. Inasmuch as a similar process
of levelling to that seen in rode has been carried through in all
preterites of Modern English, regularity prevails even here, though
a few traces of the old conflict are still visible in such poetic
forms as sung for the preterite side by side with sang. But
when we look to its results in the individual verbs we soon find
that the choice amongst the different forms which might have
served as starting-points has been entirely arbitrary. It is
indeed impossible to say why the old singular form should have
been chosen as a model in one case, as in rode, and the old plural
form in another, as in bound. From these and numerous similar
instances we must draw the conclusion that it is beyond our
power to ascertain whence analogical changes start, and to
what extent they may be carried through when once begun.
All we can do is to classify carefully the single cases that come
under our observation, and in this way to investigate where
such changes are especially apt to take place and what is their
general direction. As to the latter points, it has been observed
before that levelling of existing differences is one of the chief
features in analogical change (as in the case of rode and bound).
As to the former, it must be borne in mind that, before any ana-
logical change can take place, some mental connexion must exist
between the words or forms serving as models and those which
are remodelled after the types suggested to the minds of the
speakers through the former. Of such natural mental combina-
tions two classes deserve special notice: the mutual relationship
in which the different, say inflexional, forms of the same word
stand to each other, and the more abstract analogies between
the inflexional system of word-groups bearing a similar character,
as, for instance, the different declensions of nouns and pronouns,
or the different conjugations of verbs. The instance of rode,
bound may serve to illustrate the former category, that of books
the latter. In the first case a levelling has taken place between
the different forms of the root-vowels once exhibited in the
different preterite forms of ridan or bindan, which clearly
constitute a natural group or mental unity in consequence of
their meaning. The form of rode as a plural has simply been
taken from the old singular ræd, the long a of which has become
in Modern English a, that of bound as a singular from the old
plural bundon, the u-sound of which has in Modern English come
to be pronounced as a diphthong. In the case of book, books for
bæc, bæc, this explanation would fall short. Although we might
say that the vowel of the singular here was carried into the plural,
yet this would not explain the plural -s. So it becomes evident
that the old declension of bæc, bæc was remodelled after the
declension of words like arm: -en, -an (or in their plurals in -s. The changes indicated may generally be
shown by a proportion, the new analogical formation being the
unknown quantity to be ascertained. Thus in the case cited
above, arm: arms = book: x; and clearly the form to be
ascertained is books. Isolated words or forms which are
not part of natural groups or systems, inflexional, formative or syn-
tactical must be regarded as commonly safe from alterations
PHILOLOGY

through analogy, and are therefore of especial value with regard to establishing rules of purely phonetic development.

(c) In syntactical analogy the mental connection between the two series of constructions between which the change takes place is generally still more conspicuous. The connexion may be one of similar or of contrasted meaning. In Latin, adjectives of fullness, like other adjectives, do not originally follow by the genitive case; participles, on the other hand, were followed by the instrumental ablative. Thus Pausias in the Audaloria 813 and elsewhere could say aulam auri plenam, "a pot full of gold," or Soz aulam onustam auro, "a pot laden with gold." From these the transition was easy to the construction aulam onustam auri, as if in English one should say (as was possible in Earlier English), "a pot laden of gold." In English, contrasted words often tend to assimilate their syntactical constructions. Thus, the adjectives like and similar are followed by the preposition to (though in Modern English like need have no preposition), and upon the analogy of such words, different and dative, with which correct speakers and writers couple from, are by no means rarely followed by to. Nor is it uncommon to hear or to see differ with instead of differ from, upon the analogy of agree with. Curiously enough, Latin, from which differ is descended, is found to follow the same analogy even in good writers. Thus Cicero (Academia Pr. ii. 143) combines dissidere with cum, as later does Seneca (Epistulae, 18.1).

(d) In the development of analogy in meaning, similarity of sound is often the effective cause. Thus imperilment is properly irrelevant, not to the point, and is still so used in legal language; its more common signification of "saucy" arises from its accidental resemblance in sound to pert, a word which curiously enough has reversed its meaning, being now used in the sense of mal-apert, while the Old French aper, aper (a confusion of Lat. aperit, "open," with expertus, "skilled"), meant both "open" and "skillful." Thus from very early times the verbs fly and flee have been confused, though they are of entirely different origins. When Middle English began to lose its verb endings in -en, it was very easy for the verb leren, "learn," and lernen, "learn," to be confused. Hence frequently in Elizabethan English learn stands side by side with teache in the same signification. Cf. Tottell's Miscellany, p. 129 (Arber):

"I would not have it thought thereby The dolphin swimmie I meante to teache: Not now to teache, nor any other word, I rowe not so farre past my reache."

It is true that the distinction between phonetic and analogical change has always been acknowledged in comparative philology. At the same time it cannot be denied that analogical changes were for a long time treated with a certain disdain and contempt, as deviations from the only course of development then allowed to be truly "organic" and natural, namely, that of gradual phonetic change (hence the epithet "false" so constantly attached to analogy in former times). Amongst those who have recently contributed most towards a more correct evaluation of analogy as a motive power in language, Professor Whitney must be mentioned in the first place. Dr. Goldschmidt, Professor Scherer (Zur Geschichte der deutschen Sprache, 1868) was the first to apply analogy as a principle of explanation on a larger scale, but in a wilful and unsystematic way. Hence he failed to produce an immediate and lasting impression, and the merit of having introduced into the practice of modern comparative philology a strictly systematic consideration of both phonetic and analogical changes as co-ordinate factors in the development of language rests with Professor Leskien of Leipzig, and a number of younger scholars who had more or less experienced his personal influence. Amongst these Brugmann, Osthoff and Paul rank foremost as the most vigorous and successful defenders of the new method, the correctness of which has since been practically acknowledged by most of the leading philologists of all shades of opinion.

While the syntax of individual languages was one of the first features which attracted the grammarians' attention, at any rate in so far as particular authors differed from a given

The New School.

Historical Syntax.

of the Indo-European languages as it exists to-day has been reached by one man—Professor Berthold Delbrück of Jena. In a series of brilliant studies beginning with a pamphlet on the Locative, Ablative, and Instrumental, published in 1869, and continued in his Syntactical Researches (Syntaktische Forschungen) in five volumes, comprising a treatment of the conjunctive and optative moods in Sanskrit and Greek (1871), the theory of the Sanskrit tenses (1872), the order of words in early Sanskrit prose (Çatapatha Brâhmaṇa; 1878), the foundations of Greek syntax (1879), and the syntax of the oldest Sanskrit (Altindische Syntax), dealing exclusively with the literature of the Vedas and Brâhmaṇas (1888), Professor Delbrück laid the foundations for his treatment of comparative syntax in three volumes (1893, 1897, 1900), which has formed the completion of Brugmann's Grundriss der vergleichenden Grammatik der indogermanischen Sprachen. The only work by another hand (on a large department of the subject) which deserves to be mentioned by the side of Delbrück's studies is the small treatise by Hübschmann on the theory of the cases (Zur Kasuslehre, 1875). For the comparative neglect of this field of investigation there are several reasons.

The earlier philologists had so much to do in determining the languages which should be included within the Indo-European group, and in organizing the field of research as a whole, that it is not to be wondered at if they were unable to devote much attention to syntax. In the seventies, when attention began to be more directed towards comparative syntax, the remarkable discoveries made by Verner with regard to accentuation, and by Brugmann, Collitz and others with regard to the phonology of the Indo-European languages, again distracted attention from the subject. Moreover, the research in itself is infinitely more difficult than that into sounds and forms; for the latter may be carried on by the help of grammars and dictionaries with a comparatively small knowledge of the literature of any individual language, while on the other hand the study of syntax is impossible without a thorough and intimate knowledge of the literature and modes of expression in each separate language. It is not, therefore, matter for wonder that Delbrück has confined himself to the investigation of syntax to a part only of the languages whose sounds and forms are discussed by Brugmann in the earlier volumes of the Grundriss. To cover the whole ground is beyond the powers of a single man, and there is a great lack of preliminary studies on the syntax of many of the languages.

One of the most difficult problems connected with syntax, but primarily, as it appears, a question of morphology, is the origin of grammatical gender. It cannot be said to be an advantage to the languages which possess it, while languages which, like English, have dropped it except for an occasional metaphor, suffer no loss. Nor is the problem confined to the history of gender in the substantive. Even more perplexing is the introduction of gender into the personal pronouns of the first and second persons, which are certainly very old, show no trace of gender; the pronouns of the third person, which are more of the nature of deictic adjectives, generally possess it. To the question how grammatical gender arose in the substantive, the answer was till comparatively recently supposed to be that primitive man was given greatly to personification, endowing inanimate things with life and attributing to them influences benign or the reverse upon his own existence. The answer is not quite sufficient, for though this tendency to personification, which philologists have perhaps unduly decried or altogether denied, might account for life being attributed to inanimate objects, it hardly explains why some should be treated as masculine and others as feminine. Nor is it true, as has also been suggested, that in the case of the lower animals the generic name for the larger and stronger animals is masculine and that for the smaller or weaker feminine. In both Greek and Latin the wolf
is masculine and the fox feminine, but the lamb or the chicken which the fox robs from the fold or the hen roost is rarely feminine, generally masculine. Nor does this explanation account for the mouse in those languages being of the masculine gender, while the ferret or cat which caught them is feminine (γαλάζιο, feles). An explanation which completes the theory of personification, if it does not altogether drive it from the field, has been put forward by Brugmann. In its briefest form this explanation is that gender was attached to certain suffixes because they chanced to occur frequently in words which marked implied sex. In the Indo-European languages the commonest suffix indicating feminine gender is -a. According to this theory it had originally nothing to do with gender, but as some early words for woman or wife ended with this sound it came to be identified with feminine gender. Similarly the ending os in o-stems occurred often in names connected with males and so became identified with the masculine gender. But many stems indicate either gender indifferently, and even the very old sex words father and mother have the same ending. But when masculine and feminine endings have been attached to certain suffixes in this way, how comes it that in one series of stems the neuter should be marked not by an absence of all suffix but by a separate suffix in -m? These are the o-stems, other forms of which have been markedly identified with the masculine gender. As this characteristic, like the others mentioned, goes back apparently to a time before the separation of the Indo-European languages, explanation can hardly pass beyond speculation. It is, however, to be noted that the neuter form of the nominative is phonetically identical with the accusative form of the masculine, and it has been ingeniously argued that such forms were used originally in the accusative, such neuters not forming the subject to a verb. To the same writer the most plausible explanation of the presence of gender in the adjective is due, viz. that gender began with the deictic pronoun *so “that man,” *sā “that woman,” and that hence it passed to the adjective with which the pronoun was so frequently accompanied. If this explanation be right, analogy has brought into the Indo-European languages the useless multiplication of gender marks in such sentences as the Latin haec pulcro feminæ caesæ sunt, where the feminine gender is indicated no less than four times without any obvious gain over the English These fair women were slain, where grammatical gender is no longer obviously indicated at all.

Closely related to this question is that of the history of the neuter plural, which was first fully displayed in the work published recently by Professor Johannes Schmidt of Berlin. The curious construction, most common in ancient Greek, whereby a neuter plural is combined with a singular verb, is now demonstrated to be an archaic survival from the time when the neuter plural was a collective singular. Thus a word like the Latin ingum was a single yoke, the plural ingum, however, which was earlier inga, was a collection of yokes, with the same final a as is found generally in feminine substantives. The declension ought therefore to have been originally: nominative inga, genitive ingās, &c., like mensā, &c., of the first declension. But as ingum was used in the neuter singular for both nominative and accusative, ingā when it was felt as the corresponding plural and accusative as well as nominative, and while the other cases of the plural were taken over from the masculine o-stems, with which the singular neuter in -o-m was so closely connected. That collective words should be used for the plural is not surprising; the English youth, first an abstract, next a collective, and finally an individual, is a case in point.

For the early history of the syntax of the verb Greek and Sanskrit are important above all other languages, because in them the original forms and the original usages are better preserved than they are elsewhere. And it is in the verb that the great difficulties of comparative syntax present themselves. The noun system is so well preserved in several languages that, when the number of the original cases has once been determined, the sitting of the pro-euðics usages attaching to each case was tolerably easy, for besides Sanskrit and (to a less extent) Latin, Lithuanian and Slavonic have kept the pro-euðic case system almost complete. The ideas also which had to be expressed by the cases were on the whole of a very concrete character, so that here the problem was much simplified. On the other hand, the ideas expressed by the forms of the verb are of a much more subtle nature, while the verb system in all languages except Greek and Sanskrit has broken down earlier and more completely than the noun. It is clear that the verb of the original Indo-European language possessed two voices, and forms correspond ing to what we call the Indicative, Subjunctive, and Optative moods, and to the Present, Imperfect, Future, Aorist, and Perfect tenses. The imperative mood seems primitively to have been confined to the second person singular, just as the vocative, which, like the imperative is a stem form without suffix, was confined to the singular. The infinitive, as is well known, is in all languages of this system not originally a verbal but a substantival form. The pluperfect, where it has developed, seems to be a mixed form arising from the application of aorist endings to a perfect stem. Thus far the history of the verb system is tolerably clear. But when we attempt to define the original meaning of the moods and of the tenses we pass into a region where, in spite of assiduous investigation in many quarters during recent years, the scanty amount of light thrown on the problem has only served to make the darkness visible. As regards the tenses, at least, it has been shown that without doubt there is no difference in formation between present, future and aorist stems, while the earliest meaning of the perfect was that of a special kind of present expressing either repeated or intensive action or a state. It has also been proved that the original meaning of the aorist is not past in time, and that in fact the only element whereby these languages could express remoteness in time was the augment. The augment seems to have been originally a pronominal deictic particle. Thus, as there was no original pluperfect, as neither perfect nor aorist originally referred to past time, and as the future, except in Lithuanian (with slight traces in Slavonic) and the Indo-Iranian group, cannot be clearly distinguished from the aorist, the system as a method of expressing time absolutely breaks down. The tenses in fact did not originally express the times when the action took place, but the type of action which took place. Thus the aorist expresses in the imperfect, the imperfective in the perfect, the aorist the only fact that the action had taken place. The action indicated by the aorist might have been of considerable duration, or it might have been begun and ended in a moment; its characteristics in this respect are not in any way indicated by the aorist form, which intimates only that the action is viewed as a completed whole and not as a continuous process. The present system, however, is built up in a great variety of ways (thirty-two according to Brugmann's enumeration). It is a priori unlikely that such a multiplicity of formations had not originally some reason for its existence, and Delbrück thinks that he has discovered a difference in syntactical value between the aorist imperfect and present in Sanskrit (as in Greek) by means of etymological comparison. He compares Sanskrit rātīhi, Greek ἡλια, &c., he regards as expressing originally an action which consisted of repeated acts of the same nature (iterative), though this iterative meaning frequently passed into an intensive meaning. Present of the type seen in Sanskrit te'ṣyatī, " is thirsty," and Greek ἐφάντω, " I am glad " (for *xapju), where the ἐ of the suffix has modified the first syllable and disappeared, he regards as cursive—i.e. they express continuous action without reference to its beginning or end. Verbs which have regard to the beginning or end of the action he calls terminative, and finds them represented (a) in verbs with -n suffixes, Sanskrit yātētī, ὄρνω, sets in motion," which go back to the Sanskrit verb with the aorist Sanskrit gāchāti, "goes " (to a definite destination), Greek βάλλω, &c. The roots he classifies as momentary (punctuell) or non-momentary, according as they do or do not express an action which is begun and ended at once.
This method of classification was no doubt suggested in the first instance by the characteristics of the Slavonic verb system. In this system a clear distinction is drawn in nearly all verbs between those which express a process (durative verbs) and those which express a completed action (perfective verbs). When perfective and durative verbs are formed from the same root, the perfective are distinguished from the durative forms (a) by having a preposition prefixed, or (b) by having a different stem formation. Thus in the Old Bulgarian (Old Ecclesiastical Slavonic) to strike (hit) and to strike dead are expressed by the same verb, but in the latter meaning a preposition is found which does not appear in the former, biti (infinitive), "to strike"; u-bit, "to strike dead." To strike is durative; to strike dead is perfective. As an example of difference of stem formation expressing this difference of meaning, we may quote sestiti, "to sit down" (perfective), sestiti, "to sit" (durative). Verbs with a suffix in -n- have often a perfective meaning: cf. the Sanskrit and Greek verbs quoted above. The perfective verbs correspond in meaning to the Greek aorist, and are to be carefully distinguished from perfect forms. The same distinction of meaning is often achieved in other languages also by means of prepositions, e.g. in Latin (Seneca, Epp. xiii. 10), Quod autem ad rem pertineat, quod diuis vites, quod evitare non posset? "What does it matter how long you go on avoiding [durative] what you cannot escape [perfective]?" From this example, however, it is clear that, though the means employed to make the distinction are different, there is no difference in meaning between such perfective verbs and those classified by Delbrück as terminative. Here, as in many other parts of this study, the ideas are new, and grammatical terminology has not yet sufficiently crystallized, and still leaves something to be desired both in clearness and in precision.

As regards the moods, the difficulty has been to find any clear line whereby the functions of one word should be differentiated from those of the others. It has long been recognized that the difference between indicative and subjunctive is one of meaning and not one of formation; that, e.g., in Sanskrit bharatit (3rd sing. pres. indic.), "bears," is morphologically identical with kanti, "may slay" (3rd sing. pres. subj.), and that the latter is described as a subjunctive only because of the meaning, and because there exists a dissyllabic form, kanyi, which makes the indicative "sleys." Similarly in Greek it is impossible to distinguish morphologically between rathou, "I shall check" (fut. indic.) and rathou, "let me check" (1st aor. subj.). Most often, indeed, the earlier forms of the languages which preserve the moods best (Greek and Sanskrit), the connexion syntactically between the indicative and the subjunctive forms is closest. Not only does the future express futurity, but also the determination of the subject to carry out the action expressed, which, in Delbrück's discussion of the moods, is precisely the point chosen as characteristic of the subjunctive. On the other hand, the present optative differs from the present (and future) indicative and present subjunctive in having a special mood suffix, and in having secondary while they have primary personal endings. Nevertheless its meaning overlaps that of the other forms, and some excellent authorities, like Professor W. W. Goodwin, see a future indicative, subjunctive and optative only different degrees of remoteness of meaning, the most remote being least in the future and greatest in the optative. Delbrück, however, abides, with slight modifications, by the distinction which he propounded in 1871 that the subjunctive expresses Will and the optative Wish. Here again the problem has not been solved, and it is doubtful how far any definite solution is likely to be arrived at, since there are so many gaps in our knowledge of mood forms. These gaps, owing to the break-up of the system at so early a period, it is hardly probable we shall ever be able to fill. It is possible, however, to do a great deal more than has yet been done even in the most familiar languages. In English for instance, even now, the facts for the uses of the moods within the two centuries of the early period are very imperfectly known, and it is an exaggeration to say that more has been done in the last hundred years for Sanskrit than has been done in two thousand years of continuous study for Latin or Greek.

A still later addition to the domain of Philology—the study of meaning—presents fewer difficulties, but until recent years has been equally neglected. The study is so recent that the literature of the subject is still extremely small. The only attempts to deal with it on a large scale are M. Bréal's Essai de Sémantique (1857), now translated into English under the title of Semantics (1900), with a valuable introduction and appendix by Dr Postgate, and M. de la Grasserie's Essai d'une Sémantique Integrale (1908), a work which deserves mention for its attempt to make a thorough classification and a corresponding terminology for semantic phenomena, but the value of which is much diminished by hasty compilation and imperfect knowledge of many of the languages quoted. From the practical point of view many of the phenomena have been classified in works on rhetoric under the headings of Metaphor, Synecdoche and Metonymy. The psychological principle behind this superficial classification is that of association of ideas. Here, as elsewhere, changes proceed not by accident, but according to definite principles. Here, as elsewhere in language, in history, and the other moral sciences, the particular principle in language can be ascertained only by beginning with the result and working back. To members of the same family the same word may often have widely different associations, and, if so, the metaphors for which the word will be employed will differ in each case.

For the history of meaning it is necessary to have regard to all the forms of association of ideas which psychology recognizes. These are contiguity in place or in time, resemblance and contrast. Contrast, however, as J. S. Mill and Bain have shown, is not a simple form of association, but is evolved partly from contiguity, partly from resemblance. An artificial hollow generally implies also an artificial height made of the materials excavated from the hollow. Hence in most languages some words occur with the two contrasted meanings. Thus in English we find kitter, in use both for a ditch and for a mound fronted by a ditch, the word ditch being, in fact, but a dialectal form of dyke. In Scotland, on the other hand, where earthen mounds and stone walls form more frequent boundaries between fields than in England, the word dyke is now practically limited to elevated boundaries, while ditch is limited to excavated boundaries. Thus the proverb, "February fill dyke," which in England implies that the February rains will fill the ditches, is often understood in Scotland to mean that in February the snow will be level with the tops of the stone or turf walls. Similarly in Latin Tacitus can say fossas prorsus, which can only apply to low lying ditches, while in Greek Xenophon also talks of the ditch (trench) thrown up (τάφρος ἀναβληθέν) in this way. It is only natural, therefore, that other words with several meanings should be used similarly: moat, originally a mound of earth or peat, has come to mean a big ditch; while, conversely, soldiers in trenches are not so much in ditches, as the word ought to signify, as behind breastworks. Sometimes, when two actions opposed to one another are contiguous, a word seems to change to the exact opposite of its original meaning. Thus the English verb wean, which meant originally to accustom (to cooked food), has been transferred to the necessary preliminary, to accustom to the breast.

Resemblantia motus (L.) genuine, and (a) of external appearance, or (b) of other characteristics; or (L.) fanciful or analogical. From resemblance in the external appearance of the object, the word genu, which in Latin (gemma) usually means a bud, has
come to mean first a pearl and then by extension of the meaning any precious stone. From the concentric coils which appear in both, the Latin word for a pearl (unio, acc. unioem) appears in English as oyster. Examples where the characteristics are not of external appearance are such as the German kaiser and the Russian tsar, which are descended from Julius Caesar, while the Lithuanian word for king—karalius—is Carolus, i.e. Charlemagne. So in modern Persian, Xusser, “Lord,” comes from the Zend proper name Huravah (Chosroes). As already pointed out, the resemblances which have established a connexion between pert and imperiert (property irrelevant) are in sound only. The same is true of the supposed relation of the verb cut to cutlass, cutter and cutlet. While train oil really means oil in drops like tears (cf. German Thirrone), most people connect it with railway trains. The resemblance in some cases is merely in function. Thus, though the fir and the oak have no resemblance one to the other, the word fir is now generally identified with the Latin quercus in etymology (cf. jou and quattuor), in the same way as the Latin flagus, “beech,” is with the Greek ὄφρυς, “oak,” the users of the word having, in the course of their migrations, passed from a land with oaks to a land with firs in the same way as English and German have passed from a land of beeches to a land of oaks in the other. Resemblance as the basis of metaphor has a very widely extended influence on language.

The most numerous and most varied forms of change in meaning depend, however, upon the law of contiguity. Perhaps the commonest of all forms of contiguity is that where the word indicating some accompanying feature or condition replaces the word for the object referred to. In the countries that border the Mediterranean the heat of midday is accompanied and intensified by the dying away of the wind, a characteristic remarked upon by Aeschylus (Agam. 565): “What time upon his noonday couch, windless and waveless sank the sea round.” From the Greek word καυσία, “burning heat,” arises through Late Latin the English calm, where the absence of wind is the only idea present, that of heat having altogether disappeared. Again, in bugle, which is abbreviated for buglehorn, the word which survives properly means wild ox, and the originally more important element is lost. In a combination like silver bugle the word has gone a stage further; the original meaning of horn has also disappeared. There is no longer any thought of an animal’s horn; the only idea that survives is that of a musical instrument. From the cope or cloak (capella) of St Martin, which was preserved as a sacred relic by the Frankish kings, comes the word chapel. The word was first transferred from the cloak to the holy place wherein it was kept, and hence to similar shrines, and ultimately to any place, not being a church, where prayers were said. A jig was originally not the dance, but the fiddle which supplied the music for the dance. The names of liquors are often replaced by some accompaniment as of the place, port, sherry, champagne, or by a qualifying adjective as in brandy, properly “burnt,” from the Dutch brandewijn; or, again, only the less important element of the word is retained as in whisky, literally “water,” for the older wasshebaugh, a corruption of Gaelic words meaning the “water of life” (aqua vitae). Replacement of substantives by their accompanying adjectives is common in most languages. One of the most common methods of coining new words is by the side which it the name of the place or people whence it comes. Thus we have arras, lawn (from Laon), cravat (Croat), coach from Coce in Hungary, bilboes (both fettters and swords) from the iron mines of Bilboa in Spain. Equally common are the names of inventors—pinchbeck, tontine, silhouette, guillotine, derricke. In the word cash, which comes indirectly from Latin capsa, “a box,” the thing contained has taken its name from the container. Similarly moriar, “cement,” derives its name from the mortar in which it was mixed, while in box the material (boxwood, Lat. buxus, Greek, βους) has usurped the place of the article made. In leper the disease (Lat. lepra, the rough disease, from Greek, λέπρα φθορα) has been made into the name of the sufferer, who was earlier called a leprous man. As a consequence, a new substantive leprosy has to be taken from the adjective to indicate the disease. The various changes in meaning, which are classed together as synecdoche, have their origin in contiguity. Thus we have the species for the genus; the butcher, who properly kills goats only (Old French boe), has ousted the flesher. But we have also the genus for the species; corn, as a rule, means in England wheat; in Scotland oats; in America, maize. The individual becomes collective as in corps, navy, body (of men); the collective becomes individual when Latin racemus, “bunch of grapes,” passes into English “raisin.” Here would come the case of the so-called “word-phrase” or “metonymy,” the word-meaning, whereby, e.g. stewart, “the styward,” becomes the title of a great officer of the realm and the name of a line of kings; or, on the other side, son (Latin solitus) passes from the name of a gold coin to that of one of proverbially insignificant value. Here, too, would come many euphemistic uses which are, for the most part, applications of more general terms to avoid the mention of some specific act or object which is unpleasant, as death, murder, bankruptcy, debt, &, while metaphorical terms for the same things come under resemblance. These examples do not exhaust the forms of contiguity which appear in language, but they are enough to show how far-reaching the effect of this combination of ideas is upon language and psychology. The field is which still calls for investigation before the study of meaning attains the same development as the investigation of the other branches of the history of language.

Authorities (since 1885).—For methods of Linguistic Study: Paul, Principien der Sprachgeschichte (3rd ed., 1898); Von der Gabler, Die Sprachwissenschaft (2nd ed., 1901); Strong, Logeman & Wheeler, The History of Language (1891), an adaptation of the ideas of the Indo-European Languages: Brugmann, Principles of language (1892); Paul, Principles de Linguistique psychologique (1907). For the Controversy regarding Phonetic Laws: Curtius, Zur Kritik der neuesten Sprachkunde; Brugmann, Zum heutigen Stand der Sprachwissenschaft; Schuchard, Uber die Lautgesetze: gegen die Jungrumgrammatiker (fall in 1885); Tarbell, “Phonetic Law,” in Transactions of American Philological Association for 1886, pp. 1 sqq.; Wechsler, “Gibt es phonetische Gesetze?” (1888); Brugmann, Grundzüge der vergleichenden Grammatik der indogermanischen Sprachen (1886-1900); a new edition of the Phonology by Brugmann in 1897, of the stem-formations and inflexion of Nouns, Adjectives, Pronouns and Numerals (1900); the first edition of the Phonology and Morphology, translated into English in four volumes by Wright, Conway and Rose. For Discussion of Conception of Language: Beaucé, Essai sur l’Evolution de la Langue de la Lothaire (1892). For Syntax: Delbrück, in the works mentioned, in the text. For Semantics: besides Bréal and Postgate, see Wundt, Die Völkerpsychologie, vol. i. pt. 2, and articles by John Grote in the Journal of Philology, vol. iv. and v. A bibliography of the works which have appeared since 1890 will be found in the Anzeiger für indogermanische Sprach- und Altertumskunde; beiheft zu den indogermanischen Forschungen reduziert, by W. Streitberg. (P.Gi.; E.S.)

Summary of Philological Articles

In addition to the genetic classification of languages given above (on pp. 420-429), some further guidance as to the actual language work is given in the articles on each language. The philological section is arranged may be of service to the student. The pivot of the whole section is the article Alphabet, which traces the history of language and writing to the earliest stages, embodying the results of archaeological studies in all countries, together with the general conclusions based thereon. In this article (with further details under Crete) will be found an account of the controversy regarding the Cretan discoveries of Dr A. J. Evans. Supplementary to this comparative survey are the articles Paleography, Inscriptions, Writing and Phonetics. The first two deal with ancient documents of all kinds: Paleography with those specimens of ancient writing, literary, economic or legal, which were committed to codex, tablets or rolls by the use of the stylus, the reed or the pen; Inscriptions with documents engraved on stone or metal.
PHILOLOGY

Writing deals, chiefly from the anthropological standpoint, with primitive attempts to record ideas in an intelligible form, e.g. with "knot-signs," "message-sticks," picture-writing and the like. Phonetics covers the whole subject of speech sounds and pronunciation, the organs of speech and national sound systems.

Supplementary, from another point of view, to the article ALPHABET is a complete series of articles on the letters of the English alphabet. In these articles the history of the individual letters is traced from the Phoenician through Aramaic, Greek and Roman to modern times. All these articles may be read in connexion with a comparative table in the article ALPHABET (ad fin.), which shows in parallel columns the earliest equivalents of the modern English letters, i.e. Brahmi, Kharoṣṭhī, oldest Kharoṣṭhī, 3rd Kharoṣṭhī, Prakrit, Pali, Sanskrit, Greek, Latin, Cyriolic, and Old English.

The other important comparative table of written signs is contained in the article SLAVS, showing the various Cyriolic, Glagolitic and Latin letters used by the Slav peoples.

Passing from articles dealing with the method and general subject-matter of philology, the student will find articles on the great families of languages, each with its subordinate articles on special languages and dialects.

1. Indo-European Languages.—Of articles on language-families, the most important is that under the heading Indo-European Languages. This great division, which is dealt with from the comparative standpoint, is the second part of the article PHILOLOGY, under its own heading treated in detail. The article begins with a sub-classification into two main groups—the so-called (A) centum and (B) satem groups—each of which is further divided into four sections. In accordance with this classification there are separate articles on the individual ancient and modern languages and dialects.

A. (1) Greek Language (supplemented by sections under Homer, Dorians, &c.); (2) Latin Language (with Osca Lingua, Iguvium, &c., and articles on the Italic tribes and places, e.g. Veneti, Cæro); (3) Celtic, s.v. Celt (with subsidiary articles); and (4) Teutonic, s.v. Teutonic Languages, Scandnavian Languages, and the like.

The modern descendants of these languages are all further treated separately. Thus following Latin Language is the article Romance Languages, which traces the development of the Latin tongue during its gradual differentiation into Italian, French, Spanish, Rumanian, &c.; while a more detailed account of these will be found under Italian Language; French Language; Spanish Language; Rumanian Language. There is also a special article Provençal Language, dealing with the Romanic speech of southern France. The Teutonic languages are similarly dealt with in detail under English Language (including Anglo-Saxon); Dutch Language; German Language; Scandinavian Language itself includes Icelandic, Norwegian, Swedish, Danish.

B. In the satem group of the Indo-European family the four divisions are as follows:

(1) Indo-Iranian or Aryan. This division may be subdivided into (a) Indo-Iranian, treated mainly in the article Persia: Language and Literature (including Zend, Old, Middle and New Persian, and the modern dialects), and (b) Indian. The Indian languages are discussed primarily under Indo-Aryan Languages, which describes the relations of Pāṣāca, Sanskrit, Prakrit, and gives a paradigm of the various languages of the three great divisions of India. This central article refers to the separate articles Pāṣāca, Sanskrit, and Prakrit, which in turn are supplemented by a number of articles on particular languages. Of these reference may be made to Bengali; Bihari; Gujarati and Rajasthan; Hindostani; Kashi-Mir; Marathi; Pali. The gipsy languages, which may probably be included under the Indo-Iranian division, are described under Gipsies.

(2) The account of Armenian will be found under Armenian Language and Literature.

(3) The Balto-Slavonic Languages. Of these the three comprised in the Baltic group, viz. Lithuanian, Lettic and Old Prussian, are described under the heading Lithuanians and Letts. For the Slavonic group, the chief article is Slav: Language, which deals with the elements common to all the Slavonic tongues, with their early history and differentiation. It contains a comparative table of alphabets. It is supplemented by an article Old Slavonic, and by further information under the headings Russia, Bulgaria, Servia, Poland, Bohemia, Croatia-Slavonia, Slovaks, Slovenes, Sorbs, Kashubes, Polabs.

(4) The Albanian dialects are treated under Albania.

2. Semitic Languages.—At the heading of this section stands the article Semitic Languages, supplemented by Hebrew Language, Aramaic Languages, and linguistic sections under Phoenicia, Ethiopia, and the like.

3. Hemitic Languages.—The central article in this family is Hemitic Languages, which is supplemented, so far as the Cushitic or Ethiopian group is concerned, by further information in the articles Egypt; Ethiopia; Abyssinia; Somaliland; and, so far as the Libyan group is concerned, by the articles Berbers and Kabyles.

4. The chief feature of the Monosyllabic family is the section Language under China, supplemented again by similar sections in articles on other countries of south-eastern Asia, and by the article Tibeto-Burman Languages. There is also a language section under Japan which discusses the affinities between Chinese, Korean and Japanese.

5. The Ural-Altaic family is described in outline in the article Ural-Altaic, which gives the general relationships of Turkish, Finno-Ugrian, Mongol and Manchu, and of minor subdivisions such as Syriyenian, Mordvinian and Votyak. Turkish is discussed in the article Turks: Language, which deals with Osmanli proper and the Tatar-Turkish languages generally. The article Finno-Ugrian is a comparative survey dealing with the language of the Finns, Lapps, Samoyedes, &c.; while Magyar is treated separately in Hungary: Language. Under Mongols there is a special section Language, discussing the three groups of East Mongol, West Mongol (including Kalmuck) and Burut.

6. The principal languages of southern India, e.g. Tamil, Malayalam, Kanaarese, Telugu, &c., are dealt with generally under the heading Dravidian; while there is a separate article Tamilis, containing a section on their language; and brief notes under the headings Brahui, Telugu, Malayalam, &c.

7 and 8. The scattered languages of the Malay-Polynesian family and other Oceanic peoples are treated principally in the article Malays, which further information is given under the headings Polynesia; Samoa; Java; Negritos, Battas, &c.

9. The Caucasian family is described chiefly in the article Georgia: Ethnology. Further information will be found in Caucasus: Ethnology.

10. Of the remaining European languages only two need special mention: Basque, which is treated in a special section under the heading Basques; and the lost Etruscan, which is treated under Etruria and Latin Language.

11. The principal languages of southern and central Africa are treated fully under Bantu Languages. There is a brief account of the Bushman language under Bushmen, and of the Hottentot languages under Hottentots.

12. Intermediate African Languages.—Among the numerous languages spoken by the people of the great central belt of the African continent, the most important is the Hausa, described under that heading.

13. America.—The whole question of the languages of the North American Indians is dealt with in the article Indians, North American, which contains an elaborate linguistic paradigm.

Bibliographical information will be found in practically all the above headings. In addition to the most modern authorities there quoted, there will be found in the article Dictionary a very full list of older lexicographical works.

The above summary does not purport to present dogmatically a rigid philological classification. It disregards many problems, and is intended solely to enable the student readily to find the material of which he may be in search.
PHILOMEL—PHILOPONUS

PHILOMEL (Fr. Philomèle; Ger. Philomèle or Stahlgeige), a musical instrument similar to the violin, but having four steel, wire strings. The philemél has a body with incursions similar to those of the guitar; therefore, without corner blocks, the outline of the upper lobe forms a wavy shoulder reminiscent of the violin but more ornate and fanciful. The peg-box sometimes terminates in a fancy head instead of a scroll. The philemél, never used in the orchestra, is the instrument of the diatessaron, frequently played in Germany with the bowed zither. The accordance of the philemél is the same as for the violin; the timbre is shrill and crystal-like. There is also an alto philemél corresponding to the viola. The bowed melody is similar to the philemél, and has four steel strings of the same accordance as the violin, but arranged in inverse order; instead of being held like the violin and philemél, under the chin, it is placed on the knees of the performer, so that a book under the fingerboard rests against the table. (K. S.)

PHILON, Athenian architect of the 4th century b.c., is known as the planner of two important works—the portico of the great Hall of the Mysteries at Eleusis and an arsenal at Athens. Of the last we have exact knowledge from an inscription. E. A. Gardner (Ancient Athens, p. 557) observes that it is “perhaps known to us more in detail than any other lost monument of antiquity.” It was to hold the rigging of the galleys; and was so contrived that all its contents were visible from a central hall, and so liable to the inspection of the Athenian democracy. (See Athens.)

PHILOPATRIS, the title of a dialogue formerly attributed to Lucian, but now generally admitted to be spurious. Its date and purport have long formed the subject of discussion. The scene is laid at Constantinople. A certain Tripheon, who has been converted to Christianity by a bald, long-nosed Galilean, who was carried up through the air into the third heaven (an evident allusion to St Paul), meets a friend, Critias, who is in a state of great excitement. Tripheon inquires the reason, and the invocation of Zeus by Critias leads to a discussion on paganism and Christianity, in which all the gods proposed by Critias are rejected by Tripheon, who finally suggests that Critias should swear by the Trinity. (The sub-title, ἦ διασαφιόνομος, refers to this “instruction” of Critias in matters relating to Christianity.) Critias goes on to relate how he had been introduced to a gathering of pessimists, who predicted all kinds of disturbances in the empire and defeat at the hands of its enemies. In the meantime a third person appears on the scene, with the news that the imperial armies have obtained a glorious victory. The hope is expressed that Babel (Bagdad, the chief city of the caliphs) may soon be destroyed, Egypt subdued (that is, reconquered from the Arabs), and the attacks of the Scythians (Russians or Bulgarians) repulsed. The whole concludes with thanks to the unknown god of Athens that they have been permitted to be the subjects of such an emperor and the inhabitants of such an empire. The Philopatris was for a long time regarded as an attack upon Christianity, and assigned to the time of Julian the Apostate (emperor 361–363). Chronological indications (e.g. the allusion to a massacre of women in Crete, led Niceron, as well as the references to Phocas and other monarchs before the Philemél prophets) (960, 969), and this view is now generally supported. There being at that time no pagans in Constantinople, the “pessimists” referred to must be Christians—either monks, especially the intimate friends of the patriarch of Constantinople, who, aggrieved at the measures taken by Phocas in regard to the property of the Church, were ready to welcome the defeat of the imperial arms and the ruin of the empire; or harmless visionaries, who claimed to predict the future by fasting, prayer and vigil. In any case, the author, whether he was a sophist commissioned by Phocas to attack the monks, or some professor who hoped to profit by singing the imperial praises, represents the idea of the “patriotic” (as the title shows) as opposed to the “unpatriotic.” According to another view, which assigns the dialogue to the time of Heraclius (610–641), the author was a Christian fanatic, whose object was to make known the existence of a convention of belated pagans, the enemies alike of the Christian faith and the empire; it is doubtful, however, whether such a pagan community, sufficiently numerous to be of importance, actually existed at that date. The object of the first and longer portion of the dialogue was to combat the humanism of the period, which threatened a revival of polytheism as a rival of Christianity.

BIBLIOGRAPHY.—Editions by J. M. Gesner (1715) and C. B. Hase (in the Bonn Corpus scriptorum hist. Byz. 1838), vol. xi.; also included in Jacobitz’s edition of Lucian (1839). See R. Crampo, Philopatris. Ein heidnischen Komentari des ersten Jahrhunderts zu Constantinopel (1861); R. Garnett, “Alms for Oblivion” in Cornell Magazine (May, 1901); C. Stach, De Philopatrides (Crawc, 1894), who shows its late origin by linguistic tests; S. Reinach in Revue archéologique (1902), vol. 1; B. G. Niebuhr, Uber das Alter des Dichterpatric (Athen. Acad. 21, 422); and, for further authorities, article by Von Dobschütz in Herzog-Hauck’s Realencyklopddie für protestantische Theologie (1904).

PHILOPOEMES (253–184 B.C.), Greek general, was born at Megalopolis, and educated by the academic philosophers Eudamus and Demophanes or Megalopolis, who had distinguished themselves as champions of freedom. Avoiding the fashionable and luxurious gymnasia, he devoted himself to military studies, hunting and border forays. In 233–232 Philopoemen skillfully defended the city of Megalopolis against the forces of Cleomenes III, and distinguished himself at Sellasia (222). The next ten years he spent as a condottiere in Crete. Elected commander of the League’s cavalry on his return, he reorganized that force and defeated the Aeolians on the Elean frontier (210). Appointed to the chief command two years later, he introduced heavy armour and close formation for the infantry, and with a well-trained army beat Machanidas of Sparta, near Mantinea. The new “liberator” was now so famous that Philip V. of Macedon attempted to poison him. In 202–2 Philopoemen drove Nabas, the Spartan tyrant, from Sparta, and routed him off Tegea. After another long sojourn in Crete (he again renewed the command against Nabas). The Philemél, unsuccessful at sea, he almost annihilated Nabas’s land force near Gymth, but was prevented by the Roman Flamininus from taking Sparta. In 190 Philopoemen protected Sparta, which meanwhile had joined the League and thereupon seceded, but punished a renewed defection so cruelly as to draw the censure of Rome upon his country. At Messene he likewise checked a revolt (189), but when that city again rebelled, in 184, he was captured in a skirmish and promptly executed. His body was recovered by the Achaeans and buried with great solemnity.

Philopoemen’s great merit lies in his having restored to his compatriots that military efficiency without which the Achaean League for all its skillful diplomacy could never stand. Towards Rome he advocated a courteous but independent attitude. In politics he was a democrat, and introduced reforms of a popular character (see Achaean League).

Polybius’ Histories (x.xxii). are the chief authority. These and a special treatise on Philopoemen (now lost) were used by Plutarch (Philopoemen), Pausanias (vii. 49–51), Livy (xxvii. xxxiii.), and indirectly by Justin (xx–xxxiv).

PHILOPONUS, JOANES (John the Grammariar), Greek philosopher of Alexandria, lived in the later part of the 5th and the beginning of the 6th century of our era. The surname Grammatikos he assumed in virtue of his lectures on language and literature; that of PhilopONUS owing to the large number of treatises he composed. He was a pupil of Ammonius Hermiae, and is supposed to have written the life of Aristotle sometimes attributed to his master. To Philoponus are attributed a large number of works on theology and philosophy. It is said that, though he was a pupil of Ammonius, he was at first a Christian, and he has been credited with the authorship of a commentary on the Mosaic Cosmogony in eight books, dedicated to Sergius, patriarch of Constantinople, and edited by Balthasar Corderius (1590). Other authorities maintain that this, as well as the Disputatio de paschale, was the work of another author, John the Trithest. It was perhaps this Philoponus who tried to save the Alexandrian library from the caliph Omar after Amu’s victory in 639.
PHILOSOPHY

The more certain writings of Philoponus consist of commentaries on Aristotle. These include works on the Physics, the Prior and the Posterior Analytics, the Meteorologia, the De anima, the De generationem et interna and the De metophysica. These have been frequently edited and are interesting in connexion with the adoption of Aristotelianism by the Christian Church. They show a marked influence of the Neoplatonism of Plotinus, and are remarkable rather for elaborate care than for originality and insight. He wrote also an attack on Proclus (De aeternitate mundi). Two treatises on mathematics are ascribed to him: A Commentary on the Mathematics of Nicomachus, edited by Hoche (1864 and 1867), and a Treatise on the Use of the Astralogo, published by Hase. The latter is the most ancient work on this instrument, and its authenticity is rendered almost certain by its reference to the masar or the manumetrikos.

PHILOSOPHY (Gr. φιλοσοφία, fond of, and σοφία, wisdom), a general term whose meaning and scope have varied very considerably according to the usage of different authors and different ages. It can best be explained by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The tradition which assigns the first employment of the Greek word φιλοσοφία to Pythagoras has hardly any claim to be regarded as authentic. The term may, however, according to Diogenes Laërtius attributes the choice of the designation is, in all probability, a piece of etymology crystallized into narrative. It is true that, as a matter of fact, the earliest uses of the word (the verb φιλοσόφειν occurs in Herodotus and Thucydides) imply the idea of the pursuit of knowledge; but the distinction between the σοφία, or wise man, and the φιλόσοφος, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophen, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the shows of sense. The philosophers, he says, “are those who are able to grasp the eternal and immutable”; they are “those who set their affections on that which in each case really exists” (Rep. 486). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavour to express what that state is to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

Aristotle’s most usual name is “first philosophy” or, as a modern might say, “first principles”; but there has since been appropriated to it, apparently by accident, the title “metaphysics.” “Philosophy,” as a term of general application, was not, indeed restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. It was only in the Alexandrian period, as Zeller points out, that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came about that the name “philosophy” ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry which was long called “rational cosmology,” may be said to form part of the general subject of metaphysics, or at all events a pendant to it. By the gradual sitting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as “metaphysics” or “first philosophy.” These, according to the Wolffian scheme long current in philosophical teaching, deal with the science of being or the science of being as such, with its three-branch sciences of (rational) psychology, cosmology and (rational or natural) theology, dealing with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added aesthetics, constituting three normative sciences—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends or set forth ideals. It is evident, however, that if logic deals with conceptions which may be considered constitutive of knowledge as such, and if ethics deals with the harmonious realization of human life, which is the highest known form of existence, both sciences must have a great deal of weight in the settling of the general question of metaphysics.

In sum, then, we may say that “philosophy” has come to be understood at least in modern times as a general term covering the various disciplines just enumerated. It has frequently tended, however, and still tends, to be used as specially convertible with the narrower term “metaphysics.” This is not unnatural, seeing that it is only so far as they bear on the one central question of the nature of existence that philosophy spreads its mantle over psychology, logic or ethics. The particular organic conditions of perception and the associative laws to which the mind, as a part of nature, is subjected, are facts in themselves indifferent to the philosopher; and therefore the discipline of psychology in its modern independent form, which took place during the latter half of the 19th century and which may now be said to be complete, represents an entirely natural evolution. Similarly, logic, so far as it is an art of thought or a doctrine of fallacies, and ethics, so far as it is occupied with a natural history of impulses and moral sentiments, do neither of them belong, except by courtesy, to the philosophic province. But, although this is so, it is perhaps hardly desirable to deprive ourselves of the use of two terms instead of one. It will not be easy to infuse into so abstract and bloodless a term as “metaphysics” the fuller life (and especially the inclusion of ethical considerations) suggested by the more concrete term “philosophy.”

We shall first of all, then, attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing, and how far it belongs rather to the domain of “science” strictly so-called. The order in which, for clearness of exposition, it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and metaphysics, then logic, aesthetics and ethics. Finally, the connexion of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology), with the philosophy of history and the philosophy of religion, will call for a few words on the relation of these sciences to general philosophy.
PHILOSOPHY

PHILOSOPHY and Natural Science.—In distinguishing philosophy from the sciences, it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitely included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy, even under its most discredited name of metaphysics, has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field is either occupied or taken out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the parts from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself; it has to show that the subject-matter which we are all dealing with in detail really is a whole, consisting of articulated members. Evidently, therefore, the relation existing between philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, i.e. truly, known in their relation to the whole. A pure specialist, if such a being were possible, would merely be an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and fruitfully applied, in their own field of investigation; and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, συνοικός, the man who takes a "synoptic" or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only "concrete" science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can claim to be true in more than a provisional sense.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is not a collection of individual facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this Unding, as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, as a theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be thought out, or how far, when this is done, they refuse themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, sub specie aeternitatis. In strictness, therefore, it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including, as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implications—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explanation of what is involved in this relation, or, in Kantian phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things in its last terms, and thus to shed a light backwards upon the true nature of our subordinate conceptions.

Psychology, Epistemology and Metaphysics.—This leads to the consideration of the main divisions of philosophy—Psychology (q.v.), epistemology (theory of knowledge, Erkenntnistheorie), and metaphysics (ontology; see METAPHYSIC). A special relation has always existed between psychology and systematic philosophy, but the closeness of the connexion has been characteristic of modern and more particularly of English thought. The connexion is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacob's dictum as quoted by Sir W. Hamilton: "Nature conceals God; man reveals God." Nature by itself, that is to say, is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind as knowing, willing, &c., may be looked at in two different ways. It may be regarded simply as a fact; in which case the evolutions of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology sans phrase. In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, cannot work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and the definitive establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect

1 The revisional office which philosophy here assumes constitutes her the critic of the sciences. It is in this connexion that the meaning of the definition of philosophy as "the science of principles" can best be seen. This is perhaps the most usual definition, and, though vague, one of the least misleading.
PHILOSOPHY

that such assertions can be made as those quoted above. Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself. The distinction between mind viewed as a succession of "states of consciousness" and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson, who also made a happy suggestion of two terms to designate the double point of view:

"We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we call objective fact, or is such as is named (in different circumstances) real, valid, or subjective function, which it is, to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than Intellation. We may then say that psychology is occupied with the natural function of Intellation, seeking to discover its laws and distinguishing its various modes (perception, representative imagination, conception, &c.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of Knowledge (as that which is known)."

"Psychology and Philosophy," Mind (1883), pp. 15, 16.

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton, encouraging the confusion by speaking of "psychology or metaphysics," while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursus (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the Critique of Pure Reason was not to be taken as a psychological inquiry. He defined his problem as the quid juris or the question of the validity of knowledge, not its quid facti or the laws of the empirical genesis and evolution of intellation (to use Croom Robertson's phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute, in order to determine the limits of their application; such a criticism ab extra of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or faculties exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explanation of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term, and it lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, or, as it may be put, of objective consciousness—of a self-consciousness of a world of objects and through them conscious of itself. The inquiry is, therefore, logical or transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions we are thinking of facts causing other facts. But the logical or transcendental conditions are not causes or even factors of knowledge; they are the statement of its idea. Hence the dispute between evolutionist and transcendentalist rests, in general, on an ignoratio elenchii; for the history of the genesis of an idea (the historical or genetic method) does not contain an answer to—though it may throw light on—the philosophical question of its truth or validity. Speaking of this transcendental consciousness, Kant goes so far as to say that it is not of the slightest consequence "whether the idea of it be clear or obscure (in empirical consciousness), not even that the possibility of the logical form of all knowledge rests on its relation to this apperception as a faculty or potentiality" (Werke, ed. of Hartenstein, iii. 578 note). Or, if

1 It is true that he afterwards modifies this misleading identification by introducing the distinction between empirical psychology or the phenomenology of mind and inferential psychology or ontology, i.e., metaphysics proper. But he continues to use the terms "philosophy," "metaphysics," and "mental science" as synonymous.

we return to the distinction between epistemology and psychology, by way of illustrating the nature of the former, we may take the following summing up by Professor James Ward in a valuable article on "Psychological Principles" in Mind (April 1883, pp. 166, 167):

"Comparing psychology with metaphysics, then, we may say that the latter is essentially genetic in its method, and might, if we had the power to revise our existing terminology, be called biology; the latter, on the other hand, is essentially devoid of everything historical, and treats, sub specie aeternatalis, as Spinoza might have said, of human knowledge, conceived as the possession of mind in general."

Kant's problem is not, in its wording, very different from that which Locke set before him when he resolved to "inquire into the original, certainty and extent of human knowledge together with the grounds and degrees of belief, opinion and assent."

Locke's Essay is undoubtedly, in its intention, a contribution to the theory of knowledge. But, because time had not yet made the matter clear, Locke suffered himself to digress in his second book into the psychological question of the origin of our ideas; and his theory of knowledge is ruined by the failure to distinguish between the epistemological sense of "idea" as significant content and the psychological sense in which it is applied to a fact or process in the individual mind. The same confusion runs through Berkeley's arguments and vitiates his conclusions as well as those of Hume. But appearing with these thinkers as the problem of perception, epistemology widens its scope and becomes, in Kant's hands, the question of the possibility of experience in general. With Hegel it passes into a completely articulated "logic," which apparently claims to be at the same time a metaphysic, or an ultimate expression of the nature of the real.

This introduces us to the second part of the question we are seeking to determine, namely the relation of epistemology to metaphysics. It is evident that philosophy as theory of knowledge must have for its complement philosophy as metaphysics (ontology) or theory of being. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. But it is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer's doctrine of the Unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of "agnosticism" (q.v.), the theory has popularized itself in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of "experience," instead of its more old-fashioned designation as an inquiry into "the nature of things." As it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge, this substitution may be regarded as an advance, more especially as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must be treated as itself real, and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to metaphysics or ontology. (For, although the term "ontology" has been as much discarded, it still remains true that the aim of philosophy must be to furnish us with an ontology or a coherent and adequate theory of the nature of reality.) But if, on the other hand, knowledge and reality be ab initio opposed to one another—if consciousness be set on one side as over against reality, and merely holding up a mirror to it—then it follows with equal naturalness that the truly real must be something which lurks unrevealed
PHILOSOPHY

behind the subject’s representation of it. Hence come the different varieties of a so-called phenomenalism. The upholders of such a theory would, in general, deride the term “metaphysics” or “ontology”; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and the establishment of this theory constitutes their metaphysics.

Without prejudice, then, to the claim of epistemology to constitute the central philosophic discipline, we may simply note its liability to be pressed too far. The exclusive preoccupation of men’s minds with the question of knowledge during the neo-Kantian revival in the seventies of the last century drew from Lotze the cautionary criticism that “the sharpening of the knife becomes tiresome, if, after all, we have nothing to cut with it.” Stillinger’s complaint against Locke was that he was “one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world.” The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte’s dictum holds good that knowledge as knowledge—i.e. so long as it is looked at as knowledge—is, ipso facto, not reality. The result of the foregoing, however, is to show that, as usual, epistemology draws its conclusion, it becomes metaphysics; the theory of knowledge passes into a theory of being.

The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The metaphysic is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual knower from the knowable world, which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as logic.

Logic, Aesthetics and Ethics.—If the theory of knowledge thus passes insensibly into metaphysics it becomes somewhat difficult to assign a distinct sphere to logic (q.v.). Ueberweg’s definition of it as “the science of the regulative laws of thought” (or “the normative science of thought”) comes near enough to the traditional sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term “regulative” or “normative” is intended to differentiate the science from psychology as the science of mental processes or events. In this reference logic does not tell us how our intellects connect themselves as mental phenomena, but how we ought to connect our ideas if we are to realize truth (either as consistency with what we thought before or as agreement with observed facts). Logic, therefore, agrees with epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must inevitably form a part of the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference—with a view, that is, by an analysis of the operation, to ensure its more correct performance. According to the old phrase, logic is the art of correct thinking. Moreover we commonly find the logician assuming that the process of thought has advanced a certain length before his examination of it begins; he takes his material full-formed from perception, without, as a rule, inquiring into the nature of the conceptions which are involved in our perceptive experience. Occupying a position, therefore, within the wider sphere of the general theory of knowledge, ordinary logic consists in an analysis of the nature of general statement, and of the conditions under which we pass validly from one general statement to another. But the logic of the schools is eked out by contributions from a variety of sources (e.g. from grammar on one side and from psychology on another), and cannot claim the unity of an independent science.

Aesthetics (q.v.) may be treated as a department of psychology or physiology, and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain away any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, just as psychology in general cannot do duty for a knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of “emotions” we tend to give an unduly subjective colour to the investigation; it would be better to speak of the perception of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the resultant pleasure borrows its specific quality from the presence of determinations essentially objective in their nature, though not reducible to the categories of science. Unless, indeed, we conceive our faculties to be constituted on some arbitrary plan which puts them out of relation to the facts with which they have to deal, we have a prima facie right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is it in things that makes them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of aesthetics, considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different phases of systematic culture.

Of ethics (q.v.) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in their nature. They are subjects for a scientific psychology employing the historical method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, &c.) and the controversy concerning the freedom of the will belong entirely to psychology. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments. The first of these deals with the notion of duty, and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deducible from, or which, at least, are covered by, this abstractly stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises. However moralists may differ on first principles, there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that, where a systematic account of duties is actually given, the connexion of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (q.v.) that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy. As described above, it ought rather to be called, in Kant’s phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysic of personality. The connexion of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato’s philosophy is summed up in the idea of the good, and how
Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connexion is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an imperium in imperio, or rather (to adopt the forcible phrase) a focus and centre of the nature of things. If, on the contrary, we must hold that man is essentially related to what the same writer calls "a common nature," then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric. At all events, this method of approach must be truer than any which, by restricting itself to the external aspect of phenomena as presented in space, leaves no scope for inwardness and life and all that, in Lotze's language, gives "value" to the world. The argument ex analogia hominis has often been carried too far; but if a "chief end of man" be discoverable—σοφιάς τόπον αὑσίως, as Aristotle wisely insisted—that the ethical end must be determined—then it may be assumed that this end cannot be irrelevant to that ultimate "meaning" of the universe which, according to Lotze, is the quest of philosophy. If "the idea of humanity," as Kant called it, has ethical perfection at its core, then a universe which is really an organic whole must be ultimately representable as a moral order or a spiritual kingdom such as Leibnitz named, in words borrowed from St Augustine, a city of God.

The philosophy of the State (Political Philosophy), Philosophy of History, Philosophy of Religion.—In Plato and Aristotle ethics and politics are indissolubly connected. In other words, seeing that the highest human good is realizable only in a community, the theory of the state as the organ of morality, and itself in its structure and institutions the expression of ethical ideas or qualities, becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality we are necessarily referred, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding, which has become organic in the society of which we are members. Plato's Republic and Hegel's Phaenomenologie des Rechts are the most typical examples of a fully developed philosophy of the state, but in the earlier writers we find an almost continuous discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover, if philosophy is to complete its constructive work, it must bring the course of human history within its survey, and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study, due to the growth of a humanistic and historical point of view. Lessing's conception of history as an "education of the human race" is a typical example of this interpretation of the facts, and was indeed the precursor which stimulated many more elaborate German theories. The philosophy of history differs it will be observed, from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological; that is to say, it seeks to interpret the process as the realization of an immanent end. It may be said, therefore, to involve a complete metaphysical theory. Social institutions and customs and the different forms of state-organization are judged according to the degree in which they promote the realization of the human ideal. History is thus represented by Hegel, for example, as the realization of the idea of freedom, or rather as the reconciliation of the forces of necessity and the play of historical interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history. But although the possibility of such a philosophy seems implied in the postulated nationality of the universe, many would hold that it remains as yet an unachieved ideal.

There only remains to briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion. By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being, including his relation to the world and especially to man. But these topics have also been treated by philosophers and religious thinkers, without dependence on any historical data or special divine revelation, under the title of Natural Theology. Natural Theology is specially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated, and if we are to find a subject of metaphysical inquiry, no valid distinction can be drawn between natural theology and general metaphysics. The philosophy of religion, on the other hand, investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, "the victory that overcometh the world"—such, in slightly varying phrases, is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact, or is it a pitiful illusion of the nerves, born of man's hopes and fears and of his fundamental ignorance? The philosophy of religion assumes the first alternative. The fundamental proposition of general is the reflective analysis of human experience, and the religious experience of mankind is prima facie entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matter of feeling or immediate assurance, and are expressed in the pictorial language of imagination. It becomes the function of philosophy, dealing with these utterances, to relate them to the results of other spheres of experience, and to determine their real meaning in the more exact terms of thought. The philosophy of religion also traces in the different historical forms of religious belief and practice the gradual evolution of what it takes to be the truth of the matter. Such an account may be distinguished from what is usually called the science of religion by the teleological or metaphysical presuppositions it involves. The science of religion gives a purely historical and comparative account of the various manifestations of the religious instinct without pronouncing on their relative truth or value and without, therefore, professing to apply the idea of evolution in the philosophical sense. That idea is fundamental in the philosophy of religion, which therefore can be written only from the standpoint of a constructive metaphysical theory.

It is, indeed, only from the standpoint of such a theory that the definitions and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who, like the positivists, agnostics and sceptics, deny the possibility of metaphysics as a theory of the ultimate nature of things, are still obliged to retain philosophy as a theory of knowledge, in order to justify the asserted limitation or impotence of human reason.

BIBLIOGRAPHY.—The best general histories of philosophy are by J. E. Erdmann, Friedrich August Ueberweg and W. Windelband; the last-named being probably the freshest in its treatment and point of view. Ed. Zeller's History of Greek Philosophy still holds the field as the best continuous exposition of the subject, but more recent work in the early periods is represented by H. Diels and J. Burnet, while Zeller's view of Plato may be said to have been superseded by the later researches of Lewis Campbell, H. Jackson and others. T. Comperz's Greek Thinkers is an able, if somewhat diffuse, survey of the philosophical development. In W. Wundt's Geschichte der Philosophie, the movement of Greek life and culture. It does not go beyond Plato. H. Hauréau, A. Stückl and Karl Werner give the fullest and most trustworthy histories of the medieval period, the former by way of the works of Kuno Fischer, R. Falcenberg and H. Höfling, and R. Adamson's Lectures on the Development of Modern Philosophy,
PHILOSTRATUS—PHILOXENUS

445

may be specially mentioned. Writers on the history of philosophy generally prefix to their work a discussion of the scope of philosophy, its divisions and its relations to other departments of knowledge, and the account given by Windelband and Ueberweg will be found specially instructive. See also A. Vandenhove, Philostratus de Imitatione (Paris, 1902), and A. G. Spivey, Paulus. O. Kölpe, W. Wundt and G. T. Ladd, deal largely with this subject, which is also treated by Henry Sidgwick in his Philosophy, its Scope and Relations (1902), by Ernest Naville, La Définition de la philosophie (2 vols. Paris, 1897), and especially by his disciple, C. H. L. Schmid, System der Philosophie (1889). A useful work of general reference is J. M. Baldwin's Dictionary of Philosophy and Psychology (3 vols., 1901-05).—A. S. P.-F.

PHILOSTRATUS, the name of several, three (or four) of the Greek sophists of the Roman imperial period—(1) Philostratus "the Athenian" (c. 170-245), (2) his nephew (? Philostratus of Lemnos" (born c. 190); (3) a grandson (? of (2). Of these the most famous is Philostratus "the Athenian," author of the Life of Apollonius Tyana, which he dedicated to Julia Domna, wife of Alexander Severus and mother of Caracalla (see Apollonius of Tyana: 1). He wrote also Βιοὶ Σώφρων ἢ Σόφρωνος (Lives of the Sophists), Gymnastica and Epistelia (mainly of an erotic character). Very little is known of his career. Even his name is doubtful. The Lives of the Sophists gives the praenomen Flavius, which, however, is found elsewhere in Thucydides, Aesop and Syenetus, and he calls himself a Lemnian; Photius a Tyrian; his letters of course show his identification as an Athenian. It is probable that he was born in Lemnos, studied and taught at Athens, and then settled in Rome (where he would naturally be called atheniensis) as a member of the learned circle with which Julia Domna surrounded herself. He was born probably in 172, and is said by Suidas to have been living in the reign of Philip (244-249). The fact that the author of Apollonius is also the author of the Lives of the Sophists is confirmed by internal evidence. The latter is dedicated to a consul Antonius Gordianus, perhaps one of the two Gordians who autokratorized in 238. This work is divided into two parts: the first dealing with the modern Sophists, e.g., Gordias, the second with the later school, e.g., Herodes Atticus.

The Lives are not in the true sense biographical, but rather picturesque impressions of leading representatives of an attitude of mind full of curiosity, alert and versatile, but lacking scientific method, preferring the external excellence of style and manner to the solid achievements of serious writing. The philosopher, as he says, investigates truth; the sophist embellishes it, and takes it for granted. The Gymnastic contains interesting matter concerning the Olympic games and athletic contests generally. The Letters breathe the spirit of the New Comedy and the Alexandrine poets; portions of Letter 33 are almost literally translated in Ben Jonson's Song to Celia, "Drink to the charming letter." The Letters attributed to Philostratus the Athenian, is probably the work of Philostratus the Lemnian. It is a popular disquisition on the heroes of the Trojan War in the form of a conversation between a Thracian vine-dresser and a Trojan peasant. The latter derives his knowledge from the hero Proteus, Palamedes is exalted at the expense of Odysseus, and Homer's unfairness to him is attacked. It has been suggested that Philostratus is here describing a series of heroic paintings in the palace of Julia Domna. His other work is the Elidéa (Imagines), ostensibly a description of 64 pictures in a Neapolitan gallery. Goethe, Wecker, Brunn, E. Bertrand and Helliq, among others, have held that the descriptions are of a series of existing works of art, while Heyne and Friederichs deny this. In any case they are interesting as showing the way in which ancient artists treated mythological and other subjects, and how the characters were known and in attractive language. This work is imitated by the third Philostratus (or by someone of his school) of whose descriptions of pictures 17 remain.

There is a great difficulty, due to a confused statement of Suidas, in determining who were the founders and even the personalitites of their Philostrati. Reference is there made to Philostratus as the son of Verus, a rhetorician in Nero's time, who wrote tragedies, comedies and treatises. Suidas thus appears to give to Philostratus the Athenian, who according to our best traditions was a Lemnian Philostratus, both sophists, living in Rome. See further a full discussion by K. Münch, in Philosophia (1907), suppl. x., pp. 369-557.

Of works bearing the name Philostratus there is a collected edition by Weyl (Leipzig, 1902), and two containing the personalitites of the Westermann (Paris, 1846), with Latin translation; these supersede those by F. Morel (Paris, 1808) and Olearius (Leipzig, 1709). There are also edited by Evgenios of the Eikones by Schenk and Reisch (Leipzig, MS. Darm., 1887), and by Volckmar (Aurich, 1862), and especially Julius Jüttner (1909), with introd., comments and Ger. 1

1 As Lemnos was an Athenian island, any Lemnian could be called an Athenian.

PHILOXENUS, of Cythera (435-380 B.C.), Greek dithyrambic poet. On the conquest of the island by the Athenians he was taken as a prisoner of war to Athens, where he came into the possession of the dithyrambic poet Melanippides, who educated him and set him free. Philoxenus afterwards resided in Sicily, at the court of Dionysus, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. After leaving Sicily he travelled in Greece, Italy and Asia, reciting his poems, and died at Ephesus. According to Apollonius of Rhodos, Philoxenus composed twenty-two "dithyrambs," and a lyric poem on the genealogy of the Aesidae. In his hands the dithyramb seems to have been a sort of comic opera, and the music, composed by himself, of a debased character. His masterpiece was the Cyclops, a pastoral burlesque on the love of the Cyclops for the fair Galatea, written to avenge himself upon Dionysus, who was wholly or partially blind of one eye. It was parodied by Aristophanes in the Platus (290). Another work of Philoxenus (sometimes attributed to Philoxenus of Leucas, a notorious parasite and glutton) is the Διηνορ (Dinner), of which considerable fragments have been preserved by W. Morel. It is a elaborate bill of fare in verse, probably intended as a satire on the luxury of the Sicilian court. The great popularity of Philoxenus is attested by a complimentary resolution passed by the Athenian senate in 393. The comic poet Antiphanes spoke of him as a god among men; Alexander the Great had his poems sent to him in Asia; the Alexandrian grammarians received him into the canon; and down to the time of Polybius his works were regularly learned and annually acted by the Arcadian youth.

Fragments, with life, by G. Bippart (1843); T. Bergk, Poetae lyricorum Graecorum, 3. (2)

PHILOXENUS (Syriac, Aksēnāyās), of Mabbōb, one of the best of the Syriac prose writers, and a vehement champion of Monophysite doctrine in the end of the 5th and beginning of the 6th centuries. He was born, probably in the third quarter of the 5th century, at Taḥal, a village in the district of Bēt Carmā east of the Tigris. He was thus by birth a subject of Persia, but all his active life of which we have any record was passed in the territory of the Greek Empire. The statements that he had been a slave and was never baptized appear to be malicious inventions of his theological opponents. He was educated at Edessa, perhaps in the famous "school of the Persians," which was afterwards (in 486) expelled from Edessa 2 on account of its connexion with the Nestorian heresy. The years which followed the Council of Chalcedon (451) were spent in the Syrian Church. Philoxenus soon attracted notice by his strenuous advocacy of Monophysite doctrine, and on the expulsion of Calandio (the orthodox patriarch of Antioch) in 485 was ordained bishop of Mabbōb 3 by his Monophysite successor Peter the Fuller (Barhebræus, Chron. ecle. i. 183). It was probably during the earlier years of his episcopate that Philoxenus composed his thirteen homilies on the Christian life. Later he devoted himself to the revision of the Syriac version of the Bible, and with the help of his chancellor Polycarp produced in 508 the so-called Philoxenian version, which was in some sense the received Bible of the Monophysites during the 6th century. Meanwhile he continued his ecclesiastical activity, working as a bitter opponent of

2 According to Barhebræus (Chron. ecle. ii. 55) through the efforts of Philoxenus himself.

3 Hierapolis of the Greeks, Manbij of the Arabs, a few miles west of the Euphrates about latitude 36°. 4
Flavian II., who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 498 to 512. The Monophysites had the sympathy of the emperor Anastasius, and were finally successful in ousting Flavian in 512 and replacing him by their partisan Severus. Of Philoxenus's part in the struggle we possess not too trustworthy accounts by hostile writers, such as Theophanes and Theodorus Lector. We know that in 498 he was staying at Edessa; 1 in or about 509, according to Photius, he was appointed imperial treasurer to Constantinople; and he finally presided at a synod at Sidon which was the means of procuring the replacement of Flavian by Severus. But the triumph was short-lived. Justin I., who succeeded Anastasius in 518, was less favourable to the party of Severus and Philoxenus, and in 519 they were both sentenced to banishment. Philoxenus was sent to Philippopolis in Thrace, and afterwards to Gangra in Paphlagonia, where he met his death by foul play in 523.

Apart from his redoubtable powers as a controversialist, Philoxenus deserves commendation as a scholar, an elegant writer, and an exponent of practical Christianity. Of the chief monument of his scholarship—the Philoxenian version of the Bible—only the Gospel and Lamentations are known to survive (see Wight, J., Lit. Rev. It is an attempt to provide a more accurate rendering of the Greek Bible than had hitherto existed in Syriac, and obtained recognition among the Monophysites until superseded by the translation of the Old Testament by Ishmael Bar Tella and of the New Testament by Thomas of Harkel (both in 616-617), of which the latter at least was based on the work of Philoxenus. There are also extant portions of commentaries on the Gospels, Acts, and the Epistles of the New Testament (Gr. and Syr.), and of several of the Psalms. His oratory, which is the excellence of his style, and his practical religious zeal are evident from the homilies which have been printed and translated by Budge (London, 1894). In these he holds aloof for the most part from theological controversy, and treats in an admirable tone and spirit the themes of faith, simplicity, the fear of God, poverty, greed, abstinence and unchastity. His affinity with his earlier countryman Aphrahat is manifest both in his choice of subjects and his manner of treatment. As his quotations from Scripture appear to be from the Peshittā, he probably wrote the homilies before he embarked upon the Philoxenian version. Philoxenus's works include homilies, treatises and sermons, and are among the most useful pieces. Many of his letters survive, and at least two have been edited. Several of his writings were translated into Arabic and Ethiopic.

PHTHIRE (Lat. philitrum, from Gr. φιληρωμ, φιλείω, to love), a drug or other medicinal drink supposed to have the magical property of exciting love.

PHINEUS, in Greek legend, son of Agenor, the blind king of Salmydessos on the coast of Thrace. He was skilled in the art of navigation, and Apollo had bestowed upon him the gift of prophecy. His blindness was a punishment from the gods for his having revealed the counsels of Zeus to mortals, or for his treatment of his sons by his first wife Cleopatra. His second wife having accused her stepsone of dishonourable proposals, Phineus put out their eyes, or exposed them to the wild beasts, or buried them in the ground up to their waists and ordered them to be scourged. Zeus offered him the choice of death or blindness. Phineus chose the latter, whereupon Helios (the sun-god), offended at the slight thus put upon him, sent the Helious to Thracia. In another story, the Argonauts, (amongst whom were Calais and Zetes, the brothers of Philo- patra), on their arrival in Thrace found the sons of Phineus half-buried in the earth and demanded their liberation. Phineus refused, and a fight took place in which he was slain by Heracles, who freed Cleopatra (who had been thrown into prison) and her sons, and reinstated them as rulers of the kingdom. Tragedies on the subject of Phineus were written by Aeschylus and Sophocles. These would directly appeal to an Athenian audience, Phineus's first wife having been the daughter of Orthichia (daughter of Erechtheus, king of Athens), who had been deserted off by Zeus to his home in Thrace. The punishment of Phineus did not involve, as is so often regarded, as a just retribution for the insult put upon a princess of the royal house of Athens.

Apolo|dor|us i. 9. 21. iii. 15. 3; Sophoc|les, Antigone, 966, with Jebb's notes; Did|o|d. Sic. iv. 43. 44; Servius on Aeneid iii. 209; Schol. on Apolloniod. Rhodii.

PHIPS (or PIPPS), SIR WILLIAM (1651–1695), colonial governor of Massachusetts, was born on the 2nd of February 1651, at Woolwich, Maine, near the mouth of the Kennebec river. He was a shepherd until he was eighteen, and then a ship carpenter's apprentice for four years; worked at his trade in Boston for a year, at this time learning to read and write; and with his wife's property established a ship-yard on the Sheepscot river in Maine, but soon abandoned it because of Indian disorders. In 1684–1686, with a commission from the British Crown, he searched vainly for a wrecked Spanish treasure ship of which he had heard while on a voyage to the Bahamas; he found this vessel in 1687, and from it recovered $500,000. Of this amount much went to the duke of Albermarle, who had fitted out the second expedition. Phillips received £160,000 as his share, was knighted by James II., and was appointed sheriff of New England under Sir Edmund Andros. Poorly educated and ignorant of law, Phips could accomplish little, and returned to England. In 1689 he returned to Massa- chusetts, founded a revolutionary government in control, and at once entered into the life of the colony. He joined the North Church (Cotton Mather's) at Boston, and was soon appointed by the General Court commander of an expedition against the French in Canada, which sailed in April 1690 and easily captured Port Royal. A much larger expedition led by Phips in July against Quebec and Montreal ended disastrously. Phips generously bought at their par value, in order to give them credit in the colony, many of the colony's bills issued for the expedition. In the winter of 1690 he returned to Eng- land, vainly sought aid for another expedition against Canada, and urged, with Increase Mather, the colonial agent, a restora- tion of the colony's charter, annulled during the reign of Charles II. The Crown, at the suggestion of Mather, appointed him the first royal governor under the new charter. On reaching Boston in May 1692, Phips founded the colony in a very dis- ordered condition, and though honest, persevering and indis- posed to exact his prerogative at the expense of the people, he was unfitted for the difficult position. He appointed a special commission to try the witchcraft cases, but did nothing to stop the witchcraft mania, and suspended the sittings of the court only after great atrocities had been committed. In defending the frontier he displayed great energy, but his policy of building forts was expensive and therefore unpopular. Having the manners of a 17th-century sea captain, he became involved in many quarrels, and engaged in a bitter controversy with Governor Benjamin Fletcher of New York. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial, he died on the 18th of February 1695.

PHLEBITIS (from Gr. φλεψ, a vein), inflammation of a vein. When a vein is inflamed the blood in it is apt to form a clot, or thrombus, which, if loosened and displaced from its original position, may be carried as an embolus towards the heart and there be arrested; or it may pass through the cavities of the heart into the lungs, there to lodge and to give rise to alarming symptoms. If the thrombus is formed in the inflamed vein of a pile it may pass as an embolus (see HAEMORRHHOIDS) into the liver. If an embolus is carried through the left side of the heart it may enter the large vessels at the root of the neck and reach the brain, giving rise to serious cerebral disturbance or...
PHLEGON—PHOCAEA

447
to a fatal paralysis. The thrombus may be formed in gout
and rheumatism, or in consequence of stagnation of the blood-
current due to slowing of the circulation in various wasting
diseases. When a thrombus forms, absolute rest in the re-
cumbent posture is to be strictly enjoined; the great danger
is the displacement of the clot. An inflamed and clotted vein, if
near the surface, causes an elongated, dusky elevation beneath
the skin, where the vein may be felt as a hard cord, the size,
perhaps, of a cedar pencil, or a pen-holder. Its course is marked
by great tenderness, and the tissue which was drained by the
branches of that vein are livid from congestion, and perhaps
boggy and pitting with oedema. If, as often happens, the
inflamed vein is one of those running conspicuously upwards
from the foot—a saphenous vein (σαφής, distinct)—the patient
should be placed in bed with the limb secured on a splint in
order to protect it from any rough movement. Should the clot
become detached, it might give rise to sudden and alarming
faintness possibly even to a fatal syncope. Thus, there is
always grave risk with an inflamed and clotted vein, and modern
surgery shows that the safest course is, when practicable, to
place a ligature on the vein upon the heart-side of the clotted
piece and to remove the latter by dissection. When, as some-
times happens, the clot is invaded by septic organisms it is
particularly liable to become disintegrated, and if parts of it
are carried to various regions of the body they may there give
rise to the formation of secondary abscesses. In the ordinary
 treatment of phlebitis, in addition to the insistence on perfect
rest, and if abscessations may be applied locally, the limb
being kept raised. Massage must not be employed so long as
there is any risk of a clot being detached.

(E. O.)

PHLEGON, of Tralles in Asia Minor, Greek writer and freed-
man of the emperor Hadrian, flourished in the 2nd century A.D.
His chief work was the Olympiads, an historical compendium
in sixteen books, from the 1st down to the 22nd Olympiad (776 B.C. to A.D. 137), of which several chapters are preserved
in Photius and Syncellus. Two small works by him are extant:
On Marvels, containing some ridiculous stories about ghosts,
prophesies and monstrous births, but instructive as regards
ancient superstitions; On Long-lived Persons, a list of Italians
who had passed the age of 100, taken from the Roman censuses.

Other works ascribed to Phlegon by Suidas are a description of
Italy, a work on the Roman festivals in three books, and a
topography of Rome.

Fragments in C. Müller, Frag. hist. graec. iii.; of the Marvels and
Long-lived in O. Keller, Rerum naturalium scriptores, i. (1877); see
also T. Hyd., "Phlegon's Androgyne var nel" in Söllshsche Blatter (1890).

PHLOGOPITE, a mineral belonging to the group of
micas (q.v.). It is a magnesium mica, differing from biotite
in containing only a little iron; the chemical formula is
[H,K(MgF)3]MgAl(SiO4). It crystalizes in the monoclinic
system, but the crystals are roughly developed. There is a perfect
cleavage parallel to the basal plane; the cleavage flakes are not
quite so elastic as those of muscovite. It is sometimes very
colourless and transparent, but usually of a characteristic yellow-
ish-brown colour, and often with a silvery lustre on the cleavage
surfaces, hence the trade name "silver amber mica" for some
varieties. The name phlogopite is from Gr. φλωγωσις (fiery-
looking), the mineral being sometimes brownish-red and coppery
in appearance.

The hardness is 2½–3, and the specific gravity 2.78–2.85. The optic axial plane is parallel to the plane of
symmetry and the axial angle 2ο 30'. Phlogopite occurs
chiefly as scales and plates embedded in crystalline limestones
of the Archean formation. The mica mined in Canada and
Ceylon is mainly phlogopite, and is largely used as an insulator
for electrical purposes. In Canada it occurs with apatite in
pyroxene rocks which are intrusive in Laurentian gneisses, danger-
close to the plan of the 19th century, and the list is now in
Ottawa county in Queen and near Burgess in Lanark county,
Ontario. In Ceylon, the mineral forms irregular veins, rarely
exceeding one or two feet in width, traversing granu-
lite, especially near the contact of this rock with crystalline
limestone.

(L. J. S.)

PHLOX (Nat. Ord. Polemoniaceae), a genus of about 30
species, mostly perennial hardy plants of great beauty, natives
of North America (one occurs in Siberia), with entire, usually
opposite, leaves and showy flowers generally in terminal clusters.
Each flower has a tubular calyx with five lobes, and a salver-
shaped corolla with a long slender tube and a flat limb. The
two stamens are given off from the tube of the corolla at different
heights and do not protrude beyond it. The ovary is three-
chelled with one to two ovules in each cell; it ripens into a three-
valved capsule. Many of the species and varieties are tall
herbs yielding a wealth of bloom throughout the summer and
early autumn. These require a deep, rich, and rather heavy
loam, and a cool, moist position to flourish.

The dwarf perennial species and varieties, the " moss pinks"
of gardens, are charming plants for the rockery and as edging
to those parts of beds or borders where the rooted habit, in habit,
the branches rooting at the nodes. They succeed in poorer
soil, and drier situations than the tall kinds. Seed is seldom
produced. Propagation is effected by cuttings in July and
early August, placed in a cold frame, and by division of the
plants, which should be lifted carefully, and cut into rooted
portions as required. The tubed kinds decay in patches in
winter if the situation is moist and the weather mild and wet.

Phlox Drummondii and its numerous varieties are half-hardy
annuals in Britain. It is a small-growing hairy plant, flowering
profusely during the summer months. For early flowering it
should be sown in heat in March and April and transplanted
cut near the base in June. The seedlings must be grown in
pot, but the flowering season is later and shorter.

The tall-growing border phloxes are divided into early and
late flowering kinds respectively, the former derived mainly
from P. glaberrima and P. sufragricosa, and the latter from
P. maculata and P. paniculata. The salver-shaped flowers
with cylindrical tubes range from pure white to almost bright
scarlet in colour, passing through shades of pink, purple, magenta
lilac, mauve and salmon. New varieties are obtained by the
selection of seedlings. Owing to the frequent introduction of
new kinds, the reader is referred to the current lists published
by growers and nurseriesmen. The " moss pinks," P. subulata
and its varieties, are all worthy of a place in the alpine garden.

The varieties are relatively few. The following list includes
nearly all the best kinds:—

P. subulata, pink with dark centre; Albidophragne, rose; annulata,
brilliant white, ringed with purple; strolidacina, deep lilac; aptepurpurea
pale pink; orange and crimson, bright red; scarlet; red; fulgida,
compacta, clear rose; Fairy, lilac; G. F. Wilson, mauve; grandiflora,
pink, crimson blotch; Little Dot, white, blue centre; Nelsoni, pure
white; Vivid, rose, carmine centre; all these are about 4 in. high.

P. Cardamines, lavender, bright blue; P. Villoides, rose, purple;
P. drummondii, rose, 6 in.; and P. amoena, rose, 9 in., are also
charming alpines. P. Drummondii varieties come true from seed, but
are usually sown in mixture.

PHOCAEA (mod. Focia or Fokka) an ancient city on the
western coast of Asia Minor, famous as the mother city of
Marseilles. It was the most northern of the Ionian cities, and
was situated on the coast of the peninsula which separates
the gulf of Cyme, occupied by Aeolian settlers, from the Hersonaean
peninsula and island, which stood in the line of settlement
between two good harbours, Naustathmus and Lampiter (Livyi
xxxvii. 31), led the inhabitants to devote themselves to
maritime pursuits. According to Herodotus the Phocaeans
were the first of all the Greeks to undertake distant voyages,
and made known the coasts of the Adriatic, Tyrrhenia and Spain.
Arganthonius, king of Tartessus in Spain, invited them to
emigrate in a body to his dominions, and, on their declining,
presented them with a large sum of money. They employed
in constructing a strong wall around their city, a defence which
stood them in good stead when Ionia was attacked by Cyrus
in 546. Eventually they determined to seek a new home in
the west, where they already had flourishing colonies, e.g.

1 It was said to have been founded by a band of emigrants from
Phocicia, under the leadership of two Athenian leaders, named
Philogenes and Damon, but it joined the Ionian confederacy by accepting
the government of Athenian rulers of the house of Codrus.
PHOCAS—PHOCIS

Alalia in Corsica and Massilia (mod. Marseilles). A large part of the emigrants proceeded only as far as Chios, returned to Phocaea, and submitted to the Persian yoke.

Phocaea continued to exist under the Persian government, but greatly reduced in population and commerce. Though it joined in the Ionian revolt against Persia in 500 it was able to send only three ships to the combined fleet which fought at Lade. But a Phocaean took the supreme command. It never again played a prominent part in Ionian history, and is rarely mentioned.

In the time of Timur Fuhah was a fortress of Sarukhan, and had been previously in Genoese hands. The ruins still visible on the site bear the name of Palaea Fokia, but they are of little interest. The modern town in the immediate neighbourhood, still known as Fokia, was founded by the Genoese in 1421 on account of the rich alum mines in the neighbourhood. It has a fair natural harbour, which is the nearest outlet of the rich district of Menemen. About 1880, while the Gediz Chai was throwing its silt unchecked into the Gulf of Smyrna and gradually filling the navigable channel, there was talk of reviving Fokia as a new port for Smyrna, and connecting it with the Cassaba railway. But, in deference to Smyrna which, as a new estuary of Gediz, had acquired local importance however as a port for coasting steamers, and it is used to some degree as a summer residence by Smyrnites.

(D. G. H.)

PHOCAS, East Roman emperor (602–610), was a Cappadocian of humble origin. He was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor Maurice, and in the elevation of Phocas to the throne, which seems to have been accomplished by one of the circus factions against the wish of the troops. Phocas proved entirely incapable of governing the empire. He consented to pay an increased tribute to the Avars and allowed the Persians, who had declared war in 604 under Chosroes II., to overrun the Asiatic provinces and to penetrate to the Bosporus. When the African governor Heraclius declared against him, Phocas was deserted by the starving populace of Constantinople, and deposed with scarcely a struggle (610). He died in the same year on the scaffold.

PHOCION, Athenian statesman and general, was born about 402 B.C., the son of a small manufacturer. He became a pupil of Plato and in later life was a close friend of Xenocrates. This academic training left its mark upon him, but it was as a soldier rather than as a philosopher that he first came into notice. Under the Persians, who owned him in 376, and in the subsequent campaigns loyally supported his chief. He won the confidence of the allies by his justice and integrity. In 351–349 he entered the Persian service and helped to subdue a rebellion in Cyprus. Henceforward he always held a prominent position in Athens, and although he never canvassed he was elected general forty-five times in all. In politics he is known chiefly as the consistent opponent of the anti-Macedonian firebrands, headed by Demosthenes, Lycurus and Hypercides, whose fervent eloquence he endeavoured to damp by recounting the plain facts of Athens' military and financial weakness and her need of peace, even when the arms of Athens seemed to prosper most. But although he won the respect of his audience, his advice was frequently discarded. Yet his influence was felt at the trial of Aeschines in 343, whom he helped to defend, and after the disaster of Chaeroneia (338), when he secured very lenient terms from Philip. He also rendered good service in the field: in 348 he saved the force operating against the philo-Macedonian tyrants in Euboea by the brilliant victory of Tymarueia. Under the Macedonian predominance his reputation steadily increased.

1 Diodorus' statement that Phocion was 75 at his death (i.e. that he became general at 50 and was elected 45 years in succession) would give 394–393 as the date of birth; but he must have been quite 25 as second-in-command at Naxos (376).

2 The chronology is uncertain; the dates given for this period are Beloch's (Griechische Geschichte, ii.).

Though by no means inclined to truckle to the Macedonians, as is shown by his protection of the refugee Harpalus and his spirited campaign in defence of Attica in 322, he won the confidence of the conquerors, and in the restricted democracy which Antipater enforced he became the virtual ruler of Athens. Old age, however, was telling on him; when Polyperchon by his proclamation of "freedom" raised a new crisis in 318, Phocion's dilatoriness was interpreted as active treason on Cassander's behalf, and the people, incited by the restored democrats, deposed him from office. Phocion fled to Polyperchon, but was sent back by the latter to be tried at Athens. The assembly, containing numerous slaves and all the city mob, shunted Phocion down and condemned him to death unheard. Not long after, the Athenians decreed a public burial and a statue in his honour.

Phocion's character and policy were throughout inspired by his philosophic training, which best explains his remarkable purity of character and his prudent councils. To the same influence we may ascribe his reserve and his reluctance to co-operate heartily either with the people or with the Macedonian conquerors who put their trust in him; a greater spirit of energy and enterprise might have made him the leader of his country.

Phocion remained famous in antiquity for the pithy sayings with which he used to parcel the eloquence of his opponents. Demosthenes called him "the chopper of my periods."

Plutarch (Life of Phocion) draws much good information from Philochorus and Duris (who reproduces Hesychius of Cardia); his numerous anecdotes are repeated in other works of his and in Aelian (Var. hist.).

(M. O. B. C.)

PHOCIS, an ancient district of central Greece (now a department, pop. 62,286), about 625 sq. m. in area, bounded on the W. by Ossolonic Locris and Doris, on the N. by Opuntian Locris, the E. by Boeotia, and on the S. by the Corinthian Gulf. The Phocian ridge of Parnassus (5668 ft.), which traverses the heart of the country, divides it into two distinct portions. Between this central barrier and the northern frontier range of Cnemis (3000 ft.) is the narrow but fertile valley of the Cephissus, along which most of the Phocian townships were scattered. Under the southern slope of Parnassus were situated the two small plains of Crissa and Anticyra, separated by Mt Cirphis, an offshoot from the main range. Being neither rich in material resources nor well placed for commercial enterprise, Phocis was mainly pastoral. No large cities grew up within its territory, and its chief places were mainly of strategic importance.

The early history of Phocis remains quite obscure. From the scanty notices of Greek legend it may be gathered that an influx of Thracians from the north contributed largely to its population, which was reckoned as Aeolic. It is probable that the country was originally of greater extent, for there was a tradition that the Phocians once owned a strip of land round Daphnus on the sea opposite Euboae, and carried their frontier to Thermopylae; in addition, in early days they controlled the great sanctuary of Delphi. The restriction of their territory was due to the hostility of their neighbours of Boeotia and Thessaly, the latter of whom in the 6th century even carried their raids into the Cephissus valley. Moreover the Dorian population of Delphi constantly strove to establish its independence and about 290 B.C. induced a coalition of Greek states to proclaim a "Sacred War," and free the oracle from Phocian supervision. Their influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but by their irresolute conduct at Thermopylae lost that position for the Greeks; in the campaign of Plataea they were enrolled on the Persian side. In 457 an attempt to extend their influence to the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar enterprise against Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they
had entered into alliance in 454. The subsequent decline of Athenian land-power had the effect of weakening this new connexion; at the time of the Peloponnesian War Phocis was nominally an ally and dependent of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by its Boeotian neighbours. After helping the Spartans to invade Boeotia during the Corinthian War (395–94), the Phocians were placed on the defensive. They received assistance from Sparta in 386, but were afterwards compelled to submit to the growing power of Thebes. The Phocian levy took part in Epaminondas' 'Fleets into Thebes which he imposed—the obligation to restore the temple funds, and the dispersion of the population into open villages—were soon disregarded. In 339 the Phocians began to rebuild their cities; in the following year they fought against Philip at Chaeronea. Again in 333 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

Henceforth little more is heard of Phocis. During the 3rd century it passed into the power of Macedonia and of the Aetolian League, to which in 196 it was definitely annexed. Under the dominion of the Roman republic its national league was dissolved, but was revived by Augustus, who also restored to Phocis the voting in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean league. The Phocian League is last heard of under Trajan.

M. O. B. C.

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the Florilegium of Stobaeus), in which he expresses his contempt for the pomps and vanities of rank and wealth, and sets forth in simple language his ideas of honour, justice and wisdom. A complete didactic poem (236 hexameters) called Πόιημα νοτιτέρων or γιγάντων, bearing the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50. The Jewish element is shown in verbal agreement with passages of the Old Testament (especially the book of Sirach); the Christian by the doctrine of the immortality of the soul and the resurrection of the body. Some Jewish authorities, however, maintain that there are in reality no traces of Christian doctrine to be found in the poem, and that the author was a Jew. The poem was first printed at Venice in 1495, and was a favourite school textbook during the Reformation period.

See fragments and the serious poem in T. Bergk, Poetar lyrici greci, iv (1885); G. Teuffel, Die lateinischen Gedichte (1868); Phocylides, Poema Institutionis, with introduction and commentaries by J. B. Fening, and translation by H. D. Goodwin (Andover, Mass, 1879); F. Susenbühl, Geschichte der griechischen Literatur in der Alexandrinerzeit, (1893), ii. 642; S. Krauss (in "Phoebus-Phocylides") in The Jewish Encyclopedia and E. Schürer, Hist. of the Jewish People, div. ii., vol. iii. 313–316 (Eng. trans., 1886), where full bibliographies are given. There is an English verse translation by W. Hewett (Watford, 1840), The Perceptive Poem of Phocylides.

PHOEBE, in astronomy, the ninth satellite of Saturn in order of discovery, or the tenth and outermost now known in the order of distance. It was discovered by W. H. Pickering in 1899 by photographs of the stars surrounding Saturn. It is remarkable in that its motion around the planet is retrograde. (See Saturn.)

PHOEBUS (Gr. for "bright," "pure"), a common epithet of Apollo (q.v.). Artemis in like manner is called Phoebé, and in the Latin poets and their modern followers Phoebus and Phoebé are often used simply for the sun and moon respectively.

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebir) in the north to Mt Carmel in the south, a distance of rather more than two degrees of latitude. These several regions, however, were at various times the north of the Eleutherus lay Aradus and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. Formed partly by alluvium carried down by perennial streams from the mountains of Lebanon and Galilee, and fringed by great sand-dunes which the sea throws up, Phoenicia is covered with a rich and fertile soil. It is only at the mouth of the Eleutherus and at Acre ("Akka") that the strip of coast-land widens out into plains of any size; there is a certain amount of open country behind Beirut; but for the most part the mountains, pierced by deep river-valleys, approach to within a few miles of the sea. In this strip of country which the Romans annexed to Asia Minor, the Phoenicians were in control of the sea, and trade and manufactures reached their height in the 7th and 8th centuries B.C., when Sarrum (Sarum), now Salisbury, and the Phoenician towns of Tyre and Sidon were the leading maritime cities of the Mediterranean world. (See Phoenicians.)

M. Simpson.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. Curiously enough in Gen. x. Sidon, the "first-born" of Canaan, is classed among the descendants of Ham; but the table of nations in Gen. x. is not arranged upon strict ethnographic principles; perhaps religious antagonism induced the Hebrews to assign to the Canaanites an ancestry different from their own; at any rate the close connexion which existed from an early date between the Phoenicians and the Egyptians may have suggested the idea that both peoples belonged to the same race. The Phoenicians themselves retained some memory of having migrated from older seats on an eastern sea; Herodotus (i. 1; vii. 80) calls it the "red sea," meaning probably the

PHOENICIA

Persian Gulf; the tradition, therefore, seems to show that the Phoenicians believed that their ancestors came originally from Babylonia. By settling along the Syrian coast they developed a strangely un-Semitic love for the sea, and advanced on different lines from the other Semitic peoples. They occupied the Syrian coast, and called themselves Canaanites and their land Canaan; and with this name the Phoenicians in all later times styled "king of the Sidonians", a name which Philo of Byblos adopts into his mythology by making "China who was afterwards called Phoinix" be the eponym of the Phoenicians (Fr. hist. gr. i. 17). In the reign of Antiochus IV. and his successors the coins of Laodicea of Libanus bear the legend "Ω Laodicea which is in Canaan";5 the Old Testament also sometimes denotes Phoenicia and Phoenicians by "Canaan" and "Canaanites" (Isa. xxiii. 11; Obad. 20; Zeph. i. 11), though the latter names generally have a more extended sense. But "Sidonians" is the usual designation both in the Old Testament and in the Assyrian monuments (Sidunnu); and even at the time of Tyre's greatest ascendancy we read of Sidonians and not Tyrians in the Old Testament and in Homer; thus Ethbaal king of Tyre (Jos. Ant. viii. 13, 2) is called king of the Sidonians in i Kings xvi. 31. In the Homeric poems we meet with Σιδώνιος, Σιδών (Od. iv. 118; Il. vi. 290; Od. xiii. 285; Il. vi. 291) and Φωνίκης, Φώνικη (Od. xiii. 274, xiv. 288 seq., &c.), and both terms together (Od. iv. 33 seq., Il. 743 seq.)6. And the Phoenicians themselves used Sidonian as the name of their land, and in the Bible the name of the Phoenician city is thus in general used as the characteristic name (CIS. i. 5 = NSL. No. 11). Hiram II. king of Tyre in the 8th century is styled "king of the Sidonians." But among the Greeks "Phoenicians" was the name most in use, Φωνίκης (plur. of Φωνίς) for the people and Φωνική for the land (cf. PHOENIX). The former was probably the older word, and may be traced to φώνεω "blood-red"; the Canaanite sailors were spoken of as the "red men" on account of their sunburnt skin; then the land from which they came was called after them; and then probably the original connexion between Φώνις and φώνεω was forgotten, and new forms and meanings were invented. Thus Φώνις came to mean a "date-palm", but the date-palm is not in the least characteristic of Phoenicia, and can hardly grow there; Φώνις in this sense has no connexion with the original meaning of Phoenician. A derivation has been sought elsewhere, and the Egyptian FENKH proposed as the origin of the name; but the word FENKH was apparently used of Asiatic barbarians in general, without any special reference to the Phoenicians (W. M. Müller, Astin u. Europa, p. 208 seq.). The Lat. Poenus is of course merely an adaptation of the Greek form.

Language.—Inscriptions, coins, topographical names preserved by Greek and Latin writers, names, words, and the Punic passages in the Poenins of Plautus, all show conclusively that the Phoenician language belonged to the North-Semitic group, and to that subdivision of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary; in some respects older features have been preserved in Phoenician, others are later, others again are peculiar to the dialect; many words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor, which can be no other than the ancient Canaanite, of which a few words have survived in the Canaanite glosses to the Amarna tablets (written in BIT BYBLO, BYBLO, BYBLO). But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range; the Phoenicians were in no sense a literate people; moreover, with one exception (CIS. i. 5), almost all the inscriptions are subsequent to the 6th century B.C.; the majority belong to the 4th century and later, by which time the language must have undergone a certain amount of decay. 4 Indirectly, however, the Phoenicians rendered one great service to literature; they took a large part in the development of the alphabet, which forms the foundation of Greek (Herod. v. 58) and all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews (e.g. the Sibloam inscription, No. 1); the Mestol 1 ch., the Moab. tablets, No. 1, and the Amarna letters of north Syria (e.g. the Zenjirli inscr. ibid., Nos. 61-65). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive, flowing style on the stones from Cyprus and Attica; the tendency becomes more strongly marked at the Punic stage; until in the neo-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most perfect stage. The Phoenician alphabet, transferred from North Africa till the 5th century A.D. In his sermons St Augustine frequently quotes Punic words.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded by the gods themselves, and that their race could boast an antiquity of 30,000 years (Africanus in Synecclus, Early Period, p. 31). Herodotus quotes (ii. 44) a more moderate tradition which placed the foundation of Tyre 2300 years before the 7th century B.C. (i.e.c. 2750 B.C.). According to Justin (xviii. 8) the Phoenicians who had long been settled on the land of Sidon, founded Tyre in the year before the fall of Troy; possibly the date 1198 B.C. given by Manander of Ephesus (in Jos. Anti. viii. 3, 1 c. Ap. i. 18) as that from which the era of Tyre begins, may refer to the epoch which Justin mentions. Little certainty, however, can be allowed to these traditional chronologies. It is probable that in remote ages Babylonia exercised a considerable influence upon Tyre and its coast towns; but Mr L. W. King has shown that the tradition, which was supposed to connect Sargons c. (3500 B.C.) with the western land and sea, has been misunderstood; it was the sea in the east, i.e. the Persian Gulf, which Sargon crossed (Chronicles concerning Early Bab. Kings, vol. i. ch. 2, 1907).

The extension of the Egyptian empire in the direction of Asia began about 1600 B.C. under Apennos (Ahasmes, Amasis I.), the founder of the XVIIIth Dynasty, who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called Dahi on the Egyptian monuments (Müller, As. u. 1100 B.C. Eur. p. 181). Whether the campaign of Thothmes (Thothmosis) I. to the Euphrates produced any lasting results is doubtful; it was Thothmes III. (1503-1449) who repeated and consolidated the earlier conquest, and established Egyptian suzerainty over the petty states of Syria and Phoenicia (see EYEV: History, I.). For the Punic occupation of Carthage from the end of the 14th century B.C. we have valuable evidence in the Egyptian papyrus Anastasi I., which mentions Kepuna (Gubna, Gegal-Biblius) the holy city, and continues: "Come then to Berytus, to Sidon, to Sarepta. Where is the ford of Nat't-anna (Nahr el-Kâsimiyeh, or a town)? Where is 'Etu? (Uzu, Palatynos)? Another city on the sea is called a haven, D'ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than in sand. 6 But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh. It was a race of mariners, invaders Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were

1 Cooke, North-Semitic Inscriptions (elsewhere abbreviated NSL.), No. 149 B. 8.
2 In this passage "Phoenicians" is a general name for carriers of commerce, not the inhabitants of a particular country. Similarly "Sidonians" is a title, not the name of a nation.
3 Elsewhere "Phoenicians" are merchants, kidnappers, &c., "Sidonians" are artists; to indicate nationality both names seem to be used differently, e.g. Od. xii. 274, xiv. 288, xiv. 414.
5 A vocabulary is given in KAT. 6, 652 seq.; see further Böhl, Die Sprache d. amarnabriefe (1909).

---

divided; Aradus, Simyra, Sidon supported the rebellion; Ribhabad, the vassal of Byblus, and Abi-melech, king of Tyre, held out for Egypt; but while all the towns made professions of fidelity, they were scheming for their own interests, and in the end Egypt lost them all except Byblus. The tablets which reveal this state of affairs are written in the language and script of Babylonia, and thus show indirectly the extent to which Babylonian culture had penetrated Palestine and Phoenicia; at the same time they illustrate the closeness of the relations between the Canaanite towns and the dominant power of Egypt. After the reign of Amenophis IV. (1370-1366) that power collapsed altogether; but his successor, Horemheb, came south to recover it, and Ramses (Rameses) II. reconquered Phoenicia as far as Beirût, and carved three tablets on the rock beside the Nahr el-Kelb to commemorate his victories; under the XIXth and XXth Dynasties this seems to have remained the northern limit of the Egyptian Empire. But in the reign of Ramses III. (c. 1200) great changes began to occur owing to the invasion of Syria by peoples from Asia Minor and Europe, which ended in the establishment of the Philistines on the coast near Ashkelon. The successors of Ramses III. lost their hold over Canaan; the XXIst Dynasty no longer intervened in the affairs of Syria; but Sheshonk (Shishak), the founder of the XXIInd Dynasty, about 928 B.C. endeavoured to assert the ancient supremacy of Egypt (cf. 1 Kings xiv. 25 sqq.), but his successes were not lasting, and, as we learn from the Old Testament, the power of Egypt became henceforward practically ineffective. Not until 608 did a Pharaoh (Necho) lead an Egyptian army so far north, and he was defeated by Nebuchadnezzar. During the period which elapsed before the rise of the Assyrian power in Syria the Phoenicians were left to themselves. This was the period of their development, and Tyre became the leading city of Phoenicia.

Between the withdrawal of the Egyptian rule in Syria and the western advance of Assyria there comes an interval during which the city-states of Phoenicia owned no suzerain. The history of this period is mainly a history of Tyre, which not only rose to a sort of hegemony among the Phoenician states, but founded colonies beyond the seas (below). From 970 to 772 B.C. the bare outline of events is supplied by extracts from two Hellenistic historians, Menander of Ephesus and Dius (largely dependent upon Menander), which have been preserved by Josephus, Ant. viii. 5, 3 and c. Ap. i. 17, 18. From the data given in these passages we learn that Hiram I., son of Abi-baal, reigned in Tyre from 970 to 936 B.C. He enlarged the island-town to the east, restored and enriched the temples, built new ones to Hethusra (i.e. Melkarth or Melqart) and Astarte, founded the feast of the awakening of Heracles in the month Peritius, and reduced the inhabitants of Utica to their allegiance. The Tyrian annals, moreover, alluded to the connexion between Hiram and Solomon. Before this time, indeed, the Phoenicians had no doubt lived on friendly terms with the Israelites 1 (cf. Judges v. 17; Gen. xlix. 13); but the two nations seem to have drawn closer in the time of Solomon. 2 Sam. v. 11, which brings David and Hiram together, probably antedates what happened in the following reign. For Solomon's palace and temple Hiram contributed cedar and fir trees as well as workmen, receiving in exchange large annual payments of oil and wine, supplies which Phoenicia must have drawn regularly from Israelite districts (1 Kings v. 9, 11; cf. Ezek. xxvii. 17; Ezr. iii. 7; Acts xii. 20; Jos. Ant. xiv. 6, 6); finally, in return for the gold which he furnished for the temple, Hiram received the grant of a territory in Galilea (Caleb, 1 Kings ix. 10-14). 2 This alliance between the two monarchs led to a joint expedition from Eziongeber on the Gulf of Akaba (strictly Agaţa) to Ophir (? on the east coast of Arabia, see Ophir) for purposes of trade. The list of Hiram's successors given by Josephus indicates frequent changes of dynasty until the time of Ithobal I. priest of Astarte, whose reign (887-855) marks a return to more settled rule. In contrast to Hiram I., king of Tyre, Ithobal or Ethbaal is styled in 1 Kings xvi. 31 "king of the Sidonians," i.e. of the Phoenicians, showing that in the interval the kings of Tyre had extended their rule over the other Phoenician cities. Under Ethbaal further expansion is recorded. Botrys north of Byblus and Aoza in North Africa are said to have been founded by him; the more famous Carthage owed its origin to the civil disorders which followed the death of Metten L. (820), his next successor but one. According to tradition, Metten's son Pygmalion (820-772) slew the husband of his sister Elissa or Dido; whereupon she fled and founded Carthage (p.v.) in Libya (813; Justin xviii. 4-6). At this point Josephus's extracts from Menander come to an end.

From the time of Ethbaal onwards the independence of Phoenicia was threatened by the advance of Assyria. So far back as 1100 B.C. Tiglath-pileser I. had invaded North Syria, and in order to secure a harbour on the coast he occupied Arvad (Aradus); but no permanent occupation followed. In the 9th century, however, the systematic conquest of the west began. In 876 B.C. Assur-nazir-pal III. "washed his weapons in the great sea," and exacted tribute from the kings of Tyre, Sidon, Byblus and other cities, including Arvad (Kellinschr. Bibliothek, i. 109). The inscriptions of his son Shalmaneser II. mention the taking of tribute from the Tyrians and Sidonians in 846 and again in 849; the Byblians are included at the latter date, and among the kings defeated at Karkar in 854 or 853 was Metten-baal, king of the Arvadites (ibid. pp. 141, 143, 173). Thus Shalmaneser completed the conquests of his predecessors on the Phoenician coast, and established a supremacy which lasted for over a hundred years, and was acknowledged by occasional payments of tribute. In 741 Tiglath-pileser III. mentions on his tribute-lists "Hirum of Tyre"; and here for the first time a piece of native evidence becomes available. The earliest Phoenician inscription at present known (Cis. i. 5 = NSI. No. 11) is engraved upon the fragments of a bronze bowl dedicated by a certain governor of Qarth-hadashat (or Karti-Hadasti, "New City," i.e. Citium), "servant of Hiram king of the Sidonians to Baal of Lebanon." It is to be noted that this Hiram II. was not only king of Tyre, as the Assyrian inscription calls him, but of Sidon too; and further, that by this time Tyre had established an alliance with Assyria, and the Sidonians were allies of Assyria under the famous Ethbaal. This alliance was confirmed by the campaign of 734 Byblus and Aradus paid tribute, and an Assyrian chief officer (the Rab-shakeh) was sent to Tyre and extorted from the king, now Metten or Mattan, the large sum of 150 talents of gold (KB. ii. 23). For the period which follows a certain amount of information is furnished by Menander (in Jos. Ant. ix. 14, 2). Eluleaus IX., in Assyrian Lui, who ruled under the name of Pylas, was king of Tyre, Sidon, and other cities at this time (c. 725-690), and at the beginning of his reign suffered from an invasion by Shalmaneser IV. or Salampas (Jos.); this was probably the expedition against Hoshea of Samaria in 725, "the king of Assyria ... overran all Phoenicia, but soon made peace with them all and returned back." In the reign of Sargon Phoenicia itself seems to have been left alone; but the inhabitants of Citium revolted, showing that the authority of Tyre in Cyprus had grown weak; and Sargon received the submission of seven Cyprian princes, and set up in Larnaca (probably in 700) the triumphal stele now in the Berlin Museum (Schrader, Cuneif. Inscr. and O. T., 2nd ed., vol. ii. p. 87). But Eluleaus, according to Menander, suppressed the revolt of Citium, and early in the reign of Sennacherib joined the league of Philistia and Judah, which had considerable effect upon the cities of Phoenicia (above, Justin xviii. 3). In the Tyrian annals (Jos. c. Ap. i. 18) the reference was probably to the falling of timber in Lebanon for Hiram's temples; Josephus then misinterpreted this by 1 Kings v. 6. 1

1 In Judges x. 12 (cf. v. 6, iii. 3) the Sidonians are mentioned among the oppressors of Israel; but there is no record of any invasion of Israel by the Phoenicians, and the statement is due to the post-exilic editor who introduced generalizations of ancient history into the book of Judges.

2 Jos. Ant. viii. 3, 1, dates the building of Solomon's temple in the 11th year of Hiram, and 400 years after the foundation of the temple. This gives a Tyrian era which began in 1198-1197 B.C., i.e. at the time when the Philistines settled on the coast of Canaan, an event

PHOENICIA 451

Assyrian Rule. B.C. 876-605 B.C.
in alliance with Egypt and Ethiopia, which aimed at throwing off the oppressive yoke of Assyria; as usual, however, the city-states of Phoenicia could not combine even against a common foe, and several broke away from Tyre, so Menander tells us, and sided with Assyria. In the great campaign of Sennacherib came down upon the revolted provinces; he forced Luli, king of Sidon, to fly for refuge to Cyprus, took his chief cities, and set up Tubal’u (Ethbaal) as king, imposing a yearly tribute (KB. ii. 91). The blockade of Tyre by sea, significantly passed over in Sennacherib’s inscription, is described by Menander. The island-city proved to be impregnable, but it was the only possession left of what had been the extensive kingdom of Elulaeus. Sennacherib, however, so far accomplished his will, that he could raise up the city Sidon, which had grown into a powerful state.1 At Sidon the successor of Ethbaal was Abd-milkath; in alliance with a Cilician chief he rebelled against Esarhaddon about the year 678, with disastrous consequences. Sidon was annihilated; Abd-milkath fell into the hands of Esarhaddon, who founded a new Sidon on the mainland, peopled it with foreigners, and called it after his own name. The old name, however, survived in popular usage; but the character of the city was changed, and till the time of Cyrus the kingdom of Sidon ceased to exist (KB. ii. 149 seq., 145; KAT. 68). Tyre also came in for its share of hardship. Elulaeus was followed by Baal, which was captured and given to Tirthaka, the Ethiopian king of Egypt, in a rebellion against Assyria. Esarhaddon, on his way to Egypt for the second time, determined to deal out punishment, and blocked Tyre, and raised earthworks on the shore and cut off the water-supply; but he did not capture the city itself. His monument found at Zenjirli represents the great king holding Baal of Tyre and Tirthaka of Egypt by cords fastened in their lips;2 there is no evidence, however, that he actually took either of them prisoner. Early in the reign of Assur-bani-pal Tyre was besieged again (668), but Assur-bani-pal succeeded no better than his predece- sors. Nevertheless Baal was again in the end, along with the princes of Gebal and Arvad, Manasseh of Judah, and the other Canaanite chiefs; in the island of Cyprus the Assyrians carried all before them (KB. ii. 149 seq., 160, 173). On his return from the Arabian campaign Assur-bani-pal severely punished the rebellious inhabitants of Ushu (Palatayrus) and Akko, and transported the survivors to Assyria (ibid. 229). In Phoenicia, as elsewhere, Assyrian rule created nothing and left nothing behind it but a record of barbarous conquest and extortion. An interesting sidelight is thrown upon this period by the list of the Thalassocracies in the Chronicon of Eusebius (p. 236, ed. Schoene), which places the 45 years of the sea-power of Phoenicia at 221 B.C., that is, a much shorter period than 600 years, which is supposed to lie between 709, when Cyrus submitted to Sargon, and 664, when Egypt threw off the rule of Assyria. If this dating is correct, and the Phoenician sea-power was at its height during these years, we can understand why Tyre gave so much trouble to the Assyrian kings.3

In the last crisis of the dying power of Assyria the Egyptians for a short time laid hands on Phoenicia; but after their defeat at the battle of Carchemish (605), the Chaldeans Port. 605-622-allusion (xx. 22) in 604 to the approaching downfall of the kings of Tyre and Sidon, and the coast-land beyond the sea, i.e., the Phoenician settlements on the Mediterranean, seems to imply that the Phoenician states recovered some measure of independence; if they did it cannot have lasted long. In 588 Apries (Pharaoh Hophra) made an attempt to displace the Chaldaean supremacy; he defeated Tyre and Sidon, and terrorized the other cities into submission (Herod. ii. 161; Diod. Sic. i. 68). Some of the Phoenician chiefs, among them Ithobal II., the new king of Tyre, while forced to yield to a change of masters, were bold enough to declare their hostility to the Babylonians. This state of affairs did not escape the vigilance of Nebuchadrezzar. After the fall of Jerusalem he marched upon Phoenicia; Apries withdrew his army, and the siege of Tyre began. For thirteen years the great merchant city held out (585-575; Jos. c. Ap. i. 21; cf. Ezek. xxvi. 1 seq.). Ezekiel says that Nebuchadrezzar and his host had no reward for their heavy service against Tyre, and the presumption is that the city was yet a city of great wealth; about this time, too, Carthage made an effort for independence under Hanno the Great (538–521), the real founder of its fortunes; the old independence upon Tyre was changed for a mere relation of piety observed by the annual sending of delegates (beopoi) to the festival of Melkarth (Arrian ii. 24; Polyb. xxxi. 20, 12). The disasters and humiliations which befell Tyre during this and the foregoing period might suggest that its prosperity had been seriously damaged. But Tyre always counted for more in commerce than in politics; and in the year 586, just before the great siege, Ezekiel draws a vivid picture (ch. xxvii.) of the extent and splendour of its commercial relations. Even when cut off from its possessions on the mainland the city itself was not captured; its seafaring trade went on; and though by degrees the colonies were lost, yet the ties of race and sentiment remained strong enough to bind the Phoenicians of the mother-country to their kindred beyond the seas.

Constitution.—At this point it is convenient to mention what little is known about the constitution of the Phoenician states. All Canaanite analogues speak for kingship as the oldest form of Phoenician government; but Tyre was different (Mark. 15. 14). The name, Phoenicia itself and in Cyprus is always called king. The royal houses claimed divine descent,4 and the king could not be chosen outside their members. His power, however, was limited by the wealth of the city, which was far greater than the wealth of any other city; the sovereignty may have been fairly divided among the numerous nobles and rich families, who possessed great influence in public affairs; thus it was possible for war or peace to be decided at Tyre in the king’s absence, or at Sidon against his will (Arrian ii. 15 and 16; Curtius iv. 1, 15). The priest of Melkarth at Tyre was the second man in the kingdom. With the associated prince of a council of elders; such was the case at Gebal (Byblus) from the earliest times to the latest (Ezek. xxvii. 9); at Sidon this council consisted of 100 members (Diod. xvi. 45), perhaps also at Tyre.5 Inscriptions of the 7th and 2nd centuries B.C. mention a Rab (chief) in Sidon, Cyprus and Gaulus (Gozo); what his position was it is difficult to say; in the colonies he may have been a district governor. During Nebuchadrezzar’s time, as we see presently, the Tyreans did not think it advisable to maintain the monarchy at Tyre, and the government was administered by a succession of suffetes (judges); they held office for short terms, and in one instance two ruled together for six years. Much later, in the 3rd century B.C., an inscription from Tyre mentions a suffete (NSI. No. 8) without adding more to our knowledge. Carthage, of course, was governed by two suffetes, and these officers are frequently named in connexion with the Carthaginian colonies (NSI. p. 115 seq.); but we are not sure that we are not to draw the inference that the suffete itself had any such magistrates. Under the Persians a federal bond was formed comprising Sidon, Tyre and Arados, whose duty it was to contribute 300 triremes to the Persian fleet (Herod. vii. 89), and if after a short time he returned to his previous position, the governor had the task of supervising the Levant and making sure that the payment of a land tax was made. He was the person who was responsible for fighting wars, and he was supported by the army, which was the nearest approach to a standing army they had. He was also the person who directed the construction of the navy, which, if anything, was the most advanced of all the Phoenician arts. In the case of Tyre, it was the governor who directed the construction of the city of Carthage, which was the most advanced city of the Mediterranean.
PHOENICIA

the lesser towns being under the command of the great cities. Aradus presided over three subordinate townships (Arrian ii. 13); Berytus, which had no king of its own, probably formed with Byblos a single kingdom; while Tripolis, a federation of three cities separated by a stadium from each other, and provided a meet-
ing-place for the federal council, which was chiefly occupied in dealings with Persia (Diod. iv. 41). But federation on a larger scale was never possible in Phoenicia, as was the case with

Commercial interests dominated everything else, and while these states, of municipal life without vigour, the civil and

loyalty were but feebly felt. On occasion the towns could defend their independence with strenuous courage; the higher qualities which make for a progressive national life the Phoenicians did not possess.

Phoenicia now became part of the fifth satrapy of the Persian Empire, and entered upon a spell of comparative peace and The Persian growing prosperity. Favoured for the sake of Perioδ, 538-540 their fleet, and having common interests against 332 B.C. Greece, the Phoenicians were among the most loyal subjects of the empire. At this period Sidon occupied the position of leading state; in the fleet her king ranked next to Xerxes and before the king of Tyre (Herod. vii. 197); her situation afforded advantages for expansion which few, if any, other cities of ancient and island
rival. The city was distinguished by its cosmopolitan character; the satrap resided there when he came to Phoenicia, and the Persian monarch had his paradise outside the walls. In the first half of the 4th century Straton I. (in Phoen. 'Aqab-'ashtart or Bod-'ashtart) was king, c. 374-362. He cultivated friendly relations with Athens, indicated in a decree of prooxenia (Michel, Rec. d'inscr. gr. No. 93 = CIG. No. 87); his court was famed for its luxury; and the extent to which phil-Hellenic tendencies prevailed at this time in Sidon is shown by the royal sarcophag,

The Phoenician gold coins show the influence of Greek art, which have been excavated in the necropolis of the city. It was in the reign of Straton that Tyre fell into the hands of Evagoras, king of Cyprus, who had supplanted Phoenician with Greek civilization in Cyprus (Iseroy, Eosq. 62, Paneg. 161; Diod. iv. 2). Straton made friends with Nicoles, son of Evagoras, and with him came an untimely end through their implication in the great revolt of the satraps, 362 B.C. (see the story of Straton's death in Jerome, adv. Jovin. i. 45). A new revolt of Sidon against the Persians took place under King Nennes owing to the insults offered to the Sidonians at the federal diet in Tripolis. With the aid of Nectanebus of Egypt, who had grievances of his own to avenge, the Sidonians carried the rest of Phoenicia with them and drove the satraps of Syria and Cilicia out of the country. Nennes, however, became too independent of Artaxerxes and was overthrown, the inhabitants to the number of 40,000 are said to have set fire to their houses and perished; Nennes himself was executed after he had served the ends of the great king (346 B.C.; Diod. xvi. 41-45). The last king of Sidon was Straton II. (Aqab-

The naval expeditions against Greece in 480-449 and Sparta in 396-387 were fitted out by the pharaohs of Egypt. See PERSIA, Ancient History, for the whole of this section.

Justin x. 32 tells a story about Tyre during this period: the king of Egypt, who was not yet defeated by the Persian wars, was so enfeebled that it was seized by the Persians, who rose and massacrèd their masters; one Straton alone escaped and was afterwards made king. The reference to the Persians is obvious; the name of the monarch is, if not genuine, at least a fiction. It must refer to one of the sieges by the Assyrians or Chaldaeans, and, as Meyer suggests (Ency. Bib. col. 3760), may be derived from the story of Abdylamonus of Sidon mentioned below.

4 See especially E. Babelon, Les Peres Achéménides, and cf. NSI. No. 149.

the date of this dynasty has been much disputed; but the reference to "the lord of kings" in the great inscr. of Eshmun-'azar (line 18) points to the Ptolemaic period, for the Persian monarch is always styled 'king of kings.' The interpretation of many details of the inscr. from Bostan esh-Shékh is still uncertain.
PHOENICIA

rule of Ptolemy II. and his successors between 281 and 197, Aradus remained in the kingdom of the Seleucids, who greatly favoured the city and increased its privileges (Strabo xvi. 2, 14; Polyb. v. 68). But its subject-towns availed themselves of the political changes of the period to assert their independence, and in the time of Antiochus from Seleucia the kings of Syria employed the heads of the Ptolemies, and later on Aramaeans availed themselves of it in the same way; but in the end the Aradians recovered their supremacy. Diodorus records a barbarous and cruel massacre of Aradians, who were employed to destroy Marathus, which was frustrated by the pity and courage of an Aradian fisherman (xxxiii. 5). At last in the time of Tigranes, the Armenian holder of the kingdom of the Seleucids, or so afterwards, the city was the seat of the independence of Aradia, and its land, with that of Simyra, was parcelled out among the Aradians (Strabo xvi. 2, 12). Akko issued coins of its own down to 267 n.c., if the reckoning was from the Seleucid era (312 B.C.) and later; and these coins, bearing the name of the city (Arados, Polyb. iv. 37; Strabo xvi. 2, 25; cf. Acts xxi. 7). Laodicea of Libanus was founded by Seleucus Nicator on the plain south-east of Hemesa (Hymus) in the region of the upper Orontes, and became an important city; its coins of the 2nd century B.C. bear the interesting legend in Phoenician, “Of Laodicea which is in Canaan” (NSI. p. 349 seq.). Another Laodicea “by the sea” (ad mare), also of Seleucid foundation, is probably to be identified with the ruined site called Umm el’-Awamid, near the coast between Tyre and Akko; several Phoenician inscriptions have been found there (e.g. CJS., i. 7 = NSI. No. 9; Clermont-Ganneau, Recueil, t. v.).

After the death of Antiochus IV. Epiphanes in 164 B.C., revolts and adventurers made their appearance in many parts of Syria, heralding the collapse of the kingdom of the Seleucids. Berytus was destroyed by the usurper Tryphon in 140 B.C. Tyre in 120 and Sidon in 112 received complete independence; its traders of Tyre and Tripolis fell into the hands of “tyrants” (Strabo xvi. 2, 18; Jos. Ant. xiv. 3, 2), and Arab robbers plundered their territories from strongholds in the Lebanon. From 83-69 B.C. the entire kingdom was held by the Armenian Tigranes.

At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria; Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in the possession of their territories. In 14 B.C. Augustus rebuilt Berytus as a Roman colony and stationed two legions there; later on Ptolemais, Tyre and Sidon received colonial status. Under the beneficent government of Rome the chief towns prospered and extended their trade; but the whole character of the country underwent a change. During the Macedonian period Greek influences had been steadily gaining ground in Phoenicia; relations with the Greek world grew closer; the native language fell into disuse, and from the beginning of the Roman occupation Greek appears regularly in inscriptions and on coins, though on the later Phoenician legends do not entirely vanish till the 2nd century A.D.; while the extent to which Hellenic ideas penetrated the native traditions and mythologies is seen in the writings of Philo of Byblos. For the purposes of everyday life, however, the people spoke not Greek, but Aramaic. As elsewhere, the Roman rule tended to obliterate characteristic features of national life, and under it the native language and institutions of Phoenicia became extinct.

Navigation, Trade, Colonies.—The Phoenicians were essentially a seafaring nation. Fearless and patent navigators, they ventured into regions where no one else dared to go, and, always with an eye to their monopoly, they carefully guarded the secrets of their trade routes and discoveries, and their knowledge of winds and currents. At the beginning of the 7th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod. iv. 42). To the great powers Phoenician ships and sailors were indispensable; Sennacherib, Psammeticus and Necho, Xerxes, Ahasuerus, and Alexander employed them for their sea-ports and sea-fights. Even when Athens had developed a rival navy Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen. Oec. viii.); all the Phoenician vessels from the round merchant-boat (γαλάζου—after which the island of Gaulus, now Gozo, near Malta was called) to the great Tarshish-ships, the “East-Indiame” of the ancient world, excelled those of the Greeks in speed and equipment. As E. Meyer points out, the war between the Greeks and the Persians was mainly a contest between the sea-powers of Greece and Phoenicia. At what date did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (p. 69) may have brought to light the existence of a Cretan or “Minoan” sea-power of remote antiquity, and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea-power was at last broken up by invaders from the north, and a Carian rule became dominant in the Aegean (Herod. l. 171; Thucyd. i. 4, 8). It was a time of disorder and conflict due to the immigration of new races into the ancient seats of civilization, and it synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come, and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea and trading power has been greatly exaggerated both in ancient and in modern times; the Minoan power of Cnossus preceded it by many centuries; the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C., and, comparatively speaking, it was “foreign, late, sporadic.”

A vivid description of the Phoenicians’ trade at the time of Tyre’s prosperity is given by Ezekiel (xxviii. 12-25), and it shows that the Phoenicians were the independent and even the virtual masters of the sea, but by land as well. It was they who distributed to the rest of the world the wares of Egypt and Babylonia (Herod. l. 1). From the lands of the Euphrates and Tigris regular trade-routes led to the Mediterranean with trading-stations on the way, several of which are mentioned by Ezekiel (xxviii. 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the XXIInd and XXXIIIrd Dynasties (825-560 B.C.), when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herod. ii. 112). The Arabian caravan-trade in perfumes, spices and incense passed through Phoenician hands on its way to Greece and the West (Herod. iii. 107); these articles of commerce were mainly produced not in Arabia, but in East Africa and India, and the trade had its centre in the wealthy state of Sheba in Yemen. Between Israel and Phoenicia the relations naturally were close; the former provided certain necessary of life, and received in exchange articles of luxury and splendour (Ezek xxviii. 16-18).2 Israeliite housewives sold their homespun to Phoenician pedlars (Prov. xxxi. 24 R.V.M.); in Jerusalem Phoenician merchants and money-lenders had their quarter (Zeph. i. 11); and after the Return we hear of Tyrians selling fish and all manner of ware in the city (Neh. xii. 16), and introducing other less desirable imports, such as foreign cults (Isa. lxi. 11). The Phoenician words which made their way into Greek at an early period indicate the kind of goods in which the Phoenicians traded with the West, or made familiar through their commerce; the following are some of them—κρασά, χύτων, βίοσος, θύρην, μήδα, γίγα, κίπρος, φίδια, μα, παλακίας, βατινός. Another valuable article of commerce which the Phoenicians brought into the market was amber. They can hardly have fetched it themselves from the Baltic or the North Sea; it came to them by two well-marked routes, one from the Baltic to the Adriatic, the other up the Rhine and down the Rhone. A deposit of amber has also been found in the Lebanon, and perhaps the Phoenicians worked this and concealed its origin.

1 Burrows, Discoveries in Crete (1907), 140 seq. It may be noted that the traditional or conjectural dates based upon the list of the Thalassarches were by Diodorus Siculus; but Diodorus’ list dates back to the 23rd century B.C. See Professor John L. Myres’ essay referred to above, § iii. (4).

2 See Eupolemus (140-100 B.C.) quoted by Alexander Polyhistor, who, in a supposed letter from Solomon to the king of Tyre, mentions the food-supplies required by the Tyrians and promised from Palestine (Fr. Hist. Gr. iii. 226).
The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Cithium (from Ktimit, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Idâlium, Tamassus, Lapethus, Larnaka, Qarth-adastas (Karti-adastas) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potentiates in the island call themselves "kings of Kition and Idalion" (N.S.I. pp. 55-89). But the Phoenician rule was not so ancient as is supposed to be supposed. At an early period Greeks from the south coast of Asia Minor had settled in Cyprus before the Phoenicians founded any colonies there; and it is noticeable that in the Assyrian tribute-lists of the latter half of the 7th century (K.B. ii. pp. 149, 241) not one of the ten Cyprian kings mentioned appears to be Phoenician by name. Menander states (Jos. Ant. ix. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 8th century; but a clear proof that the Phoenician rule was neither ancient nor uninterrupted is given by the fact that the Cyprian Greeks took the trouble to invent a Greek cuneiform character (Cypristo) modelled on Phoenician.

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (U. xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elisah of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Egyptian world the Phoenicians made themselves husbandry extensively; their characteristic passion for gain (φόλοχρυσαν, Plato, Rep. iv. 435 E.) was not likely to ingratiate them with those who were compelled to make use of their services while they suffered from their greed.

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily, on the south coast, at Heraclea or Ras Megarath; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gausus and Cussora were also occupied (Diod. v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still, and on the Atlantic coasts to the right and left of the straits, more permanent colonies were established. It was the trade with Tarshish to which, in the Bible, the Phoenicians are referred (2 Kings iv. 6-9), and the first Punic stele (cf. Dahi, Dahi, Sqq., cf. Dahi, Sqq.), which contributed most to the Phoenicians' wealth; for in this region they owned not only profitable fisheries, but rich mines of silver and other metals. The profits of the trade were enormous; it was said that even the anchors of ships returning from Spain were made of silver (Diod. v. 35). From Gadeira (Punic Gâdêr, Lat. Gades, now Cadiz), the town which they built on an island near the mouth of the Guadalquivir, the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides, i.e. the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (i. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C. Most of the African colonies were no doubt younger; we have traditional dates for Aosta (889-855) and Carthage (813). A large part of North-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, just as Latin and Arabic did in later times, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqarth, and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. Tyre claimed to have been the first to make the most of the advantage of situation over far-away Tyre; the traditional bonds grew lax and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Melqarth. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambê (i.e. Carthage), Hippo, Kition, Tyre" (N.S.I. p. 352).

Manufactures, Inventions, Art. From an early date the towns of the Phoenician coast were occupied, not only with distributing the manufacture of other colonies but with industries of their own; especially purple-dyeing and textile fabrics (H. vi. 28). Metal work was carried on to a far higher degree than in any other work of Phoenician art. The cypress, olive and gourds, of the Phoenician coast, were made into vessels of gold and silver, iron and copper, made by the Dah, i.e. the Phoenicians (W. M. Müller, As. e. Eur. 306) and in Cyprus and at Nimrud bronze and silver paterae have been found, engraved with die work of Phoenicians (see the cases C and D in the Nimrud gallery of the Brit. Mus.). The invention of these various arts and industries was regularly ascribed to the Phoenicians, no doubt merely because Phoenician traders brought the products into the market. But dyeing and embroidery probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weighing measures must be laid to the credit of the Babylonians. The ancients believed that the Phoenicians invented the use of the alphabet (e.g. Pliny, N.H. v. 13. cf. vii. 57; Lucan, Bell. Civ. iii. 220 seqq.); but it is unlikely that any genuine tradition on the subject existed, and though the Phoenician theory has found favour in modern times it is open to much question. The Phoenicians cannot be said to have invented any of the arts or industries, as the ancient world imagined; but what they did was something remarkable, and their example was copied by them with a singular skill, and disseminated the knowledge and use of them.

The art of Phoenicia is characterized generally by its dependence upon that of Egypt, and of the rest of the Near East. The Middle line of its own, and borrowed freely from foreign, especially Egyptian, models. Remains of sculpture, engraved bronzes and gems, show clearly the source to which the Phoenician artists went for inspiration. But their art, and the temples and tombs which they decorated were the most artistic phases of the Semitic element. Phoenician art, if we except that of the mummy-cases, painted with colours and ornamented with carvings in low relief; and towards and during the Greek period the contours of the body begin to be marked more clearly on the cover. The finest work that have been discovered in the necropolis of Tyre (in the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important

of Melqarth at Tyre a few traces of the temple of Adonis near Byblus
were discovered by Renan, and a peculiar mausoleum, Burj alBezzaq, is still to be seen near Amrit; recent excavations at Bostan
esh-Shekh near Sidon have unearthed parts of the enclosure or
foundations of the temple of Eshmun (NSI. p. 401); the conduits
of Ras el-'Ain, south of Tyre, are considered to be of ancient date.
With regard to the plan and design of a Phoenician temple, it is
probable that they were in many respects similar to those of the
temple at Jerusalem, and the probability is confirmed by the remains of a sanctuary near Amrit, in which there is a cella standing
in the midst of a large court hewn out of the rock, together with
other buildings in an Egyptian style. The two pillars before the
porch of Solomon's temple (i Kings vii. 21) remind us of the two
at Tyre
pillars which Herodotus saw in the temple of Melqarth
(Herod, ii. 44), and of those which stood before the temples of

and mountains, headlands and rivers and springs, were
believed to be inhabited by different divinities, who were
therefore primarily local, many in number, with no one in
particular supreme over the rest. It seems, however, that as time
went on some of them acquired a more extended character; thus
Ba'al and Astarte assumed celestial attributes in addition to
their earthly ones, and the Tyrian Melqarth combined a celestial
with a marine aspect. 2 The gods in general were called 'elonim,
'elim; Plautus uses alonium valonuth for "gods and goddesses"
(Poen. v. i, i). These plurals go back to the singular form 'El,
the common Semitic name for God but neither the singular nor the
plural is at all common in the inscriptions (NSI. pp. 24, 41, 5');
El by itself has been found only once; 3 the fern. 'Elath is also rare

god, especially popular in Cyprus and derived originally
lightning
from Syria, whom the Greeks called Apollo. A tendency to form a
distinct deity by combining the attributes of two produced such
curious fusions as Milk-'ashtart, Milk-ba'al, Milk- osir, Eshmunmelqarth, Melqarth-resef, &c. As in the case of art and industries,
so in religion the Phoenicians readily assimilated foreign ideas. The
influence of Egypt was specially strong (NSI. pp. 62, 69, 148, 154);
thus the Astarte represented on the stele of Yebaw-milk, mentioned
above, has all the appearance of Isis, who, according to the legend
preserved by Plutarch (de Is. et Os. 15), journeyed to Byblus, where
she was called Astarte. The Phoenician settlers at the Peiraeus
worshipped the Assyrian Nergal, and their proper names are compounded with the names of Babylonian and Arabian deities (NSI.
Closer intimacy with the Greek world naturally brought
p. 101).
about modifications in the character of the native gods, which
became apparent when Ba'al of Sidon or Ba'al-shamem was identified
with Zeus, Tanith with Demeter or Artemis, 'Anath with Athena,
&c. ; the notion of a supreme Ba'al, which finds expression in the
Greek /3ij\os and /JaaXris or ^Xflijs (the goddess of Byblus), was no
doubt encouraged by foreign influences. On the other hand, the
Phoenicians produced a considerable effect upon Greek and Roman
religion, especially from the religious centres in Cyprus and Sicily.
A great number of divinities are known only as elements in proper
names, e.g. Sakun-yathon (Sanchuniathon), 'Abd-sasom, ^ed-yathon,
and fresh ones are continually being discovered. It was the custom
among the Phoenicians, as among other Semitic nations, to use the
names of the gods in forming proper names and thus to express devotion or invoke favour; thus Hanni-ba'al, 'Abd-melqarth, HanniThe proper names further illustrate the

way in which the relation of man to God was regarded the commonest forms are servant ('abd, e.g. 'Abd-'ashtart), member or limb bod,
e.g. Bod-melqarth), client or guest (ger, e.g. Ger-eshmun); the
religious idea of the guest of a deity had its origin in the social custom
of extending hospitality to a stranger and in the old Semitic right
of sanctuary.
The interpretation of such names as 'Abi-ba'al
(father of Ba'al), Himilkath (brother of Milkath), Hiram (brother
of the exalted one) is not altogether certain, and can hardly be
discussed here. 8
like other Canaanites the Phoenicians offered worship
"
" Probably
on every high hill and under every green tree
but to judge from
the allusions to sanctuaries in the inscriptions and elsewhere, the Ba'al or 'Ashtart of a place was usually
worshipped at a temple, which consisted of a court or
enclosure and a roofed shrine with a portico or pillared
hall at the entrance.
In the court sometimes stood a conical stone,
probably the symbol of Astarte, as on the Roman coins of Byblus
(illustrated in Rawlinson, Phoenicia, 146, Perrot et Chipiez, Hist,
de Vart, iii. 60; see also Ohnefalsch-Richter, Cyprus, pi. Ivi., the
temenos at Idalion). Stone or bronze images of the gods were set
up in the sanctuaries (NSI. Nos. 13 seq., 23-27, 30, &c.) and besides
these the baetylia (meteoric stones) which were regarded as symbols
of the gods. Pillars, again, had a prominent place in the court or before the shrine (najoft, ibid. pp. 102 seq.) but it is not known whether
the sacred pole ('asherah), an invariable feature of a Canaanite sanctuary, was usual in a Phoenician temple (ibid. pp. 50 seq.). The

PHOENIX

The Greek word is also used for a date-palm, a musical instrument like a guitar, and the colour purple-red or crimson. According to the story told to Herodotus (ii. 73), the bird came from Arabia every 900 years, bearing his father embalmed in a ball of myrrh, and buried him in the temple of the sun. Herodotus, who had never seen the phoenix himself, did not believe this story, but he tells us that the pictures of it represented a bird with golden and red plumage, closely resembling an eagle in size and shape. According to Plan (Nat. hist. x, 2), there is only one phoenix at a time, and he, at the close of his long life, builds himself a nest with twigs of cassia and frankincense, on which he dies; from his corpse is generated a worm which grows into the young phoenix. Tacitus (Ann. vi. 28) says that the young bird lays his father on the altar in the city of the sun, or burns him there; but the most familiar form of the legend is that in the Physiologus (q.e.), where the phoenix is described as an Indian bird which subsists on air for 500 years, after which, lading his wings with spices, he flies to Heliopolis, enters the temple there, and is burned to ashes on the altar. Next day the young phoenix is already feathered; on the third day his pinions are full grown, he salutes the priest and flies away.

The period at which the phoenix reappears is very variously stated, some authors giving as much as 1461 or even 7006 years, but 500 years is the period usually named; and Tacitus tells us that the bird was said to have appeared first under Sesostris (Senwosret), then under Amonas (Ahmosi) II., under Ptolemy III., and once again in A.D. 34, after an interval so short that the genuineness of the last phoenix was suspected. The phoenix that was shown in Alexandria in 1632, as one of the religious games (a.D. 47) was universally admitted to be an imposture.

The form and variations of these stories characterize them as popular tales rather than official teaching; but they evidently must have had points of attachment in the mystic religion of Egypt, and indeed both Horapollo and Tacitus speak of the phoenix as a symbol of the sun. Now we know from the Book of the Dead, and other Egyptian texts, that a stork, heron or egret called the benu was one of the sacred symbols of the worship of Heliopolis, and A. Wiedemann (“Die Phönix-Sage im alten Aegypten” in Zeitschrift für ägyptische Sprache, xvi. 98) has made it tolerably clear that the benu was a symbol of the rising sun, whence it is represented as “self-generating” and called the “soul of the Ra (the sun),” “the heart of the renewed Sun.” All the mystic symbolism of the morning sun, especially in connexion with the doctrine of the future life, could thus be transferred to the benu, and the language of the hymns in which the Egyptians praised the luminary of dawn as he drew near the eastern horizon, is almost a verbatim translation of the words used in the benu hymns. For some other ancient accounts may be here referred to. That ascribed to Heceataeus is in the judgment of C. G. Gobet (Menomiesis, 1883), stolen from Herodotus by a late forger. The poem of the Jew Ezekiel quoted by Eusebius (Praep. ev. ix. 29, 30) appears to be the phoenix song as we know it, but is not a translation of it, for it is addressed to the singer rather than to the birds, and the benu is a song which, according to the poem on the phoenix ascribed to Lactantius, accompanies the rising sun. The bird is often spoken of in Latin poetry, and is the subject of an idyll by Claudian. See also the collection of piéteties in the Coptic Psalter, and Psalms 100, i. 21, 25, 27, 28, 29; and the (Clementine) Apostolical Constitutions, v. 7.
from Arabia, delighting the gods with his fragrance and rising from the sinking flames of the morning glow, was enough to suggest most of the traits materialized in the classical pictures of the phoenix. That the benu is the prototype of the phoenix is further confirmed by the fact that the former word in Egyptian means also "palm-tree," just as the latter does in Greek. The very various periods named make it probable that the periodical return of the phoenix belongs only to vulgar legend, materializing what the priests knew to be symbolic. Of the birds of the heron family the gorgeous colours and plumed head spoken of by Pliny and others would be least inappropriate to the purple heron (Ardea purpurea), with which, or with the allied Ardea cinerea, it has been identified by Lepsius and Peters (Alleste Texte des Todtenbuchs, 1867, p. 51). But the golden and purple hues described by Herodotus may be the colours of sunrise rather than the actual hues of the purple heron. How Herodotus came to think that the bird was like an eagle is quite unexplained; perhaps this is merely a slip of memory.

Many commentators still understand the word benu, chôl, in Job xxix. 18 (A.V. "sand") of the phoenix. This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews. Among the Arabs the story of the phoenix was confused with that of the phoenix, a kind of parrot; and these same scribes called by the same name (cf. Yaquit i. 529, and Dozy, s.v.). The "anâk (Pers. sâmarúh), a stupendous bird like the roc (rubh) of Marco Polo and the Arabian Nights, also borrows some features of the phoenix. According to Kazimi (L. 490) it lives 1000 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of Kâtila and Dimma the sâmâr or "anâk is the king of the birds, the Indian garûla, on whom Vishnu rides.

**PHOENIX**— the capital of Arizona, U.S.A., and the county-seat of Maricopa county, situated on the Salt river, in the south central part of the state. Pop. (1890), 3752; (1900), 5544 (1933 being foreign-born and 148 negroes); (1910) 11,134. It is served by the Arizona Eastern and the Santa Fé, Prescott & Phoenix railways, the former connecting at Maricopa (35 m. distant) with the Southern Pacific and the latter connecting at Ash Fork, near Prescott (104 m. distant), with the Atchison, Topeka & Santa Fé. The city is a popular winter and health resort, with a fine dry climate. The city is the see of a Protestant Episcopal bishopric. About 3 m. north of the city is the Phoenix (non-reservation) boarding-school for Indians, supported by the United States government, with an average attendance of pre-pupils, and were themselves called by the same name (cf. Yaquit i. 529, and Dozy, s.v.). The "anâk (Pers. sâmarúh), a stupendous bird like the roc (rubh) of Marco Polo and the Arabian Nights, also borrows some features of the phoenix. According to Kazimi (L. 490) it lives 1000 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of Kâtila and Dimma the sâmâr or "anâk is the king of the birds, the Indian garûla, on whom Vishnu rides.

**PHOENIX ISLANDS**, a group of eight small islands in the Pacific Ocean, about 3° S., and 170° W., belonging to Great Britain. The largest and most important is called Phoenix, and has a population of 60. Their names are Phoenix, Gardner's (Kermin), Hull, Sydney, Birnie, Enderbury, Canton (Mary) and McLean. To the north-west of the group (between the equator and 1° N.) lie two more islets—Baker and Howland. The islands were annexed by Great Britain in 1899.

**PHOENIXVILLE**, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill river at the mouth of French Creek, about 28 m. north-west of Philadelphia. Pop. (1890), 8514; (1900), 9706, of whom 2221 were foreign-born and 278 were negroes; (1910 census), 10,743. It is served by the Pennsylvania (Schuylkill division) and the Philadelphia & Reading railways, and is connected by rail to Spring City (pop. in 1910, 2680), 5 m. north-west of Phoenixville on the Schuylkill. Phoenixville is chiefly a manufacturing borough. Its blast-furnaces and iron mills were long among the largest in the country, and the manufacture of steel is still the borough’s predominant industry. Phoenixville was settled in 1732, and was incorporated in 1849.

**PHONETICS** (Gr. φώνη, voice), the science of speech-sounds and the art of pronunciation. In its widest sense it is the "science of voice," dealing not only with articulate, but also with the inarticulate sounds of animals as well as men. The originally synonymous term, "phonology," is now restricted to the history and theory of sound-changes. The most obvious of the practical applications of phonetics is to the acquisition of a correct pronunciation of foreign languages. But its applications to the study of the native language are not less important: it is only by the help of phonetics that it is possible to deal effectively with vulgarisms and provincialisms of pronunciation and secure uniformity of speech; and it is only on a phonetic basis that the deaf and dumb can be taught articulate speech. From a more theoretical point of view phonetics is, in the first place, the science of linguistic observation. Without phonetic training the dialectologist, and the missionary who is confronted with a hitherto unwritten language, can neither observe fully nor record accurately the phenomena with which they have to deal. These investigations have greatly widened the scope of the science of language. The modern philologist no longer despises colloquial and iliterate forms of speech. On the contrary, he considers that in them the life and growth of language is seen more clearly than in dead literary languages, on whose study the science of comparative philology was at first exclusively built up. It was not till philologists began to ask what were the real facts underlying the comparisons of the written words in Sanskrit, Greek, Latin, and the other Indo-European languages, embodied in such generalizations as Grimm’s Law, that "letter-science" developed into "sound-science" (phonology). The rise and decay of inflexions, and the development of grammatical forms generally, are, from the formal point of view, mainly phonetic problems; and phonetics enters more or less into every department of historical and comparative grammar.

**Methods of Study and Investigation.**—Phonetics is the science of speech-sounds. But sounds may be considered from two opposite points of view—the organic and the acoustic. From the organic point of view a sound is the result of certain actions and positions of the organs of speech, as when we define f as a lip-sound (dento-labial) consonant. This is the point of view of the speaker of a language. To the hearer, on the other hand, f is not a lip-teeth, but a hiss consonant similar to that denoted by the tongue or teeth; it is a sound. Phonetically, the organic study of phonetics is a branch of anatomy and physiology: that part of these sciences which deals with the organs of speech (see Moutr’s) and their functions (see Voce); while, from the opposite point of view, the study of phonetics is based on that branch of physical science known as acoustics (see Sound), together with the anatomy and physiology of the organs of Hearing (q.v.).

Unfortunately, this basis is still imperfect. The principles of acoustics are well established, and we know much about the anatomy of the ear. But how the ear transmits to the brain the impression of sound is still a mystery. Again, although the mechanism of the ear is clear enough, there is still no generally received acoustic theory of its formation. In fact, from the physical science point of view there is, as yet, no science of phonetics.

The real function of phonetics is philological and literary. The only sound basis of a theoretical knowledge of phonetics is the practical mastery of a limited number of sounds—that is to say, of the sounds which are already familiar to the learner in his own language. It is evident that the more familiar a sound is, the easier it is to gain insight into its mechanism and to recognize it when heard. It is indispensable to cultivate both the organic and the acoustic sense. These processes we are continually carrying out in ordinary conversation. All, therefore, that we have to do in dealing with native sounds is to develop this unconscious organic and acoustic sense into a conscious and analytic one. The first step is to learn to isolate each sound: to
PHONETICS

pronounce it, as far as possible, apart from its context; and to preserve it unchanged through every variation of length and force, and in every combination of sounds. The next step is to analyse its formation. Let the student, for instance, compare the sound "ch" as it is pronounced by the French, with the English pronunciation, isolate and lengthening them till he can both hear and feel the difference in the second one. In the same way let him learn to feel the changes in the position of the tongue and lips in passing from one vowel to another. When the native sounds have been thoroughly studied in this way, the learner will proceed to foreign sounds, deducing each new sound from those which are already familiar to him.

The natural method of learning sounds is mainly a subjective one. We listen patiently till our ears are steeped, as it were, in the sounds, and after repetition, we hit the position of the organs of speech by which we can reproduce the sound to the speaker's satisfaction. But the natural method admits also of objective control and criticism of the movements of the lips and jaws by direct observation. The movements and positions of the tongue and soft palate, and other modifications of the mouth and throat passages are also more or less accessible to observation—in the case of self-observation with the help of a small mirror held in the hand, or of observation with the aid of a hand-lens or a camera obscura, or by using a laryngoscope, which is a universal tool that is fixed obliquely to a handle, so that it can be held against the back of the mouth at such an angle as to reflect a ray of light down the throat, thus allowing the larynx to be seen. Laryngoscopy has confirmed earlier results and enabled us to observe the movements of the throat sounds. But, on the other hand, it has been a fruitful source of error. There has been great discrepancy between the results of self-observation and those of mirrors which were at first received with implicit confidence for their rigorously scientific and objective character have been found to be worthless. It seemed at first as if Röntgen's discovery of the so-called X-rays would meet the want of a means of direct observation of the positions of the tongue, not lengthways, but from the side, as also of the interior of the throat. But although the checks are to a certain extent transparent to these rays, the shadow of the tongue under observation is usually too faint to be of use.

But there are other methods besides those of direct observation by which the positions of the tongue may be objectively determined and measured with more or less accuracy. The interior of the mouth may be opened by the fingers. If the little finger is held against the gums during the articulation of the vowels in it, ae, at, the difference in the height of the tongue will at once become apparent: in the formation of the first vowel the tongue is pressed strongly against the anterior palate, while in that of the second it only just touches it, and in that of the third it does not touch at all.

Several forms of apparatus have been devised for a more accurate determination of the positions of the tongue and the other movable organs of speech. The best results hitherto as regards the vowel-positions have been obtained by Grädgent, who uses disks of card-board, on which are marked out the forms of the tongue, and with the aid of this and other methods will be found in Scripture's Elements of Experimental Phonetics.

There are other methods whose results are obtained only indirectly, but which afford much information. Palatograms are obtained "palatograms" recording the contact of the tongue with the palate. The apparatus most generally used consists of a thin, shell-like artificial palate, which is covered with chalk and placed in the mouth; when the sound is made, the articulation of the tongue is inferred from the contact-marks on the plate. This method is evidently limited in its application. It, too, has the drawback of not being applicable to the sounds formed in the back of the mouth. The outline of the contact area is, however, more than they appear in the published drawings of them; and it is a question whether the thickness even of the thinnest plate does not prevent this difference being noted.

The methods hitherto considered are all comparatively simple. They require no special knowledge or training, and are accessible to all. But there are more elaborate methods—with which the native sounds are determined, especially those involving special training in practical and theoretical physics and mathematics, and requiring the help of often complicated and costly, and not easily accessible, apparatus. The investigation of the sounds of the English and other languages has been largely carried on in this way, for instance, by E. A. Meyer's investigations of vowel-quantity in English (Englische Lauttäler, Uppsala, 1903). Their characteristic feature is their delight in showing the extremes of their distinctions, which often go beyond the range of the human ear. Although their results are often of value, they must always be received with caution: the sources of error are so numerous.

The claims of instrumental phonetics have been so prominently brought forward of late years that they can no longer be ignored, even by the most conservative of the older generation of phoneticians.

But it is possible to go too far the other way. Some of the advocates seem to think that the instrumental methods have superseded the natural ones in the same way as the Arabic superseded the Roman numerals. This assumption has had disastrous results. It cannot be too often repeated that instrumental phonetics is, strictly speaking, not phonetics at all. It is only an aid; it supplies materials which are useless till they have been tested and accepted from the linguistic phonetician's point of view. The answer to the phonetician's questions is the trained ear of a practical phonetician; data which cannot be rejected—or at least may be—ignored; what contradicts the trained ear cannot be accepted.

Sound-Notations; Spelling Reform.—Next to the analysis of the sounds themselves, the most important problem of phonetics is their representation by means of written and printed symbols. The traditional or "nomic" orthographies of most languages are only imperfectly phonetic. And, unfortunately, of the languages in most general use, two are exceptionally unphonetic in their orthographies, French showing the greatest divergence between sound and symbol, while English shows the maximum of irregularity and arbitrariness. The German orthography is comparatively phonetic; it has hardly any silent letters, and it generally has one symbol for each sound, each symbol having only one value, the exceptions falling under a few simple rules, which are easily remembered. There are other languages which have still more phonetic orthographies, such as Spanish, Welsh and Finnish. But even the best of them are not perfect: even when they are not actually misleading, they are always inadequate. On the other hand, no system of writing is wholly unphonetic. Even in French and English there are many words whose spelling not even the most radical reformer would think worth of altering. In fact, all writing which has once emerged from the hieroglyphic stage is at first purely phonetic, as far as its defective means will allow. The divergence between sound and symbol which makes spelling unphonetic is the result of the retention of phonetic spellings after they have become unphonetic through changes in the pronunciation of the words themselves. Thus, such English spelling as knight and wright were still phonetic in the time of Chaucer; for at that time the initial consonants of these words were still pronounced, and the gh still had the sound of ch in German ich. So also see and sea are written differently, not by way of arbitrary distinction, but because they were pronounced differently till within the last few centuries—as they still are in Irish-English.

Where there is no traditional orthography, as when Old English (Anglo-Saxon) was first written down in Latin letters, spelling was necessarily phonetic; but where there is a large literature and a class of professional scribes, the influence of the traditional orthography becomes stronger, till at last the invention of printing and the diffusion of one standard dialect over a large area occupied originally by a variety of other dialects make changes of spelling as inconvenient as they were once easy and natural. The ideal orthography for printers is one which is absolutely uniform over the whole territory of the language, and absolutely unchangeable. In such orthographies as those of the present English and French there is no longer any living correspondence between sound and symbol: they are, in intention at least, wholly unphonetic; they are preserved by graphic, not by oral, tradition.

But unphoneticness has its practical limits. A purely unphonetic degradation of an originally phonetic system of writing—one in which there is absolutely no correspondence between sounds and letters—could not be mastered even by the most retentive memory: it would be even more difficult than the Chinese writing. Hence a phonetic reaction is inevitable. In the middle ages the spelling was periodically readjusted in accordance with the changes in pronunciation, as far as of course, as the imperfections of the existing orthography would allow. This adjustment went on even after the introduction of printing. In fact, it is only within the last hundred years or so that the orthographies of English and French have become fixed.

One result of this fixity is that any attempt to continue the process of adjustment assumes a revolutionary character. When, in 1849, the pioneers of the modern spelling-reform
movement—A. J. Ellis and I. Pitman—brought out the 
Fonetic Nae, few of those who joined in the chorus of ridicule excited by 
the new alphabet stopped to consider that this uncouthness was 
purely the result of habit, and that the Authorized Version of the 
Bible in the spelling of its first edition would seem to us not 
less strange and uncouth than in the new-fangled phonoty 
of Messrs. Ellis and Pitman. Nor did they stop to consider 
that phonetics and phonetic spelling, so far from being innovations, 
are as old as civilization itself. The Alexandrian grammarians 
were not only phoneticians—they were spelling-reformers; they 
invited the Greek accents for the purpose of making the pro- 
nunciation of Greek easier to foreigners. The Romans, too, were 
phoneticians: they learnt Greek by phonetic methods, and paid 
great attention to niceties of pronunciation. The Sanskrit 
grammarians were still better phoneticians.

As a matter of fact, English spelling was still phonetic as late 
as the time of Shakespeare—in intention, at least. But although 
people still tried to write as they spoke, the inherited imperfection 
of their orthography made it more and more difficult for 
them to do so. Hence already in the 16th century a number of 
spelling-reformers made their appearance, including classical 
standing: such as Sir John Cheke, and A. Gill, who was head-master 
of St Paul's School in London. Gill has left us extracts from 
Spenser's Faerie Queene in phonetic spelling; but, strange to 
say, nothing of Shakespeare's, although he and Shakespeare 
were exact contemporaries. But Gill's and the other alphabets 
proposed were too intricate and cumbersome for popular use. 

Nevertheless, some important phonetic reforms were success- 
fully carried through, such as getting rid of most of the super- 
fluous final e's, utilizing the originally superfluous distinctions 
in form between i and j, u and v, by using i, u only as vowels, 
j, v only as consonants, instead of at random—a reform which 
seems to have begun in Italy. Another important reform was 
the introduction of oe and ow, as in see and boat, which had 
hitherto been written with ee and oo, being thus confused with 
see and boot.

All these were as much phonetic reforms as it would be to 
utilize long s and tailed z ( e, 3) to denote the final consonants 
in fish and rouge respectively; a reform first suggested by A. J. 
Ellis, who was himself the first to call attention to the works 
of these early phoneticians and to utilize them in the investiga- 
tions enjoined in his great work on Early English Pronunciation.

With all its defects, the present English spelling is still mainly 
phonetic. We may approximate to the phonetic spelling of the 
vast majority of words from their spelling. So when we 
say that English spelling is unphonetic we merely mean that 
it is a bad phonetic spelling; and all that spelling-reformers aim 
at is to make this bad into a good phonetic spelling, that is, an 
efficient and easy one. But the difficulties are great; and the 
more we know of phonetics, and the more we experiment with 
different systems of spelling, the more formidable do they appear. 
One of the difficulties, however, is that commonly supposed to 
stand in the way of spelling-reform is quite imaginary: namely, 
that it would destroy the historical and etymological value of 
the present system. Thus E. A. Freeman used to protest 
against suggestions to change a "reckless wiping out of the whole history of the language." Such critics fail to see that historical spelling, if 
carried out consistently, would destroy the materials on which 
a series of phonetic spellings of different periods of the language, and that if a consistent historical and etymological spelling could have been kept up from the beginning, there would 
have been no Grimm's Law, no etymology; in short, no com- 
parative or historical philology possible.

The advantages of beginning a foreign language in a phonetic 
notation are many and obvious. In the first place, the learner 
who has once mastered the notation and learnt to pronounce the 
words the letter represents, is not only able to recognize that 
is presented to him without doubt or hesitation, and without 
hesitating to form the correct form of his native language. 
Another advantage of phonetic spelling is that when the 
leuned sees the words written in a representation of their

actual spoken form he is able to recognize them at once when he 
hears them. And if the learner begins with the phonetic 
notation, and uses it exclusively till he has thoroughly mastered 
the spoken language, he will then be able to learn the ordinary 
spelling without fear of confusion, and quicker than he would 
otherwise have done.

Spelling-reform may be carried out with various degrees of 
thoroughness. After the failure of many schemes of radical 
reform, an attempt was made to begin with those numerous 
spellings which are both unphonetic and unhistorical, or are 
against the analogy of other traditional spellings. Accordingly, 
in 1881 the Philological Society of London "approved (sic) of 
certain partial corrections (sic) of English spellings," which 
were also approved of by the American Spelling-reform Association; 
and a list of them was issued jointly by the two bodies, 
and recommended for general adoption. A similar movement 
has been started in France. But the general feeling appears to 
be that it is better to keep the ordinary spelling unchanged, 
and wait till it is possible to supersede it by one on a more or less 
independent basis.

If the existing Roman alphabet is made the basis of the new 
phonetic notation of any one language, the most obvious course 
is to select one of the various traditional representations of each 
word, and use that symbol exclusively, omitting, of course, 
at the same time all silent letters. A. J. Ellis's English Glossic is 
an example of such a phonetic spelling on a national basis. The following is a specimen:—

Inglis Glosik iz veet cee too reed. Vich proper training a child for dayer oald kan ber rettla tu too zest Glosik buks.

But a system which, like this, writes short and long vowels 
with totally different symbols (i, ee) is only half phonetic: it is 
phonetic on an unphonetic basis.

A fully phonetic system, in which, for instance, long vowels 
and diphthongs are expressed by consistent modifications or 
combinations of the symbols of the short vowels, and in which 
simple sounds are, as far as is reasonable and convenient, 
expressed by single letters instead of digraphs such as sh, must 
necessarily discard any national basis. "The best basis on 
the whole is obtained by giving the letters their original common 
European sounds, i.e. by returning to the Late Latin pronuncia- 
tion, with such modifications and additions as may be advisable. 
As it is, the sounds of the Late Latin basis is very well 
preserved in German and Italian. In French, on the other hand, 
the Latin tradition was greatly corrupted already in the earliest 
period through the rapid changes which the language underwent. 
Thus when the Latin u in luna assumed the sound it now has 
in French lune, the symbol u was still kept; and when the sound 
q afterwards developed again out of the diphthong ou, this diphthong was used to denote the sound. So when the French 
system of spelling came into use in England after the Norman Conquest these unphonetic symbols were introduced into English spelling, so that such a word as Old English and Early Middle English 
hus, "house," was written hous in the Late Middle English of Chaucer, although the sound was still that of Scotch hoos, on (ow) 
being also used to denote a true diphthong (ou) in such words as 
knou, know, from Old English cinwun.

By returning, then, to the original values of the letters we 
get the "Romic" or international (Continental) basis as opposed to 
the Glossic or national basis. Thus the passage quoted above 
appears as follows in Sweet's "Broad Romic" notation:

"i ngli s glosik iz veri iiu tu riid. viis prope trei t s ealld fai i oal goul kan bi reediI t t to riid glosik buks.

Another important general distinction is that between "broad " 
and "narrow" systems of notation. A broad notation is one 
which makes only the practically necessary distinctions in each 
language, and makes them in the simplest manner possible, 
omitting all that is superfluous. From a practical point of view 
the necessary distinctions are those on which differences of meaning depend. A single phonetic symbol, which is significant 
in one language may be insignificant in another. Thus the 
distinction between close e and open e, e is significant in French, 
as in pêcher, pêcher; so if in French phonetic-writing the former
is denoted by (e), it is necessary to find a new symbol (e) for the open sound. But in languages such as English and German, where the short e is always open, there is objection to using the unmodified (e) to denote the open sound, even if we regard (e) as the proper symbol of the close sound. And in those languages in which the short e is always open and the long e always close it is enough to mark the distinction of quantity, and leave the distinction of quality to be inferred from it (e, ee).

In such a case as this it is, of course, possible to apply the principle of ignoring superfluous distinctions in the opposite way: by writing the long and short vowels in such a language (e, e), leaving the quantity to be inferred from the quality. But the former method is the more convenient, as it does not require any modification of the "broad" principle especially convenient in writing diphthongs. Thus in English Broad Romic we write the diphthongs in high and how with the same vowel as ask (hai, hau, ask), although all these (a) represent different sounds in ordinary southern English pronunciation. But the pronunciation of these diphthongs varies so much in different parts of the English-speaking territory, and the distinctions are so minute that it would be inconvenient to express them in writing; and as these distinctions are non-significant, it would be useless to do so. (a) and (au) are symbols, not of special diphthongs, but of two classes of diphthongs: they can stand for any diphthongs which begin with a vowel resembling the Italian a, and end with approximations to i and u respectively. Theoretically it would be just as correct in English and German to write these diphthongs (ae, ao). But these notations are misleading, because they suggest simple sounds.

In comparing the sounds of a variety of languages, or of dialects of a language, and still more in dealing with sounds in general, we require a "narrow," that is a minutely accurate notation covering the whole field of possible sounds. It is evident from what has been said above that such a universal scientific alphabet is not suited for practical work in any one language. But the symbols of such a notation as Sweet's "Narrow Romic" are of the greatest use as keys to the exact pronunciation of the vulgar symbols of the Broad Romic notations of each language.

To prevent confusion between these two systems of notations Broad Romic symbols are enclosed in (), Narrow Romic in [], which at the same time serve to distinguish between phonetic and nomic spellings. This in English i (i) = [i] means that the English vowel in funny is the "wide" sound, not the "narrow" one in French fini, although in the Broad Romic notations of both languages (fini) is written for funny and fini alike.

Narrow Romic was originally based on A. J. Ellis's "Palaeotype," in which, as the name implies, no new letters are employed. The symbols of Palaeotype are made up, as far as possible, of the letters generally accessible in printing-offices, the ordinary Roman lower-case letters being supplemented by italics and small capitals (i, i, 1) and turned letters (a, 2), many digraphs (th, sh) being also used. This notation was a reaction from Ellis's earlier phonotopy, in which a large number of new letters were used. Some of these, however, such as (a, zh), (zh), were afterwards adopted into Broad and Narrow Romic. In his Palaeotype Ellis also discarded diacritical letters, which, as he rightly says, are from a typographical point of view equivalent to new letters. In Narrow Romic a certain number of diacritical letters are used, such as (fi, fi), most of which are already accessible. Palaeotype is a Roman-value notation, the main difference as regards the values of the symbols between it and the later systems being that it is more complex and arbitrary. Ellis afterwards had the unhappy idea of constructing a "Universal Glossic" on an English-values basis, which is even more curious and difficult to remember than Palaeotype.

Sweet's Romic systems were made the basis of the "International" alphabet used in Le Maitre Phonétique, which is the organ of the International Phonetic Association, directed by P. Passy. Although this system is at the present time more widely known and used than any other, and although it is constructed on the international Romic principle, it is not really an international system. It is rather an attempt to make a special adaptation of the Romic basis to the needs of the French language into a general notation for all languages. But the phonetic structure of French is so abnormal, so different from that of other languages, that the attempt to force a Broad Romic French notation on such a language as English is even more hopeless than it would be to reverse the process. Although well suited for French, this alphabet must from a wider point of view be regarded as a failure: it is too minute and rigid for practical, and yet not precise enough for scientific purposes. In short, although it has done excellent service, and has helped to clear the way for a notation which shall command general acceptance, it cannot be regarded as a final solution of the problem.

Of the numerous other notations now in use, there are still adheres to the diacritic principle of Lepsius's Standard Alphabet (1855), intended for missionary use, but found quite unfit for that purpose because of the enormous number of new types required. Most of them prefer to use new letters formed by more or less consistent modifications of the existing italic letters. A. J. Lundell's Swedish dialect alphabet and O. Jespersen's Danish dialect alphabet are good specimens of this tendency. In the latter Roman letters are used for special distinctions, just as the italic letters are used in the Romic systems.

But in spite of all diversity, there is much agreement. As regards the vowels, the following approximate values are now generally accepted:

<table>
<thead>
<tr>
<th>Sound</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[a]</td>
</tr>
<tr>
<td>ai</td>
<td>[ai]</td>
</tr>
<tr>
<td>au</td>
<td>[au]</td>
</tr>
<tr>
<td>e</td>
<td>[e]</td>
</tr>
<tr>
<td>ei</td>
<td>[ei]</td>
</tr>
<tr>
<td>o</td>
<td>[o]</td>
</tr>
<tr>
<td>ou</td>
<td>[ou]</td>
</tr>
</tbody>
</table>

Vowel-length is in some systems denoted by doubling (aa), in others by special marks (a: &c.), the diacritic in being used only in the nomic orthographies of dead and oriental languages.

The only consonant-symbols that require special notice are the following:

<table>
<thead>
<tr>
<th>Sound</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>[c]</td>
</tr>
<tr>
<td>cc</td>
<td>[cc]</td>
</tr>
<tr>
<td>ds</td>
<td>[ds]</td>
</tr>
<tr>
<td>j</td>
<td>[j]</td>
</tr>
<tr>
<td>ny</td>
<td>[ny]</td>
</tr>
</tbody>
</table>

All the systems of phonetic notation hitherto considered are based on the Roman alphabet. But although the Roman alphabet has many advantages from a practical point of view, it is entirely impossible to build up a consistent and systematic notation on such an inadequate foundation of arbitrary signs. What is wanted, for scientific purposes especially, is a notation independent of the Roman alphabet, built up systematically—an alphabet in which there is a definite relation between sound and symbol.

This relation may be regarded either from the organic or the acoustic point of view. The tendency of the earlier attempts at an a priori universal alphabet was to symbolize the consonants organically, the vowels acoustically, as in E. Brücke's Phonetische Transcriptionen (1865). It is now generally acknowledged that the vowels as well as the consonants must be represented on a strictly organic basis. This was first done in A. M. Bell's Visible Speech (1867), which appeared again (1882) in a shorter form and with some modifications under the title of Sounds and their Relations. Bell's pupil, H. Sweet, gave a detailed criticism of Visible Speech in a paper on Sound-notation (Trans. of Philological Society, 1880-1881), in which he described a revised form of it called the Organic Alphabet, which he afterwards employed in his Primer of Phonetics and other works. Sweet's Narrow Romic notation already mentioned is practically a transcription of the Organic Alphabet into Roman letters.

Such notations are alphabetic: they go on the general principle of providing separate symbols for each simple sound. But as
PHONETICS

The number of possible shades of sounds is almost infinite, even the most minutely accurate of them can do so only within certain limits. In fact, there are no "raw" phonetic symbols, but only "modifiers"—characters which are added to the other symbols to indicate nasal, palatal, &c., modifications of the sounds represented by the latter, these modifiers being generally represented by italic letters in the Narrow Romic transcription; thus (/) = nasalized (l).

In the Roman alphabet such symbols as /, v are arbitrary, showing no connection in form either with one another or with the organic actions by which they are formed; but in the Organic symbol of v, for instance, we can see the graphic representation of its components "lips, teeth, voice-murmur." By omitting superfluous marks and utilizing various typographical devices, the symbols are simplified so that the symbols of their minute accuracy, are often simpler than in the corresponding Roman notation. The simplicity of the system is shown by the fact that it requires only about 110 types, as compared with the 280 of Lepsius's very imperfect Standard Alphabet.

All the systems hitherto considered are also alphabetic in a wider sense: they are intended for continuous writing, the more cumbrous "narrow" notations being, however, generally employed only in writing single words or short groups. An "alphabetic" basis was first definitely advocated by Jespersen, who represents each sound by a group of symbols resembling a chemical formula, each symbol representing not a sound, but an element of a sound: the part of the palate, tongue, &c., where the sound is formed, the degree of separation (openness) of the organs of speech, and so on. The two great advantages of such a system are that it allows perfect freedom in selecting and combining the elements and that it can be built up on the foundation of a small number of generally accessible signs.

As regards Jespersen's scheme, it is to be regretted that he has not worked it out in a more practical manner: that in his choice of the thirty odd symbols that he requires he should have gone out of his way to mix up Greek with Roman letters, together with other characters which would be avoided by any one constructing even a scientific alphabetic notation. And his use of these symbols is open to much criticism. In fact, it cannot be said that the alphabetic principle has yet had a fair trial.

The Organs of Speech.—Most speech-sounds are formed with air expelled from the lungs (voice-bellows), which passes through the two contractible bronchi or bronchial tubes into the also contractible wind-pipe or trachea, on the top of which is fixed the larynx (voice-box). Across the interior of the larynx are stretched two elastic ledges or cushions called "the vocal chords." They are inserted in front of the larynx at one end, and at the other they are fixed to two movable cartilaginous bodies "the arytoids," so that the passage between them—the glottis—can be narrowed or closed at pleasure. The glottis is, as we see, twofold: consisting of the chord glottis and the cartilage glottis. The two can be narrowed or closed independently. The chords can also be tightened or relaxed, lengthened and shortened in various degrees.

When the whole glottis is wide open, no sound is produced by the outgoing breath except that caused by the friction of the air. Sounds in whose formation the glottis is in this passive state are called "breath" sounds. Thus (/) is the breath consonant corresponding to the "voice" or "voiced" consonant (v). In the production of voice, the chords are brought close enough together to be set in vibration by the air passing between them. In the "thin" register of the voice (chest voice) the chords vibrate in their whole length, in the "thick" register or falsetto only in part of their length. If the glottis is narrowed without vibration, "whisper" is the result. In the "weak whisper" there is narrowing the whole glottis; in the "strong whisper," which is the ordinary form, the chord glottis is entirely closed, so that the breath passes only through the cartilage glottis. In what is popularly called "whisper" that is, speaking without voice—the breath sounds remain unchanged, while voiced sounds substitute whisper (in the phonetic sense) for voice. Thus in whispering such a word as feel the (/) remains unchanged, while the following vowel and consonant are formed with the glottis in half closed. Whispered sounds—both vowels and consonants—are called "whispered" or "inarticulate" sounds, or "amphitheatres," or "enclitic" and are used in many loud speech in many languages. Thus the final consonants in such English words as leaves, oblique are whispered, except when followed without a pause by a voiced sound, as in obliging, where the (3) is fully voiced.

Above the glottis—still within the larynx—comes the "upper" or "false" glottis, by which the passage can be narrowed. On the top of the larynx is fixed a leaf-like body, the "epiglottis," which in swallowing, and sometimes in speech, is pressed down over the opening of the larynx. The contractible cavity between the larynx and the mouth is called the "pharynx." The roof of the pharynx consists of the "soft," and the "hard palate." The lower pendulous elasticity of the soft palate, the "uvula," in its passive state leaves the passage into the nose open. In the formation of non-nasal sounds, such as (b), the uvula is pressed up so as to close the passage from the pharynx into the nose. If (b) is formed with the passage open, it becomes the corresponding nasal consonant (m). The other extremity of the (hard) palate is bounded by the teeth, behind which are the gums, extending from the teeth-rim to the arch-rim—the projection of the teeth-roots or alveolars.

There is great diversity among phoneticians as regards the mapping out—the divisions—of the palate and tongue, and their names. Foreign phoneticians generally adopt very minute distinctions, to which they give Latin names. Bell in his Visible Speech makes a few broad fundamental divisions. In the arrangement adopted here (mainly based on his) sounds formed on the soft palate are called "back," and are subdivided into "inner" nearer the throat, and "outer" nearer the teeth, further subdivisions being made by the terms "innermost," "outermost," the position exactly half way between these two last being defined as "intermediate back." Sounds formed on the hard palate or teeth may be included under the common term "forward," more accurately distinguished as "teeth" (dental), "gum," "front" (palatal, afterwards called "top" by Bell), which last is really equivalent to "mid-palatal," including the whole of the hard palate behind the gums. All of these divisions are further subdivided into "inner," &c., as with the back positions.

Of the tongue we distinguish the "back" (root), "front" or middle, "point" (tip), and "blade," which includes the point and the surface of the tongue immediately behind it. The tongue can also articulate against the lips, which, again, can articulate against the teeth. The lip passage can be closed, or narrowed in various degrees. Sounds modified by lip-narrowing are called "lip-modified" (labialized) or "round" (rounded), the last being specially used in speaking of vowels.

Speech-sounds.—The most general test of a simple as opposed to a compound sound (sound-group) is that it can be lengthened without change. As regards place of articulation, no sound is really simple: every sound is the result of the shape of the whole configurative passage from the lungs to the lips; and the ultimate sound-elements, such as voice, are never heard isolated. The most indistinct voice-murmur is as much the result of the shape of the superglottal passages as the clearest and most distinct of the other vowels; and its organic formation is as definite as theirs is, the only difference being that while in what we regard as unmodified voice all the organs except the vocal chords are in their passive, neutral positions, the other vowels are formed by actively modifying the shape of the super- glottal passages—by raising the tongue towards the palate, narrowing the lips, &c.

The most important elements of speech-sounds are those which are dependent on the shape of the glottis and of the mouth passage respectively. It is on the relation between these two factors that one of the oldest distinctions between sounds is based: that of vowel and consonant. In vowels the element of voice is the predominant one: a vowel is voice modified by the different shapes of the superglottal passages. In consonants, on the other hand, the state of the glottis is only secondary.
Consonants are generally the result of audible friction, as in (f), or of complete stoppage, as in (p). If the glottis is at the same time left open, as in (i, p), the consonant is " breath " or " voiceless "—if it is narrowed enough to make the chords vibrate, as in (v, b), the consonant is " voice " or " voiced "; intermediate positions producing the corresponding " whispered " consonants. Vowels are characterized negatively by the absence of audible friction or stoppage: if an (i) is formed with the tongue so close to the palate as to cause buzzing, it becomes a variety of the front consonant (j). There is, of course, no difficulty in forming a vowel with the glottis in the position for breath and whisper. Thus breath (i) may often be heard in French in such words as ainsì at the end of a sentence, the result being practically a weak form of the front-breath consonant (g). The division between vowel and consonant is not an absolutely definite one. As we see, the closer a vowel is—that is, the narrower its configurative passage is—the more like it is to a consonant, and the more natural it is to devocalize it. Some voice consonants, on the other hand, have so little buzz that acoustically they constitute a class between consonants and vowels—a class of " vowel-like " or " liquid " consonants, such as n, m, l.

The changes in sounds which result from active narrowing of the passage admission of an important distinction as " sound-modifying ", and " sound-colouring," although the distinction is not always definite. Nasality and rounding are examples of sound-modifying processes. Thus we hear a certain resemblance between (b) and (m), (i) and (y), but we regard all these four as distinct and practically independent sounds. Contraction of the pharynx, on the other hand, as also of the false glottis and windpipe, have only a sound-colouring effect: if a vowel is formed with such contractions its quality (timbre) is altered, but it still remains the same vowel. It follows from the definition of speech-sounds that they admit of a twofold classification: (1) organic and (2) acoustic. As already remarked, the older phoneticians used to classify the consonants organically, the vowels mainly from the acoustic point of view. The first to give an adequate organic classification of the vowels was the author of Visible Speech. Bell gave at the same time an independent acoustic classification of the consonants as well as the vowels. His acoustic classification consists simply in arranging the sounds in the order of their " pitches " (tone-heights). The pitches of the breath consonants are absolutely fixed in each individual pronunciation, while those of spoken vowels can be varied indefinitely within the compass of each voice by tightening the vocal chords in various ways and shortening their vibrating portions: the tighter and shorter the vibrating body, the quicker its vibrations, and the higher the tone. But when a vowel is whispered or breathed nothing is heard but the consonant sound. These perceptual differences, especially in the mouth, and the pitches of these resonant cavities are as fixed as those of the breath consonants; in other words, a whispered (or breathed) vowel cannot be sung. Although the absolute pitches of voiceless sounds may vary from individual to individual the relations of the pitches are constant: thus in all pronunciations (o) and (i) are the highest, breath (w) in what and whispered (u) nearly the lowest in pitch among consonants and vowels respectively.

If phonetics were an ideally perfect science there would be no occasion to discuss whether the acoustic or the organic study of the vowels and the other speech-sounds is the more important: a full description of each sound would necessarily imply (1) an exact determination of its organic formation, (2) an acoustic analysis of the sound itself, both from the objective physical point of view and from the subjective one of the impression received by the ear, and (3) an explanation of how (2) is the necessary result of (1). Even this last question has already been solved to some extent. In fact, the connection between the organic formation and the acoustic effect is often self-evident. It is evident, for instance, that (i) and (o) owe their clear sound and high pitch to their being formed by short, narrow passages in the front of the mouth, while (u) owes its low pitch to being formed in exactly the opposite way, the sound being further muffled and the pitch consequently still more lowered by the rounding.

One reason why it is impossible to classify the vowels exclusively on acoustic principles is that two vowels formed in quite different ways may have the same pitch. Thus the " high-front-round " (y) and the " high-mixed " (i) have the same pitch, the tongue-retraction of the mixed position of the latter having the same effect as the rounding of the former. It is evident, therefore, that the fundamental classification of the vowels must, like that of the consonants, be purely organic. And although for practical purposes it is often convenient to divide the vowels and consonants from the acoustic point of view, all scientific treatment must keep the two points of view strictly apart, and make a special chapter of the relations between them.

Vowels. The most obvious distinction between vowels is that which depends on the share of the lips in their articulation. In such non-round vowels as (i) and (u) the lips are passive, or even separated and spread out at their corners, by which the vowels acquire a clearer resonance. If, on the other hand, the lips are actively approximated, they become the round vowels (y) and " open " (o) respectively.

Vowels are formed with different degrees of rounding. As a general rule, the narrowness of the lip-passage corresponds to the narrowness of the mouth-passage. Thus, in passing from the vowel of low to those of no and saw the back of the tongue is progressively lowered, and the rounding is diminishing in the same proportion. But there is also abnormal rounding. Thus, if we pronounce (o) with the lips in the position they have in forming (u), the vowel sounds half-wide (o) and (u); the second element of the diphthong (ou) in go is formed in this way. Conversely, the (u) in put is "under-rounded " in the North of England, in the tongue position is kept, but the lips are only brought together a little at the corners, as in (u).

The mouth positions of the vowels are the result of two factors: (1) the height of the tongue—its nearness to the palate—and (2) the degree of its retraction. Bell distinguishes three degrees of height; in his system (u) is " high," the (o) of boy is " mid," and the (y) of saw is " low." He also has three degrees of retraction: in " back " vowels, such as (u), the root of the tongue is drawn down from the top of the tongue position, but in " front " vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from back to front. In " front " vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back.

Most of these slope-positions yield vowels of a distinct and clear resonance. There is also a class of " flat " vowels, such as (e), in which the tongue is in a more or less neutral position. If the tongue is raised from the low-flat position of (o) in bird to the degree of its retraction, Bell distinguishes three degrees of height; in his system (u) is " high," (o) is " mid," and (y) is " low." He also has three degrees of retraction: in " back " vowels, such as (u), the root of the tongue is drawn down from the top of the tongue position, but in " front " vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back. In " front " vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from back to front.

In this arrangement " high-back," etc., are fixed points like those of latitude and longitude. Thus normal " high " means that the tongue is raised as close to the palate as is possible without causing constriction of the passage, and " back " implies retraction of the same kind. Intermediate positions are defined as " raised," " lowered," " inner," " outer." The most original and at the same time the most disputed part of Bell's vowel-scheme is his distinction of " primary " and " wide." All vowels fall under one of these categories. Thus, the primary French (i) and the corresponding English wide (e) are both high-front-vowels, and (i) and (e) are distinct in sound: the English vowel is a semitone lower in pitch. Bell explained the greater openness of the wide vowels as the result of greater expansion of the pharynx; and he considered the other class to be most nearly the original French vowels. The correspondence of these vowel-soundings and voice-sounds in the formation of primary vowels being expanded only so far as to remove all fricative quality, but alterations in the shape of the pharynx have only a sound-colouring, not a sound-changing, effect. Bell explained the different openness of the narrow French (u) in sou, while the English (w) preserves the wide quality of the (u) in put.

In forming narrow sounds there is a feeling of tension in that
part of the tongue where the sound is formed, the tongue being clenched or lunched up lengthwise, so as to be more convex than in its relaxed or "wide" condition.

The distinction between narrow and wide can often be ignored in practice, for it generally depends on quantity: length and narrowness, shortness and wideness going together. When the distinction is marked, wide vowels may be expressed by italics, as in German; and a variety of "mixed-round" vowels had from the beginning been a source of difficulty to students of Visible Speech. But it was not till 1901 that Sweet showed that they are only mixed as regards backness; that there are really two back vowels, the back vowels moved forward into the middle of the mouth while preserving the slope of back vowels, instead of having the tongue flat as in the (unround) mixed vowels. They are "out-back" vowels and are formed by the tongue being raised back, to a back-rounded vowel as the English (u) compared with the full back (u) in German mutter.

In the same way by moving the tongue backwards while forming a front vowel another series of "in-front" vowels is obtained.

There are a large number of other vowel-schemes, of which a survey will be found in W. Victor’s Elemente der Phonistik. Many of the older ones are in the form of triangles, with the three vowels a, i, u at the three corners, the other vowels being inserted between these and forming appropriate "borders"; it is the appearance of Visible Speech many attempts have been made to fix his new vowels into these older schemes.

Of all the vowel-schemes the one most generally known is probably that of the International Phonetic Association already mentioned. In this scheme the distinction of narrow and wide, though admitted and occasionally marked, is not an integral part of the system, the vowels being classified first as "velar" (back) and "palatal" (front), and then according to openness as "close", "half-close", "medium", "half-open" and "open".

Consonants.—These are the result of audible friction or stoppage, where the point of contact is either a part of the tongue or of the palate.

Consonants admit of a two-fold division (1) by form, and (2) by place. Thus (p, b) are by place lip-consonants, while by form they are stopped consonants or stops.

If a sound is formed by friction and the passage is kept open, the stop becomes the corresponding "nasal"; thus (b) with the soft palate lowered becomes the nasal (m).

In "open" consonants the sound is formed by simply narrowing the passage, as in the back-open-breath (x) in Scotch and German loch. In some open consonants, such as the lip-teeth (t), there is slight contact of the organs, but without impeding the flow of breath.

In "divided" consonants there is central stoppage with openings at the sides, as in the familiar point-divided (l). These consonants are sometimes unilateral,—with the opening on the side only of the character of the sound not being sensibly modified thereby.

When open and divided consonants are formed, the lip-passage open they are said to be "naiized." Thus (m) with incomplete lip-closure becomes the nasalized lip-open-voice consonant.

"Trills" (or rolled) consonants are a special variety of un-stopped consonants resulting from the vibration of flexible parts against one another, as when the lips are trickled, or against some firm surface, as when the point of the tongue trills against the gums in the Scotch (r), or the uvula against the back of the tongue, as in the Northumbrian spurred (t), and the French and Germain (r), where—especially in German—the trill is often reduced to a minimum or suppressed altogether.

As regards the place of consonants, there is, as already remarked, great difficulty in inserting the concept of the tongue in its morphological position, and tongue and in the names given to these divisions. The classification and nomenclature given here is, in the main, that of Bell.

By place, then, we distinguish seven main classes of consonants: back—(or palatal), lip, lip-velar, palatal, and front—(or dental).

"Back" (guttural) consonants are formed between the root of the tongue and the soft palate. In most languages the positions of these consonants vary according to those of the accompanying vowels, the back of the tongue being more forward than in conquer.

Front—(palatal) consonants are formed between the middle of the tongue and hard palate, the point of the tongue lying passively behind the front teeth. To make the front-open-voice (j) in you into the corresponding stop (j) by narrowing the passage till there is complete closure, as in Hungarian nagy (n), to English say (s), is called a "knee-down breath." In German ich may be made into the stop (g) = Hungarians ý. (j) nasalized becomes (h)—Italian gh, Spanish ñ, French gn in vague. The front-divided-voice consonant is the Italian gi and Spanish ñ.

All simple sounds, distinct from the (l), (n) in French and English million and English onion.

"Point" consonants when formed against the teeth are called "points." (dents) in English, and the back-open-breath consonant, (8) in then the corresponding voice consonant. If (b) is modified by turning the tip of the tongue back into the inner position—about on the arch—-it becomes the "backward " (dents) in English, but if it is more easily trilled, the trilling becoming more and more difficult the more the tongue is approximated to the point-teeth position. In French and many other languages all the point consonants (i.e., the back-open-breath, except (s), which is always more retracted than the other point consonants. If the tip of the tongue is turned so far back as to articulate with its lower edge against the arch of the palate, that is, farther back than for the corresponding voice consonants—a sound is said to be a "back (dents)" frequent in the dialects of the south-west of England. The opposite of inversion in "protrusion," in which the tip of the tongue is moved away from the palate.

"Blade" consonants are formed by the blade or flattened tip of the tongue against the gums, as in English (s, z), or against the teeth, as in the corresponding French sounds. If these consonants are modified by turning the tongue a little back, so as to bring the point more into play, they become the "blade-point" consonants (j, f), as in fish, measure. (j) is acoustically a dull (s). In some languages, such as German, sounds similar to (f) and (j) are formed by the articulation which lowers the point of the hiss in the same way as retraction does, so that the tongue-articulation is only imperfectly carried out. When the rounding is very small there is only a slight raising of the front of the tongue, as in some Yugoslavian dialects. If (f) and (j) are modified by being shifted back, and the rounding diminished in the same proportion, (j) can at last develop into the pure back-open consonant (k), as in English pronouns, or by the same process as (f), into (t).

The English point consonants (t, d, n, l) are formed on the gums just behind the teeth, the point of the tongue being flattened, so that they are almost blade consonants.

"Fan" (spread) consonant the "emphatic" consonants of Arabic—are modifications of point and blade consonants, in which the sides of the tongue are spread out, so that the hss of such a consonant as (s) is formed partly between the sides of the tongue and the back teeth, which gives a peculiar deep, dull quality to these sounds.

"Lip" consonants, such as (p, m), and "lip-teeth" consonants, such as (b, v), offer no difficulty. The simple lip-open-breath (b, v) produces not sound in English; it is the sound produced in blowing out a candle. The corresponding voice sound is frequent in German,—especially in Middle Germany,—in such words as quiet.

If the lip-open consonants are modified by raising the back of the tongue, they become the "lip-back" consonants (wh, w) in English what, see, which may also be regarded as consonantized (a). In German the lip articulation is "back-lip consonants, as in German ach, the reverse is the case.

This last is one of a large number of "lip-modified" consonants, of which the already-mentioned German ich is a further example.

In many other languages it is formed with the tongue more convex than in English, and consequently with a tendency to front-modification. Front-open breast and point consonants have been called, in German, as gus "goose," tsar "emperor," where the final vowels are silent. Some consonants are formed below the mouth.

When the glottis is sharply opened or closed on a passage of breath or voice, the effect is produced similar to that of a stop in the mouth, such as (k). This "glottal stop" is the sound produced in hiccuping; and is an independent sound in some languages, such as Arabic, where it is called "hamza." In German all words beginning with a stressed (accented) vowel have a more or less distinct glottal stop before the vowel.

Of the passages below the glottis, the bronchial and the wind-pipe passages are not considered here.

Spasmodic transmission of the bronchial passages is the main factor in producing what is known as the "asthmatic wheeze." If this condensation is regulated and made voluntary it results in the deep hiss of the Arabic ash. If this sound is voiced, it causes a peculiar intermittent vibration of voice, which is habitual with some speakers, especially in Germany. If this effect is softened by slightly expanding the bronchial passages, an (r)-like sound is produced which is called the "Arabic r." While the production of a sound similar to the Arabic d, but weaker, which when followed by a vowel has the effect of a strong aspirate. When voiced it becomes a more coloured sound forming voiceless murmurs, or vores, to which it is the deep treble.

Non-explosive Sounds.—All the sounds hitherto described imply out-breathing or inspiration. Many of the other sounds are connected with in-breathing or inspiration. In English it is a not uncommon trick of speech to pronounce o in this manner, to express emphatic denial.

PHONETICS
Some consonants are formed without either in- or out-breathing, but solely with the air in the throat or mouth. In forming "suction-stops" or "clicks," the tongue or lips are put in the position for a stop, then released without out-breathing or out-flow of the organically conditioned air, so that when the stop is loosened, a smacking sound is produced by the air rushing in to fill the vacuous. Thus the point-click is the interjection of impatience commonly written // in many savages, and a sign of a particular speech.

**Synthesis.**—Besides analysing each sound separately, phonetics has to deal with the phenomena which accompany synthesis or the combination of sounds. Although a sentence may consist of a single word, and that word of a single vowel, sounds mostly occur only in combination with one another. The ordinary division into sentences and words is logical, not phonetic: we cannot mark off sentences and cut them up into words until we know what they mean and are able to analyse them grammatically. But the logical division into sentences corresponds to some extent with the phonetic division into "breath-groups," marked off by our inability to utter more than a certain number of syllables in succession without pausing to take breath. Within each of these breath-groups there is no necessary pause between the words, except when we pause for emphasis. The only necessary phonetic divisions within the breath-group are those into syllables, sounds and intervening "glides." But before considering these last it will be necessary to say something about the general factors of synthesis: quantity, stress and intonation.

As regards *quantity*, it is enough for ordinary purposes to distinguish between full, half and voiceless consonants. If a full consonant is pronounced in English, what are called long vowels keep their full length when stressed and before final voice consonants, as in see, broad: and become half-long before voiceless consonants, as in cease, brought. In half-long, the full length is preserved alike before all classes of consonants. The Romance languages have short first stressed vowels, as in French zi. Unstressed vowels tend to become short in most languages. The distinctions of quantity apply to consonants as well as vowels. Thus English tends to distinguish consonants after short stressed vowels, as in man compared with German mann, where the final consonant is quite short. Consonants, like vowels, tend to become short when unstressed. But in some languages, such as Spanish, stress has no effect on quantity, so that in these languages long vowels and double consonants occur as frequently in unstressed as in stressed syllables. Even in English we often lengthen final unstressed vowels in exclamations, as in *what a pity!* Some languages, such as the Romance languages and Russian, tend to level the distinctions of vowel-quantity: most of their vowels are half-long.

As regards *stress*, the respiratory force with which the breath is expelled from the lungs; while acoustically it produces the effect of loudness, which is dependent on the size of the sound-vibrations: the bigger the waves, the louder the sound, and the greater the stress of which we may distinguish infinite degrees. If we distinguish only three, they are called *weak, medium* and *strong.* The use of stress in different languages shows the same variety as quantity. Some languages, such as French, make comparatively little use of stress, using all kinds of words and sentences with a more or less even degree of force. English, on the other hand, makes great use of minute distinctions of stress both to distinguish the meanings of words and to mark their relations in sentences. With stress is closely connected the question of *syllable-division.* A syllable is a group of sounds containing a "syllabic" or syllable-forming vowel which is, of course, capable of sounding as a syllable by itself. The distinction between syllables and non-syllables depends on sonority, the more sonorous sounds being the voiceless ones, while of these again, the most open are the most sonorous, the most sonorous vowels being the glide, while the vowels, as a class, are the most sonorous. But these differences are only relative. When a vowel and a consonant come together the sonoroussness of the vowel always overpowers that of the consonant, so that the two are to be considered as forming into one syllable, just as in *the* (t) is more sonorous than the accompanying voiceless stop that it assumes syllabic function, and the whole group becomes dissyllabic to the ear. The beginning of a syllable corresponds to the beginning of an impulse of the voice or of the glottis being uttered. Thus in *a tone* the strong stress and the second syllable begin on the (t), and in *bookcase* the second (k), the first (k) belonging to the first syllable, so that the (k) is here double, not mere "nasalization" (nn) by "weak" (ku).

**Intonation** or variation of tone (pitch) depends on the rapidity of the sound-vibrations; the more rapid the vibrations, the higher the pitch. Intonation is heard only in voiced sounds, as being the only ones capable of variations of pitch. In singing the voice generally dwells on each note without change of pitch, and then leaps up or down to the next note as quickly as possible, so that the intervening "glide" is not noticed—except in what is called portamento. In speaking, on the other hand, the voice hardly ever dwells on any one note, but is constantly gliding up in the "breath-groups," and downwards or downwards and backwards in that an absolutely level tone hardly ever occurs in speech. But the right kind of pitch or intonation we can distinguish between "voice-glaides" (portaments or slurs) and "voice-leaps," although the distinction is not so definite as in music.

Of the three primary forms of intonation the level tone (,) can be approximately heard in as an expression of musing—although it really ends with a slight rise; the rising (') in the question *well?* (How?) and the level (,) in the word *nothing* are formed by uniting the two last in one syllable. The compound rising tone (') may be heard in *take care* the compound falling tone (,) in the sarcastic *oh!* All these tones may be varied according to the position through which they pass. The greater the velocity with which they approach the height, the more emphatic the tone. Thus a high rise, which begins high, and consequently can only raise a little higher, expresses simple question, while the same word, if uttered with a low rise extending over an interval of between a fifth and an octave—or even more—expresses various degrees of surprise or indignation, as in the emphatic *what?* compared with the simply interrogative *what?*

In English and most European languages intonation serves to modify the general meaning and character of sentences. This is *sentence-intonation.* But some languages, such as Swedish and Norwegian, and Chinese have *word-intonation,* by which words which would otherwise be identical in sound are distinguished. The distinction between Gr. oški and oškoi was no doubt one of intonation.

**Glides.**—Such a word as *cat* consists not only of the vowel and the two consonants of which it is made up, but also of a number of transitions between these sounds. The glide from the initial consonant of the word *cat* to the vowel consists of all the intermediate positions through which the tongue passes on its way from the (k)-position to the (ae)-position. The number of these positions is infinite, but they are all implied by the mere *juxta-position* of the symbols, for it is assumed that in all transitions from one position to another the shortest way is taken. Although the direction of a glide is independent of the positions of the two fixed points between which it lies, its character may be varied both by the shape of the configurative passages—especially the glottis—and by stress and quantity.

In the word given above the "off-glides" from the consonants and from the breath-voyelles, the glottis being kept open during the transition from the voiceless consonant to the following vowel, or, as in the case of the final consonant, to silence. The *on-glide* from the vowel to the (t) is, on the other hand, a voice-glide, the closure of the glottis being maintained till the stop is made.

In French and most of the languages of the south of Europe voiceless consonants are followed by voice-glides. Thus in *French qui* there is no escape of breath after the (k), as there is in English *Key.* Other languages again have breath on-glides before voiceless stops.

If an independent strong stress is put on the breath-glide of English *Key,* it is heard almost as a full independent consonant, and becomes an "aspirate." Aspirated steps may be heard in the Irish-English pronunciation of such words as *tell,* and also in Danish, and in Sanskrit as pronounced in India. If the voice-glade after a voice stop is emphasized in a similar way the *sonant aspirates* of Sanskrit and its modern descendants are produced, as in Sanskrit *dhau.*

Glides are especially important from an acoustic point of view. Acoustically speaking, indeed, voiceless stops are pure glidesounds, the stop itself being inaudible. In voice-stops, on the other hand, the stop itself can be made audible as well as the intervening glides. In English these latter are fully voiced when they come between voice sounds, as in age; but when preceded by voiceless sounds or by a pause, as in get they are formed with imperfect vocality, full voice being heard only just before the stop is loosened. So also initial English (z) as in zeal is formed with imperfect vocality under the same conditions, so that it sounds like (z). In French and other languages which have voice-glides after voiceless consonants initial (g z) &c. are fully voiced.

Consonant-glides may be further modified in various ways. In the formation of "implosive" stops, such as occur in Saxon German, Armenian and other languages, voiceless stops followed
by voice-glides are modified by simultaneous closure of the glottis, the larynx being raised by means of its muscles, so that it acts like a plug, thuspressing the air between the closed glottis and the mouth-stop, so that when the latter is released a peculiar choky effect is given to the off-glide.

Rounded glides may be heard in Russian in such words as komnata, where the rounding of the (o) is anticipated in the preceding consonant, being heard, of course, only in the off-glide of the consonant. The acoustic effect is between that of (kwo) and ordinary (ko).

Glideless consonant-combinations remain to be considered. The general articulative principle of taking the shortest way between sounds in juxtaposition necessarily results in certain transitions being effected without any glide at all. This is regular in the consonants of the same place and differ only in form, as in (nd, dlt), where the point of the tongue remains un mouved through the whole sound-group. In such combinations as (ml) the very slight glide is often got rid of entirely by assimilating the place of the first consonant to that of the second, so that the (m) becomes a lip teeth consonant, as in English nymph.

Even when consonants are formed in different parts of the mouth it is often possible to join them without any glide. In English such combinations as (kt, pt) are glideless, the point of the tongue being brought into position before the preceding stop is loosened. In French and most other languages such combinations are produced by a breathy effect.

Combinations of stops and vowel-like consonants (tr, gl, kw) are glideless in English and most other languages. In English the breath glide after a voiceless stop unvoices the beginning of the following vowel-like consonant; thus try is almost (trh-

Vowel-glides.—Vowels are begun and ended in various ways. In the "gradual beginning," which is the usual one in English, the vowel begins by a gradual raising of the tongue, which is finally made to an acute end by the lip being raised. There are other "passive" vowel-positions, such as the "aspirate" or (a), in which English and most other languages have a glide only in the throat but in the mouth as well, the tongue and lips gradually moving up into the position for the following vowel while the glottis is being closed. There is also a "strong" aspirate, which occurs in Finnish and other languages, in the formation of which the full vowel-position is assumed from the beginning of the aspiration, which is therefore a vowel sound.

In many languages, when an aspirate comes between voiced sounds it is formed with imperfect vocality, the contrast of which with the full vowel-positions is considerable, and produces the effect of breath. Thus in English behold the voice runs on without any actual break, the glottal closing being simply relaxed, not fully opened for breath, as in the emphatic ada! In some languages, such as Bohemian, this "aspirate" is used everywhere, initially as well as medially.

Vowels are finished analogously, either by a gradual opening of the glottis, or by a cessation of aspiration while the glottis is still closed for vowel. If stop is in the glottal ending it becomes a distinct aspirate, as in the Sanskrit "visarga" in such a word as manab.

Organic Basis.—Every language has certain general tendencies which control the formation of its sounds, constituting its "organic basis" or basis of articulation. The tendency of the lips in English is to get ballot and lower the tongue and draw it back from the teeth, while the lips are kept as much as possible in a neutral position. The flattening of the tongue makes our vowels wide and favours the development of mixed vowels, and gives the dull quality which is especially noticeable in our (l) and its retraction is unfavourable to development of teeth sounds; while the neutrality of the lips eliminates front-round vowels. In such a language as French everything is reversed. The tongue is arched, and raised, and advanced, and the lips articulate with energy. Hence French sounds tend to narrowness, dentality and distinct rounding.

National Sound-systems.—Each language uses only a part of the general phonetic material. Each one has only a limited number of sounds; and each one makes only a limited use of the synthetic distinctions of quantity, stress and intonation. As we have seen, many of these differences between individual languages are the result of, or may be referred to, differences in their organic basis.

Just as cognate languages differ from each other in phonetic structure, so also dialects of the same languages differ from each other more or less. Thus the sound-system of Lowland Scot—

which is, historically, a dialect of Northern English—differs considerably from that of standard English. Standard English itself was originally that mixture of the Midland and the Southern dialect which was spoken in London in the middle ages, just as standard French is, historically, the dialect of that district which was spoken in Paris. Like standard English, it is now more a class-dialect than a local dialect, and is the language of the educated all over Great Britain. But it is not yet perfectly uniform. It is still liable to be influenced by the local dialects in grammar and vocabulary, and still more in pronunciation.

Again, English, like all other living languages, changes from generation to generation. Pronunciations which are vulgar in one century may become fashionable in the next. Sounds which are distinct in one generation may be confounded in another, and new distinctions may be made, new sounds may arise. A spoken language is, therefore, necessarily a vague and fluctuating entity, and there is no exception to the rule. The very finity of its written form gives all the freer play to the influences which cause change.

A standard spoken language is, strictly speaking, an abstraction. No two speakers of standard English pronounce exactly alike. And yet they all have something in common in every sound they utter. There are some diversifications, some peculiarities of pronunciation, which pass unnoticed, while others, less considerable perhaps in themselves, are at once felt as archaisms, vulgarisms or provincialisms, as the case may be, by the majority of educated speakers.

Sounds of English.—The following is a convenient classification of the vowels of standard English—

<table>
<thead>
<tr>
<th>Vowel</th>
<th>Pronunciation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Long, open, wide</td>
<td>as in cat</td>
</tr>
<tr>
<td>e/i</td>
<td>Short, open, wide</td>
<td>as in bet</td>
</tr>
<tr>
<td>o/u</td>
<td>Short, round</td>
<td>as in out</td>
</tr>
<tr>
<td>ə</td>
<td>Short, unrounded</td>
<td>as in can</td>
</tr>
</tbody>
</table>

Here the vowels are in four rows: (1) normally short, or, more correctly, monophongic, (2) long, or half-diphongic, (3) full diphongic, (4) murmur-diphongic.

In (1) the (a) is commonly monophongic in monosyllables such as ten, good, but they always remain absolutely monophongic. The only one in the next row that is always strictly monophongic is (aa); all the others, as we shall see, tend to become more or less diphongic, especially in educated English, being often exaggerated into full diphongics of the (ai) and (au)-type in vulgar speech.

(a), as in come up, is the short vowel corresponding to the (aa) in calm. (aa) is the mid-back-wide vowel, and (a) differs from it only in being narrow. Acoustically, (a) is a muffled or obscure (aa); and the same effect may be produced by advancing the tongue from the mid-back to the corresponding out-back position, preserving the wide articulation; this pronunciation of (a) is common in the south of England. Historically, these sounds are the result of unrounding and older (u).

(o), as in sofa, is a mixed vowel, tending to width and mid position which occurs only unstressed. (oo) in turn, earth, is low-mixed-narrow. It is the result of absorption of an older (r), weakened into (o).

(e), as in man, is low-front-wide, from older mid-back-wide.

(i) in is is high-front-wide. The long (ii) in eat is narrow in the north of England, while in the south it is wide (i) followed by (i).

(e) in men is generally mid-front-wide, (ei) in mane is the same vowel either narrow or wide, raised in its latter half towards (i).

(u) in good is high-back-wide-round. Narrow (u) in too becomes (wv) in southern English.

(o) in not is low-back-wide-round. In (ou), as in no, the mid-back-vowel, either narrow or wide, is over-rounded in its latter half. (o), as in all, is low-back-narrow-round.

The full diphongs (ai, au, ao), as in eye, now, oil, all end in lowered high vowels. Their first elements are only roughly indicated by the transcription, and vary in the mouths of different speakers. That of (ai) is generally the out-mid-back-wide, that of (oi) the broader low-mixed-wide, that of (ao) the mid-back-wide.

The murmur-diphongs (ia) as in here, (ea) as in air, (ua) as in
poor, all tend to broaden their first elements. That of (o) is the low-front-narrow vowel. The other two begin with lowered forms of the wide (i) and (u) respectively. In (ua) the lowering is often carried so far as to make poor almost, or completely, into pore (prae).

The following arrangement of the English consonants will show their organic relations to one another:

\[
\begin{align*}
& j \quad r \quad b \quad s \quad z \quad s; \quad j \quad 3 \quad w \quad h \quad f \quad v \\
& l \quad k \quad g \quad d \quad t \quad p \quad b
\end{align*}
\]

The "aspirate" (h) may be regarded either as a throat-consonant or as a glide.

Characteristic features of the English consonant-system are the large number of hisses and buzzes, the sharp distinction of breath and voice, and, negatively, the absence of the open-back consonants, and of the backness of the voiceless consonants (l, r) and the nasals, most of which still existed in Old English.

**Phonograph** (Gr. φωνή, sound, γράφειν, to write), an instrument for imprinting the vibrations of sound on a moving surface of tinfoil or wax in such a form that the original sounds can be faithfully reproduced by certain mechanical means. Attempts had been made by earlier experimenters to obtain tracings of the vibrations of bodies emitting sound, such as tuning-forks, membranes, and glass or metallic disks. In 1807 Thomas Young (Lectures, i. 19) described a method of recording the vibrations of a tuning-fork on the surface of a drum; his method was first carried out by Wilhelm Wertheim in 1842 (Recherches sur l'élasticité, 1st ed., 1842). Recording the vibrations of a membrane was first accomplished by Leon Scott in 1857 by the invention of the "phonograph," which may be regarded as the precursor of the phonograph (Comptes rendus, 53, p. 108). This instrument consisted of a thin membrane to which a delicate lever was attached. The membrane was stretched over the narrow end of an irregularly shaped funnel or drum, while the end of the funnel was filled with lampblack, thus, the surface of a cylinder covered with paper on which soot had been deposited from a flame of turpentine or camphor. The cylinder was fixed on a fine screw moving horizontally when the cylinder was rotated. The marker thus described a spiral line on the blackened surface. When sounds were transmitted to the membrane and the cylinder was rotated the oscillations of the marker were recorded. These tracings of vibrations were obtained. This instrument was much improved by Karl Rudolph König, of Paris, who also made with it many valuable observations. (See Nature, Dec 25, 1891, p. 184.) The mechanism of the recording lever or marker was improved by William Henry Barlow, in 1874, in an instrument called by him the "legerographic" (Tracts. Roy. Soc. Edinb., 1874). The next step was König's invention of manometric flames by which the oscillations of a thin membrane under sound-pressure acted on a small reservoir of gas connected with a flame, and the oscillations were viewed in a rotating rectangular mirror, according to a method devised by Charles Wheatstone. Thus flame-pictures of the vibrations of sound were obtained (Pogg. Ann., 1861, cxixii. 242, 66; see also Quelques expériences d'acoustique, Paris, 1882). Clarence Blake in 1876 employed the drumhead of the human ear as a logograph, and thus obtained tracings similar to those made by artificial membranes and disks (Archiv füür Öphälmol., 1876, v. 1). In the same year Sigmund Theodor Stein photographed the vibrations of tuning-forks, violin strings, &c. (Pogg. Ann., 1876, p. 142). Thus from Thomas Young downwards successful efforts had been made to record graphically moving surfaces the vibrations of sounds, but the sounds so recorded could not be reproduced. This was accomplished by T. A. Edison in 1876, the first patent being dated January 1877.

In the first phonograph a spiral groove was cut on a brass drum fixed on a horizontal screw, so that when the drum was rotated the stylus, fixed to the right end of a long lever, caused a change in the value of the various consonants (l, r) and the nasals, most of which still existed in Old English.
the wax cylinder is rotating, the point of the marker is angled downwards, and this cuts deeply into the wax; and when there is diminution of pressure the point is angled upwards, so as to act less deeply. In reproducing the sound, the blunt end of the marker runs over all the elevations and depressions in the bottom of the groove cut on the wax cylinder. There is thus increased pressure transmitted upwards to the glass disk when the point runs over an elevation, and less pressure when the point runs over a depression on the wax cylinder. The glass disk is, as it were, pulled inwards and thrust outwards with each vibration, but these pulls

and thrusts follow each other so rapidly that the ear takes no cognizance of the difference of phase of the vibrations of the glass plate in imprinting and in reproducing. The variations of pressure are communicated to the glass plate, and these, by the medium of the air, are transmitted to the drum-head of the ear, and the sound is reproduced with remarkable fidelity. It is necessary for accurate reproduction that the point of the marker be in the centre of the groove. In the older phonographs this required accurate adjustment by a fine screw, but in newer forms a certain amount of lateral oscillation is allowed to the marker, by which it slips automatically into the groove. Two other improvements have been effected in the construction of the instrument. A powerful triple-spring motor has been substituted for the electric motor, and the circumference of the wax cylinder has been increased from 6\(\frac{1}{2}\) in. to 12 in., whilst the disc is 12 in. in diameter. The cylinders make about two revolutions per second, so that with the smaller cylinder the point of the marker runs over nearly 14 in. in one second, while with the larger it runs over about 30 in. The marks corresponding to the individual vibrations of tones of high pitch are therefore less likely to be crowded together with the larger cylinder, and these higher tones in particular are more accurately reproduced. In a form of instrument called the 200-thread machine motion of the drum bearing the cylinder was taken off a screw the thread of which was 50 to the inch, and by a system of gearing the grooves on the cylinder were 200 to the inch, or \(\frac{3}{16}\) of an inch apart. Thus with the large cylinder a spiral groove of over 300 yds. may be described by the recorder, and with a speed of about two revolutions per second this distance is covered by the marker in about six minutes. By diminishing the speed of revolution, which can be easily done, the time may be considerably lengthened.

In the plate machine the disk is fixed to a table which is rotated at a fixed speed of about 76 revolutions a minute. The speed of the lateral movement of the table is also uniform, and by a regular progression brings the wax blank under the sound-box to the sapphire cutting point, which detaches a fine unbroken thread of wax as it cuts into the surface of the blank to a depth of 34 to 4-thousandths of an inch, beginning at about half an inch from the circumference and continuing the spiral groove to within a couple of inches of the centre, according to the length of the music to be recorded. The essential difference between the disk and cylinder machine is that in the former the waves are recorded by horizontal motion over the disk, while in the latter the waves are recorded as indentations.

The following is the *modus operandi* of making a record. The person grasping the needle in the right hand presses it against the wax, and by the means described is used for the purpose of focusing the sound-waves upon the diaphragm. The artist and the funnel are on one side of a screen and the recording apparatus in charge of an operator on the other.

The arrangement of the various instruments in the recording room at proper relative distances from the horn is of the utmost importance in order to preserve the balance of tone. At about 4 ft. from the horn are grouped the violins and the wood winds (flutes, oboes and clarinets); behind the brass wind (horns, trumpets, trombones and tubers), and right at the back the violoncellos and double basses and the kettle-drums and other instruments of percussion which may be required. On the other side of the screen is the sound-box and the recording cylinder or disk.

Cylinder records are duplicated by taking a plaster cast, electroplating, and then using it as a matrix. The disk record admits of similar treatment. After dusting with graphite it is electroplated to about 9 mm. thick. This forms the permanent or master record, from which the working negatives are made by taking wax impressions of it and obtaining copper electros in turn from them. The matrix is then nickel-plated and polished and is ready for use in pressing out the commercial records by means of an hydraulic press, the material used being a tough and elastic substance containing shellac and other compounds such as wood charcoal, baryum sulphate, earthy colouring matters and cotton flock.

There is still a defect to be overcome in the gramophone, and that is the hissing of the needle produced by friction both during recording and intensified in reproduction. In one device for remedying this the stylus acts like a stylographic pen, depositing on a polished surface a fine stream of some liquid which solidifies and hardens very rapidly, forming a sinuous ridge instead of a groove on a wax blank, the negative is taken of the record and the matrix is made from it in the usual way.
column of compressed air is controlled by a delicately adjusted grid-valve consisting of a metal comb rigidly connected to the stylus bar, so that as the needle moves the metal comb moves with it, following the lines of vibration fixed on the record and opening or closing the slots in the valve seat. The column of compressed air to which the valve gives access thus receives series of minute pulsations identical with those which originally produced the sounds recorded. In connection with the sound-box is the apparatus for supplying the compressed air, consisting of a sixth-horse power electric motor driving the compressor, an oil filter, a reservoir and a dust collector to keep the air absolutely free from foreign substances likely to interfere with the action of the valve.

The practical possibilities of the gramophone are being realized in many countries. Matrices of the records of well-known artists have been deposited at the British Museum and at the Grand Opéra in Paris. Austria established a public phonogram record office in 1903, in which are collected folk-songs and records of all kinds for enriching the department of ethnography. The same idea is being carried out in Germany by private societies and by royal museums. In Hungary records of the various dialects have been secured. The possibilities of the gramophone as a teacher are far-reaching, not only in the domain of music but in learning languages, &c.

To understand how the phonograph records and reproduces musical tones, it is necessary to remember (1) that pitch or frequency depends on the number of vibrations executed by the vibrating body in a given period of time, or on the duration of each vibration; (2) that intensity or loudness depends on the amplitude of the movement of the vibrating body; and (3) that quality, timbre or clang, first, depends on the form of the individual vibrations, or rather on the power the ear possesses of appreciating a simple pendular vibration producing a pure tone, or of decomposing more or less completely a compound vibration into the simple pendular vibrations of which it is composed. If we apply this to the record of the phonograph, we find that, given a constant and sufficiently rapid velocity of the record, a note or tone of a certain pitch will be heard when the marker runs over a number of elevations and depressions corresponding to the frequency of that note. Thus if the note was produced by 200 vibrations per second, and suppose that it lasted in the music for \( \frac{1}{10} \) of a second, 20 marks, each made in \( \frac{1}{10} \) of a second, would be impregnated on the wax. Consequently, in reproduction, the marker would run over the 20 marks in \( \frac{1}{10} \) of a second, and a tone of that frequency would be reproduced.

The loudness would correspond to the depth of each individual mark on the cylinder or the width on the disk. The greater the depth of a series of successive marks produced by a loud tone, the greater, in reproduction, would be the amplitude of the excursions of the glass disk and the louder would be the tone reproduced. Lastly, the form of the marks corresponding to individual vibrations would determine the quality of the tone or note reproduced, by which we can distinguish the tone of one instrument from another, or the sensation produced by a tone of pure and simple quality, like that from a well-bowed tuning-fork or an open organ pipe, and that given by a trumpet or an orchestra, in which the sounds of many instruments are blended together. When the phonograph records the sound of an orchestra it does not record the tones of each instrument, but it imprints the form of impression corresponding to the very complex sound-wave formed by all the instruments combined. This particular form, infinitely varied, will reproduce backwards, as has been explained, by acting on the glass plate, the particular form of sound-wave corresponding to the sound of the orchestra. Numerous instruments blend their tones to make one wave-form, and when one instrument predominates, or if a human voice is singing to the accompaniment of the orchestra, another form of sound-wave, or rather a complex series of sound waves, is imprinted. When reproduced, the wave-forms again exist in the air as very complex variations of pressure; these act on the drum-head of the human ear, there is transmission to the brain, and there an analysis of the complex sensation takes place, and we distinguish the trombone from the oboe, or the human voice from the violin obbligato.

Many efforts have been made to obtain graphic tracings of wave-forms imprinted on the wax phonograph records. Thus J. G. M’Kendrick took (1) celloidin casts of the surface, and (2) micro-photographs of a small portion of the cylinder (Journal of Anat. and Phys., July 1895). He also devised a phonograph recorder by which the curves were much amplified (Trans. Roy. Soc. Edin., vol. xxxvii.: Proc. Roy. Soc. Edin., 1896–1897, Opening Address; Sound and Speech Waves as revealed by the Phonograph, London, 1897; and Schäfer’s Physiol., vol. ii. “Vocal Sounds,” p. 1220). As already mentioned, so long ago as 1878 Fleeming Jenkin and Ewing had examined the marks on the tinfoil phonograph. Professor Ludimar Hermann, of Königsberg, took up the subject about 1890, using the wax-cylinder phonograph. He obtained photographs of the curves on the wax cylinder, a beam of light reflected from a small mirror attached to the vibrating disk of the phonograph being allowed to fall on a sensitive plate while the phonograph was slowly travelling. (For references to Hermann’s important papers, see Schäfer’s Physiology, ii. 1222.) Boeke, of Alkmaar, has devised an ingenious and accurate method of obtaining curves from the wax cylinder. He measured by means of a microscope the transverse diameter of the impressions on the surface of the cylinder, on different (generally equal) parts of the period, and he infers
from these measurements the depth of the impressions on the same spot, or, in other words, he derives from these measurements the curve of the vibrations of the tone which produced the impression.

Fig. 4.

From a communication to the Dutch Otorhinolaryngological Society Dr Boeke has permitted the author to select the accompanying illustrations, which will give the reader a fair conception of the nature of the marks on the wax cylinder produced by various tones. Fig. 2 shows portions of the curves obtained by Hermann, and enlarged by Boeke one and a half times. The numbers 1 to 4 refer to periods of the vowel A (as in "hard"), sung by Hermann on the notes c e g c. Numbers 5 to 8 show the curves of the vowel o (as in "go") sung to the same notes. The number of vibrations is also noted. Boeke measured the marks for the same vowels by his method, from the same cylinder, and constructing the curves, found the relative lengths to be the same. In fig. 3 we see the indentations produced by the same vowels, sung by Hermann on the notes c e g c, on the same phonograph cylinder, but delineated by Boeke after his method. The curves are also shown in linear fashion beside each group of indentations. From these measure-

ments the curves were calculated and reproduced, as in fig. 4. Thus the curves of the same vowel sounds on the same cylinder are shown by two methods, that of Hermann and that of Boeke.

From a communication to the Dutch Otorhinolaryngological Society Dr Boeke has permitted the author to select the accompanying illustrations, which will give the reader a fair conception of the nature of the marks on the wax cylinder produced by various tones. Fig. 2 shows portions of the curves obtained by Hermann, and enlarged by Boeke one and a half times. The numbers 1 to 4 refer to periods of the vowel A (as in "hard"), sung by Hermann on the notes c e g c. Numbers 5 to 8 show the curves of the vowel o (as in "go") sung to the same notes. The number of vibrations is also noted. Boeke measured the marks for the same vowels by his method, from the same cylinder, and constructing the curves, found the relative lengths to be the same. In fig. 3 we see the indentations produced by the same vowels, sung by Hermann on the notes c e g c, on the same phonograph cylinder, but delineated by Boeke after his method. The curves are also shown in linear fashion beside each group of indentations. From these measure-

ments the curves were calculated and reproduced, as in fig. 4. Thus the curves of the same vowel sounds on the same cylinder are shown by two methods, that of Hermann and that of Boeke.

Fig. 5.

In fig. 5 we see the indentations on the vowel a, sung by Dr Boeke, aged 55, on the notes c d e f g a b e', and near the frequencies of 128, 144, 160, 170-6, 192, 213-3, 240 and 256. The numbers 33 to 40 show the marks produced by the same vowel, sung by his son, aged 15. It will be seen that the boy sang the notes exactly an octave higher. Fig. 6 shows the marks produced by some musical sounds. Each shows on the right-hand side the curve deduced from the marks, and under it a graphical representation of the results of its harmonic analysis after the theorem of Fourier, in which the ordinates represent the amplitude of the subsequent harmonic constituents. No. 41 is the period of the sound of a pitch-pipe giving a' (425 double vibrations per second), No. 42 the period of a Dutch pitch-pipe, also sounding a' (424-64 double vibrations per second). No. 43 is a record of the period of a sound produced by blowing between two strips of indiarubber to imitate the vocal cords, with a frequency of 453 double vibrations per second. No. 44 is that of a telephone pipe used by Hermann (503 double vibrations per second). Nos. 45 and 46 show the marks of a cornet sounding the notes a of 400 double vibrations per second, and e of 300 double vibrations per second. In fig. 7 are shown a number of vowel curves for the vowels o, oe, a, e and i. Each curve has on the right-hand side a graphical representation of its harmonic analysis. The curves are in five vertical columns, having on the
left-hand side of each drawing, by Boeke's method, of the periods of the marks of the voice. The marks are shown for the Dutch, German, English and French languages. The sounds of the vowels are o, like o in "go"; ee, like ee in "too"; u, like the German "ü" in "Führer"; a, like a in "an"; i, like i in "beat"; and, like ee in "beer." The first section contains only Dutch vowel sounds, either sung or spoken by Boeke or members of his family. The second section contains curves from the "Atlas of Phonetics," the third from the voice of the author from a cylinder sent him by S. Dr Deoke, and the fourth from the voice of Mons. H. Marichelle, professeur de l'Institut des Sours-Muees, also forwarded by him to Dr Deoke.

PHONOLITE (Gr. φωνή, sound, and ἄλδος, stone), in petrology, a group of volcanic lavas containing much nepheline and sanidine felspar. The term "phonolite" was formerly given by geologists to many fine grained compact lavas, which split into thin tough plates, and gave out a ringing sound when struck with the hammer. Some of these clinkstones were phonolites in the modern sense, but as the name clinkstone was used for a large variety of rocks, many of which have no close affinities with one another, it has been discarded and "phonolite" is substituted for it. The group includes rocks which are rich in alkalis with only a moderate percentage of silica; hence they contain no free quartz but much alkali felspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks; the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure, both in the orientation of their phenocrysts and in the smaller crystals which make up the ground-mass; and this determines to a large extent the plagioclase jointing. Although vitreous and pumiceous forms are known, they are rare, and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground-mass. Marked characteristics are the readiness with which they decompose, and the frequency of veins and cavities occupied by natrolite, analcite, scolecite, and other zeolites. Small black grains of augite or hornblende and sometimes blue specks of haüyne may be seen in the rocks when they are fresh.

The dominant minerals are sanidine, nepheline, pyroxene, amphibole, various felspathoids and iron oxides. The sanidine is usually in two generations, the first consisting of large crystals of flattened and tabular shape, while the second generation is represented by small rectangular prisms arranged in parallel streams in the ground-mass; these felspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends, and may be completely replaced by fibrous zeolites, so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant.

magnetite and zircon occur in the phonolites, and sphenane is often rather common. Another mineral which is more frequent in phonolites than in many other rocks is brown melanite garnet.

The majority of the rocks of this group are of Tertiary or Recent age, but in Scotland Carboniferous phonolites occur in several localities, e.g. Traprain in Haddingtonshire, also in the Eildon Hills and in Renfrewshire. In Brazil phonolites belonging to the same epoch are also known. There are several districts in Europe where Tertiary or Recent phonolites occur in considerable numbers, as in Auvergne (Mont Dore), the Eifel, and Bohemia. The Wolf Rock which lies off the south coast of Cornwall, and is the site of a well-known lighthouse, is the only mass of phonolite in England; it is supposed to be the remains of a Tertiary lava or intrusion. The Canary Islands, Cape Verde Islands, Sardinia, Aden, British East Africa and New Zealand contain many types of phonolites; they are known also in New South Wales, while in the United States phonolites occur in Colorado (at Cripple Creek) and in the Black Hills of South Dakota.

Leucite occurs in place of nepheline in a small group of phonolites (the leucite-phonolites), known principally from Rocca Monfina and other places near Naples. Blue haüyne is rather a conspicuous mineral in some of these rocks, and they also contain a good deal of sphenane. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucitophyres (see PETROLOGY, Plate III, fig. 2).

The chemical analyses of phonolites given below show that these rocks are very rich in alkalies and alumina, with only a moderate amount of silica, while lime, magnesia and iron oxides are present in only small quantity. They have a close resemblance in these respects to the nepheline-syenites of which they provide the effusive types.

PHORCYS (Phorcrus, Phorcyus), in Greek mythology, son of Pontus (Sea) and Gaea (Earth), father of the Gorgons, Scylla, and Ladon (the dragon that guarded the golden apples of the Hesperides). In Homer (Odyssey, xiii. 96) he is an aged sea-deity, after whom a harbour in Ithaca was named. According to Varro (quoted by Servius in Aeneid, v. 824) Phorcys was a king of Corsica and Sardinia, who, having been defeated by King Atlas in a naval engagement in the course of which he was drowned, was subsequently worshipped as a marine divinity.

PHORMIUM, or NEW ZEALAND FLAX (also called "New Zealand hemp"), a fibre obtained from the leaves of Phormium tenax (nat. ord. Liliaceae), a native of New Zealand, the Chatham Islands and Norfolk Island. This useful plant is one of the many which were discovered by Sir Joseph Banks and Dr Solander who accompanied Captain Cook on his first voyage of discovery. The seeds brought home by Banks in 1771 did not succeed, but the plant was introduced by him to the Royal Gardens at Kew in 1789, and was thence liberally distributed in Great Britain and the continent of Europe. It grows luxuriously in the south of Ireland, where it was introduced in 1798, and also flourishes on the west coast of Scotland, and is generally cultivated as an ornamental garden plant in Europe. It has been introduced for economic purposes into the Azores and California. The name Phormium is from Gr. φόρμις, a basket, allusion to one of the uses made of its leaves by the New Zealanders.

In its native country the plant is generally found near the coast. It has a fleshy rootstock, creeping beneath the surface of the soil and sending up luxuriant tufts of narrow, sword-shaped leaves, from 4 to 8 ft. long and from 2 to 4 in. in diameter. The leaves are vertical, and arranged in two rows as in the garden flag; they are very thick, stiff and leathery, dark green above, paler below, with the margin and nerve reddish-orange. From the centre of the tuft ultimately arises a tall flower-bearing stem, 5 to 15 ft. high, bearing on its numerous
branches a very large number of lurid red or yellow, somewhat tubular flowers, recalling those of an aloe, and from 1 to 2 in. long. After flowering the plant dies down, but increases by new lateral growths from the rootstock. The plant will grow in almost any soil, but best on light rich soil, by the side of rivers and brooks, where sheltered from the wind. Phoronid has been treated as a cultivated plant in New Zealand, though only to a limited extent; for the supplies of the raw material dependence has been principally placed on the abundance of the wild stocks and on sets planted as hedges and boundaries by the Maoris. Among these people the fibre has always been an article of considerable importance, yielding cloaks, mats, cordage, fishing-lines, &c., its valuable properties having attracted the attention of traders even before colonists settled in the islands. The leaves, for fibre-yielding purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Andularia, as is prepared with great care by native methods, only the mature fibres from the under-side of the leaves being taken. These are collected in water, scraped over the edge of a shell to free them from adhering cellular tissue and epidermis, and more than once washed in a running stream, followed by renewed scraping till the desired purity of fibre is attained. This native process is exceedingly wasteful, not more than one-fourth of the leaf-fibre being there-fore available. But up till 1860 it was only native-prepared phorium that was known in the market, and it was on the material so carefully, but wastefully, selected that the reputation of the fibre was built up. The troubles with the Maoris at that period led the colonists to engage in the industry, and the sudden demand for all available fibres caused soon afterwards by the Civil War in America greatly stimulated their endeavours. Machinery was invented for disintegrating the leaves and freeing the fibre, and at the same time the experiments were made with the view of obtaining it by water-retting, and by means of alkaline solutions and other chemical agencies. But the fibre produced by these rapid and economical means was very inferior in quality to the product of Maori handiwork, mainly because weak and undevolved strands are, by machine preparation, unavoidably intermixed with the perfect fibres, which alone the Maoris select, and so the uniform quality and strength of the material are destroyed. The New Zealand government in 1893 offered a premium of £1750 for a machine which would treat the fibre satisfactorily, and a further £250 for a process of treating the tow; and with a view to creating further interest in the manufacture of improved fibre, the Government of England during 1897. The premium was again issued in 1899. In 1903 it was stated that a German chemist had discovered a method of working and spinning the New Zealand fibre. An idea of the growth of the fibre may be gathered in the fact that the exports for 1905 amounted to 28,877 bales at a value of nearly £700,000.

Phorium is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally a cordage fibre, and in textile strength it is second only to Manila hemp; but it does not bear the abrasive qualities of wet and dry to which shipropes are subjected. The fibre has come into use as a suitable material for binder-twine as used in self-binding reaping machines.

PHORONIDEA, a zoological order, containing a single genus Phoronis, which is known to be of practically world-wide distribution, while there are many records of its larva, Actinohrocha, from localities where the adult has not been found. Phorontis is often gregarious, the tubes which it secretes being sometimes intertwined in an inextricable mass. These associations of individuals can hardly be the result of the metamorphosis of a corresponding number of larvae, but are probably due to a spontaneous fragmentation of the adult animals, each such fragment developing into a complete Phorontis (De Selys-Longchamps). The animal is from a quarter of an inch to six inches (P. australis) in length. The free end of the long vermiciform body ends in a horsehoe-shaped "lophophore," or tentacle-bearing region (fig. 1, a), which strikingly resembles that of the Phylactolaematae Polyzoa (see Polyzoa).

In the australis species (figs. 2, 3) the two ends of the lophophore are rolled into tubes, the peristomial (fig. 2 i., e) tube the mouth (m), continuous on either side with the groove between the two series of tentacles; the anus (a), in the middle line, at no great distance from the mouth; a transversely elongated epistome (ep), between the mouth and the anus; and, in the concavity of the lophophore, the apertures of the nephridia (n.d.) which, according to De Selys-Longchamps, open into the two large sensory or glandular mesenteries. The offices of which are seen at (g.). The mouth leads into the oesophagus, which extends straight down the body nearly to the aboral end or "ampulla," where it dilates into a stomach, from which the ascending limb of the U-shaped alimentary canal passes directly to the anus. The coelomic body-cavity is divided by a transverse septum (fig. 3, s) which lies near the bases of the tentacles. The preseptal or lophophoral coelom is continued into each of the tentacles and into the

![Fig. 1. The Tentacular End of Phorontis, with some of the tentacles removed.](image)

![Fig. 2. Dorsal View of Phorontis australis, showing the spirally coiled ends of the lophophore.](image)
the hollow central nervous system of some Enteropneusta and of Vertebrates. This comparison is not admitted by De Selys-Longchamps. The vascular system contains numerous red blood-corpuscles. The principal blood-channels are two longitudinal vessels which run down the entire length of the body, and are known as the "afferent" vessel (af) and the "efferent" vessel (ef) respectively, from their relation to the tentacles. According to researches in 1907 by De Selys-Longchamps, the blood is driven by the efferent vessel (ef) to a crescentic lophophoral vessel (dv) which supplies the tentacles. Each of these contains a single blindly

An oblique septum which follows the bases of the tentacles and corresponds with that of the adult animal divides the body-cavity into two portions. The postseptal division is a coelomic space, partially subdivided by a ventral mesentery. The preseptal cavity is a vascular space, since it is in free communication with the dorsal vessel of the larva, and it persists in part as the two lophophoral vascular crescents of the adult. It contains two tufts of peculiar excretory cells, described by Goodrich (5) as "solenocytes," which surround the alimentary canal. These pass backwards through the septum and open to the exterior ventrally. After the Actinotrocha has led a pelagic life for some time it develops a large ventral invagination of its body-wall (fig. 4, 2, 3v). At the metamorphosis, this sac is everted and the alimentary canal is drawn into it in the form of a loop (fig. 4, 3, 4). Most of the praententacular region and the larval tentacles separate off, being then taken into the alimentary canal, where they are digested. The relations of the surfaces after the metamorphosis are clearly very different from those which obtained in the larva. The dorsal surface of the adult is the one between the mouth and the anus, while the median ventral line is the one which corresponds with the convexity of the alimentary canal. This view of the surfaces is, however, disputed by De Selys-Longchamps, who regards the aboral extremity of the adult as the posterior end.

The development of Phoronis was supposed by Caldwell (1) to furnish the explanation of the relations of the surfaces in Brachiopoda, Polyzoa and perhaps the Sipunculoid Gephyrea, in which the ontogenetic evidence is less clear. Caldwell's views were accepted by Lankester (8) in the 8th edition of this work. The Phylum Podaxonia, being there instituted to include the groups just mentioned, together with the Pterobranchia. The peduncle of the Brachiopoda was supposed to correspond with the everted ventral sac of Actinotrocha, with a "posterior anus," and some want of any complete investigation of the development of the Brachiopoda, and by the absence of the anus in the majority of the genera. There is, however, a considerable amount of resemblance between the lophophore of Phoronis australis, with its spiral twisted ends, and that of a typical Brachiopod; nor do the structural details of the adult Brachiopods forbid the view that they may be related to Phoronis. The comparative study of the development does not support the hypothesis that the Polyzoa (q.v.) are comparable with Phoronis. In Pedicellina, the only Polyzoa in which the alimentary canal of the larva is known to become that of the first adult individual, the line between the mouth and anus is ventral in the larva; and since there is no reversal of the curvature of the digestive loop during the metamorphosis it must be regarded as ventral in the adult. There are, indeed, remarkable similarities between the Phylactolaemata, Polyzoa, and the Phoronidea, and notably between their lophophores. The supposed occurrence of a pair of nephridia in certain Phylactolaemata, in a position corresponding with that of the nephridia of Phoronis, must also be mentioned.

Although it has been maintained that the "nephridia" of Phylactolaemata are merely ciliated portions of the body-cavity and not indeed nephridia at all. But a serious objection to the comparison is that the development of Phylactolaemata cannot be explained by supposing it to be a modification of what occurs in other Polyzoa, while it appears to have no relation whatever to that of Phoronis. Most observers consider that Actinotrocha is a highly modified Trochosphere, and this would give it some claim to be regarded as distantly related to the Entoproct Polyzoa and to other groups which have a Trochosphere larva.
PHORORHACOS—PHOSPHATES

Phororhacos has long been regarded as a possible ally of Rhabdopleura (see Pterobranchia); and Masterman (10) has attempted to demonstrate the existence of a certain Ascidian in Actinotricha which occurs in the Pterobranchia. According to his view the praeoral hood of Actinotricha (cf. fig. 4) corresponds with the "proboscs" of Pterobranchia; the succeeding region, as far as the tentacles with the collar; and the posterior-tentacular region with the metasome. Masterman's more detailed comparisons have for the most part been rejected by other morphologists. One of the most formidable difficulties in the way of the attempt to reduce Actinotricha to the Pterobranchiate type of structure is the condition of the coelom in the former. There is indeed a perfectly definite transverse septum which divides the body-cavity in the region of the tentacles. Even in the most complete transverse septum may be the metasomatic cavity, the praeoral space can hardly be regarded as coelomic in nature, since it is in continuity with the vascular system; while Masterman's conclusion that the cavity of the praeoral hood (the supposed proboscis-cavity) is separated from that of the supposed collar has received no confirmation.

In spite of these difficulties it must be conceded that the dorsal branchial of the alimentary canal of the Pterobranchia is very Phororhacide. It has, moreover, been shown (see especially Goodrich, 5) that before its metamorphosis, Actinotricha develops a coelomic space which lies immediately in front of the oblique septum, and gives rise later to the cavity of the lophophore and tentacles. Regarding this as a collar-cavity, it becomes possible to agree with Masterman that the region shown in fig. 4, 1, between the tentacles and the praeoral hood, is really a collar of the kind in which the Actinotricha of most of the structures. The lophophore of Phororhacos is, on this assumption, a derivative of the collar just as it is in the Pterobranchia. The epistome of the adult Phororhacos cannot well be the proboscis since its cavity is continuous with the lophophoral coelom, but the praeoral hood of Actinotricha is entirely lost at the metamorphosis. It is possible that this consideration will account for the want of an anterior body-cavity in Phororhacos. Since the proboscis-cavity is a larval organ in this genus, it may be supposed that the coelomic space which properly belongs to it fails to develop, but that the praeoral hood itself is none the less the morphological representative of the proboscis. In spite of the criticisms which have been made on the conclusion that Phororhacos is allied to the Pterobranchia, it is thus possible that the view is a sound one and that the Phororhacide should take their place, with the Enteropneusta and the Pterobranchia, as an order of the Hemichordata.

PHORORHACOS, the best-known genus of the extinct Patagonian Stereomorphs (see Bird: Fossil). Among the bones found in the strata of the Santa Cruz formation (now considered as midway of Miocene date) was a piece of a mandible which F. Ameghino described in 1887 as that of an edentate mammal, under the name of Pharyrhorhacos longissimus (Bolet. Mus. de la Plata, i. 24). In 1891 (Rev. Argent. Hist. nat. i. 225) he amended the name and recognized the bone as that of a bird, Phororhacos, which with Brontornis and others constituted the family Phororhacidæ. About six species of the type genus are now known, the most complete being Ph. inflatus, with skull, mandible, pelvis, limbs and some of the vertebrae.

These birds were at first considered as either belonging to the Ratitæ, or at least related to them, until C. W. Andrews, after much of the interesting material had been acquired by the British Museum, showed the grufiform affinities of Phororhacos (Ibis, 1866, pp. 1–12), a conclusion which he was able to further corroborate by the finding of the almost complete skeleton of Phororhacos longissimus about 2 ft. long and 10 in. high, that of Ph. inflatus is 13 in. long, and this creature is supposed to have stood only 3 ft. high at the middle of the back. The under jaw is slightly curved upwards and it contains a large foramen as for instance in Psophia and in Meryta. The strongly hooked upper beak is very high, and very much compressed laterally. The palate is imperfectly desmognathous, as in Dicholophus, with an inconspicuous vomer. The quadrate has a double knob for its articulation with the skull, and basipterygoid processes are absent. What little is known of the shoulder-ridge (breastbone still unknown) points to a flightless bird, and so do the short wing bones, although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender, the tibia of Ph. inflatus being between 15 and 16 in. in length.

For further detail see F. Ameghino, "Sur les oiseaux fossiles de la Patagonie," Bolet. inst. geogr. argentina, xv., chs. 11 and 12 (1895); F. F. Moreno and A. Mercat, Catálogo de los pajaros de la República Argentina, An. Mus. La Plata (1906), vol. 1, with 21 plates. 

PHOSGENE, a rare mineral consisting of lead chlorocarbonate, (PbCl)CO3. The tetragonal (holosymmetric) crystals are prismatic or tabular in habit, and are bounded by smooth, bright faces: they are usually colourless and transparent, and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 3 and the specific gravity 6·3. The mineral is rather settleable, and consequently was early known as "corneous lead" (Ger. Hornkels). The fanciful name phosgene was given by A. Breithaupt in 1820, from phosgene, the old name of carbon oxychloride, because the mineral contains the elements carbon, oxygen and chlorine. At Cromford, near Matlock, it was long ago found in an old lead mine, being associated with anglesite and matlockite (PbSO4Cl) in cavities in decomposed galena: hence its common name cronofrite. Fine crystals are also found in galena at Montepoii near Iglesias in Sardinia, but the largest are those recently found near Dundas in Tasmania. Crystals of phosgene, and also of the corresponding bromine compound [PbBr]2CO3, have been prepared artificially.

PHOSPHATES, in chemistry, the name given to salts of phosphoric acid. As stated under Phosphorus, phosphoric oxide, P2O5, combines with water in three proportions to form H2O·P2O5 or HPO4, metaphosphoric acid; 2H2O·P2O5 or H2P2O7, pyrophosphoric acid; and 3H2O·P2O5 or H3P2O7, orthophosphoric or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important, and, in addition, are widely distributed in the mineral kingdom (see below under Mineral Phosphates).

Orthophosphoric acid, H3PO4, a tribasic acid, is obtained by boiling a solution of the pentoxide in water; by oxidizing red phosphorus with nitric acid, or yellow phosphorus under the surface of water by bromine or iodine; and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard, transparent, rhombic prisms which melt at 41·7°. On long heating the syrup is partially converted into pyrophosphoric and metaphosphoric acids, but on adding water and boiling the orthophosphoric acid is produced. It gives rise to three classes of salts: M2H2PO4 or M2H2PO4; M2H2PO4 or M2H2PO4; M2PO4 or M2PO4 or M2PO4 or M2PO4, wherein M, M, M, M' denote a mono-, di-, and tri-valent metal. The first set may be called monometallic, the second dimetallc, and the third trimetallc salts. Per-acid salts of the alkalis, e.g. (K,Na,NH4)H2PO4, are also known; these may be regarded as composed of a monometallc phosphate
with phosphoric acid, thus $\text{M}_2\text{H}_2\text{PO}_4$, $\text{H}_3\text{PO}_4$. The three principal groups differ remarkably in their behaviour towards indicators. The monometallic salts are strongly acid, the dimetallie are neutral or faintly alkaline, while the trivalent trimerallic salts are strongly alkaline. The monometallic salts of the alcohols and alkali earths may be obtained in crystal form, but those of the heavy metals are only stable when in solution. The soluble trimerallic salts are decomposed by carbonic acid into a dimetallie salt and an acid carbonate. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate, $\text{Ag}_3\text{PO}_4$, soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid: $\text{Na}_2\text{H}_2\text{PO}_4 + 3\text{AgNO}_3 = \text{Ag}_3\text{PO}_4 + \text{Na}_2\text{NO}_3 + 2\text{HNO}_3$, $\text{Na}_2\text{H}_2\text{PO}_4 + 3\text{AgNO}_3 = \text{Ag}_3\text{PO}_4 + 2\text{NaNO}_3 + \text{HNO}_3$, it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid is desired. The three series also differ when heated: the trimerallic salts, containing fixed bases are unaltered, whilst the mono- and dimetallie salts yield meta- and pyrophosphates respectively. If the heating be with charcoal, the trimerallic salts of the alkalis and alkaline earths are unaltered, whilst the mono- and di-salts give free phosphorus and a trimerallic salt. Other precipitants of phosphoric acid or its salts in solution are: ammonium molybdate in nitric acid, which gives on heating a canary-yellow precipitate of ammonium phosphomolybdate, $2(\text{MoO}_3)\text{H}_2\text{PO}_4$, insoluble in acids but readily soluble in ammonia; magnesium chloride, ammonium chloride and ammonia, which give on standing in a warm place a white crystalline precipitate of magnesium ammonium phosphate, $\text{Mg(NO}_3)_2\text{H}_2\text{PO}_4\cdot\text{H}_2\text{O}$, which is soluble in acids but highly insoluble in ammonia solutions, and on heating to redness gives magnesium pyrophosphate, $\text{Mg}_3\text{P}_2\text{O}_7$; uranic nitrate and ferric chloride, which give a yellowish-white precipitate, soluble in hydrochloric acid and ammonia, but insoluble in acetic acid; mercurous nitrate which gives a white precipitate, soluble in nitric acid, and bismuth nitrate which gives a white precipitate, insoluble in nitric acid.

**Pyrophosphoric acid**, $\text{H}_2\text{P}_2\text{O}_7$, is a tetrabasic acid which may be regarded as derived by eliminating a molecule of water between two molecules of ordinary phosphoric acid; its constitution may therefore be written $(\text{HO})_2\text{P}_2\text{O}_6\cdot\text{H}_2\text{O}$. It may be obtained as a glassy mass, indistinguishable from metaphosphoric acid, by heating phosphoric acid to 215°. When boiled with water it forms the ortho-acid, and when heated to redness the meta-acid. After neutralization, it gives a white precipitate with silver nitrate. Being a tetrabasic acid it can form four classes of salts; for example, the four sulphur salts $\text{Na}_2\text{P}_2\text{O}_7$, $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$, $\text{Na}_2\text{H}_3\text{P}_2\text{O}_7$, $\text{Na}_2\text{H}_4\text{P}_2\text{O}_7$ are known. The most important is the normal salt, $\text{Na}_2\text{P}_2\text{O}_7$, which is readily obtained by heating disodium orthophosphate, $\text{Na}_2\text{HPO}_4$. It forms monoclinic prisms (with $\text{H}_2\text{O}$) which are permanent in air. All soluble pyrophosphates when boiled with water for a long time are converted into orthophosphates.

**Metaphosphoric acid**, $\text{H}_2\text{P}_5\text{O}_8$, is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water, thus $\text{H}_2\text{P}_5\text{O}_8 - \text{H}_2\text{O} = \text{H}_2\text{P}_4\text{O}_6$; its constitution is therefore (HO)PO$_4$. The acid is formed by dissolving phosphorus pentoxide in cold water, or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass, hence its name “glacial phosphoric acid.” It is readily soluble in water, the solution being gradually transformed into the ortho-acid, a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic, salts of polymeric forms exist of the types (MPO)$_n$, where $n$ may be 1, 2, 3, 4, 6. They may be obtained by heating a monometallic orthophosphate of a fixed base, or by heating a mixture of phosphates of one fixed and one variable base, e.g. microcosmic salt: $\text{M}_2\text{PO}_4 + \text{MPO}_4 + \text{H}_2\text{O} (\text{NH}_4)\text{NaHPO}_4 = \text{Na}_2\text{HPO}_4 + \text{NH}_4\text{H}_2\text{PO}_4$; they may also be obtained by acting with phosphorus pentoxide on trimerallic orthophosphates: $\text{Na}_3\text{PO}_4 + \text{P}_2\text{O}_5 = 2\text{Na}_2\text{P}_2\text{O}_7$. The salts are usually non-crystalline and fusible. On boiling their solutions they yield orthophosphates, whilst those of the heavy metals on boiling with water give a trivalent orthophosphate and orthophosphoric acid: $3\text{AgPO}_4 + 3\text{H}_2\text{O} = \text{Ag}_3\text{PO}_4 + 2\text{H}_3\text{PO}_4$. On heating with an oxide or carbonate they yield a trimerallic orthophosphate, carbon dioxide being evolved in the latter case. Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen, and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia.

**Mineral Phosphates.**—Those varieties of native calcium phosphate which are not distinctly crystallized, like apatite (q.v.), but occur in fibrous, compact or earthy masses, often nodular, and more or less impure, are included under the general term phophorite. The name seems to have been given originally to the Spanish phosphorite, probably because it phosphoresced when heated. This mineral, known as Estremadura phosphate, occurs at Logrossan and Cáceres, where it forms an important deposit. Way-sla Torga is a deposit of about 10% of calcium phosphate, with about 7% of magnesium phosphate. A somewhat similar mineral, forming a fibrous incrustation, with a mammillar surface, and containing about 0% of calcium carbonate, is known as staffellite, a name given by A. Stein in 1866 from the locality Staffel, in the valley of the Lower Lahn, where (as also in the valley of its tributary the Dill) large deposits of phosphorite occur. Dallilite is a Norwegian phosphorite, containing calcium carbonate, named in 1888 by W. Brögger and H. Bäckström after the Norwegian geologists T. and J. Dahl. Osteolite is a white earthy phosphorite occurring in the caves of the Basaltic rocks, named in 1851 by J. C. Bromeis from the Greek ὄστεον (bone).

Phosphorite, when occurring in large deposits, is a mineral of much economic value for conversion into the superphosphate largely used as a fertilizing agent. Many of the impure substances thus utilized are not strictly phosphorite, but pass under such names as “rock-phosphate,” or, when nodular, as “copolrite” (q.v.), even if not of true coprolitic origin. The ultimate source of these mineral phosphates may be referred to in most cases to the apatite widely distributed in crystalline rocks. Being soluble in water containing carbonic acid or organic acids it may be readily removed in solution, and may thus furnish plants and animals with the phosphates required in their structures. On the decay of these structures the phosphates are returned to the inorganic world, thus completing the cycle.

There are three sources of phosphates which are of importance geologically. They occur (a) in crystalline igneous and metamorphic rocks as an original constituent, (b) in veins associated with igneous rocks, and (c) in sedimentary rocks either as organic fragments or in secondary concretionary forms.

The first mode of occurrence is of little significance practically, for the crystalline rocks generally contain too little phosphate to the ores, though they are occasionally enough apatite to form an inferior fertilizing agent, e.g. the trachyte of Cabo de Gata in south-east Spain, which contains 12–15% of phosphoric acid. In many deposits of iron ores found in connexion with igneous or metamorphic rocks small quantities of phosphate occur. The Swedish, Norwegian, Ontario and Michigan mines yield ores of this kind; and though none of them can be profitably worked as a source of phosphate, yet on reducing the ore it may be retained in the slags, and thus rendered available for agriculture.

Another group of phosphatic deposits connected with igneous rocks comprises the apatite veins of south Norway, Ottawa and other districts in Canada. These are of pneumatolytic origin (see Pneumatolysis), and have been formed by the action of vapours emanating from cooling bodies of basic eruptive rock. Veins of this type occur at Oedegarden in Norway and Dundret in Lapland. From 500 to 3500 tons of apatite are obtained yearly in Norway from these veins. In Ontario apatite has been worked for a long time in deposits of similar nature. The total output of Canada in 1907 was only 680 tons.

The third source, which occur among the sedimentary strata are the principal sources of phosphates for commerce and agriculture. They are found in formations of all ages from the Cambrian to those which are accumulating at the present day. Of the latter the best known is the guano (see MANURE). Where guano-beds are exposed to rain their soluble constituents are removed and the insoluble matters left behind. The soluble phosphates washed out of the guano may be rendered fixed by entering into combination with the elements of the rock beneath. Many of the oceanic islets are composed of coral limestone, which in this
PHOSPHORESCENCE

way becomes phosphatized; others are igneous, consisting of trachyte or basalt, and these rocks are also phosphatized on their surfaces. Magnificent deposits of phosphate rock in the form of nodules, or clods, in any quantity renders them unsuited for the preparation of artificial manures.

The leached guano and phosphatized rocks, which are grouped under the term guano phosphates, have been obtained in great quantities in many islands of the Pacific Ocean (such as Baker, Howland, Jarvis and McKean Islands) between long. 150° to 180° W. and lat. 10° N. to 10° S. In the West Indies from Venezuela to the Bahamas and in the Caribbean Sea, many islands yield supplies of leached guano; the following are important in this respect: Sombrero, Navassa, Aves, Aruba, Curacao. Christmas Island has been a great source of phosphates of this class. J. and A. Obert in the Malabar Archipelago have obtained very large quantities of phosphates in the Banda or Ocean Island, and Nauru or Pleasant Island. On Christmas Island the phosphate has been quarried to depths of 100 ft. To these leached guanos and phosphatized limestones the name sombrerite has been given. It has been estimated that 500,000 tons of phosphate were obtained in Aruba, 1,000,000 tons from Curacao since the deposits were discovered in 1870, and Christmas Island in 1907 yielded 290,000 tons.

In the older formations the phosphates tend to become more and more mineralized by chemical processes. In whatever operations they were originally deposited they often suffer complete or partial solution and are redeposited as concretionary lumps and nodules, often called coprolites. The "Challenger" and other oceanographic expeditions have shown that on the bottom of the deep sea concretions of phosphate are now gathering around the dead bodies of fishes lying in the ooze; consequently the formation of the concretions may have been carried on simultaneously with the deposition of the strata in which they occur.

Important deposits of mineral phosphates are now worked on a large scale in the United States, the annual yield far surpassing that of any other part of the world. The most active operations are carried on in Florida, where the phosphate was first worked in 1887; in the form of pebbles in the gravels of Peace River. Then followed the discovery of "hard rock-phosphate," a massive mineral, often having cavities lined with nearly pure phosphorite. Other kinds not distinctly hard and consisting of less rich phosphatic limestone, are known as "soft phosphate": those found as smooth pebbles of variable colour are called "land-pegg-phosphate," whilst the pebbles of the river-beds and old river-valleys, usually of dark colour, are distinguished as "river pegg-phosphate." The land pegg is worked in central South Florida; the hard rock chiefly between Fort Lauderdale and Cape Canaveral. In Central Florida, there are important deposits of phosphate, formerly more productive than at present, the "land rock" is worked near Charleston, and the "river rock" in the Coosaw river and other streams near Beaufort. The phosphate beds contain Eocene fossils derived from the underlying strata and many fragments of Pleistocene vertebrata such as mastodon, elephant, stag, horse, pig, &c. The phosphate occurs as lumps varying greatly in size, scattered through a sand or clay; they often contain phosphatized Eocene fossils (Mollusca, &c.). Sometimes the phosphate is found at the surface, but generally it is covered by alluvial sands and clays. Phosphate mining began in South Carolina in 1865, and the state has become the principal producer. Then the Florida deposits began to be worked. In 1892 the phosphates of Tennessee, derived from Ordovician limestones, came into the market. From North Carolina, Alabama and Pennsylvania, also, phosphates have been obtained but only in comparatively small quantities. In 1900 mining for phosphates was commenced in Arkansas. In 1908 Florida produced 1,073,051 tons of phosphate valued at $11 million dollars. All the other states together produce less phosphate than Florida, and among them Tennessee takes the first place with an output of 493,180 tons.

Algeria contains important deposits of phosphorite, especially near Tebessa and at Tocqueville in the province of Constantine. Near Jebel Kouif, on the frontier between Algeria and Tunisia, there are phosphate workings, as also in Tunisia, at Gafsa. The deposits belong to the Lower Eocene, where it rests unconformably upon the Cretaceous. The joint production of Tunisia and Algeria in 1907 was not less than a million tons. Phosphates also occur in Egypt, in the desert east of Keneh and in the Dakla oasis in the Libyan desert.

France is rich in mineral phosphates, the chief deposits being the departments of the Pas-de-Calais, Somme, Aisne, Oise in and Meuse, in the north-east, and another group in the departments of Lot, Tarn-et-Garonne and Aveyron, in the south-west: the Paris Basin, the Pyrenees, and the Massif Central. A similar deposit is found in the Calyus and in Quercy occupy fissures and pockets in Jurassic limestone, and have yielded a remarkable assemblage of the relics of Tertiary mammals and other fossils. Phosphates occur in Belgium, especially near Mons, and these, like those of north-east France, are principally in the Upper Chalk. Two varieties of phosphate rock are recognized in these districts, viz. the phosphatic chalk and the phosphate sand, the latter resulting from the decomposition of the former. Large and valuable deposits of the sand have been obtained in sinks and depressions on the surface of the chalk. The production is on the whole diminishing in Belgium (180,000 tons in 1907), but in France it is still large (375,000 tons in 1907).

In the Lahn district of Nassau (Germany) there are phosphate beds in Devonian rocks. The deposits were rich but irregular and local, and were much worked from 1866 to 1884, but are no longer of economic importance. In northern Estremadura in Spain and Alentejo in Portugal there are vein deposits of phosphate of lime. As much as 200,000 tons of phosphate have been raised in these provinces, but in 1906 the total production of Spain was only 1300 tons. Large deposits of phosphate occur in Russia, and those in the neighbourhood of Kertch have attracted some attention; it is said that the Cretaceous beds in the Lower Don river and Volga contain very large supplies of phosphate, though probably of low grade.

Phosphatic nodules and concretions, with phosphatized fossils and their casts, occur at various geological horizons in Great Britain. Bands of black nodules, highly phosphatic, are found at the top of the Bala limestone in North Wales; beds of concretions occur in the Lower Greensand at Upware and Wicken in Cambridgeshire. The Cambridge Greensand, rich in phosphatic nodules, occurs at the base of the Chalk Marl. The chalk occasionally becomes phosphatized, as at Taplow (Bucks) and Lewes (Sussex). At the base of the Red Crag Mole Valley, and in the Chalk Marl near Petersfield, there are "nodules," consisting of phosphatic nodules, with rolled teeth and bones, which were formerly worked as "coprolites" for the preparation of artificial manure. Professor J. J. Strutt has found that phosphatized nodules have been used as radioactive constituents, and has brought this into relation with their geological age.

(J. S. F.; F. W. R.)

PHOSPHORESCENCE, a name given to a variety of physical phenomena due to different causes, but all consisting in the emission of a pale, more or less ill-defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. This property has since been referred to various substances, some of which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of this property which apparently attracted scientific attention seems to have been that of the Bologna stone (barium sulphide), which was discovered
by Vincenzo Cascariolo, a cobbler of Bologna, in about 1662. This was followed by the discovery of a number of other substances which become luminous either after exposure to light or on heating, or by attrition, and to which the general name of "phosphor" (from φως and φόρος, bringing light) was given. Among these may be mentioned Homberg's phosphorus (calcium chloride), John Canton's phosphorus (calcium sulphide) and Baldinu's phosphorus (calcium nitrate). Of late years it has been found convenient to limit the strict meaning of the word "phosphorescence" to the case of bodies which, after exposure to light, become self-luminous (even if only for a fraction of a second). The general term "luminescence" has been proposed by some writers to include all cases in which bodies give off light not due to ignition. The term "luminescence" embraces several subdivisions. Thus, fluorescence (q.v.) and phosphorescence are included under the same heading, "photoluminescence," being distinguished from each other by the fact that fluorescent bodies emit their characteristic light only while under the influence of the exciting illumination, while phosphorescent bodies are luminous for an appreciable time after the exciting light is cut off.

Phosphorescence, in its restricted meaning as above explained, is most strikingly exhibited by the artificial sulphides of calcium, strontium, and barium. If any such substance is exposed for some time to daylight, or, better, to direct sunlight, on the fracture of the electric arc, it will shine for hours in the dark with a soft coloured light. The colour depends not only on the nature of the substance, but also on its physical state; thus, for instance, the light on ice is violet, but on fire is yellow during insolation, that is, exposure to the sun's rays. Thus the phosphorescent light emitted by calcium sulphide may be orange-yellow, yellow, green or violet, according to the method of preparation and the materials used. Balmain's luminous paint, a preparation of calcium sulphide, shines with a white light. The colour also depends on the temperature during exposure to light. Thus A. E. Becquerel found that the light given by a specimen of strontium sulphide was changed from pale blue to blue-green and orange, as the temperature during the corresponding previous insolation was 20°, 40°, 70°, 100° or 200° C. The duration of the light is very greatly with different substances. It may last for days or for only a fraction of a second.

As in the case of fluorescent bodies, the light produced by phosphorescent substances consists commonly of rays less refrangible than those of the exciting light. Thus the ultra-violet portion of the spectrum is usually the most efficient in exciting rays belonging to the visible part of the spectrum. V. Klatt and Ph. Lenard (Wied. Ann., 1889, xxxviii. 90) have shown that the phosphorescence of enamin carbonates and other phosphor depends on the presence of minute quantities of other substances, such as copper, bismuth and manganese. The maximum intensity of phosphorescent light is obtained when a certain definite proportion of the impurity is present. Above or below this proportion the intensity of the light diminishes. But it appears that Becquerel, and others, have shown that the sulphides of the alkaline earths lose the property of phosphorescing when subjected to heavy pressure. Many fluorescent solutions become briefly phosphorescent when rendered solid by gelatin.

When the duration of phosphorescence is brief, some mechanical device becomes necessary to detect it. The earliest and best-known instrument for this purpose is Becquerel's phosphorescope. It consists essentially of a shallow drum, in whose end two eccentric holes, exactly opposite one another, are cut. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and driven slowly by a clockwork. One or the other of them is alternately concealed and brought into view, each being cut out. One of the disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are made to rotate, the hole in one end is open while that in the other is closed, and vice versa. If the disks be made of a metal which is white, each one showing a part of a train of teeth, the wheels the object will be presented to the eye almost instantly after it has been exposed to sunlight, and these presentations succeed one another so rapidly as to produce a sense of continuous vision. But it is found that this instrument is not well adapted to measure the duration of the phenomenon after the light has been cut off. For this purpose we require to know merely the number of sectors in the disks and the rate at which they are turned.

Thermoluminescence. Some bodies which do not emit light at ordinary temperatures in a dark room begin to do so if they are heated to a temperature below a visible red heat. In the case of chlorophane, a variety of flour-spar, the heat of the hand is sufficient. Many yellow diamonds exhibit this form of luminescence. V. has been shown, however, that a previous exposure to light is always necessary. Sir James Dewar found that if ammonium platinocyanide is heated and exposed to light, they do not phosphoresce, but as soon as they are allowed to warm up to the ordinary temperature they emit a brilliant light. On the other hand, some bodies, as a little copper, cellulin, jacinth and ivory, are phosphorescent at very low temperatures, but lose the property at ordinary temperatures.

Triboluminescence (from τρίβω, to rub) is luminescence excited by friction, percussion, vibration or such mechanical means as the rubbing of a piece of sulphide of calcium, prepared at a red heat, exhibits this property. If sugar is broken in the dark, or two crystals of quartz rubbed together, or a piece of mica cleat, a flash of light is seen, but this is probably due to the change from mechanical to thermal energy, and not merely to the mechanical energy. In this case the luminescence is given off at the point of contact. It has been observed that a phosphorescent light seen when some substances crystallize from solution or after fusion. This property is caused by arsenic acid when crystallizing from solution in hydrochloric acid.

Chemiluminescence is the name given to those cases in which chemical action produces light without any great rise of temperature. Phosphorus exposed to moist air in a dark room shines with a soft light due to slow oxidation. Decaying wood and other vegetable substances often exhibit the same property.

Electroluminescence is luminescence due to electrical causes. Metal sulphides and some other bodies when a discharge has been passed through them, and some solid substances, especially diamonds and rubies, are strongly phosphorescent when exposed to cathode rays in a vacuum tube.

Cascariolo, Ph. Wied. Handbuch der Physik, Bd. vi. (1906); E. Becquerel, La Lumière (1897).

Phosphorescence in Zoology.

The emission of light by living substance is a widespread occurrence, and is part of the general metabolism by which the potential energy introduced as food is transformed into kinetic energy and appears in the form of movement, heat, electricity and light. In many cases it is probably an accidental by-product, and like the heat radiated by living tissues, is not necessarily of use to the organism. But in other cases the capacity to produce light is awakened on stimulation, as when a sunbeam strikes the surface of the sea, or when the water is disturbed by the blade of a man's paddle. It has been suggested that the response to the stimulus may be protective, and that enemies are frightened by the flash of light. In luminous insects and deep-sea fish the power of emitting light appears to have a special significance, and very elaborate mechanisms have been developed. The pale glow of phosphorescence has a certain resemblance to the light emitted by phosphorus, and it was an early suggestion that the phenomenon in living organisms was due to that substance. Phosphorus, however, and its luminous compounds are deadly poisons to all living tissues, and never occur in them in the course of natural metabolism, and the phosphorescence of life cannot therefore be assigned to the oxidation of phosphorus. On the other hand, it is certainly the result of a process of oxidation, as the emission of light continues only in the presence of oxygen.

J. H. Fabre showed in 1855 that the luminous fungus, Afericus, discharges more carbonic acid when it is emitting light, and Max Schultz in 1865 showed that in insects the luminous cells are closely associated with the tracheae, and that during phosphorescence they withdraw oxygen from them. In 1880 B. Radziszewski showed that many fats, etherial oils and alcohols emit light when slowly combined with oxygen in alkaline fluids at appropriate temperatures. Probably the phosphorescence of organisms is due to a similar process acting on the many fats, oils and similar substances found in living cells. The colour varies much in different organisms; green has been observed in the glow-worm, fire-flies, brittle-stars, centipedes and annelids; blue in the Italian fire-fly (Luciola italica); blue and light green are the predominant colours in the phosphorescence of marine organisms, but red and lilac have also been observed. The Lantern-Fly (Fulgora pyorrhynchus) is said to have a purple light, and E. H. Giglioli has recorded that an individual Appendicularia appeared first red, and then blue, and then green, P. Panceri, chiefly in the case of Salps, and S. P. Langley and F. W. Very in the case of Pyrophorus, have investigated the light spectrosopically, and
PHOSPHORITE—PHOSPHORUS

found that it consisted of a continuous band without separate bright lines. The solar spectrum extends farther both towards the violet and the red ends, but is less intense in the green when equal luminosities are compared.

Many of the bacteria of putrefaction are phosphorescent, and the light emitted by dead fish or molluscs or flesh is probably due in every case, at least, to the miseries of the miseries of these small individuals. The bacteria of the sea-water are usually due to the presence of very large numbers of small luminous organisms, either protozoa or protophyta. Of these Noctiluca miliaris and species of Peridinium and Pyrocystis are the most frequent, the two former near land and the latter in the mid-ocean.

In higher animals the phosphorescence tends to be limited to special parts of the body which may form elaborate and highly specialized organs. The Crustacea, for instance, have numerous organs producing phosphorescent light, and the luminous body of the Phascolosoma, a specialized organ, is the so-called phosphorescent tail. In the labrum of the Ostracod Pyrocyrtis and the maxillae of the Mytilus Grazhausia similarly produce a luminous secretion. In the Euphausiacea, on the other hand, phosphorescence is produced by elaborate luminous organs which are situated on the thoracic appendages and the abdomen, and which are at first believed to be eyes or gills. The so-called phosphorescent organs of the copepods belonging to many families are luminous. A. Alloch observed that in some of the deep-sea prawns a luminous secretion was discharged at the bases of the antennae, but in most cases the luminous organs are of a more or less elaborate structure and arrangement.

The rock-boring mollusc, Pholas, which Pliny knew to be phosphorescent, has luminous organs along the anterior border of the mantle, two small triangular patches at the entrance of the anterior siphon, and two long parallel cords within the siphon. The cells of these organs have peculiar, granulated contents. W. E. Howe, in his presidential address to the Zoological Section of the British Association in 1897, brought together some observations on the light organs of certain cephalopods. In Heteroteuthis, Sepiola and Rossia the light is produced by the secretion of a glandular organ on the ventral side; but in Pholus the function is performed by the transparent wall with a greenish colour, but, at least in the case of Heteroteuthis, continues to glow after being ejected into the water. In most cases the luminous organs are nonglanular and may be simple, or possess not only a generator but a reflector, lens and diaphragm. The different organs shine with different coloured lights, and as the Cephalopods are for the most part inhabitants of the depths of the sea, it has been suggested that they serve as recognition marks. Some centipedes (e.g. Geophilus electricus and G. phosphorus) are luminous, and, if allowed to crawl over the hand, are stated to leave a luminous trail. Amongst insects, elaborate luminous organs are found in certain cases. The abalone of a Ceylonese May-fly (Tegeladenea) is luminous. The so-called New Zealand "glow-worm" is the larva of the fly Bolephilus luminosus, and some gums have been observed to be luminous, although the suggestion is that in their case disease is present and the light emanates from phosphorescent bacteria. An ant (Oryx) and a poduran (Anurophorus) are occasionally luminous. The so-called lantern flies are Allophorus, and the so-called fire-fly (Lampyris) is a huge projection of the front of the head, regarding the luminosity of which there is some doubt. The glow-worms and true fire-flies are beetles. Eggs, larvae and adults are in some cases luminous. The phosphorescence of the male of many species of fish gives the light, and a deeper layer which may act as a reflector. They are in close connection with the tracheae and the light is produced by the oxidation of a substance formed under the influence of the sex hormones. In the siliciferous genera of crustacea the phosphorescence is probably a sexual lure; in the males its function is unknown.

Phosphorescent organs known as phosphores are characteristic structures in many organs. Many coelenterates show the beginning of such localization; in medusae the whole surface may be luminous, but the light is brighter along the radial canals, in the ovariies, or in the marginal sense organs. In Penuta each polyp has eight widely spread out on the outer surface of the digestive cavity. Some Chaetopods (Chaetopera and Tomopera) have luminous organs at the bases of the lateral processes of the body. Pyrosmi, a decapod crustacean, emits the luminous display of phosphorescence in tropical seas; it has two small patches of cells at the base of each inhalent tube which on stimulation discharge light, and the luminosity has been observed to spread through the whole body from this point on outwards.

Amongst the Crustacea, many pelagic Copepods are phosphorescent. W. Giesbrecht has shown that the light is produced by a fluid secreted by certain dermal glands. A similar fluid in other Copepods is supposed to be the protecting fluid of the phosphorescent display of light is in such cases an accidental by-product. Glades in the labrum of the Ostracod Pyrocyrtis and on the maxillae of the Mytilus Grazhausia similarly produce a luminous secretion. In the Euphausiacea, on the other hand, phosphorescence is produced by elaborate luminous organs which are situated on the thoracic appendages and the abdomen, and which were at first believed to be eyes or gills. The so-called phosphorescent organs of the copepods belonging to many families are luminous. A. Alloch observed that in some of the deep-sea prawns a luminous secretion was discharged at the bases of the antennae, but in most cases the luminous organs are of a more or less elaborate structure and arrangement.

PHOSPHORITE, in mineralogy, the name given to impure massiveapatite (q.v. see also PHOSPHATES). PHOSPHORUS (Gr. φόκες, light, φειδω, to bear), the name originally given to any substance which possessed the property of phosphorescence (q.v.), i.e. the power of shining in the dark, but now generally restricted to a non-metallic element, which was first known as Phosphorus mirabilis or igneus. This element is very widely distributed in nature in combination, but is never found free. In the mineral kingdom it is exceptionally abundant, forming large deposits of phosphates (q.v.). It is also necessary to animal and vegetable life (see MANURE). It occurs in the urine, blood, tissues, and bones of animals, calcium phosphorus forming about 5% of bones, which owe their rigidity to its presence.

The element appears to have been first obtained in 1669 by Brand of Hamburg; Kraft bought his secret and in 1677 exhibited specimens in England, where it created an immense sensation. Its preparation was assiduously sought for, and Kuncke in 1768 and Boyle in 1686 succeeded in obtaining it by the same process as was discovered by Brand, i.e. by evaporating urine to dryness and distilled the residue with sand. This method was generally adopted until 1775, when Scheele prepared it from bones, which had been shown by Gahn in 1769 to contain calcium phosphate. Scheele treated bone ash with nitric acid, precipitated the calcium as sulphate, filtered, evaporated and distilled the residue with charcoal. Nicolas and Pelletier improved the process by decomposing the bone-ash directly with sulphuric acid; whilst Fourcroy and Vauquelin introduced further economies. In modern practice degreased bones (see GELATIN), or bone-ash which has lost its virtue as a filtering medium, &c., or a mineral phosphate is treated with sufficient sulphuric acid to precipitate all the calcium, the calcium sulphate filtered off, and the filtrate concentrated, mixed with charcoal, coke or sawdust and dried in a muffle furnace. The product is then distilled from Stourbridge clay retorts, arranged in a galley furnace, previously heated to a red heat. The temperature is now raised to a white heat, and the product led by malleable iron pipes into condensing troughs containing water, when it condenses. The chemical reactions are as follows: the treatment of the calcium phosphate with the acid gives phosphoric acid, H₂PO₄, which at a red heat loses water to give metaphosphoric acid, H₃PO₄; this at a white heat reacts with carbon to give hydrogen, carbon monoxide and phosphorus, thus: 2H₂PO₄ + 6C = H₂ + 6CO + P₄.

Electrothermal processes have also employed. Calcium phosphate, mixed with wood ash and carbon, is fed into an electric furnace. The muffle is provided with a closely fitting cover with an outlet leading to a condenser. At the temperature of the furnace the silica (sand) attacks the calcium phosphate, forming silicate, and setting free phosphorus pentoxide, which is attacked by the carbon, forming phosphorus and carbon monoxide. As phosphorus boils at 209°C (545°F.), it is produced in the form of vapour, which, mingled with carbon monoxide, passes to the
condenser, where it is condensed. It is then cast under water. The calcium silicate remains in the furnace in the form of a liquid slag, which may be run off, so that the action is practically continuous. Kaolin may with advantage be used as addition to or in part substitution for sand, because the double silicate thus formed is more fusible than the single silicate of lime. The alternating current is generally used, the action not being electrolytic. One of the special advantages of the electrical over the older process is that the distilling vessels have a longer life, owing to the fact that they are not externally heated, and so subjected to a relatively high temperature when in contact with the corrosive slag formed in the process. The Readman-Parker process (see Jour. Soc. Chem. Ind., 1891, x. 443) appears to be very generally adopted. Readman, experimenting with a Cowles furnace in the United States patent department, and in the same year Parker and Robinson, working independently, patented a similar one. The two inventors then cooperated, and an experimental plant was run successfully, and the patents were taken over by the leading manufacturers. With the object of obtaining a valuable by-product in place of the slag produced in this furnace, several patentees (e.g. Hilbert and Frank, Billaudot, Bradley and Jacobs, and others) have sought to combine the manufacture of calcium carbide and phosphorus by using only calcium phosphate and carbon, effecting direct reduction by carbon at a high temperature.

The crude phosphorus is purified by melting under water and then filtering through animal black and afterwards through chamois leather, or by treating it, when molten, with chromic acid or a mixture of potassium bichromate and sulphuric acid; this causes the impurities to rise to the surface as a scum which can be skimmed off. It is usually sent on the market in the form of sticks, which were at one time prepared by sucking the molten material up glass tubes; but the dangers to the workmen and other disadvantages of this method have led to its replacement by a continuous process, in which the phosphorus leaves the molten-pot for a pipe surrounded by water, in which it solidifies and can be removed as a continuous rod.

**Phosphorus.**—When perfectly pure phosphorus is a white, transparent, waxy solid, but as usually prepared it is yellowish owing to the presence of the allotrope "red phosphorus," J. Böseken (Abh. Jour. Chem. Soc., 1907, ii. 343, 760) prepares perfectly pure phosphorus by heating the crude product with chromic acid solution, washing and drying in a vacuum, first at 40°, then at 80°. It remains colourless in vacuum tubes in the dark, but on exposure it rapidly turns yellow. At 25° to 30° C. it is soft and flexible, but it hardens when strongly cooled, and can then only be cut with difficulty. The fracture is distinctly crystal-like; large crystals, either regular dodecahedra or octahedra, may be obtained by crystallization from carbon bisulphide, sulphur chloride, &c., or by sublimation. It is a non-conductor of electricity. Its density at 0° is 1.936; this regularly diminishes up to the melting-point, 44°, when a sudden drop occurs. Molten phosphorus is a viscous, oily, highly refractive liquid, which may be supercooled to 32° before solidification. It boils at 209°, forming a colourless vapour which just about the boiling-point corresponds in density to tetrametric molecules, P4; at 1500° to 1700°, however, Biltz and Meyer detected dissociation into P3 molecules. Beckman obtained P4 molecules from the boiling-point of carbon bisulphide solutions, and Hertz arrived at the same conclusion from the lowering of the freezing-point in benzene solution; E. Pernot and Nasini, however, detected dissociation. Phosphorus is nearly insoluble in water, but dissolves in carbon bisulphide, sulphur chloride, benzene and oil of turpentine.

The element is highly inflammable, taking fire in air at 34° and burning with a bright white flame and forming dense white clouds of the pentoxide; in perfectly dry air or oxygen, however, it may be distilled unchanged, H. B. Baker showing that a trace of water vapour was necessary for combination to occur. When exposed to the air a stick of phosphorus undergoes slow combustion, which is revealed by a greenish-white phosphorescence when the stick is viewed in the dark. This phenomenon was minutely studied by Boyle, who found that solutions in some essential oils (oil of cloves) showed the same character, whilst in others (oils of mace and unseed) there was no phosphorescence. He also noticed a strong garlic-like odour, which we now know to be due to oxygen. Frederick Slare noticed that the luminosity increased when the air was rarefied, an observation confirmed by Hawkses and Homberg, and which was possibly the basis of Berzelius's theory that the luminosity depended on the volatility of the element and not on the presence of oxygen. Lampadius, however, showed that there was no phosphorescence in a Torricellian vacuum; and other experimenters proved that oxygen was essential to the process. It depends on the partial pressure of the oxygen and also on temperature. In compressed air at ordinary temperature there is no glowing, but it may be brought about by reducing the air pressure. Again, in oxygen under ordinary conditions there is no phosphorescence on being heated. In oxygen at 25° glowing occurs, as is also the case if the pressure be diminished or the gas diluted. It is also remarkable that many gases and vapours, e.g. Cl, Br, I, NH3, N2O, NO, H2, SO2, CS2, CH4, C2H4, inhibit the phosphorescence.

The theory of this action is not settled. It is certain that the formation of hydrogen peroxide and ozone accompany the glowing, and in 1848 Schonbein tried to demonstrate that it depended on the ozone. E. Jungfleisch (Comptes rendus, 1905, p. 444) suggested that it is due to the combustion of an oxide more volatile than phosphorus, a view which appears to be supported by the observations of Scharff (Zeit. physik. Chem., 1906, 62, p. 178) and of L. and E. Bloch (Comptes rendus, 1906, 147, p. 842).

The element combines directly with the halogens, sulphur and selenium, and most of the metals burn in its vapour forming phosphides. When finely divided it decomposes water giving hydrogen phosphide; it also reduces sulphurous and sulphuric acids, and when boiled with water gives phosphine and hypophosphoric acid; when slowly oxidized under water it yields hypophosphoric acid.

**Allotropic Phosphorus.**—Several allotropic forms of phosphorus have been described, and in recent years much work has been done towards settling their identities. When the ordinary form immersed in water is exposed to light, it gradually loses its transparency and becomes coated with a thin film. This substance was regarded as an allotrope, but since it is not produced in non-aerated water it is probably an oxide. More important is the so-called "red phosphorus," which is produced by heating yellow phosphorus to about 230° for 24 hours in an inert atmosphere, or in closed vessels to 300°, when the change is effected in a few minutes. E. Kopp in 1844 and B. C. Brodie in 1853 showed that a trace of iodine also expedited the change. The same form is also produced by submitting ordinary phosphorus to the silent electric discharge, to sunlight or the ultra-violet light. Since this form does not inflame until heated to above 350°, it is manufactured in large quantities for consumption in the match industry. The process consists in heating yellow phosphorus in iron pots provided with air-tight lids, which, however, bear a long pipe open to the air. A small quantity of the phosphorus combines with the oxygen in the vessel, and after this the operation is practically conducted in an atmosphere of nitrogen with the additional safety from any risk of explosion. The product is ground under water, and any unchanged yellow form is eliminated by boiling with caustic soda, the product being then washed and dried and finally packed in tin boxes. The red variety is remarkably different from the yellow. It is a dark red microcrystalline powder, insoluble in carbon bisulphide, oil of turpentine, &c., and having a density of 2.2. It is stable to air and light, and does not combine with oxygen until heated to above 350° in air or 260° in oxygen, forming the pentoxide. It is also non-poisonous. When heated in a vacuum to 320° it sublimes, and on condensation forms microscopic needles.

Hittorf's phosphorus is another crystalline allotrope formed by heating phosphorus with lead in a sealed tube to redness, and removing the lead by boiling the product with nitric and
PHOSPHORUS

hydrochloric acid. It is also obtained by heating red phosphorus under pressure to 580°. It forms a lustrous, nearly black crystalline mass, composed of minute rhombohedra. G. E. Link and P. Möller (Ber., 1898, 41, p. 1404) have confirmed that the product of the first process always contains lead. E. Cohen and J. Olie, Jun. (Abs. Jour. Chem. Soc., 1909, ii, 998), regard red phosphorus as a solid solution of the white in Hittorf's, but this is contradicted by A. Stock (Ber., 1909, 42, p. 4510), who points out that ordinary red phosphorus melts at 605°-610°, whilst Hittorf's melts at 620°; moreover, the latter is less reactive than the former at high temperatures.

Another isomer, yellow phosphorus, is formed by R. Schenck (Zeits. Elektrochem., 1905, ii, 147) as a scarlet amorphous powder by deposition of solutions of phosphorus in the tri-iodide, tribromide or sulphide (P2S5).

It phosphoresces in ozone, but not in air, and is non-poisonous; from its solution in alcoholic potash acids precipitate the hydride, PH3H2, and when heated it is transformed into the red modification. It has been used in combination with potassium chlorate as a composition for matches to strike on any surface. Finally a black phosphorus was described by Thénard as formed by rapidly-cooling melted phosphorus.

Phosphine (phosphoretated hydrogen), PH3, a gas formed in the putrefaction of organic matter containing phosphorus, was obtained by Bunsen and Hittorf, 1869, 4, 1089. In the presence of moist air, phosphine readily combines with water to form phosphoric acid. There is a phase of phosphorus, produced by Hittorf, called phosphine, which is not phosphorus at all, but a hydride, PH3H2, and when heated it is transformed into the red modification. It has been used in combination with potassium chlorate as a composition for matches to strike on any surface. Finally a black phosphorus was described by Thénard as formed by rapidly-cooling melted phosphorus.

PHOSPHORUS

481

other oxides, when the element is burnt in a limited supply of air or in pure oxygen under reduced pressure (E. Jungfleisch, Abs. Jena. Chem. Soc. Roy. Soc. 1910, 1, 111). The reaction is:

\[ \text{P} + 3\text{O}_2 \rightarrow \text{P}_2\text{O}_3 \]

The phosphorus oxides are obtained by heating phosphorus in the trichloride or trichloride is exposed to light. It is a yellow or red powder which becomes dark red on heating; it is stable in air, and can be heated to 300° without decomposition. Its ex-

isolation is mainly obtained by heating phosphorus in a mixture of meta- and pyrophosphates, with a little phosphorus.

They react as reducing agents. On boiling with caustic potash they evolve hydrogen, yielding a phosphine.

Hydrogen phosphates, discovered by Davy in 1812, may be prepared by dissolving its anhydride, P\textsubscript{2}O\textsubscript{5}, in cold water; by mixing sticks of phosphorus in a solution of copper sulphate contained in a well-closed flask, filtering off the copper sulphide produced, and adding phosphorus dissolved in baryta water, and concentrating the solution in vacuo; or by passing chlorine into melted phosphorus covered with water, the solution decomposing into phosphorus and hydrochloric acids. It may also be prepared by yielding a phosphorus trichloride at 60° and passing the vapours into water at 0°, the crystals thus formed being purified by washing with water, and converted into the acid by the double dissociation:

\[ \text{H}_2\text{PO}_4 + \text{H}_2\text{O} \rightarrow 2\text{H}_2\text{O} + \text{P}_2\text{O}_5 \]

The crystals melt at 70°. The acid is very deliquescent, and oxidizes on exposure to air to phosphoric acid. It decomposes on heating into phosphorus and phosphoric acid. It is an energetic reducing agent, and when added to copper sulphate solutions, metallic copper is precipitated and hydrogen evolved. Although nominally tribasic the commonest metallic salts are dibasic. Organic ethers, however, are known in which one, two and three of the hydrogen atoms of phosphoric acid may be replaced by one, two, or three of the hydrogen atoms of ethyl alcohol. The metallic phosphites are stable both dry and in solution; when strongly heated they evolve hydrogen and yield a pyrophosphite, the reaction being much more rapid than with the oxides. They give hydrogen and a mixture of phosphorus and pyrophosphorus.

Hydrophosphoric acid, H\textsubscript{3}PO\textsubscript{4} or H\textsubscript{3}PO\textsubscript{4}, discovered by Salzer in 1877 among the oxidation products of phosphorus by moist air, may be prepared by oxidizing phosphorus in an aqueous solution of copper nitrate, or by oxidizing sticks of phosphorus under water, neutralizing with sodium carbonate, forming the lead salt and decomposing this with sulphuretted hydrogen (J. Cavaliere and E. Cornee, Abs. Jena. Chem. Soc. Roy. Soc. 1910, 1, 111). The solution may be boiled without decomposition, but on concentration it yields phosphoric acid and phosphoric acid. Difluence, rectangular tablets of H\textsubscript{3}PO\textsubscript{4}H\textsubscript{2}O separate out on concentrating a solution of phosphoric acid. At phosphoric acid above 45°, and decomposes suddenly when heated to 70° into phosphorus and metaphosphoric acids with a certain amount of hydrogen fluoride. The solution is strongly oxidizing, and in contact with argentum nitrate, copper nitrate, or lead nitrate, the metal is dissolved, and in solution is strongly alkaline; the acid salt, Na\textsubscript{2}H\textsubscript{2}PO\textsubscript{4}, forms monoclinic crystals. The formula of the acid is not quite definite. Cryoscopic measurements on the sodium salt point to its existence as a form: \( \text{Na}_2\text{H}_2\text{PO}_4 \). The formula of the acid is obtained from H\textsubscript{2}PO\textsubscript{4} (see A. Rosenheim and M. Pritze, Ber. 1908, 41, 2708; E. Cornee, Abs. Jena. Chem. Soc. Roy. Soc. 1910, 1, 111).

Monophosphoric and phosphoric acids, H\textsubscript{3}PO\textsubscript{4} and H\textsubscript{3}PO\textsubscript{4}, were studied by W. von Miesch, Abs. Jena. Chem. Soc. Roy. Soc. 1910, 1, 112.

The first is formed when 30° hydrogen peroxide reacts with phosphorus pentoxide or meta- or pyrophosphoric acids at low temperatures and the mixture distilled with iced-cold water. The solution is strongly oxidizing, even converting nitrogen as ammonia to nitrate. Potassium permanganate in the cold, a property not possessed by monopersulfuric acid.

Perphosphoric acid is formed when phosphoric acid is treated with a large excess of hydrogen peroxide.

Halogen Compounds.—Phosphorus trifluoride, PF\textsubscript{3}, discovered by Davy, may be obtained mixed with the pentfluoride; by direct combination of its elements; from the trichloride and arsenic trifluoride; or from phosphorus, hydrogen fluoride, and copper chloride. Phosphorus trifluoride reacts with copper phosphide and lead fluoride (H. Moisson). It is a colourless, non-fuming gas, which gives a colourless, mobile liquid at ~16° and 20 atmospheres; the liquid boils at ~16° and solidifies at ~16° (Moisson, Comptes rendus, 1904, 138, p. 295). It does not burn in air, but it explosively, under the action of a flame or the electric spark, when mixed with half its volume of oxygen, giving the oxyfluoride, PO\textsubscript{3}F. It is slowly decomposed by water giving hydrofluoric and phosphoric acids, and hydrogen fluoride.

It has no action in glass in the cold, but when heated it gives phosphorus and silicon tetrafluoride. Phosphorus pentfluoride, Pf\textsubscript{5}, discovered by Thorpe (Proc. Roy. Soc. 1917, 27, p. 122), may be obtained by burning phosphoric and phosphorus pentoxide, and crystallizing the filtrate. The acid may be prepared by evaporating in a vacuum the solution obtained by decomposing the barium salt with the equivalent amount of sulphuric acid. The acid forms a white crystalline mass, melting at 17.4° and having a strong acid reaction. Exposure to air gives phosphorus and phosphoric acids, and on heating it gives phosphine and phosphoric acid. A red precipitate on phosphoric acid, Cu\textsubscript{3}H\textsubscript{2}PO\textsubscript{4}, when heated with copper carbonate to 60°, is a monobasic acid forming salts which are permanent in air, but which are gradually oxidized in aqueous solution. On the other hand, it decomposes in meta- and pyrophosphates, or a mixture of meta- and pyrophosphates, with a little phosphorus. They react as reducing agents. On boiling with caustic potash they evolve hydrogen, yielding a phosphine.
PHOSPHORUS

acids. It does not dissociate on heating as do the pentachloride and pentabromide, thus indicating the existence of pentavalent phosphorus in a gaseous compound; dissociation, however, into the trifluoride and free fluorine may be brought about by heating in a closed tube at 17°, or by heating with potassium trifluoride, KF\(\text{F}_3\), when some potassium fluoride is formed, which combines with ammonia to give the proportion 2\(\text{PF}_3\)+5\(\text{NH}_3\), and with nitrogen peroxide at \(-10^\circ\) in the proportion \(\text{PF}_3\cdot\text{NO}\). Phosphorus trifluoride, \(\text{PF}_3\cdot\text{Cl}\), prepared from the chloride, is an odourless, colourless, and amorphous gas, which at \(250^\circ\) gives the pentachloride and fluorine. The trifluorobromide (see above) is an amber-coloured mobile liquid. Phosphoryl trifluoride, \(\text{POF}_3\), may be obtained by exploding 2 volumes of phosphorus pentfluoride with 1 volume of oxygen (Molaison, 1880), or by heating 2 parts of finely-divided cryolite and 3 parts of phosphorus pentoxide (Thorp and Hambly, *Jour. Chem. Soc.*, 1889, p. 759); or from phosphorus chloride and zinc fluoride at 40°. Phosphoryl trifluoride is a mobile colourless liquid, which under ordinary pressure at \(-5^\circ\), and under a pressure of 15 atmospheres at \(16^\circ\), may be solidified to a snow-like mass. Water gives hydrofluoric and phosphoric acid. The corresponding sulphur compound, chloride, fluoride, \(\text{PSF}_3\), obtained by heating lead fluoride and phosphorus pentasulphide to \(200^\circ\), is a colourless gas, which may be condensed to a clear transparent liquid. It spontaneously infurnaces in air or oxygen; and when the gas is issuing from a jet into greyish green, with a faintly luminous and yellow tip; the flame is probably one of the coldest known. The combustion probably follows the equation \(\text{PSF}_3+\text{O}_2=\text{PS}_4\cdot\text{F}_2+\text{O}_2\), the pentachloride and oxide being the dissociation products of the burning (taking \(2\text{PF}_3\)+5\(\text{NH}_3\)=2\(\text{PF}_3\cdot\text{F}_3\)+\(\text{NO}\) as the complete reaction tending to the equation: \(10\text{PF}_3+13\text{O}_2=6\text{PF}_3\cdot\text{F}_3+6\text{PF}_4\cdot\text{O}_{10}\), \(2\text{PF}_3\cdot\text{F}_3+\text{O}_2=2\text{PF}_3\cdot\text{F}_3+\text{O}_2\)); this oxidation gives away with difficulty oxygen, \(\text{H}_2\cdot\text{H}_2\text{PO}_3\cdot\text{O}_4\), but is more readily taken up by alkyls with the formation of fluoride and thiophosphate: \(\text{PSF}_3+6\text{NaOH}=\text{Na}_3\text{P}_3\text{O}_7+3\text{NaF}\). Heated in a glass tube it gives allies fluorides and sulphur, and is at first black, \(\text{SiF}_3\cdot\text{P}_3\cdot\text{O}_4\). Electric sparks give at first free sulphur and the trifluoride, the latter at a higher temperature splitting into the pentfluoride and phosphorus. With dry ammonia it gives ammonia, and with water, \(\text{H}_2\cdot\text{H}_2\text{PO}_3\cdot\text{O}_4\). Phosphorus trichloride or phosphorous chloride, \(\text{PCl}_3\), discovered by Gay-Lussac and Thénard in 1808, is obtained by passing a slow current of chlorine over heated red phosphorus or through a solution of phosphorus pentachloride in carbon disulphide or carbon tetrachloride (the last method being given by P. Fournier, *Jour. Chem. Soc.*, 1840, p. 2062; 1910, 43, pp. 150, 414) that shows three exist, \(\text{PCl}_3\cdot\text{PCl}_5\). The first is prepared by heating red phosphorus with finely powdered sulphur in a tube sealed at one end and filled with carbon dioxide. The second, \(\text{PCl}_3\cdot\text{PCl}_5\), is prepared by dissolving the free red phosphorus acid being produced by the interaction of the previously formed sulphuric acid, and phosphoric acid. Phosphorus trichloride, (\(\text{PCl}_3\)=\(\text{PCl}_5\)), and phosphorus trichloride, \(\text{PCl}_3\)=\(\text{PCl}_4\), are alike.

Phosphorus forms three iodides. The subiodide, \(\text{PI}_3\), was obtained by R. Boulough (*Comptes rendus*, 1905, 141, p. 256), who acted with dry iodine on phosphorus dissolved in carbon disulphide; and phosphorus, \(\text{PI}_3\), was obtained by the ordinary method; \(\text{PCl}_3\cdot\text{PI}_3\). There is a similar compound, \(\text{PCl}_5\cdot\text{PI}_3\), which is formed when the pentachloride acts with sodium hydrosulphide at \(26^\circ\). All the phosphates are decomposed by acids giving sulphotetated hydrogen and sometimes free sulphur. They also act in many cases as reducing agents.

*Nitrogen Compounds.—Phosphorus pentachloride combines directly with ammonia, and the compound when heated to redness loses ammonia chloride and hydrochloric acid and gives phosphorus trichloride, \(\text{PCl}_3\cdot\text{NH}_3\), a first described by Davy in 1814. It is a white, insubflectable, and very solid, which decomposes water on heating, giving ammonia and metaphosphoric acid, whilst alkalies give an analogous reaction. With methyl and ethyl alcohol it forms methyl and ethyl phosphates, \(\text{MeC}_2\text{H}_4\text{PO}_4\) and \(\text{EtC}_2\text{H}_4\text{PO}_4\), obtained by heating the above solution only to \(50^\circ\) or \(60^\circ\) and the mixture is a salt in which the dihydroxy is combined with the pentachloride acts with sodium hydrosulphide at \(26^\circ\). All the phosphates are decomposed by acids giving sulphotetated hydrogen and sometimes free sulphur. They also act in many cases as reducing agents.

Acids obtained by the decomposition of the pentachloride, 

\[\text{PCl}_5\cdot\text{NH}_3\rightarrow\text{PCl}_3+\text{NH}_3\cdot\text{H}_2\text{O}\]

When it is boiled with water, the phosphorus trichloride is formed, and with carbon dioxide, anhydrous ammonia, and sulphuric acid: 

\[\text{PCl}_5\cdot\text{NH}_3+\text{CO}_2\rightarrow\text{PCl}_3+\text{NH}_2\text{C}_2\text{H}_4\text{CO}_2\text{H}\]

When the pentachloride acts with sodium hydrosulphide at \(26^\circ\), it is a white, insubflectable, and very solid, which decomposes water on heating, giving ammonia and metaphosphoric acid, whilst alkalies give an analogous reaction. With methyl and ethyl alcohol it forms methyl and ethyl phosphates, \(\text{MeC}_2\text{H}_4\text{PO}_4\) and \(\text{EtC}_2\text{H}_4\text{PO}_4\), obtained by heating the above solution only to \(50^\circ\) or \(60^\circ\) and the mixture is a salt in which the dihydroxy is combined with the pentachloride acts with sodium hydrosulphide at \(26^\circ\). All the phosphates are decomposed by acids giving sulphotetated hydrogen and sometimes free sulphur. They also act in many cases as reducing agents.

**Phosphoric acid** is a colourless, mobile liquid, boiling at \(125^\circ\) and having a pungent, slightly aromatic odour. It is slowly decomposed by water giving phosphoric and hydrochloric acids, with sulphured hydrogen; alkalis form a thioephosphate, e.g. \(\text{PS}(\text{OH})\), and a triiodide, \(\text{PI}_3\), formed by mixing solutions of its elements in carbon disulphide and dissolving in water, boiling at \(175^\circ\) and resembling the trichloride chemically. The pentabromide, \(\text{PBr}_5\), which results from phosphorus and an excess of bromine, is a yellow solid, and closely resembles the pentafluoride, \(\text{PF}_5\), a solid, 

\[\text{PCl}_5+\text{Br}_2=\text{PBr}_5+\text{PCl}_3\]

acted with bromine the mixture was boiled and gave a yellow octahedra which melt at \(38^\circ\), and have a penetrating, aromatic odour. With water it gives sulphur, sulphuric acid, hydrochloric acid, and, in solution, a pungent, yellow acid being produced by the interaction of the previously formed sulphuric acid and phosphoric acid. Phosphoryl triiodide, (\(\text{PI}_3\)=\(\text{PI}_2\)), and phosphomyl triiodide, \(\text{PBr}_3\cdot\text{I}_2\), are alike.

Phosphorus forms three iodides. The subiodide, \(\text{PI}_3\), was obtained by R. Boulough (*Comptes rendus*, 1905, 141, p. 256), who acted with dry iodine on phosphorus dissolved in carbon disulphide; and phosphorus, \(\text{PI}_3\), was obtained by the ordinary method; \(\text{PCl}_3\cdot\text{PI}_3\). There is a similar compound, \(\text{PCl}_5\cdot\text{PI}_3\), which is formed when the pentachloride acts with sodium hydrosulphide at \(26^\circ\). All the phosphates are decomposed by acids giving sulphotetated hydrogen and sometimes free sulphur. They also act in many cases as reducing agents.
PHOTIUS

483

1893, 15, p. 165; 1894, 16, pp. 123, 154) has described PO(OH)NH and PO(OH)(NH)3 whilst the compound PO(OH)(OH) was obtained by Schiff (Ann., 1857, 103, p. 168) by acting with ammonium persulphate. Numerous other nitrogen compounds have been obtained.

The atomic weight of phosphorus was determined by Berzelius, Puckle, Berthollet, Bunsen, and van den Bergh. More recent are the investigations of G. Ter Gazarian (Comm. rend., 1909, 148, p. 1397) on hydrogen phosphate, which gave the value 30-906, and of G. F. Baxter and G. Jones (Journ. Amer. Chem. Soc., 1902, 32, p. 298) on silver phosphate, which gave the value 31-04.

Theophrastus.—The phosphorus used in the British pharmacopoeia is obtained from calcium phosphate, and is a waxy-like non-metallic substance soluble in oils and luminous in the dark. There are various medicinal preparations. In young animals phosphorus has a remarkable influence on the growth of bone, causing a proliferation of the jelly-like masses and finally a deposit in them of true bony material. Owing to this influence it has been used in rickets and osteomalacia. Its most effective use, however, is as a nerve tonic in paralysis agitans, locomotor ataxia, impotence and nervous exhaustion. In some skin diseases such as psoriasis, chronic eczema and acne inducta, phosphorus is very useful, and cases of diabetes mellitus and lymphadenoma have improved under some of its compounds.

The hypophosphites have been recommended in pulmonary affections, being said to act as free phosphorus without being irritant, and the glycerophosphates are certainly useful to stimulate metabolism. Dilute phosphoric acid is used as a gastric stimulant. It does not resemble phosphorus in its physiological action and cannot be used to replace it.

Toxicology.—Poisonous amounts of phosphorus are frequently taken or administered, criminally or accidentally, it being easily accessible to the public in the form of matches or of vermin pastes. They may have been swallowed several hours before symptoms of acute poisoning show themselves, with nausea and vomiting, and a burning in the oesophagus, stomach, and abdomen. The important thing is to prevent the absorption of the poison, so emetics and purgatives should be given at once. Sulphate of copper, in doses of 3 to 5 gr., freely diluted and repeated every few minutes forms the harmless, black phosphide of copper, which is rapidly eliminated by the kidneys. The stomach may be washed out with warm water and then with a 2% solution of permanganate of potash, an enema of the same solution being given. The old French oil of turpentine is the best antidote to use in phosphorus poisoning, delaying the effect of the poison. It is said to be harmful. When some time has elapsed before treatment and the phosphorus has become absorbed, the organic degenerative changes cannot be easily controlled. For the chronic form of industrial poisoning in the manufacture of Lucifer matches—a form of aspho get and in France as "mai chimique," a localized inflammatory infection of the peritoneum, ending with the death and exfoliation of part of the bone—see MATCH.

PHOTIUS (c. 830–891), patriarch of Constantinople (858–867, and 876–886). From his early years he displayed an extraordinary talent and appetite for knowledge, and as soon as he had completed his own education he began to amass books and distill their wisdom. He is said to have had a library of twenty thousand volumes of all kinds of subjects, especially字典 and philosophy. The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. The dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful Emperor Michael III., brought promotion to Photius. Ignatius was arrested and imprisoned (Nov. 858), and upon refusing to resign his office was illegally deposed, while Photius, although a layman, received all the necessary ecclesiastical orders within six days, and was installed as patriarch in his place. Photius, continuing to refuse the abbot's mitre, which could alone have given Photius's elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and when in 863 Nicholas finally anathematized and deposed him, he replied by a counter-excommunication. Meanwhile, the situation was suddenly changed by the murder of Photius's patron, Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and Ignatius was reinstated on the 23rd of November. About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius, after a decent show of reluctance, again filled the patriarchal throne. He then proceeded to obtain the formal recognition of the Christian world. In November 879 a synod was convened at Constantinople. The legates of Pope John VIII. attended, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was rewarded by the submission of Basil. He stood firm, however, on the other two points which had long been contested between the Eastern and Western Churches, the ecclesiastical jurisdiction over Bulgaria and the introduction of the "filioque" clause into the creed. He disowned his legates, who had shown a tendency to yield, again excommunicated Photius, and thus aroused the open hostility which has never been appealed to this day. Strong in the support of the council, Photius simply ignored him. At the height of glory and success he was suddenly precipitated from his dignity by another palace revolution. After the death of Basil (886), his son and successor Leo, who had formerly been devoted to Photius, but in recent years displayed great hatred towards him, deprived him of his office and banished him to the monastery of Porta Panagia. From this time Photius disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on the 6th of February 891.

For long after Photius's death his memory was held in no special honour by his countrymen. But when, in the crusading age, the Greek Church and state took an attitude in defence from Latin encroachments, Photius became a national hero, and is at present regarded as little short of a saint. To this character he has not the least pretension. Few men, it is probable, have been more atrociously calumniated; but when the particulars of his case have been rejected, he still appears on a general review of his actions worldly, crafty and unscrupulous. Yet he shows to no little advantage as an ecclesiastical statesman. His Bardas opposed the Nestorian heresy, and Photius was instrumental in supporting and furthering it. He supported good and evil fortune with equal dignity; and his fall was op both occasions due to revolutions beyond his control. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary.

The most important of the works of Photius is his renowned Bibliotheca or Myriobiblon (ed. I. Bekker, 1824–1825), a collection of excerpts from and abridgments of 280 volumes of classical authors (usually cited as Codices), the original of which are now to a great extent lost. The work is specially rich in extracts from historical writers. To Photius we are indebted for almost all we possess of the writings of Demosthenes, Herodotus, Thucydides, Heracleides, and Synesius. The lost writings of Arrian. Theology and ecclesiastical history are also very fully represented, but poetry and ancient philosophy are almost entirely ignored. It seems that he did not think it necessary to deal with those authors with whom every well-educated man would naturally be familiar. The literary criticisms, generally distinguished by keen and independent judgment, and the excerpts, vary considerably in length. The numerous biographical notices, taken from the works of Hesychius and Miltius. The Lexicon (Mewg Zovangwr), published later than the Bibliotheca, was probably in the main the work of some of his pupils. It was intended as a book of reference to facilitate the reader's acquaintance with the vocabulary, and its contents are of great value. The only MS. of the Lexicon is the Codex Galeanus, formerly in the possession of Thomas Gale (q.v.), and now in the library of Trinity College, Cambridge (ed. S. A. Nasen, 1864), and of the English translation and valuable indices). His most important theological work is the Ambrosian, a collection of some 300 questions and answers on difficult points in Scripture, addressed to Ambrose, archbishop of Cyzicus (ed. Sophocles Oeconomus, Athens, 1820). Other similar works are his treatise in four books.
PHOTOCHEMISTRY

Fabricius, Bibliotheca hydrocarbon, x. 670–776, xl. 1–37; C. Krumbacker, Geschichte der byzantinischen Literatur, pp. 73–79, 515–524 (2nd ed., 1897); J. E. Sandys, History of Classical Scholarship (2nd ed., 1906).

PHOTOCHEMISTRY (Gr. φως, light, and "chemistry"), in the widest sense, the chemical science which deals with the chemical properties of substances and their relations to light and heat; and the narrower sense it is concerned with the action of light on chemical change. The first definition includes such subjects as refractive and dispersive power, colour, fluorescence, phosphorescence, optical isomerism, spectroscopy, &c.—subjects which are treated under other headings; here we only discuss the subject matter of the narrower definition.

Photochemistry was associated with the darkening of certain silver salts under the action of light, processes which were subsequently utilized in photography (q.v.). At the same time, however, it had been observed that other chemical changes were regulated by the action of light; and the first complete study of such a problem was made by J. W. Draper in 1843, who investigated the combination of hydrogen and chlorine to form hydrochloric acid, a reaction which had been previously studied by Gay-Lussac and Thénard. Draper concluded that the first act of sunlight consisted in producing an allotrope of chlorine, which subsequently combined with the hydrogen. This was denied by Bunsen and Roscoe in 1857; and in 1887 Pringsheim suggested that the reaction proceeded in two stages: H₂O + Cl₂ = Cl₂O + H₂, 2H₂ + Cl₂O = H₂O + 2HCl. This view demands the presence of water vapour (H. B. Baker showed that the perfectly dry gases would not react), and the chlorocarbons, while forming, are unstable (the "photochemical induction" of Bunsen and Roscoe) as taken up by the formation of the chlorine monoxide necessary to the second part of the reaction. The decomposition of hydriodic acid into hydrogen and iodine was studied by Lemoine in 1877, who found that 80% decomposed after a month's exposure; he also observed that the reaction proceeded quicker in blue vessels than in red. A broader work was published by P. L. Chaustain in 1878, who showed that the red rays generally oxidized inorganic compounds, whilst the violet reduces them, and that with organic compounds the action was entirely oxidizing. These and other reactions suggested the making of artificial suns or instruments for simulating the actinic effect of light waves.

Chlorine combines with half its volume of methane explosively in sunlight, whilst in diffused light it substitutes; with toluene it gives benzyl chloride, C₇H₅CH₂Cl, in sunlight, and chlorotoluene, C₆H₅(CH₂)Cl, in the dark; with benzene it gives an addition product, C₇H₈Cl₂, in sunlight, and substitutes in the dark. Bromine deports itself similarly, substituting and forming addition products with unsaturated compounds more readily in sunlight. Sometimes isomerization may occur; for instance, an aldehyde reacts with the addition of chlorine in the dark, and dibromtiglic acid in sunlight. Many substances decompose when exposed to sunlight; for example, alkyl iodides darken, owing to the liberation of iodine; aliphatic acids (especially dibasic) in the presence of uranic oxide lose carbon dioxide; polyhydric alcohols give products identical with those produced by fermentation; whilst aliphatic ketones give a hydrocarbon and an acid.

Among aromatic compounds, benzaldehydes produce a trimeric and tetrameronic benzaldehyde, benzoic acid and hydrobenzoin (G. L. Ciamiciana and P. Silber, Atti. R. Accad. Lincei, 1906), in alcoholic solution it gives hydrobambus; whilst with nitrobenzene the nitrobenzene suffers reduction to nitrobenzene and phenyl-β-hydroxylamine; the latter isomerizes to ortho- and para-aminophenol, which, in turn, combine with the previously formed benzoic acid. Similarly acetophenone and benzophenone in alcoholic solution give dimethylhydrobenzoin and benzopinacine. With nitro compounds, in the ortho position to the NO₂ group were decomposed by light. For example, ortho-nitrobenzaldehyde in alcoholic solution gives nitrosobenzene and ester azoxybenzoic acid, with the intermediate formation of nitrobenzaldehydediethylic alccol, NO₂CH₂CH2(OCH₃)₂ (E. Bamberger and F. Elgar, Ann. 1907, 371, p. 310). Bamberger also investigated nitrobenzene, obtaining azoxybenzene as chief product, together with various azo compounds, nitrobenzene, aniline, hydroquinone and a resin.

For the photochemistry of diazo derivatives see Ruff and Stein, Ber., 1901, 34, p. 1668, and of the terpenes see G. L. Ciamiciana and P. Silber, Ber., 1907 and 1908.

Light is also powerful in producing isomerization and polymerization. Isomerization chiefly appears in the formation of stable stereoisomers from the labile forms, and more rarely in inducing real isomerization or phototropy (Markwald, 1890). As examples we may notice the observation of Chattaway (Journ. Chem. Soc. 1906, 89, p. 462) that many phenylhydrazones (yellow) change into azo compounds (red), of M. Poda and F. Elgar, Ann. 1907, 371, p. 310; of J. J. de Heer and E. Stroemer, who, in a similar manner, studied the effect of light on the β-naphthylhydrazones (the α-compounds are not phototropic), and of A. Senier and F. G. Shephard (Journ. Chem. Soc. 1906, 95, p. 1493) on the aryldiene- and naphthylidine-amines, which change from yellow to orange on exposure to sunlight. Light need not act in the same direction as heat (changes due to heat may be termed thermotropic). For example, heat changes the a-form of benzyl-β-aminoanisotenic ester into the β form, whereas light reverses this; similarly heat and light have reverse actions with α-diphenyl ethylene, C₆H₅-C(C₆H₅)₂ (R. Stoecker, Ber., 1909, 42, p. 4865); the change, however, is in the same direction with Senier and Shephard's compounds. With regard to polymerization we may notice the production of benzene derivatives from acetylène and a homologue, and of tetramethylenes from the olefins.

Theory of Photochemical Action.—Although much work has been done in the qualitative and quantitative study of photochemical reactions relatively little attention has been given to the theoretical explanation of these phenomena. That the solution was to be found in an analogy to electrolysis was suggested by Grothuss in 1818, who laid down: (i) only those rays which are absorbed can produce chemical change, (ii) the action of the light is analogous to that of a voltaic cell; and he regarded light as made up of positive and negative electricity. The first principle received early acceptance; but the development of the second is due to W. D. Bancroft, who, in a series of
PHOTOGRAPHY

PHOTOGRAPHY (Gr. φως, light, and γράφειν, to write), the science and art of producing pictures by the action of light on chemically prepared (sensitized) plates or films.

History.

It would be somewhat difficult to fix a date when what we now know as "photographic action" was first recorded. No doubt the tanning of the skin by the sun's rays was what was first noticed, and this is as truly the effect of solar radiation as is the darkening of the sensitive paper which is now in use in photographic printing operations. We may take it that K. W. Scheele was the first to investigate the darkening action of sunlight on silver chloride. He found that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of lunar caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying a solution of ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele's time, we have the first who applied combined chemical and spectrum analysis to the science of photography. In 1782 J. Senebier repeated Scheele's experiments, and found that in fifteen seconds the violet rays blackened silver chloride as much as the red rays did in twenty minutes.

1 In 1798 Count Rumford contributed a paper to the Philosophical Transactions entitled "An inquiry concerning the chemical properties that have been attributed to light," in which he tried to demonstrate that all effects produced on metallic solution could be brought about by a temperature somewhat less than that of boiling water. Robert Harrup in 1802, however, conclusively showed in Nicholson's Journal that, at all events, salts of mercury were reduced by visible radiation and not by change of temperature.

In 1801 we come to the next decided step in the study of photographic action, when Johann Wilhelm Ritter (1776-1810) proved the existence of a violet light beyond the violet, and found that the violet act decomposed the blackening silver chloride. Such a discovery naturally gave a direction to the investigations of others, and Thomas Johann Seebeck (1770-1831) (between 1802 and 1808) and, in 1812, Jacques Étienne Bérard (1789-1869) turned their attention to this particular subject, eliciting valuable information. We need only mention two or three other cases where the influence of light was noticed at the beginning of the 19th century. William Hyde Wollaston observed the conversion of yellow gum guaiacum into a green tint by the violet rays, and the restoration of the colour by the red rays—both of which are the effect of absorption of light, the original yellow colour of the gum absorbing the violet rays, whilst the green colour to which it is changed absorbs the red rays. Sir Humphry Davy found that puce-coloured lead oxide, when damped, became red in the red rays, whilst it blackened in the violet rays, and that the green mercury oxide became red in the red rays—a gain an example of the necessity of absorption to effect a chemical or chemical change in a substance. U. R. T. Le Bouvier Desmortes in 1801 observed the change effected in Prussian blue, and Carl Wilhelm Böckman noted the action of the two ends of the spectrum on phosphorus, a research which John William Draper extended farther in America at a later date.

To England belongs the honour of first producing a photograph by utilizing Scheele's observations on silver chloride. In June 1802 Thomas Wedgwood (1771-1852) published in the Journal of the Royal Institution the paper—"An account of a method of painting pictures upon glass and of making profiles in metal by the action of light." He remarks that white paper or white leather moistened with a solution of silver nitrate undergoes no change when kept in a dark place, but on being exposed to the daylight it speedily changes colour, and, after passing through various shades of grey and brown, becomes at length nearly black. The alteration of colour takes place more specifically in proportion as the light is more intense.

"In the direct beam of the sun two or three minutes are sufficient to produce the full effect; but if several hours are required, and light transmitted through different-colored glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little action upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects."

Wedgwood goes on to describe the method of using this prepared paper by throwing shadows on it, and inferentially by what we now call "contact printing." He states that he has been unable to fix his prints, no washing being sufficient to eliminate the traces of the silver salt which occupied the exposed or shaded portions. Davy in a note states that he has found that, though the images formed by an ordinary camera obscura were too faint to print out in the solar microscope, the images of small objects could easily be copied on such paper.

"In comparing the effects produced by light upon muriate of silver (silver chloride) with those upon the tinted glasses acts upon it with similar circumstances' no intermediate alteration was produced upon the nitrate. . . . Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the sun is wanting to render this process as useful as it is elegant."

In this method of preparing the paper lies the germ of the silver-printing processes of modern times, and it was only by the spread of chemical knowledge that the hiatus which was to render the "process as useful as it is elegant" was filled up—when sodium thiosulphate (hyposulphite of soda), discovered by François Chausnier in 1799, or three years before Wedgwood published his paper, was used for making the print permanent. Here we must call attention to an important observation by Seebeck of Jena in 1810. In the Forbuchen of Goethe he says:—

"When a spectrum produced by a properly constructed prism is thrown upon a sheet of moire paper coated with silver, or if the printing be continued for fifteen to twenty minutes, whilst a constant position for the spectrum is maintained by any means, I observe the following. In the violet the chloride changes to reddish brown (sometimes blue, sometimes more blue), and this coloration extends well beyond the limit of the violet; in the blue the chloride takes a clear blue tint, which fades away, becoming lighter in the green. In the yellow the chloride is a reddish brown (sometimes blue, sometimes more blue), and this coloration extends well beyond the limit of the violet; in the red there is a clear red tint. This image of the spectrum shows beyond the red and violet a region more or less light and uncoloured. This is how the decomposition of the silver chloride is seen in this region. Beyond
PHOTOGRAPHY

Photography is the process of capturing and manipulating light to create images. The earliest form of photography was developed in the early 19th century by Joseph Nicéphore Niepce and Louis Daguerre. They both experimented with different methods of capturing images, with Daguerre eventually perfecting the daguerreotype process.

Niepce's early work involved the use of bitumen to capture images on a silver surface. He used a similar process to the heliographie, which involved a piece of paper placed in the sun to create an image. Later, he developed a process where he used a camera obscura to project an image onto a sensitized surface, which was then exposed to light. This allowed for the creation of a permanent image.

Daguerre, on the other hand, experimented with the use of iodine vapor to sensitize a metal plate, which was then exposed to light and developed. He called this process the daguerreotype, and it became the first commercially successful photography process.

The daguerreotype process involved the use of a highly sensitive plate, which was exposed to light and then developed to create an image. The image was then fixed by a chemical process and could be preserved indefinitely. This made it possible to reproduce images and create a permanent record of events.

Daguerre's process was later modified by other inventors, including William Henry Fox Talbot, who developed the calotype process. This process used paper instead of metal plates and was less expensive. Talbot's process was later refined by others, including Samuel F. B. Morse, who created the first practical photographic printing process.

Today, photography is a popular and widely used form of art and communication. Digital photography has revolutionized the field, allowing for rapid and easy manipulation of images. Whether capturing a moment in time or creating a work of art, photography continues to be an essential tool in our lives.
caused by the different thicknesses of the minutely thin film of iodide. The stage of maximum sensitiveness is obtained when it is of a golden orange colour. In this state the plate is withdrawn and exposed to sunlight for a few minutes, and then placed in a tank of hypo, ready for exposure. A plan frequently adopted to give an even film of iodide was to saturate a card with iodine and hold the plate a short distance above the card. Long exposures were required, varying in Paris from three to five days. The iodine is then washed off with a solution of hyposulphite, and the plate exposed to an alternation of red light and darkness, until a matter of judgment, more particularly as over-exposure introduced an evil which was called “solarization,” but which was in reality due to the oxidation of the iodide by prolonged exposure to light. By exposure of the iodized plate to a mixture of hyposulphite and water, the image of mercury vapour is said to be due to a chance discovery of Daguerre. It appears that for some time previous to the publication of the daguerreotype method he had been experimenting with plates of silver, producing images by what would now be called the “printing out process.” This operation involved so long an exposure that he sought some means of reducing it by the application of heat. In 1818, he found that he could reduce the exposure by placing a plate of silver salt to a camera-image, he accidentally placed it in the oven containing various chemicals, and found after the lapse of a night that he had a perfect image developed.

By the process of exhaustion he arrived at the fact that it was the mercury vapour, which even at ordinary temperatures volatilizes; that is to say, this process caused the sensitization of the almost invisible camera-image. It was this discovery that enabled the exposures to be very considerably reduced, and for which it was found necessary to give in more camera-printing.

The development of the image was effected by placing the exposed plate over a slightly heated (about 75° C.) cup of mercury. The vapour of mercury in contact with these silver plates, producing images by what would now be called the “printing out process.” This operation involved so long an exposure that he sought some means of reducing it by the application of heat. In 1818, he found that he could reduce the exposure by placing a plate of silver salt to a camera-image, he accidentally placed it in the oven containing various chemicals, and found after the lapse of a night that he had a perfect image developed.

PHOTOGRAPHY

In 1850, on the introduction of collodion (q.v.), a very convenient vehicle on account of the facility with which the plates are prepared, and also because it is a substance as nearly as possible unaffected by silver nitrate, which is not the case with other organic substances. Thus albumen forms a definite silver compound, as do gelatin, starch and gum. The employment of collodion was first suggested by Le Gray, but it remained for Frederick Scott Archer of London, closely followed by P. W. Fry, to make a really practical use of the discovery. When collodion is poured on a glass plate it leaves on drying a hard transparent film which under the microscope is slightly reticulated. Before drying, the film is gelatinous and perfectly adapted for holding in situ salts soluble in ether and alcohol. Where such salts are present they crystallize out when the film is dry, and such a film is only soluble where the plates are ready to be immersed in the silver bath. As a rule, about five grains of the soluble gum-cotton are dissolved in an ounce of a mixture of equal parts of ether and alcohol, both of which must be of low specific gravity, +725 and +805 respectively. If the alcohol or ether be much diluted with water the gum-cotton (pyroxylin) precipitates, but, even if less diluted, it forms a film which is “crepe” and uneven. Such was the material which Le Gray proposed and which Archer brought into practical use. The opaque silver plate with its one impression was abandoned; and the paper support of Talbot, with its inequalities of grain and thickness, followed suit, though with delay. It is unnecessary to describe a negative impression obtained with collodion on a glass plate—the image showing high lights by almost complete opacity and the shadows by transparency (as was the case, too, in the calotype process)—any number of impressions could be obtained by means of the silver-printing process introduced by Fox Talbot, and they were found to possess a delicacy and refinement of detail that certainly eclipsed the finest print obtained from a calotype negative. To any one who had practised the somewhat tedious calotype process, or the waxed-paper process of Le Gray with its still longer preparation and development, the advent of the collodion method must have been extremely welcome, since it entirely dispensed with manipulation, and the production of a different character of pictures thus became possible. We give an outline of the procedure. A glass plate is carefully cleaned by a detergent such as a cream of tripoli powder and spirits of wine (to which a little ammonia is often added), then wiped with a soft rag, and finally polished with a silk handkerchief or chamomile leaves. A single thin layer of collodion is spread over the plate, and allowed to dry before it is immersed in the silver bath. A good standard formula for the collodion is:—55 grains of pyroxylin, 5 oz. of alcohol, 5 oz. of ether; and in this liquid are dissolved 20 grains of ammonium nitrate, 2 grains of albumen, and 3 grains of cadmium bromide. When the collodion is set the plate is immersed in a bath of silver nitrate—a vertical form being that mostly used in England, whilst a horizontal dish is used on the continent of Europe—a good formula for which is 350 grains of silver nitrate with 10 oz. of water. The plate is steadily lowered into this solution, and moved in it until all the repellant action between the aqueous solution of the silver and the solvents of the collodion is removed, when it is allowed to rest for a couple of minutes, after which period it is taken out and placed in the dark slide ready for exposure in the camera. After undergoing proper exposure the plate is washed in a solution of light, yellowish, but very light, solution is applied, which originally was a solution of pyrogallic acid in water restrained in its action by the addition of acetic acid. One of the old formulae employed by P. H. Delamotte was 9 grains of pyrogallic acid, 2 drachms of glacial acetic acid and 3 oz. of water. The image gradually appears after the application of this solution, building itself up from the silver nitrate clinging to the film, which is reduced to the metallic state by degrees. Should the development of the silver nitrate proceed too rapidly, it is stopped by adding the pyrogallic acid solution and the developing action continued. In 1854 Robert Hunt introduced another reducing agent, which is still the favourite, viz. ferrous sulphate. By its use the time of development was reduced, and the image developed after with great rapidity. A sample of this developing solution is 20 grains of ferrous sulphate, 20 minims of acetic acid, with 1 oz. of water. By using this the intensity of hues is increased more than in any other manner, and the formation of a good print, and it is intensified with pyrogallic acid and silver. Other intensifiers are used to increase the deposit on a plate by means of mercury or uranium, followed by other solutions to still further darken the double salts formed on the film. Such intensifying agents have to be applied to the image after the plate is fixed, which is done by a concentrated solution of hypo- sulphite of soda or by potassium cyanide, the latter salt having been first introduced by Marc Antoine Auguste Gaudin in 1853 (Le Lumière, April 23, 1853). Twenty-five grains of potassium cyanide to one ounce of water is the strength of the solution usually employed. The reaction of both these fixing agents is to form with the sensitive salts of silver double hypophosphites or cyanides, which are soluble in water and salt. The utility of bromides in the collodion process seems to have been recognized in its earliest days, Scott Archer (1852) and R. J. Bingham (1850) both mentioning it. We refer the reader as late as 1866 a patent-right in its use was sought to be enforced in America, the patent being taken out by James Cutting in July 1854.

Positive Pictures by the Collodion Process.—In the infancy of the collodion process it was shown by Horne that a negative image could be made to assume the appearance of a positive by whitening the metallic silver deposit. This he effected by using with the pyrogallic acid developer a small quantity of nitric acid. A better result was obtained by P. W. Fry with ferrous sulphate and ferrous nitrate, whilst Hugh Diamond gave effect to the matter in a practical way. F. Scott Archer used mercuric chloride to whiten the image. To Robert Hunt, however, must be regarded the credit of noticing the action of nitric acid in this respect. In 1856, the image was shown to be made to stand out against black velvet, or black varnish may be poured over the film to give the necessary black background, or, more recently, the positive pictures may be produced on japanned iron plates (ferrotype plates) or on japanned leather. This process is still occasionally practised by itinerant photographers.

Moist Collodion Process.—It is seen that for the successful working of the collodion process it was necessary that the plate should be exposed very shortly after its preparation; this was a drawback, inasmuch as it necessitated taking a heavy equipment into the field. In 1856, Sir William Crookes and J. Spiller published in the Philosophical Magazine a process whereby they were enabled to keep a film moist (so as to prevent crystallization of the silver nitrate) several days, enabling plates to be prepared at home, exposed in the field, and then developed in the dark room. The plate was prepared in the usual way and a solution of zinc nitrate and silver nitrate in water was made to flow over it. The hygroscopic nature of the zinc salt kept sufficient moisture on the plate to attain the desired end. Various modifications in procedure have been made.

Dry Plates.—It would appear that the first experiments with collodion dry plates were due to Marc Antoine Augustin Gaudin. In Le Lumière of the 23rd of April and the 27th of May 1854 Gaudin, in his researches on the question of wet and dry processes, noted that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. J. M. Taupenot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallic acid and silver. In this method we have the same manipulation, which is long in execution, though perfectly effective.

A great advance was made in all dry-plate processes by the introduction of what is known as the “alkaline developer,” which is, however, inapplicable to all plates on which silver nitrate is present in the free state. The developers previously described, either for collodion or paper processes, were dependent on the reduction of metallic silver by some such agent as ferrous sulphate, the reduction taking place gradually and the reduced particles aggregating on those portions of the film which had been acted upon by light. The action of light being to reduce the silver iodide, bromide or chloride, these reduced particles really acted as nuclei for the crystallized metal. It will be evident that in such a method of development the molecular attraction
acts at distances relatively great compared with the diameters of the molecules themselves. If it were possible to reduce the altered particles of silver salt it was plain that development would be more rapid, and also that the number of molecules reduced by light would be smaller if the metallic silver could be derived from silver compounds within shorter distances of the centres of molecular attraction. Alkaline development accomplished this to a very remarkable extent; but the method is only really practicable when applied to films containing silver bromide and chlorine which is only slightly soluble in the alkaline development. The introduction of this developer is believed to be of American origin; and it is known that in the year 1862 Major C. Russell used it with the dry plates he introduced.

An alkaline developer consists of an alkali, a reducing agent and a restraining agent. These bodies, when combined and applied to the solid silver bromide or chloride, after being acted upon by light, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromide intact, except so far as it was used in the building up. In 1877 Sir W. Abney investigated this action. A dry plate was prepared by the bath process (as in the wet process, as described below), and exposed in the camera. The exposed film was covered with another film of collodio-bromide emulsion, which of course had not seen the light. An image was obtained from the double film by means of the alkaline developer, which penetrated through the upper unexposed film. The development was prolonged until an image appeared through the unexposed film, when the plate was fixed, washed and dried. A piece of gelatinous paper was cemented on the upper film, and a similar piece on the lower after both had been stripped off the glass. When quite dry the two papers were forcibly separated, a film adhering to each. The upper film, although never exposed to light, showed an image in some cases more intense than the under film. The action of the alkaline developer was here manifest: the silver bromide in close contiguity to the exposed particles was reduced to the metallic state. Hence, from this and similar experiments, Abney concluded that silver bromide could not exist in the presence of a freshly precipitated or reduced metallic silver, and that a sub-bromide was immediately formed. From this it will be seen that the deposited silver is well within the sphere of molecular attraction, and that consequently a less exposure (i.e. the reduction of fewer molecules of the sensitive salt) would give a developable image.

The alkalis used embraced the alkalis themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallic acid. In the year 1880 Abney found that hydroquinone was even more effective than pyrogallic acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents until recently.

The following are some of the most effective:

**Eikongen Developer.**
- Eikongen........ 25 parts.
- Sodium sulphate... 50 
- Sodium carbonate... 50 
- Potassium bromide... 1 
- Water........ 1000

This is a one-solution developer, and acts energetically.

**Metal Developer.**
- Metal........ 2 parts.
- Sodium sulphate... 18 
- Water........ 100

Solution A.

**Solution B.**
- Sodium carbonate... 6 parts.
- Potassium bromide... 1 
- Water........ 100

For use, take one part of A to from 1 to 3 parts of B.

**Amidol Developer.**
- Amidol........ 3 parts.
- Sodium sulphate... 100 
- Potassium bromide... 1 to 3 
- Water........ 100

This developer requires no addition of alkali.

**Ortol Developer.**
- Ortol........ 15 parts.
- Sodium metabisulphite... 1 
- Water........ 1000

Solution A.

A and B solutions are mixed together in equal proportions.

Besides these, there are several more, such as adurol, glycan, pyrocatechin, which have been used with more or less success. They all give a black in lieu of that dark olive-green deposit of silver which is so often found with pyrogallic developers. All are alkaline developers, and the image is built up from the sensitive salt within the film. Some are applicable to gelatin or collodion plates, but for the latter more bromide of an alkali is added, to retard fogging.

Another set of developers for dry plates dependant on the reduction of the silver bromide and the metallic state is founded on the fact that certain organic salts of iron can be utilized. In 1877 M. Carey Lea of Philadelphia and William Willis announced almost simultaneously that a solution of ferrous oxalate in neutral potassium oxalate was effective as a developer, and from that time its use has been acknowledged. In 1882 J. M. Eder demonstrated that gelatino-silver chloride plates could be developed with ferrous citrate, which could not be so readily accomplished with ferrous oxalate. The exposure for chloride plates when developed by the latter was extremely prolonged. In the same year Abney showed that if ferrous oxalate were dissolved in potassium citrate a much more powerful agent was formed, which allowed not only gelatino-chloride plates to be readily developed but also collodio-chloride plates. These plates were undevelopable except by the precipitation method until the advent of the agents last-mentioned owing to the fact that the chloride was readily reduced by the sub-chloride.

Amongst the components of an alkaline developer we mentioned a restrainer. This factor, generally a bromide or chloride of an alkali, serves probably to form a compound with the silver salt which has not been acted upon by light, and which is less easily reduced than is the silver salt alone—the altered particles being left intact. The action of the restrainer is regarded by some as due to its combination with the alkali. But whichever theory is correct the fact remains that the restrainer does make the primitive salt less amenable to reduction. Such restrainers as the bromides of the alkalis act through chemical means; but there are others which act through physical means, an example of which we have in the preparation of a gelatin plate. In this case the gelatin wraps up the particles of the silver compound in a colloidal sheath, as it were, and the developing solution only gets at them in a very gradual manner, for the natural tendency of all such reducing agents is to attack the particles on which least work has to be expended. In the case of silver sub-bromide the developer has only to remove one atom of bromine, whereas it has to remove two in the case of silver bromide. The sub-bromide formed by light and that subsequently produced in the act of development are therefore reduced. A large proportion of gelatin compared with the silver salt in a film enables an alkaline developer to be used without any chemical restrainer; but when the gelatin bears a small proportion to the silver such a restrainer has to be used. With collodion films the particles of bromide are more or less unenveloped, and hence in this case some kind of chemical restrainer is absolutely necessary. We may say that the organic iron developers require less restraining in their action than do the alkaline developers.

In Major Russell's process the plate was prepared by immersion in a strong solution of silver nitrate and then washed and a preservative alcohol added. The last-named, one agent executes two functions, one being to absorb the halogen liberated by the action of light and the other to preserve the film from atmospheric action. Tannin, which Major Russell well employed, if we may judge from the halogenation of the film, acts as a varnish to the film. Other collodion dry-plate processes carried out by means of the silver-nitrates bath were very numerous at one time, many different organic bodies being also employed. In the most cases ordinary boiled collodion took the place of, a small percentage of soluble bromide being as a rule added to it. When plates were developed by the alkaline method this extra bromide induced density, since it was the silver bromide alone which was amenable to it, the iodide being almost entirely unaffected by the wet developer which was at that time in general use.
PHOTOGRAPHY

Dry-Plate Bath Process.—One of the most successful bath dry-plate processes was introduced by R. Manners Gordon. The plate was given an edging of albumen and then coated with ordinary iodized collodion to which one grain per ounce of caustic acid bromide had been added. It was kept in the silver-nitrate bath for ten minutes, after which it was washed thoroughly. The following preservative was then applied:

1. Gum arabic 20 grs.
2. Sugar candy 2 dr.
3. Water 6 dr.
4. Alkaloid 3 grs.
5. Water 2 dr.

These ingredients were mixed just before use and, after filtering, applied for one minute to the plate, which was allowed to drain and set up to dry naturally. Great latitude is admissible in the exposure; it should rarely be less than four times or more than twenty times that which would be required for a wet plate under ordinary circumstances. The image may be developed with ferrous sulphate restrained by a solution of gelatin and glacial acetic acid, to which a solution of silver nitrate is added just before application, or by an alkali developer.

In photographic processes not only has the chemical condition of the film to be taken into account but also the optical. When light falls on a semi-opaque or translucent film it is scattered by the particles of the albumen pass through the glass plate to the back of the film where the rays are partly transmitted and partly reflected, a very small quantity of them being absorbed by the material of the glass. Theory shows that the strongest contrast is given from the back of the glass should take place at the “critical” angle. In 1874 Sayce investigated the subject and proved that practice agreed with theory in every respect, and that the image of a point of light in development on a plate was surrounded by a ring of reduced silver caused by the reflection of the scattered light from the back surface of the glass, and that this ring was shaded inwards and outwards in such a manner that the shading varied with the intensity of the light reflected at different angles. To avoid “halation,” as this phenomenon is called, it was usual to cover the back of dry plates with some material which should be in optical contact with it, and as nearly as possible of the same density as glass, and which at the same time should absorb all the colorimetrically active rays. This was called “backing a plate.”

Collodion Emulsion Processes.—In 1864 W. B. Bolton and B. J. Sayce published the germ of a process which revolutionized photographic manipulations. In the ordinary collodion process a sensitive film is procured by coating a glass plate with collodion containing the iodide and bromide of some soluble salt, and then, when set, immersing it in a solution of silver nitrate in order to form silver iodide and bromide in the film. The question that presented itself to Bolton and Sayce was whether it might not be possible to get the sensitive salts of silver formed in the collodion process in a sensitized condition and given to a plate by merely letting this collodion, containing the cords in suspension, flow over the glass plate. Gaudin had attempted to do this with silver chloride, and later G. W. Simpson had succeeded in perfecting a printing process with collodion containing silver chloride, citric acid and silver nitrate; but the chloride until recently has been considered a slow working salt, and nearly incapable of development. Up to the time of W. B. Bolton and B. J. Sayce’s experiments silver iodide had been considered the staple of a sensitive film on which to take negatives; and though bromide had been used by Major Russell and others, it had not met with so much favor as to lead to the omission of the iodide. At the date mentioned the suspension of silver iodide in collodion was not thought practicable, and the inventors of the process turned their attention to silver bromide, which they found could be secured in such a fine state of division that it remained suspended for a considerable time in collodion, and even when precipitated could be resuspended by simple agitation. The outline of the method was to dissolve a soluble bromide in plain collodion, and add to it drop by drop an alcoholic solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the emulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate of silver bath, and thus avoiding a tiresome operation. The plates were developed by the alkaline method, and gave images which, if not primarily dense enough, could be intensified by the application of pyrogallic acid and silver nitrate as in the wet collodion process. Such was the crude germ of a method which was destined to effect a complete change in the aspect of photographic negative taking; but for some time it lay dormant. In 1874 Sayce was at first discouraged by the trial of it, since the plates often became veiled on development.

M. Carey Lea of Philadelphia, and W. Cooper, jun., of Reading, may be said to have given the real impetus to the method. Carey Lea, by introducing an acid into the emulsion, established a practicable collodion emulsion process, which was rapid and at the same time gave negative pictures free from veil. To secure the rapidity Carey Lea employed a fair excess of silver nitrate, and Colonel H. Stuart Wortley gained further rapidity by a still greater increase of it; the free use of acid was the only means by which this could be effected without hopelessly spoiling the emulsion. The addition of the mineral acids such as Carey Lea employed is to prevent the formation of (or to destroy when formed) any silver sub-bromide or silver iodide or crystals which might otherwise deposit in the emulsion.

An early method employed by B. Bolton, one of the originators of the process, who allowed the ether and the alcohol of the collodion to evaporate, and then washed away all the soluble salts from the gelatinous mass formed of pyroxylin and sensitive salt. After washing, a third time, the plate was dried naturally or washed with alcohol, and then the pyroxylin redissolved in ether and alcohol, leaving an emulsion of silver bromide, silver chloride and silver iodide, or mixtures of all suspended in collodion. In this state the plate could be coated and dried at once for use. Sometimes, in fact generally, preservatives were used, as in the case of dry plates with the bath, in order to prevent the atmosphere from exerting a deleterious effect on the surface of the emulsion.

This modification had the great advantage of giving a large quantity of sensitive salt to be prepared of precisely the same value as to rapidity of action and quality of film.

The great advantage of the use of the collodion bromide process was made by Colonel Stuart Wortley, who in June 1873 made known the powerful nature of a strongly alkaline developer as opposed to the weak one which up to that time had usually been employed for a collodion emulsion plate (vinyl) for any dry plate. An example of the preparation of a collodion emulsion and the developer is the following: 24 oz. of alcohol, 5 oz. of ether, 75 grains of pyroxylin. In 1 oz. of alcohol are dissolved 200 grains of zinc acetate, and this solution is then acidulated with 4 or 5 drops of nitric acid, and added to half the above collodion. In 2 drachms of water are dissolved 330 grains of silver nitrate, 1 oz. of alcohol being added. The mixture of alcohol and water is poured into the other half of the collodion and the brominated collodion dropped in, care being taken that a slack between the operations. An emulsion of silver bromide is formed in suspension; and it is in every case left for 10 to 20 hours to what is technically called “ripen,” or, in other words, to become creamy when poured out upon a glass plate. When the emulsion has ripened it may be used at once or be poured out into a flat dish and the solvents allowed to evaporate till the pyroxylin becomes gelatinous. In this state it is washed in water till all the soluble salts are carried away. After this it may be either spread out on a cloth and dried or treated with two or three doses of alcohol, and then dissolved in equal parts of alcohol (specific gravity, 0.85) and ether (specific gravity, 750). In this condition the plate is ready. A gelatin plate, and a glass plate can be coated with it and the film dried, or it may be washed and some of the many preservatives, such as albumen, benzoate, gum, &c., applied. The use of a useful alkaline developer for collodion plates is as follows:—

1. Pyrogallic acid
2. Potassium bromide
3. Ammonium carbonate

96 grs. 12 grs. 80 grs.

Alcohol Water distilled Water.

To develop the plate 6 minims of No. 1, 1 drachm of No. 2, and 3 drachms of No. 3 are applied. The plate is then covered for exposure, and washed in water after washing the preserved off under the tap. Sometimes the

1 An account of Sayce’s process is to be found in the Photographic News of October 1865, or the Photographic Journal of the same date.

2 The advantages of this salt were pointed out by Leon Warnerke in 1875.
"CARROLLING." By H. P. Robinson.
The warming process introduced by Bennett was soon superseded. Colonel Stuart Wortley in 1879 announced that, by raising the temperature of the vessel containing the emulsion to 150° F., instead of days being required to give the desired sensibility only a few hours were necessary. A further advance was made by boiling the emulsion, first practised, we believe, by G. Mansfield in 1879. Another improvement was effected by W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. Many minor improvements in this process have been made from time to time. It may be useful to give an idea of the relative rapidities of the various processes we have described.

**Gelatin Emulsion Process.**—The facility with which silver bromide emulsion could be prepared in collodion had turned investigation into substitutes for it. As early as September 1871 Dr R. L. Maddox had tried emulsifying the silver salt in gelatin, and had produced negatives of rare excellence. In November 1873 J. King described a similar process, getting rid of the soluble salts by washing. Efforts had also been made in this direction by J. Burgess in July 1873. R. Kennett in 1874 may be said to have been the first to put forward the gelatin emulsion process in a practical and workable form, as he then published a formula which gave good and quick results. It was not till 1878, however, that the great capabilities of silver bromide when held in suspension by gelatin were fairly known; in March of that year C. Bennett showed that by keeping the gelatin solution liquid at a low temperature for as long as seven days extraordinary rapidity was conferred on the sensitive salt. The molecular condition of the silver bromide seemed to be altered, and to be amenable to a far more powerful developer than had hitherto been dreamt of. In 1874 J. S. Stas had shown that various modifications of silver bromide and chloride were possible, and it seemed that the green molecular condition (one of those noted by Stas) of the bromide was attained by prolonged warming. It may be said that the advent of rapid plates was 1878, and that the full credit of this discovery should be allotted to C. Bennett. Kennett and Bennett got rid of the soluble salts from the emulsion by washing; and in order to attain success it was requisite that the bromide should be in excess of that necessary to combine with the silver nitrate used to form the emulsion. In June 1879 Abney showed that a good emulsion might be formed by precipitating a silver bromide by dropping a solution of a soluble bromide into a dilute solution of silver nitrate. The supernatant liquid was decanted, and after two or three washings with water the precipitate was mixed with the proper amount of gelatin. D. B. van Monckhoven of Ghent, in experimenting with this process, hit upon the plan of obtaining the emulsion by acting on silver carbonate with hydrobromic acid, which left no soluble salts to be extracted. He further, in August 1879, announced that he had obtained great rapidity by adding to the bromide emulsion a certain quantity of ammonia. This addition rapidly altered the silver bromide from its ordinary state to the green molecular condition referred to above. At this point we have the branching off of the gelatin emulsion process into two great divisions, viz. that in which rapidity was gained by long-continued heating, and the other in which it was gained by the use of ammonia—a subdivision which is maintained to the present day. Opinions as to the merits of the two methods are much divided, some maintaining that the quality of the heated emulsion is better than that produced by alkali, and vice versa. We may mention that in 1881 Dr A. Herschel introduced a plan for making an alcoholic action (2) by the idea of individual rootlets of the plates, and in the same year H. W. Vogel of Berlin introduced a method of combining gelatin and pyroxylin by means of a solvent which acted on the gelatin and allowed the addition of alcohol in order to dissolve the pyroxylin. This "collodio-gelatin emulsion" was only a shortlived process, which is not surprising, since its preparation involved the inhalation of the fumes of acetic acid.

1 For further details the reader is referred to *Instruction in Photography*, 11th ed., p. 362.
PHOTOGRAPHY

Toning and Fixing the Print.—The next operation is to tone and fix the print. In the earlier days this was accomplished by means of a bath of hypophosphate of sodium and gold chloride. This gilded the darkened parts of the print which light had reduced to the semi-metallic state; and on the removal of the chloride by means of boiling water and ammonia, a layer of metallic gold or silver, which had been left behind, was washed off and removed. There was a suspicion, however, that part of the coloration was due to a combination of sulphur with the silver, not that pure silver sulphide was really formed; but the latter degree of fusing seems to be liable to change. This gave place to a method of alkaline toning, or rather, we should say, of neutral toning, by employing gold chloride with a salt, such as the carbonate or nitrate, or both, of potassium or sodium. There was no danger of sulphurization during the toning, to which the method by sel d'or was prone owing to the decomposition of the hypophostate. The substances which can be employed in toning are the alkaline salts of gold and silver, the latter being readily displaced by a stronger acid, such as nitric acid, which must exist in the paper after printing. This branch of photography owes much to the Rev. T. F. Hardwich, he having carried on extensive researches in connexion with it during 1854 and subsequent years. A. Davanne and A. Girard, a little later, also investigated the matter with fruitful result.

The following may be taken as two typical toning-baths:—

<table>
<thead>
<tr>
<th>(Gold chloride)</th>
<th>3 parts.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sodium carbonate</td>
<td>10 parts.</td>
</tr>
<tr>
<td>Water</td>
<td>5000 (ft).</td>
</tr>
<tr>
<td>Borax</td>
<td>100 grs.</td>
</tr>
<tr>
<td>Water</td>
<td>800 (ft).</td>
</tr>
<tr>
<td>Gold chloride</td>
<td>1 part.</td>
</tr>
<tr>
<td>Water</td>
<td>4000 parts.</td>
</tr>
</tbody>
</table>

In the latter (a) and (b) are mixed in equal parts immediately before use. Each of these is better used only once. A third bath is:

| Gold chloride | 2 parts. |
| Chloride of lime | 2 |
| Sodium carbonate | 400 grs. |
| Water | 8000 |

These are mixed together, the water being warmed. When cool the solution is ready for use. In toning prints there is a distinct difference between the action of this and the one described, and the same is also true of the baths just employed. Thus in the first two baths the print must be thoroughly washed in water to remove all free silver nitrate, that salt forming no part in the chemical reactions. On the other hand, where free nitric acid is used, no reduction of the silver chloride absorbent is a necessity. In 1872 Abney showed that with such a toning-bath free silver nitrate might be eliminated, and if the print were immersed in a solution of a salt such as lead nitrate the toning action proceeded rapidly and without causing any fading of the image whilst toning, which was not the case when the free silver nitrate was totally removed and no other chloride absorbent substituted. This was a considerable factor, and one which had been overlooked. In the third bath the free silver nitrate should only be partially removed by washing. The print, having been partially washed or thoroughly washed, as the case may be, is immersed in the toning-bath till the image gives a purple or bluish tone, after which it is ready for fixing. The solution used for this purpose is a 20% solution of hypophosphate of soda, to which it is best to add a few drops of ammonia in order to render it alkaline. About ten minutes suffice to effect the conversion of the chloride into hypophosphate of silver, which is soluble in hypophosphate of soda and can be removed by washing. The organic salts of silver, however, to form a different salt, and silver, is partially insoluble, but which the ammonia helps to remove. If it is not removed there is a sulphur compound left behind, according to J. Spiller, which by time and exposure becomes yellow.

The use of potassium cyanide for fixing prints is to be avoided, as the acid cyanide thus added adds to the reflection and renders the print a poor gold. A water solution in which sodium nitrate is the main constituent, having been floated on the plates, which colouring is to take place, plain salted paper is useful. It can be made of the following proportions—50 parts of ammonium chloride, 240 parts of spirits of wine and 200 parts of water, through the proportions may vary. These ingredients are dissolved, and the whites of three to four eggs are beaten up to a froth. In hot weather it is advisable to add a drop of carbolic acid to prevent decomposition. The albumen is allowed to remain in the liquid for two or three hours, after which it is filtered through a piece of flannel placed in a funnel, or through two or three thicknesses of fine muslin, and transferred to a flat dish. The paper is cut of convenient size and allowed to float on the solution for about a minute, when it is laid on a paper towel and dried in a warm room. For dead prints, on the other hand, in which the image is lighter, the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears darker than it should finally appear.

Sensitising Bath.—To sensitize the paper it is floated on a 10% solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears darker than it should finally appear.
stated that, on a couple of sheets of albuminized paper fully printed, the gold necessary to give a decided tone does not exceed half a grain.

Collodio-chloride Silver Printing Process.—In the history of the emulsion processes we stated that Gaudin attempted to use a chloride suspended in colloid, but it was not till the year 1864 that any practical use was made of the suggestion so far as silver printing is concerned. In the autumn of that year George Wharton Simpson worked out a method which has been more successfully employed. The formula appended is Simpson’s:

1. Silver nitrate
   - 60 parts.
2. Distilled water
   - 60 parts.
3. Collodion chloride
   - 100 parts.
4. Alcohol
   - 64 parts.
5. Alcohol
   - 1000 parts.

To every 1000 parts of plain colloid 30 parts of No. 1, previously warmed with parts of alcohol, are added; 60 parts of No. 2 are next mixed with the colloid, and finally 30 parts of No. 3. This forms an emulsion of silver chloride and also contains citric acid and silver nitrate. The defect of this emulsion is that it contains a large proportion of soluble salts, which are apt to crystallize out on drying, more particularly if it be applied to glass plates. The addition of the citric acid and the excess of silver nitrate is the key to the whole process; for, unless some body were present which on exposure to light was capable of forming a highly colored, organic oxide of silver, no vigour would be obtained in printing. If pure chloride be used, though an apparently strong image would be printed, it is only for a very short time: a feeble trace of it will be left, and the print will be worthless. The collodio-chloride emulsion may be applied to glass, or to paper, and the printing carried on in the usual manner. The toning takes place by means of the chloride of silver; nitrate and sulphadimidine and gold, which is practically a return to the sel d’or bath. The organic salt formed in this procedure does not seem so prone to be decomposed by keeping as does that formed by albumen, and the washing can be more complete in consequence. There are in the market several papers which are collodio-chloride.

Gelatino-citro-chloride Emulsion.—A modified emulsion printing process was introduced by Abney in 1851, which in suspended silver nitrate and gelatin of citric acid somewhat resembles the above, but has no excess of silver present. The formula of producing it is as follows:—

1. Sodium chloride
   - 5 parts.
2. Potassium citrate
   - 4 parts.
3. Water
   - 300 parts.
4. Gelatin
   - 150 parts.
5. Water
   - 500 parts.
6. Gelatin
   - 300 parts.
7. Water
   - 1700 parts.

Nos. 2 and 3 are mixed together while warm, and No. 1 is then gently added, the gelatin solution being kept in brisk agitation. This gelatin is then introduced with gelatin of citric acid and a little excess of citric acid and of gelatin chloride. The gelatin containing the suspended salts is heated for five minutes at boiling point, when it is allowed to cool and subsequently slightly washed, as in the gelatino-bromide emulsion. It is then ready for application to the surface on which the printing is to be done. The following solution of gelatin chloride is added:

1. Gelatin
   - 30 parts.
2. Potassium citrate
   - 4 parts.
3. Water
   - 300 parts.

In this solution, the gelatin is floated on the surface. When dry it is exposed beneath a negative, and a very faint image is produced; but it can be developed into a strong one by 6 to 10% solution of silver nitrate to which a trace of acetic acid has been added. The products are of a beautiful colour, and seem to be fairly permanent. They may be readily toned by the borax or by the chloride of lime toning-bath, and are fixed with the hypophosphite solution of the strength given before. Most, if not all, of the gelatin papers now extant are made somewhat after this manner.

Printing with Salts of Uranium.—The sensibility of the salts of uranium to light seems to have been discovered in 1856, but was subsequently applied to photography by J. E. Burnett in England. One of the original formulae consisted of 20 parts of uranyl nitrate with 600 parts of water. Paper, which is better if slightly sized with gelatin, is floated on this solution. When dry it is exposed beneath a negative, and a very faint image is produced; but it can be developed into a strong one by 6 to 10% solution of silver nitrate to which a trace of acetic acid has been added. The products are of a beautiful colour, and seem to be fairly permanent. They may be readily toned by the borax or by the chloride of lime toning-bath, and are fixed with the hypophosphite solution of the strength given before. Most, if not all, of the gelatin papers now extant are made somewhat after this manner.

Self-toning Papers.—There are several self-toning papers based on the chloride emulsion process. These contain the necessary amount of nitrate in the print. The print is placed in the ordinary way and then immersed in salt water and in some cases potassium sulphocyanide. The print is finished by immersing in weak hypochlorite of soda.

Bichromate of Potassium: Carbon Prints.—The first mention of the use of potassium bichromate for printing purposes seems to have been made by Mungo Ponton in May 1839, when he stated that paper, if saturated with this salt and dried, and then exposed to the sun’s rays through a drawing, would produce a yellow picture on an orange ground, nothing more being required to fix it than washing it in water, when a white picture on an orange ground was obtained. In 1839 Edmond Becquerel announced that paper sized with iodide of starch and soaked in potassium bichromate was, on drying, more sensitive than unsized paper. Joseph Dixon of Manchester, in 1839, in the following year, improved on the process by using gum arabic with potassium bichromate spread upon a lithographic stone, and, after exposure of the sensitive surface through a bank-note, by washing away the unaltered gum and ink, thereby leaving the stone somewhat exposed. Thereafter a host of modifications, has been used by Simonau and Toovey of Brussels, and produces excellent results. Dixon’s method, however, was published in the Scientific American for 1854, and continued in practice, as regards further improvements in the process. The remainder of the process resembles that of the lithographic process (see below), published in 1852. On the 13th of December 1853 Alphonse Poitevin took out a patent in England, in which certain modifications are described, the process consisting in printing a carbon print by rendering gelatin insoluble through the action of light on potassium bichromate. This idea was taken up by John Pouncey of Dorchester, who perhaps was the first to produce veritable prints with bichromate. Another patent was taken out by Abbé Laborde in 1858, whilst describing a kindred process in a note to the French Photographic Society. He says, “In the sensitive film, however it may be, two distinct surfaces must be recognized, an outer surface where the exposure has been made, and an inner surface, which is not lighted.” The action of light commences on the outer surface; in the washing, therefore, the half-tones lose their hold on the paper and are washed away. 1859 Poitevin took out a patent in France. They are placed in contact with the negative in the pressure-frame, as it is only by printing in this way that we can expect to be able afterwards to remove by washing the unacted-upon portions of the print. In a positive, on the other hand, the removal of half-tones is brought about by the action of the water used in washing; so that either nothing is removed, or by steeping very long till the inner soluble part is softened, the stone comes bodily away, leaving the paper white.” This method of exposing through the back of the paper was crude and unsatisfactory, and in 1860 Fargier patented a process in which, after exposure to light of the gelatine materials of the print, the paper was printed on one side and the print placed in warm water, where it separated from the paper support and could be transferred to glass. Poitevin successfully opposed this patent, for he had used this means of detaching the image from its support, so long before Poitevin’s time, but in which the bichromate and nitrate of aluminium were used. Fargier at any rate gave an impetus to carbon-printing, and J. W. Swan took up the matter, and in 1864 secured a patent. One of the great features in Swan’s innovations was the substitution of carbon black for the aluminous or tartaric acid, which were used by Choules. Swan made by coating paper with a mixture of gelatin, sugar and colouring matter, and rendered sensitive to light by means of potassium or ammonium bichromate. After exposure to light Swan placed the painted side on the stone or hot plate to which it was made to adhere by pressure. The print was immersed in hot water, the paper backing stripped off, and the soluble gelatin containing the colouring matter washed away. The picture could then be retransferred to its final support of paper. In 1869 R. Johnson of London took out a patent in which he claimed that carbon-tissue which had been soaked in water for a short period, by the presence of the carbon in its colloidal state, would give as good a surface such as glass, metal, waxed paper, &c., without any adhesive material being applied. This was a most important improvement. Johnson also applied soap to the gelatin to prevent its excessive brittleness, and dried its side on dry paper, paper, rendered insoluble by chrome alum. In 1874 J. R. Sawyer patented a flexible support for developing on; this was a sized paper coated with gelatin and treated with an ammoniacal solution of shellac in borax, on which wax or resin was rubbed. The advantage of this flexible support is that it is capable of more easily being transferred to the lighter paper, which was apt to do when a metal plate was used, as was the case in Johnson’s original process. Paper made of this kind, known as carbon paper, has been made since, carbon-printing has arrived at its present state of perfection.

According to P. E. Liesegang, the carbon-tissue when prepared on a large scale consists of from 120 to 150 grains of gelatin (a soft kind), 15 grains of soap, 21 grains of sugar and from 4 to 8 grains of dry colouring matter. The last-named may be of various kinds, from lamp-black pigment to soluble colours such as alizarin. The gelatin, sugar and soap are put in water and allowed to stand for an hour, and then, after the liquid afterwards receiving the
PHOTOGRAPHY

There is a difference between the term "photography" and "photo-lithography". Photography describes the process of capturing images by exposing a light-sensitive surface to light, with the potential to produce a permanent image. Photo-lithography, on the other hand, is a process used to transfer images to lithography plates, which are then used to print texts or images. The term "photography" also refers to the art of capturing images using light, whereas "photo-lithography" is a specific process used in the printing industry.

The process of photography involves the use of a light-sensitive material, usually a piece of paper or film, to capture an image. The image is then developed, fixed, and printed to create a permanent record. The first photographs were taken in the mid-19th century, with the invention of the daguerreotype process by Louis-Jacques Mandé Daguerre in 1839. This process involved the use of a light-sensitive metal plate, which was exposed to light and then developed to create an image. The daguerreotype process was later replaced by other processes, such as the calotype and collodion processes.

In the late 19th century, the process of photolithography was developed. This process involved the use of a light-sensitive plate, which was exposed to light and then developed to create an image. The image was then used to create a printing plate, which was used to print the image. The photolithography process was used to create a variety of printed materials, including newspapers, magazines, and books.

The process of photography and photolithography are both important in the history of printing and the creation of printed materials. These processes have been developed and refined over time, and have played a key role in the development of the modern printing industry.

Colours, which have been ground on a slab. The mixture is filtered through fine muslin. In making the tissue in large quantities the two ends of a piece of rolling-paper are exposed to the sun together, and the heavier part of the roll when about two inches of wood about 5 in. in diameter is fixed near the top of the room and the other over a trough containing the gelatin solution, the paper being brought into contact with the solution by means of a roller. The thickness of the coating is proportional to the rate at which the paper is drawn over the gelatin; the slower the movement, the thicker the coating. The paper is taken off the rollers, cut through, and rolled up in the form of tubes, a certain number of tubes containing the coating being put into each box. The coating is then dried, 

After the coating is dried the paper is placed in a box, and is then allowed to ripen for some time. After ripening, the paper is exposed to light until the gelatin is completely sensitized. Before exposing the front surface to the film and the image, the necessary hardness might be given to the gelatin without adding any chemical hardeners to it. In Tessie de Matoy's process the use of the negative is not considered as a distinct process, and the coating the paper with gelatin is the same one as described above. In the general process of Tessie de Matoy, the gelatin solution is applied to the paper by means of a fine-sprinkling, and the paper is then placed in a bath of gelatin solution in such a manner that the gelatin solution is uniformly distributed over the surface of the paper, and the excess is removed by squeezing the paper before exposing it to the light. The process is then repeated as necessary until the desired degree of hardness is obtained.

The photograph is then developed, fixed, and printed to create a permanent record. The process of developing the photograph involves the use of various chemicals, such as hypo and oxalic acid, to remove the unexposed silver halide from the gelatin. The photograph is then fixed, which involves the use of sodium thiosulfate to stop the chemical reaction. The photograph is then washed to remove any remaining chemicals and to create a permanent record. The photograph is then dried and mounted on a board for storage or display.

The process of photography and photolithography are both important in the history of printing and the creation of printed materials. These processes have been developed and refined over time, and have played a key role in the development of the modern printing industry.
produced the spectrum colours, but it was found better to heat the plate till it assumed a rose tint. At a later date Niepce de St. Victor chlorinized by chloride of lime, and made the surface more sensitive by applying a solution of lead chloride in water. G. W. Simpson also obtained coloured images on silver chloride emulsion in collodion, but they were less vivid and satisfactory than those obtained on daguerreotype plates. Poitevin obtained coloured images on ordinary silver chloride paper by preparing it in the usual manner and washing it and exposing it to light. It has been exposed with a solution of potassium bichromate and cupric sulphate, and dried in darkness. Shortly after, he gave coloured images from coloured pictures, which he stated could be fixed by sulphuric acid (Comptes rendus, 1858, 61, p. 11). In the Bulletin de la Société Française (1874) Colonel St. Florent described experiments which he made with the same object. He immersed ordinary or albuminized paper in silver nitrate and afterwards plunged it into a solution of uranium nitrate and zinc chloride acidulated with hydrochloric acid; it was then exposed to light till it took a violet, blue or lavender tint. Before exposure the paper was floated on a solution of mercure nitrate, its surface dried, and exposed to a coloured image.

It is pretty doubtful if it is so that the nature of the chloride used to obtain the silver chloride has a great effect on the colours impressed; and Niepce in 1857 made some observations on the relationship which seemed to exist between the coloured flames produced by the metal and the colour impressed on a plate prepared with a chloride of such a metal. In 1880 Abney showed that the production of colour really resulted from the oxidation of the chloride that was coloured by light. Plates immersed in a solution of hydrogen peroxide took the colours of the spectrum much more rapidly than when not immersed, and the size of the molecules seemed to regularize the colour. He further stated that the whole of the spectrum colours might be derived from a mixture of two or at most three sizes of molecules.

In 1841, Robert Hunt published some results of colour-photography by means of silver chloride. A paper was washed with silver nitrate and with sodium chloride, and afterwards exposed to the spectrum. The action of the spectrum commenced at the centre of the yellow ray and rapidly proceeded upwards, arriving at its maximum in the blue ray. As far as the indigo the action was uniform, whilst in the violet the paper took a brown tint. When it was previously exposed, however, a yellow space was occupied where the yellow rays had acted, a green band where the green had acted, whilst in the blue and indigo it took an intense blue, and over the violet the effect was not produced. In referring to these conclusions on paper it must not be forgotten that pure salts of silver are not being dealt with as a rule. An organic salt of silver is usually mixed with silver chloride paper, the organic salt being due to the sizing of the piece. It is found that these colours do not yield different tints, whereas on paper it must not be forgotten that pure salts of silver are not being dealt with as a rule.

A method devised by Gabrielle Lippmann, of Paris, by which the natural curvatures of a surface can be rendered visible was briefly described as follows: A sensitive plate is placed in contact with a film of mercury, and the exposure to the spectrum, or to the image of coloured objects to be photographed, is made through the back of the plate. On developing, the colour of the object coloured when viewed at one particular angle, the colours being approximately those of the object. The necessary exposure to produce this result was very prolonged in the first experiments in which the discharge of the subject was photographed, but had to be given to the red than was required for the blue. Lippmann at first employed collodion dry plates, prepared, it is believed, with albumen, and it required considerable manipulation to bring out the colours correctly. A Lumiére used gelatin plates dyed with appropriate dyes (orthochromatic plates); the exposure was much diminished, and very excellent representations were produced of all natural colours. The main point to aim at in the preparation of the plates seems to be a very sensitive film without any vapour, or, at all events, with the least possible, "grain" in the sensitive salt. A formula published by Lumiére seems to attain this object. Viewed directly, the developed images appear like ordinary negatives, or such as when held against the sunlight, but if viewed in the dark they are vivid. They are not pure monochromatic colours, but have very much the quality of colours obtained by polarized light. It appears that these products must be termed "nodes" of different-coloured lights acting within the film. Thus in photographing the spectrum, rays penetrate to the reflecting surfaces, and are reflected back from it, and these, with the incident waves of light, form the spectrum we see in the dark, and the relative lengths which formed these nodes are reflected to the eye, and thus we get an impression of colour.

Action of Light on Chemical Compounds.

Reference has been made above to early investigations on the chemical action of light. In 1777 Karl Wilhelm Scheele (Hunt's Researches in Light) made the following experiments on silver salts:

"I precipitated a solution of silver by sal-ammoniac; then I edulcorated it and dried the precipitate and exposed it to the beams of the sun for two weeks; after which I stirred the powder, and found that the nebulous mass had taken on a caustic spirit of sal-ammoniac (strong ammonia) on this, in all appearance, black powder, and set it by for digestion. This menstruum dissolved a quantity of luna cornua (horn silver), though some black powder remained undissolved. The powder after it was washed was, for the greater part, dissolved by a pure acid of nitre (nitric acid), which, by the operation, acquired volatility. This solution I precipitated again by means of sal-ammoniac into horn silver. Hence it follows that the blackness which the luna cornua acquires from the sun's light, and likewise the solution of silver poured on chalk, is silver by reduction... I mixed some finely divided silver with powdered sal-ammoniac and just cover this powder. The half of this mixture I poured into a white crystal phial, exposed it to the beams of the sun, and shook it several times each day; the other half I set in a dark place. After having exposed the one mixture during the space of two weeks, I filtrated the water standing over the horn silver, grown already black; I let some of this water fall by drops in a solution of silver, which was immediately precipitated into horn silver."

This, as far as we know, is the first intimation of the reducing action of light. From this it is evident that Scheele had found that the silver chloride was decomposed by the action of light. He had, however, made some former experiments and found that chlorine is really liberated from the chloride; but it is necessary that some body should be present which would absorb the chlorine, or, at all events, that the chloride should be free to escape. A tube of dried silver chloride, sealed up in vacuo, will not discolor in the light, but keeps its ordinary white colour. A pretty experiment is to seal up in vacuo, at one end of a bent tube, perfectly dry chloride, and at the other a drop of mercury. The mercury vapour volatilizes to a certain extent and fills the tube. When exposed to light chlorine is liberated from the chloride, and calomel forms on the sides of the tube. In this case the chloride darkens. Again, dried silver chloride sealed up in vacuo does not discolor, but the yellow colour obtained is due to the combination of the chloride with the hydrogen. Poitevin and H. W. Vogel first enunciated the law that for the reduction by light of the haloid salts of silver halogen absorbers were necessary, and it was by following out this law that the present rapidity in obtaining camera images has been rendered possible. To put it briefly, then, the visible action of light is a reducing action, which is aided by or entirely due to the fact that other bodies are present which will absorb the halogens.

In the above we have alluded to the visible results on silver salts. It by no means follows that the exposure of a silver salt to light for such a brief period as to leave no visible effect must be due to the same effect, that is, that any of the molecules are absolutely reduced or split up by the light. That this or some other action takes place is shown by the fact that the silver salt is capable of alkaline development, that is, the particles
PHOTOGRAPHY

which have suffered a change in their molecules can be reduced to metallic silver, whilst those which have not been acted upon remain unaltered by the same chemical agency. Two theories have been offered to explain the invisible change which takes place in the salts of silver. One is based on the supposition that the molecules of the salt can rearrange their atoms under the vibrations caused by the ether waves placing them in more unstable positions than they were in before the impact of light took place. This, it is presumed, would allow the developer to separate the atoms of such shaken molecules when it came in contact with them. The other theory is that, as in the case of the visible effects of light, some of the molecules are at once reduced and that the developer finishes the disintegration which the light has begun. In the case of the alkaline development the unaltered molecules next those primarily reduced combine with the reduced silver atom and again form an unstable compound and are in their turn reduced.

The first theory would require some such action as that just mentioned to take place and cause the invisible image formed by the shaking apart of the light-stricken molecules to become visible. It is hard to see why other unacted upon molecules close to those which were made unstable and which have been shaken apart by the developer should themselves be placed in unstable equilibrium and amenable to reduction. In the second theory, called the "chemical theory," the reduction is perfectly easy to understand. Abney adopts the chemical theory as the balance of unsubstantiated evidence is in its favour. There is another action which seems to occur almost simultaneously when exposure takes place in the absence of an active halogen absorber, as is the case when the exposure is given in the air, that is, an oxidizing action occurs. The molecules of the altered haloid salts take up oxygen and form oxides. If a sensitive salt be briefly exposed to light and then treated with an oxidizing substance, such as potassium bichromate, potassium permanganate, hydrogen peroxide, ozone, an image is not developed, but remains unaltered, showing that a change has been effected in the compound which under ordinary circumstances is developable. If such an oxidized salt be treated very cautiously with nascent hydrogen, the oxygen is withdrawn and the image is again capable of development.

Spectrum Effects on Silver Compounds.—The next inquiry is as to the effect of the spectrum on the different silver compounds. We have already described Seebeck's (1810) experiments on silver chloride with the spectrum whereby he obtained coloured photographs, but Scheele in 1777 allowed a spectrum to fall on the same material, and found that it blackened much more readily in the violet rays than in any other. Senebier's experiments have been already quoted. We merely mention these have become the foundation of nearly all subsequent researches of the same kind. The effects of the spectrum have been studied by various experimenters since that time, amongst whom we may mention Edmond Becquerel, John William Draper, Alphonse Louis Poitevin, H. W. Vogel, Victor Schumann and W. de W. Abney. Fig. 1 is compiled from a cut which appeared in the Proc. Roy. Soc. for 1882, and shows the researches made by Abney as regards the action of the spectrum on the three principal haloid salts of silver. No. 7 shows the effect of the spectrum on a peculiar modification of silver bromide made by Abney, which is seen to be sensitive to the infra-red rays.

Effect of Dyes on Sensitive Films.—In 1874 Dr H. W. Vogel of Berlin found that when films were stained with certain dyes and exposed to the spectrum an increased action on development was shown in those parts of the spectrum which the dye absorbed. The dyes which produced this action he called "optical sensitizers," whilst preservatives which absorbed the halogen liberated by light he called "chemical sensitizers." A dye might, according to him, be an optical and a chemical sensitizer. He further claimed that, if a film were prepared in which the haloid soluble salt was in excess and then dyed, no action took place unless some "chemical sensitizer" were present. The term "optical sensitizer" seems a misnomer, since it is meant to imply that it renders the salts of silver sensitive to those regions of the spectrum to which they were previously insensitive, merely by the addition of the dye. The idea of the action of dyes was at first contested, but it was soon recognized that such an action did really exist. Abney showed in 1875 that certain dyes combined with silver and formed true coloured organic salts of silver which were sensitive to light; and Dr Robert Amory went so far as to take a spectrum on a combination of silver with eosin, which was one of the dyes experimented upon by J. Waterhouse, who had closely followed Dr Vogel, and proved that the spectrum acted simply on those parts which were absorbed by the compound. Abney further demonstrated that, in many cases at all events, the dyes were themselves reduced by light, thus acting as nuclei on which the silver could be deposited. He further showed that even when the haloid soluble salt was in excess the same character of spectrum was produced as when the silver nitrate was in excess, though the exposure had to be prolonged. This action he concluded was due to the dye.

Correct Rendering of Colours in Monochrome.—In Plate II., fig. 14 the sensitiveness of a plate stained with homocoll is shown, and it is evident that as it is sensitive throughout the visible spectrum there must be some means of cutting off by a transparent screen so much of the spectrum luminosity at different parts that every colour having the same luminosity to the eye shall be shown on a negative of equal density. When this is done the relative luminosities of all colours will be shown by the same relative densities or in a print by different depths of grey. Abney devised a sensitometer which should be used to ascertain the colour of the screen that should be employed. By proper means the luminosity of the light of day coming through a red, a green, a blue and an orange glass can be very accurately measured; if 1/2 in. squares of these coloured glasses, together with a white glass of the same area, be placed in a row and cemented on white glass, we have a colour-screen which we can make available for finding the kind of light-filter to be employed. This is readily done by reducing the luminosity of the light coming through any one of the six glasses, 5 and 7 of the luminosity of the light coming through the blue glass. If the luminosity of the blue be 5 and that of the white light 10, then the luminosity of the former must be reduced to 3/5 of its original value, and so with the other glasses. The luminosity of the light coming through each small glass square can be made equal by rotating in front of them a disk in which apertures are cut corresponding to the reduction required. The

blue glass, for instance, would not be covered by the disk at all, while opposite the white square the disk would have an aperture of an angle of 18°. When a plate is exposed behind the row of glass squares, with the light passing through the rotating disk, having the appropriate apertures for each glass, the negative obtained would under ordinary conditions, show square patches of very different opacity. A light-filter of some transparent colour, if placed in the path of the light, will alter the opacities, and eventually one can be found which will only allow such coloured light to be transmitted as will cause all the opacities in the negative to be the same. As the luminosities of the white light passing through the glasses are made equal, and as the photographic deposits are also rendered equal, this light-filter, if used in front of the camera lens, will render all coloured objects in correct monochromic luminosity. Another plan, based on the same principles, is to place segments of annuluses of vermilion, chrome yellow, emerald green, French blue and white on a disk, and to complete the annuluses with black segments, the amount of black depending on the luminosity of the pigments, which can be readily measured. When the disk is rotated, rings of colour, modified in brightness by black, are seen, and each ring will be of the same luminosity. As before, a screen (light-filter) to be used in front of the lens must be found which will cause the developed images of all the rings to appear of equal opacity. It must be remembered that the light in which the object is to be photographed must be the same as that in which the luminosity of the glasses or pigment is measured.

Action of the Spectrum on Ceramic Salts.—The salts most usually employed in photography are the bichromates of the alkalies. The result of spectrum action is confined to its own most refrangible end, commencing in the ultra-violet and reaching as far as in the solar spectrum. Fig. 2 shows the relative action of potassium and ferric chloride. If these two be brushed over paper, and the paper be then exposed to a bright solar spectrum, action is exhibited into the infra-red region. This is one of the few instances in which these light-waves of low refrangibility are capable of producing any effect. The colour of this solution is a muddy green, and analysis shows that it cuts off these rays as well as generally absorbs those of higher refrangibility.

Action of Light on Uranium.—The salts of uranium are affected by light in the presence of organic matter, and they too are only acted upon by those rays which they absorb. Thus nitrate of uranium, which shows, too, absorption-bands in the green blue, is affected more where these occur than in any other portion of the spectrum.

Some salts of mercury, gold, copper, lead, manganese, molybdenum, platinum, vanadium, are affected by light, but in a less degree than those which we have discussed. In the organic world there are very few substances which do not change by the continuous action of light, and it will be found that as a rule they are affected by the blue end of the spectrum rather than by the red end (see Photochemistry).

The following table gives the names of the observers of the action of light on different substances, with the date of publication of the several observations. It is nearly identical with one given by Dr Eder in his Geschichte der Photo-Chemie.

**Effect of Hydrogen Peroxide on Sensitive Plates.**—Dr. W. J. Russell made a series of experiments on the effect of exposure of sensitive plates to the action of vapours and gases for long periods. It has long been known that contact of plates with such substances as wood caused a sensitive surface to show "fog" on development. By a somewhat exhaustive series of experiments, Russell showed that the probable cause of this fog is hydrogen peroxide, since substances which favoured its formation produced the same effect. This is somewhat remarkable, as this same substance will completely destroy the effect that light has had on a sensitive plate; indeed, it affords one way of destroying a light image on a sensitive collodion plate. The experiments of Russell give a warning to store exposed plates for brief periods. It appears that negatives wrapped in paraffin paper are secure from this danger.

**The Application of Photography to Quantitative Measures.**—In order to employ photography for the measurement of light it was necessary that some means should be devised by which the opacity of the deposit produced on the development of a plate could be determined. It is believed that in 1874 the first attempt was made by Sir W. Abney to do this. In the Phil. Mag. he showed how density could be measured by means of an instrument, the diaphanometer, he had devised, in which transparent
black wedges were used to make matches between the naked light and the same light after passing through the photographic opacity that had to be measured. In 1857, owing to the perfecting of the rotating sectors, which could be made to increase or diminish the aperture at pleasure during its rotation, the measurement of opacities became easy. The Cambridge method of comparing the light through the deposit with a known beam, using the sectors to equalize the illumination, was adopted, if the position being placed between the light and the screen, the comparison light being a beam reflected from the same light on to the screen.

Owing to the fact that photographic deposit scatters light more or less, the opacities measured by this plan were slightly greater than those given by the opacities that were to be used for contact printing. The final plan adopted by Abney was to place the part of the plate carrying the deposit to be measured behind a screen constructed as above. C D (fig. 4) is a continuous spectrum taken with the electric light; no. 7 is the impressing continuous spectrum; no. 8 shows the bright lines of metals; no. 3 the line spectrum of volatilized lithium and sodium to indicate the position of the spectrum colours. Nos. 4 and 2 are the absorption and fluorescent spectra of eosin. No. 5 is the graduation scale formed by a bromogelatin "seed" plate stained with homocoll, a cyanine derivative sensitive to the red; no. 6 is a similar scale formed by an unstained plate. The small numbers placed between the different bands show the empirical scale which is made to apply to each of them. The first step is to measure the opacity of the gradation scale, next the opacity of the continuous spectrum at the various numbers of the empiric scale, and also the opacity of the other bands at the same scale numbers. The continuous spectrum will give the sensitiveness of the plate to the different parts of the spectrum below its visible region. When the plate is exposed to a light of any colour, the absorption of the plate will be measured at the various numbers of the empiric scale. If the gradation scale is illuminated by a lamp having a very red light, the measured densities can be plotted as 499 SE + 

When the exposure was subtracted from the light falling on the plate, the intensity of the light falling on the plate, and the opacity of the plate at the same point, the sensitiveness of the plate will be found. This method was adopted in a number of experiments, and it was found that in 1857, when a plate was exposed to the light of a gas and a carbon arc, the sensitivity of the plate was 0.51, and the sensitiveness of the plate at the exposure was 0.57.

Measurement of the Rapidity of a Plate.—The first attempt that was made to ascertain the rapidity of a plate was by Abney (Phil. Mag. 1874), who demonstrated that within limits the transparency of deposit varied as the logarithm of the exposure.

The last formula has been accepted for general use, though it is believed that it is not absolutely correct, though very approximations, and sufficiently to be true, is a very good approximation.

In 1888 Sir W. Abney pointed out that the speed of a plate could be determined by the formula: \[ T = E \log E + C \], where \( T \) is the time required by the plate to be exposed to a light of intensity \( E \), and \( C \) a constant. If the abscissae (exposures) are plotted as logarithms, the curve takes the same form as that of the law of error, which has a singularity point, a tangent through which lies closely along the axis of \( E \), and cuts the axis of \( E \) at a point which has a value of \( E \). If the total transparency be unity, this ordinate has a value of 1-212, the singular point having a value of 0-606. The ordinate of the zero point of the curve will be where the tangent to the singular point cuts the line drawn at 1-212. The difference between the measurements of this point for two kinds of plates (i.e. C in the formula) from the points in the empirical equation the constants and are found for each plate, and the constant of the two plates in terms of log \( E \). In 1890 Hurter and Driffield (Journ. Soc. Chem. Ind. Jan. 19, 1891) worked out a less empirical formula connecting the exposure \( E \) with the density \( D \) of the deposit, which is given by the equation \( Y = E \), where \( D \) is the density of the deposit (or log \( t \)), \( i \) the "inertia" of the plate, \( T \) the transparency of the deposit. In the customary way a rectangular plate is exposed to a constant light at a fixed distance, and for a fixed time, and another small portion to the same light for double the time, and so on. By measuring the densities of the various deposits and constructing a curve, a large part of which is approximately a straight line, it was found possible, by the production of the straight portion to meet the axis of \( X \), to give the relative sensitiveness of different plates by the distance of the intersection from the zero point of \( L \). (See also Exposure Meters, under \( \epsilon \) Aperture.)

Effect of Temperature on Sensitiveness.—In 1876 Abney showed that heat apparently increased, while cold diminished, the sensitiveness of a plate, but the experiments were rather of the qualitative than the quantitative order. In 1893, from fresh experiments, he found that the effect of a difference in temperature of some 40° C. invariably caused a diminution in sensitiveness of the sensitive salt at the lower temperature, a plate often requiring more than double the exposure at a temperature of about -18° C. than it did when the temperature was increased to +33° C. The general deduction from the experiments was that increase in temperature involved increase in sensitiveness so long as the constituents of the plate (gelatin, &c.) were unaltered.

In 1896 Sir W. Abney of the Royal Institution in 1896 that at a temperature of -180° C. certain small bands regarded in sensitiveness to less than a quarter of that which they possess at ordinary temperatures. It appears also, from his subsequent inquiry, that when the same films were subjected to the temperature of liquid hydrogen (-250° C.) the loss in sensitiveness becomes asymptotic as the absolute zero is approached. Presumably, therefore, some degree of sensitiveness would still be preserved even at the absolute zero.

Effect of Small Intensities of Light on a Sensitive Salt.—When a plate is exposed for a certain time to a light of given intensity, it is commonly said to have received so much exposure (E). If the time be altered, and the intensity of the light also, so that the exposure (time \( X \) intensity) is the same, it was usually accepted that the energy expended in doing chemical work in the film was the same. A series of experiments conducted under differing conditions has shown that such is not the case, and that the more intense the light (within certain limits) the greater is the chemical action, as shown on the development of a plate. Fig. 6 illustrates the results obtained in three cases. The exposure E is the same in all cases. The curves are so drawn that the scale of abscissa contains only the exposure E.
is the intensity of the light in powers of \(-2\), and the ordinates show the percentages of chemical action produced. If the chemical action remained the same when the intensity of light was reduced, \(E\) remaining the same, each of the curves would be shown as a straight line at the height of 100, which is the transparency of deposit with the unit of light. As it is, they show diminishing percentages as the light intensity is diminished.

Fig. 6.

Thus, when the intensity of the light is reduced to \(2^\frac{1}{2}\) of the original, and the time of exposure is prolonged 64 times, the useful energy expended on a lantern plate is only 50% of that expended when the light and time of exposure are each unity. In the cases to which the diagram refers, the light used was a standard amyl acetate lamp, and the unit of intensity taken was this light at a distance of 2 ft. from the plate, and the unit of time was 10 seconds. The lamp being moved to 16 ft. from the plate, gave an intensity of \(2^\frac{1}{8}\) the unit, and the time of exposure had to be increased to 640 seconds, so that \(E\) was the same in both cases. Further, it was found that when the times of exposure on different parts of the plate were successively doubled, light at a fixed distance being used for one series, and altered for a second series, the slopes of the curves of transparency (i.e., the gradation) were parallel to one another. This investigation is of use when camera images are in question, as the picture is formed by different intensities of light, not very different from those of the amyl acetate lamp, the time of exposure being the same for all intensities. The deductions made from the investigation are that with a slow plate the energy expended in chemical action is smaller as the intensity is diminished, while with a quick plate the variation is much less. As a practical deduction, we may say that to obtain proper contrast in a badly lighted picture it is advisable to use a slow plate.

Effect of very Intense Light on a Sensitive Salt.

Another investigation was made as to the effect of very intense light on sensitive surfaces. In this case a series of step-by-step graduated opacities was made use of, and plates exposed through it to the action of lights markedly differing in intensity, one being that of the amyl acetate lamp, another that of the arc light, and a third the light emitted from the spark of a Wimshurst machine. The exposures were so made that one of the opacities produced on the plate from exposure to each source of light was approximately the same. The unit of intensity of light is, of course, in each case widely different. The slope of the curve due to the spark light is less steep than that due to the arc light, and the latter, again, is much less steep than that due to the amyl acetate lamp. A further investigation was made of the effect of increasing the time of exposure when the intensity was diminished, and it was found that with all plates the useful chemical energy acting on a plate was least with the most intense light, but increased as the intensity diminished, though the time was correspondingly increased. This is the reverse of what we have recorded as taking place when a comparatively feeble light was employed. Further, it was proved that the variation was greatest in those plates which are ordinarily considered to be the most rapid. It follows, therefore, that there is some intensity of light when the useful chemical energy is at a maximum, and that this intensity varies for each kind of plate.

Intermittent Exposure of a Sensitive Salt.—The same investigator has shown that, if a total exposure is made up of intermittent exposures, the chemical action on a sensitive salt is less than it is when the same exposure is not intermittent. It was also proved that the longer the time of rest between the intermittent exposures (within limits) the less was the chemical action. We may quote one case. Exposures were first made to a naked light, and afterwards to the same light for six times longer, as a rotating disk intervened which had 12 apertures of \(4^\circ\) each at equal intervals apart, and 720 intermittent exposures per second were given. The plate was moved to different distances from the light, so that the intensity was altered. The apparent loss of exposure by the intervention of the disk increases as the intensity diminishes, the ratio between the chemical energy usefully employed of the naked light exposure to that of the alternate exposures being:

For intensity 1

\[
\begin{align*}
\text{For intensity} & : 1 \text{ to } 815 \\
\text{Intensity} & : 1 \text{ to } 500 \\
\text{Intensity} & : 1 \text{ to } 423 \\
\text{Intensity} & : 1 \text{ to } 370
\end{align*}
\]

These results appear to be explicable by the theoretical considerations regarding molecular motion.

Effect of Monochromatic Light of Varying Wave-lengths on a Sensitive Salt.—It has been a subject of investigation as to whether the gradation on a plate is altered when exposures are made to lights of different colours; that is to say, whether the shade of tone in a negative of a white object illuminated by, say, a red light, would be the same as those in the negative if illuminated by a blue light. Abney \(^1\) announced that the gradation was different; and, quite independently, Chapman Jones made a general deduction for isochromatic plates that, except with a certain developer, the gradation was steeper (that is, the curve shown graphically would be steeper) the greater the wave-lengths of the light to which the sensitive salt was subjected. For plates made with the ordinary haloid salts of silver Chapman Jones’s deduction requires modification. When monochromatic light from the spectrum is employed, it is found that the gradation increases with wave-lengths of light which are less, and also with those which are greater, than the light whose wave-lengths has a maximum effect on the sensitive salt experimented with. Thus with bromo-iodide of silver the maximum effect produced by the spectrum is close to the blue lithium line, and the gradation of the plate illuminated with that light is less steep than when the light is spectrum violet, green, yellow or red. From the red to the yellow the gradation is much the steepest. Whether these results have any practical bearing on ordinary photographic exposures is not settled, but that they must have some decided effect on the accuracy of three-colour work for the production of pictures in approximately natural colours is undoubtedly, and they may have a direct influence on the determination of star magnitudes by means of photography.

Reproduction of Coloured Objects by means of Three Photographic Positives.—Ives’s Process.—A practical plan of producing images in approximately the true colours of nature has been devised by preparing three positives of the same object, one

illuminated by a red, the other by a green, and the third by a blue light; the images from these three transparencies, when visually combined, will show the colours of the object. This plan was scientifically and practically worked out by F. E. Ives of Philadelphia, though in France and elsewhere it had been formulated, especially by Hauron Du Clos.

The following passage may be taken as that of Ives's process, by the trichromatic theory of colour-vision every colour in nature can be accounted for by the mixture of two or three of the three-colour sensations, red, green, and blue, to which the eye is supposed to respond. Thus a mixture of a red and green sensation produces the sensation of yellow; of a green and blue, that of a blue-green; of red and blue, that of purple; and of all three, that of white. For the sensations we may substitute those colours which most nearly respond to the theoretical sensations without any material loss of purity in the resulting sensation. We must take the spectrum of white light as the only perfect scale of pure colours. It has been proved that the red sensation in the eye is excited by a large part of the visible spectrum, but with varying intensities. If, then, we can on a photographic plate produce a developed image of the spectrum which exactly corresponds in opacity and position to the amount of red stimulation excited in those regions, we shall, on illuminating a transparent positive taken from such a negative with a pure red light, have a representation of the spectrum such as would be seen by an eye which was only endowed with the sensation of red. Similarly, if negatives could be taken to fulfil the like conditions for the green and for the blue sensations, we should obtain positives from them which, when illuminated by pure green and blue light respectively, would show the spectrum as seen by an eye which was only endowed with a green or a blue sensation. Evidently if by some artifice we can throw the coloured images of these three positives on a screen, superposing them one over the other in their proper relative positions, the spectrum will be reproduced, for the overlapping colours, by their variation in intensity, will form the colours intermediate between those used for the illumination of the positives. For the purpose of producing the three suitable negatives of the spectrum, three light-filters, through which the image has to pass before reaching the photographic plate, have to be found. With all present plates these are compromises. Roughly speaking, the screens used for taking the three negatives are an orange, a bluish-green and a blue. These transmit those parts of the spectrum which are red, blue-green or blue respectively. When these are obtained an image of a coloured object can be reproduced in its true colours.

Abney devised sensitometers for determining the colours of the screens to be placed before the lens in order to secure the three-colour negatives which should answer these requirements. Their production depends upon the same principles indicated as necessary for the correct rendering in monochrome of a coloured object. When the sensitometer takes the form of glasses through which light is transmitted to the plate, the luminosities of the coloured lights transmitted are determined, and also their percentage composition in terms of red, green, and blue lights, and these are deduced the luminosities in terms of red, green and blue. For ascertaining what screen should be used to produce the red negative the luminosity transmitted through each glass is so adjusted that a luminosity of the red components is exactly made equal by rotating a disk with correct apertures cut out close to the row of glasses. This gives a sensitometer of equal red values. A coloured screen has to be placed between the three placed in the three positions, the opacities of the deposit on the plate, corresponding to each square of glass, to be the same throughout. This is done by trial, the colour being altered till the proper result is obtained. In a similar way the green and blue screens are determined, the pigments rotating on a disk can also be employed, as indicated in the paragraph on the correct rendering of colour in monochrome.

As to the camera for the amateur, whose plates are not as a rule large enough to accommodate all the negatives should be obtained on one plate, since only in this way can they be developed and the densities increased together. [For commercial work the negatives often cannot be taken on the same plate, as it would make the plate too large to manipulate, but many of them may be arranged side by side, bringing successively the three portions of the plate opposite the lens. It is convenient to have a slide, in front of which a holder containing the three screens can be fixed, which will then be close to the plate; such a one has been devised by E. Sanger-Shepherd. The light passes through them one by one as the plate is moved into the three positions. The exposures are given separately, after which the plate is ready for development. The exposures may be a source of trouble at times, particularly in the case of landscapes, for the lighting may vary and the sky may have moving clouds, in which case the pictures would show variations which should not be.] Sanger-Shepherd's camera is of an important class in which the three images are thrown side by side on the plate. Thus any movement in the picture affects all three negatives alike.

Abney has also introduced a new camera in which he can work in a larger angle than that of Sanger-Shepherd. The next point is the exposures which should be given through each screen. This can be done by placing in front of the plate and extending its whole length a scale of graduated squares. The light resting on a sun-illuminated white card passes, as well as through the screens. In the case of the three-exposure camera the times of exposure are varied till the densities of the image of the gradation appear the same in each of the three images. In the case of the single camera, the light reaching the plate through the screens is altered by cutting off with a shutter more or less of the lens used. As the plates employed for the practice of the three-colour negatives must be sensitive to every colour, the ordinary dark-room light should be most cautiously used. If used at all, it should be very feeble and development must be carried out in a dish with a cover to it. The plate is manipulated in the usual way.

Joly's Process.—Professor J. Joly, of Dublin, in 1897 introduced a colour process by which an image in approximately natural colours could be thrown upon a screen by an optical lantern, only one transparency being employed, instead of three, as in the Ives process. A "taking" screen was ruled with alternating orange, blue-green and blue lines 1/10 to 1/8 in. apart, touching one another and following one another in the above order. When such a screen was placed in front of a sensitive plate in the camera, and exposure made to the image of a coloured object, there were practically three negatives on the same plate, each being confined to the area occupied by lines of the same colour. The shades of colour and the depth of the colours used in ruling depended on the brand of plate. When a perfect triune negative was obtained, a transparency was made from it, and in contact with this was placed a screen ruled with lines the same distance apart, but of the colours corresponding to the three colour sensations, namely red, green and blue. The red lines were made to fall on the image taken through the orange lines, the green on that of the blue-green, and the blue or violet on that of the blue. On the screen there are practically three differently coloured images, one by one, the transparency. The eye blends the different colours together, and a picture is seen in approximately the correct colours of the original.

Autochrome.—A very remarkable process, founded on J. Joly's process, was introduced in 1907 by A. Lumière et ses Fils of Lyons. Starch grains of very minute size, some of which were dyed with a red stain, a second portion with a green, and a third portion with a blue, are mixed together in such proportions that a line layer of them appears grey when viewed by transmitted light. Under a magnifying glass the grains are coloured, but owing to the want of focus in the eye the colours blend one with the other. Such a layer is embedded on the surface of a glass plate in a waterproof vehicle, and a film of sensitive emulsion held in situ in some material, the composition of which has not been published, covers this layer. When such a plate is placed in the camera, with the back of the plate next the lens, the light passes through the coloured grains, and again we have three negatives on one plate, but instead of each negative being represented by lines as in the Joly process they are represented by dots of silver deposit. Owing to the way in which the three-coloured film is prepared, it is evident that a positive taken from such a negative could not be backed with granules of the right colour, as the granules are placed at random in the layer. Lumière, to overcome this difficulty, converted the negative into a positive, by very ingenious means. The plate was developer first by pyrogallic and ammonia in the usual way, but instead of fixing it was plunged into a solution of potassium permanganate and sulphuric acid. This dissolved all the silver that had been deposited during development and left a film of unaltered silver salt. On looking through the plate the colours of the coloured layer coming through the different dots where the silver was at
first deposited appeared in view, and the image was the image in colour of the object photographed. The plate after being washed was taken into the light and redeveloped with an alkaline developer, which converted the sensitive salt of silver to the metallic state. The image now consisted of black particles of silver and the coloured image. The plate was next fixed in hypo of soda to remove any unreduced silver salt that might be left, and the picture after washing was completed. The coloured image so obtained is a very close representation of the true colours, but as the "taking" screen is the same as the "viewing" screen some little variation must result.

**Positives in Three Colours.**—Ives was the first to show that a transparency displaying approximately all the colours in nature could be produced on the same principles that underlie the three-colour printing. This he effected by printing each of the three negatives, produced for his triple projection process as already described, on gelatine films sensitized by bichromate of potash. Each of the three transparent films was dyed with a colour complementary to the colour of the light which he transmitted through the positives when used for projection. Thus the "red" positive he dyed with a blue-green dye, the "green" positive with a purple dye, and the "blue" positive with a yellow dye. These three films, when superposed, gave the colours of the original object. Sanger-Shepherd has made the process a commercial success (see *Process*) and produces lantern slides of great beauty, in which all colours are correctly rendered. Instead of using a dye for the "red" transparency, he converts the silver image of a positive image into an iron salt resembling Prussian blue in colour. (W. DE W. A.)

**II.—Photographic Apparatus**

Photographic apparatus consists essentially of the camera with lens and stand, lens shutters, exposure meters, prepared plates for the production of negatives or transparencies, sensitive papers and apparatus for producing positive prints, direct or by enlargement. Besides these there are many subsidiary accessories.

Since the introduction of highly sensitive dry plates and their extended use in hand cameras, the art and practice of photography have been revolutionized. Numerous special forms of apparatus have been created suitable for the requirements of the new photography, and their manufacture and sale have become important industries. The value of the exports of photographic materials from the United Kingdom in 1906 was £2,716. The most important improvement has been in the construction of anastigmatic lenses, which, having great covering power, flatness of field, and freedom from astigmatism, can be worked with very much larger apertures than was possible with the earlier forms of rectilinear or aplanatic lenses. This increased rapidity of framing thus gained has rendered it easy to photograph objects in very rapid motion with great perfection. This has encouraged the construction of the very light and portable hand cameras now so universally in use, while, again, their use has been greatly simplified by improvements in the manufacture of sensitive plates and films and the introduction of light, flexible, sensitive films which can be changed freely in daylight. The introduction in 1907 of Messrs Lumière's "Autochrome" process of colour photography has also been a great advance, tending to popularize photographic work by the facility it offers for reproducing objects in the colours of nature.

**The Camera.**

**Historical.**—The camera obscura (q.v.) was first applied to photographic use by Thomas Wedgwood between 1792 and 1802. No description of his camera is available, but it was probably one of the sketching cameras then in use. In 1813 W. H. Wollaston found that by using a meniscus lens with a concave surface towards the object and the convex towards the screen, a diaphragm being placed in front, the projected image of the camera obscura was greatly improved in sharpness over a larger field. The first photographic lenses made by V. and Ch. L. Chevalier in Paris (1820–1840) were on this principle. The photographic camera in its simplest form is a rectangular box, one end of which is fitted to carry a lens and the opposite one with a recess for holding the focusing screen and plate holders, these ends being connected by a rigid or expanding base-board and body, constructed to keep out all light from the sensitive plate except that passing through the lens. In 1816 Joseph Nicéphore Nièpce, of Chalon-sur-Saône, made a little camera or, artificial eye, with a box six inches square fitted with an elongated tube carrying a len
ticular glass. There are now in the Chalon Museum cameras of his with an iris diaphragm for admitting more or less light to the lens; some with an accordion bellows, others with a double expanding rigid body for adjusting the focus. The iris dia
phragm was adopted later by Chevalier for his photographic lenses. In 1835 W. H. Fox Talbot constructed simple box cameras for taking views of his house on sensitive paper, and claimed them as the first photographs of a building (Phil. Mag. 1839, 14, p. 206). Fr. von Kobell and C. A. Steinheil, early in 1836, made a camera with an opera glass lens for taking lands
scapes on paper. Later in 1839 J. W. Draper successfully used a camera for his daguerreotype experiments made of a spectacle lens, 1½ in. focus, fitted into a cigar box. He also used a camera fitted with a concave mirror instead of a lens. Similar cameras were constructed by A. T. Wolcott (1830) and R. Beard (1841) for reversing the image in daguerreotype portraits. They have also been recommended by V. Zenger (1875) and D. Mach (1880) for scientific work.

L. J. Daguerre's camera, as made by Chevalier in 1839 for daguerreotype, was of Nièpce's rigid double body type, fitted with an achromat meniscus lens with diaphragm in front. Using Wollaston's principle, the back part with the plate moving away from the lens for focusing, and fixed in its place with a thumbscrew. This expanding arrangement enabled lenses of different focal lengths to be used. With modifications cameras of this type were in use for many years afterwards for portrait and studio purposes. For work in the field they were found inconvenient, and many more portable forms were brought out, among them G. Knight's and T. Ottewill's single and double folding cameras (1853), made collapsible with hinges, so as to fold on to the base-board. Cameras with light bodies made of waterproof cloth, &c., also came into use, but these were superseded by cameras with collapsible bellows-body of leather, which, invented by Nièpce, were used in France, in 1839, by Baron A. P. de Ségurier and others for daguerreotype. The first record of them in England is, apparently, J. Atkinson's portable stereoscopic camera of parallel-side bellows form (Ph. Journ. 1857, 3, p. 261), which was soon followed by C. T. H. Kinneir's lighter conical form, made by Bell of Edinburgh (Ph. Journ. 1858, 4, p. 166). They have since been made in various patterns, conical, oblong and square, by F. Meagher, G. Hare and others, and are still, in modified forms, in general use as studio, field or hand cameras. When wet collodion plates were used many cameras were fitted with arrangements for developing in the field.

Information on these and other early cameras will be found in the photographic journals, in C. Fabre's *Traité encyclopédique de photographie*, vol. i., and in J. M. Edet's *Ausführliches Handbuch der Photographie*, 2nd ed., vol. i., pt. ii.

The distinctive feature of present day photography is the world-wide use of the hand camera. Its convenience, the ease with which it can be carried and worked, and the remarkably low prices at which good, useful cameras of the kind can be supplied, concurrently with improvements in rapid sensitive plates and lenses, have conducd to this result. It has also had a valuable educational influence in quickening artistic perception and scientific inquiry, besides its use in depicting scenes and passing events for historical record. Small portable cameras had been made by G. G. Edwards (1855), T. Scaife (Pistolograph, 1858), A. Bertsch (1860), T. Ottewill (1861), and others, but it was not until rapid gelatin dry plates were available in 1831 that T. Bolas brought out his "detective" camera (Ph. Journ. 1881, p. 59). It consisted of a double camera (one as finder, the other for taking the picture) enclosed in another box, suitably covered, which also contained the double-plate carriers and had apertures
PHOTOGRAPHY

APPARATUS

In front of the viewing and taking lenses. In another form the finder was omitted. A month later A. Loiseau and J. B. Germeull-Bonnaud patented an opera glass camera. Various forms of a portable camera followed, among them A. Phippshe’s “Repeating Camera” (1854) W. Howlett’s “Frontier Camera” (1857), R. Kruger’s camera (book form, 1888), and others in collapsible or box forms disguised as books, watches, &c., but they did not come into general use before 1888, when the Eastman Company of Rochester, U.S.A., brought out their very portable roll-film cameras, now known under the trade name of “Kodak.” The manufacture of these and other light hand cameras has since become a very important and flourishing industry in Great Britain, Germany, France, and the United States. It is noteworthy that the most modern form of hand camera, the reflex, goes back to an early type of portable camera obscura, figured by Johann Zahn in 1686, in which a mirror was used for reflecting the image to a paper or dark slaving screen, at the same time reversing it. The first photographic camera on this principle was T. Sutton’s (1860), which has served as a basis for many subsequent developments. A. D. Lomans’s (1859) and R. Kruger’s (1891) were early examples of the hand camera type, but great improvements have since been made.

Modern cameras differ so much in details of improved construction that only a few of the more important requirements can be noticed. A camera should be well and strongly made of seasoned wood or of metal. From a time when set on the table any part of the axis of the lens in respect to the sensitive plate. The front and back of the camera should normally be vertical and parallel, and the axis of the lens perpendicular to the centre of the plate, but arrangements are usually made by vertical and lateral adjustments on the camera front for raising the lens to take in less foreground or vice versa, or for moving it right or left, the latter becoming a vertical adjustment when the camera has been turned on its side. In the Adams “Idento” camera the lens and film are mounted together on the rising front according as the camera is used horizontally or vertically, the finder showing in either case the identical view of the scene in front of the lens. The best modern cameras are fitted with a swing-back or swing-front and sometimes a swing-back is necessary for bringing back the plate to the vertical position, so as to prevent convergence of vertical lines, when the camera is moved vertically. The front of the modern camera is tilted, answers the same purpose, provided the camera is kept level. If further tilting is necessary, when taking high buildings &c., the swing-back and front may both be required, but must be kept vertical and parallel and the effect is that of an abnormal rising front. Many modern cameras are fitted with a double rising front. The vertical and side swings are also useful for equalising the definition of objects at different distances from the camera, but they affect the perspective, and the swing-back is the preferred way of round the central horizontal or vertical axis of the back or front, but are frequently effected by simple inclination of the back or lens front on a hinge. When the rising front is used a double rising front is necessary, in which case provision must be made to stop the front down to obtain good definition over the extended area of the picture. A slight inclination of the lens may also be useful in readjusting the focus. The camera and plate carriers must be provided with reversing mechanisms to be used in the base-board. In some French cameras the back part of the camera with the bellows is reversible, to be used upright or horizontal.

Focusing.—The earlier cameras were focused by drawing out the back and focusing with a hand-lens or by adjusting the base-board. When bellows cameras were introduced they were focused by an endless screw, and these are still used for large copying cameras. Most modern cameras are fitted with rack and pinion mechanism, or some form of rack and pinion mechanism in front of the camera or on either side. Many hand cameras, requiring to be brought to focus at once, are fitted with studs (infinity catches) which fix the front in focus for distant objects, nearer distances being noted on an engraved scale on the camera, or in some cases by measurement. In hand cameras with fixed infinity focus, the necessary adjustments for distance of near objects are made on the lens mount. The focusing screen may be ruled with parallel lines for measuring the distance, or it may be of a rectangular form, for gauging the verticality of the camera when photographing buildings or other objects with vertical lines. The distance of the lens from the focusing screen and vertical line in the plate with the slide must coincide exactly. This can be tested by measurement or by focusing a bright, well-defined object on the screen and then on a ground-glass screen placed in the camera back, showing the exact extent of the picture on the focusing glass. In long or wide for the miroetro, still films are placed mounted at the back of the camera as it appears in a frame with cross wires on the rising front, adjusted to the size of the plate and the focus of the lens. Finders are practically small reflex cameras, and the subject is viewed in a focused image through a plane mirror mounted at the back of the camera as appears in a frame with cross wires on the rising front, adjusted to the size of the plate and the focus of the lens. This is done in the “Adams Identoscope” (1908), which is fitted to the swing front and adjusted by a lever to follow the movement of the lens.

As the slides to be examined, A level of the other, rectilinear objects in the view together is preferably used for the examination of the slides, the rectangular concave glass mounted on the camera is also a convenient form, it can be combined with a mirror for vertical observations, in Watson’s view form is also arranged as a level and telemeter (B. J. A. p. 736). The distances used for facing should correspond exactly with that on the plate. When the rising front is used special arrangements have to be made to ensure the air of coincidence of the mirror and ground-glass. This is done in the “Adams Identoscope” (1908), which is fitted to the swing front and adjusted by a lever to follow the movement of the lens.

The book-form double dark-slide has been in use since the early days of calotype paper negatives, and contains two plates separated by a blackened metal plate; three of them usually form a set, the shutters being numbered 1 to 6, the odd numbers on the opening side. Inner shapers can be used for smaller plates if desired. The slides should fit exactly in the camera, and the shutters run smoothly out and in. They must be perfectly light-tight, the corner joints, the hinges in the shutters, and the openings in the sides and top of the book-form. The latter have openings requiring careful examination or protection by metal plates. The shutters of dark-slides are either jointed or solid and removable; the former is perhaps the more convenient, but both forms may become liable to let in light. Various forms of solid slides, single and double, are now made in wood or metal, or of wood for the frame and metal for the shutters; they are lighter, more compact and less liable to admit light to the plates. In some cases one slide can suffice for the exposure of several slides in quick succession, and deserve to be in envelopes, as in the “Wishart-Mackenzie” slide, the “Victrix” and other similar ones, or contained in a single packet, as in the Premo Film-pack, and is a convenient arrangement. The Premo Film-pack contains a set of twelve thin celluloid films to be placed in the camera, exposed, removed, and replaced, and stored in envelopes, as in the “Wishart-Mackenzie” slide, the “Victrix” and other similar ones, or contained in a single packet, as in the Premo Film-pack.

FIG. 2.—Sinclair Folding Camera.

of ordinary indoor or outdoor work can be undertaken within the size of the plate, and the extension of the bellows, which should be quite double the focus of the lens.

The multiplicity of forms and arrangements of hand cameras makes it difficult to classify them into distinct types; but they may be mainly divided into box and folding cameras, and further into
(a) cameras with enclosed changing magazines for plates or flat films;
(b) with enclosed roll film on spools;
(c) with separate changing magazines, changing boxes or roll-holders;
(d) with single, double or multiple plate carriers or film-packs.

Most cameras that will take glass plates in the ordinary plate-holders will take cut films in suitable sheaths or can be fitted with enrole slides, film-packs or roll-holders. The normal size for hand cameras is 6 x 6, 7 x 7, 8 x 8 cm. It is also a popular size, and cameras for the post-card size, 5½ x 3½ in. or 15 x 10 cm., have been largely adopted. Smaller sizes are also made for lantern plates and for the light-diffusion frame in the form of stereoscopes, field-glasses or watches, as in the "Ticka," but the pictures are small and require enlarging. Hand cameras are constructed on the same principles as stand cameras, but, being specially intended for instantaneous work, they are simplified and adapted for rapid focusing and exposing. The focusing screen is superseded or supplemented by finders arranged to show the limits of the subject on the plate, the focus being adjusted by the infinity catches and focusing scales above noticed. Swing-backs and fronts are often dispensed with, but are desirable adjuncts, and a rising and falling front particularly so. Lenses of fairly large aperture giving good covering power, preferably of the anastigmatic type, or a rapid aplanat, should be used, but for very rapid work anastigmats working from f/4 to f/6 will be more widely fitted and can also be used in hand cameras, and for ordinary purposes should give fairly accurate exposures from 1/5 to 1/10 of a second or less and also time exposures. Some central shutters are speeded for shorter exposures to 1/2 second, but for these focal plane shutters are the desirable, and for the more rapid exposures to 1/100 of a second and less are necessary. The shutter should be efficient, regular in action, and readily set by gentle pressure, pneumatic or otherwise. Mechanism for advancing films should be simple and not readily put out of order, special care being taken to avoid rubbing or charring of the plates in changing or transport. In changing plates or films the number of plates exposed should be recorded automatically, and duplicate exposures prevented as far as practicable. A circular level placed near the finder is useful.

The choice of a hand camera depends upon the circumstances in which it is to be used, and the purpose for which it is principally required. For general work and with the modern facilities for changing and cutting plates and films in daylight, the numerous folding hand or stand cameras for plates, flat or roll films, with full adjustments, will be found most useful. Box or magazine cameras in which a supply of cut films or plates can be carried, changed mechanically, and exposed rapidly in succession, are convenient, but their use is limited and they are liable to get out of order.

A third class are the reflex and other hand cameras with focal plane shutters, usually specially rapid instantaneous work as noticed below. The two types of light folding hand or stand cameras, specially adapted for hand camera work—those plates are kept in one recess and cut films, and the folding pocket Kodak or other roll-film cameras. The former are now made of very light construction with mahogany or metal bodies, wooden or aluminium base-boards, thin metal dark-slides (fig. 3). The cameras of the pocket Kodak type are generally simple, but can be made to take roll films on spools, or with an attachment for focusing glass and dark-slides for taking plates and cut films. Attached to a slide-strap the quarter-plate size can be quite conveniently carried in a side-pocket. Watson's "Def" folding camera is fitted with a focal plane shutter (fig. 4). The "Selfix carbine" camera has a self-erecting front bringing the lens at once into position for use on opening out. Those fitted with lenses of fairly large aperture, double extension, and rising and falling fronts are to be preferred. Of box or magazine cameras there is an immense variety. In some the lens is fixed for all objects within a certain distance, in others it is adjusted by a focusing scale on the lens or by an extending front. Some are designed for panoramic work, others for single magazine, others two or more. Some take only glass plates, others plates or cut films. All of them are, however, self-contained and ready for immediate exposure. One of the earliest forms of single-magazine cameras, still in use, as in the "Eureka" and "Yale," is the "bag," in

FIG. 3.—Ermann's Pocket Camera.

FIG. 4.—The "Def" Folding Focal-plane Camera.

FIG. 5.—Double-magazine Box Camera.

FIG. 6.—The Verascope, Richard.

which a supply of plates or films in sheaths, is kept in a magazine behind the camera, ready for exposure. The plates as exposed being lifted with the fingers into a bag or expanding chamber above the magazine and placed behind the rest of the plates at the back, a fresh plate taking its place in front. In some forms the magazines are removable, in others replaceable by others. The arrangement is simple and effective, but the bag, usually made of soft leather or cloth, is liable to wear and puncture, and may make dust. The cameras with double magazines in which unexposed and exposed plates are carried simultaneously, are prone to get out of order, and often to get out of order after exposure to a second recess.
ingenious devices have been invented for effecting the change (fig. 5). Some forms are effective and popular on account of their compactness and readiness for immediate exposure, but there is always a risk of the mechanism failing, and care has to be taken in charging them to lay the plates truly in their places. The very handy, binocular cameras, or photo-jumelles, of which the "Vera-scope" (fig. 6) is a type, are of this class, and have additional to be exposed when desired. Binocular hand cameras are also made on this principle, one compartment serving for focusing, the other holding lens and plates. Stereoscopic cameras are another form of twin-lens cameras, and are usually made for also taking single panoramic pictures.

In reflex cameras only one lens is necessary, though two are convenient, and can be used somewhat as in fig. 9. They generally consist of a cubical box camera containing a movable mirror facing the lens at an angle of 45° and throwing up the image projected from it on to a horizontal focusing screen, on which it is viewed through a flexible hood which folds down in the upper part of the camera when not in use (fig. 10). In order to get the greatest rapidity of exposure a focal-plane shutter is generally fitted, and by a single movement of the release the mirror is smoothly lifted and the plate exposed simultaneously. They should be fitted with anastigmatic lenses working at large apertures for very rapid work. In some forms the lens is fixed, but usually there is a front bellows extension for long-focus lenses, with rising and falling front, to which swing motion may be given, a swing-back not being generally used with the focal plane shutter. In the "Ernex" camera E. Human has made an arrangement by which the camera back, horizontal viewing screen and reflector are made to swing simultaneously, by a rack and pinion movement. They may also have reversing or revolving backs for quickly changing the position of the plate. 3 in. X 4 in. and 4½ in. X 6 in. are the usual sizes of the plates, but larger and smaller sizes are also available. These cameras require the best workmanship and perfect mechanism for successful working and freedom from any jarring movement in releasing the shutter or mirror. The focusing screen must be in accurate register with the focus of the lens on the plate. Those forms in which the image can also be viewed at the height of the eye, as in the Graflex fig. 10, are preferable. Although reflex cameras are rather heavy and bulky as hand cameras, they have many advantages over the ordinary hand camera with finder and focusing scales for the purpose of the press photographer, the naturalist and others, in observing and recording very rapid movements, and have come into very general use for such purposes. They permit the accurate focusing of a full-sized image on the ground-glass up to the moment of exposure, especially useful when lenses of very short focus are required and when the rising or swing front is in use. The aspect of this image on the ground-glass is also a great aid in the selection and placing of the subject, and in judging the exposure required for it. They practically have all the advantages of a stand camera and can be used as such on a stand for subjects requiring prolonged exposure. They are also coming into increasing use in studio work for portraits of children, &c. Their use and adjustments are discussed by G. E. Brown in the British Journal Almanac for 1909.

Panoramic Cameras.—Many so-called "panoramic cameras have been introduced from time to time, among them T. Sutton's (1861), and J. R. Johnson's "Panoramic" (1864), but did not come into general use till the use of curved surfaces of celluloid film enabled such cameras of convenient size and weight to be put on the market. They are on the same principle as one made by F. von Martens in 1845 for curved daguerreotype plates, and covering an angle of 150°. P. Motassard's "Cylindrographe" of 1889 was the first of the modern type. It consists of a semi-circular
PHOTOGRAPHY

[AAPPARATUS]

camera, the front of it formed of light-proof cloth and the back by the curved flexible carriers. The lens is fitted on a vertical axis, so that the nodal point of emergence remains motionless; it is revolved round it by means of a handle striking a view meter. The illumination of the image is regulated by an adjustable vertical slit in a tube attached to the lens inside the box, and by altering the rate at which the plate receives the image (ivd. 112 and 112). The apparatus folds up together and is quite portable; it is fully described in Môssard's Le Cylindrographe (Paris, 1889). The "Al-Vista" (1901) and the "Panoram Kodak" (1900) are on the same principle as roll-holder hand cameras, in two sizes, carrying film for several exposures, 7 in. × 12 in. or 4 in. × 12 in. They work instantaneously, and by means of a clock-spring the lens rotates rapidly over a half-circle when released. The above views illustrate (figs. 11 and 12). The views taken with this kind of camera are disappointingly, on account of the development of cylindrical perspective, a face causing apparent distortion. This distortion is avoided in Carl Zeiss's 16 plate camera, and recently in a camera for plates 6½ in. × 3½ in., fitted with "Tesmar" lens and plate holder. This camera has two apertures and two different circular cameras which can be used for stereoscopic or single pictures. Other more elaborate instruments driven by clockwork have been made, among them C. Daurbezeau's "Cyclographe," which can be used with lenses of different foci and takes the pictures on a roll-film, which is unraveled as the instrument revolves on its axis, the lens also rotating on its nodal point of emergence; and thus the image always remains sharp (Bull. Soc. Franc. d. Phot., 1891, p. 183). Commandant A. Daubresse has improved on Môssard's apparatus, by placing the lens vertically between two right-angled prisms, the upper part of which receives the image cast by the revolving system on the plate (Bull. Soc. Franc. d. Phot., 1897, p. 91). The "Periphote" and Ederman's "Rundblick" camera are improved forms (E. Jb., 1908, p. 322).

Many early forms of panoramic cameras are described in B. J. A., 1894, p. 171, Colonel R. W. Stewart's "Theodolite," and A. Chevalier's "Photographic Plane Table," J. Bridges Lee's "Photo-Theodolite" (1894), and similar cameras fitted with telescopes, levels and divided circles, are instruments of precision suitable for photographic surveying. This subject is treated extensively in the topographical surveying with stereo-photographic apparatus, on the principle worked out by Dr C. Pulfrich, of Messrs Zeiss & Co., in his stereo-comparator (1903), are being practically developed, and much information regarding them will be found in the work of E. Dolezel and others in J. M. Eder's Jahrbücher, 1903 to 1908; also a paper by Lieut. F. F. Thompson in Geographical Journal, 1908, xxxi. 334.

Camera for Three-Colour Photography.—Many forms of cameras have been constructed for making the three negatives required forichromatic photography. They fall into two types: (1) those with a repeating back fitted with three colour-screens or filters—red, green and violet—and the colour impressions are made successively with one lens upon a single colour-sensitive plate, as in the Sanger-Shepherd system. The colour images are made successively in front of the sensitive plate, in the repeating back, which is moved on for each exposure. In a more recent form, by the same maker, the three images are taken on the sensitive plate with one exposure. The camera is divided into three compartments, and fitted with a sliding diaphragm, which can be regulated for the varying sensitiveness of different plates of the same kind. The central image is impressed directly on the plate; the other two by reflection from prisms and gratings, so as to equalize the sizes of the three images on the sensitive plates, the light being reflected twice. The camera is divided into three compartments: an artificial light being regulated by the reflected image coming from the lens by plane mirrors on to the sensitive plates, and its filtrum is divided through the optical system, but the image charges vary according to the number of this variation of this method have been proposed, in which reflecting prisms replace the mirrors. The different systems have been discussed by W. Gamble (Ph. Jour., 1905, xiv. 150), the latter also by E. Eder (Jahrbücher, 1903, p. 49) and E. Dolezel (Ibid., 1903, p. 314). Some recent forms of "daylight enlargers" can be worked with an ordinary camera. Other cheaper ones are on the fixed focus principle. Enlargers for use with artificial light are made like a lantern, complete with a projection lamp and condenser, and are usually connected to a sensitive plate or paper fixed on an easel or screen. A simple arrangement for daylight enlarging is to fix a suitable camera on to a larger one by a sliding front, and mount the two on a studio stand, which is then shifted in an open sky.

Cinematographs.—Many special cameras and lenses have been introduced for taking on a long flexible sensitized film an extended series of small photographs of the successive phases of movements, and for projecting short films. Among the first successful attempts were Collard & Co.'s "Astragaph," which gave an illusion of motion, in what are known as "living pictures," biographies, &c. Each photograph requires a certain minimum space, which must be maintained in true position in sequence with the rest, some means of regulating the speed of exposure, and keeping the film in position have to be adopted; and there are many different ways of doing it, either by a continuous or intermittent camera and film, or by the motion-picture method, from one roller on to another. The films used are similar to the ordinary celluloid films, but in narrow bands from 1½ in. to 2½ in. in width, the length varying with the number of exposures required, at the rate of 16 to 20 per second. They are perforated on both sides, so that they may run true and have the necessary intermittent motion, the perforations fitting on to studs on a spool-wheel in connexion with the driving wheel and crank handle. Special cameras and projectors are used. This apparatus is used with films of 16 or 18 exposures per foot, a mechanism with two perforations, with large and small perforations, being required both for photographing and projecting; several such are noted below. Absolute rigidity in the camera is essential. Special stands are made for the purpose, but a few portable ones are also used. Special apparatus is required for developing and fixing the exposed films. They are wound on large rollers supported over troughs (pl. 2, fig. 10) (Ibid. xiv. 331). The necessary mechanism, the mechanical arrangements are treated in H. V. Hopwood, Living Pictures (1899); F. P. Liesegang, Handbuch der praktischen Kine- matographie (1907); K. W. Wolf-Czapék, Die Kinephotographie (1907); A. Friedel, Lindsay Johnson, Photographic Optics (1909); Eder's Jahrbücher.

A method of cinematography in colour was introduced by G. A. Smith and C. Urban in 1906, the main features of it being the use of a system for taking, developing and projecting pictures, without imposing the colour records by persistence of vision; the use of two-colour records instead of three, in order to reduce the interval between the successive presentations; adaptation to existing cinematograph machinery and films. These conditions are fulfilled by the use, in place of the ordinary revolving sector shutter in front of the lens passing intermittent white light, of a special, more rapidly revolving shutter divided into four sectors, one fitted with orange-red glass, and another plate with blue-green, and two intermediate opaque sectors, so that at every revolution of the shutter an exposure is made through the red and green glasses alternately. The former passes white and yellow, and then orange, scarlet to deepest red; whilst the latter passes with white, blue, light blue, blue-green, blue, all in proportion according to the red and green sensitiveness of the specially sensitized panchromatic emulsion on the film. The same shutter colour-screens are used for the projection, with an adaptation of the same, supplementary blue rays being added. The results are satisfactory and the method promises to be of great practical value (see Jour. Roy. Soc. Arts, 1906, 57, No. 2936).

Special cameras are made for various kinds of scientific research in photo-micrography, photo-spectroscopy, astronomical photography, &c.

Tripod Stands.—Field cameras are usually supported on wooden tripods, folding, tripod sandals, tripod stools, and the tripod can be adjusted separately in the base-board of the camera. The legs should be capable of extension to about 5 ft. and adjustable in length for use on uneven ground. A tripod stand may be light, but must be steady; a rigid white wooden tripod is recommended, and rubber or cork may be fitted to the points of the legs, and in some cases it may be desirable to strengthen the tripod by a folding adjustable brace. W. Butler's "Swivcam" camera stand is made to enable the camera to be securely fixed in awkward positions and has many valuable special features, great extension, swivel points to the feet, &c. For hand cameras the very light, portable metal folding and walking-stick stands are convenient.

Fig. 13.—Diagram of Camera for Three-colour Photography.
Photographic Objectives or Lenses.

The objective is the most important item of photographic apparatus, because upon it depends the perfection with which a photograph will be produced. Penalties in the projected image are caused by the sensitivity of objects in different planes forming the field of view, which naturally would come to a focus upon a sensitive surface. Therefore, the object must be equally and sharply defined, within a limit of correction from 1/45 to 1/8 of an inch, over a sufficiently wide angle. A good objective must also pass sufficient light to produce the required effect upon all objects within the exposure; the chemical and visual effect must coincide exactly, and it must not distort straight or parallel lines. The fulfillment of these conditions is complicated by the presence of sundry focal displacements or aberrations, which will require the introduction of the central and marginal pencils of rays passing through the lens. It is corrected by varying the curves of the component lenses and by the use of a diaphragm. (2) Coma, or blur, due to lateral spherical aberration of the rays, and the introduction of a characteristic of the rays and the lack of definition and difference of focus between horizontal and vertical lines away from the centre. (4) Curvature of field, also increasing with the obliquity of the rays. (5) Distortion, or the failure of circular to appear as such according to the focal length of the objective. With the single meniscus view lens, used with its concave surface towards the object and a diaphragm in front, a square will appear barrel shaped from inward contraction of the line of the diagonal, while with its convex surface towards the object and the diaphragm behind, it will appear with concave sides from outward expansion from the centre. It can be corrected by using two such lenses with the convex sides outwards and a central negative lens, or periscopic-achromatic lenses, to form the element of the orthoscopic and telephoto types generally show the latter form of distortion. (6) Chromatic aberration, produced by the dispersion of the light, is corrected by making the diaphragm of the coloured rays composing it coming to a focus at different distances from the image focus. It thus affects both the positions and sizes of the image for different objects and causes a bisection of the diagonal forming an object or focusing to a point, giving an image well defined and undistorted. This perfect correction could never be effective in objectives made before 1857, and very few could be effectively used at the same objectives, because although linear and chromatic aberration would be overcome there were always residual aberrations affecting the oblique rays and necessitating the use of a diaphragm, which by lengthening out the rays causes them to define clearly an image of sufficient intensity and rapidity of working. The introduction of rapid gelatin dry plates enabled photographers to work with much greater rapidity than before, and led to a demand for greater intensity of light and greater rapidity of working, and the requirements of the necessary very rapid exposures in hand cameras. For studio and copying work quick-acting lenses are also valuable in dull weather or in winter.

In constructing photographic objectives these aberrations and distortions have to be neutralized, by regulating the curves of the different positive and negative component lenses, the refractive and dispersive indices of the glasses from which they are made, and the distances of the refracting surfaces, so as to produce a bisection of a diagonal forming an object or focusing to a point, giving an image well defined and undistorted. This perfect correction could never be effective in objectives made before 1857, and very few could be effectively used at the same objectives, because although linear and chromatic aberration would be overcome there were always residual aberrations affecting the oblique rays and necessitating the use of a diaphragm, which by lengthening out the rays causes them to define clearly an image of sufficient intensity and rapidity of working. The introduction of rapid gelatin dry plates enabled photographers to work with much greater rapidity than before, and led to a demand for greater intensity of light and greater rapidity of working, and the requirements of the necessary very rapid exposures in hand cameras. For studio and copying work quick-acting lenses are also valuable in dull weather or in winter.

The following are some of the best-known improved objectives of this type: T. Grubb's "Aplanatic" (1878), f/15 to f/10 enabling objectives to be made free from astigmatism, working at the full aperture of the diaphragm independently of the aperture of the objective, and the so-called "depth of focus" for objects in different planes. Photographic objectives may be classified as follows:

1. Single achromatic combinations.
2. Unsymmetrical doublets.
3. Symmetrical doublets.
4. Triple combinations.
5. Anastigmatic combinations—symmetrical and unsymmetrical.
6. Telephotographic objectives.
7. Anamorphic combinations.

They are also sometimes classified according to their rapidity, as expressed by their effective apertures, into "extra rapid," with apertures larger than f/6; "rapid," with apertures from f/6 to f/8; "slow," with apertures less than f/11. Another classification is according to the angle of view, narrow angle "up to 35°; medium angle "up to 60°; wide angle "up to 90°, 100," or more. Many lenses are made in series, differing in rapidity and angle of view as well as in length of focus.

1. Single Achromatic Combination or Landscape Lens.—This is the earliest form of photographic objective, evolved from W. H. Wollaston's improved single perisopic meniscus camera obscura objective, which was achromatic by Ch. Chevalier, and so used by L. J. M. Daguerre, though it required correction for chemical focus, as did the object glasses of telescopes or opera glasses first used for photography. The single landscape lens usually consists of an achromatic meniscus, formed of a biconvex positive crown cemented to a biconvex negative flint to secure achromatism and partially correct the spherical aberration, and may be taken as the type of the "old photographic achromatic lens." (fig. 14.)

2. Aplanatic Combination or Landscape Lens.—This is the only type of photographic objective, evolved from W. H. Wollaston's improved single perisopic meniscus camera obscura objective, which was achromatic by Ch. Chevalier, and so used by L. J. M. Daguerre, though it required correction for chemical focus, as did the object glasses of telescopes or opera glasses first used for photography. The single landscape lens usually consists of an achromatic meniscus, formed of a biconvex positive crown cemented to a biconvex negative flint to secure achromatism and partially correct the spherical aberration, and may be taken as the type of the "old photographic achromatic lens." (fig. 14.)

1. In the diagrams of lenses which follow, a uniform system of indicating the nature of the glass employed by means of the shading has been adopted.

Flint glass is indicated thus:—

Crown glass of low refractive power thus:—

Crown glass of high refractive power thus:—

(These two are used indiscriminately in lenses made before the introduction of the new Jena glass.)

Extra light flint glass thus:—

In most cases the front of the lens is on the right.
PHOTOGRAPHY

f/15, angle 90°, with great covering power and depth of focus. T. R. Dallmeyer's "Rectilinear Landscape Lens" (1888), f/14, angle 60° (fig. 17), was of novel construction, free from brilliance in working and useful for copying. Messrs. Ross's "Wide-Angle Landscape Lens" (1890), f/16, angle 70°, triple cemented and made of Jena glass. Many other excellent objectives of this type have been made by British and foreign makers and are still used, though somewhat superseded by the fully corrected anastigmats specially made to work singly, or as single elements of anastigmatic doublets, as noticed in § 5.

2. Unsymmetrical Doublets—Old Types.—This class includes objectives with comparatively large apertures formed of two disimilar combinations, in most cases correcting each other, with a diaphragm between them. In some the single elements may be used independently. All the older "portrait" lenses, some of the aplanatic doublets and Fr. von Voigtlander's "Orthoscopic" Lens (1857), now disused, are of this type. Even with the present improved conditions, the portraitist working in a studio requires a quick-acting objective of large effective aperture and comparatively slow focus, giving a brilliant well-defined image of near objects in different planes over a restricted field of view. The early single lenses were found to be too slow for portraiture by the daguerreotype and talbottype processes, and the efforts of opticians were directed to the problem of obtaining the maximum amount of light, together with good definition and flatness of field, and about 1840 compound lenses were brought out by Andrew Ross and C. Chevalier, consisting of two achromatic compounds, one at each end of a tube. Ross's lens, made for H. Collen, is interesting as the first lens corrected photographically, so that the visual and chemical foci were coincident (fig. 18). Ch. Chevalier also combined lenses of different foci, as is now done for "convertible" objectives, used singly or combined. He also fitted them with iris diaphragms. These formed a group. They are but a few of the many肖 like form.

It had six reflecting surfaces and nearly approached a triplet (fig. 21). Steinheil's "Group Aplanats" (1878), f/6, angle 70°, were an improvement on the ordinary "Aplanats," but were superseded in 1881 by the "Group Antiplanes," f/5, angle 70°, lenses of a distinct type (fig. 22). They were a further advance on the "Aplanats," working at larger apertures and giving better definition. This lens is interesting as the first in which astigmatism was eliminated by combining a "crown-shaped" lens of high refractivity, with a "flint-shaped" one of lower refractivity, thus making the form of the old doublet. In his "Ring Antiplane" (1893), f/6-5, angle 30°, Dr. R. Steinheil improved the "Group Antiplane" as regards astigmatism and covering power by replacing the third doublet combination by a triple long-focus negative element consisting of a crown between two flints, with a heavy barium crown in the front element instead of a flint (fig. 23). Voigtlander, who originally constructed the Petzval portraits, improved it in 1885 and 1886, and now makes two Figs. 23-26.}

APPARATUS

Fig. 23.—R. Steinheil's Improved Group Antiplane. Most of the above are portrait objectives of large aperture, but unsymmetrical doublets have also been made for landscape work. J. T. Goddard's "Combination Landscape Lens" (1859) was one of the first, and was free from distortion, and could be used as a convertible lens. In 1864 T. Ross issued his "Actinic Doublets," modified from the Collen lens, in three series —"small angle," f/8, angle 40° to 50°; "ordinary angle," f/14, angle 60° to 70° (fig. 24); "large angle," f/16, angle 80° to 90°. These lenses were similar to the "Globe," but unsymmetrical and more rapid. The separate elements could be used alone. Some of them were fitted with a shutter near the diaphragm. They were superseded by the "Symmetrical" lens.

3. Symmetrical Doublets.—This class includes objectives formed of two similar combinations of lenses, usually of the convergent meniscus form, with their concave surfaces inwards and a diaphragm between them; consequently they are rectilinear and practically free from marginal distortion. Until the introduction of anastigmatic doublets they were in general use for all purposes under the names "Aplanat," "Rectilinear," "Symmetrical," "Euryscope," etc. They are still largely used and have been improved by the use of Jena glasses in their construction.

The first recorded lens of this type was Dr. J. W. Draper's combination used in 1829 for daguerreotype portraits, consisting of two double-convex lenses 4 in. diameter, with a unified focus of 8 in., mounted in a tube with a diaphragm 33 in. in front. In 1841 T. Davidson made a combination of two single landscape meniscus lenses, of similar type and use, but with a doublet behind, for a Petzval portrait lens its value as a non-distorting lens for general purposes was recognized, G. S. Cundell (1844) combined two uncorrected meniscus lenses with a diaphragm between them. In 1860 T. Sutton brought out his "Panoramic Lens," which worked on curved plates covering about 100°. It was followed by C. C. Harrison's "Globe Lens" (1862), angle 75°, composed of a symmetrical pair of deep compound menisci, the exterior surfaces forming part of a sphere. Though defective and slow it was popular for a time. A. Steinheil's "Periskop" (1865), f/5, angle 90°, was a symmetrical doublet formed of two plain crown menisci with central diaphragm (fig. 25). It gave a larger field than the "Globe," the lenses being closer together. Being nonachromatic it had to be adjusted for photographic work. It was free from finite distortion, with a very flat field, and both nodal points coincide. It is considered the best possible combination of two plain lenses, and is still used in many of the cheaper hand cameras. The plane diaphragm is fitted with a zero focus, the difference of the chemical and visual fields being allowed for in the camera or by adjustable lens mounts. G. Rodenstock's "Bistigmas" are of this class. J. Zeintmayer made a similar unsymmetrical lens. In A. Steinheil's "Aplanat" (1866) the same principle was carried out with achromatized lenses, and a great
improvement was effected in the construction of non-distorting objectives of large aperture. It consisted of two positive cemented flint meniscus, each composed of a doublet with negative focus outside and a light flint with positive focus inside, its concave surfaces facing the centre (fig. 26). This use of flint glasses alone was peculiar to the achromatic lenses having been bacterial and crown. These lenses were made in three rapidities: "Ordinary," f/6 or f/7, angle 60°; "Landscape," f/12 to f/15, angle 90°, also used in convertible sets; "Wide Angle Landscape," f/20 to f/25, angle 104°; "Wide Angle Reproduction," similar to the last, and with sharper definition. The "Aplanat" had many advantages over previous doublets and the triplet, being more rapidly, perfectly symmetrical, so that there was no necessity for turning them when enlarging, and free from distortion or flare. There was no chemical focus. Each component could be used alone for landscape work with double focus, subject to the ordinary defects of single lenses. By the use of Jena glasses in the "Universal Aplanat" (1886) the components of this lens were brought closer together, its intensity increased, and it was made more portable. J. H. Dallmeyer had been working in the same direction simultaneously with Steinheil, and his "Triplet" (1881), f/100, made of flint and crown, the front element being larger than the back (fig. 27). It was slow for ordinary purposes and was succeeded in 1867 by the well-known "Rapid Rectilinear," f/6, on the same principle as Steinheil's "Aplanat, but made of flint and crown (fig. 28). Ross's "Rapid" and "Portable Symmetrical" lenses, Voigtlander's "Euryscopes," and other similar lenses of British and foreign manufacture are of the same type, and still in use. They are excellent for general purposes and copying, but attaining it always present, and although they can be used with larger apertures than the triplets they displaced, they require stopping down to secure good marginal definition over the size of plate they are said to cover. By the use of Jena glasses they have been improved in work of larger apertures, and some are made with triple cemented elements.

4. Triplet Combinations: Old Types.—This class comprises objectives composed of three separate lenses, the apertures separated from each other. An early form of this type was made by Andrew Ross (1841) for W. H. Fox Talbot, others by F. S. Archer, J. T. Goddard (1859), T. Sutton (1860), but they never came into general use. J. H. Dallmeyer's "Triplet Achromatic Lens" (1861), f/10, angle 60°, now out of date, was an excellent non-distorting lens, and was used for general work and copying (fig. 29). As made by Dallmeyer, the inner surfaces of the front and back components were slightly concave, but in T. Ross's "Actinic Triplet," (1861), f/16, they were flat. The centre lens was an achromatic negative serving to flatten the field.

5. Achromatic Combinations: Symmetrical and Unsymmetrical.—As already stated, it was found practically impossible to obtain flatness of field, together with freedom from astigmatism, in objectives constructed with the old optical glasses, and Steinheil attempted it in the "Antiplanets," but with only partial success. The Abbe and Schott Jena glasses, issued in 1886, put a new power into the hands of opticians by largely increasing their choice of glasses with different refractive indices of fairly large power. Whereas the old glasses had high refractivity with higher dispersion, in the new ones high refractivity with lower dispersion could be set against lower refractivity with higher dispersion.

Between 1888 and 1893 the first attempts to make anastigmatic objectives with the new glasses were made by M. Mittenzwei of Zwickau, R. D. Gray of New Jersey, E. Hartnack and A. Miethe of Berlin K. Paramecium, and F. Schacht of Vienna ("Apochromat") and Fr. von Voigtlander of Brunswick, with more or less success, but progress was hindered by the instability of some of the early glasses. Schacht was then able to overcome it by selecting the best glasses between two hard ones. In 1888 Dr. H. L. H. Schroeder worked out for Messrs Ross the Congruent Lens (fig. 30) issued in 1890, which was a symmetrical doublet of novel construction, each element consisting of a plano-convex crown of high refractivity cemented to a plano-concave flint of lower refractivity, but about equal or higher dispersion. Both the un cemented surfaces were spherical and concentric. At f/6 it gave sharp definition and flatness of field with freedom from astigmatism, distortion there over an angle of 75°. It was an excellent lens, though slow, and has been superseded by the "Homocentric" and other more rapid anastigmats. Dr. Paul Rudolph, of Messrs Carl Zeiss & Co., Jena, worked out in 1889 a new and successful method of constructing a photographic objective by which astigmatism of the oblique rays and the want of marginal definition due to it could be eliminated without loss of rapidity, so that a comparatively extended field could be covered with a large aperture. This he did on the principle of the opposite or opposed graduation of the refractive indices in the front and back lenses, by a combination of two dissimilar systems of single lenses cemented together, the positive element of each having in one case a higher and in the other a lower refractive index than that of the negative element with which it was associated. The front system, relied upon for the correction of spherical aberration, was made of the old glasses, a crown positive of low and a flint negative of high refractivity, while the back system, relied upon for the anastigmatic flattening of the field, was made of the new glasses, a crown positive of high and a flint negative of low refractivity. Both systems being spherically and chromatically corrected for a large aperture, the field was flattened, the astigmatism of the one being corrected by the opposite astigmatism of the other, without destroying the flatness of the field over a large angle (see Jb., 1891 and 1893; M. von Rohr's Geschichte, and O. Lunner, Photographische Optik, for further details). They were issued by Messrs Zeiss and their licenciées (in England, Messrs Ross), in 1890, in two different types. The more rapid had five lenses (fig. 31), two of ordinary glasses in the front normal achromat, and three in the back abnormal achromat, two crowns of very high refractive power, with a negative flint of very low refractive power between them.

Fig. 31.—Anastigmat. Series II. f/6-3. Fig. 32.—Anastigmat. Series IIIa. f/9.

The fifth lens assisted in removing spherical aberrations of higher orders with large apertures. The second type, series IIIa. f/9, 1899 (fig. 32), had only two lenses, the functions of which were as above. These combinations could not be used separately as single lenses, for they are not Aplanats. The series IIa (1893), f/10; IIIa, f/10; V, f/18. In 1891 Dr. Rudolph devoted himself to perfecting the single landscape lens, and constructed on the same principle a single combination of three lenses, the central one having a refractive index between the indices of the two others, and one of its cemented surfaces diverging, while the other was converging. At f/14.5 this lens gave an anastigmatically flat image with freedom from spherical aberration on or off the axis. It was, however, brought out till 1893, as a convertible lens or "Sat-Astigmat," series VI, f/10.5 and VIa, f/17; (figs. 33 and 34). In the meantime Dr. E. von Hoge (C. B. Goerz) and Dr. A. Steinheil had also been working at the problem and had independently calculated lenses similar to Rudolph's, but whereas he devoted himself to perfecting the single lens, they sought more perfect correction by combining two single anastigmatic lenses to form a doublet. Dr. Rudolph had the same idea, but Messrs Goerz secured the priority of patent in 1892, and in 1893 brought out their "Double Anastigmat," now known as Ross Goerz's "Dagor." Series III. Ross Goerz. Series IV.

"Dagor." It was the first symmetrical anastigmat which combined freedom from astigmatism with flatness of field and great covering power at the large aperture of 1/7. (fig. 35). Both these types of Zeiss's "Protars" and Goerz's "Dagor" anastigmats have since

These lenses are designed to be free from diaphragm corrections, while the focal power of the negative lens is made as closely equal to the combined focal powers of the two positive lenses as may be necessary for the flattening of the field and correcting marginal astigmatism. They are not convertible, but arrangements are made for replacing the back lens by a low-power extension lens (Ph. Jour. 1895, p. 64). Series III., f/5-6 (fig. 40), and series IV., f/5-6, are portrait lenses. In the larger objectives of series II., the back lenses are adjustable for uniform sharp definition or a soft diffusion of focus. In a later series VI. (1907), f/5-6, this adjustment for diffusion is given to the front lens and is so arranged for portraiture that the diffusing adjustment and iris diaphragm can be operated from the back of the camera while viewing the focusing screen.

A special fully corrected "Process" lens on the same general principle has recently been brought out for three-colour work and fine-line reproduction. Another distinctively new type of anastigmatic objective, involving several new principles of construction was patented by H. L. Alldis in 1895, and brought out by Messrs. Dallmeyer in three series, under the name of "Stigmatic" (Ph. Jour. 1895, p. 197). It has been made in two forms, with a triplet front and, and a back negative system formed of a single thick crown lens of high refractivity with a negative cemented meniscus. In the second form (fig. 41) the front component consists of a cemented positive and negative, and both parts of the back component are cemented lenses. All the converging lenses are of crown baryta crown glass, while both the diverging lenses in the back component are a light silicate crown. It is fully corrected for spherical and chromatic aberration, free from spherical and nearly so for astigmatism, giving equal illumination over a flat field of 60°. Diffusion of focus is obtained by unscrewing the back cell. Series II. (1897) is on the same principle but differs in construction, working at f/6 over an angle of 65° as a universal and convertible lens (fig. 42). The front or back component can be used alone, giving the choice of two focal lengths, 1f and twice the focal length of the complete lens. The principles of its construction were described by T. R. Dallmeyer in Ph. Jour. 1897, p. 167, series III., f/7-5, at f/10 gives sharp definition over a plate two sizes larger. The single components are not convertible.

In 1897 Messrs Zeiss issued the "Planar," an objective of large aperture based on the principle of the Gauss telephoto objective. It is a symmetrical doublet, each element consisting of three lenses, the central one being a double convex and a double concave, each of equal refractive but different dispersive power, cemented together and separated by an air-space from the outer convex meniscus (fig. 43). Its special points are its good colour correction, large relative aperture and intensity, varying from f/3-5 to f/6, with perfectly sharp definition and anastigmatic flatness of field over an angle of view from 62° to 72°. It is a very rapid wide-angle lens useful for instantaneous work with the cinematograph and hand cameras, also for portrait and ground photo-macrography and enlargements of reductions (see E. Jh., 1898, p. 79, Von Rohr, p. 390, and Lummer, p. 81). Apochromatic planars with reduced secondary spectrum were brought out in 1903 for three-colour photography, and are also useful for astrophotography, the circle of diffusion being very small. The "Unar" (1900), f/4.5 in the smaller and f/6.5 in the larger sizes, angle 65° and 68°, was a further improvement by Dr. Rudolph. It
PHOTOGRAPHY

consists of two unsymmetrical combinations, each formed of two single lenses of very transparent glass, dense baryta crown and light flint, separated by positive and negative air-spaces (fig. 44). The separate halves cannot be used as single lenses, neither being fully corrected for colour. It is well adapted for portraiture, groups or landscapes, especially for rapid hand camera work, on account of its covering power, freedom from astigmatism and sharp definition with large relative aperture.

FIG. 43.—Planar. Series Ia. f/4.
In 1898 Messrs Goerz patented their "Double Anastigmat Color," series 1b, f/4-5 to f/5-5. It is a symmetrical doublet, each element consisting of two thin single lenses: a positive of high and a negative of low refractive index, separated by an air-space (fig. 45). It is derived from the triple anastigmas by decreasing the refractive power of the central convex meniscus to the refractive power of air, so that it becomes a convex air-space between a double convex and a double concave lens. Less deeply curved surfaces can be given to the lenses, and the doublet gives anastigmatic flatness of field over an angle of 62° to 66°, equal to the best anastigmats with a still larger aperture. Series Ic, f/6-3, is similar and recommended for hand cameras, the aperture being smaller. Goerz's "Hypergon," (1900) f/22, angle 135°, is a convex back lens. It is a long-focus objective with short back focus, and is made in two forms, series II, f/6 (fig. 47), and series III. (1909) f/7 (fig. 48). In the latter the back element is a cemented meniscus, and the front combination of infinite focal length. By discarding the symmetrical form simplicity is secured, while open or reflecting surfaces are avoided. Special attention has been paid to perfect correction of spherical aberration in the centre of the field, the "Duo" lens of the same maker (1907) is intended to replace the front lens and double the focus, but with less rapidity and with less loss of quality. The "Tripo" (1908) is similar, but only increases the focus one and a half times and is thus more suitable for cameras of short extension. The Aldis "Oysis" anastigmat, series II. (1908), f/5-5, angle 85°, is an improved form. Being an unsymmetrical cemented doublet it is free from the defects incidental to air-spaces and is constructed to give more perfect correction for flatness of field with large aperture and wide angle.

It is generally stated that it is impossible to make a spherically, chromatically and anastigmatically corrected photographic objective with the old optical glasses. K. Martin, of Messrs Busch of Rathenow, has, however, shown (E. Jb., 1902, p. 68) that it is quite possible to do so with a system of separated lenses, and that it is immaterial whether the index of the flint or the crown is the higher. An anastigmat on this principle was issued by Messrs Busch in 1902, as the "Omnar," series III, f/4-5 (fig. 49), series II, f/5-5, angle 75°, and I, f/4.5, have since been issued. It is a symmetrical doublet, each element consisting of a negative flint meniscus of higher refraction, and a positive crown of lower refraction with an air-space between them in the form of a negative lens. The back element can be used alone. The "Lumat" series Ic, f/4-5, is a Rodenstock, similar. In 1902 Messrs Ross brought out the "Homocentric," a symmetrical doublet, each element consisting of a negative and positive meniscus separated by an air-space (fig. 50). It is corrected so that all the elements of the object are converged again into one point in the image. It is also quite free from spherical zones, is not altered in focus with different diaphragms, and thus has exquisite definition. The colour correction is so perfect that the different coloured images are identical in size and position, thus rendering it specially suitable for three-colour and process work. The back lens can be used alone, with diaphragms, as a single lens of about double the focus of the doublets. The "Omnar" series Ic, f/4-5, is used for rapid and instantaneous work; VI, f/8, for process work and three-colour reproduction. A later series, IV, (1907), "Compound Homocentric," f/6-8, differs from the others in being a symmetrical doublet composed of two triple cemented lenses, very close together and separated by a diaphragm. It is specially suitable for outdoor work, also for copies and enlarging, with good covering power. Zeiss's "Tessar" (1902) is a rapid unsymmetrical doublet, formed of two separated uncemented positive and negative lenses in the front element and a cemented meniscus at the back (fig. 51). It is used for two halves separately.

FIG. 44.—Zeiss's "Unar.

In 1902 H. L. Aldis issued the "Aldis Lens," f/6, a doublet composed of a cemented meniscus in front and a single double-
of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate frit, the two positive of the heavy crown glass. Besides being a large universal lens, it is specially suitable for half-tone process work, with a large diaphragm (E. Jb., 1903, p. 117). The "Dynar" (1903), f/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pair being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colours Jen glasses, giving great brilliancy and uniformity of illumination at an angle of 60°, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), f/4.5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour corrections explained by Conrad Beck in Pk. Journ. (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of f/4.5 can be produced with telescopic central definition, perfect freedom from distortion and flare gives a flattening of 1.4 with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., f/4.5, for portraiture, rapid hand-camera work, telephotography and projection; and I., f/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeiter's "Euryplan" anastigmas (1903), made by Schulze Bros, Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a wide angle, made in four series: I., f/4.5, angle 80°; II., f/5.6, angle 90°; III., f/6.8 to 7.5, angle 82°; IV., f/6, f/5.5. They are symmetrical doublets, each element consisting of three lenses, a new achromat compounded of symmetrical crowns. They have a high density and low dispersion, separated by an air-space from a positive meniscus of the same crown, with its concave side towards the diaphragm. They are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly or in double focus (E. Jb. 1904, p. 35).

Beck's "Isostigmatic" (1907), is a new anastigmat work and general purposes. (fig. 55).

60° to 90°. The half combinations can also be used alone with a diaphragm as long-focus combinations of cedapo, objectives at any angle (fig. 56). The lens has been improved by increase in the working aperture and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining detailed images of inaccessible objects at a distance, whether architectural, topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better definition by using the large f/5.6--6.5, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera, while focusing.

The above represent the principal types of anastigmas, but many more objectives of the kind, triple or quadruple, cemented or un cemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. Telephoto graphic Ob jectives.—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being more than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative diverging lens, by which the image is picked up and enlarged to varying degrees, according to the separation of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of much very much longer focus. Enlarged images of this kind can also be studied by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and focal length of the lenses and sensitive plate. The photo-telephotographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1869 by MM. Borie and de Tournemire, and later by Jarret, but the system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

A certain telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (c. 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of far and distant objects (Magia Naturalis, lib. 17, cap. 10, 1893). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, and J. Zahn's Oculus artificilis (1704) mentions use of a convex-lens with a compound lens for enlarging objects. C. P. Steinheil made use of the same principle in his "Helioscope" for solar observations (Rosa Urtina, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's Oculus artificilis (1704) mentions use of a convex-lens with a compound lens for enlarging images on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suited to the object and to the plate, and put a sensitive plate in place of the paper, we have the modern telephotographic system. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic simple lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. A. Steinheil constructed one in 1888 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin, and J. A. M. Molyneux. These later combinations have been greatly improved by increase in the working aperture and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining detailed images of inaccessible objects at a distance, whether architectural, topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better definition by using the large f/5.6--6.5, variable portrait lenses, adjustable for soft or sharp definition from the back of the camera, while focusing.

With the very perfect telephoto-
PHOTOGRAPHY

with those of ordinary intensity the exposures are not unduly prolonged, and good definition can be obtained over an extended field.

The optical principle on which these combinations are based is very simple, and will be understood from fig. 56. It depends mainly on the fact that it is possible to throw an image on the screen of an object AB, the rays proceeding from it, which pass through the positive system L₁, must come to a focus at a point f₁ in the secondary focus f' of the negative system L₂. Fur-thermore the rays will be partially or wholly divergent, so that instead of coming to a focus at f₁, they will continue to converge till they reach the screen at f₂, and will there form a proportionally larger image a'b' of AB than the image ab given by the positive lens alone at f₁. Just as stated in Kepler's problem. Moreover, this image a'b' will be of the same size as if it had been produced directly by a positive lens L₃ with a focal length equal to f'f₂, and this distance is the equivalent focal length of the entire system. It can be found from the formula

\[ f = \frac{1}{f_1} + \frac{1}{f_2} - \frac{1}{f} \]

where \( f_1 \) and \( f_2 \) are the focal lengths of \( L_1 \) and \( L_2 \) respectively, and \( f = d - f_1 - f_2 - a \) being the distance between the lenses. In many instances of the kind a scale showing the value of \( d \) is engraved on the mount. If the rays from AB come to a focus in front of \( L_1 \), on it, or beyond \( f' \), no real image can be projected on the screen. There is therefore a certain limit, which is greater in proportion to the length of the focus of the negative system, within which the focal length of the positive system \( L_1 \) may fall and produce a series of well-defined images on the screen, which can be varied in size by altering the amount of separation of the two systems of lenses within the above limits, and the distance of the screen. The position of the screen will involve a corresponding adjustment of the lenses. The greater the extension of the camera and the length of the lenses, the greater the image, and vice versa. The camera extension is a measure of the instantaneous extension of the focal length of the negative system by the number of magnifications, less one. The magnification produced by a given camera extension is found by dividing the latter by the focal length of the negative system less one.

In its usual form (fig. 57) the telephotographic combination consists of a quick-acting portrait lens, or an astigmatic doublet of finite focal length and relative intensity of suitable focal length, fitted into a variable iris diaphragm, and the two combinations can be carried on a proper negative system, which may vary in focus, but must be of shorter focus than the positive (usually about half); the shorter the focus the greater the magnifying power for a given extension of camera, and the image is, of course, on the one hand by the position of the focus of the negative system, and on the other by the focus of the negative system, as explained above, and can be adjusted within these limits by a rack and pinion. The two systems of lenses are separated by a distance \( d \) determined by Poinsot's formula, which can be approximately \( \frac{a}{3} \) or nearly so, and \( d = o \), its minimum value; and when opened to its fullest extent the positive focus may fall upon the negative system, or so that \( d \) may not exceed the focal length of the negative system. Within these limits the focal length of the combination will be positive, and a real image formed on the screen. Several forms of them have been brought out by various makers, some, as Zeiss's, with a special positive lens, others for use with astigmatisms and other lenses of large apertures. The negative lenses are also made of various powers.

Messrs Dallmeyer's "Adon" (1902) is a telephotographic lens, for use with hand cameras, composed of two achromatic combinations adjusted for parallel rays, a front positive lens \( 4 \frac{1}{2} \) in. focal length, and a back negative lens of \( 2 \frac{1}{2} \) in. focus. These are mounted to permit of great variation in the separation, so that when the "Adon" is fixed on the front of a suitable lens, near or distant objects may be taken on an enlarged scale without altering the focus of the camera, or the enlargement can be varied with further extension of the camera. Used alone it is a complete telephoto lens, and is known by the banker "Junior Adon," 1903. A special form, the "Junior Adon," was made in three kinds for use with kodak and similar folding hand cameras, single and double, and giving a fixed degree of magnification without loss of rapidity, while focusing can be adjusted in scale. It is intended to replace the front lens of an R.R. or anastigmat lens and cannot be used independently. Messrs Busch's "Bis-Teler," fig 56, is another compact fixed focus telephoto lens, specially for use with hand cameras. It is a complete lens in itself requiring no attachments and can be fitted to a central shutter. It is made in three sizes magnifying from two to three times. An improved form of this lens (1908), working at the large aperture of f/7, is similar to an old form of "Dialytic" lens worked out by J. Petzval, having a positive front and negative back meniscus, each concave surfaces inwards (fig. 58). As in the old "Orthoscopic and lenses of that class the type there is some distortion, but it is very slight. These lenses are made in five sizes with foci from 8 to 22 in., requiring two extension frames from L₁ and must have a 3 1/4 in. magnifying two groups. According to K. Martin, a telephoto-combination of the Bis-Teler type needed for a camera of larger size, is used in a revolving projection lens as a projecting lens for the lantern, with the advantage of increasing the illumination from a given source of light (£. Jh. 1908, p. 46).

The first fixed-focus tele-lens to be made in 1907 a high-power telephoto arrangement, by Messrs Staley, in which the negative aperture consists of three negative lenses, any single one of which can be used separately, giving magnifications of about 6, 9, and 13 diameters, with a camera extension of 14 in. a side, is, in general a magnification of 30 diameters is attainable with the same extension, which is a great advantage in many ways. In 1908 Messrs Zeiss issued their "Special Tele-objectives" in two sizes working at f/10, the larger with an aperture of 3 1/4 in. and 3 1/4 in. focal length fitted in a special "tele-camera" for plates 9 x 12 cm. with a monocular field glass magnifying four times as finder. The objective was in two parts, one negative and the other positive, but the bellows extension. They consist of specially corrected positive and negative combination with a definite focal length and requiring a definite camera extension, and are especially suitable for balloon photography. The telephotographic and tele-cine, the tele-lens, tele-cine, and tele-cine use of telephoto lenses has been fully described by T. R. Dallmeyer in his Telephotography.

Anachromatic Lenses.—For large portraits a certain amount of elongation and diffusion of the image has always been recognised by artists as desirable, and in 1895 the "Dallmeyer-Bergheim Lens" was constructed with this special object. It is composed of a single using double positive meniscus front lens, with a diaphragm in front of it, and an uncorrected negative meniscus back lens. In the larger sizes it has great range of focal length on the telephotographic principle. The spherical and chromatic aberration produced by the uncorrected single lens in this double focus produces which the peculiarly soft and delicate effect aimed at is unattainable for large heads and life-size studies, the great depth of field leading to uniformity of definition. There is no distortion, and by stopping down to about one-fourth of the maximum aperture it works with great brilliancy, both elements being single glasses. It was the first of the anachromatic portrait lenses. Since 1903 Messrs C. Puyo and L. de Pulligny have been experimenting with these combinations, and have obtained a very good effect in portrait and landscape photography by the diffusion of focus produced by chromatic aberration, and suitable lenses of this kind have recently been brought out in Paris as Les Objectifs d'artiste. These lenses are made in the following way: (1) a plano-convex crown lens convex side in front at f/8 or f/5, or even f/5 for heads; (2) a simple concavo-convex meniscus, with concave side in front, is better and suitable for full lengths at f/10; (3) a symmetrical system formed of two similar crown menisci, in which the effect is useful when worked at f/10, or even f/5. Arrangements are made in mounting these lenses for automatically making the necessary correction for colour. Another form is the "Adaptable Landscape Lens," formed of an anterior plano-convex crown, 3 cm. diameter, and a posterior plano-concave crown, each of 10 cm. focus, and the same radius of curvature. In contact they have an infinite focus, and all infinity separations can be obtained by adjusting the diaphragm. Various forms, portrait and landscape, have been made by Messrs Hermagis, Turillon & Morin (see Fabre, T. E. P. Suppl. D. 101).

Diaphragm Apertures.—In order to regulate the intensity of the illumination, the diaphragm is placed in its field, being in the use of the old forms of objectives, to extend the area of good marginal definition, diaphragms are used, usually with circular apertures. They are made in different ways: (1) as single metal plates, fitting in the front or back of the lens or in the case of a single plate revolving on a central axis and pierced with apertures cut to fit centrally in the opening of the lens; (2) Iris: a form of diaphragm now very generally used, and very convenient, because it can be easily adjusted as required for intermediate apertures. As a rule they are placed at the optical centre between the elements of a compound lens or in front of a single one.

In order to provide a uniform system of diaphragm apertures,
The general use of rapid plane plates and hand cameras has rendered it necessary to have some mechanical means of regulating exposure, since the time of exposure is not easily measured by a simple, comparative length of time. The introduction of this kind of apparatus is absolutely necessary; it is necessary in order to produce the desired photographic effect within that time. With a lens of 8 in. focal length the displacement would have increased in the first instance to 0.25 in. per second, and the maximum exposure time would have been 30000 seconds (8.3 days). This shows that there is an advantage in using short-focus lenses for very rapid exposures. In practice, most work of this kind is done upon quarter-plates (4×3 in.) with lenses of 4 to 5 in. focus. As the exposure time in any case will be based upon the diameter across the axis of the lens, an exposure sufficient for this case will be suitable for any other. Sir William Abney has discussed this question practically in his *Instantaneous Photography*, and it is there stated that a lens of focal length 10 in. has been made for the Hand Camera, in which will be found formulae and tables for ascertaining the distances and limiting exposures for moving objects, allowing for a blur of 1/8 of an inch. In foreign treatises the limit is sometimes calculated for a displacement of 1/4 of a millimetre, or about 1/16 of an inch.

An efficient shutter should fulfil the following conditions: It should (1) provide for the correct adjustment of the diaphragm, strongly made, and not liable to get out of order; capable of being set without admitting light into the camera; easily released with a slight pressure of the finger, if a pneumatic release is not fitted, and free from any tendency to shake the camera on release. It should open and close quickly, allowing the largest possible proportion of the exposure to be made with the full aperture, and it must not cut off any of the effective light passing through the lens, but should permit every portion of the image on the plate to be exposed. Then, if it is an advantage to give the foreground more exposure than the sky, it should be adjustable for variable instantaneous and for prolonged or "time" exposures. With a good shutter there is little risk of the edges of the image being out of focus, or of the whole scene being out of focus, and the image must not be liable to tremor or shaking. A very good shutter is the W. B. Coventry as far as the best. They are usually released by the pressure of the finger on the end of a lever holding the moving part in a state of tension; or, better, by J. Cadet's system of pneumatic action. The W. B. Coventry shutters, which may drive a piston acting on the lever holding the shutter, or initiate a collapsible bulb at the other end of the tube and thus exert the necessary pressure on the lever, are admirably constructed. With W. Watson's "Antinous" release a flexible wire acts directly on the piston or trigger release of a-cylinder shutter. It is also adapted for roller-blind, focal plane, flap, and various forms of between-lens shutters. It is durable, effective and convenient (see fig. 3). In many cases both methods may be used as desired, the nature of the work being taken into account on its convenience and freedom from liability to shake the camera.

Following are the principal types of instantaneous shutter: (1) Flap, (2) drop, (3) combined drop and flap, (4) rotary, (5) roller blind, (6) focal plane, (7) moving blade central, (8) iris. They can be applied in four different positions: (a) in front of the lens; (b) between the lens and the plate; (c) in front of the septum plate, and (d) in front of the sensitive plate. They all, however, come under two main classes: Lateral, including those in which the exposure commences and ends at the circumference of the lens aperture; or, secondly, those in which the exposure begins and ends at the aperture of the aperture. Some of them are "lateral" in their single form and "central" when double. The form and position of the effective aperture of a shutter, relatively to the lens and plate, have a strong bearing on the character of the exposure. A "lateral" shutter is characterized by the effective light passing through the lens, and its even distribution over the plate. This is especially the case during the incomplete phases of opening and closing the aperture. It seems to be agreed that the best position for lens shutters of the lateral type is behind the objective, and for those of the central type, between the component lenses. In this latter position the whole of the plate is illuminated during the full period of exposure, with a gradually increasing exposure in the case of a mechanical shutter. The illumination gradually falls off until the shutter is closed. The most effective shutter is one in which the first and third phases of exposure are equal, and the second phases are shortest compared with the second phase of full opening.

With the focal plane shutters, however, different portions of the plate are exposed in succession, the lens working at its full aperture and the plate at a given fraction of the focal length. To secure successful results in using instantaneous shutters, the operator should make himself acquainted with the working of his shutter and its efficiency in various circumstances of exposure with the plates, lenses and developer he proposes to use; ascertaining the actual value of the various exposures marked on the indicator, and,
Photography

what is more important, how far they can be depended on for regularity. There are many simple ways in which the actual time of exposure from opening to closing can be ascertained sufficiently closely for practical purposes. They depend upon the measurement of the trace left on a sensitive plate by the passage of a brightly illuminated object revolving at a known speed or falling vertically through a known distance, when photographed with different speeds of the shutter against a dark background. These, and the more elaborate methods for obtaining more accurate determinations of the shutter-exposure periods and of the corresponding effective velocities—i.e., showing the actual effect of the shutter through its different phases from opening to closing—have been described by Sir William Abney in the work already mentioned, La Photographie moderne and La Photographie instantanée. An apparatus for testing shutters at the National Physical Laboratory was described by J. de Graaf Hunter in the Optician, 1896.

1. Single Slit Shutters.—The simplest shutters for photography are a pair of vertical slits cut in a sheet of glass or metal. Light passing from them and falling vertically to the photographic plate will be of different intensities at different parts of the plate, depending on the index of refraction of the glass and the thickness of the slit. A simple but still more effective form of this kind of shutter is one in which the glass plate is supported by a pair of wires and spring so that it may be moved in a vertical plane by means of a hand or cable. Such a shutter was described in 1860 by M. W. J. Guérin, who called it a "système de verre et métal".

2. Drop Shutters.—The old simple drop shutter, in which a plate having an opening in it falls in front of the lens aperture, has been superseded by the more compact and quicker-working roller-blind shutter. They are based on the same principle. It gives the simplest interest in connexion with the effect of different forms of aperture—circular, square, or elongated—used with shutters of the lateral type, but it is now generally recognized that a more or less extended rectilinear opening, of at least the full width of the lens aperture, is best for securing the even admission of light from all parts of the image with shutters of the rectilinear lateral type, to which this and similar shutters, in which a single opening passes across the lens aperture, belong. In Busch's "sky shade" shutter (1867), fitting on the front of the lens a single leaf moves vertically upwards and descends again, giving less exposure to the sky.

3. Combined Drop and Flap Shutters.—In early dry-plate days several forms of this kind of shutter were brought out, under the names of Phoenix, Phantom, &c., but are now little used. In these shutters, in addition to the drop slide, there was also a lifting flap, which on release opened from below, and, having fully uncovered the aperture, released the drop slide, which fell and closed the shutter. They were useful and effective in the smaller sizes, but heavy and cumbersome in the larger. Speed could only be estimated very roughly by the use of india-rubber bands for giving tension.

4. Rotary Shutters.—These are of the lateral type, and consist of a circular metal disc revolving on an axis eccentric to the axis of the lens, and furnished with a radial sector-shaped opening, which passes laterally in front of the lens aperture when the spring is released (fig. 61). They are used in various patterns in cheap hand cameras, usually in front of the objective, though they may be placed in front of the latter or between the component lenses. So long as the opening is as least equal to the size of the lens aperture, the illumination is sufficiently even, but the openings are usually elongated so as to give a longer period of time to the working of the shutter, and to render it inconvenient than drop shutters. Beck's "Célerex" between-lens shutter (1906) is of this type, the disk being revolved by a spring and the variations of exposure obtained by altering the size of the opening passing over the lens aperture, and not the tension of the spring. It is speeded for exposures of 1/10, 1/20, 1/30, &c., and also "bulb" and "time." It is fairly accurate and convenient in action, but loses efficiency at the highest speeds by the diminution of the opening.

5. Roller-Blind Shutters.—For general use the well-known roller-blind shutter of the single lateral type, as made by Thornton-Pickard and others, is undoubtedly one of the most popular and efficient. It possesses most of the qualities laid down as essential to a good shutter, gives good illumination, appears to be fairly regular in its action, and can be used for time or instantaneous exposures. It consists of a light metal or aluminum box, arranged so that it can be fitted in front of or behind the objective. It is made in different sizes, and each size can be adjusted to smaller objectives (fig. 62). It is also made with a disappearing cord, and in an improved pattern, the "Royal," all the fittings are inside the box. By pulling the cord

![Fig. 59.—Guérin's Single-flap Shutter.](image)

![Fig. 60.—Guérin's Double-flap Shutter.](image)

![Fig. 61.—Rotary Shutter.](image)

![Fig. 62.—Thornton-Pickard Roller-Blind Shutter with automatic exposure appliance.](image)
tensions of the springs. Thus the new Goerz-Anschütz shutter has ten tensions and nine curtain apertures, providing for ninety different speeds or exposures, ranging from \( \frac{1}{2} \) to \( \frac{1}{60} \) of a second, besides automatic exposures from \( \frac{1}{10} \) to \( \frac{1}{30} \) of a second (fig. 64). Most of these shutters are now provided with a self-capping device for protecting the sensitive plate during the setting of the shutter. As the slit moves progressively over the plate, if it is not accurately or moving too slowly, it may cause distortion of the images of quickly-moving objects, especially if it is near the centre, but with due care in regulating the width of the slit and the duration of exposure this is practically not often perceptible, especially if the slit is arranged to move in the same direction as the object.

The theory of these shutters is discussed by Coventry (op. cit. p. 69), more fully by Fabre (T. E. P. Suppl., C. p. 128), and their practical use in Focal Plane Photography (\"Photo-Miniature Series,\" No. 77, 1904).

7. Moving Blade Central Shutters. These shutters, in which two thin metal or ebonite plates or opaque curtains with round or rectangular apertures, or in other cases two curved blades, pass very quickly over each other in opposite directions, are largely used in many patterns fitted between the lenses of a combination or attached to them in front or behind. Formed of two single central shutters opening and closing in the centre of the lens aperture, when they become central, the exposure taking place during the short period in which the openings are passing each other or the curved blades opening out and closing again. To obtain the greatest efficiency the size of the openings should correspond with the full aperture of the lens. If each plate moves as a flat as a drop shutter the combination gives double the speed, corresponding to half the exposure. The sensitive plate will be most evenly and strongly illuminated when the leaves of the shutter are closed at one plane near the diaphragm, as in Bausch and Lomb's \"Unique\" and other similar between-lens shutters, in general use (fig. 65). This necessitates the fitting of the lens to the shutter, but with adapters

8. Iris Shutters. These are further development of the double curved-shutter and central type, and are constructed on the principle of the \"Iris\" diaphragm, with several leaves opening out from the centre of the lens and closing again. They are usually fitted between the lenses of double objectives, and can be made very light and compactly, and can be controlled by a single hand. The shutter is the best, and the \"Iris\" is the best form for ensuring the most equal distribution of light over the plate, provided, as before, that the opening is equal to the full aperture of the lens. The opening as made so that the periods of opening and closing may be as short as possible compared with that of full opening. They require great care in construction, not only to the lens, and so are expensive. They can, however, be used with all the flexible sets of lenses and the iris fitting the same mount. Several forms are made by British and foreign makers, with three, four, or five leaves. Goerz's \"sector\" shutter (fig. 67) may be taken as a type. Georgan's \"central\" shutter is very light and smooth in working, and is used for telephoto work. Further details regarding the different forms of shutters, theoretical and practical, are found in an article by John Abney, Coventry, Eder, Fabre and Londo.
