of the kind is to be found. Perhaps the nearest approach to it is a jest by the Rev. Dr. Johnstone. It is printed in the Pauline phrase about the evidence of things not seen," which the author removed from the later editions. But irreverences of this kind, as well as the frequent burlesque citations of the Bible, whether commendable or not, have their use. It is as much a part of the nature of Rabelais as it is of the nature of his orthodoxy; and it must be remembered that the later Middle Age, which in many respects Rabelais represents almost more than he does the Renaissance, was, with all its unquietness, and its conflict of beliefs and heretical tendencies, in its use of the sacred words and images, which were to it the most familiar of all images and words. On the other hand, there are scattered throughout the pages of Rabelais's works, which have been, for many to be found from the Renaissance to the end of the 18th century, obvious flags of truce to cover attacks—mere bowings in the house of Rimmon to prevent evil consequences. There is also the style of the period. The works were always written in the author's highest style, a style perfectly eloquent and unaffected; they can only be interpreted (on the free-thinking hypothesis) as allegorical with the greatest difficulty and obscurity, and it is pretty certain that no one reading the book without a thesis to prove would dream of taking them in a non-sense sense. It is not, indeed, to be contended that Rabelais was a man with whom you could have any chance of getting a tender conscience or a very scrupulous orthodoxy. His form of religious sentiment was not evangelical or mystical, any more than it was ascetic or ceremonial or dogmatic. As regards one of the accoutrements of the church, the defence of the doctrine of the eternity of the soul, of the existence in life, of poverty, and of elaborate obedience to a rule, he no doubt was a strong dissident; but the evidence that, as a Christian, he was unorthodox, that he was even a heretical or luttitudinarian thinker in regard to those doctrines which the various, heterogeneous churches in common, is not merely weak, it is practically nonexistent. The counter-testimony is, indeed, not very strong, and still less detailed. But that is not the point. It is sufficient to say that there is absolutely nothing within the covering of the works incompatible with an orthodoxy which would be recognized as sufficient by Christendom at large, leaving out of the question those things considered by the Church of Christ to differ. Beyond this no wise man will go, and short shrift; hardly any prejudiced man will stop.

BIBLIOGRAPHY.—The dates of the original editions of Rabelais's works have been given where possible already. The earlier books were repeatedly reissued during the author's life, and always with some correction. What may be called the first complete edition appeared in 1567 at Lyons, published by Jean Martin. It is computed that no less than sixty editions were printed before the close of the 17th century. Nearly all these works were, before the works were, properly speaking, edited. Hurt devoted much pains to them, but his results were not made public. The first edition which calls for notice, except in a complete bibliography, is that of Le Monnot (1631). Le Monnot was a very careful student, and on the whole a very efficient editor, being, perhaps, of the group of students of old French at the beginning of the 17th century, which included La Monnoye and others, the modern historians, who reconstructed that which the knowledge of the period was scarcely far enough advanced. The important date in the bibliography of Rabelais is 1825, in which year appeared the most elaborate edition of his works published, that of Esmangart and Janniot (9 vols.), including, for the first time the Songs Drolatiques, a spurious but early and not uninteresting collection of grotesque figure drawings illustrating Larganta and Pantagruel, and the second edition of M. de l'Aulnaye, containing a bad text but a useful glossary. From this time the editions have been very numerous. Among them may be mentioned those illustrated by Gustave Doré, first on a small scale (W. Scott, 1857), and then in a larger edition (1890) in the Collection Didot by Burgaud des Maretis and Rathery (1857 and later); the Bibliothèque Élégivrière edition by MM. Lacour and A. de la Patellière of the Novel des Lurons (1867), the Collection Janniot (seven small volumes, 1867-74), completed by M. Moland and very useful and lastly, the edition of M. Marty-Laveaux in the Collection Lemere (1868-1903), the handsomest, the most accurate, and the most literary. It is only within the last century that any real work has been done on Rabelais, independent of editions, have been numerous from the work of Jean Bernier, Jugement et nouvelles observations sur les œu... de M. François Rabelais (1697), onwards. Of those of the last quarter, the most important in the works of most of the great critics: E. Noel, Rabelais (1850); A. Mayrargues Rabelais (1868); Jean Fleury (1876); Paul Stapfer (the best of all) (1889); and G. Vallot (1893). Separate points have been treated in various works: the Vies de Rabelais by P. Abadie of the fourteenth and fifteenth; the Vie de Rabelais by P. Abadie of the fifteenth and others; while the Revue des études Rabelaisiennes (1903 onwards) contains valuable studies, especially those of M. Abel Lefranc. Rabelais was very early popular in England. There are possible allusions to him in Shakespeare, and the current clerical notion of him in the house of the Marquess of Winchester, has not been, but the motives of the author of "Rabelais"; but Baco described him better as the great jester of France, and a Scot, Sir Thomas Urquhart, translated the earlier books in 1633. This was not worthily completed till the luckless Molesworth (1808), after which the "Rabelais" has been published with an extensive commentary. It has been frequently reprinted. A new translation by W. F. Smith appeared in 1893. Criticism of a scattered kind on Rabelais in English is abundant, that of Hildreth being the most important, while the constant "influence of his influence in Southey's Doctor" is also noteworthy. But he was hardly treated as a whole before Sir Walter Besant's book on the subject; the "More Concerns for English Readers" which the author followed up with Readings from Rabelais (1885). Somewhat elaborate treatments of him in connexion with contemporary literature will be found in George Saintsbury's The Earlier History of Novels (1901) and in A. Tilley's Literature of the South Renaissance (1904). RABENER, GOTTLIEB WILHELM (1714-1771), German satirist, was born on the 17th of September 1714 at Wachau near Leipzig, and died at Dresden on the 22nd of March 1771. In 1741 he made his début as satirist in Schwabe's Belustigungen des Verstandes und Wissens, and was subsequently a contributor to the Brooner Beiträge. Rabener's satires are in prose and mainly directed at the rubbish of the period. The papers published in the Brooner Beiträge were subsequently collected in a Sammlung satirischer Schriften (2 vols., 1757), to which two volumes were added in 1755. RABENER'S Sämtliche Werke appeared in 6 vols., in 1777; the edition by E. Ortlepp (1839) also contains his correspondence. first published in the correspondence of Le Moteau. The papers published in the Brooner Beiträge were subsequently collected in a Sammlung satirischer Schriften (2 vols., 1757). RABIRIUS, a Latin epic poet of the age of Augustus. Among the papyri fragments discovered at Herculaneum in the early part of the 19th century were sixty-seven (multilated) hexameters, referring to the first struggle between Antony and Octavian and the death of Cleopatra, generally supposed to be part of a poem by Rabirius, since Seneca (De Benef. vi. 3.) informs us that he wrote on those subjects. If genuine, they justify the channelled commendation of Quintilian rather than the exaggerated praise of Velleius Paterculus (ii. 36. 3.), who couples Rabirius and Virgil as the two most eminent poets of his time.

FRAGMENTS in E. Bühren's, Fragmenta Posthuma Romanorum (1868); W. Scott, Fragmenta Herculanensia (Oxford, 1885); O. Ribbeck, Geschichte der römischen Dichtung, ii. (1889). M. Schanz, Geschichte der römischen Literatur, i. (1899); Teuffel, Hist. of Roman Literature (Eng. trans., 1893); E. Bühren, Fragmenta Romanorum, ii. (1899). RABIRIUS, GAUS, a Roman senator, who was defended (63 B.C.) by Cicero in a speech still extant. Nearly forty years after the death of L. Appuleius Saturninus, Titus Labienus (whose uncle had lost his life among the followers of Saturninus on that occasion) was put up by Caesar to accuse Rabirius of having been implicated in the murder. Caesar's real object was to warn the Senate against interference by force with popular movements, to uphold the sovereignty of the people and the inviolability of the person of the tribune. The obsolete accusation of perduellio was revived, and the case was heard before Julius and Lucius Caesar as commissioners specially appointed (duumiri perduellionis). Rabirius was condemned, and the people, to whom the accused had exercised the right of appeal, were on the point of ratifying the decision, when Metellus Celer pulled down the military flag from the Janiculum, which was equivalent to the dissolution of the assembly. Caesar's object having been attained, the matter was then allowed to drop. A nephew, known as C. RABIRIUS POSTUMUS, was also defended by Cicero (54 B.C.) in the extant speech Pro Rabirio Postumo, when charged with extortion in Egypt and complicity with Aulus Gabinius (q.v.). See Cicero, Pro Rabirio, ed. W. E. H. C., 2nd ed. (1882); Dio Cassius, xxxvi. 5. 2. H. P. lover, "Rabirius et aegrotus judicis de Re Alexiae," Pro C. Rabirio (Jena, 1881); O. Schultheiss, Der Prozess des C. R. Rabirius (Frauenfeld, 1891). RACAN, HONORÉ DE BUELL, MARQUIS DE (1589-1670), French poet, was born at the château of La Roche-Racan in 1589. He became page at the court of Henry IV. and then entered the army, seeing some active service. Racan was very poor and was practically uneducated, for, if his own account
may be credited, he had not learnt even Latin. But in middle life he inherited some property, and he was thus able to devote himself to the practice of poetry, in which he was the faithful, and perhaps the most distinguished, disciple of Malherbe. He had known Malherbe when he was a page at the court of Henry IV., and had early contributed to the fashionable albums of the day. In 1635 he published his most important work, *Bergeries*, a dramatic pastoral in five acts, a part of which, entitled *Artiténice*, was played in 1618. Racan was also the author of *Sept psaumes* (1631), *Odes sacrées tirées des psaumes de David* (1651), *Dernières œuvres et poésies chrétiennes* (1660), in all of which he was hampered by his inability to read the sacred writings except in other French paraphrases. He was one of the original members of the French Academy. He died in February 1670.

His *Œuvres complètes* were edited by Tenant de Latour in 1857, and the edition includes a biographical notice. See Sainte-Beuve, *Coutures du lundi.*

**RACCONIGI,** a town of Piedmont, Italy, in the province of Cuneo, 24 m. S. of Turin, and 31 m. N. of Cuneo by rail, 837 ft. above sea-level. Pop. (1901) 7364 (town); 9077 (commune). It has a royal château built in 1570, with a large park laid out in 1755 by the French-gardener Molard from designs by Le Notre, and enlarged in 1835. Since 1901 it has been the summer residence of the king of Italy.

**RACCOON** (or *Raccoon*), a name borne by the typical representative of a group of American arboreal placental mammals belonging to the order *Carnivora* (q.v.) and the family Procyonidae. The word is a corruption of the North-American Indian "arrakthikne" or "arathcine." The Fr. *râton* or *râton laveur*, Ger. *Washbär*, and other European names are derived from a curious habit the raccoon has of dipping or washing its food in water before eating it. The typical raccoon (*Procyon lotor*) is a thickly built animal about the size of a badger, with a coat of long coarse greyish-brown hairs, short ears, and a bushy black-and-white-ringed tail. Its range extends over the whole of the United States, and stretches on the west northwards to Alaska and southwards well into Central America, where it attains its maximum size. The following notes on the habits of the raccoon are from Dr C. Hart Merriam's *The Mammals of the Adirondacks*:

"Raccoons are omnivorous beasts and feed upon mice, small birds, birds' eggs, turtles and their eggs, frogs, fish, crayfish, molluscs, insects, nuts, fruits, maize and sometimes poultry. Excepting alone the bats and flying-squirrels, they are the most strictly nocturnal of all our mammals, and yet I have several times seen them abroad on cloudy days. They haunt the banks of ponds and streams, and find much of their food in these places, such as crayfish, mussels and fish, although they are unable to dive and purse the latter under water, like the otter and mink. They are good swimmers and do not hesitate to cross rivers that lie in their path. . . . The raccoon hibernates during the severest part of the winter, retiring to its nest rather early, and appearing again in February or March, according to the earliness or lateness of the season. It makes its home high up in the hollow of some large tree, preferring a dead limb to the trunk itself. It does little in the way of constructing a nest, and from four to six young are commonly born at a time, generally early in April in this region. They remain with the mother about a year.

The South-American species, *P. cancrivora*, the crab-eating raccoon, is very similar to *P. lotor*, but differs by its shorter fur, larger size, proportionally more powerful teeth and other minor characters. It extends over the whole of South America, as far south as the Rio Negro, and is common in all suitable localities. Its habits are similar to those of the North-American species. **RACCOON-DOG** (*Nydereutes procyonoides*), a small wild dog, with sharp-pointed muzzle, short rounded ears, bushy tail and long fur, found in China, Japan and Amurland. The total length is about 32 in., of which the tail measures 4 in. The prevailing hues are black and dusky yellow, the distribution of which varies in different individuals. In habit these dogs are chiefly nocturnal, and they are said to hibernate. In winter they feed on fish, and in summer on mice, forming small packs to hunt their prey.

**RACE,** an homonymous word of which the principal meanings are (1) a trial or contest of speed; (2) a tribe, breed, a group of individuals descended from a common ancestor. In the first case the word is an adaptation of O.Nor. *rds*, a cognate form in O.E. being *râds*, rush, onset; while the O.E. descendant *reese* was frequently used in medieval poetry. The particular use of the word for a swift current of water running through a narrow channel, *e.g.* the Race of Alderney, and for the water conducted in an artificial channel to a point where its power is to be used, as in "mill-race," may be due to the O.Fr. *ras* or *raff* probably of Breton origin. The second word, an ethnic or national stock, comes from Fr. *rasa*, adapted from Ital. *ranno*, cf. Span. *raza*. It has been referred to an O.H.G. *reisa*, line, mark, cognate with Eng. "write," *i.e.* the line marking descent.

**RACHEL** (1811-1838), French actress, whose real name was Elizabeth Felix, the daughter of poor Jew pedlars, was born on the 28th of February 1811, at Mumpf, in the canton of Aargau, Switzerland. At Reims she and her elder sister, Sophia, afterwards known as Sarah, joined a troupe of Italian children who made their living by singing in the cafés, Sarah singing and Eléonore playing the violin. They went to Paris, where they sang in the streets, Rachel giving such patriotic songs as the *Pariissienne* and the *Marseillaise* with a rude but precocious energy which evoked special admiration, and an abundant shower of copper. Étiéenne Choron, a famous teacher of singing, was so impressed with the talents of the two sisters that he undertook to give them gratuitous instruction, and after his death in 1833 they were received into the Conservatoire. Rachel made her first appearance at the Gymnase in Paul Dupot's *La Vendémienne* on the 4th of April 1837, with only mediocre success. But on the 12th of June in the following year she succeeded, after great difficulty, in making a début at the Théâtre Français, as Camille in Cornelle's *Horace*, where her remarkable genius at once received general recognition. In the same year she played Roxane in Racine's *Bajazet*, winning a complete triumph, but it was in Racine's *Phèdre*, which she first played on the 21st of January 1843, that her peculiar gifts were most strikingly manifested. Her range of characters was limited, but within it she was unsurpassable. She excelled particularly in the impersonation of evil or malignant passion, in her presentation of which there was a majesty and dignity which fascinated while it repelled. Her careful training her voice, originally hard and harsh, had become light and melodious, and its low and rich notes under the influence of passion possessed a thrilling and penetrating quality that was irresistible. In plays by contemporary authors she created the characters of Judith and Cleopatra in the tragedies of Madame de Girardin, but perhaps her most successful appearance was in 1849 in Scribe and Legouvé's *Adrienne Lecouvreur*, which was written for her. In 1841 and in 1842 she visited London, where her interpretations of Cornelle,
and Racine were the sensation of the season. In 1855 she made a
tour in the United States with comparatively small success, but
this was after her powers, through continued ill-health, had
begun to deteriorate. She died of consumption at Cannet, near
Nice, on the 4th of January 1858, and was buried in the Jewish
part of the cemetery of Père Lachaise in Paris. Racine’s third
sister was Lia Felix (p.v.).

See Jules G. Janin, Rachel et la tragédie (1856); Mrs Arthur
Kennard, Rachel (Boston, 1888); and A. de Faucigny-Lucinge,
Rachel et son temps (1910).

RACINE, JEAN (1639–1699), French tragic dramatist, was
born at La Ferté Milon in the old duchy of Valois on an uncertain
date in December 1639. He was certainly christened on the 23rd
of December, and the memories were always that time often, though
invariably, performed on the day of birth. Racine belonged to a
family of the upper bourgeois, which had indeed been techni-

cally ennobled some generations earlier, and bore the punning
arms of a rat and a swan (rat, cygne). The poet himself sub-
sequently dropped the rat. His family were connected with
others of the same or a slightly higher station in La Ferté and
its neighbourhood—the Desmoins, the Scouins, the Vitarts,
all of whom appear in Racine’s life. His mother was Jeanne
Scouin. His father, of the same name as himself, was only
four-and-twenty at the time of the poet’s birth. He seems to
have been a solicitor (procureur) or a professional money-

Racine’s letters show that he was intimate with more than one actress at this time; he also made acquaintance
with La Fontaine, and the foundations at any rate of the
legendary “society of four” (Boileau, La Fontaine, Molèr
and Racine) were thus laid.

His relations were pretty certainly alarmed by this very
pardonable worldliness, though a severe expostulation with
him for keeping company with the abominable actors is perhaps
later in date. Racine was accordingly disturbed in his easy-

It was in November 1665 that he went to Uzès in Languedoc to live with his uncle the Père Scouin, vicar-general
of that diocese, whose attempts to secure a benefice for his
nephew were, however, in vain. Racine was back in Paris
before the end of 1665. His letters from Uzès to La Fontaine,
to Le Vasseur, and others are in much the same strain as
before, but there is here and there a marked tone of cynism
in Racine’s language which is not the more fanatical, study
of the recovery of Louis XIV. from a slight illness probably
secured him the promise of a pension, of which he speaks to his
friend in the summer of 1664. It is uncertain whether this
pension is identical with “gratifications” which we know that
Racine for some years received, and which were sometimes
eight and sometimes six hundred livres. It would seem not,
as one of these gratifications had been allotted to him the year
before he so wrote to his sister. The ode in which he thanked
the king for his presents, La Renomée, is said to have intro-
duced him to Boileau, to whose censorship there is no doubt
that he owed much, if not everything; and from this date,
November 1663, the familiarity of “the four” seems to have
existed in full force. Unfortunately it is precisely at this
date that his correspondence ceases, and it is not renewed till after
the close of his brief but brilliant career as a dramatist (Esther
and Athalie excluded). From this time forward the gossip of
the period, and the Life by his son Louis, are the chief sources
of information. Unfortunately Louis Racine, though a man of
some ability and of unimpeached character, was only six years
old when his father died, and had no direct knowledge.
Still his account represents family papers and traditions; and seems
to have been carefully, as it is certainly in the main impartially,
without bias from outside sources—notably Boileau, Claude
Brosette and Jean Baptiste de Vallincourt—a good deal of
pretty certainly authentic information is obtainable, and there
exists a considerable body of correspondence between Boileau
and the poet during the last ten years of Racine’s life.

The first but the least characteristic of the dramas by which
Racine is known, La Thébaïde, was finished by the end of 1663,
and on Friday 20th June 1664 it was played by Molèr’s com-
pany at the Palais Royal theatre. Some editors assert that
Molère himself acted in it, but the earliest account of the
work we have, and that is sixty years after date, omits his
name, though those of Madeleine Béjar and Mademoiselle de Brie
occur. There is also a tradition that Molère suggested the
subject; but Louis Racine distinctly says that his father
wrote most of the play at Uzès before he knew Molère.
From Racine’s own earlier letters it appears that the play was
designed for the rival theatre, and that “La Déchâncée,” Racine’s
familiar name for Mademoiselle de Beauchâteau, with whom
he was intimate, was to play Antigone. The play itself is by
far the weakest of Racine’s works. He has borrowed much
from Euripides and not a little from Jean de Rotrou; and in
his general style and plan he has as yet struck out no great
variation from Corneille. It was acted twelve times during
the first month, and was occasionally revived during the year
following. This is apparently the date of the pleasant picture
of the four friends which La Fontaine draws in his *Psyche*, Racine figuring as Acante, "qui aimait extrêmement les jardins, les fleurs, les ombraages," in which surroundings he helped to compose the lampoon of *Chapelain déoctiff* on a writer who had helped him with criticism, obtained royal gifts for him, and, in a fashion, started him in the literary career. We have no definite details as to Racine's doings during the year 1664, but in February 1665 he read at the Hôtel de Nevers before La Rochefoucauld, Madame de la Fayette, Madame de Sévigné, and other scarcely less deductible judges the greater part of his second acted play, *Alexandre le Grand*, or, as Pomponne (who tells the fact) calls it, *Porus*. It was anxiously expected by the public, and Mollière's company played it on the 4th of December—Monsieur, his wife Henrietta of England, and many other distinguished persons being present. The gazetteer, Adrien Peltou de Subligny vouches for its success, and the receipts were good and steady. But a fortnight afterwards Alexandre was played, "de compott avec M. Racine," says La Grange, by the rival actors (who had four days before performed it in private) at the Hôtel de Bourgogne. A vast amount of ink has been spilt on this question, but no one has produced any valid justification for Racine. That the piece failed at the Palais Royal, as is stated in the earliest attempt to excuse Racine, and the only one made in his lifetime, is not true. His son simply says that he was "mécontent des acteurs," which indeed is self-evident. It is certain that Mollière and he ceased to be friends in consequence of this proceeding; and that Mollière was in fault no one who has studied the character of the two men will easily believe. If, however, Alexandre was the occasion of showing the defects of Racine's character as a man, it raised him vastly in public estimation as a poet. He was now for the first time proposed as a serious rival to Corneille. There is a story that he read the piece to the author of the *Cid* and asked his verdict. Corneille praised the piece highly, but not as a drama, "Il l'assurant qu'il n'était pas propre à la poésie dramatique." There is no reason for disbelieving this, for the character of Alexander could not fail to shock Corneille, and he was notorious for not mincing his words. The contrast between the two even at this early period was accurately apprehended and put by Saint Evremont in his masterly *Dissertation sur l'Alexandre*, but this was not published for a year or two. To this day it is the best criticism of the faults of Racine, though not, it may be, of the merits, which had not yet been fully seen. It may be added that in the preface of the printed play the poet showed the extreme sensitiveness to criticism which perhaps excuses, and which certainly often accompanies, a tendency to criticize others. These defects of character showed themselves still more fully in another matter. The Port Royalists, as has been said, detested the theatre, and in January 1666 Nicole, their chief writer, spoke in one of his *Lettres sur les visionnaires*, directed against Desmarres de Saint-Sulpice, of dramatic poets as "emponeurs de cœurs de publics." Racine immediately published a letter to the author. It is very smartly written, and if Racine had contended himself with protesting against the exaggeration of the decriers of the stage there would have been little harm done. But he filled the piece with personalities, telling an absurd story of Mère Angélique Arnauld's supposed intolerance, drawing a ridiculous picture of Le Maitre (a dead man and his own special teacher and friend), and sneering savagely at Nicole himself. The latter made no reply, but two lay adherents of Port Royal took out the quarrel with more zeal than discretion or ability. Racine was not only impudently equal as the first, but less amusing, and was about to publish it when fortunately Boileau, who had been absent from Paris, returned and protested against the publication. It remained accordingly unprinted till after the author's death, as well as a preface to both which he had prepared with a view to publishing them together and so discharging the accumulated resentment arising from a long course of "excommunications."

After this disagreeable episode Racine's life, for ten years and more, becomes simply the history of his plays, if we except his liaisons with the actresses Mademoiselle du Parc and Made moiselle de Champmeslé, and his election to the Academy on the 17th of July 1673. Mademoiselle du Parc (marquise de Gorla) was no very great actress, but was very beautiful, and she had previously captivated Mollière. Racine induced her to leave the Palais Royal company and join the Hôtel. She died in 1668, and one cock out of seven. Vaudeville de Catherine Voisin accused Racine of having poisoned her. Made moiselle de Champmeslé was plain, but an admirable actress, and apparently very attractive in some way, for not merely Racine but Charles de Sévigné and many others adored her. For five years before his marriage Racine seems to have been her amant en titre, but long afterwards, just before his own death, when he heard of her mortal illness, he spoke of her to his son without a flash of tenderness.

The series of his unquestioned dramatic triumphs began with *Andromaque*, and this play may perhaps dispute with *Phèdre* and *Athalie* the title of his masterpiece. It is much more uniformly good than *Phèdre*, and the character of Hermione is the most personally interesting on the French tragic stage. It is said that the first representation of *Andromaque* was on 10th November 1667, in public and by the actors of the Hôtel de Bourgogne, but the first contemporary mention of it by the gazettes, prose and verse, is on the 17th, as performed in the queen's apartment. Perrault, by no means a friendly critic as far as Racine is concerned, says that it made as much noise as the *Cid*, and so it ought to have done. Whatever may be thought of the tragique pathétique (a less favourable criticism might call it the "sentimental tragedy"), it could hardly be better exemplified than in this admirable play. A ferocious epigram of Racine's own tells us that some critics thought Pyrrhus too fond of his mistress, and Andromache too fond of her husband, but in the contemporary depreciations is to be found the avowal of its real merit. Pyrrhus was taken by Floridor, the best tragic actor by common consent of his time, and Orestes by Montfeurly, also an accomplished player. But Mademoiselle du Parc, who played Andromache, had generally been thought below, not above, her parts, and Mademoiselle des Oeilletes, who played the difficult rôle of Hermione, was old and had few physical advantages. No one who reads *Andromaque* without prejudice is likely to mistake the secret of its success, which is, in few words, the application of the most delicate art to the conception of really tragic passion. Before leaving the play it may be mentioned that it is said to have been in the part of Hermione, three years later, that Mademoiselle de Champmeslé captivated the author. *Andromaque* was succeeded, at the distance of not more than a year, by the charming comedietta of *Les Plaideurs*. We do not know exactly when it was played, but it was printed on the 5th of December 1668. Many anecdotes are told about its origin and composition. The *Wasps* of Aristophanes, and the known fact that Racine originally destined it, not for a French company, but for the Italian troupe which was then playing the *Commedia dell'arte* in Paris, dispense us from enumerating them. The result is a piece admirably dramatic, but sufficiently literary to shock the *profunum vulgus*, which too frequently gives the tone at theatres. It failed completely, the chief favouring voice being, according to a story sufficiently well attested and worthy of belief even without attestation, that of the man who was best qualified to praise and who might have been most tempted to blame of any man then living. Mollière, says Vallincourt, the special friend of Racine, said in reply to Racine, "If I might say anything to him, I would merit qu'on se moquion d'eux." But the piece was suddenly played at court a month later; the king laughed, and its fortunes were restored. It need only be added that, if Louis XIV. admired *Les Plaideurs*, Napoleon did not, and excluded it from his travelling library. It was followed by a very different work, *Britannicus*, which appeared on 13th December 1669. This was much less successful than *Andromaque*, and seems to have held its own but a very few nights. Afterwards it became very popular, and even from the first the
exquisite versification was not denied. But there is no doubt that in *Britannicus* the defects of Racine display themselves pretty clearly to any competent critic. The complete nullity of Britannicus himself and of Junie, and the insuficient attempt to display the complex and dangerous character of Nero are not redeemed by Agrippina, who is really good, and Burrhus, who is solidly painted as a secondary character. Voltaire calls it "la pièce des connasseurs," a double-edged compliment. The next play of Racine has, except *Phèdre*, the most successful history of all. "Bérénice," says Fontenelle succinctly, "fut un duel," and he acknowledges that his uncle was not the conqueror. Henrietta of Orleans proposed (it is said without letting them know the double commission) the subject to Corneille and Racine at the same time, and rumour gives no very credible reasons for her choice of the subject. Her death preceded the performance of the two plays, both of which, but especially Racine's, were successful. There is no doubt that it is the better of the two, but Claude Chapelle's not unfriendly criticism in quoting the two lines of an old song—

"Marion pleure, Marion crie, Marion veut qu'on la marie,"

is said to have annoyed Racine very much, and it has a most malicious appropriateness. *Bajazet*, which was first played on 4th January 1672, is perhaps better. As a play, technically speaking, it has great merit, but the reproach commonly brought against its author was urged specially and with great force against this by Corneille. It is impossible to imagine anything less Oriental than the atmosphere of *Bajazet*, the whole thing is not only French but chimerically French—French of the day and hour; and its ingenious scenario and admirable style scarcely save it. This charge is equally applicable with the same reservations to *Mithridate*, which appears to have been produced on 13th January 1673, the day after the author's reception at the Academy. It was extremely popular, and Racine could hardly have lodged a more triumphant diploma piece. His next attempt, *Iphigénie*, was a long step backwards and upwards in the direction of *Andromaque*. It is not that the characters are eminently Greek, but that Greek tragedy gave Racine examples which prevented him from flying in the face of the propriety of character as he had done in *Bérénice*, *Bajazet*, and *Mithridate*, and that he here called in, as in *Andromaque*, other passions to the aid of the mere sighing and crying which form the sole appeal of these three tragedies. Racine's drama was not yet at its height, the date of its appearance is very uncertain. It was acted at court on the 18th of August 1674, but it does not seem to have been given to the public till the early spring of 1675.

The last and finest of the series of tragedies proper was the most unlucky. *Phèdre* was represented for the first time on New Year's Day 1677, at the Hôtel de Bourgogne. Within a week the opposition company or *troupe du roi* launched an opposition *Phèdre* by Nicolas Pradon. This singular competition, which had momentous results for Racine, and in which he to some extent paid the penalty of the *les talons* for his own rivalry with Corneille, had long been foreseen. Racine had from the first been bitterly opposed, and his enemies at this time had the powerful support of the duchess of Bouillon, one of Mazarin's nieces, together with her brother the duch of Nevers and divers other personages of high position. These persons of quality, guided, it is said, by Madame Deshouillères, selected Pradon, a dramatist of little talent but of much facility, to compose a *Phèdre* in competition with that which it was known that Racine had been elaborating. The partisans on both sides did not neglect means for correcting fortune. On her side the duchess of Bouillon is accused of having bought up the front places in both theatres for the first six nights; on his, Racine is said to have prevailed on the best actresses of the company that played Pradon's piece to refuse the title part. There is even some ground for believing that he endeavoured to prevent the opposition play from being played at all. It was of no value, but the measures of the cabal had so well taken that the finest tragedy of the French classical school was all but driven from the stage, while Pradon's was a positive success. A war of sonnets and epigrams followed, during which it is said that the duke of Nevers menaced Racine and Boileau with the same treatment which Dryden and Voltaire actually received, and was only deterred by the protection which Condé extended to them.

The unjust cabal against his peace no doubt made a deep impression on Racine. But it is impossible to decide exactly how much influence this had on the subsequent change in his life. For thirteen years he had been constantly employed on a series of brilliant dramas. He now broke off his dramatic work entirely and in the remaining twenty years of his life wrote but two more plays, and those under special circumstances and of quite a different kind. He had been during his early manhood a libertine in morals and religion; he now married, became irreproachably domestic, and almost ostentatiously devout. No authentic account of this change exists; for that of Louis Racine, which attributes the whole to a sudden religious impulse, is manifestly more than the refect upon his former patrones. But a report is current that all the motives which friends and foes have attributed more or less into his action. At any rate, what is certain is that he reconciled himself with Arnauld and Port Royal generally, accepted, with whatever sincerity, their doctrine of the incompatibility of the stage and the Christian life, and on the 1st of June married Catherine de Romanet and definitely settled down to a quiet domestic life, alternated with the duties of a courtier. For his repentance was by no means a repentance in sackcloth and ashes. The drama was not then very profitable to dramatists, but Louis Racine tells us that his father had been able to furnish a house, collect a library of some value, and save 6000 livres. His wife had money, and he had possessed for some time (it is not certain how long) the honourable and valuable post of treasurer of France at Moulins. His annual "gratification" had been increased from 800 to 1500 livres, then to 2000, and in the October of the year of his marriage he and Boileau were made historiographers-royal with a salary of 2000 crowns. Besides all this he had, though a layman, one or two benefices. It would have been pleasanter if Louis Racine had not told us that his father regarded His Majesty's choice as "an act of the grace of God to catch him entirely from poetry." For the historian of Louis XIV. was certainly his chief flatterer. However, little came of this historiography. The joint incumbents of the office made some campaigns with the king, sketched plans of histories and left a certain number of materials and memoirs; but they executed no substantive work. Racine, whether he set down to his credit or not, was certainly a fortunate and apparently an adroit courtier. His very relapse into Jansenism coincided with his rise at court, where Jansenism was in no favour, and the fact that he had been in the good graces of Madame de Montespan did not deprive him of those of Madame de Maintenon. Neither in *Esther* did he hesitate the theory of a mandarin in both senses of the word. For a report of the king, who was sharp-eyed enough, "Cavoie avec Racine se croit bel esprit; Racine avec Cavoie se croit courtisan," makes it appear that his comparatively low birth was not forgotten at Versailles.

Racine's first campaign was at the siege of Ypres in 1678, where some practical jokes are said to have been played on the two civilians who acted this early and peculiar variety of the part of special correspondent. Again in 1683, in 1687 and in each year from 1691 to 1693 Racine accompanied the king on similar expeditions. The literary results of these have been spoken of. His labours brought him, in addition to his other gains, frequent special presents from the king, one of which was as much as 1000 pistoles. In 1690 he further received the office of "gentilhomme ordinaire du roi," which afterwards passed to his son. Thus during the later years of his life he was more prosperous than is usual with poets. His domestic life appears to have been a happy one.
Louis Racine tells us that his mother “did not know what a verse was,” but Racine certainly knew enough about verses for both. They had seven children. The eldest, Jean Baptiste, was born in 1678; the youngest, Louis, in 1692. It has been said that he was thus too young to have many personal memories of his father, but he tells one or two stories which show Racine to have been at any rate a man of strong family affection, as, moreover, his letters prove. Between the two sons came five daughters, Marie, Anne, Elizabeth, Françoise and Madeleine. The eldest, after showing a “vocation,” married in 1699, Anne and Elizabeth took the veil; the youngest two remained single but did not enter the cloister. To complete the notice of family matters—much of Racine’s later correspondence is addressed to his sister Marie, Madame Rivièvre.

The almost complete silence which Racine imposed on himself after the comparative failure of Phèdre was broken once or twice even before the appearance of his two last exquisite tragedies. The most honourable of these was the reception of Thomas Corneille on 2nd January 1685 at the Academy in the room of his brother. The discourse which Racine then pronounced turned almost as much on the rivalry, of whom he spoke even more than becomingly. But it was an odd conjunction of the two reigning passions of the latter part of his life—devoutness and obsequiousness to the court—which made him once more a dramatist. Madame de Maintenon had established an institution, first called the Maison Saint Louis, and afterwards (from the place to which it was transferred) the Maison de Saint Cyr, for the education of poor girls of noble family. The tradition of including acting in education was not obsolete. At first the governness, Madame de Grignon, composed pieces for representation, but, says Madame de Caylus, a witness at first hand and a good judge, they were “detestable.” Then recourse was had to chosen plays of Corneille and Racine, but there were obvious objections. The favourite herself wrote to Racine that “nos petites filles” had played Andromaque “a great deal too well.” She asked the poet for a new play suited to the circumstances, and, though Boileau advised him against it, it is not wonderful that he yielded. The result was the masterpiece of Esther, with music by Moreau, the court composer and organist of Saint Cyr. Although played by schoolgirls and in a dormitory, it had an enormous success, with which it may be charitably hoped that the transparent comparison of the patroness to the hero of the tragedy was not demeaning. The plot had to suffer a certain reaction, or perhaps a certain vengeance, from those who had not been admitted to the private stage. But no competent judge could hesitate. Racine probably had read and to some extent followed the Aman of Antoine de Montchrestien, but he made of it only the use which a proved master in literature has a perfect right to make of his fore-runners. The beauty of the chorus, which Racine had restored more probably from a study of the Pléiade tragedy than from classical suggestions, the perfection of the characters and the wonderful art of the whole piece need no praise. Almost indescribable was the power with which the new tragic composer, besides having a sense of music, and a sense of the artistic side of the drama, had in his hands the art of the orator. The very first piece of the kind, and he had probably finished Athalie before the end of 1690. The fate of the play, however, was very different from that of Esther. Some fuss had been made about the worldliness of great court fétes at Saint Cyr, and the new play, with settings as before by Moreau, was acted both at Versailles and at Saint Cyr with much less pomp and ceremony than Esther. It was printed in March 1691, and the public cared very little for it. The truth is that the last five-and-twenty years of the reign of Louis XIV were marked by one of the lowest titles of literary accomplishment and appreciation in the history of France. The just judgment of posterity has ranked Athalie, if not as Racine’s best work (and there are good grounds for considering it to be this), at any rate as equal to his best. Thenforeword Racine was practically silent, except for four cantiques spirituelles, in the style and with much of the merit of the choruses of Esther and Athalie. The general literary sentiment led by Fontenelle (who inherited
of Ophelia and the remorse of Lady Macbeth, but beside the sincerer if less perfectly expressed passion of Cornuelle’s Céphéade and Camille. In men’s parts he fails still more completely. As the decency of his stage would not allow him to make his heroes frankly heroic, so it would not allow him to make them utterly passionate. He had, moreover, cut away from himself, by his proper sentiments, all the opportunities which would have been offered to his remarkably varied talent on a freer stage. It is indeed tolerably certain that he never could have achieved the purely poetical comedy of *As You Like It* or the *Vida es Sueño*, but the admirable success of *Les Plaisirèdes* makes it at least probable that he might have done something in a lower and a more conventional style. From all this, however, he deliberately cut himself off. Of the whole world which is subject to the poet he took only a narrow artificial and conventional fraction. Within these narrow bounds he did work which no admirer of literary craftsmanship can regard without admiration. It would be unnecessary to contrast his performances with his limitations so sharply if those limitations had not been denied. But they have been and are still denied by persons whose sentence carries weight, and therefore it is still necessary to point out the fact of their existence.

**Bibliography.**—Nearly all Racine’s works are mentioned in the above notice. There is here no room for a bibliographical account of the various separate editions. The two collected works of 1772 and 1787 were published in 1806; the other editions of *M. de Scudéry* were reprinted in 1812, *Bérénice* in 1813, the *Iphigénie* in 1815 and 1817, the *Dardennes* in 1840, and the *Œuvres complètes* (6 vols.) in 1808.

**RACINE, LOUIS** (1639-1793), French poet, second son of Jean Racine, was born in Paris on the 6th of November 1639. Early conscious of a vocation for poetry, he had been dissuaded from following his inclination by Boileau on the ground that the gift never existed in two successive generations. In 1722 his small means induced him to accept a position in the revenue in Provence, but a marriage with a certain Madeleineille Presle secured his independence. In 1735 he lost his position in the disasters consequent on the Lisbon earthquake. This misfortune, commemorated by Échoud Lebrun, broke Racine’s spirit. He sold his library, and gave himself up entirely to the practice of religion. In 1719 he had become a member of the Académie des Inscriptions, but had never offered himself as a member of the Académie Française, for fear, it is said, of incurring refusal on account of his Jansenist opinions. *La Grace* (1720) and *Religion* (1742), his most important work, are inspired by a sincere piety, and are written in verse of uniform clearness and excellence. His other works include epistles, odes, among which the Ode sur l’harmonie (1736) should be mentioned, *Mémoires* (1747) of Jean Racine, and a prose translation of *Paradise Lost* (1755). Louis Racine died on the 29th of January 1763. He was characterized by Voltaire as “le bon versificateur Racine, fils du grand poète Racine.”

His *Œuvres complètes* were collected (6 vols.) in 1808.

**RACINE, L., the city and the county-seat of Racine county, Wisconsin, U.S.A., on the east shore of Lake Michigan at the mouth of the River.root, about 25 m. S.S.E. of Milwaukee and about 60 m. N. of Chicago. Pop. (1890) 21,014; (1900) 29,102, of whom 9142 were foreign-born; (1910 census) 38,002. Racine is served by the Chicago & North Western and the Chicago, Milwaukee & St Paul railways, by two interurban electric railways, connecting with Milwaukee and Chicago, and by steamboat lines. The river has been deepened and its mouth protected by breakwaters, providing an excellent harbour; in 1909 vessels drawing 19 ft. could pass through the channel. Among the public buildings are the City Hall, the County Court House, the Federal Building, the Carnegie Library, the ‘High School, two hospitals and the Taylor Orphan Asylum (1872). Among educational institutions, besides the public schools, are Racine College (Protestant Episcopal, 1853), St Catherine’s Academy (Roman Catholic) and two business colleges. Racine is, next to Milwaukee, the most important manufacturing centre in Wisconsin. The value of its factory products in 1905 was $16,458,065, an increase of 41% over that of 1900. Of this, $5,177,070 (or 31% of the city’s total) represented agricultural implements and machinery. Carriages and wagons ($2,729,311) and automobiles ranked next in importance.

Racine was the French form of the name of the root river. The first Europeans positively known to have visited the site of Racine were Vincennes, Tenty and several Jesuit missionaries, who stopped here for a time on their way down the coast in 1699. Early in the 19th century Jammeau, a French trader, established himself on the Root river, and in 1834 Gilbert Knapp (1798-1889), who had been a lake captain since 1818, induced several residents of Chicago to make their homes at its mouth. The place was at first called Port Gilbert. The settlement grew rapidly, a sawmill was built in 1835, and the present name was adopted in 1837. In 1841 Racine was incorporated as a village and in 1848 was chartered as a city.

See S. S. Hurlbut, *Early Days at Racine* (Racine, 1872); *History of Racine and Kenosha Counties* (Chicago, 1879).

**RACK** (as in “rack and ruin”), an homonymous word of which the principal branches are the words meaning (1) a mass of cloud driving before the wind in the upper air, (2) to draw off wine or other liquor from the lees, (3) a bar or framework of bars, (4) an instrument of torture. The etymology of (1) shows that it is ultimately to be connected with “wreck” and “wrack,” drifted seaweed, and means that which is driven by or drifts with the wind; cf. Norw. *rak*, wreckage, refuse, Icel. *reka*, to drive, toss. In (2) the term seems to have come from the Gascon wine-trade, as Skeat (*Etym. Dict.*, 1910) points out, and was adapted from Prov. *arracar*, to decant wine, *raca*, the stems and husks of grapes, dregs. Both (2) and (3) are in origin to be connected. The O.E. *recan* and Ger. *recken* mean “to stretch,” and so “rack” means something stretched out, a straight bar or rail, especially a toothed bar gearing with a cog-wheel, a framework of bars, as in the cradle of upright bars in which fodder can be placed for cattle, and the instrument of torture, which in Ger. is *Recke* or *Rackbank*. The “rack” for torture was an oblong frame of wood, slightly raised from the ground, having at one end a fixed bar to which the legs were fastened, and at the other a movable bar to which the hands were tied. By means of pulleys and levers this latter could be rolled on its own axis, thus straining the ropes till the sufferer’s joints were dislocated. Its first employment in England is said to have been due to John Holland, 4th duke of Exeter, constable of the Tower in 1447, whence it was popularly known as “the Duke of Exeter’s daughter.”
In 1628 the whole question of its legality was raised by the attempt of the privy council to rack John Felton, the assassin of the duke of Buckingham: this the judges resisted, unanimously declaring its use to be contrary to the laws of England.

**RACKETT** or **RACKETT-BASSOON** (Fr. cerellos or cercelot; Ger. Rackett, Rankett or Wursfagott), a kind of dwarf bassoon, now obsolete, with a body measuring only from 4½ to 11 in. in length, but nevertheless containing the necessary length of tubing to give the bassoon or contra-bassoon pitch. The rackett consists of a barrel-like body, resembling the barrel drone of the musette (see Bagpipe), made of wood or ivory. Round a centre tube are grouped eight parallel channels of very narrow cylindrical bore communicating with each other and forming a continuous tube nine times the length of the small body.

A reed mouthpiece in combination with a cylindrical tube invests the latter with the acoustic properties of a closed pipe by creating a node at the mouthpiece end; the fundamental note given by such a tube is, therefore, an octave deeper in pitch than would be an open pipe of the same length. The bassoon has a conical bore and the properties of the open pipe, wherefore the aggregate length of the channels in the rackett only requires to be half that of the bassoon, a physical phenomenon to which this curious freak owes its existence. In the rackett the holes are bored obliquely through from the channels to the reed—three in front for the left and three for the right hand, with an additional hole for the little finger; while at the back are placed the vent and three holes, one for the left thumb and two for the right, the second hole being controlled by the ball of the thumb. The rackett is played by means of a large double reed placed within a pirouette or cap, so that the lips do not come into contact with the reed, but only send a stream of compressed air into the pirouette, whereby the reed is set in vibration. The consequence of this principle of construction, peculiar to the bagpipe chunter and drones (with a slight variation) and to cromornes, hautbois de Poitou and a few other obsolete instruments, is that no harmonics can be obtained, since the vibrating length and the tension of the reed cannot be controlled by the player; the compass is therefore obtained by means of the fundamental and of the ten holes of the instrument, aided by cross-fingering.

**RACQUETS, or RACKETS**, a game played in an enclosed court with a ball and an implement with which the ball is struck called a racquet, from which the game takes its name.

The racquet1 is about 2½ ft. long, the head, which was formerly pear-shaped, being in the modern racquet nearly circular, from 7 to 8 in. in diameter and tightly cross-strung with cat-gut. The balls, which are about 1½ in. in diameter, are made of strips of cloth tightly wound over each other, with a sewn covering of smooth white leather, the floor and walls of English courts being coloured black; in India, where the floor and walls of the court are painted white, black balls are used. There are no regulation dimensions for a racquet court, nor for the racquet or ball, though substantial uniformity is observed in practice. The game is usually played either by two or by four players; and in England the court is the same for the four-handed and the two-handed game, the floor measuring usually 60 ft. by 30 ft., or occasionally an inch or two more each way; but in America larger courts measuring on the floor 80 ft. by 40 ft., a size formerly not uncommon in England, are sometimes built for the four-handed game. Modern racquet courts have four walls and are roofed, but in India they are sometimes left unroofed for the sake of coolness. The floor, which must be perfectly level and smooth, should be made of cement; but is sometimes paved, with less perfect results. The floor cannot be too hard, since the faster the ball travels the better the game; similarly the walls, which should be built of masonry faced with cement and most carefully smoothed, cannot be too hard and fast. The front and side walls are about 30 ft. high, the back wall being about half that height, with a gallery for spectators (containing the marker's and umpires' box) above it. The court is entered by a door in the centre of the back wall, which when shut must be perfectly flush with that wall, and without joint or gap. The court is lighted from within.

The diagram (fig. 2) shows the divisions and markings of the court. On the front wall is fixed a wooden board, the upper edge of which, 26 in. from the floor, constitutes the "play-line," and which usually fills the whole space from that height to the floor; and at a height from the floor of 8 ft. or a few inches more is a second line, called the "cut-line" or "service-line," painted white or in colour. At a distance of 38 ft. (in a court 60 ft. by 30 ft.) from the front wall and parallel to it, a white line is painted on the floor from wall to wall, called the "short-line;" and from the centre of the short-line to the centre of the back wall is the "fault-line," dividing into two equal rectangles the space between the back wall and the short-line. These rectangles are the service-courts and the right-hand and left-hand court respectively. Against the side walls outside these courts, but so that one side in each case is formed by the short-line, are squares 8 ft. by 8 ft. called the service-boxes.

*The Game.*—**Racquets** is usually played either by two persons ("singles"), or by four persons playing two against two ("doubles"); and the general idea of the game is the same as that in tennis, lawn tennis and fives, the object of the player in all these games being to score a point by striking the ball either before it reaches the ground or on its first bound, in accordance with the rules of the game such that his adversary may fail to make a "good," i.e. a valid, stroke in return. In the four-handed game one of each set of partners takes the right-hand court and his partner the left. The game consists of 15 points called "aces." Aces can only be scored by the "hand-in" (the player, or side, having the "innings"), and the "hand-out" must therefore win a stroke or strokes to obtain innings before he or they can score an ace; in "doubles" each of the partners has an innings, and both must therefore be ousted before "hand-out" obtains the innings; but to this the first innings of each game affords an exception (see below). The "hand-in" always has "service," i.e. he opens the rally (the "rally" being the series of strokes made alternately by the two sides until one or other of them fails to make a good return) by "serving" the ball from the hand. This first stroke, or "serve," must be made in the following manner. The server, standing with one foot at least inside one of the service-boxes, must toss the ball from his hand, and while it is in the air he must hit it with his racquet so that it strikes the front wall above the service-line and falls to the floor within the service-court on the opposite side; after striking the front wall the ball may, but need not, strike the side wall or back wall, or both, and it may do so either before or after touching the floor. The serve is a "fault" if the ball (1) strikes the front wall

---

1 The word comes, through Fr. raquette, from Sp. and Port. raqueta. The origin is doubtful, but Arab. râqa(t), palm of the hand, has been suggested; "ives " played with the hand long preceded the game with a bat; cf. also Fr. name for fives, paume.
above the board but or on below the service-line, in which case it is called a "cut"; or (z) touches the floor on the first bound, outside the proper service-court, when it is called "served" or "fault" according to the position of its pitch (see below). If the "hand-out" to player to whom the fault is served takes it (i.e., if he plays at it), the fault is condescended and he play proceeds as if the serve had been good. If, however, the fault be not taken, the server must serve again from the same box; and if he serves a second fault he loses his "hand" or innings, and his partner or his opponent, as the case may be, takes his place. Two consecutive faults have thus the same result as the loss of a stroke in the rally by the "hand-in." A serve which makes the ball strike the board, or the floor before reaching the front wall, or which sends it "out-of-court" (i.e., into the gallery or roof of the court), counts the same as two consecutive faults; it costs the server his innings. Skill in service is a most important factor in the service-court. A player can rarely become first-rate unless he possesses a "strong service." As in tennis a great deal of "cut" may be imparted to the ball by the stroke of the racquet, which makes the ball in its rebound from the wall behave like a billiard ball carrying "side" when striking a cushion; and when this "cut" is combined with great pace in the ball of the side wall, the back wall, and the floor, at varying angles which the server has to a great degree under his control, it becomes exceedingly difficult for hand-out to "get up" the serve (i.e., to hit it on the first bound, sending it above the play-line on the back wall), and still more so if the ball is a good stroke, as it is often for his adversary in his turn to get up the ball and thus continue the rally. It often happens, therefore, that a long sequence of aces, sometimes the whole 15 aces of a game, are scored consecutively by service which hand-out is unable to return. A noteworthy instance of successful service occurred in the semi-final tie of the doubles Amateur Championship matches at the Queen's Club in 1897 when W. L. Foster opened service and scored all the aces in the first two games, and added six in the third, thus putting on a sequence of 36 aces before losing his "hand." To obtain first innings is therefore an important advantage, although in doubles it is limited by the rule that only one partner shall have a "hand" (innings) in the opening service.

The question which side shall have this advantage is decided by spinning a racquet, the "rough" and "smooth" sides of which take the place of "heads" and "tails" when a coin is tossed. The side winning the spin opens the game by serving as described above. The server may begin in either of the service boxes; but when he has started, the service must proceed from the two boxes alternately till the close of the innings of the side, whether singles or doubles. When the other side obtains the innings they may in like manner begin in either box, without regard to where the last service of their opponents was delivered. In singles, hand-out changes sides in the opening service; in doubles the service is taken alternately by the two hand-out players, who permanently occupy the right- and left-hand courts respectively, being allowed to change the order in which they receive the service only once in any game, or at the end of any game or rubber. Except in the very rare case of left-handed players most of the play in the left half of the court, including the taking of all service on that side, is back-handed; and the stronger of the two partners in back-hand play usually therefore takes the left-hand court. The best position in the court for the hand-out about to take the serve depends entirely on the nature of the service, and he has to use his judgment the instant the ball leaves the server's racquet in order to determine where it will strike the floor and at what precise point in its course it will be best for him to attempt to take it. A strong fast service, heavily cut, that sends the ball darting round the corner of the court, leaving the back wall at an extremely acute angle, or dropping almost dead off it, can only be got up by standing near the back wall a long way across the court and taking the ball by a wrist stroke at the last instant before it falls to the ground a second time. On the other hand when the server avoids the side wall altogether and strikes the back wall direct and hard, whether he achieves a "nick" serve (i.e. the ball striking precisely in the angle between the back wall and the floor) or hits the wall high up, hand-out will have little time to spare in changing position to get within reach of the ball. Some good players make a practice of this, especially in the case of heavily cut service, of taking the serve on the volley (i.e., before the ball reaches the ground), sometimes of taking the ball after it leaves the side wall and before it reaches the back wall; practice alone enables the player to decide with the necessary promptitude how each stroke is to be played. In returning the serve, or in playing any stroke during the rally, the ball may strike any of the other walls before the front wall; but though this "boasted" stroke is quite legitimate, and is sometimes the only way of getting up a difficult ball, it is not considered good style deliberately to slash the ball round the corners in order to keep it in the fore court of the court. Good play-consists for the most part in hard low hitting, especially as close as possible along the side walls into the corners of the back wall. One of the most effective strokes in racquets is the "drop," which means that the ball is hit so that it just reaches the front wall and drops close to it, while the player conceals his intention by appearing to strike hard. "The drop-stroke," says Mr Eustace Miles, who regrets that it is less cultivated than formerly, "is one of the most beautiful, and of all drop-strokes, the volley or half-volley is the best." The "half-volley," in which the ball is struck at the moment of its contact with the rebounding ball, is not a stroke which has had time to rise, is also employed with great effect in hard play; it makes the return much quicker than when the ball is allowed to rise to the full length of the bound, and requires corresponding quickness on the part of the adversary. It sometimes happens, too, that the player finding himself too near the pitch of the ball to take it at the end of the bound, yet not near enough to volley it, is compelled to take it on the half-volley as the only chance of getting it up. Accuracy in volleying and half-volleying, especially if the ball be kept low, is most difficult art to acquire, but a good long rally in which are included a number of hard rapid half-volleys within a couple of inches of the board, is the prettiest feature of the game. If hand-out succeeds in returning the serve, the rally proceeds until one side or the other fails to make a good return. A good return means (1) that the ball is struck by the racquet before its second bound on the floor, and without its having touched any part of the clothes or person of the striker or his partner; (2) that it is hit against the front wall above the board without first touching the floor or going out of court; and (3) that it returns off the front wall into play (i.e. to the floor of the court or to an adversary's racquet) without going out of court. If hand-in be the one to fail in making a good return, he loses his "hand," or innings, and (in singles) hand-out goes in and prepares to serve; in doubles one of the hand-in partners loses his "hand," and the second partner goes in and serves till he in turn similarly loses his "hand," except that in the case of the opening service in the game there is (as already mentioned) only one "hand" in any event. If hand-out fails to make a good return to the serve or to any stroke in the rally, hand-in scores an ace, and the side that first scores 15 aces wins the game. When, however, the score reaches "13-all" (i.e. when each side has scored 13 aces), hand-out may, before the next serve is delivered, declare that he elects to "set" the game either to 5 or 3, whichever he prefers; and similarly when the score stands at "14-all," hand-out may "set" the game to 3. He makes this declaration by calling "set-5" or "set-3," and if it means that 5 aces, or 3 aces, as the case may be, shall be required to win the game.

In the confined space of a racquet court it is not always easy, especially in doubles, for the players to avoid obstructing each other. It is provided in the rules that "each player must get out of his opponents' way as much as possible," and that it shall be a "let" (an Old English word for impediment or hindrance) and "the service or rally shall count for nothing, and the server shall serve again from the same service-box,
(a) if the ball in play touch the striker's opponent on or above the knee, and if in the marker's opinion it was thereby prevented from reaching the front wall above the board (the play-line); or (b) if either player unadvisedly prevent his opponent from returning the ball served in play. If a player considers that he has been thus obstructed by his opponent he may "claim a let," and the marker adjudicates his claim. The marker's decision is final; but "if in doubt which way to decide, the marker may direct that the ace be played over again."

It is the duty of the marker, who occupies a box in the gallery, to "call the game." As soon as the server serves the ball the marker calls "Play!" if the ball strikes the front wall above the service-line; and "Cut!" if it strikes below the service-line: the marker calls "Ace!" if the short-line is served, and "Short!" if, the wrong side of the fault-line he calls "Fault!"; but whether it be "Cut," "Short," or "Fault," the serve counts as a fault in its effect. To every good return, as to every good serve, the marker calls "Play!" If a return is made after the second bound of the ball (called a "double") the marker calls "Double!" or "Not up!" if, the ball is hit into the gallery, or against its posts or cushions, or above the girders or cross-beams of the roof, he calls "Out-of-court!"

At the end of every rally he calls the state of the game, always naming first the score of hand-in:—"One-love," (love being the term for zero) meaning that hand-in has scored one ace and hand-out nothing. "Two-love," "Five-all," "Five-ten," "Fourteen-eleven," and so on, till one side has scored 15, when the marker calls "Game!" He then in similar fashion calls the state of the match—"Two games to one," or whatever it may be—before the commencement of the next game. The server in possession at the end of the game continues to serve in the new game, subject as before to the rule limiting the first innings of the game to a single "hand." The usual number of games in matches is five for singles, and seven for doubles. In matches when there are umbrellas and a referee, there is an appeal to them from the marker's decision on questions relating to the service, on which the marker's decision is final.

Records.—Attempts have been made to trace racquets, like tennis, to an ancient origin; but although it is doubtless true that the striking of a ball with the hand or some primitive form of bat is one of the oldest forms of pastimes, and that racquets has been evolved from such an origin, the game as now known can hardly be said to have existed before the 19th century. Joseph Strutt's work on The Sports and Pastimes of the People of England, published at the beginning of the 19th century, makes no mention of racquets; and the game was far advanced before the modern court was properly formed: being an adjunct of the pot-house and the gaol, in which connection the court within the precincts of the Fleet prison has been immortalized in the pages of Pickwick, to a position scarcely less dignified than that of the tennis-court with its royal and historical associations. It was at the public schools that racquets first obtained repute. The school courts were at first unroofed, and in some cases open also at the back and sides, or on one side. Among the most famous of the early racquets professionals, before the period of the modern closed court, were the brothers Gray of Harrow, John Pittman, J. Lamb, J. C. Mitchell and Francis Erwood (1860). One of the most famous matches ever played at racquets was that in which Erwood was beaten by Sir William Hart-Dyke, who used the "drop" stroke with telling effect, and who, after representing Oxford in the first four inter-university matches, was the only amateur racquet player who ever defeated the open champion. A notable date in the history of racquets was the year 1853, when the court at the old Prince's Club in Hans Place, London, was built. Here the annual racquet matches between Oxford and Cambridge Universities, singles and doubles, were first played in 1853, and the Public Schools Championship (doubles only) ten years later.

Modern racquets may perhaps be said to date from the time of the brothers Gray, who as professionals greatly raised the standard of the game, and as teachers at the schools and universities improved the play of amateurs. William Gray, the Foulkes, the champion of America, in 1867; Henry Gray, and Joseph Gray, were also the most popular. The latter was beaten in 1875 by H. B. Fairs ("Punch") but held the championship from 1878 to 1887. Another member of the same family was Walter Gray, who was as distinguished for the power of his stroke as his brother William was for the accuracy of his "drop" and the ease and grace of his volley and half-volley. Walter Gray was followed in the championship by Peter Latham, the first professional to combine the open Tennis Championship with the Racquets Championship; and in the opinion of Mr Eustace Miles "there has probably lived no player who could have beaten him at either game. Latham was the first to use the heavily cushioned ball, in which Peter Latham himself took part, and which was won by Jennings of Aldershot. As a result of this contest a challenge was issued by W. Hawes, the marker at Wellington College, to play any other professional for £200 a side and the championship of England. The challenge was accepted by C. Williams, a young player of Prince's Club, who easily won the match, and with it the title of champion.

The institution of annual matches between Oxford and Cambridge Universities in 1858, and of the Public Schools Championship in 1860, brought an impetus to the game of racquets, which was a new form of pastime. Of the 51 inter-university (singles) matches from 1858 to 1908, Oxford won 26 and Cambridge 25; of the 52 contests in doubles, Oxford won 25 and Cambridge 27. Among the public schools Harrow has been far the most successful, having won the championship challenge cup 19 times out of 42 contests. Moreover, under the condition permitting any school winning it in three consecutive years to retain the challenge cup permanently, Harrow became possessed of three cups, having won the championship 1871-1874 inclusive, 1879-1881 inclusive, and 1883-1887 inclusive. The next most successful school has been Eton, eight times champion; Cambridge University Club, having won it and no other school more than three times. For the first twenty years of the contest, with a single exception when Rugby won in 1870, no school except Eton or Harrow gained the championship; and it is not surprising to find that the majority of famous amateurs learnt the game at one or other of these schools. Among Etonians were W. Hart-Dyke, C. J. Ottaway, the Hon. Alfred Lyttelton, the Rev. Robert Bligh, Sir Lords Long, Sir W. G. Stewart and H. Phillipson; Harrow has produced R. D. Walker, one of the best of the earliest amateur racquet players, C. F. Buller, T. S. Dury, A. J. Webbe, M. C. Kemp, E. M. Butler, the brothers Eustace Crawley and H. E. Crawley, C. D. Buxton, H. M. Leaf, Peru Ashworth and C. Browning. The famous Malvern family of Foster has been as conspicuous in the racquet court as on the cricket field, the eldest, H. K. Foster, being probably the finest amateur player of his generation. Festus Dames Longworth, Major A. Cooper-Kay, Colonel Spens, E. M. Baerlein and Eustace H. M. Miles have also been in the front rank of amateur players. The opening of the Queen's Club at Kensington was a notable event in the annals of the game, especially as it was followed by the establishment of amateur championships in singles and doubles in 1888, of which the results have been as follows:

**Amateur Championship**

**I. Singles**

A military championship was inaugurated in 1903 and is played annually at Princes' Club. In 1908, mainly through the exertions of Major A. Cooper-Key, a "Tennis, Racquets and Fives Association" was formed with the purpose of encouraging these games, safeguarding their interests and providing a legislative body whose authority would be recognized by all tennis and racquet players.

Racquets in America.—In the United States and in Canada racquets is a popular game, and Scotch and American athletic clubs have good courts. The American champions Foundles, Boakes and George Standing were all beaten by English professionals, but had a great reputation in their own country; and Tom Pettitt, Ellis and Co. are the names in that branch of the game. Among American amateurs, Lamontayne did much to encourage racquets in New York in the early period of its history; and in modern times, Quinnen, Asquith, St. John, Langworthy, and Spalding, have been prominent. One American player, whose name was Foster, would give any American amateur upwards of seven aces.

Squash racquets is a form of the game which provides admirable practice for the beginner, and has advantages of its own which offer attractions even to those who are proficient players of real racquets. It is played with a hollow india-rubber ball about the size of a fives ball (i.e., nearly twice the size of an ordinary racquet ball) and with a racquet rather shorter in the handle than those used in racquets proper. The court may be of any dimensions, but is always much smaller than a real racquet court; the squash ball, being not nearly so fast as the racquet ball, would not reach the back wall in a 60 ft. court on the first bound unless hit high as well as hard against the front wall. The rules of the game itself are precisely the same in both games. Squash racquets originated at Harrow, where the boys were in the habit of playing in an improvised court in the corner of the school-yard against the old school building; the windows, buttresses and water-pipe on the face of the wall forming irregularities which developed great skill on the part of the players in taking advantage of the difficulties thus caused. The marked success of Harrow in the Public Schools Championship at racquets, especially during the first twenty years of its institution (see above), has been attributed to the early training and practice gained at squash racquets in the school-yard, and in other courts which came into use as the popularity of this form of the game increased. Towards the end of the 19th century squash racquets became adopted at other schools and at the universities; and as the court is much cheaper to build than that required for real or "hard ball" racquets, and the game is cheaper as well as easier to play, many private courts came into existence. On the initiative of Lord Desborough, who had learnt the game at Harrow, several squash courts were provided at the Bath Club, London, where handicap tournaments are annually played. At Lord's cricket ground, when a new pavilion was erected in 1890, squash racquet courts were included in the building. The dimensions of the courts at Lord's, which may be taken as the best model, are as follows: length 42 ft. by 24 ft.; height of back wall 8 ft. 8 in.; height of service-line from floor 8 ft. 9 in.; height of play-line 2 ft. 4 in. The short-line is 23 ft. from the front wall. The place which squash racquets has come to occupy may be estimated from the fact that M. Eustace Miles pronounces it "an almost indispensable preparation" for tennis and racquets as those games are played under modern conditions; and the same authority sufficiently describes its merits when he observes that it "gives, at a small cost of time or money, abundance of hard and brisk and simple yet exciting exercise for all times of life, of the year, and even of the day—if we have good artificial light." The squash courts at Lord's and at the Bath Club are lighted by electricity, so that play is not dependent on the condition of the atmosphere, or on the season of the year.

RADCLIFFE, ANN (1764—1823), English novelist, only daughter of William and Ann Ward, was born on London on the 9th of July 1764. She was the author of three famous novels: The Romance of the Forest (1791), The Mysteries of Udolpho (1794) and The Italian (1797). When she was twenty-three years old she married William Radcliffe, an Oxford graduate and student of law. He gave up his profession for literature, and afterwards became proprietor and editor of the English Chronicle. After The Italian she gave up writing for publication, and was reported to have been driven mad.
by the horrors of her own creations, but the nearest approach to eccentricity on Mrs Radcliffe's part was dislike of public notice. Of scenery Mrs Radcliffe was an enthusiastic admirer, and she made driving tours with her husband every other summer through the English counties. She died on the 7th of February 1823. In the history of the English novel, Mrs Radcliffe holds an interesting place. She is too often confounded with her imitators, who vulgarized her favourite "properties" of rambling and ruinous old castles, dark, desperate and cadaverous villains, secret passages, vaults, trapdoors, evidences of deeds of monstrous crime, sights and sounds of mysterious horror. She deserves at least the credit of originating a school of which she was the most distinguished exponent; and none of her numerous imitators approach her in ingenuity of plot, fertility of incident or skill in devising apparently supernatural occurrences capable of explanation by human agency and natural coincidence. She had a genuine gift for scenic effect, and her vivid imagination provided every tragic situation in her stories with its appropriate setting. Sir Walter Scott wrote an appreciative essay for the edition of 1824, and Miss Christina Rossetti was one of her admirers. She exercised a great influence on her contemporaries, and "Schedoni" in The Italian is one of the prototypes of the Byronic hero.

**RADCLIFFE, SIR GEORGE** (1593-1657), English politician, son of Nicholas Radcliffe (d. 1599) of Overthorpe, Yorkshire, was educated at Oldham and at University College, Oxford. He attained some measure of success as a barrister, and about 1626 became the confidential adviser of Sir Thomas Wentworth, afterwards earl of Strafford, who was related to his wife, Anne Trappes (d. 1639). Like his master he was imprisoned in 1627 for declining to contribute to a forced loan, but he shared the good, as well as the ill, fortunes of Wentworth, acting as his adviser when he was president of the council of the north. When Wentworth was made lord deputy of Ireland, Radcliffe, in January 1633, preceded him to that country, and having been made a member of the Irish privy council he was trusted by the deputy in the fullest possible way, his advice being of the greatest service. In 1640, Radcliffe, like Strafford, was arrested and was impeached, but the charges against him were not pressed, and in 1643 he was with Charles I. at Oxford. He died at Flushing in May 1657. Radcliffe wrote An essay towards the life of my Lord Strafford, from which the material for the various lives of the statesman has been largely taken.

See Sir T. D. Whitaker, Life and Correspondence of Sir G. Radcliffe (1810).

**RADCLIFFE, JOHN** (1650-1714), English physician, was born at Wakefield in 1650. He matriculated at University College, Oxford, and after taking his degree in 1669 was elected to a fellowship at Lincoln College, which he gave up in 1677 when, under the statutes of the college, he was called on to take orders. Graduating in medicine in 1673, he practised first in Oxford, but in 1684 removed to London, where he soon became one of the leading physicians. He frequently attended William III. until 1699, when he caused offence by remarking, as he looked at the King's swollen ankles, that he would not have his legs for his three kingdoms. On the 1st of November 1714 he died of apoplexy at his house in Carshalton. By his will he left property to University College for founding two medical travelling fellowships and for other purposes. Other property was put at the disposal of his executors to use as they thought best, and was employed, among other things, in building the Radcliffe Observatory, Hospital and Library at Oxford, and in enlarging St Bartholomew's Hospital in London. Radcliffe was elected M.P. for Bembridge in 1690 and for Buckingham in 1713.

**RADCLIFFE, an urban district in the Radcliffe-cum-Farnworth parliamentary division of Lancashire, England, on the river Irwell, 2 m. S.S.W. of Bury, on the Lancashire & Yorkshire railway. Pop. (1901) 25,568. The church of St Bartholomew dates from the time of Henry IV.; some of the Norman portions of the building remain. Cotton-weaving, calico-printing, and bleaching, dyeing, paper-making, iron-founding and machine-making are the principal industries, and there are extensive collieries in the neighbourhood.

**RADEBERG, a town of Germany, in the kingdom of Saxony, pleasantly situated in a fertile district on the Röder, 10 m. N.E. of Dresden, by the railway to Görlitz and Breslau. Pop. (1905) 13,301. It has an Evangelical and a Roman Catholic church, and an old castle. Its principal industries are the manufacture of glass, machinery, furniture and paper, and it produces a light Pilsener beer which is largely exported. Near the town are the Augustusbad and the Hermannsbad, two medicinal springs.

**RADEGUNDA, ST** (d. 587), Frankish queen, was the daughter of Berthaire, king of the Thuringians. Berthaire was killed by his brother Hermannfried, who took Radegunda and educated her, but was himself slain by the Frankish kings Theuderich and Clotaire (529), and Radegunda fell to Clotaire, who later married her. Her piety was already so noteworthy that it was said that Clotaire had married a nun, not a queen. She left him when he unjustly killed her brother, and fled to Medardus, bishop of Poitiers, who, notwithstanding the danger of the act, consecrated her as a nun. Radegunda stayed in Poitiers, founded a monastery there, and lived for a while in peace. Here Venantius Fortunatus, the Italian poet, found a friendly reception, and two of the poems printed under his name are usually attributed to Radegunda. From him we gain a most pleasing picture of life at the monastery. The queen died on the 13th of August 587.

See the references in A. Molnier, Sources de l'histoire de France.

**RADETZKY, JOSEF, COUNT of RADETZ (1766-1858), Austrian soldier, was born at Trzebnitz in Bohemia in 1766, to the nobility of which province his family, originally Hungarian, had for several centuries belonged. Orphaned at an early age, he was educated by his grandfather, and after the old count's death, at the Theresa academy at Vienna. The academy was dissolved during his first year's residence, and he joined the army as a cadet in 1785. Next year he became an officer, and in 1787 a first lieutenant in a cuirassier regiment. He served as a gallowper on Lacy's staff in the Turkish War, and in the Low Countries during the Revolutionary War. In 1795 he fought on the Rhine. Next year he served with Beaulieu against Napoleon in Italy, and inwardly rebelled at the indecisive "cordon" system of warfare which his first chief, Lacy, had instituted. After other Austrian generals only too faithfully imitated. His personal courage was conspicuous; at Fleurus he led a party of cavalry through the French lines to discover the fate of Charleroi, and at Vaeleggio on the Mincio, with a few hussars, he rescued Beaulieu from the midst of the enemy. Promoted major, he took part in Wurmser's Mantua campaign, which ended in the fall of the place. As lieutenant-colonel and colonel he displayed both bravery and skill in the battles of the Trebbia and Novi (1799), and at Marengo, as colonel on the staff of Melns, he was hit by five bullets, after endeavouring on the previous evening to bring about modifications in the plan suggested by the "scientific" Zach. In 1801 Radetzky received the knighthood of the Maria Theresa order. In 1805, on the march to Ulm, he received news of his promotion to major-general and his assignment to a command in Italy under the archduke Charles, and thus took part in the successful campaign of Caldiero. Peace again afforded him a short leisure, which he used in studying and teaching the art of war. In 1809, now a lieutenant field marshal, he fought at Wagram, and in 1810 he received the commandship of the Maria Theresa order and the colonelcy of the 5th Radetzky hussars. From 1809 to 1812, as chief of the general staff, he was active in the reorganization of northern and other Austrian general orders only too faithfully imitated. The reforms he desired owing to the opposition of the Treasury, he resigned the post. In 1813 he was Schwarzenberg's chief of staff, and as such had considerable influence on the councils of the Allied sovereigns and generals. Langenau, the quarter-master-general of the Grand Army, found him an indispensable assistant, and he had a considerable share in planning the Leipzig campaign and as a tactician won great praises in the
RADEVORMWALD—RADIATION

battles of Brienne and Arcis sur Aube. He entered Paris with the allied sovereigns in March 1814, and returned with them to the congress of Vienna, where he appears to have acted as an intermediary between Metternich and the czar Alexander, when these great personages were not on speaking terms.

During the succeeding years of peace he disappeared from the public view. He resumed his functions as chief of the staff, but his ardent ideas for reforming the army came to nothing in the face of the general war-weariness and desire to "let well alone." His zeal added to the number of his enemies, and in 1829, after he had been for twenty years a lieutenant field marshal, it was proposed to place him on the retired list. The emperor, unwilling to go so far as this, promoted him general of cavalry and shelved him by making him governor of a fortress. But very soon afterwards the Restoration settlement of Europe was shaken by fresh upheavals, and Radetzky was brought into the field of war again. He took part under Frimont in the campaign against the Papal States insurgents, and succeeded that general in the chief command of the Austrian army in Italy in 1834. In 1836 he became a field marshal. He was now seventy years of age, but he displayed the activity of youth in training and disciplining the army he commanded. But here too he was in advance of his time, and the government not only disregarded his suggestions and warnings but also refused the money that would have enabled the finest army it possessed to take the field at a moment's notice. Thus the events of 1848 in Italy, which gave the old field marshal his place in history among the great commanders, found him, in the beginning, not indeed unprepared but seriously handicapped in the struggle with Charles Albert's army and the insurgents. How by falling back to the Quadrilateral and there, checking one opponent after another, he was able to spin out time until reinforcements arrived, and how thenceforward up to the final triumph of Novara on the 23rd of March 1849, and he and his army carried all before them, is described in the article ITALIAN WAR. The well-disciplined service of duty to the superior officer, which was retained even in the brilliant and sanguine young army reformer of 1810, had become more intense in the long years of peace, and after keeping his army loyal in the midst of the confusion of 1848, he made no attempt to play the part of Wallenstein or even to assume Wellington's rôle of family adviser to the nation. While as a patriot he dreamt a little of a united Germany, he remained to the end simply the commander of one of the emperor's armies. He died, still in harness, though infirm, on the 5th of January 1858.

In military history Radetzky's fame rests upon one great achievement, but in the history of the Austrian army he lives as the frank and kindly "Vater Radetzky" whom the soldiers idolized. He was fortunate in the moment of his death. In the year following, another and a greater Italian war broke out, his beloved army, disintegrated by peace economies which the old field marshal had been unable any longer to redress by ceaseless personal training, and in addition suffering from divided command and confused staff work, was defeated in every encounter.

RADEVORMWALD, a town of Germany, in the Prussian Rhine province, 10 m. E. from Remscheid, on the branch line of railway from Krefeld. Pop. (1905) 10,978. It consists of the town proper and of several suburbs, and has five Evangelical and two Roman Catholic churches. Its chief manufactures are skates, files, locks and similar articles, and it has also cloth and cotton factories.

See J. H. Becker, Geschichte der Stadt Radevormwald (Cologne, 1864).

RADHANPUR, a native state of India, in the Palanpur agency, Bombay. It is situated in the north-western corner of Gujarat, close to the Kunn of Cutch. The country is an open plain, without hills and with few trees. It contains an area of 1,150 sq. m. with a population in 1901 of 61,548, showing a decrease of 37% during the decade, due to the results of famine. The estimated revenue is £27,000. The chief products are cotton, wheat and the common varieties of grain; the only manufacture of any importance is the preparation of a fine description of saltpetre. Radhanpur first came under British protection in 1813. The chief, whose title is Nawab, belongs to the Babri family, who have held power in Gujarat for more than two centuries. The town of Radhanpur had a population in 1901 of 11,870. It is a walled town, with an export trade in rapeseed, grain and cotton.

RADIATA, a term introduced by Cuvier in 1812 to denote the lowest of his four great animal groups or "embracements." He defined them as possessing radial instead of bilateral symmetry, and as apparently destitute of nervous system and sense organs, as having the circulatory system rudimentary, or at most possessing respiratory organs on or co-extensive with the surface of the body; he included under this title and definition five classes,—Echinodermata, Acalepha, Entozoa, Polypoli and Infusoria. Lamarck (Hist. nat. d. Anim. s. Vertébrés) also used the term, as when he spoke of the Medusae as radiata medusaria et anomala; but he preferred the term Radiaria, under which he included Echinodermata and Medusae. Cuvier's term in its wide extension, however, passed into general use; but, as the anatomy of the different forms became more fully known, the difficulty of including them under the common designation made itself increasingly obvious. M. M. Edouard Poulard, in 1839, also proposed the term Radiata for the group of Echinoderms. This last usage was soon furthered by the exclusion of the Protocorallia on the one hand and the Entozoa on the other; while in 1848 Leuckart and Frey clearly distinguished the Coelenterata from the Echinodermata as a separate sub-kingdom, thus condemning the usage by which the term still continued to be applied to these two groups at least. In 1855, however, Owen included under Lamarck's term Radiaria the Echinodermata, Anthozoa, Acalepha and Hydrozoa, while Agassiz also clung to the term Radiata as including Echinodermata, Acalepha and Polypi, regarding their separation into Coelenterata and Echinodermata as "an exaggeration of their anatomical differences" (Essay on Classification of Animals. London, 1856). These views, however, perpetuate the usage were finally discredited by Huxley's important Lectures on Comparative Anatomy (1864), in which the term was finally abolished, and the "radiate mob" finally distributed among the Echinodermata, Polypoia, Vermes (Platyhelminthes), Coelenterata and Protozoa.

RADIATION, THEORY OF. The physical activities that flourish on the surface of the earth derive their energy, in a form which is highly available thermodynamically, from the radiation of the sun. This has been ascertained to be dynamic energy, transmitted in waves by the vibrations of a medium occupying space, and as the energy of the waves is transmitted by the vibrations of the atmosphere. The elasticity that transmits it may be assumed to be mathematically perfect: any slight loss in transit of the light from the most distant stars, which recent statistical comparisons of brightness with distance may possibly indicate, is to be explained far more suitably by the presence of nebulous matter than by any imperfection of the aether. The latter would be thus the one perfect frictionless medium known to us: it could not be such if it were constituted, like matter, of independent molecules. It is thus on a higher plane, and may even be considered to be a dynamical specification of space itself. A molecule of matter is a kinetic system compounded of simpler elements; its energy may be classified into constitutive energy essential to its continued existence, and vibratory energy which it can receive from or radiate away into aether. A piece of matter isolated in free aether would in time lose all energy of the latter type by radiation; but the former will remain so long as the matter persists, along with the energy of the uniform translatory motion to which it is ultimately reduced. Thus all matter is in continual exchange of vibratory energy with the aether: it is with the laws of this exchange of energy that the general theory of Radiation deals, as distinguished from the mechanics of the aetheral vibrations, which is usually treated as the Theory of Light (see Aether).

1. The foundation of this subject is the principle, arrived
at independently by Balfour Stewart and Kirchhoff about the year 1858, that the constitution (§ 6) of the radiation which pervades an enclosure, surrounded by bodies in a steady thermal state, must be a function of the temperature of those bodies, and of nothing else. It was subsequently pointed out by Stewart (Brit. Assoc. Rep., 1871) that if the enclosure contain a radiating and absorbing body which is put in motion, all being at the same temperature, the condition that the radiation in front of it and behind it will differ in period on account of the Doppler-Fizeau effect, so that there will be an opportunity of gaining mechanical work in its settling down to an equilibrium; there must thus be some kind of thermodynamic compensation, which might arise either from aetherial friction, or from work required to produce the motion of the body against pressure exerted on it by the surrounding radiation. The hypothesis of friction is now excluded in ultimate molecular physics, while the thermodynamic bearing of a pressure exerted by radiation, such as is demanded by Maxwell's electric theory, has been more recently developed on other lines by Bartoli and Boltzmann (1884), and combined with that of the Doppler effect by W. Wien (1863) in development of the ideas above expressed.

The original reasoning of Stewart and Kirchhoff rests on the dynamical principle, that by no process of ordinary reflection or transmission can the period, and therefore the wave-length, of any harmonic constituent of the radiation be changed; each constituent remains of the same wave-length from the time it is emitted until the time it is again absorbed. If we imagine a field of radiation to be enclosed within perfectly reflecting walls, then, provided there is no material substance in the field which can radiate and absorb, the constitution of the radiation in it may be anything, and it will remain permanent. It is only the presence of material bodies that by their continued emission and absorption can transform the surrounding radiation towards the unique constitution which corresponds to their temperature. We can define the temperature of an isolated field of radiation, of this definite ultimate constitution; to be the same as that of the material bodies with which it would thus be in equilibrium. Further, the mutual independence of the various constituents of any field of radiation enclosed by perfect reflectors allows us to assign a temperature to each constituent, such as the part involving wave-lengths lying between λ and λ+δλ; that will be the temperature of a material system with which this constituent by itself is in equilibrium of emission and absorption. But to reason about the temperature of radiation in this way we must be sure that it completely pervades the space, and has no special direction; this is ensured by the continual refractions from the walls of the enclosure. The question of the temperature of a directed wave-train travelling through space, such as a beam of light, will come up later. The temperature of each constituent in a region of undirected radiation is thus a function of its wave-length and its intensity alone.

It is the fundamental principle of thermodynamics, that temperatures tend to become uniform. In the present case of a field of radiation, this equalization cannot take place directly between the various constituents of the radiation that occupy the same space, but only through the intervention of the emission and absorption of material bodies; the constituent radiations are virtually partitioned off adiabatically from direct interchange. Thus in discussing the transformations of temperatures of the constituent elements of radiation, we are really reasoning about the activity of material bodies that are in thermal equilibrium with those constituents; and the theoretical basis of the idea of temperature, as depending on the fortuitous residue of the energy of molecular motions, is preserved.

2. Mechanical Pressure of Undulatory Motions.—Consider a wave-train of any kind, in which the displacement is \( \xi = a \cos mx + cft \), so that it is propagated in the direction in which \( x \) decreases; let it be directly incident on a perfect reflector travelling towards it with velocity \( v \), whose position is there-

fore given at time \( t \) by \( x = vt \). There will be a reflected train given by \( \xi' = a' \cos m(x - bt) \), the velocity of propagation \( c' \) being of the same value for both. The disturbance does not travel into the reflector, and must therefore be annulled at its surface; thus when \( x = vt \) we must have \( \xi + \xi' = 0 \) identically. This gives \( a' = -a \), and \( m(c - v) = m(c + v) \). The amplitude of the reflected disturbance is therefore equal to that of the incident one; while the wave-length is altered on the ratio \( c - v \). This alteration of wave-length is approximately \( 2 \frac{c}{v} \), where \( v/c \) is small, and is thus in agreement with the usual statement of the Doppler effect. The energy in the wave-train being half potential and half kinetic, it is given by the integration of \( p(d\xi/dt)^2 \) along the train, where \( p \) represents density. In the reflected train it is therefore augmented, when equal lengths are compared, in the ratio \( (c + v)^2 \); but the length of the train is diminished by the reflection in the ratio \( c - v \), so that the whole energy transmitted per unit time is increased by the reflection in the ratio \( (c - v)^2 \). This increase per unit time can arise only from work done by the advancing reflector against pressure exerted by the radiation. That pressure, per unit surface, must therefore be equal to the fraction \( \frac{2}{c - v} \) of the energy in a length \( c - v \) of the incident wave-train; thus it is the fraction \( \frac{c - v}{c + v} \) of the total density of energy in front of the reflector, belonging to both the incident and reflected trains. When \( v \) is small compared with \( c \), this makes the pressure equal to the density of vibrational energy, in accordance with Maxwell's electrodynamic formula (Elec. and Mag., 1874).

The argument may be illustrated by the transverse vibrations of a tense cord, the reflector being then a lamina through a small aperture in which the cord passes; the lamina can thus slide along the cord and sweep the vibratory motion in front of it. In this case the force acting on the lamina is the resultant of the tensions \( T \) of the cord on the two sides of the aperture, giving a lengthwise force \( \frac{1}{2}T d|\xi'|/dx \), where, as usual, powers higher than the second of the ratio of amplitude to wave-length are neglected; this, when \( v/c \) is small, is an oscillatory force of amount \( 4p|d\xi'/dt| \), whose time-average agrees with the value above obtained. If we consider a finite train of waves thus sent back from a moving reflector, the time integral of the pressure must represent force transmitted along the cord, or a gain of longitudinal momentum in the reflected waves, or both together.

When it is a case of transverse waves in an elastic medium, reflected by an advancing obstacle, the origin of the working pressure is not so obvious, because we cannot easily formulate a mechanism for the advancing reflector like that of the lamina above employed. In the case of light-waves we can, however, imagine an ideal material body, constituted of very small molecules, that would sweep them in front of it with the same perfection as a metallic mirror actually reflects the longer Hertzian waves. The pressure will then be identified physically, as in the case of the latter waves, with the mechanical forces acting on the screening oscillatory electric current-sheet which is induced on the surface of the reflector. The displacement represented above by \( \xi \), which is annulled at the reflector, may then be taken to be either the tangential electric force or the normal component of the vector whose velocity is the magnetic force.

The latter interpretation is theoretically interesting, because that vector, which is the dynamical displacement in electrodynamics, usually occurs only through its velocity. The general case of oblique incidence can be treated on similar lines; each filament of radiation (ray) in fact exerts its own longitudinal push equal to its energy per unit length, and it is only a matter of summation.

The usual formula for the pressure of electric radiation is
derived from a theory, namely, that of the ordinary electrodynamic equations, which considers the velocity of the matter, or rather of the electrons associated with it, to be so small compared with that of radiation that the square of the ratio of these velocities can be neglected. The formula above obtained is of general application, and shows that for high values of \( v \) the pressure must fall off. It has been urged as an objection to this thermodynamic reversibility of a ray (§ 8) that the work of the radiant pressure exerted at its front is lost, as there is no obstacle to sustain it; but on an obstacle moving with the velocity of the wave-front the pressure would vanish, so that this objection does not now hold.

In every such case of an advancing perfect reflector the aggregate amplitude of the superposed incident and reflected wave-trains, of different wave-lengths and periods, will be represented by

\[
\xi + \xi' = 2a \sin \left( \frac{\nu c}{c - v} \left( x - \frac{c}{v} t \right) \right) \sin \left( \frac{mc}{c - v} \left( x - vt \right) \right);
\]

thus the appearance presented will be that of a train of waves each of length \((x - vt)/c\pi/m\), and progressing with the velocity \(v\) of the reflector, which travels at one of the nodes of the train. This slowly travelling wave-train corresponds to the stationary train which would be produced by a stationary perfect reflector; but the amplitude is now a varying quantity, which, once uniform vibration has been fully established along any path, may itself be described as running on after the manner of a superposed wave-train of very great wave-length \((c/v - 1)\pi/m\) and of very great velocity \(c/v\). A somewhat similar state of things arises when a wave-train is incident on a stationary reflector very nearly normally, as may sometimes be seen with incoming rollers along a shelving beach; the visible disturbance at a reflecting ridge, arising from each single wave-crest, then rushes along the ridge at a speed which is at first sight surprising, as it is enormous in excess of the speed possible for any simple train of waves travelling into quiescent aether.

3. Wien's Law.—Let us consider a spherical enclosure filled with radiation, and having walls of ideal perfectly reflecting quality so that none of the radiation can escape. If there is no material body inside it, any arbitrarily assigned constitution of this radiation will be permanent. Let us suppose that the radius \( a \) of the enclosure is shrinking with extremely small velocity \( u \). A ray inside it, incident at angle \( \iota \), will always be incident on the walls in its successive refractions at the same angle, except as regards a negligible change due to the motion of the reflector (§ 2); and the length of its path between successive refractions is \( 2a \cos \iota \). Each undulation on this ray will thus undergo reflexion at intervals of time equal to \( 2a \cos \iota/c \), where \( c \) is the velocity of light, and it is easily verified that on each reflexion it is shortened by the fraction \( 2v \cos \iota/c \) of itself; thus in the very long time \( T \) required to complete the shrinkage it is shortened by the fraction \( vT/c^2 \), which is \( \delta a/a \) where \( \delta a \) is the total shrinkage in radius, and is independent of the value of \( c \).

The wave-length of each undulation in the radiation inside the enclosure is therefore reduced in the same ratio as the radius. Now suppose that the constitution of the enclosed radiation corresponded initially to a definite temperature. During the shrinkage the thermal equilibrium must be maintained among its constituents; otherwise there would be a running down of their energies towards uniformity of temperature, if material radiating bodies are present, which would be superposed on the mechanical operations belonging to the shrinkage, and the process could not be reversible. Such a state of affairs is not possible, for it would do away with the function of the walls of the enclosure, gaining the mechanical work of the radiant pressure against its walls, whatever that may be. Then equalize the intensities of the constituent radiations to those corresponding to a common temperature, by taking advantage of the absorptions of material bodies at the actual temperatures of these radiations; when this is done, as it may actually be to some extent by aid of the sifting produced by partitions which transmit some kind of radiation more rapidly than others, a further gain of work can be obtained at the expense of the radiant energy. Then contract the remaining radiant energy to its previous volume, which requires an expenditure of less work on the walls of the enclosure than the expansion of the greater amount of radiation originally afforded; and, finally, gain still more work by again equalizing the temperatures of its constituents. The energy now remaining, being of smaller amount and under similar conditions, must have a temperature lower than the initial one. This process might be repeated indefinitely, and would constitute an engine without an extraneous refrigerator, violating Carnot's principle by deriving an unlimited supply of mechanical work from thermal sources at a uniform temperature.

Thus, independently of any knowledge of the intensity of the mechanical pressure of radiation, or indeed of whether such a pressure exists at all, it is established that the shrinkage of the enclosure must directly transform the contained radiation to the constitution which corresponds to some definite new temperature. Now we have seen that the wave-lengths of its constituents are all reduced in the same ratio by this process. If, then, we can prove that the intensities of these constituents are also all changed in a common ratio by the reflexions at the shrinking envelope, it will follow that the distributions of the radiation among the various wave-lengths are, at these two temperatures, and therefore at any two temperatures, homologous, in the sense that the intensity curves, after the wave-lengths in one of them have been reduced in a ratio depending definitely on the two temperatures, differ only in the absolute scale of magnitude of the ordinates.

This procedure modifies Wien's argument by employing a uniformly shrinking spherical enclosure (cf. Brit. Assoc. Report, 1900). If the enclosure is not spherical, the angles of incidence at successive reflexions of the same ray will differ by finite amounts; we must then estimate the average effect of the shrinkage. In the form of enclosure here employed all rays are affected alike, and no averaging is required; while by the principle of Stewart and Kirchhoff what is established for any one form is of general validity.

4. Pressure of Natural Radiation.—The question reserved above has now to be settled. At first sight it might have appeared that the reflexion is simply total but, as has been seen in § 3, the advancing perfect reflector is working against the pressure of the radiation, and this work must be changed into radiant energy and thus go to increase the intensity of the reflected ray. Considering electric radiation incident at angle \( \iota \), the tangential electric force is annulled at the reflector; hence the amplitude of the electric vibration is conserved reflexion, though its phase is reversed. As already seen, the wave-length is shortened approximately by the fraction \( 2v \cos \iota/c \) in each reflexion; thus, just as in § 2, the energy transmitted per unit time per unit area is increased in the same ratio; and allowing for the factor \( \cos \iota \) of foreshortening, there is therefore a radiate pressure equal to the total density of radiant energy in front of the reflector multiplied by \( \cos \iota \). This argument, being independent of the wave-length, applies to each constituent of the radiation in this direction separately; thus their energies are all increased in the same ratio by the reflexion, as was to be proved. When we are dealing with the natural radiation in an enclosure, which is distributed equally in all directions, this factor \( \cos \iota \) must be averaged; and we thus attain Boltzmann's result that the pressure is then one-third of the density of radiant energy in front of the reflector, this statement holding good as regards each constituent of the natural radiation taken separately.

5. Adiabatic Relations.—Consider the enclosure filled with radiation of energy-density \( E \) at volume \( V \), of any given constitution but devoid of special direction, and let it be shrunk to volume \( V - \Delta V \) against its own pressure; if the density thereby become \( E - \delta E \), the conservation of the energy requires

\[
E + \frac{1}{2} \nu E V = (E - \delta E) (V - \Delta V),
\]

so that \( \delta E V + V \delta E = 0 \), or \( E \) varies as \( V^{-1} \). Again—but now with a restriction to radiation with its energy
RADIATION

distributed as regards wave-length so as to be of uniform temperature—the performance of this mechanical work \( \frac{1}{2} E\nu \) has changed the energy of radiation \( EV \) from the state that is in equilibrium of absorption and emission with a thermal source at temperature \( T \) to the state in equilibrium with an absorber of some other temperature \( T - \delta T \), and that in a reversible manner; thus by Carnot’s principle

\[
\frac{1}{2} E\nu/EV = - \delta T/T,
\]

so that \( T \) varies as \( V^{-1} \), or inversely as the linear dimensions when the enclosure is shrunk uniformly.

Combining these results, it appears that \( E \) varies as \( T^4 \); this is Stefan’s empirical law for the complete radiation corresponding to the temperature, first established on these lines by Boltzmann. Starting from the principle that this radiation must be a function of the temperature alone, this adiabatic process has in fact given us the form of the function. These results cannot, however, be extended without modification to each separate constituent of the complete radiation, because the shrinkage of the enclosure alters its wave-length and so transforms it into a different constituent.

6. Law of Distribution of Energy.—The effect of compressing the complete radiation is thus to change it into the constitution belonging to a certain higher temperature, by shortening all its wave-lengths by the proportion of one-third of the compression by volume, the temperature being in fact raised by the same proportion; at the same time increasing in a uniform ratio the amounts corresponding to each interval \( \delta T \), so as to get the correct total amount of energy for the new temperature. In the compression each constituent alters so that \( \delta T \) remains constant, and the energy \( E\delta T \) in the range \( \delta T \) in other respects changes as a function of \( T \) alone. Hence generally \( E\delta T \) must be of form \( F(T)/(T\delta T) \). But for each temperature \( T \), \( E\delta T \) is equal to \( E \) and so varies as \( T^4 \), by Stefan’s law; that is,

\[
T^{-12}F(T) = \int (T\delta T) \propto T^4,
\]

so that \( T^{-1}F(T) \propto T^4 \). Thus, finally, \( E\delta T \) is of form \( AT^4/(T\delta T) \) or \( A\lambda^4/(T\delta T) \), which is Wien’s general formula.

7. Transformation of a Single Constituent.—It is of interest to follow out this adiabatic process for each separate constituent of the radiation, as a verification, and also in order to ascertain whether anything new is thereby gained. To this end let now \( E(T)T \delta T \) represent the intensity of the radiation between \( \lambda \) and \( \lambda + \delta \lambda \) which corresponds to the temperature \( T \). The pressure of this radiation, when it is without special direction, is in intensity one-third of this; thus the application of Carnot’s principle shows, as before, that in adiabatic compression \( T \propto \delta T \), so that a small linear shrinkage in the ratio \( 1 - x \) raises \( T \) in the ratio \( 1 + x \). We have still to express the equation of energy. The vibratory energy \( E(T)T\delta T \) inside in volume \( V \), together with the mechanical work \( \int E(T)T\delta T \), \( 3A\nu \), yields the vibratory energy

\[
E = (1 - x) T, \quad (T + x) \delta T + (1 - x) T = 3A\nu,
\]

thus writing \( E \) and \( E_x \) or \( E(T) \) we have, neglecting \( x^2 \),

\[
E(1 + x) = (E - x^2) T \frac{dE}{d\delta T} + x T^4 \frac{dE}{dT} (1 - 4x),
\]

so that

\[
5E + x \frac{dE}{d\delta T} - \frac{dE}{dT} = 0,
\]

a partial differential equation of which the integral is

\[
E = A\lambda^4/(T\delta T),
\]

the same formula as was before obtained.

This method, treating each constituent of the radiation separately, has in one respect some advantage, in that it is necessary only to postulate an enclosure which totally reflectes that constituent, this being a more restricted hypothesis than an absolutely complete reflector.

To determine theoretically the form of the function \( \phi \) we must have some means of transforming one type of radiation into another, different in essence from the adiabatic compression already utilized. The condition that the entropy of the independent radiations in an enclosure is a minimum when they are all transformed to the same temperature with total energy unaltered, is already implicitly fulfilled; it would thus appear that any further advance must involve (§ 11) the dynamics of the radiation and absorption of material bodies.

8. Temperature of an Isolated Ray.—The temperature of each independent constituent of a radiation has here been taken to be a function of the intensity \( E_x \), where \( E_x \) is the energy per unit volume in the range between wave-lengths \( \lambda \) and \( \lambda + \delta \lambda \); the condition is, however, imposed that this radiation is indifferent as to direction. When a beam of radiation travels without loss in a definite direction across a medium, its form varies as it progresses; but it is reversible inasmuch as it can be turned back at any stage, or concentrated without loss by perfect reflectors. If the energy of the beam has a temperature, its value must therefore remain constant throughout the progress of the beam, by the principle of Carnot. Now by virtue of a relation in geometrical optics, which on a corpuscular theory would be one aspect of the fundamental dynamical principle of Action, the cross-section \( S \) of any place on the beam, and the conical angle \( d\theta \) within which the directions of its rays there are included, are such that the value of \( V - \delta \theta S \) is conserved along the beam, \( V \) being the velocity of propagation of the radiation, \( S \) representing the amount of radiant energy transmitted per unit time across the cross-section \( S \) of the beam by \( I \delta \theta \). It will follow that in passing along the beam its intensity of illumination \( I \) varies as \( V^{-1} \), or as the square of the index of refraction, provided there is no loss of energy in transmission. This condition requires that changes of index shall be gradual, otherwise there would be loss of energy by partial reflexions; in free aether \( I \) is itself constant along the beam. The volume-density of the energy in any part of the directed beam is \( V^{-1} I \); it is thus inversely as the solid angular concentration of the rays and directly as the cube of the index of refraction. Now we may consider this beam, of aggregate intensity \( I \delta \theta S \), to form an elementary filament of the radiation issuing in the direction of the normal from a perfect radiator. As such a body absorbs completely and therefore radiates equally in all directions in front of it, the total intensity of radiation from its element of surface \( d\theta = d\theta \cos d\phi \), or \( d\phi \), while the volume-density of the total advancing and receding radiation in front of it is \( 2V^{-1} I \delta \theta \), and therefore \( 2\pi V^{-1} \). If we take here \( I \delta \theta \) to represent the intensity between wave-lengths \( \lambda \) and \( \lambda + \delta \lambda \), this density is the quantity \( E_\lambda \) of which the temperature of the radiator is a function of the quantity \( I \)—which optically is a measure of the brightness of the beam, and is conserved along it to the extent that \( I \) is the same from whichever of its cross-sections the beam is supposed to be emitted—also determines its temperature, the latter being that of an enclosure containing undirected radiation of the same range \( \delta \lambda \) which is density \( E_\lambda \) given by \( E_\lambda = 4\pi V^{-1} \), where \( V \) is the velocity of radiation in the enclosure. When a beam of radiation travels without suffering absorption, its temperature thus continues to be that of its source multiplied by the coefficient of emission of the source for that kind of radiation; this coefficient being less than unity except in the case of a perfect radiator; but when the beam is converted into radiant energy by \( \delta \theta \). In any part of its path owing to absorption or other irreversible process, this involves a further fall of temperature of the energy of the beam and a rise of entropy which can be completely determined when the relation connecting \( I \delta \theta \) with \( T \) and \( \lambda \) is known. Any directed quality in radiant energy increases its effective temperature. Splitting a beam into two at a reflecting and refracting surface diminishes the temperature of each part; it is true that if the reflecting surface were non-molecular the operation could be reversed, but actually the reversed rays would encounter the reflecting molecules in different directions, and could not (§ 11) recombine into the same detailed phase-relations as before. The direct solar radiation falling on the Earth is almost completely convertible into mechanical effect on account of its very high temperature; there seems ground for believing that certain constituents of it can actually be more wholly turned to account by the
green leaves of plants. But the same solar radiation, when broken up into diffused sky light, which has no definite direction, has fallen into equilibrium with a much lower temperature, through loss of its reversibility. It has been remarked that the temperatures of the planets can be roughly compared by means of this principle, which determines the temperature of the solar radiation are assumed; that of Neptune comes out below \(-200^\circ\text{C}\), if we suppose that it is not kept higher by a supply of internal heat.

To obtain dynamical precision in this discussion an exact definition of the narrow beam such as is usually called a ray is essential. It can be specified as a narrow filament of radiation, such as may be isolated within an infinitely thin, impermeable, bounding tube without thereby producing any disturbance of the motion. If either the tube or the surrounding radiation were not present to keep the beam in shape, it would spread sideways, the wave-lengths of maximum energy vary inversely as the temperature, for the case of a perfectly radiating source, gives a result 5500\(^\circ\text{C}\). These numbers will naturally differ because (i) the Sun is not a perfect radiator, the constitution of his radiation in fact not following the law of that of a black body, (ii) the various radiating layers have different temperatures, (iii) the radiation may be in part due to chemical and electrical causes, and in so far would not be determined by the temperature alone. The fair agreement of these two estimates indicates, however, that the radiation is largely regulated by the temperature, that the layers from which the main part of it comes are at temperatures not very different, and that not very much of the complete radiation established in these layers and emitted from them is absorbed by the overlying layers.

9. Temperature of the Sun.—The mean temperature of the radiating layers of the Sun may be estimated from Stefan's law, by computing the intensity of the radiation at his surface from that terrestrially observed, on the basis of the law of inverse squares; the result is about 6500\(^\circ\text{C}\). The application of Wien's law, which makes the wave-lengths of maximum energy vary inversely as the temperature, for the case of a perfectly radiating source, gives a result 5500\(^\circ\text{C}\). These numbers will naturally differ because (i) the Sun is not a perfect radiator, the constitution of his radiation in fact not following the law of that of a black body, (ii) the various radiating layers have different temperatures, (iii) the radiation may be in part due to chemical and electrical causes, and in so far would not be determined by the temperature alone. The fair agreement of these two estimates indicates, however, that the radiation is largely regulated by the temperature, that the layers from which the main part of it comes are at temperatures not very different, and that not very much of the complete radiation established in these layers and emitted from them is absorbed by the overlying layers.

10. Fluorescence.—When radiation of certain wave-lengths falls on a fluorescent body, it is largely absorbed, but in such manner as directly to excite other radiation of different type which is emitted in addition to the true temperature-radiation of the body. The distinction involved is that the latter radiation is spontaneously convertible with the heat of the absorbing body at its own temperature, without any external stimulus or compensation; it is, in fact, on the basis of this convertibility that the two zero-theoretical definitions of the temperature-radius of the tube is one of pure constraint; thus the change of energy content of a given length of the tube is represented by energy flowing into it at the end where the radiation enters, and leaving it at the other end, but with no leakage at the sides. The total radiation may be considered as made up of such filaments.

\(\text{RADIATION}\)

\(\text{§ 8, since part of it might be degraded into low-temperature heat, or there might be other compensation of chemical type for any abnormally high availability that might exist in the fluorescent radiation. It has been found that fluorescent radiation, showing a continuous or band spectre, can be excited in many gases and vapours; milky phosphorescence of considerable duration, and thus doubtless associated with chemical change, is produced in vacuum tubes, containing oxygen or other complexly constituted gases, by the electric discharge.}

11. Entropy of a Ray.—If each definitely constituted beam of radiation has its own temperature and everything is reversible as above, a question arises as to the location of the process of averaging which enters into the idea of temperature. The answer can depend only on the fact, that although the beam is definite as to wave-length and intensity, yet it is far from being a single one, the beam-train in that, is constituted of trains of limited lengths and various phases and polarizations, coming from the independent radiating molecules. When such a beam has once emerged, it travels without change, and can be reflected back intact to its source, and is in so far reversible; but when it has arrived there, the molecules of the source will have changed their positions, and it cannot be wholly reabsorbed in the same manner as it was emitted. There must thus be some feature in the ultimate averaged constitution of the beam, emitted from a body in the definite steady state of internal motion determined by its temperature, which adapts it for spontaneous unaccompanied reabsorption into a body at its own (or a lower) temperature, but not at a higher one.

The question of the determination of the form of the function \(\phi\) in § 6 would thus appear to be closely connected with the other problems, hitherto imperfectly fathomed, relating to the statistics of kinetic molecular theory. A very interesting attack on the problem from this point of view has recently been made in various forms by Planck. It of course suffices to examine some simple type of radiating system, and the results will be of general validity. He considers an enclosure filled with radiation involving an entirely arbitrary succession of phases and polarizations along each ray, and also containing a system of fixed linear electric oscillators of the Hermitian type, which are taken to represent the transforming action of radiating and absorbing matter. The radiation contained in the enclosure will be passed through these oscillators over and over again, now absorbed, now radiated, and each constituent will thus settle down in a unilateral or irreversible manner towards some definite intensity and composition. But it does not appear that a system of vibrators of this kind, each with its own period, can perform one of the main functions of a material absorber, namely, the transformation of the relative intensities of the various types of radiation in the enclosure to those corresponding to a common temperature. There would be equilibrium established only between the mean internal vibratory energy in the vibrators of each period and the density of radiation of that period; there is needed also some means of interchanging energy between vibrators of different periods, which probably involves doing away with their fixity, or else employing more complex vibrators and assuming a law of distribution of their internal energy. In the absence of any method of introducing this temperature equilibrium directly, Planck originally sought, in the case of each independent constituent, for a function of its intensity of energy and its wave-length, restricted as to form by a certain assumed molecular relation, which has the property of continually increasing after the manner of entropy, during the progress of that constituent of the radiation in such a system towards its steady state. If the actual entropy \(S\) per unit volume could be thus determined, the relation of Clausius \(\delta S = \delta E/T\) would supply the connexion between the temperature and the density of radiant energy \(E\). This procedure led him, in an indirect and tentative manner, to the relation \(\delta S = \delta E/T = -\alpha/\gamma\), so that \(S = -\alpha/\gamma \log \beta E\), where \(\alpha, \beta\) are functions of \(\chi\); an expression which conducts through Clausius's relation to \(E = (\beta)\gamma/\alpha^\chi\).
The previous argument then gives \( E(\lambda, T) \delta\lambda = \sigma c e^{-c/\lambda T} \), a type of formula which was originally suggested by Wien on the basis of the analogy that it assigns the same distribution for the radiant energy, among the various frequencies of vibration, as for the energy of the molecules in a gas among their various velocities of translation. But the experimental inaccuracy of this formula afterwards suggested a new procedure, as infra.

Processes may be theoretically assigned for the direct continuous transformation of radiant energy into molecular energy. Thus we can imagine a radiating body at the centre of a wheel, carrying oblique vanes along its circumference, which reflect the radiation on to a ring of parallel fixed vanes, which finally reverse its path and return it to the body. The portion of the wheel drawn will drive the wheel, and in case its motion is not resisted, a very great velocity may be theoretically obtained. The thermodynamic compensation in such cases lies in the reduction of the effective temperature of the portion of the radiation thus not used up. We might even do away with the radiating body at the centre of the wheel, and consider a beam of definite radiation reflected backwards and forwards across a diameter. It is easy to see that its path will remain diametral, the work done by it in driving the wheel will be concomitant with the increase of the wave-length, and therefore with expansion of the length occupied by the beam. The thermodynamic features are thus analogous to those of the more familiar case of a material filled with gas, which can change its thermal energy into mechanical energy by expansion of the envelope against mechanical resistances. In the case of the expanding gas \( \sigma = \text{const.} \), where \( E \) is the total translational energy of the molecules, which can be expressed \( \text{as } E = n k T \). Thus the work done in unlimited expansion, \( \text{dp} = \text{d}E \), is \( E = \sigma T \).

The final temperature being absolute zero, this should by Carnot’s principle be equal to the total initial energy of the gas that can be converted into mechanical energy. Thus the molecules being excluded; when \( \gamma - 1 \) is less than \( \frac{1}{2} \), there is thus internal thermal energy in the molecules in the transitory energy. In the case of the beam of radiation, of length \( l \), between \( n + n' - n/bn \) reflexions, where \( \delta \eta \) is an integer, its total energy \( E \) is by \( 2 \) reduced according to the law \( \frac{\delta\eta}{E} = \frac{4\lambda\eta n}{c(c + 1)^{n - 1}} \).

\[ \frac{\delta\eta}{E} = -\frac{2c}{c + 1}. \]

When \( v \) is small compared with \( c \), this gives \( E = \frac{c}{c - 1} \). and \( \phi \) is then \( 2E/c \), so that \( \text{d}E = -E \), the temperature of the beam being ultimately reduced to absolute zero by the unlimited expansion. This is in accord with Carnot’s principle, in that the whole energy of the beam travelling in a vacuum is mechanically available when reduction to absolute zero of temperature is in our power.

12. Experimental Knowledge.—Under the stimulus of Wien’s investigation and of improvements in the construction of linear thermopiles, a far more familiar measurement of the distribution of energy along a spectrum, the general character of the curve connecting energy and wave-length in the complete radiation at a given temperature has been experimentally ascertained over a wide range. At each temperature there is a wave-length \( \lambda_m \) of maximum radiation, which is displaced towards the ultra-violet as the temperature rises, and Wien’s law of homology (§ 6) shows that \( \lambda_m T \) should be constant. This deduction, and the law of homology itself, as also the law of Stefan and Boltzmann that the total radiation varies as \( T^4 \), have been closely verified by the experiments of Rubens and Kurlbaum, Lummer and Pringsheim, and others.

They established a steady field of radiation inside a material enclosure by raising the walls to a definite temperature, and measured the radiant intensity emitted from it through an opening or slit in the walls, by means of a bolometer or thermopile, this being the radiation of the so-called perfectly black body. The principle here involved formed one of the foundations of Balfour Stewart’s early treatment of the theory, and had already been employed by him and Stokes (1860) in experiments on the polarized emission from tourmaline: cf. Stokes, Math. and Phys. Papers, iv. 136. It has been remarked by Planck and by Lord Rayleigh that the coefficient of \( T^4 \) in Stefan’s law, and the value of the equation \( \lambda_m T \) are two absolute constants, independent of any particular kind of matter, which in conjunction with the constancy of gravitation would determine an entirely absolute system of physical units. The form of the function \( \phi(T) \), adopted by Wien and in Planck’s earlier discussions, namely, \( c e^{-c/T} \), was found to agree fairly with experiment over the range from \( 100^\circ \) to \( 1300^\circ \), when \( c = 1.24 \times 10^{-8} \), and \( c = 1.44 \times 10^{-9} \) in c.g.s. measure, but not so well when the range is farther extended; it appeared that a larger value of \( c \) was needed to represent the radiation for high values of \( T \), that is, for high temperature or for very long wave-lengths. Thiesen proposed the somewhat more general form \( \phi(T) = e^{-c/T} \), and suggested that the value \( c = 3 \) agrees better with the experimental numbers than Wien’s value \( k = 0 \). Lord Rayleigh was led (Phil. Mag., June 1900) towards this form with \( k = 0 \) to equal to unity from entirely different theoretical considerations, on the assumption of the Maxwell-Boltzmann distribution of the energy of a system, and of an isolated block of ether, among its free periods of vibration, infinite in number; in some cases this form appeared to give as good results as Wien’s own.

Acting on a suggestion advanced by Lord Rayleigh, Rubens and Kurlbaum soon afterwards widely extended the test of the formula by means of the so-called Reststrahlen. A substance such as an aniline dye, which exhibits selective absorption of any group of rays, also powerfully reflects those rays; and Rubens has been able thus to isolate in considerable purity the rays belonging to absorption bands very far down in the invisible ultra-red, having wave-lengths of order \( 10^{-7} \) cm, which are considered as purely infra-red, by means of five or six successive reflexions of the beam of radiation. By experiments ranging between \( -200^\circ \) and \( +1500^\circ \) C. of the source of radiation, it has been found that the intensity of this definite radiation tends to vary simply as \( T \), with close approximation, thus increasing indefinitely with the temperature, whereas Wien’s formula would make it tend to a definite limit. The only existing formula (except the one suggested by Lord Rayleigh) that proved to be in accord with this result was a new one advanced shortly before and supported on theoretical grounds by Planck, namely, \( E = c - \Delta \eta \), which agrees with Wien’s original form, known to be there satisfactory, while for larger values it tends towards \( c/T \); the new formula is, in fact, the simplest and most likely form that satisfies these two conditions.

The point of Lord Rayleigh’s argument was that, at any rate at low frequencies, the law of distribution would suggest an equal partition of the energy between temperature heat and radiant vibrations, and that therefore the energy of the latter should ultimately vary as \( T \); and this prediction, which has thus been verified, may be grafted on to any formula that is in other respects appropriate.

Regarding the fact that the previous hypothesis, restricting the nature of the entropy in addition to its property of continually increasing, had thus to be abandoned, Planck had in fact made a fresh start on the basis of a train of ideas which was introduced by Boltzmann in 1877, in order to obtain a precise physical conception of entropy. According to the latter, for an indefinitely numerous system of molecules, with known properties and in given circumstances, there is a definite probability of the occurrence of each statistical distribution of velocities, or say each "complexion" of the system, that is formally possible when all velocities consistent with given total energy are considered to be equally likely as such by the molecules; the distribution of greatest possible probability is the state of thermal equilibrium of the system, and the probability of any other state is a function of the entropy of that state. This conception can be developed only in very simple cases; the application to an ideal monatomic gas-system led Boltzmann to the entropy proportional to the logarithm of the probability. This logarithmic law is in fact demanded in advance by the principle that the entropy of a system should be the sum of the entropies of its parts. By means of a priori considerations of this nature, referring to the distribution of internal vibrational energy among a system of linear electric vibrators of given period, and its equilibrium of exchanges with the surrounding radiant energy, Planck has been guided to an expression for the law of dependence of the entropy of that system on the temperature, which corresponds to the form of the law of radiation above stated. The result gains support from the fact that the expressions for the coefficients to which he is led give determinations of the
absolute physical constants of molecular theory, such as the constant of Avogadro, which are in close accord with other recent determinations. But on the other hand these determinations are already involved in the earlier formula of Rayleigh, which expresses the distribution for long waves, based merely on the Maxwell-Boltzmann principle of the equable partition of energy among the high-frequency motions belonging to the enclosure which contains it. It is maintained by Jeans that the reason why this principle is of avail only for very long wavelengths is that a steady state is never reached for the shorter ones, a doctrine which as he admits would entirely remove the foundations of the application of thermodynamic principles to this subject. By an argument based on the theory of dimensions, Lorentz has been led to the conclusion that consistency between temperatures, as measured molecularly, and as measured by the laws of radiation, requires that the ultimate indivisible electric charges or electrons must be the same in all kinds of matter.

The abstract statistical theory of entropy, which is here invoked, admits of generalization in a way which is a modification of that of Planck, itself essentially different from the earlier idea of Boltzmann. The molecules of matter, whose interactions control physical phenomena, including radiation, are too numerous to be attended to separately in our knowledge. They, and the phenomena in which they interact, must thus be sorted out into differential groups or classes. Elements of energy of specified types might at first sight constitute such classes: but the identity of a portion of energy cannot be traced during its transformations, while an element of physical disturbance can be definitely followed, though its energy changes by interaction with other elements as it proceeds. The whole disturbance may thus be divided into classes, or groups of similar elements, each with permanent existence: and these may be considered as distributed in series of cells, all equivalent in extent, which constitute and map out the material system or other domain of the phenomena. The test of this equivalence of extent is superposition, in the sense that the same element of disturbance always occupies during its wanderings the same number of cells. This framework being granted, the probability of any assigned statistical distribution of the elements of disturbance now admits of calculation; and it represents, as above, the logarithm of the entropy of that distribution, multiplied however by a coefficient which must depend on the minuteness of scale of the statistics. But in the calculation, all the physical laws which impose restrictions on the migrations of the elements of disturbance must be taken into account; it is only after this is done that the rest of the circumstances can be treated as fortuitous. All these physical laws are, however, required and used up in determining the complex of equivalent cells into which the system which forms the seat of the energy is mapped out. On this basis thermodynamics can be constructed in a priori abstract fashion, and with deeper and more complete implications than the formal Carnot principle of operation of perpetual motions can by itself attain to. But the ratio of the magnitude of the standard element of disturbance to the extent of the standard cell remains inherent in the results, appearing as an absolute physical constant whose value is determined somehow by the other fundamental physical constants of nature. A prescribed ratio of this kind is, however, a different thing from the hypothesis that energy is constituted atomically, which underlies, as Lorentz pointed out, Planck’s form of the theory. It has indeed already been remarked that the mere fact of the existence of a wave-length, of maximum radiation, which is in accordance with the law of Laplace ; that this maximum is obtained by itself some prescribed absolute physical quantity of this kind, whose existence thus cannot be evaded, though we may be at a loss to specify its nature.

13. Modification by a Magnetic Field.—The theory of exchanges of radiation, which makes the equilibrium of radiating bodies depend on temperature alone, requires that, when an element of surface of one body is radiating to an element of surface of another body at the same temperature, the amounts of energy interchanged (when reflection is counted in along with radiation) should be equal. This proposition is a general dynamical consequence—on the basis of the laws of reciprocity developed in this connexion (after W. Rowan Hamilton) mainly by Helmholtz, Kirchhoff, and Rayleigh—of the form of the equations of propagation of vibrations in the medium. But in a material medium under the influence of a strong magnetic field these equations are altered by the addition of extraordinary terms involving differential coefficients of the third order, and the dynamical consistency of the cardinal principle of the theory of exchanges is no longer thus directly verified. A system of this kind has, in fact, been imagined by Wien in which the principle is imperfectly fulfilled. A beam coming from a body A, and polarized by passage through a nicol, may have its plane of vibration rotated through half a right angle by crossing a magnetically active plate, and may then pass through another nicol, properly orientated for transmission, so as finally to fall on another body B. On the other hand, the radiation from B which gets through this adjacent nicol will have its plane of vibration rotated through another half right angle by the magnetically active plate, and so will not get through the first nicol to the body A. Such possibilities of unequal exchange of radiation between A and B are the result of the want of reversibility of the radiation in the extraneous magnetic field, which might have been expected to lead to proportionate inequalities of concentration; in this example, however, though the defect of reversibility is itself slight, its results appear at first sight to prevent any equilibrium at all. But a closer examination removes this discrepancy. In order to make the system self-contained, reflectors must be added to it, so as to send back into the sources the polarized constituents that are turned aside out of the direct line by the nicols. Then, as Brillouin has pointed out, and as in fact Rayleigh had explained some years before, the radiation from B does ultimately get across to A after passage backward and forward to the reflectors and between the nicols: this, it is true, increases the length of its path, and therefore diminishes the concentration of a single narrow beam, but any large change of path would make the beam too wide for the nicols, and thus require other corrections which may be supposed to compensate. The explanation of the slight difference that is to be anticipated on theoretical grounds might conceivably be that in such a case the magnetic influence, being operative on the phases, alters the statistical constitution of the radiation of given wave-length from the special type that is in equilibrium with a definite temperature, so that after passage through the magnetic medium it is not in a condition to be entirely absorbed at that temperature; there would then be some other element, in addition to temperature, involved in equilibrium in a magnetic field. If this is not so, there must be some thermodynamic compensation involving reaction, extremely small, however, on the magnetizing system.

14. Origin of Spectra.—In addition to the thermal radiation of material substances, those, again, which establish the temperature-equilibrium of the enclosure in which they are confined, there are the fluorescent and other radiations excited by extraneous causes, radiant or electric or chemical. Such radiations are an indication, by the presence of higher wave-lengths than belong in any sensible degree to the temperature, that the steady state has not arrived; they thus fade away, either immediately on the cessation of the exciting cause, or after an interval. The radiations, consisting of definite narrow bright bands in the spectrum, that are characteristic of the gaseous state in which each molecule can vibrate freely by itself, are usually excited by electric or chemical agency; thus there is a group of lines which arise in a glass cell at a certain temperature radiation. The absorption of these radiations by strata of the same gases at low temperatures seems to prove that the unaltered molecules themselves possess these free periods, which do not, therefore, belong specially to dissociated ions. Although very difficult to excite directly, these free vibrations are then excited and absorb the energy of the incident waves, under the influence of the resonance, which naturally becomes extremely powerful when the tuning is exact; this
RADIATION indicates, moreover, that the true absorption bands in a gas of sufficiently low density must be extremely narrow. There is direct evidence that many of the more permanent gases do not sensibly emit light on being subjected to high temperature alone, when chemical action is excluded, while others give in these circumstances feeble continuous spectra; in fact, looking at the matter from the other side, the more permanent gases are very transparent to most kinds of radiation, and therefore must be very bad radiators as regards those kinds. The dark radiation of flames has been identified with that belonging to the specific radiation of their gaseous products of combustion. There is thus ground for the view that the impacts of the colliding molecules in a gas, or rather their mutual actions as they swing sharply round each other in their orbits during an encounter, may not be sufficiently violent to excite sensibly the free vibrations of the definite periods belonging to the molecules. But they may produce radiation in other ways. While the velocity of an electron or other electric charge is being altered, it necessarily sends out a stream of radiation. Now the orbital motions of the electrons in an actual molecule must be so adjusted, as appears to be theoretically possible, that it does not emit radiation when in a steady state and moving with constant velocity. But in the violent changes of velocity that occur during an encounter this equi-poise will be disturbed, and a stream of radiation, without definite periods, but such as might constitute its share of the equilibrium thermal radiation of the substance, may be expected while the encounter lasts. At very high temperatures the energy of this thermal radiation in an enclosure entirely overpowers the kinetic energy of the molecules present, for the former varies as $T^4$, while the latter measures $T$ itself when the number of molecules remains the same. The radiation which can be excited in gases, confined as it is to extremely narrow bands in the spectrum, may indeed be expected to possess such intensity as to be thermally in equilibrium with extremely high temperatures. That the same gases absorb such radiations when comparatively cold and dark does not, of course, affect the case, because emissive and absorptive powers are proportional only for incident radiations of the intensity and type corresponding to the temperature of the body. Thus if our adiabatic enclosure of § 3 is prolonged into a tube of unlimited length which is filled with the gas, then when the temperature has become uniform that gas must send back out of the tube as much radiation as it originally absorbed in the tube and has been absorbed by it; but if the tube is maintained at a lower temperature, it may return much less. The fact that it is now possible by great optical dispersion to make the line-spectra of prominenes in the middle of the Sun’s disk stand out bright against the background of the continuous solar spectrum, shows that the intensities of the radiations of these prominenes correspond to a much higher temperature than that of the general radiating layer underneath them; their luminosity would thus seem to be due to some cause (electric or chemical) other than mere temperature. On the other hand, in the Sun’s disk there are lines and bands whose origin which originates the dark Fraunhofer lines is at a lower temperature than the radiating layer; it is only when the light from the lower layers is eclipsed that its own direct bright-line spectrum flashes out. It is not necessary to attribute this selective flash-spectrum to temperature radiation; it can very well be ascribed to fluorescence stimulated by the intense illumination from beneath. When the radiation in a spectrum is constituted of wide bands it may on these principles be expected to be in equilibrium with a lower temperature than when it is constituted of narrow lines. The total intensity is the same in the cases compared; this is in keeping with the easier excitation of the band spectra (cf. the banded absorption spectra), and with the fact that various gases and vapours do appear to emit band spectra more or less related to the temperature.

15. Constitution of Spectra.—In the problem of the unravelling of the constitutions of the very complex systems of spectral lines belonging to the various kinds of matter, considerable progress has been made in recent years. The beginning of definite knowledge was the discovery of Balmer in 1885, that the frequencies of vibration $(n)$ of the hydrogen lines could be represented, very closely and within the limits of error of observation, by the formula $n \sim 1 - 4m^2$, when for $m$ is substituted the series of natural numbers $3, 4, 5, \ldots$ 15. Soon afterwards series of related lines were picked out from the spectra of other elements by Liveing and Dewar. Rydberg conducted a systematic investigation on the basis of a modification of Balmer’s law for hydrogen, namely, $n = n_0 + \mu N/[(m+n)]^2$. He found that in the group of alkaline metals three series of lines exist, the so-called principal and two subordinate series, whose frequencies fit approximately into this formula, and that similar statements apply to other natural groups of elements; that the constant $N$ is sensibly the same for all series and all substances, while $n_0$ and $\mu$ have different values for each; and that other approximate numerical relations exist. In each series the lines of high frequency crowd together towards a definite limit on the more refrangible side; near this limit they would, if visible, constitute a band. The principal or strongest series of lines shows reversal very readily. The lines of the first subordinate series are usually very weak, while those of the second subordinate or weakest series are sharp; but with a tendency to broaden towards the less refrangible side. In most series there are, however, not more than six lines visible: helium and hydrogen are exceptions, no fewer than thirty lines of the principal series of the latter having been identified, the higher ones in stellar spectra only. But very remarkable progress has recently been made by R. W. Wood, by exciting fluorescent spectra in a metallic vapour, and also by applying a magnetic field to restore the lines sensitive to the Zeeman effect after the spectrum has been cut off by crossed nicols. The large aggregates of lines thus definitely revealed are also resolved by him into systems in other ways; when the stimulating light is confined to one period, say a single bright line of another substance, the spectrum excited consists of a limited number of lines equidistant in frequency, the interval common to all being presumably the frequency of some intrinsic orbital motion of the molecule. In this way the series belonging to some of the alkali metals have been obtained nearly complete.

Simultaneously with Rydberg, the problem of series was attacked by Kayser and Runge, who, in reducing their extensive tables of observed lines to a form corresponding to the Rydberg formula, $n_0 + \mu N/[(m+n)]^2$, noted that higher terms in this descending series being presumed to be negligible. This cannot be reconciled with Rydberg’s form, which gives on expansion terms involving $m^2$; but for the higher values of $m$ the discrepancies rapidly diminish, and do not prevent the picking out of the lines, the frequency-differences between successive lines then varying roughly as the inverse squares of the series of natural numbers. For low values of $m$ neither mode of expression is applicable, as was to be expected; and it remains a problem for the future to ascertain if possible the rational formula to which they are approximating. A number of these theories have been suggested by Ritz and others, partly on theoretical grounds.

Considered dynamically, the question is that of the determination of the formula for the disturbed motions of the system which constitutes the molecule. Although we are still far from any definite line of attack, there are various indications that the quest is a practicable one. The lines of each series, sorted out by aid of the formulae above given, have properties in common: they are usually multiple lines, either all doublets in the case of monad elements, or generally triplets in the case of those of higher chemical valency; in very few cases are the series constituted of single lines. It is found also that the components of all the double or triple lines of a subordinate series are equidistant as regards frequency. In the case of a related group of elements, for example the alkaline metals, it appears that corresponding series are displaced continually towards the less refrangible end as the atomic weight rises; it is found also that the interval in frequency between the double-
lines of a series diminishes with the atomic weight, and is proportional to its square. These relations suggest that the atomic weight might here act in part after the manner of a load attached to a fundamental vibrating system, which might conceivably be formed on the same plan for all the metals of the group; such a load would depress all the periods, and at the same time it would come up in the manner above described, if it introduced disymmetry into the vibrator. The discovery of Zeeman that a magnetic field triples each spectral line, and produces definite polarizations of the three components, in many cases further subdividing each component into lines placed usually all at equal intervals of frequency, is explained, and was in part predicted, by Lorentz on the basis of the electron theory, which finds the origin of radiation in a system of unitary electric charges describing orbits or executing vibrations in the molecule. Although these facts form substantial sign-posts, it has not yet been found possible to assign any likely structure to a vibrating system which would lead to a frequency formula for its free periods of the types given above. Indeed, the view is open that the group of lines constituting a series form a harmonic analysis of a single fundamental vibration not itself harmonic. If that be so, the intensities and other properties of the lines of a series ought all to vary together; it has in fact been found by Preston, and more fully verified by Runge and others, that the lines are multiplied into the same number of constituents in a magnetic field, with intervals in frequency that are the same for all of them. When the series consists of double or triple lines the separate components of the same compound line are not affected similarly, which shows that they are differently constituted. The view has also found support that the different behaviours of the various groups of lines in a spectrum show that they belong to independent vibrators. The form of the vibration sent out from a molecule into the aether depends on the form of the aggregate hodograph of the electronic orbits, which is in keeping with Rayleigh's remark that the series-laws suggest the kinematic relations of revolving bodies rather than the vibrations of steady dynamical systems.

According to Rydberg, there is ground for the view that a natural group of chemical elements have all the same type of series spectrum, and that the various constants associated with this spectrum change rapidly in the same directions in passing from the elements of one group to the corresponding ones of the following groups, after the manner illustrated in graphical representations of Mendeleeff's law by means of a continuous wavy curve in which each group of elements lies along this same ascending or descending branch; the chemical elements thus being built up in a series of types or groups, so that the individuals in successive groups correspond one to one in a regular progression, which may be put in evidence by connecting them by transverse curves. Illustrations have been worked out mathematically by J. J. Thomson by the effect of adding successive outer rings of electrons to stable vibrating collocactions.

The frequencies of the series of very close lines which constitute a single band in a banded spectrum are connected by a law of quite different type, namely, in the simpler cases \( n^2 = \lambda - B m^2 \). It may be remarked that this is the kind of relation that would apply to a row of independent similar vibrators in which the neighbours exert slight mutual influence of elastic type. If \( \xi \) denote displacement and \( x \) distance along the row, it would be

\[
\frac{d^2 \xi}{dt^2} + 2 \beta \frac{d\xi}{dt} + \omega^2 \xi = \text{constant},
\]

where \( \beta = \frac{m^2}{\lambda m} \) and \( m \) is integral; further \( p^2 + k^2 = gu^2 \), hence \( p^2 = u^2 + \frac{E^2}{k} m^2 \), which is of the type above stated. Dynamical systems of this kind are illustrated by the Lagrangean linear system of connected bodies, such as, for example, a row of masses fixed along a tense cord, and each subject to a restoring elastic force of its own in addition to the tension of the cord. A single spectral line might thus be transformed into a band of this type, as the effect of distorting the atoms from slight elastic connexions established in the molecule between a system of similar vibrators. But the series in line-spectra are of entirely different constitution; thus for the series expressed by the formula \( p^2 + p_0^2 = B m^2 \) the corresponding period-equation might be expressed in some such form as \( sin k(p^2 - p_0^2) = \text{constant} \), which belongs to no type of vibrator hitherto analysed.

RADICAL (Lat. radix, a root), in English politics, a term applied to politicians who desire to make thorough, or radical, changes in the constitution and in the social order generally. Although it had been used in a somewhat similar way during the reign of Charles II., the term Radical, in its political sense, originated about the end of the 18th century, probably owing its existence to Charles James Fox, who, in 1777, declared that “radical reform” was necessary. The ideas of the first Radicals were borrowed largely from the authors of the French Revolution. The word was more generally employed during the disturbed period between the close of the Napoleonic wars and the passing of the great Reform Bill of 1832, and was applied to agitators like Henry Hunt and William Cobbett. After the Reform Bill had become law, the advocates of violent change were drawn into the Chartist movement, and the Radicals became lessrevolutionary than in speech and object. Thus in 1842 an observer writes:—"The term Radical, once employed as a name of low-republican origin, has found its way into high places, and is gone forth as the title of a class who glory in their designation." About this time many members of Parliament were known as Radicals, among these men being George Grote and Joseph Hume. The Radicals never formed a distinct party in the House of Commons, and subsequently they formed simply the advanced section of the Liberal party. For a few years in the 19th century the wearing of a white hat was looked upon as the distinguishing mark of a Radical, a hat of this colour having been worn by Hunt when addressing meetings.

**Radioactivity.** The subject of radioactivity deals with phenomena exhibited by a special class of bodies of high atomic weight of which uranium, thorium, radium and actinium are the best known examples. These substances possess the property of spontaneously emitting radiations of a special character which are able to penetrate through matter opaque to ordinary light. The beginning of this subject dates from 1895, and was an incident consequent of the discovery of the X rays made a few months before by Röntgen. It was known that the production of X rays in a vacuum tube was accompanied by a strong phosphorescence of the glass, and it occurred to several investigators that ordinary substances made phosphorescent by visible light might emit a penetrating radiation similar to X rays. Following out this idea, H. Becquerel (1), a distinguished French physicist, exposed amongst other substances a phosphorescent compound of uranium, uranium-

---

1 These numbers refer to papers noted under *References* (below).
Potassium sulphate, enveloped in paper beneath a photographic plate. A weak photographic effect was obtained. This was shown to be due to a penetrating radiation capable of passing through sheets of matter opaque to ordinary light. Further investigation showed that this photographic action was exhibited by all compounds of uranium and by the metal itself, and had nothing to do with phosphorescence. It was shown equally if the uranium were kept in darkness and did not vary appreciably with time. Becquerel showed that the rays from uranium like X rays were capable of discharging a body whether positively or negatively electrified. A uranium compound brought close to the charged plate of a gold leaf electroscope causes a rapid collapse of the gold leaves. This property of uranium, and also of the radioactive bodies in general, has supplied a delicate and quantitative method of accurate comparison of the intensity of the radiations from substances under varying conditions. A modified form of gold leaf electroscope has come into general use for comparison of the radioactivity of substances. Rutherford (2) made a systematic examination of the discharging effect produced by the rays from uranium and showed that it was due to the production of charged carriers or ions in the volume of the gas through which the radiations pass. In an electric field, the positive ions travel to the negative electrode and vice versa, thus causing a discharge of the electrified body. If a sufficiently strong field is used, the ions are all swept to the electrodes before appreciable loss of their number can occur by recombination. The rate of discharge then reaches a steady maximum value which is not altered by a large increase in voltage. This maximum current through the gas is called the saturation current. The ions produced in gases by the rays from uranium and other radioactive substances are in general identical with those produced by X rays, and the mechanism of conductivity of the gas is very similar in both cases (see Conduction, Electric; § Through Gases).

Some time after Becquerel's discovery, Mme Curie (3) made a systematic examination of the electric method of a large number of chemical elements and their compounds to test whether they possessed the "radioactive" property of uranium. Only one other element, thorium, was found to show this effect to a degree comparable with that of uranium—a result independently observed by Schmidt. Mme Curie examined the activity of the various compounds of uranium and found that their radioactivity was an atomic property, i.e., the activity was proportional to the amount of the element uranium present, and was independent of its combination with other substances. In testing the activity of the minerals containing uranium, Mme Curie found that the activity was always four to five times as great as that to be expected from their content of uranium. If the radioactivity were an atomic phenomenon, this could only be explained by the presence in these minerals of another substance more active than uranium itself. Relying on this hypothesis, Mme Curie made a chemical examination of uranium minerals in order to try to separate this new radioactive substance. In these experiments, the Austrian Government generously provided Mme Curie with a ton of the residues of the State manufacture of uranium at Joachimsthal, Bohemia. At that place there are extensive deposits of pitchblende or uranite which are mined for the uranium. After separation of the latter, the residues are three to five times as radioactive weight for weight as the uranium. From this residue Mme Curie separated a substance far more radioactive than uranium, which she called polonium in honour of the country of her birth. This substance is usually separated with bismuth in the mineral, but by special methods can be partly separated from it. A further examination revealed the presence of a second radioactive substance which is normally separated with the barium, to which the name "radium" was given. This name was happily chosen, for in the pure state radium bromide has a very great activity—about two million times as great as an equal weight of uranium. By means of successive fractionations of the chloride, the radium was gradually concentrated, until finally the radium was obtained so that the barium lines showed very faintly. The atomic weight was found by Mme Curie to be 225. In a recent redetermination, using a larger quantity of 0.4 grams of pure radium chloride, Mme Curie (4) found the atomic weight to be 226.5. Thorpe (5) using a smaller quantity obtained a value 227. The spectrum of the purified sample of radium chloride obtained by Mme Curie was first examined by Demarçay. It was found to have a characteristic spark spectrum of bright lines analogous in many respects to the spectra of the alkaline earths. Giesel (6) found that pure radium bromide gives a brilliant carmine colour to the bunsen flame. The flame spectrum shows two broad bright bands in the orange-red. There is also a line in the blue-green and two weak lines in the violet. Giesel (7) has taken an active part in the preparation of pure radium compounds, and was the first to place preparations of pure radium bromide on the market. He found that the separation of radium from the barium mixed with it proceeded much more rapidly if the crystallizations were carried out using the bromide instead of the chloride. He states that six to eight crystallizations are sufficient for an almost complete separation. From the chemical point of view radium possesses all the characteristic properties of a new element. It has a definite atomic weight, a well-marked and characteristic spectrum, and distinct chemical properties. Its comparative ease of separation and great activity has attracted much attention to this substance, although we shall see that very similar radioactive properties are possessed by a large number of distinct substances.

Radium emits three distinct types of radiation, known as the α, β and γ rays, of which an account will be given later. It produces in addition a radioactive emanation or gas which is about 100,000 times as active weight for weight as radium itself. The emanation released from 10 milligrams of pure radium bromide causes a glass tube into which it is introduced to phosphoresce brightly. A brilliant luminescence is produced in phosphorescent substances like zinc sulphide, willemite and barium platinio-cyanide when introduced into a tube containing the emanation. The radium emanation, a more detailed account of which will be given later, has proved of the greatest utility in radioactive experiments. The properties of this emanation have been utilized as a very delicate and certain method, not only of detection but of estimation of small quantities of radium. This "emanation method" depends upon the introduction of the emanation, liberated from a substance by boiling or heating, into a suitable electroscope. The rate of discharge of the electroscope due to the emanation affords a quantitative measure of the amount of radium present. In this way, it is not difficult to determine with certainty the
presence of radium in a body which contains only 10⁻¹⁵ gram of radium. With care, 10⁻¹⁴ gram can just be detected. This emanation method has been employed with great success in measuring the quantity of radium in minerals and in rocks. A very simple method has been devised of determining the quantity of radium present when it is not less than 1/100 milligram. The tube containing the radium is placed some distance from an electroscope which is surrounded by a lead screen about 3 mms. thick. This cuts off the α and β rays and the effect in the electroscope is then due to the penetrating γ rays. By comparison of the rate of discharge with that of a standard preparation of radium at the same distance, the quantity of radium in the sample at once be deduced, provided the radium is in equilibrium with its emanation. This is usually the case if the radium preparation is one month old. This method is simple and direct, and has the great advantage that the radium tube under test need not be opened, nor its contents weighed. We shall see later that the amount of radium in an old mineral is always proportional to the amount of uranium present. Rutherford and Boltwood (8) found that 3-4 parts of radium by weight are present in ten million parts of uranium. Consequently an old mineral containing 1000 kilos of uranium should contain 340 milligrams of pure radium.

In addition to radium and polonium, a number of other radioactive substances have been found in uranium minerals. With the exception of the radium emanation, none of these have yet been isolated in a pure state, although preparations of some of them have been obtained comparable in activity with radium itself. Debierne (9) found a radioactive substance which was separated from pitchblende with the rare earths and had chemical properties similar to those of thorium. This he called actinium. Giesel (10) independently noted the presence of a new radioactive substance which was usually separated with hantahum and cerium from the mineral. It possessed the property of giving out a radioactive emanation or gas, the activity of which dissipated in a few seconds. For this reason he called it the emanating substance and afterwards emanium. Later work has shown that emanium is identical in chemical and radioactive properties with actinium, so that the former name will be retained.

We have already seen that Mme Curie gave the name polonium to a radioactive substance separated with bismuth. Later Markwald found that a very radioactive substance was deposited from a solution of a radioactive mineral on a polished bismuth plate. The active matter was found to be deposited in the bismuth with tellurium, and he gave the name radium tellurium to this substance. In later work, he showed that the new substance could be chemically separated from tellurium. By treating the residues from 15 tons of Joachimsthal pitchblende, Markwald (11) finally obtained 3 milligrams of intensely active material—far more active weight for weight than radium. It has been definitely settled that the active substance of Markwald is identical with polonium. Both substances give out a type of easily absorbed α rays and both lose their activity at the same rate. The activity of polonium decays in a geometric progression; the intensity falls to half its initial value in 1460 days. This law of decay is characteristic of all radioactive products, although the period of decay is different in each case.

Mme Curie and Debierne (12) have described further experiments with polonium. The latter substance was extracted from several tons of pitchblende and purified until 2 milligrams of material were obtained containing about 1/10 milligram of pure polonium. From a knowledge of the relative periods of transformation of radium and polonium, it can be calculated that the amount of polonium in a radium mineral is 1/5000 of the amount of radium, while the activity of pure polonium measured by the α rays should be 5000 times greater than that of radium. As we have seen, polonium is rapidly transformed, and it is of great interest to determine the nature of the substance into which polonium changes. We shall see later that there is considerable evidence that polonium changes into lead.

Recently Boltwood (13) has separated another substance from uranium minerals which he has called "ionium." This substance is sometimes separated from the mineral with actinium and has chemical properties very similar to those of thorium. Preparations of ionium have been obtained several thousand times as active as uranium. Ionium emits α rays of short range and has a period of transformation probably much longer than that of radium. Ionium has a special interest inasmuch as it is the substance which changes directly into radium. A preparation of ionium initially free from radium grows radium at a rapid rate. Hofmann found that the lead separated from uranium minerals and named it radiolead. The active constituent in the lead is radium D, which changes into radium E and then into radium F (polonium). Both radium D and radium F are products of the transformation of radium. In addition to these radioactive substances mentioned above, a large number of other radioactive substances have been discovered. Most of these lose their activity in the course of a few hours or days. The properties of these substances and their position in the radioactive series will be discussed later.

Radiations from Radioactive Substances.—All the radioactive substances possess in common the property of emitting radiations which darken a photographic plate and cause a discharge of electrified bodies. Very radioactive preparations of radium, actinium and polonium also possess the property of causing strong phosphorescence in some substances. Bodies which phosphoresce under X rays usually do so under the rays from radioactive matter. Barium platinoxyanide, the mineral willemite (zinc silicate) and zinc sulphide are the best known examples.

There are in general three types of radiation emitted by the radioactive bodies, called the α, β and γ rays. Rutherford (2) in 1899 showed that the radiation from uranium was complex and consisted of (a) an easily absorbed radiation stopped by a sheet of paper, (b) a ray passing through a plate of the same material by which it had been emitted, and (c) a ray passing through a plate of the same material by which it had been emitted. Later Villard found that radium emitted a very penetrating kind of radiation called the γ rays capable of passing before absorption through twenty centimetres of iron and several centimetres of lead.

Giesel and, later, Curie and Becquerel showed that the β rays of radium were deflected by a magnetic field. By the work of Becquerel and Kaufmann the β rays have been shown to consist of negatively charged particles projected with a velocity approaching that of light, and having the same mass as the electrons set free in a vacuum tube. In fact the β rays are the electrons spontaneously ejected from the radioactive matter at a speed on an average much greater than that observed in the electrons set free in a vacuum tube.

The very penetrating γ rays are not deflected in a magnetic or electric field and are believed to be a type of radiation similar to X rays. The γ rays are only observed in radioactive substances which emit β rays, and the penetrating power of the γ rays appears to be connected with the initial velocity of emission of the β rays. Two general theories have been advanced to account for the properties of these rays. On one view, the γ rays are to be regarded as electromagnetic pulsions which have their origin in the expulsion of the β particle from the atom. On the other hand Bragg has collected evidence in support of the view that the γ rays are corpuscular and consist of uncharged particles or "neutral doublets." There is as yet no general consensus of opinion as to the true nature of the γ rays.

Rutherford (14) showed in 1903 that the α rays were deflected in a powerful magnetic or electric field. The amount of deflection is very small compared with the β rays under similar conditions. The direction of deflection in a magnetic field is opposite to that of the β rays, showing that these rays to radium are of a stream of positively charged particles. A pencil of rays from a thick layer of radioactive matter is complex and consists of particles moving at varying velocities. If, however,
RADIOACTIVITY

A thin film of radioactive matter of one kind is taken, the particles which escape without absorption are found to be homogeneous and consist of particles projected at an identical speed. Observations of the velocity and mass of the particle have been made by Rutherford. The general method employed for this purpose is similar to that used for the determination of the velocity and mass of the electron in a vacuum tube. The pencil of radiation was determined for both a magnetic and electric field. From these observations the velocity and value of $e/m$ (the ratio of the charge carried by the particle to its mass) are determined. The value of $e/m$ has been found to be the same for the particles from all the types of radioactive matter that have been examined, indicating that the $\alpha$ particles from all radioactive substances are identical in mass. The value of $e/m$ found for the $\alpha$ particle is $5.57 \times 10^8$. Now the value of $e/m$ for the hydrogen atom set free in the electrolysis of water is $9660$. On the assumption that the value of the charge $e$ is the same for the $\alpha$ particle as for the hydrogen atom, the value would indicate that the $\alpha$ particle has about twice the mass of the hydrogen atom, i.e., has the same mass as the hydrogen molecule. If the charge on the $\alpha$ particle is twice that on the hydrogen atom, the value of $e/m$ indicates that the $\alpha$ particle is a helium atom, for the latter has an atomic weight of four times that of hydrogen.

It was difficult at first to decide between these and other hypotheses, but we shall show later that there is now no doubt that the $\alpha$ particle is in reality a helium atom carrying two elementary charges. We may consequently regard the $\alpha$ rays as a stream of helium atoms which are projected from a radioactive substance with a high velocity. The maximum velocity of the $\alpha$ particle from radium is $2.0 \times 10^6$ cms. per second, or one-fifteenth of the velocity of light. Although the $\alpha$ rays are the least penetrating of the radiations, it will be seen that they play an extremely important part in radioactive phenomena. They are responsible for the greater part of the ionization and heating effects of radioactive matter and are closely connected with the transformations occurring in them.

Under ordinary experimental conditions the greater part of the ionization observed in a gas is due to the $\alpha$ particles. This ionization due to the $\alpha$ rays does not extend in air at atmospheric pressure for more than 7 cms. from radium, and 8-6 cms. from thorium. If a screen of aluminium about 0.1 cm. thick is placed over the active material, the $\alpha$ rays are completely absorbed, and the ionization above the screen is then due to the $\beta$ and $\gamma$ rays alone. If a layer of lead about 2 mm. thick is placed over the active material, the $\beta$ rays are stopped, and the ionization is then due almost entirely to the penetrating $\gamma$ rays. By the use of screens of suitable thickness we are thus able to sift out the various types of rays. These three types of radiations all set up secondary radiations in passing through matter. A pencil of $\beta$ rays falling on matter is widely scattered in all directions. This scattered radiation is sometimes called the secondary $\beta$ rays. The $\gamma$ rays give rise to secondary rays which consist in part of scattered $\gamma$ rays and in part electrons moving with a high velocity. These secondary rays in turn produce tertiary rays and so on. The impact of the $\alpha$ rays on matter sets free a number of slow moving electrons which are very easily deflected by a magnetic or electric field. This type of radiation was first observed by J. J. Thomson, and has been called by him the $\delta$ rays.

**Emanations or Radioactive Gases.**—In addition to their power of emitting penetrating radiations, the substances thorium, actinium and radium possess another, very striking and important property. Rutherford (13) showed that the emanation products (especially the oxide) continuously emitted a radioactive emanation or gas. This emanation can be carried away by a current of air and its properties tested apart from the substance which produces it. A little later Dorn showed that radium possesses a similar property, while Giesel and Debiere observed a similar effect with actinium. These emanations all possess the property of ionizing a gas and, if sufficiently intense, of producing marked photographic and phosphorescent action. The activity of the radioactive gases is not permanent but disappears according to a definite law with the time, viz. the activity falls off in a geometric progression with the time. The emanations are distinguished by the different rates at which they lose their activity. The emanation of actinium is very shortlived, the time for the activity to fall off by half is about 5-07 days of the emanation, being 2-7 seconds. The period of the thorium emanation is 54 seconds and of the radium emanation 3-9 days. This property of emitting an emanation is shown in a very striking manner by actinium. A compound of actinium is wrapped in a sheet of thin paper and laid on a screen of phosphorescent zinc sulphide. In a dark room the phosphorescence, marked by the characteristic scintillation, is seen to extend on all sides from the active body. A puff of air is seen to remove the emanation and with it the greater part of the phosphorescence.

Fresh emanation immediately diffuses out and the experiment may be repeated indefinitely. The emanations have all the properties of radioactive gases. They can be transferred from point to point by currents of air. The emanations can be separated from the air or other gas with which they are mixed by the action of extreme cold. Rutherford and Soddy (16) showed that under ordinary conditions the temperature of condensation of the radium emanation mixed was $-170^\circ$ C.

The emanations are produced from the parent matter and escape into the air under some conditions. Rutherford and Soddy (17) made a systematic examination of the emanating power of thorium compounds under different conditions. The hydroxide emanates most freely, while in thorium nitrate, practically none of the emanation escapes into the air. Most of the compounds of actinium emanate very freely. Radium compounds, except in very thin films, retain most of the emanation in the compound. The occluded emanation can in all cases be released by solution or by heating. On account of its very slow period of decay, the emanation of radium can be collected like a gas and stored, when it retains its characteristic properties for a month or more.

**Induced Activity.**—Curie (18) showed that radium possessed another remarkable property. The surface of any body placed near radium, or still better, immersed in the emanation from it, acquires a new property. The surface after removal is found to be strongly active. Like the emanations, this induced activity in a body decays with the time, though at quite a different rate from the emanation itself. Rutherford (19) independently showed that thorium possessed a like property. He showed that the bodies made active behaved as if a thin film of intensely active matter was deposited on their surface. The active matter could be partly removed by rubbing, and could be dissolved off by strong acids. When the acid was evaporated the active matter remained behind. It was shown that induced activity was due to the emanations, and could not be produced if no emanation was present. We shall see that induced activity on bodies is due to a deposit of non-gaseous matter derived from the transformation of the emanations. Each emanation gives a distinctive active deposit which decays at different rates. The active deposits of radium, thorium and actinium are very complex, and consist of several types of matter.

Several hours after removal from the emanation the active deposit from radium decays to half-value—26 minutes, for actinium half-value—34 minutes, for thorium half-value—10-5 hours. The active deposits obtained on a platinum wire or plate are volatilized before a white heat, and are again deposited on the cooler bodies in the neighbourhood. Rutherford showed that the induced activity could be concentrated on the negative electrode in a strong electric field, indicating that the radioactive carriers had a positive charge. The distribution of the active deposit in a gas at low pressure has been investigated in detail by Makower and Russ.

**Theory of Radioactive Transformations.**—We have seen that the radioactive bodies spontaneously and continuously emit a great number of $\alpha$ and $\beta$ particles. In addition, new types of radioactive matter like the emanations and active deposits
appears, and these are quite distinct in chemical and physical properties from the parent matter. The radiating power is an atomic property, for it is unaffected by combination of the active element with inactive bodies, and is uninfluenced by the most powerful chemical and physical agencies at our command.

In order to explain these results, Rutherford and Soddy (26) in 1903 put forward a simple but comprehensive theory. The atoms of radioactive matter are unstable, and each second a definite fraction of the number of atoms present break up with explosive violence, in most cases expelling an α or β particle with great velocity. Taking as a simple illustration that an atom is a particle and that the particle is expelled during the explosion, the resulting atom has decreased in mass and possesses chemical and physical properties entirely distinct from the parent atom. A new type of matter has thus appeared as a result of the transformation.

The atoms of this new matter are again unstable and break up in turn, the process of successive disintegration of the atom continuing through a number of distinct stages. On this view, a substance like the radium emanation is derived from the transformation of radium. The atoms of the emanation are far more unstable than the atoms of radium, and break up at a much quicker rate. We shall now consider the law of radioactive transformation according to this theory. It is experimentally observed that in all simple radioactive substances, the intensity of the radiation decreases in a geometrical progression with the time, i.e., \(I/I_0 = e^{-\lambda t}\) where \(I\) is the intensity of the radiation at any time \(t\), \(I_0\) the initial intensity, and \(\lambda\) a constant. Now according to this theory, the intensity of the radiation is proportional to the number of atoms breaking up per second. From this it follows that the atoms of active matter present decrease in a geometrical progression with the time, i.e., \(N/N_0 = e^{-\lambda t}\) where \(N\) is the number of atoms present at a time \(t\), \(N_0\) the initial number, and \(\lambda\) the same constant as before. Differentiating, we have \(dN/dt = -\lambda N\), i.e., \(\lambda\) represents the fraction of the total number of atoms present which break up per second. The radioactive constant \(\lambda\) has a definite and characteristic value for each type of matter. Since \(\lambda\) is usually a very small fraction, it is convenient to distinguish the products by stating the time required for half the matter to be transformed. This will be called the period of the product, and is numerically equal to \(\log 2/\lambda\). As far as our observation has gone, the law of radioactive change is applicable to all radioactive matter without exception. It appears to be an expression of the law of probability, for the average number breaking up per second is proportional to the number present.

Viewed from this point of view, the number of atoms breaking up per second should have a certain average value, but the number from second to second should vary within certain limits according to the theory of probability. The theory of this effect was first put forward by Schrödinger, and has since been verified by a number of experimenters, including Kohlrausch, Meyer, and Begener and H. Geiger. This variation in the number of atoms breaking up from moment to moment becomes marked with weak radioactive matter, where only a few atoms break up per second. The variations observed are in agreement with those to be expected from the theory of probability. This effect does not exist in any way invalidate the law of radioactive change. On an average the number of atoms of any simple kind of matter breaking up per second is proportional to the number present. We shall now consider how the amount of radioactive matter which is supplied at a constant rate from a source varies with the time. For clearness, we shall take the case of the production of emanation, by radium.

The rate of transformation of radium is so slow compared with that of the emanation that we may assume without sensible error that the number of atoms of radium breaking up per second, i.e., the supply of fresh emanation, is on the average constant throughout the observation. Suppose that initially radium is completely freed from emanation. In consequence of the steady supply, the amount of emanation present increases, but not at a constant rate, for the emanation is in turn breaking up. Let \(q\) be the number of atoms of emanation produced by the radium per second and \(N\) the number present after an interval \(t\), then \(dN/dt = q - \lambda N\) where \(\lambda\) is the radioactive constant of the emanation. It is obvious that a steady state will ultimately be reached when the number of atoms of emanation supplied per second are on the average to the atoms which break up per second. If \(N_0\) be the maximum number, \(g = N_0\). Integrating the above equation, it follows that \(N/N_0 = 1 - e^{-\lambda t}\). If a curve be plotted with \(N\) as ordinates and time as abscissae, it is seen that the recovery curve is complementary to the decay curve. The two curves for the radium emanation period, 3-9 days, are shown in fig. 1, the maximum ordinate being in each case 100.

This process of production and disappearance of active matter holds for all the radioactive bodies. We shall now consider some special cases of the variation of the amount of active matter with time which have proved of great importance in the analysis of radioactive changes.

(a) Suppose that initially the matter A is present, and this changes into B and C into C, it is required to find the number of atoms \(P\) and \(R\) of A, B and C present at any subsequent time \(t\). Let \(\lambda_1, \lambda_2, \lambda_3\) be the constants of transformation of A, B and C respectively. Suppose \(n\) be the number of atoms of A initially present. From the law of radioactive change it follows:

\[
dQ/dt = -\lambda_1 Q + \lambda_2 R + \lambda_3 P\]

Substituting the values of \(n, Q, R, P\) in (1), \(dQ/dt = \lambda_1 n e^{-\lambda_1 t} + \lambda_3 P\) and the solution of which is of the form

\[
Q = \frac{Q_0}{1 - e^{-\lambda_1 t}} + \lambda_3 P e^{-\lambda_3 t},
\]

where \(Q_0\) is the initial number of atoms A present. By substitution it is seen that \(a = \lambda_1 (\lambda_2 - \lambda_3)\). Since \(Q = 0\) when \(t = 0\), \(b = -\lambda_1 (\lambda_2 - \lambda_3)\).

Thus \(Q = \frac{n \lambda_1}{\lambda_2 - \lambda_3} (1 - e^{-\lambda_1 t})\)

Similarly it can be shown that

\[
R = \frac{n \lambda_3}{\lambda_1 - \lambda_3} (1 - e^{-\lambda_3 t})
\]

where \(a = \lambda_3 (\lambda_2 - \lambda_3)\) and \(b = -\lambda_3 (\lambda_1 - \lambda_3)\).

It will be seen from (3), that the value of \(Q\), initially zero, increases to a maximum and then decays; finally, according to an exponential law, with the period of the more slowly transformed product, whether A or B.

(b) A primary source supplies the matter A at a constant rate, and the process has continued so long that the amounts of the products A, B, C have reached a steady limited value. The primary source is then suddenly removed. It is required to find the amounts of A, B and C remaining at any subsequent time \(t\).

In this case of equilibrium, the number \(n_0\) of particles of A supplied per second is equal to the number of particles of B which change into C per second, and also of B into C. This requires the relation

\[
n_0 = \frac{\lambda_1 P_0}{\lambda_2} = \frac{Q_0}{\lambda_3} = \frac{R_0}{\lambda_1 - \lambda_3}
\]

where \(P_0, Q_0, R_0\) are the initial number of atoms of A, B, C present, and \(\lambda_1, \lambda_2, \lambda_3\) are the constants of transformation.

Using the same quotations as in case (1), but remembering the new initial conditions, it can easily be shown that the number of particles \(P, Q, R\) of the matter A, B, C existing at the time \(t\) after removal are given by

\[
P = \frac{n_0}{\lambda_1} e^{-\lambda_1 t},
\]

\[
Q = \frac{n_0}{\lambda_2} \left(1 - e^{-\lambda_1 t}\right),
\]

\[
R = \frac{n_0}{\lambda_3} \left(1 - e^{-\lambda_3 t}\right),
\]

where \(a = \lambda_1 (\lambda_2 - \lambda_3)\) and \(b = -\lambda_3 (\lambda_1 - \lambda_3)\).

The curves expressing the rate of variation of \(P, Q, R\) with time are in these cases very different from case (1).

(c) The matter A is supplied at a constant rate from a primary source. Required to find the number of particles of A, B and C at any time \(t\) later, when initially A, B, and C were absent.

This is a converse case from case (2) and the solutions can be obtained in general form by inversion. Initially suppose A, B and C are in equilibrium with the primary source which supplied A at the same constant rate. The source is then removed and the amounts of A, B and C vary according to the equation given in case (2). The source after removal is unable to supply any C at the same rate as before. Since initially the product A was in equilibrium with the source, and the radioactive processes are in no way changed by the removal of the source, it is clear that the amount of A present in the two parts in which the matter is distributed is unchanged. If \(P\) be the amount of A produced by the source in the time \(t\), and \(P\)
In general, it has been found that each product shows distinctive chemical or physical behavior which allows of its partial or complete separation from a mixture of other products. It must be remembered that in most cases the amount of radioactivity is very small, and the presence of radioactivity is inferred from its characteristic radioactivity by differences in velocity when isolated. For example, a separation may be achieved by placing the mixture on a strip of filter paper and assisting the migration of the constituent radiations by means of the electric current. In some cases, a separation may be achieved by allowing the mixture to pass through a column of a suitable adsorbent substance, and then deducing the various products from the column, or by allowing the mixture to pass through a suitable crystallization solution, and then deducing the various products from the crystallized mass. In other cases, a separation may be achieved by depositing the mixture on a suitable adsorbent substance, and then deducing the various products from the adsorbed material, or by allowing the mixture to pass through a suitable crystallization solution, and then deducing the various products from the crystallized mass. removal from the emanation for 20 minutes, radium A has practically disappeared and the a rays arise entirely from radium C. Radium C has proved very valuable in radioactive measurements as providing an intense source of homogeneous a rays. Twenty-four hours after removal, the activity due to radium B and C has become exceedingly small. The wire, however, still shows a very small residual activity, first noted by Mme Curie. This residual activity measured by the a rays rapidly increases with the time and reaches a maximum in about three years. The active deposit of slow change has been measured in detail by Rutherford (23) and by Meyer and Schweidler (24). From such results as these, lasting three-successive a rays—radium D, E and F. Radium D is a rayless substance of slow period of transformation. Its period has been calculated by Rutherford to be about 40 years, and by Meyer and Schweidler about 12 years. Antoff (25) finds the period of about 17 years. Radium D changes into E, a b ray product of period about 5 days, and E into F, an a ray product of period 140 days. It was at first thought that radium E was complex, but no evidence of this has been observed by Antoff. The product radium F is of special interest, for it is identical with polonium—the first active body separated by Mme Curie. In a similar way it has been shown that radium D is the primary source of the activity observed in lead or "radiolead" separated by Hofmann. It is interesting to note what valuable results have been obtained from an examination of the minute residual activity observed on bodies exposed in the presence of the radium emanation.

Radium Emanation.—The radium emanation is to be regarded as a typical radioactive product or transition element which exists in a gaseous form. It is produced from radium at a constant rate, and is transformed into radium A and helium. Its half-period of transformation is 3-86 days. The emanation from radium has been purified by condensing it in liquid air, and pumping out the residual gases. The volume (26) of the emanation at normal pressure and temperature to be derived from one gram of radium in equilibrium is about 0-6 cubic millimetres. This small quantity of gas contains initially more than three-quarters of the total activity of the radium before its separation. In a pure state, the emanation is 100,000 times as active weight for weight as pure radium. Pure emanation in a spectrum tube gives a characteristic spectrum of bright lines (27). The discharge in the gas is bluish in colour. With continued sparking, the emanation is driven into the walls of the tube and the electrodes. Notwithstanding the minute volume of emanation available, the boiling-point of the emanation has been determined at various pressures. At atmospheric pressure Rutherford (28) found the boiling-point to be −67°C, and Gray and Ramsay (29) 71°C. Liquid emanation appears colourless when first condensed; when the temperature is lowered, the liquid emanation freezes, and at the temperature of liquid air glows with a bright rose colour. The density of liquid emanation has been estimated at 3.5 or 6.

Approximate estimates of the molecular weight of the radium emanation were early made by diffusion methods. The molecule radium in most cases is assumed about 83% of the atom helium, its atomic weight should be 226-4=222. The emanation appears to have no definite chemical properties, and in this respect belongs to the group of inert monatomic gases of which helium and argon are the best known examples. It is partially soluble in water, and readily absorbed by charcoal.

Thorium.—The first product observed in thorium was the emanation. This gives rise to the active deposit which has been analysed by Rutherford, Miss Brooks and by Hahn, and shown to consist of probably four products—thorium A, B, C and D. Thorium A is a rayless product of period 10-5 hours; thorium B an a ray product of period about one hour. The presence of thorium C has been inferred from the two types of a rays present in the active deposit, but no chemical separation of B and C has yet been found possible. Hahn has shown that thorium D—a b ray product of period 3 minutes—can be separated by the recoil method. A special interest attaches to the product thorium X (30), which was first separated by Rutherford and Soddy, since experiments with this substance laid the foundation of the general theory of radioactive transformations. A close analysis of thorium has led to the separation of a number of new products. Hahn (31) found that a very active substance emitting a rays, which gave rise to thorium X, could be separated from thorium minerals. This active substance, which is called radiothorium, has been closely examined by Hahn and Blanc. Its period of decay was found by Hahn to be about 2 years, and by Blanc to be 737 days. From an examination of the activity of commercial thorium nitrate of different ages, Hahn showed that another product must be present, which he called mesothorium. This is separated from thorium with Th X by precipitation with ammonia. Thorium is first transformed into the rayless product mesothorium, of period about 5 years. This gives rise to a b ray product of quick transformation, which in turn changes into radithorium. This changes into thorium X, and so on through a long series of changes. When isolated in the pure state, radithorium would have an activity about a thousand times greater than radium, but would lose its activity with time with a period of about 2 years. Mesothorium, when first separated, would be inactive, but in consequence of the production of radiothorium, its activity would rapidly increase for several years. After reaching a maximum, it would finally decay with a period of five years. Since a large amount of thorium is separated annually from thorium minerals, it would be of great importance at the same time to separate the radiothorium and mesothorium present. For many purposes active preparations of these substances would be as valuable as radium itself, and the amount of active matter from this source would be greater than that at present available from the separation of radium from uranium minerals.

Actinium.—The transformations observed in actinium are very analogous to those in thorium. Actinium itself is a rayless product which changes into radioactinium, an a ray product of period 10-5 days, first separated by Hahn (32). This changes into actinium X, of period 10-2 days, first separated by Godlewski (33). Actinium X is transformed into the emanation which in turn gives rise to three further products, called actinium A, B and C. Although very active preparations of actinium have been prepared, it has thus far not been found possible to separate the actinium from the rare earths with which it is mixed. We do not in consequence know its atomic weight or spectrum.

Origin of Radium.—According to the transformation theory, radium, like all other radioactive products, must be regarded as a changing element. Preliminary calculations showed that radium must have a period of transformation of several thousand years. Consequently in order that any radium could exist in old minerals, the supply must be kept up by the transformation of some other substance. Since radium is always found associated with uranium minerals, it seemed probable from the beginning that uranium must be the primary element from which radium is derived. If this were the case, in old minerals which have not been altered by the action of percolating waters, the ratio of the amount of radium to uranium in a mineral must be a constant. This must evidently be the case, for in a state of equilibrium the rate of breaking up of radium must equal the rate of supply of radium from uranium. If P, Q be the number of atoms of uranium and radium respectively in equilibrium, and λ1, λ2 their constants of change, then

\[ \frac{\alpha_0}{\alpha} = \frac{\lambda_1}{\lambda_2} = \frac{P}{Q} = \frac{\lambda_2}{\lambda_1} = T_a/T_r, \]

where T_a and T_r are the half-periods of transformation of uranium and radium respectively. The work of Boltwood (34), Strutt (35) and McCoy (36) has conclusively shown that the ratio of radium to uranium in old minerals is a constant. Boltwood and Strutt determined the quantity of radium present in a mineral by the emanation method, and the amount of uranium by analysis.
RADIOACTIVITY

In order, however, to obtain a direct proof of the genetic relation between uranium and radium, it is necessary to show that radium appears after some time in a uranium compound from which all trace of radium has been initially removed. It can readily be calculated that the growth of radium should be easily observed by the emanation method in the course of one week, using a kilogram of uranium nitrate. Experiments of this kind were first made by Soddy (37), but initially no definite evidence was obtained that radium grew in the solution at all. The rate of production of radium, if it took place at all, was certainly less than 1/10,000th part of the amount to be expected if uranium were transformed directly into radium. It thus appeared probable that one or more products of slow period of transformation existed between uranium and radium. Since uranium must be transformed through these intermediate stages before radium appears, it is evident that the initial rate of production of radium under these conditions might be extremely small. This conclusion has been confirmed by Soddy, who has shown that radium does appear in the solution which has been placed aside for several years.

Since the direct parent of radium must be present in radioactive minerals, one of the constituents separated from the mineral must grow radium. This was shown to be the case by Boltwood (38), who found that actinium preparations produced radium at a fairly rapid rate. By the work of Rutherford and Boltwood, it was found that the growth of radium was not due to actinium itself, but to a new substance separated in some cases with the actinium. This new substance, which emits alpha rays, was separated by Boltwood (38), and called by him Actinium. It has chemical properties very similar to thorium. Soddy has shown that the period of ionium is probably not less than 20,000 years, indicating that ionium must exist in uranium minerals in not less than ten times the quantity of radium. It has not yet been directly shown that uranium produces ionium, but there can be no doubt that it does so. Since ionium produces radium, Boltwood (38) has determined by direct experiment that radium is half transformed in 2000 years—a number in good agreement with other data on that subject. The constant relation between uranium and radium will only hold for old minerals where there has been no opportunity for chemical alteration or removal of its constituents by the action of percolating water or other agencies. It is quite possible that altered minerals of no great age will not show this constant relation. It seems probable that this is the explanation of some results of Mlle Gleditsch, where the relation between uranium and radium has been found not to be constant for some mineral specimens.

Connexion of the Radioelements.—We have already seen that a number of slowly transforming radioactive substances, viz., polonium (radium F), radiolead (radium D) and ionium are linked up to the uranium-radium series of transformations. Boltwood (30) has made a systematic examination of the relative activity in the form of very thin films due to each of the products present in the uranium-radium family. The results are shown in the following table, where the activity of pure uranium itself is taken as unity—

Taking into account the differences in the ionization due to an alpha particle from the various products, the results indicate that uranium expels two alpha particles for one from each of the other alpha ray products in the series of transformations. This indicates either that two particles are expelled during the transformation of the atom of uranium, or that another alpha ray product is present which has so far not been separated from the uranium.

Although thorium is nearly always present in old uranium minerals and uranium in thorium minerals, there does not appear to be any radioactive connexion between these two elements. Uranium and thorium are to be regarded as two distinct radioactive elements. With regard to actinium, there is still no definite information of its place in the scheme of transformations. Boltwood has shown that the amount of actinium in uranium minerals is proportional to the content of uranium. This indicates that actinium, like radium, is in genetic connexion with uranium. On the other hand, the activity of actinium with its series of alpha rays is less than that of radium itself or uranium. In order to explain this anomaly, Rutherford has suggested that, at a certain stage of disintegration of the uranium-radium series, the disintegration is complex, and two distinct kinds of matter appear, one in much larger quantity than the other. On this view, the smaller fraction is actinium, so that the latter is a branch descendant of the main uranium-radium series.

End Products of Transformation.—It is now definitely established that the alpha particle expelled from any type of radioactive matter is an atom of helium, so that helium is a necessary accompaniment of radioactive changes involving the expulsion of alpha particles. After the radioactive transformations have come to an end, each atom of uranium or thorium and actinium should give rise to an end or final product, which may be either a known element or some unknown element of very slow period of transformation. Supposing, as seems probable, that the expulsion of an alpha particle lowers the atomic weight of an element by four units—the atomic weight of helium—the atomic weights of each of the products in the uranium and radium series can be simply calculated. Since uranium expels two alpha particles, the atomic weight of the next ray product, helium, is 238-2-8 or 230-5. The atomic weight of radium comes out to be 266-5, a number in agreement with the experimental value. Similarly the atomic weight of polonium is 210-5, and that of the final product after the transformation of polonium should be 206-5. This value is very close to the atomic weight of lead, and indicates that this substance is the final product of the transformation of radium.

This suggestion was first put forward by Boltwood (40), who has collected a large amount of evidence bearing on this subject. Since in old minerals the transformations have been in progress for periods of time, in some cases measured by hundreds of millions of years, it is obvious that the end product, if a stable element, should be an invariable companion of the radielement, and be present in considerable quantity. Thus, in the radioactive minerals from Debierne have independently shown that polonium produces helium—a result to be expected, since it emits alpha particles.

Production of Helium.—In 1902 Rutherford and Soddy suggested that the helium which is invariably found in radioactive minerals was derived from the disintegration of radioactive matter. In 1903 Ramsay and Soddy definitely showed that helium was produced by radium and also by its emanation. From the observed mass of the alpha particle, it seemed probable from the first that the alpha particle was an atom of helium. This conclusion was confirmed by the work of Rutherford and Geiger (43), who showed that the alpha particle was an atom of helium carrying two unit charges of electricity. In order to prove definitely this relation, it was necessary to show that the alpha particles, quite independently of the active matter from which they were expelled, gave rise to helium. This was done by Rutherford and Royle (42), who allowed the alpha particles from a large quantity of emanation to be fired through the
very thin glass walls of the containing tube. The collected particle gave the spectrum of helium, showing, without doubt, that the α particle must be a helium atom.

Since the α particle is an atom of helium, all radioactive matter which expels α particles must give rise to helium. In agreement with this, Debarne and Giesel have shown that actinium as well as radium produces helium. Observations of the production of helium by radium have been made by Ramsay and Soddy, Curie and Dewar, Hinstedt and others.

The rate of production of helium per gram of radium was first definitely measured by Dewar (43). His preliminary measurements gave a value of 134 cubic mms. of helium per year per gram of radium and its products. Later observations extending over a larger interval give a rate of production about 168 cubic mms. per year. As a result of preliminary measurements, Boltwood and Rutherford (44) have found a growth of 163 cubic mms. per year. It is of interest to note that the rate of production of helium by radium is in excellent agreement with the value calculated theoretically. From their work of counting the particles and measuring their charge, Rutherford and Geiger showed that the rate of production of helium should be 152 cubic mms. per year.

Properties of the α Rays.—We have seen that the rays are positively charged atoms of helium projected at a high velocity, which are capable of penetrating through thin metal sheets and several centimetres of air. Early observations indicated that the ionization due to a layer of radioactive matter decreased approximately according to an exponential law with the thickness of the absorbing matter placed over the active matter. The true nature of the absorption of the α rays was first shown by Bragg and by Bragg and Kleeman (45). The active particles projected from a thin film of active matter of one kind have identical velocities, and are able to ionize the air for a definite distance, termed the "range" of the α particle. It was found that the ionization per centimetre of path due to a narrow pencil of α rays increases with the distance from the active matter, at first slowly, then more rapidly, near the end of the range. After passing through a maximum value the ionization falls off rapidly to zero. The range of an α particle in air has a definite value which can be accurately measured. If a uniform screen of matter is placed in the path of the pencil of rays the range is reduced by a definite amount proportional to the thickness of the screen. All the α particles have the velocity reduced by the same amount in their passage through the screen. The ranges in air of the α rays from the various products of the radioelements have been measured. The ranges for the different products vary between 2-8 cms. and 8-6 cms.

Bragg has shown that the range of an α particle in different elements is nearly proportional to the square roots of their atomic weights. Using the photographic method, Rutherford (46) showed that the velocity V of an α particle of range R cms. in air is given by \( V^2 = K(R + 1:29) \), where \( K \) is a constant. In his experiments he was unable to detect particles which had a velocity lower than 3-8 X 107 cm. per second. Geiger (47), using the scintillation method, has recently found that particles of still lower velocity can be detected under suitable conditions by the scintillations produced on a zinc sulphide screen. He has found that the connexion between velocity and range can be closely expressed by \( V^2 = KR \), where \( K \) is a constant.

On account of the great energy of motion of the α particle, it was at first thought that it pursued a rectilinear path in the gas without appreciable deflection due to its encounters with the molecules. Geiger (48) has, however, shown by the scintillation method that the α particles are scattered to a marked extent in passing through matter, and that the scattering increases with the atomic weight of the substance traversed, and becomes more marked with decreasing velocity of the α particle. A small fraction of the α particles falling on a thick screen are deflected through more than a right angle, and emerge again on the side of incidence.

Rutherford and Geiger (49) have devised an electrical method of counting the α particles expelled from radioactive matter. The α particle enters through a small opening into a metal tube containing a gas at a reduced pressure. The ionization produced by the α particle in its passage through the gas is magnified several thousand times by the movement of the ions in a strong electric field. In this way, the entrance of an α particle into the detecting vessel is shown by a sudden and large deflection of the measuring instrument. By this method, they determined that 3-4 × 1018 α particles are ejected per second from one gram of radium itself and from each of its α ray products in equilibrium with it. By measuring the charge on a counted number of α particles, it was found that the α particle carries a positive charge of 9-3 × 10−18 electrostatic units. From other evidence, it is known that this must be twice the fundamental unit of charge carried by the hydrogen atom. It follows that this unit charge is 4-65 × 10−18 units. This value is in good agreement with numerous recent determinations of this fundamental quantity by other methods.

With this data, it is possible to calculate directly the values of some important radioactive data. The calculated and observed values are given below:

\[
\begin{align*}
\text{Volume of the emanation in cubic millimetres per gram of radium} & = 585 \times 10^{-6} \\
\text{Volume of helium in cubic millimetres produced per year per gram of radium} & = 158 \times 10^{-6} \\
\text{Heating effect of radium per gram per hour in gram calories} & = 113 \times 10^{-6} \\
\text{Half-period of transformation of radium in years} & = 1760 \\
\end{align*}
\]

The calculated values are in all cases in good agreement with the experimental numbers.

It is well known from the experiments of Sir William Crookes (50) that the α rays produce visible scintillations when they fall on a screen of phosphorescent zinc sulphide. This is shown in the instrument called the spinthariscope. By means of a suitable microscope, the number of these scintillations on a given area in a given time can be counted. The number so obtained is practically identical with the number of α particles incident on the screen, determined by the electrical method of counting. This shows that each α particle produces a visible flash of light when it falls on a suitable zinc sulphide screen.

The scintillations produced by α rays are observed in certain diamonds, and their number has been counted by Regener (51) and the charge on each particle has been deduced. The latter was the first to employ the scintillation method for actual counting of α particles. Kinoshita has shown that the number of α particles can also be counted by the photographic method, and that each particle must produce a detectable effect.

Absorption of the β Rays.—We have seen that the β particles, which are emitted from a number of radioactive products, carry a negative charge and have the same small mass as the particles constituting the cathode rays. The velocity of expulsion and penetrating power of the β rays varies widely for different products. For example, the rays from radium B are very easily absorbed, while some of the rays from radium C are of a very penetrating type. It has been found that for a single β ray product, the particles are absorbed according to an exponential law with the thickness of matter traversed, and Hahn has made use of this fact to isolate a number of new products. It has been generally assumed that the exponential law of absorption is a criterion that the β rays are all expelled at the same speed. In addition, it has been supposed that the β particles do not decrease much in velocity in passing through matter. Wilson has recently made experiments upon homogeneous β rays, and finds that the intensity of the radiation falls off in some cases according to a linear rather than to an exponential law, and that there is undoubted evidence that the β particles decrease in velocity in traversing matter. Experiments upon the absorption of β rays are greatly complicated by the scattering of the β rays in their encounters with the molecules. For example, if a pencil of β rays falls on a metal, a large fraction of the rays are scattered...
sufficiently to emerge on the side of incidence. This scattering of the $\beta$ rays has been investigated by Eve, McClenann, Schmidt, Crowther and others. It has been found that the scattering for different chemical elements is connected with their atomic weight and their position in the periodic table. McCelland and Schmidt have given theories to account for the absorption of $\beta$ rays by matter. The whole problem of absorption and scattering of particles by substances is very complicated, and the question is still under active examination and discussion. The negative charge carried by the $\beta$ rays has been measured by a number of observers. It has been shown by Rutherford and Makower that the number of $\beta$ particles expelled per second from one gram of radium in equilibrium is about that to be expected if each atom of the $\beta$ ray products in breaking up emits one $\beta$ particle.

Heat Emission of Radioactive Matter.—In 1903 it was shown by Curie and Laborde (52) that a radium compound was always hotter than the surrounding medium, and radiated heat at a constant rate of about 100 gram calories per hour per gram of radium. The rate of evolution of heat by radium has been measured subsequently by a number of observers. The latest and most accurate determination by Schweidler and Hess, using about half a gram of radium, gave 118 gram calories per gram per hour (53). There is now no doubt that the evolution of heat by radium and other radioactive matter is mainly a secondary phenomenon, resulting mainly from the expulsion of $\alpha$ particles. Since the latter have a large kinetic energy and are easily absorbed by matter, all of these particles are stopped in the radium itself or in the envelope surrounding it, and their energy of motion is transformed into heat. On this view, the evolution of heat from any type of radioactive matter is proportional to the kinetic energy of the expelled $\alpha$ particles. The view that the heating effect of radium was a measure of the kinetic energy of the $\alpha$ particles was strongly confirmed by the experiments of Rutherford and Barnes (54). They showed that the emanation and its products when removed from radium were responsible for about three-quarters of the heating effect of radium in equilibrium. The heating effect of the radium emanation decayed at the same rate as its activity. In addition, it was found that the ray products, viz. the emanation radium A and radium C, each gave a heating effect approximately proportional to their activity. Measurements have been made of the heating effects of thorium and uranium, and the results are given in the form of a table. In each case, the evolution of heat has been shown to be approximately a measure of the kinetic energy of the $\alpha$ particles.

Experiments on the evolution of heat from radium and its emanation have brought to light the enormous amount of energy accompanying the transformation of radioactive matter where $\alpha$ particles are emitted. For example, the emanation from one gram of radium in equilibrium with its products emits heat initially at the rate of about 90 gram calories per hour. The total heat emitted during its transformation is about 12,000 gram calories of New. the initial volume of the emanation from one gram of radium is 6 cubic millimetres. Consequently one cubic centimetre of emanation during its life emits 2 $\times$ 10$^8$ gram calories. Taking the atomic weight of the emanation as 222, one gram of the emanation emits during its life 2 $\times$ 10$^8$ gram calories of heat. This evolution of heat is enormous compared with that emitted in any known chemical reaction. There is every reason to believe that the total emission of energy from any type of radioactive matter during its transformation is of the same order of magnitude as for the emanation. The atoms of matter must consequently be regarded as containing enormous energy which are only released by the disintegration of the atom.

A large amount of work has been done in measuring the amount of the thorium and radium emanation in the atmosphere, and in determining the quantity of radium and thorium distributed on the surface of the earth. The information already obtained has an important bearing on geology and atmospheric electricity.

RADIOLARIA, so called by E. Haeckel in 1852 (Polycystina, by C. G. Ehrenberg, 1838), the name given to Marine Sarcodina, in which the cytoplasmic body gives off numerous fine radiating pseudopods (rarely anastomosing) from its surface, and is provided with a chitinous "central capsule," surrounding the inner part which encloses the nucleus, the inner and outer cytoplasm communicating through either one or three apertures or numerous pores in the capsule. The extracapsular cytoplasm is largely transformed into a gelatinous substance ("calymya"), through which a granular network of plant-like, or when a continuous layer bearing the pseudopods at the surface; this gelatinous layer is full of large vacuoles, "alveoli," as in other pelagic Sarcodina (Heliozoa, g.s.), Globigerinacea, &c., among Foraminifera (g.s.). The protoplasm may contain oil-globules, pigment-grains, reserve-grains and crystals. There is frequently a skeleton present, either of silica (pure or containing a certain amount of organic admixture), or of "acanthin" (possibly a protelid, allied to vellitin, but regarded by W. Schewikoffi as a hydrated silicate of calcium and aluminium); never calcareous or arenaceous. The skeleton may consist of isolated or cellularized or even a latticed shell, which, in correlation with the greater resistance of its substance, is of lighter and more elegant structure than in the Foraminifera. The alveoli contain a liquid; which, as shown by Brandt, is rich in carbon dioxide, and in proportion to its abundance may become much lighter than sea-water; and possibly the gelatinous substance of the calymya is also lighter than the medium. In Acantharia the protoplasm at the base
of the projecting spines is often differentiated into a bundle of fibres converging on to the spines some way up (distally); these, comparable to the myonemes of Infusoria (p.2. &c., and termed "myophricts", possibly serve to drag outwards the surface and so extend it, with concurrent dilatation of the alveoli, and lower the specific gravity of the animal. In this group also a thick temporary flagellum "sarcoflagellum" may be formed, apparently by the coalescence of a number of pseudopodia. The pigmented mass or "phaeodium" in the ectoplasm of Phaeodaria appears to be an excretory product, formed within the central capsule and passing immediately outwards; a similar uniform deposit of pigmented granules occurs in the Colloid species, Thalassicola nucleata. The wall of the central capsule is simple in the Spumellaria, but formed of two layers in the Nassellaria and Phaeodaria. In the Nassellaria the oscule is simply a perforated area, and a cone of differentiated fibres in the intracapsular cytoplasm has its base on it: it is termed the "porocone," and the fibres may possibly be muscular (myonemes). In Phaeodaria, the inner membrane at each oscule is prolonged through the outer into a tube ("proboscis"): the outer membrane of the principal oscule forms a large radially striated circular plate, the "astropyile," or "operculum." The innermost shell of some with concentric shells may lie within the central capsule, or even entirely within the nucleus; this is due to the growth of these organs after the initial shell is formed, so that they pass out by lobes through the latticed openings of the embryonic shell, which lobes ultimately coalesce outside the embryonic chamber, and so come finally to invest it (fig. III. 17). In some, a symbiosis occurs with Zooxanthella, Brandt, a Flagellate of the group Chrysomadinae, which in the resting state inhabits the extracapsular cytoplasm growing and dividing freely therein, and only (under study) becoming free and flagellate on the death of the host (fig. III. 4, 6-13). The Silicoflagellata or Dictyochidae, also possessing a vegetable colouring matter, but with a skeleton of impure silica (like that of Phaeodaria), may pass some of their lives in symbiosis with Radiolaria.

Living Radiolaria were first observed and partially described by W. J. Tilesius in 1803-6 and 1814, by W. Baird in 1830, and by C. G. Ehrenberg in 1831, as luminous organisms in the sea; F. J. F. Meyer in 1834 recognized their animal character and the silicious nature of their spicules. Ehrenberg a little later described a large number of Nassellarian skeletons under the name of Polycystina (1838), but without more than a very slight knowledge of a few living forms. T. H. Huxley in 1851 made the first adequate study of the living animal, and was followed by Joh. Müller in the same decade. E. Haeckel began his publications in 1862, and in two enormous, abundantly illustrated, systematic works, besides minor publications, has dealt exhaustively with the cytology, classification, and distribution of the class. Next in value come the contributions of Richard Hertwig (largely developmental), besides those of L. Cienkowski, Karl Brandt and A. Borgert, while to F. Dreyer and V. Haecker we owe valuable studies on the physical relations of the skeleton.

Our classification is taken from Haeckel.

A. Spumellaria, Haeck. (Peripyleae, Hertwig). Central capsule perforated with numerous evenly distributed pores. Skeleton siliceous, lattice or of detached spicules, or absent. Form homaxonic or with at least three planes of symmetry intersecting at right angles, rarely irregular or spiral, sometimes forming colonies, i.e. with several central capsules in a common external cytoplasm.

B. Nassellaria, Haeck. (Actinyleae, Hertw.). Skeleton of spicules of acanthin radiating from a centre, and usually twenty,

![Fig. I.—Thalassicola pelagica, Haeckel; X25. CK, central capsule; EL', extracapsular protoplasm; al, alveoli, liquid-holding vacuoles in the protoplasm similar to those of Heliozoa, Hastingera, &c.; ps, pseudopodia. The minute unlettered dots are the "yellow cells."](image1)

![Fig. II.—Eucyrtidium cranioides, Haeck.; X150; one of the Nassellaria. Entire animal as seen in the living condition. The central capsule is hidden by the beehive-shaped siliceous shell within which it is lodged.](image2)
RADIOLARIA

disposed on five successive zones of four on alternating meridians, the zones corresponding to equator, tropics and circumpolar circles on the globe; pores of central capsule in scattered groups.

Fam. 2. *Acanthonida*. Spines twenty, simple, usually equal. *Acanthometra*, *J. Möll.; (fig. iv. 6, 7); Astroleocline, *Haeck.; Amphileion*, *Haeck.

(fg. iii. 18).

Fam. 3. *Sphaerophractida*. Spines equal, branching and often coalescing into a latticed shell, homaxonic.

Fam. 4. *Prinophractida*. Branching spines coalescing into a latticed shell which is elongated and elliptical in any plane.

C. *Nassellarida*. *Haeck. (Monopylea, Hertw.). Silico-skeletal Radiolaria in which the central capsule is typically monaxonic (con-shaped), with a single perforate area (pore-plate) placed on the basal face of the cone, or in the nucleus single, the skeleton is extracapsular, and forms a scaffold-like or beehive-like structure of monaxonic form, a tripod or calthrop, a sagittal ring, or a combination of these.

Fam. 3. *Spyroidea*. Shell latticed around the sagittal ring ("cephals") sometimes with a lower chamber added.

Fam. 5. *Cyrtidea*, *Haeck. Skeleton a monaxonic or triradiate shell, or continuous piece (beehive-shaped). Genera: *Halicyclpya*, *Haeck.; Eucyclidium*, *Haeck. (fig. ii.); Corpoconium*, *Haeck. (fig. iv. 3).

(fg. iv. 1).

D. *Phaeodaria*. *Haeck. (Triplacca, Hertw.). Radiolaria of cruciate symmetry, prolonged into tubular processes with three oscula to the central capsule, one inferior, the principal, and two symmetrically placed on either side of the opposite pole; skeleton spicles, a network of hollow filaments, or a minutely alveolate shell, of a combination of silica with organic substance; extracapsular protoplasm containing in front of the large osculus an agglomeration of dusky purplish or greenish pigment ("phae-oicum").

Fam. 2. *Phaeophora*, *Haeck. Spicles united into a latticed shell. Genera: *Aulospheera*, *Haeck. (fig. iv. 9); Alouspheera, *Haeck.; Canna-

Fam. 3. *Phaeogramida*. *Haeck. Skeleton continuous, traversed by fine canals or finely alveolate, provided with at least one pylone. Genera: *Challengeria*, *Wvy.; Thomson; Lithograma*, *Haeck.

Fam. 4. *Phaeonconida*. *Haeck. Shell as in Phaeophractida, but of two symmetrical halves (valves), which move in the plane of the three oscules ("frontal") of Haeckel, who terms the plane of symmetry through the shells ("sagittal"). Genera: *Conchus*, *Haeck.; Coelocandrum*, *Haeck. (fig. iv. 4).

The following passages may be repeated here from Sir E. Ray Lankester’s article "Protozoa" in the 9th edition of this Encyclopaedia:

"The important differences in the structure of the central capsule of different Radiolaria were first shown by Hertwig, who also discovered that the spines of the Acanthometridea consist not of silica but of an organic compound (but see above). In view of this latter fact and of the peculiar numerical and architectural features of the Acanthometrid skeleton, it seems proper to separate them altogether from the other Radiolaria. The Periplacca may be regarded as the starting-point of the Radiolarian pedigree, and have given rise on the one hand to the Acanthometridea, which

Fig. III.—Radiolaria. 1. Central capsule of *Thalassioctyla* nucleata, Huxley, in radial section. a, the large nucleus (Binnenblaschen); b, corpuscular structures of the intracapsular protoplasm containing concretions; c, wall of the capsule (membranous shell), showing the fine radial pore-canals; d, nucleolar fibres (chromatin substance) of the nucleus. 2, 3. *Collozoa inermis*, J. Müller, two different forms of colonies, of the natural size. 4. Central capsule from a colony of *Collozoa inermis*, showing the intracapsular protoplasm and nucleus, broken up into a number of spores, the germs of swarm-spores or flagellulae; each encloses a crystalline rod. 6, yellow cells lying in the extracapsular protoplasm. 6. A small colony of *Collozoa inermis*, magnified 25 diameters. a, alveoli (vaccules) of the extracapsular protoplasm; b, central capsules, each containing besides protoplasm a large oil-globule, 6-13. Yellow cells of various Radiolaria: 6, normal yellow cell; 7, 8, division with formation of transverse septum; 9, a modified condition according to Brandt; 10, division of a yellow cell into four; 11, amoeboid condition of a yellow cell from the body of a dead Sphaerozoa; 12, a similar cell in process of division; 13, a yellow cell the protoplasm of which is creeping out of its cellulose envelope. 14. *Heliosphora inermis*, Haeck., living example; X 400. 6, nucleus; 5, central capsule; 6, siliceous basket-work skeleton. 15. Two swarm-spores (flagellulae) of *Collozoa inermis*, set free.
from such a central capsule as that drawn in 4; each contains a crystal b and a nucleus a. 16. Two swarm-spores of Coelode
crion interme, of the second kind, viz. devoid of crystals, and of
two sizes, a macrospore and a microspore. They have been set
free from central capsules with contents of a different appearance
from that drawn in 4. a, nucleus. 17. Acanthometrida. Entire animal
in optical section. a, nucleus; b, wall of the central capsule;
c, innermost siliceous shell enclosed in the nucleus; d, middle
shell lying within the central capsule; e, outer shell lying in the
extracapsular protoplasm. Four radial siliceous spines holding
the three spherical shells together are seen. The radial fibril-
lation of the protoplasm and the fine extracapsular pseudopodia are
to be noted. 18. Amphilocidc mesaninis, Haeck.; X 200; one of the Acanthometrida. Entire animal as seen living.

Fig. IV.—Radiolaria. 1. Lithocircus annularis, Hertwig; one
of the Monoplexa. Whole animal in the living state (optical
section); a, nucleus; b, wall of the central capsule; c, yellow
cells; d, perforated area of the central capsule (Monoplexa).
2. Cystidium interme, Hertwig; one of the Monoplexa. Living
animal. An example of a Monoplexan destitute of skeleton.
a, nucleus; b, capsule-wall; c, yellow cells in the extracapsular
protoplasm. 3. Carposaculum diadema, Haeck.; optical
section of the beehive-shaped shell to show the form and position
of the protoplasmic body. a, the tri-lobed nucleus; b, the
siliceous shell; c, oil-globules; d, the perforate area (pore-plate)
of the central capsule. 4. Coelolampra frasculum, Haeck.;
living animal, compound; one of the Tripylela. c, peculiar
characteristic dark pigment (phacoium) surrounding the central capsule b.
The peculiar branched siliceous skeleton, consisting of hollow
fibres, and the expanded pseudopodia are seen. 5. Central
capsule of one of the Peripylela, isolated, showing a, the nucleus;
b, c, the inner and the outer laminae of the capsule wall; d, the
chief or polar aperture; e, the two secondary apertures.
6. 7. Acanthometrida; see Haeck. 7 shows the animal in optical
section, so as to bring out the characteristic meeting of the
spines at the central point as in all Acanthometrida; 6 shows the
transition from the uninuclear to the multinuclear condition by
the breaking up of the large nucleus. a, small nucleus; b, large
fragments of the single nucleus; c, wall of the central capsule;
d, extracapsular jelly (not protoplasm); e, peculiar intracapsular
yellow cells. 8. Spongosphora streptocantha, Haeck.; one of the Peripylela. Siliceous skeleton not quite completely drawn
on the right side. a, the spherical extracapsular shell (compare
fig. III. 17), supporting very large radial spines which are
connected by a spongy network of siliceous fibres. 9. Aulo-
sphaera eleganssima, Haeck.; one of the Phaeodaria. Half of the
spherical siliceous skeleton.

RADIOLARIA

Peripylela.

Arch-peripylela. Radiolaria.

"The occasional total absence of any siliceous or acanthinous
skeleton does not appear to be a matter of classificatory importance,
since skeletal elements occur in close connexion with very few form-genera
which are totally devoid of skeleton. Similarly it does not appear
to be of great significance that some forms (Polycyttaria)
form colonies, instead of the central capsules separating from one
another after fission has occurred.

"It is important to note that the skeleton of siles or acanthin
does not correspond to the shell of other Sarcodina, which appears
rather to be represented by the membranous central capsule. The
skeloton does, however, appear to correspond to the spicules of
Heliozoa, and there is an undeniable affinity between such a form as
Clathrula and the Sphaerid Peripylela (such as Heliosphaera.
fig. II. 14). The Radiolaria are, however, a very strongly marked
group, definitely separated from all other Sarcodina by the
membranous central capsule sunk in their protoplasm. Their
differences inter se do not affect their essential structure. The varia-
tions in the chemical composition of the skeleton and in the perfora-
tion of the capsule do not appear superficially. The most obvious
features in which they differ from one another relate to the form
and complexity of the skeleton, a part of the organism so little charac-
teristic of the group that it may be wanting altogether. It is not
known how far the form-species and form-genera which have been
distinguished in such profusion by Haeckel as a result of a study of
the skeletons are permanent (i.e., relatively permanent) physio-
logical species. There is no doubt that very many are local
and conditional varieties, or even merely stages of growth, of a single
Protean species. The same remark applies to the species discrimi-
ated among the shell-bearing Reticularia. It must not be supposed,
however, that less importance is to be attached to the distinguishing
and recording of such forms because we are not able to assert that
they are permanent species.

"The streaming of the granules of the protoplasm has been observed in
the pseudopodia of Radiolaria as in those of Heliozoa and
Reticularia; it has also been seen in the deeper protoplasm; and
granules have been definitely seen to pass through the pores of the
central capsule from the extracapsular to the extracapsular pro-
toplasm. A feebie vibrating movement of the pseudopodia has been occasionally noticed.

"The production of swarm-spores has been observed only in
Acanthometra and in the Polycyttaria and Thalassicodidae;
and only in the two latter groups have any detailed observations been
made. Two distinct processes of swarm-spore production have
been observed by Haeckel: one is distinguished by the character of the resulting spores, which are
called 'crystalligerous' and 'isospires' (fig. III. 15) in the one
case, and 'dimorphous' or 'anisospores' in the other (fig. III.
16). In both processes the nucleated protoplasm within the central
capsule breaks up by a more or less regular cell-division into small
pieces, the details of the process differing a little in the two cases. In those individuals which produce crystalline swarm-spires, each spore encloses a small crystal (fig. 111. 15). On the other hand, in those individuals which produce dimorphous swarm-spires, the contents of the capsule (which in both instances are set free by its natural rupture) are seen to consist of individuals of two sizes, 'megaspores' and 'microspores' of which the former (fig. 111. 16). The further development of the spores has not been observed in either case. Both processes have been observed in the same species, and it is suggested that there is an alternation of sexual and asexual generations, the crystalline spires developing directly into adults, which in their turn produce in their central capsules dimorphous swarm-spires (megaspores and microspores), which in a manner analogous to that observed in the Volvocinean Flagellata, with the same result—that is, another (and another still smaller) generation in the group. In Spumellaria it gives rise to colonial "polycystarian" forms when the extracapsular protoplasm does not divide.

The siliceous shells of the Radiolaria are found abundantly in certain rocks from Palaeozoic times onwards. They furnish, together with Diatoms and Sponge spicles, the silica which has been segregated out of the sea water. The most common accumulations of it occur in the "quartzite" (as much as 10%) in the Atlantic ooze, and in the celebrated "Barbados earth" (a Tertiary deposit) are the chief components.

In GRAPPIH.—The most important systematic works are those of E. Haeckel, Die Radiolarien (1862-67), and the "Report" on the Radiolaria of the "Challenger" Expedition (vol. xvii., 1887), which contains full lists of the older literature. Among the most important recent studies we may cite: B. Brandt, "Die Kolloidplatten der Radiolarien" in Fauna und Flora des Golfs von Neapel, xii. (1885); A. Borgert in Zeitschrift f. Wissenschaftliche Zoologie, li. (1901), and Zoologische Jahrbücher (Anatomic), xiii. (1900); F. Müller in Jahrb. für Naturw., xix. (1892); E. Haeckel in Zeitschr. f. Wiss. Zool., lxxxiii. (1905).

RADIOMETER. It had been remarked at various times, amongst others by Fresnel, that bodies delicately suspended within a partial vacuum are subject to apparent repulsion by radiation. The question was definitely investigated by Sir W. Crookes, who showed that a large leaf of paper, which had been ignited, was repelled by this process. The same effect was produced by radiation from the sun, from an incandescent body, and from a furnace. The rays from the sun are of course more powerful than those from a furnace, and the effect was greater. The question was then to ascertain whether the effect was produced by the direct action of the rays, or by the repulsion of the matter produced in the atmosphere by the rays of the sun. This was answered by Sir W. Crookes, who showed that the effect was produced by the direct action of the rays, and that the repulsion was a result of the pressure produced by the rays on the atmosphere. The question was then to determine the magnitude of the effect. This was done by means of a radiometer, which consists of a hollow metal tube, closed at one end, and provided with a small opening at the other. The tube is filled with a mixture of air and mercury, and the opening is covered with a glass plate. The glass plate is then removed, and the mixture of air and mercury is allowed to escape. The tube is then placed in a position where it is exposed to the action of the sun, and the effects produced are observed. The effect of the rays is to produce a pressure on the walls of the tube, which is measured by the deflection of a pointer attached to the tube. The deflection is proportional to the intensity of the radiation. The instrument is therefore a convenient means of measuring the intensity of the radiations.
the gas that is directly in contact with them, this equilibrium would be the actual state of affairs; and it would follow from the principle of Archimedes that, when extraneous forces such as gravity are not considered, the gas would exert no resultant force on any body immersed in it. On this ground Maxwell inferred that the forces acting in the radiometer are connected with gliding of the gas along the unequally heated boundaries; and as the laws of this slipping, as well as the constitution of the adjacent layer, are uncertain, the problem becomes very intricate. Such slipping had shown itself at high exhaustions in the experiments of A. A. Kundt and E. G. Warburg in 1875 on the viscosity of gases; its effects would be corrected for, in general, by a slight effective addition to the thickness of the gaseous layer.

Reynolds, in his investigation, introducing no new form of law of distribution of velocities, uses a linear quantity, proportional to the mean free path of the gaseous molecules, which he takes to represent (somewhat roughly) the average distance from which molecules directly affect, by their convection, the state of the medium; the gas not being uniform on account of the gradient of temperature, the change going on at each point is calculated from the elements contributed by the parts at this particular distance in all directions. He lays stress on the dimensional relations of the problem, pointing out that the phenomena which occur with large vanes in highly rarefied gas could also occur with proportionally smaller vanes in gas at higher pressure. The results coincide with Maxwell's so far as above stated, though the numerical coefficients do not agree. According to Maxwell, priority in showing the necessity for slipping over the boundary rests with Reynolds, who also discovered the cognate fact of thermal transpiration, meaning thereby that gas travels up the gradient of temperature in a capillary tube, owing to surface-actions, until it establishes such a gradient of pressure (extremely minute) as will prevent further flow. In later memoirs Reynolds followed up this subject by proceeding to establish definitions of the velocity and the momentum and the energy at an element of volume of the molecular medium, with the precision necessary in order that the dynamical equations of the medium in bulk, based in the usual manner on these quantities alone, without directly considering thermal stresses, shall be strictly valid—a discussion in which the relation of ordinary molar mechanics to the more complete molecular theory is involved.

Of late years the peculiarities of the radiometer at higher gas-pressures have been very completely studied by E. F. Nichols and G. F. Hull, with the result that there is a certain pressure at which the molecular effect of the gas on a pair of nearly vertical vanes is balanced by that of convection currents in it. By thus controlling and partially eliminating the aggregate gas-effect, they succeeded in making a small radiometer, horizontally suspended, into a delicate and reliable measurer of the intensity of the radiation incident on it. With the experience thus gained in manipulating the vacuum, the achievement of thoroughly verifying the pressure of radiation on both opaque and transparent bodies, in accordance with Clerk Maxwell's formula, has been effected (Physical Review, 1901, and later papers) by E. F. Nichols and G. F. Hull; some months earlier Lebédew had published in the Annalen der Physik a verification for metallic vanes so thin as to avoid the gas-action, by preventing the production of sensible difference of temperature between the two faces by the incident radiation. (See Radiation.)

More recently J. H. Poynting has separated the two effects experimentally on the principle that the radiometer pressure acts along the normal, while the radiation pressure acts along the ray which may be directed obliquely. (J. L.)

RADIUM, Raphanus sativus (nat. order Cruciferae), in botany, a fleshy-rooted annual, unknown in the wild state. Some varieties of the wild radish, R. Raphanistrum, however, met with on the Mediterranean coasts, come so near to it as to suggest that it may possibly be a cultivated race of the same species. It is very popular as a raw salad. There, are two principal forms, the spindle-rooted and the turnip-rooted.

The radish succeeds in any well-worked not too heavy garden soil, but requires a warm, sheltered situation. The seed is generally sown broadcast, in beds 4 to 5 ft. wide, with alleys between, the beds requiring to be netted over to protect them from birds. The earliest crop may be sown about the middle of December, the seed-beds being at once covered with litter, which should not be removed till the plants come up, and then only in the daytime, and when there is no frost. If the crop succeeds, which depends on the state of the weather, it will be in use about the beginning of March. Another sowing may be made in January, a third early in February, if the season is a favourable one, and still another towards the end of February, from which time till October a small sowing should be made every fortnight or three weeks in spring, and rather more frequently during summer. About the end of October, and again in November, a late sowing may be made on a south border or bank, the plants being protected in severe weather with litter or mats. The winter radishes, which grow to a large size, should be sown in a soil rich in manure, and thinned out 6 to 9 in. apart, the plants being thinned out to 5 or 6 in. in the row. The roots become fit for use during the autumn. For winter use they should be taken up before severe frost sets in, and stored in dry sand. Radishes, like other fleshy roots, are attacked by insects, the most dangerous being the larvae of several species of fly, especially the radish fly (Athornia radicum). The most effectual means of destroying these is by watering the plants with a dilute solution of carbolic acid, or much diluted gas-water; or gas-lime may be sprinkled along the rows.

Forcing.—To obtain early radishes a sowing in the British Isles should be made about the beginning of November, and continued fortnightly till the middle or end of February; the crop will generally be fit for use about six weeks after sowing. The seed should be sown in light rich soil, 8 or 9 in. thick, on a moderate hoed, or in a pit with a temperature of from 55° to 65°. Gentle waterings must be given, and air admitted at every favourable opportunity; but the sashes must be protected at night and in frosty weather with straw mats or other materials. Some of these crops are often grown with forced potatoes. The best forcing sorts are Wood's early frame, and the early rose globe, early dwarf-top scarlet turnip, and early dwarf-top white turnip.

The best suited for forcing and for the early results in the radimeter are the following:

Spindle-rooted.—Long scarlet, including the sub-varieties scarlet short-top, early frame scarlet, and Wood's early frame; long scarlet scarlet, best for forcing; French scarlet, short, oblong-shaped; red turnip and white turnip, for summer crops.

Winter sorts.—Black Spanish, white Chinese, Californian mammont.

RADIUM (from Lat. radius, ray), a metallic chemical element obtained from pitchblende, a uranium mineral, by F. and Mme. Curie and G. Bémont in 1896; it was so named on account of the intensity of the radioactive emanations which it yielded. Its discovery was a sequel to H. Becquerel's observation in 1896 that certain uranium preparations emitted a radiation resembling the X rays observed by Röntgen in 1895. Like the X rays, the Becquerel rays are invisible; they both traverse thin sheets of glass or metal, and cannot be refracted; moreover, they both ionize gases, i.e. they discharge a charged electroscope, the latter, however, much more feebly than the former. Characteristic also, is their action on a photographic plate, and the phosphorescence which they occasion when they impinge on zinc sulphide and some other salts. Notwithstanding these appearances, these two sets of rays are not indentical. Mme. Curie, regarding radioactivity—i.e. the emission of rays, like those just mentioned—as a property of some undiscovered substance, submitted pitchblende to a most careful analysis. After removing the uranium, it was found that the bismuth separated with a very active substance—polonium; this element was afterwards isolated by Markwald, and proved to be identical with his radiotellurium; that the barium could be
RADIUS—RADNORSHIRE

separated with another active substance—radium; whilst a third fraction, composed mainly of the rare earths (thorium, &c.,), yielded to Debeirne another radioactive action—actinium, which proved to be identical with the emanation of Giesel. Another radioactive substance—ionium—was isolated from carnotite, a uranium mineral, by B. B. Boltwood in 1905. Radioactive properties have also been ascribed to other elements, e.g. thorium and Americium. There is more radium than any other radioactive element, but its excessive rarity may be gauged by the facts that Mme. Curie obtained only a fraction of a gramme of the chloride and Giesel 2 to 3 gramme of the bromide from a ton of uranium residues.

There is a mass of evidence to show that radium is to be regarded as an element, and in general its properties resemble those of the metals of the alkaline earths, more particularly barium. To the bunsen flame a radium salt imparts an intense carmine-red colour (barium gives a green). The spectrum, also, is very characteristic. The atomic weight, 226-4, places the element in a vacant position in group II. of the periodic classification, along with the alkaline earth metals.

Generally speaking, the radiation is not simple. Radium itself emits three types of rays: (1) the α rays, which are regarded as positively charged helium atoms; these rays are stopped by a single sheet of paper; (2) the β rays, which are identified with the cathode rays, i.e. as a single electron charged negatively; these rays can penetrate sheets of aluminium, glass, &c., several millimetres thick; and (3) the γ rays—which are non-electrolyted radiations characterized by a high penetrating power, 1% surviving after traversing 7 cm. of lead or 150 cm. of water. In addition, radium evolves an “emanation” which is an extraordinarily inert gas, recalling the “inactive” gases of the atmosphere. We thus see that radium is continually losing matter and energy as electricity; it is also losing energy as heat, for, as was observed by Curie and Laborde, the temperature of a radium salt is always a degree or two above that of the atmosphere, and they estimated that a gramme of pure radium would emit about 100 gramme-calories per hour.

The Becquerel rays have a marked chemical action on certain substances. The Curies showed that oxygen was convertible into ozone, and Sudborough that yellow phosphorus gave the red modification when submitted to their influence. More interesting are the observations of D. Berthelot, F. Bordas, C. Radiou and others, that the rays引起 changes in the colours of many minerals. (See Radiometry.)

The action of radium on human tissues was unknown until 1901, when, Professor Becquerel of Paris having incautiously carried a tube in his waistcoat pocket, there appeared on the skin within fourteen days a severe inflammation which was known as the famous “Becquerel burn.” Since that time active investigation into the action of radium on diseased tissues has been carried on, resulting in the establishment in Paris in 1906 of the “Laboratoire biologique du Radium.” Similar centres for study have been inaugurated in other countries, notably one, in London in 1906. The diseases to which the application has been hitherto confined are papilloma, lupus vulgarius, epithelial tumours, syphilitic ulcers, pigmented naevi, angioma, and pruritus and chronic itching of the skin; but the use of radium in therapeutics is still experimental. The different varieties of rays used are controlled by the intervention of screens or filtering substances, such as silver, lead or aluminium. Radium is analogous and bactericidal in its action.

See Radiotherapie, by Wickham and Degrais (1909); Die therapeutische Wirkung der Radiumstrahlen, by O. Lasar, in Report of the Royal College of Surgeons, 1903; Lecture by S. Valentin in Physique Zeitschrift (1905); Abbé in Medical Record (October 1907).

RADIUS, properly a straight rod, bar or staff, the original meaning of the Latin word, to which also many of the various meanings seen in English were attached; it was thus applied to the spokes of a wheel, to the semi-diameter of a circle or sphere and to a ray or beam of light, “ray” itself coming through the Fr. räge from radius. From this last sense comes “radiant,” “radiation,” and allied words. In mathematics, a radius is a straight line drawn from the centre to the circumference of a circle or to the surface of a sphere; in anatomy the name is applied to the outer one of the two bones of the fore-arm in man or to the corresponding bone in the fore-leg of animals. It is also used in various other anatomical senses in botany, ichthyology, entomology, &c. A further application of the term is to an area the extent of which is marked by the length of the radius from the point which is taken as the centre; thus, in London, for the purpose of reckoning the fare of hackney carriages, the radius is taken as extending four miles in any direction from Charing Cross.

RADNOR, EARLS OF. The 1st earl of Radnor was John Robartes (1606-1658), who succeeded his father, Richard Robartes, as 2nd baron Robartes of Truro in May 1634, the barony having been purchased under compulsion for £10,000 in 1625. The family had amassed great wealth by trading in tin and wool. Educated at Exeter College, Oxford, John Robartes fought on the side of the Parliament during the Civil War, being present at the battle of Edgehill and at the first battle of Newbury, and was a member of the committee of both kingdoms. He is said to have persuaded the earl of Essex to make his ill-fated march into Cornwall in 1644; he escaped with the earl from Lostwithiel and was afterwards governor of Plymouth. Between the execution of Charles I. and the restoration of Charles II. he took practically no part in public life, but after 1660 he became a prominent public man, owing his prominence partly to his influence among the Presbyterians, and ranged himself among Clarendon’s enemies. He was lord deputy of Ireland in 1660-1661 and was lord lieutenant in 1660-1670; from 1661 to 1673 he was lord privy seal, and from 1670 to 1684 lord president of the council. In 1679 he was created viscount Bodmin and earl of Radnor, and he died at Chelsea on the 17th of July 1685. His eldest son, Robert, viscount Bodmin, who was British envoy to Denmark, having predeceased his father, the latter was succeeded as 2nd earl by his grandson, Charles Bodvile Robartes (1660-1723), who was a member of parliament under Charles II. and James II., and was lord lieutenant of Cornwall from 1669 to 1705 and again from 1714 to 1723. Henry, the 3rd earl (c. 1690-1741), was also a grandson of the 1st earl, and John, the 4th earl (c. 1686-1757), was another grandson. When John, whose father was Francis Robartes, the 3rd viscount Clifden (1661-1738), was created baron Robartes of Lanhydrock and of Truro in 1806, after having represented East Cornwall in seven parliaments. His son and successor, Thomas Charles Agar-Robartes, the 2nd baron (b. 1814), succeeded his kinsman as 6th viscount Clifden in 1809.

In 1765 William Bouvier, 2nd viscount Folkestone (1725-1776), son of Sir Jacob Bouvier, bart. (d. 1761), of Longford, Wiltshire, who was created viscount Folkestone in 1747, was made earl of Radnor. Descended from a Huguenot family, William Bouvier was a member of parliament from 1747 until he succeeded to the peerage in February 1761. He died on the 28th of January 1776. His son and successor, Jacob, the 2nd earl (1750-1828), who took the name of Pleydell- Bouvier in accordance with the will of his maternal grandfather, Mark Strickland Pleydell, bart. (d. 1768), was the father of William Pleydell-Bouverie, the 3rd earl (1779-1869), a politician of some note. In 1900 his great-grandson, Jacob Pleydell-Bouverie (b. 1866), became 6th earl of Radnor.

RADNORSHIRE (Sir Faesyled), an inland county of Wales, bounded N. by Montgomery, N.E. by Shropshire, E. by Hereford, S. and S.W. by Brecknock and N.W. by Cardigan. This county, which is lozenge-shaped, contains 471 sq. m., and is
consequently the smallest in area of the six South Welsh counties. Nearly the whole surface of Radnorshire is hilly or undulating, whilst the centre is occupied by the mountainous tract known as Radnor Forest, of which the highest point attains an elevation of 2163 ft. Towards the S. and S.E. the hills subside into rolling vales, and are surrounded by plains abounding in rivulets. The hills for the most part present smooth, rounded outlines, and are covered with heather, bracken and short grass, though tracts of boggy soil in the uplands are not uncommon. There are rich pastures and numerous woods in the valleys of the Wye and Teme. The Wye Valley has long been celebrated for its beauty, while Radnor Forest and the wild district of Cwmduawdror present striking views of primeval and unspoiled scenery. Radnorshire is well supplied with water, its principal river being the Wye (Gwy), which, after crossing the N.W. corner of the county, forms its boundary from Rhayader on to the English border. Salmon, trout and grayling are plentiful, and the Wye is consequently much frequented by anglers; as are also its tributaries—the Elan (which has been utilised for the great Birmingham reservoirs) the Ithon, the Edw or Edwy, the Lug, the Arrow and the Somergill. The Teme, which divides Radnor from Shropshire on the N.E., is a tributary of the Severn. All these streams are clear and rapid, and abound in fish. In the numerous rocky ravines of the mountainous districts are found many waterfalls, of which the most celebrated is Water-break-its-Neck, to the W. of New Radnor. Omitting these artificially constructed reservoirs in the valleys of the Elan and Claerwen, the lakes of Radnorshire are represented only by a few pools of which Llynbychlyn near Painscastle is the largest.

Geology.—Ordovician rocks occupy most of the western side of the county, they are succeeded eastward by the Silurian formations, the Llandovery, Wenlock and Ludlow beds in the order here given. East of New Radnor an infall of Wenlock rocks is succeeded by Ludlow beds; while at Old Radnor a ridge of very ancient rocks appears. In the south-east of the county Old Red Sandstone rock appears upon the Shirkern between Llandrindod, where there are saline, sulphurous and chalybeate waters, and Builth, is a dissection area of Ordovician strata with masses of andesitic and diabasic igneous rocks. In the vicinity of Rhayader the strata have been classed as the Rhayader pale shales (Tarannon), the Caban group (Upper Llandovery), the Gwassten group (Lower Llandovery); these rest upon shales of Bala age.

Climate and Industries.—The climate of Radnorshire is bracing, if not typically rainy, its rainfall is in the average yearly 35 inches, the neighbouring counties of Montgomery and Brecknock, but thickly drizzling mists are of constant occurrence. The winters are often very severe, and deep snowfalls are not uncommon. Good hay and tobacco are raised in the valleys, and the raising of turnips, an important branch of cultivation has risen considerably since 1850. The extensive upland tracts, which still cover over one-third of the total area of the county, are pastured for mountain ponies and for large flocks of sheep. The quality of the wool of Radnorshire has long been celebrated, and also the delicacy of the Welsh mutton of the small sheep that are bred in this county. The most important sheep fairs are held at Rhayader, which also contains some woolen factories. There are practically no mining industries, nor are the quarries of great value. The valley of the Wye is rich in medicinal springs, and the saline, sulphur and chalybeate waters of Llandrindod have long been famous and profitable, and are growing in popular esteem.

Communications.—The Central Wales branch of the London & North Western railway enters the county at Knighton, traverses it by way of Builth and Presteigne and the Brecon and Radnor railway road junction on the Wye. The Cambrian railway, after passing through the N.W. corner of the county to Rhayader, follows the course of the Wye to Builth and Hay. Two small branch lines connect New Radnor and Presteigne with the system of the Great Western.

Population and Administration.—The area of Radnorshire is 301,164 acres, and the population in 1891 was 21,791, while in 1901 it had risen to 23,362; an increase chiefly due to the immigration of outside labourers to the Elan Valley waterworks. There is now no existing municipal borough, although New Radnor, now a mere village with 405 inhabitants (1901), was incorporated in 1861 and its municipal privileges were not formally abolished till 1883. The chief towns are Presteigne (pop. 1245); Llandrindod (1827); Knighton (2139), and Rhayader (1215); all, except Rhayader, being urban districts. Radnorshire is included in the South Wales circuit, and assizes are held at Presteigne, which ranks as the county town. There is no existing parliamentary borough, and the whole county returns one member to parliament. Ecclesiastically, Radnorshire is divided into 6 archdeaconries, of which 4 lie in the diocese of St Davids, and 2 in that of Hereford.

History.—The wild district of Maesyfed (a name of which the derivation is much disputed), corresponding substantially with the modern Radnorshire, originally formed part of the territory of the Silures, who were vanquished by the Romans. Christianity seems to have been introduced into this barren region during the 5th and 6th centuries by itinerant Celtic missionaries, notably by St David, St Padarn and St Cynilo. Towards the close of the 9th century Maesyfed was absorbed into the middle kingdom of Powys, and in the 10th century it was included in the principality of Elystan. Old Radnor, prince of Flerius, or Feryllwg, who ruled over all land lying between the Wye and Severn. In the reign of William the Conqueror, the Normans began to penetrate into Maesyfed, where, according to Domesday Book, the king already laid claim to Radenoure, or Radnor (a name of doubtful meaning), in the lordship of Melenith (Moelynaldw), which was subsequently bestowed on the Mortimer family, when castles were erected at Old Radnor (Penygraig), New Radnor and Cefnllwy. Later, the Norman invaders forced their way up the Wye Valley, the de Breos family, lords of Elvel (Eelfaid), building fortresses at Painscastle and at Colwyn or Maud’s Castle. In 1188 Archbishop Baldwin, accompanied by Ranulf de Glanville and Giraldus Cambrensis, entered Wales for the purposes of preaching the Third Crusade, and was met in full state at New Radnor by the Lord Rhys, prince of South Wales. The Wye Valley long formed one of the debatable districts between Welsh and Normans, and in 1282 Llewelwyn ap Griffith, prince of Wales, was at Aberedw shortly before his death in a skirmish near Builth. After the annexation of Wales by Edward I., the district of Maesyfed remained under the immediate jurisdiction of the Lords-Marchers, represented by the great families of Mortimer and Todeney. During the summer of 1492 Owen Glendower entered the Marches and raided the lands of the young Edward Mortimer, Earl of March, whilst the royal troops were severely defeated at the battle of Bryn Glas near Pilleth. By the Act of Union (1536) Maesyfed was erected out of the suppressed lordships into an English shire on the usual model. For administrative purposes it was now divided into six hundreds, and assizes were ordained to be held in alternate years at Presteigne and New Radnor. The newly created county was likewise privileged to return two members to parliament; one for the county, and one for the united boroughs of New Radnor, Rhayader, Knighton, Cefnllwy and Knucklas (Cwnclas). The parliamentary district of the Radnorshire county was, however, a disfranchised and mortified in the county representation under the act of 1885. The shire of Radnor with its immense tracts of sheep-walk, its absence of large towns and its sparse rural population has always been reckoned the poorest and least important of the Welsh counties, nor since its creation under Henry VIII. has it ever played a prominent part in the national life of Wales. During the Commonwealth the local clergy were made to suffer severely under the drastic administration of Vavasor Powell (1617-1670), himself a Radnorshire man as a native of Knucklas. Of recent years the rise of Llandrindod as a fashionable watering-place and the construction of the Birmingham reservoirs in the Elan Valley have tended to improve the material prosperity of the county.

Among the leading families of Radnorshire, may be mentioned Lewis of Harpton Court; Baskerville of Cryo; Thomas (formerly Jones) of Pencerrig; Lewis-Lloyd of Nantgwyllt; Gwynne of Llandevedd, and Prickard of Dderw.

Antiquities.—Radnorshire contains numerous memorials of early British times, of which the entrenchment called Crug-y-buddar in the parish of Beguildy is specially worthy of note. Of Roman remains, the most important are those of the fortified camp at Cwm near Llandrindod, which is believed to be identical.
with the military station of Magos or Magna. The course of Offa's Dyke (Clawdd Offa) is perceptible at various points in the hilly regions west of Knighton and Presteigne. Very slight traces exist of the many castles erected at various times after the Norman invasion. The parish churches of Radnorshire are for the most part small and of rude construction, and many of them have been modernized or rebuilt. The churches at Old Radnor, Presteign and Llanbister, however, are interesting edifices, and a few possess fine oaken screens, as at Llananno and Llandegley. There was only one monastic house of consequence, the Cistercian abbey of St Mary, founded by Cadwallon ap Madoc in 1145 in "the long valley" of the Clywedog, six miles east of Rhayader, and from its site commonly called Abbey Cwm Hir. Its existing ruins are insignificant, but the proportions of the church, which was 238 ft. long, are still traceable. The modern mansion adjoining, known as Abbey Cwm Hir, was for some generations the residence of the Fowler family, once reputed the wealthiest in the county.

Customs, &c.—Although in most instances the old Celtic place-names survive throughout the western portion of the county, it is only in the wild remote districts of Cwmddauddwr and St Harmon's that the Welsh tongue predominates, and in this region some of the old Welsh superstitions linger amongst the peasants and shepherds of the hills. In the eastern part of the county English is spoken universally, and the manners and customs of the inhabitants differ little from those prevailing in the neighbouring county of Hereford. On the western side of Radnor Forest the modern spirit of progress has destroyed most of the old local customs. Until the beginning of the 19th century the ancient Welsh service of the pyلجوين on Christmas morning was observed in Rhayader church; and the same town was formerly remarkable for an interesting ceremony, evidently of great antiquity, whereat after a funeral each attendant mourner was wont to throw a stone upon a certain spot near the church with the words " Càrn ar dy ben " (a stone on thy head). The laying of malicious spites by means of lighted tapers was formerly practised in the churches of the Wye Valley; and a curious service, commemorative of the dead and known as "the Month's End," is still observed in certain parish churches, a month after the actual funeral has taken place. The practice of farmers and their wives or daughters riding to the local markets on ponies, the older women sometimes knitting as they proceed, still continues, and is specially characteristic of agricultural life in Radnorshire.

See A General History of the County of Radnor (compiled from the MS. of the late Rev. Jonathan Williams and other sources) (Brecknock, 1905).

RADOM, a government of Russian Poland, occupying a triangular space between the Vistula and Filica, and bounded N. by the governments of Warsaw and Siedlce, E. by Lublin, S. by the crownland of Austrian Galicia and the Polish government of Kielce, and W. by that of Plotzkow. The area is 4768 sq. m. Its southern part stretches over the well-wooded Sandomir heights, a series of short ranges of hills, 800 to 1000 ft. in altitude, intersected by deep valleys, which, running west and east and drained by tributaries of the Vistula, are excellently adapted for agriculture. In its central parts, the government is level, the soil fertile, and the surface, which is diversified here and there with wood, is broken up by occasional spurs (800 ft.) of the Lyza Góra Mountains. The northern districts consist of low, flat tracts with undefined valleys, exposed to frequent floods and covered over large areas with marshes; the basin of the Filica, notorious for its unhealthyness, is throughout a low marshy plain. Devonian, Carboniferous, Permian and Triassic deposits appear in the south, Cretaceous and Jurassic in the middle, and Tertiary in the north. Extensive tracts are covered with Glacial deposits,—the Scandinavian erratics reaching as far south as Iza; these last in their turn are overlain by widespread post-Glaciar lacustrine deposits. The climate is cold and moist, the mean temperature for the year being 47.5 Fahr., for January —5.8, and for July 77°. The Vistula skirts the government on the south and east, and is an important means of communication, steamers plying as far up as Sandomir (Sđomierz). The Sandomir district suffers occasionally from disastrous inundations of the river. The tributaries of the Vistula are short and small, those of the Filica are sluggish streams meandering amidst marshes. The enumerated population was in 1905 933,500. The government is divided into seven districts, the chief towns of which are Radom, Iłża, Konskie, Koziencice, Opatów, Opoczno and Sandomir. Out of the total area about 50% is under cultivation and 28% under forests. The principal crops are wheat, rye, barley, oats, buckwheat, hemp, flax and potatoes, these last chiefly cultivated for distilleries. Grain is exported. Live stock is kept in large numbers. Manufactures have considerably developed of late years, the government being rich in iron ore, while coal and zinc occur, as also marble, gypsum, alabaster, potters' clay and red sandstone. The iron industry occupies more than 60,000 workmen, and turns out annually some 100,000 tons of pig iron, 25,000 tons of iron, and 550,000 tons of steel. There are several sugar-factories, tanneries, flour-mills, machinery works, distilleries, breweries and brickworks. Trade is not very extensive, the only channel of commerce being the Vistula. (P. A. K., J. T. B.)

RADOM, a town of Russia, capital of the government of the same name, 100 m. by raff. S. from Warsaw. Pop. 28,749, half of whom were Jews. It is one of the best built provincial towns of Poland. The church of St Wladaw, contemporary with the foundation of the town, was transformed by the Austrians into a storehouse, and subsequently by the Russian government into a military prison. The old castle is in ruins, and the old Bernardine monastery is used as barracks. Radom has several iron and agricultural machinery works and tanneries. In 1216 it occupied the site of what is now Old Radom. New Radom was founded in 1340 by Casimir the Great, king of Poland. Here Jadwiga was elected queen of Poland in 1382, and here too in 1401 the first act relating to the union of Poland with Lithuania was signed; the seim or diet of 1505, where the organic law of Poland was sworn by the king, was also held at Radom. Several great fires, and still more the Swedish war of 1707—7, were the ruin of the old city. After the third partition of Poland in 1795 it fell under Austrian rule; it was in 1815 annexed to Russia, and became chief town of the province of Sandomir.

RADOMYSL, formerly Mychek, a town of Russia, in the government of Kiev, 31 m. W. of the city of Kiev, on the Teteriv river. Pop. 18,154. It is a very old town, being mentioned in 1150; from 1746 to 1793 it was the residence of the metropolitan of the United Greek Church. It has tanneries and flour-mills, and exports timber, corn and mushrooms.

RADOWITZ, JOSEPH MARIA VON (1707—1853), Russian general and statesman, was born at Blankenburg in the Harz Mountains, his family being of Hungarian origin. As a young lieutenant in the Westphalian artillery he was wounded and taken prisoner at the battle of Leipzig (1813), subsequently entered the Hanoverian service, and in 1823 that of Prussia. His promotion was rapid, and in 1836 he became chief of the general staff of the artillery. In 1836 he went as Russian military plenipotentiary to the federal diet at Frankfurt, and in 1842 was appointed envoy to the courts of Carlsruhe, Darmstadt and Nassau. He had early become an intimate friend of the crown prince (afterwards King Frederick William IV.), and the Prussian constitution of February 1848. In 1849 he helped to realize the ideas put forward by him in his Gespräche aus der Gegenwart über Staat und Kirche, published under the pseudonym "Waldheim" in 1846. In November 1847 and March 1848 Radowitz was sent by King Frederick William to Vienna to attempt to arrange common action for the reconstruction of the German Confederation. In the Frankfurt parliament he was leader of the extreme Right; and after its break-up he was zealous in promoting the Unionist policy of Prussia, which he defended both in the Prussian diet and in the Erfurt parliament. He was practically responsible for the foreign policy of Prussia from May 1848 onwards, and on the 27th of September 1850.
he was appointed minister of foreign affairs. He resigned, however, on the 2nd of November, owing to the king's refusal to settle the difficulties with Austria by an appeal to arms. In August 1852 he was appointed director of military education; but the rest of his life was devoted mainly to literary pursuits. He died on the 25th of December 1853.

Radovitz published, in addition to several political treatises, *Gnomographie der Heiligen*, ein Beitrag zur Kunstgeschichte (Berlin, 1834) and *Devisen und Motto der spätern Mittelelter* (ib., 1850). His Gesammelte Schriften were published in 5 vols. at Berlin, 1828-35.

See Haswell, *Joseph Maria von Radovitz* (Berlin, 1905, &c.).

RAE, JOHN (1813-1893), Scottish Arctic explorer, was born on the 30th of September 1813, in the Orkney Islands, which he left at an early age to study medicine at Edinburgh University, qualifying as a surgeon in 1833. He made a voyage in a professional capacity in one of the ships of the Hudson's Bay Company, and entering the service of the company as resident surgeon for ten years at their station at Moose Factory, at the head of James Bay. In 1846 he made a boat-voyage to Repulse Bay, and having wintered there, in the following spring surveyed 700 miles of new coast-line connecting the earlier surveys of Ross and Parry. An account of this expedition, *Narrative of an Expedition to the shores of the Arctic Sea* in 1846 and 1847, was published by him in 1850. During a visit to London in 1848 he joined the expedition which was then preparing to go out under Sir John Richardson in search of Franklin; and in 1851, at the request of the Government and with a very slender outfit, he travelled some 5300 miles, much of it on foot, and explored and mapped 700 miles of new coast on the south side of Wollaston and Victoria Lands. For this achievement he received the Founder's gold medal of the Royal Geographical Society. In 1853 he commanded another boat-expedition which was fitted out by the Hudson's Bay Company, which connected the surveys of Ross with that of Deane and Simpson, and proved King William's Land to be an island. It was on this journey that he obtained the first authentic news regarding the fate of Franklin, thereby winning the reward of £10,000 promised by the admiralty. He subsequently travelled across Iceland, and in Greenland and the northern parts of America, surveying routes for telegraph lines. Dr Rae attributed much to his success in Arctic travel to his adoption of the methods of the Eskimo, a people whom he had studied very closely. He was a keen sportsman, an accurate and scientific observer. He died at his house in London and was buried in St Mary Le Bow.

RAE BARELI, a town and district of British India, in the Lucknow division of the United Provinces. The town is on the river Sai, 48 m. S.E. of Lucknow, on the Oudh & Rohilkhand railway. Pop. (1901) 15,880. It possesses many architectural features, chief of which is a strong and spacious fort erected in 1493, and constructed of bricks 2 ft. long by 1 ft. thick and 1 ft. wide. Among other ancient buildings are the magnificent palace and tomb of nawab Jahan Khan, governor in the time of Shah Jahan, and four fine mosques. The town is an important centre of trade, and muslins and cotton cloth are woven.

The district of Rae Bareli has an area of 1748 sq. m. The general aspect of the district is slightly undulating, and the country is beautifully wooded. The soil is remarkably fertile, and the cultivation of a high class. The principal rivers of the district are the Ganges and the Sai; the former skirts it for 54 miles and is everywhere navigable for boats of 40 tons; the latter traverses it from N.W. to S.E. In 1901 the population was 1,033,761, showing a slight decrease during the decade. The principal crops are rice, pulse, wheat, barley, millet and poppy. Rae Bareli town is connected with Lucknow by a branch of the Oudh & Rohilkhand railway, which in 1868 was extended to Benares.

See Rae Bareli District Gazetteer, Allahabad, 1905.

RAEBURN, Sir Henry (1756-1823), Scottish portrait-painter, was born at Stockbridge, a suburb of Edinburgh, on the 4th of March 1756, the son of a manufacturer of the city.

He was early left an orphan. Being placed in Heriot's Hospital, he received there the elements of a sound education, and at the age of fifteen was apprenticed to a goldsmith in Edinburgh. Here he had some little opportunity for the practice of the humbler kinds of art, and various pieces of jewelry, mourning rings, and the like, adorned with minute drawings on ivory by his hand, are still extant. Soon he took to the production of carefully finished miniatures; and, meeting with success and patronage, he extended his practice to oil-painting, being all the while quite self-taught. The worthy goldsmith his master watched the progress of his pupil with interest, gave him every encouragement, and introduced him to David Martin, who had been the favourite assistant of Allan Ramsay junior. This early insurance against the disappointment of his chosen profession, did not, however, diminish his anxiety to excel. The acquisition of wealth affected neither his enthusiasm nor his industry, but rather spurred him to greater efforts to acquire a thorough knowledge of his craft. After the approved fashion of artists of the time, it was resolved that Raeburn should visit Italy, and he accordingly started with his wife. In London he was kindly received by Sir Joshua Reynolds, who gave him excellent advice as to his study in Rome, especially recommending to his attention the works of Michelangelo. He also offered him more substantial pecuniary aid, which was declined as uneccesary; but Raeburn related with him to Italy many valuable introductions from the president of the Academy. In Rome he made the acquaintance of Gavin Hamilton, of Batoni, and of Byers. For the advice of the last-named he used to acknowledge himself greatly indebted, particularly for the recommendation that "he should never copy an object from memory, but, from the principal figure to the minutest accessory, have it placed before him." After two years of study in Italy he returned to Edinburgh in 1787, where he began a most successful career as a portrait-painter. In that year he executed an admirable seated portrait of the second Lord President Dundas.

On his earlier expeditions he acquired interesting examples in the beautiful likenesses of Mrs Johnstone of Baldovie and in the three-quarter-length of Dr James Hutton, works which, if they are somewhat timid and tentative in handling and wanting in the trenchant brush-work and assured mastery of subsequent productions, are full of delicacy and character. The portraits of John Clerk, Lord Eldin, and of Principal Hill of St Andrews belong to a somewhat later period. Raeburn was fortunate in the time in which he practised portraiture. Sir Walter Scott, Blair, Mackenzie, Woodhouselee, Robertson, Home, Ferguson, and Dugald Stewart were resident in Edinburgh, and they all, along with a host of others less celebrated, honoured the painter's canvases. Of his fully matured manner we could have no finer examples than his own portrait and that of the Rev. Sir Henry Moncrieff Wellwood, the bust of Dr Wardrop of Torbane Hill, the two full-lengths of Adam Rolland of Gask, the remarkable paintings of Lord Newton and Dr Alexander Adam in the National Gallery of Scotland, and that of William Macdonald of St Martin's. It was commonly believed that Raeburn was less successful in his female than in his male portraits, but the exquisite full-length of his wife, the smaller likeness of Mrs R. Scott Moncrieff in the Scottish National Gallery, and that of Mrs Robert Bell, and others, are sufficient to prove that he could portray all the grace and beauty of the gentler sex.
Raeburn spent his life in Edinburgh, rarely visiting the metropolis, and then only for brief periods, thus preserving his own sturdy individuality, if he missed the opportunity of engraving on it some of the fuller refinement and delicacy of the London portraitists. But though he, personally, may have lost some of the advantages which might presumably have resulted from closer association with the leaders of English art, and from contact with a wider public, Scottish art certainly gained much from his disindisposition to leave his native land. He became the acknowledged chief of the school which was growing up in Scotland during the earlier years of the 19th century, and to his example and influence at a critical period is undoubtedly due much of the striking vitality by which the work of his immediate followers is so distinguished. Evidences of this influence can be perceived even in the present day. His leisure was employed in athletic sports, in his garden, and in architectural and mechanical pursuits, and so varied were the interests that filled his life that his sitters used to say of him, "You would never take him for a painter till he seizes the brush and palette." Professional honours fell thick upon him. In 1812 he was elected president of the Society of Artists in Edinburgh, in 1814 associate, and in the following year full member of the Royal Academy. In 1822 he was knighted by George IV. and appointed His Majesty's limner for Scotland. He died at Edinburgh on the 8th of July 1823.

In his own day the portraits of Raeburn were excellently and voluminously engraved, especially by the last members of the great school of English mezzotint. In 1876 a collection of over 300 of his works was brought together in the Royal Scottish Academy galleries; in the following year a series of twelve of his finest portraits was included in the winter exhibition of the Royal Academy, London; and a volume of photographs from his paintings was edited by Dr John Brown.

Raeburn possessed all the necessary requirements of a popular and successful portrait-painter. He had the power of producing work that was equal to the best drawing; he was a master of the brush; he had a great faculty for work that is most individual and personal, and by breadth of effect, by admirable force of handling, his paintings are among the most perfect and most resolute of the "square touch" of Raeburn. But the portraits of Velázquez are unsurpassable examples of tone as well as of handling, and it is in the former quality that Raeburn is often wanting, possibly because his inclinations led him to study effects of diffused light in preference to those which were strong in contrasts of light and shade. The colour of his portraits is at times crude and out of relation, inclining to the use of immediate brush strokes, and the little that he added here and there to the pigments, or what is frequently the case, a little perceptive of the changeable subtleties and modifications of atmospheric effect. His draperies frequently consist of little more than two colours—the local hue of the fabric and the black which, more or less graduated, expresses its shadows and modelling. In his flesh, too, he wants—in all but his very best productions—the delicate refinements of colouring which distinguish the works of the great English portrait-painters. His faces, with all their excellent truth of form and splendid vigour of handling, are often hard and bricky in hue. Yet, after all allowances have been made for the deficiencies there may be in his work, his right to a place among the greater British masters cannot be contested. The masculine power, the vitality and the strength of characterization which are so apparent in his paintings entitle him to the serious attention of all lovers of fine achievement; and there is much to be learned from study of his methods. His sincerity and freedom from artificial graces of style can be specially recognized, and his frank directness is always attractive.

See Life of Sir Henry Raeburn, R.A., by his great-grandson William Raeburn Andrew, M.A. Oxon. (2nd ed., 1894), which contains some of the latest information, together with a complete catalogue of the exhibition of 1876. There may also be consulted Works of Sir Henry Raeburn, R.A., with tributes by Dr John Brown and others, published by Andrew Elliot, Edinburgh; Tribute to the Memory of Raeburn by Dr Andrew Ducan, the Catalogues of the loan exhibitions in Edinburgh of 1884 and 1901; and the Essay by W. E. Henley—Sir Henry Raeburn by William Ernest Henley (1890) with a finely produced series of plates, printed by T. & A. Constable for the now defunct Royal Association for Promotion of the Fine Arts in Scotland. But the leading work on the subject, and the most splendidly illustrated, is Sir Henry Raeburn by Sir Walter Armstrong, with an introduction by R. A. M. Stevenson and a biographical and descriptive catalogue by J. L. Caw (1901).

**RAEDWALD** (d. c. 620), king of the East Angles, was the son of King Tyttli. He became a Christian during a stay in Kent, but on his return to East Anglia he sanctioned the worship both of the Christian and the heathen religions. Very little is known about his reign, which probably began soon after 615. For a time he recognized the overlordship of Athelbert, but in 617, when Jæhelfrith, king of the Kentish yoke, sacked London, Raedwald protected the fugitive Edwin, afterwards king of Northumbria, and in his interests he fought a sanguinary battle with the reigning Northumbrian king, Æthelbert of Kent, and was defeated and killed in April 617. He was followed as king of the East Angles by his son Eorwald.

**RAETIA** (so always in inscriptions; in classical MSS. usually Rhaetia), in ancient geography, a province of the Roman Empire, bounded on the W. by the country of the Helvetii, on the E. by Noricum, on the N. by Vindelicia and on the S. by Cisalpine Gaul. It thus comprised the districts occupied in modern times by the Grisons, the greater part of Tirol, and part of Lombardy. The land was very mountainous, and the inhabitants, when not engaged in predatory expeditions, chiefly supported themselves by cattle-breeding and cutting timber, little attention being paid to agriculture. Some of the valleys, however, were rich and fertile, and produced corn and flax. It is certain that the Rhaetians used to send their wool to any in Italy, and that the prefered Raetian wine to any other. Considerable trade was also carried on in pitch, honey, wax and cheese. Little is known of the origin or history of the Raetians, who are described as one of the most powerful and warlike of the Alpine tribes. It is distinctly stated by Livy (v. 33) that they were of Etruscan origin (a view favoured by Niebuhr and Mommsen). A tradition reported by Justin (xx. 5) and Piny (Nat. Hist. iii. 24, 133) affirmed that they were a portion of that people who had settled in the plains of the Po and were driven into the mountains by the invading Gauls, when they assumed the name of Raetians from their leader Rausus; a more probable derivation, after Rupp, is from Rome, "the hill." Even if their Etruscan origin be accepted, at the time when the land became known to the Romans, Celtic tribes were already in possession of it and had amalgamated so completely with the original inhabitants that, generally speaking, the Raetians of later times may be regarded as a Celtic people, although non-Celtic tribes (Lepontii, Euganei) were settled among them. The Raetians are first mentioned (but only incidentally) by Polybius (xxiv. 10, 18), and little is heard of them till after the end of the Republic. There is little doubt, however, that they retained their independence until their subjugation in 39 B.C. by Tibullus and Drusus (cf. Horace, Odes, iv. 4 and 14). At first Raetia formed a distinct province, but towards the end of the 1st century A.D. Vindelicia was added to it; hence Tacitus (Germania, 41) could speak of Augusta Vindelicorum (Augustburg) as "a colony of the province of Raetia." The whole province (including Vindelicia) was at first under a military prefect, then under a procurator; it had no standing army quartered in it, but relied on its own native troops and militia for protection. In the reign of Marcus Aurelius it was governed by the commander of the Legio iii. Italica. Under Diocletian it formed part of the diocese of the vicarius Italicus, and was subdivided into several "provinces" (each under a praefectus), the former corresponding to the old Raetia, the latter to Vindelicia. The boundary between them is not clearly defined, but may be...
stated generally as a line drawn eastwards from the lacus Briganitius (Lake of Constance) to the river Oenus (Inn). During the last years of the Western Empire, the land was in a desolate condition, but its occupation by the Ostrogoths in the time of Theodoric, who placed it under a dux, to some extent revived its prosperity. The chief towns of Raetia (excluding Vindelicia) were Tridentum (Trent) and Curia (Coire or Chur). It was traversed by two great lines of Roman roads—one leading from Verona and Tridentum across the Brenner (in which the name of the Brenn has survived) to Oenopinos (Innsbruck) and thence to Augusta Vindelicorum; the other from Brigantium (Bregenz) on Lake Constance, by Coire and Chiavenna to Como and Milan.

Peaks, The General Civil and Military Administration of Noricum and Raetia (Chicago, 1897).

RAFF, JOSEPH JOACHIM (1822—1882), German composer and orchestral conductor, was born near Zürich, Switzerland, on the 27th of May 1822, and educated chiefly at Schwyz. Here, under the care of the Jesuit fathers, he soon became an excellent classical and mathematical scholar, but received scarcely any instruction in his favourite art of music, in which, nevertheless, he made extraordinary progress through sheer force of natural genius, developed by the extraordinary study which no external obstacles could induce him to discontinue. So successful were his unaided efforts that, when in 1843 he sent some MSS. to Mendelssohn, that warm encourager of youthful talent felt justified in at once recommending him to Breitkopf & Härtel, the Leipzig publishers, who brought out a large selection of his early works. Soon after this he became acquainted with Liszt, who gave him much generous encouragement. He first became personally acquainted with Mendelssohn at Cologne in 1846, and gave up all his other engagements for the purpose of following him to Leipzig, but his intention was frustrated by the great composer’s death in 1847. After this disappointment he remained for some time at Cologne, where his attention was alternately devoted to composition and to the preparation of critiques for the periodical Célébîda. Far thus he was a self-taught artist; but he felt the need of systematic instruction so deeply that, retiring for a time from public life, he entered at Stuttgart upon a long course of severe and uninterrupted study, and with so much success that in 1850 he appeared before the world in the character of an accomplished and highly cultivated musician. Raff now settled for a time in Weimar in order to be near Liszt. Hans von Bülow had already brought him into notice by playing his Concertstück for piano- forte and orchestra in public, and the favour with which this fine work was everywhere received encouraged him to attempt a greater one. During his stay in Stuttgart he had begun the composition of an opera entitled König Alfred, and had good hope of securing its performance at Dresden; but the political troubles with which Germany was then overwhelmed rendered its production in the Saxon capital impossible. At Weimar he was more fortunate. In due time König Alfred was produced there under Liszt’s able direction at the court theatre with complete success; and later, in 1870, he wrote his second opera, Dame Koldob, for performance at the same theatre. A third opera, Samson, remained unstaged. Raff lived at Weimar until 1856, when he obtained a large clientsèle at Wiesbaden as a teacher of the pianoforte. In 1859 he married Doris Genast, an actress of high repute, and thenceforward devoted himself with renewed energy to the work of composition, displaying an inexhaustible fertility of invention tempered by great technical skill. He resided chiefly at Wiesbaden till 1877, when he was appointed director of the Hoch Conservatorium at Frankfort, an office he continued till his death on the 25th of June 1882.

More than 200 of Raff’s compositions have been published, including ten symphonies—undoubtedly his finest works—quartets, concertos, sonatas, songs, and examples of nearly every known variety of style; yet he never repeats himself. Notwithstanding his strong love for the romantic school, he is never guilty of extravagance, and, if in his minor works he is sometimes a little commonplace, he never descends to vulgarity. His symphonies Lenore and Im Wald are wonderful examples of musical painting.

RAFFAELEONI DEL GARBO (1466, or perhaps 1476—1524), Florentine painter. His real name was Raffaello Capani; Del Garbo was a nickname, bestowed upon him seemingly from the graceful nicety (garbo) of his earlier works. He has also been called Raffaello de Florentia, and Raffaello de Carolis. He was a pupil of Filippino Lippi, with whom he remained till 1490, if not later. He showed great facility in design, and excited hopes which the completed body of his works fell short of realizing. He carried far from his master’s emulations a haphazard manner of work ensued; and a kind of melancholy entered into a very dejected and penurious condition. Three of his best tempera pictures are in the Berlin Gallery; one of the Madonna standing with her Infant between two musician- angels, is particularly attractive. We may also name the oil-painting of the “Resurrection” done for the church of Monte Oliveto, Florence, now in the academy of the same city, ordinarily reputed to be Raffaello’s masterpiece; the ceiling of the Carafa Chapel in the church of the Minerva, Rome; and a “Coronation of the Virgin” in the Louvre, which is a production of much merit, though with somewhat over-studied grace. Angelo Allori was his pupil.

RAFFET, DENIS AUGUSTE MARIE (1804—1866), French illustrator and lithographer, was born in Paris in 1804. At an early age he was apprenticed to a wood turner, but took up the study of art at evening classes. He became acquainted with Cabanel, who made him apply his skill to the decoration of china, and with Rudor, from whom he received instruction in lithography, in the practice of which he was to rise to fame. He then entered the École des Beaux-Arts, but returned definitely to lithography in 1830, when he produced on stone his famous designs of “Lutzen,” “Waterloo,” “Le bal,” “La revue” and “Les adieux de la garnison,” by which his reputation became immediately established. Raffet’s chief works were his lithographs of the Napoleonic campaigns, from Egypt to Waterloo, vigorous designs that are inspired by ardent patriotic enthusiasm. As an illustrator his activity was prodigious, the list of works illustrated by his crayon amounting to about forty-five, among which are Béranger’s poems, the History of the Revolution by Thiers, the History of Napoleon by de Norvins, the great Walter Scott by Defauconpret, the French Plutarch and Frédéric Béart’s Songs. He went to Rome in 1849, was present at the siege of Rome, which he made the subject of several lithographs, and followed the Italian campaign of 1859, of which he left a record in his Épisodes de la campagne d’Italie de 1859. His portraits in pencil and water-colour are full of character. He died at Genoa in 1866. In 1803 a monument by Frémiet was unveiled in the Jardin de l’Infante at the Louvre, Paris.

See Raffet, by F. Lhomme (Paris, 1892).

RAFFLE, a special kind of lottery, in which a particular article is put up as the prize, the winner being drawn for by lot out of the number of those who have paid a fixed sum for admission to the drawing; the total amount realized by the sale of the tickets is supposed to approximate to the value of the object raffled for. The word appears in English as early as Charter (The Parson’s Tale) where it is used in its original sense of a game of dice—he winner being that one who threw three dice all alike; or, next, the highest pair. The French, Med. Lat. raffle, was also used in the sense of a “swapping-off” of the stakes in a game; it has been connected with Ger. raffen, to carry off.

RAFFLES, SIR THOMAS STAMFORD (1781—1826), English administrator, founder of Singapore, was born on the 5th of July 1781, on board a merchantman commanded by his father, Benjamin Raffles, when off Port Morant, Jamaica. He received
his early education at a school at Hammersmith, but when only fourteen he obtained temporary work in the secretary's office of the East India Company. In 1800 he was appointed junior clerk on the establishment. In 1805 the East India Company decided to make Penang a regular presidency, and sent out a governor with a large staff, including Stamford Raffles, who was appointed assistant-secretary. On the eve of his departure he married Mrs Fancourt (Olivia Mariamne Devenish), widow of a surgeon on the Madras Establishment; she proved herself a helpful wife and counsellor to her husband in his rapid rise to fortune during the following nine years, dying prematurely in Java in November 1814. On his way out to Penang, Raffles began the study of the Malay language, and had mastered its grammar before his arrival. He continued his studies, finding a congenial fellow-worker and kindred spirit in John Leyden, who was invalided to Penang. In August 1806 Raffles was appointed acting secretary during the illness of that official, and in 1807 he received the full appointment. In the meantime he had acted as Malay interpreter, which entailed heavy and unappreciated work in addition to his regular duties. In 1808 his health gave way, and he was ordered for a change to Malacca. This proved a turning-point in his career. The East India Company had decided to abandon Malacca, and orders had been issued to dismantle it. Raffles perfected his study of Malay during his stay at this place, and learning from the Malays, with whom he mixed freely, that the abandonment of so important a position would be a grave fault, he drew up a report explaining the great importance of Malacca, and urging in the strongest manner its retention. This report was sent by the Penang authorities not only to London, but to the governor-general, the earl of Minto. The latter was so impressed by the report that he at once gave orders for suspending the evacuation of Malacca, and in 1809 the company decided to reverse its own decision. When the whole question was calmly considered in the light of subsequent events, many years later, the verdict was that Raffles had “prevented the alienation of Malacca from the British Crown.” A direct correspondence with Lord Minto was established by the mediation of Leyden, who wrote to Raffles that the governor-general would be gratified in receiving communications direct from him. In June 1810 Raffles, of his own accord, proceeded to Calcutta, where Lord Minto gave him the kindest reception. Raffles remained four months in Calcutta, and gained the complete confidence of the governor-general. He brought Lord Minto round to his opinion that the conquest of the island of Java, then in the hands of the French, was an imperative necessity. To prepare the way for the expedition, Raffles was sent to Malacca as “agent to the Governor-General with the Malay States.” He did his work well and thoroughly—even to the extent of discovering that the short and direct route to Batavia by the Caramata passage would be safe for the fleet. In August 1811 the expedition, accompanied by Lord Minto, and with Sir Samuel Auchmuty in command of the troops (11,000 in number, half English and half Indian), occupied Batavia without fighting. On the 25th of the same month a battle was fought at Corneills, a few miles south of Batavia, and resulted in a complete English victory. On the 18th of September the French commander, General Janssens, formally capitulated at Samarang, and the conquest of the island was completed. Lord Minto’s first act was to appoint Raffles lieutenant-governor of Java. From September 1811 until his departure for England in March 1816, Raffles ruled this large island with conspicuous success and the most gratifying results. To give only one fact in support of this statement, he increased the revenue eightfold at the same time that he abolished transit dues, reduced port dues to one-third and removed the fetters imposed on trade and intercourse with the Javanese by Dutch officialdom. In his own words, his administration aimed at being “not only without fear, but without reproach.” He had a still greater ambition, which was, in his own words, “to make Java the centre of an Eastern insular Empire,” and to establish the closest relations of friendship and alliance with the Japanese, whom he described as “a highly polished people, considerably advanced in science, highly inquisitive and full of penetration.” It is interesting to note that when another great Englishman, Rajah Brooke, began his career in Sarawak in 1838, he announced: “I go to carry Sir Stamford Raffles’s views in Java over the whole Archipelago.”

The policy of Raffles was based on the assumption that Java would be retained, but for reasons of European policy it was decided that it must be restored to Holland. After his return to England in 1816 he endeavoured to obtain a reconsideration of the question, but the decision taken was embodied in a treaty and beyond all possibility of modification. During his stay in England Raffles was knighted by the prince regent, published his History of Java (1817) and discussed with Sir Joseph Banks a project for the foundation in London of a zoological museum and garden on the model of the Jardin des Plantes at Paris. Raffles married his second wife, Sophia, daughter of T. W. Hull of Co. Down; he had many children by both marriages, but the only one to live beyond childhood was a daughter, who died fifteen years after her father’s death, and before she was twenty. He left, therefore, no direct descendants.

In November 1817 Sir Stamford quitted England on his return to the East, where the lieutenant-governorship of Fort Marlborough (Sumatra) had been kept in reserve for him. His administration of Sumatra, which lasted from March 1818 till December 1823, was characterized by the same breadth of view, consistency of purpose and energy in action that had made his government of Java remarkable. He had not, however, done with the Dutch, who, on their recovery of Java, endeavoured to establish a complete control over the Eastern archipelago, and to oust British trade. This design Sir Stamford set himself to baffle, and although he was more frequently censured than praised by his superiors for his efforts, he had already met with no inconsiderable success in minor matters when, by a stroke of genius and unrivalled statescraft, he stopped for all time the Dutch project of a mare clausum by the acquisition and founding of Singapore on the 29th of January 1819.

In 1824 Sir Stamford returned to England, but unfortunately the differences between him and the East India Company had resulted in an accumulation of disputes which placed a severe strain on his enfeebled constitution. The memorials and statements that he had to compile for his own vindication would fill a large volume, but at last the court passed (12th of April 1826) a formal decision in his favour. It did not omit, however, to censure him for his precipitate and unauthorized emancipation of the Company’s slaves,” or after his death to make his widow pay £10,000 for various items, which included the expense of his mission to found Singapore. Harassed as he was by these personal affairs, he still found time to carry out his original scheme with regard to a zoological society in London. He took the largest part in the creation of the existing society, and his fine Sumatra collection formed its endowment. He was unanimously elected its president at the first meeting, and by a remarkable unanimity of opinion on the part of those who helped in the work, he has been recognized as “the Founder of the Zoological Society.” He was contemplating entering parliamentary life when his sudden death on his birthday, 1826, ended his brilliant career at the early age of forty-five. Sir Frederick Weld, lieutenant-governor at Singapore, when unveiling the statue of his predecessor at that place in 1887, crystallized the thoughts of his countrymen and anticipated the verdict of history in a single sentence: “In Raffles, England had one of her greatest sons.”

See Lady Raffles, Memoir of Sir Thomas Stamford Raffles (1830); D. C. Bouger, Life of Sir Stamford Raffles (1867); Hugh Egerton, Sir Stamford Raffles (1899); J. Buckley, Records of Singapore (1903).

RAFN, KARL CHRISTIAN (1795-1864), Danish archaologist, was born in Brahesborg, Fünen, on the 16th of January 1795, and died at Copenhagen on the 20th of October 1864. He is chiefly known in connexion with the controversy as to the question of the discovery of America by the Norsemen, his
RAFTER—RAG-STONE 815

views being contained in his chief work, *Antiquitates Americanae* (Copenhagen, 1837). See LEIF ERICSSON.

RAFTER, a beam in a sloping roof to which is attached the framework for the slating, tiling or other external covering (see Roofs). The O.Eng. *rafter* is cognate with Scand. *ræft*, Dan. and Swed. *røft* or *råft*, a beam, which, in the special sense of a building component, gives rise to the English "raft." The ultimate base of these words is the root *ræft*, to cover, seen in Gr. *δυσφορή,* roof.

RAGATZ, a famous watering-place in the Swiss canton of St Gall, situated on the left bank of the Rhine, and by rail 13½ m. N. of Coire or 6½ m. S.E. of Zürich. It stands at a height of 96 ft., at the entrance to the magnificent gorge of the Tamina, about 3 m. up which by carriage road are the extraordinarily placed Baths of Pfäfers (2247 ft.). Since 1840 the hot mineral waters of Pfäfers are conducted in pipes to Ragatz, which is in a more pleasant position. Consequently Ragatz has much increased in importance since that date. In 1900 its native population was 1866, mainly German-speaking, while there were 1472 Romanists to 392 Protestants. The annual number of visitors is reckoned at 30,000. In the churchyard is the grave of the philosopher Schelling (d. here in 1854). About 2 m. by road above Ragatz are the 17th-century buildings (now the cantonal lunatic asylum) of the great Benedictine abbey of Pfäfers (720-1838), to which all this region belonged till 1798; while midway between them and Ragatz are the ruins of the 14th-century castle of Wartenstein, now accessible from Ragatz by means of a funicular railway. (W. A. B. C.)

JAMES HENRY SOMERSET, 1st Baron Raglan (1788-1855), British field marshal, was the eighth and youngest son of Henry, 5th duke of Beaufort, by Elizabeth, daughter of Admiral the Hon. Edward Boscowan, and was born on the 30th of September 1788. His elder brother, General Lord (Robert) Edward (Henry) Somerset (1776-1842), distinguished himself as the leader of the Household Cavalry brigade at Waterloo. Lord Fitzroy Somerset was educated at Westminster school, and entered the army in 1804. In 1807 he was attached to the Hon. Sir Arthur Paget's embassy to Turkey, and the same year he was selected to serve on the staff of Sir Arthur Wellesley in the expedition to Copenhagen. In the following year he accompanied the same general in a limited capacity to Portugal, and during the whole of the Peninsular War was at his right hand, first as aide-de-camp and then as military secretary. He was wounded at Busaco, became brevet-major after Fuentes de Oñoro, accompanied the stormers of the 52nd light infantry as a volunteer at Ciudad Rodrigo and specially distinguished himself at the storming of Badajoz, being the first to mount the breach, and afterwards showing great resolution and promptitude in securing one of the gates before the French could organize a fresh defence. During the short period of the Bourbon rule in 1814 and 1815 he was secretary to the English embassy at Paris. On the renewal of the war he again became aide-de-camp and military secretary to the duke of Wellington. About this time he married Emily Harriet, daughter of the 3rd earl of Mornington, and Wellington's niece. At Waterloo he was wounded in the right arm and had to undergo amputation, but he quickly learned to write with his left hand, and on the conclusion of the war resumed his duties as secretary to the embassy at Paris. From 1818 to 1820, and again in 1826-29, he sat in the House of Commons as member for Truro. In 1819 he was appointed secretary to the duke of Wellington as master-general of the ordnance, and from 1827 till the death of the duke in 1852 was military secretary to him as commander-in-chief. He was then appointed master-general of the ordnance, and was created Baron Raglan. In 1854 he was promoted general and appointed to the command of the English troops sent to the Crimea (see CRIMEAN WAR) in co-operation with a strong French army under Marshal St Arnaud and afterwards, up to May 1855, under Marshal Canrobert. Here the advantage of his training under the duke of Wellington was seen in the soundness of his generalship, and his diplomatic experience stood him in good stead in dealing with the generals and admirals, British, French and Turkish, who were associated with him. But the trying winter campaign in the Crimea also brought into prominence defects perhaps traceable to his long connection with the formalities and uniform regulations of military offices in peace and brought more severely to the hardships and sufferings of the English soldiers in the terrible Crimean winter before Sevastopol, owing to failure in the commissariat, both as regards food and clothing. Lord Raglan and his staff were at the time severely censured by the press and the government; but, while Lord Raglan was possibly to blame in representing matters in a too sanguine light, it afterwards appeared that the chief neglect rested with the home authorities. But this hopefulness was a shining military quality in the midst of the despondency that settled upon the allied generals after their first failures, and at Balaklava and Inkermann he displayed the promptness and resolution of his youth. He was made a field marshal after Inkermann. During the trying winter of 1854-55, the suffering he was compelled to witness, the censures, in great part unjust, which he had to endure and all the manifold anxieties of the siege seriously undermined his health, and although he found a friend and ardent supporter in his new French colleague, General Pélissier (q.v.), disappointment at the failure of the assault of the 18th of June 1855 finally broke his spirit, and very shortly afterwards, on the 28th of June 1855, he died of dysentery. His body was brought home and interred at Badminton.

His elder son having been killed at the battle of Ferozeshah (1849), the title descended to his younger son Richard Henry Fitzroy-Somerset, and Baron Raglan (1817-1854); and subsequently to the latter's son, George Fitzroy Henry Somerset, 3rd baron (b. 1857), under-secretary for war 1900-2, lieutenant-governor of the Isle of Man (1902) and a prominent military officer.

RAGMAN ROLLS, the name given to the collection of instruments by which the nobility and gentry of Scotland were compelled to subscribe allegiance to Edward I. of England between the conference of Norham in May 1291 and the final award in favour of Balliol in November 1292, and again in 1296. Of the former of these records two copies were preserved in the chapter-house at Westminster (now in the Record Office, London), and it has been printed by Rymer (Foroeda, ii. 454). Another copy, preserved originally in the Tower of London, is now also in the Record Office. The latter record, containing the various acts of homage and fealty extorted by Edward from Balliol and others in the course of his progress through Scotland in the summer of 1296 and in August at the parliament of Berwick, was published by Prynne from the copy in the Tower and now in the Record Office. Both records were printed by the Bannatyne Club in 1834. The derivation of the word "ragman" has never been satisfactorily explained, but various guesses as to its meaning and a list of examples of its use for legal instruments both in England and Scotland will be found in the preface to the Bannatyne Club's volume, and in Jamieson's *Scottish Dictionary,* s.v. "Ragman." The name "ragman roll" survives in the colloquial "rigmarole," a rambling, incoherent statement.

The name of "Ragman" has been sometimes confounded to the record of 1296, of which an account is given in *Calendar of Documents relating to Scotland preserved in the Public Record Office,* London (1884), vol. ii., Intro., p. xxi.; and as to the seals see p. lii. and appendices.

RAG-STONE (probably equivalent to "ragged" stone), a name given by some architectural writers to work done with stones which are laid in the places such as the Horsham sandstone, Yorkshire stone, the slate slabs, &c., that are more properly flag or slab work. By rag-stone, near London, is meant an excellent material from the neighbourhood of Maidstone. It is a very hard limestone of bluish-grey colour, and peculiarly suited for medieval work. It is often laid as uncoursed work, or random work (see RANDOM), sometimes as random coursed work and sometimes as regular ashlar. The first method, however, is the more picturesque. (See MASONRY.)
RAGUSA (Serbo-Croatian Dubrovnik), an episcopal city, and the centre of an administrative district in Dalmatia, Austria. Pop. (1880) of town and commune, 13,774, including a garrison of 1,112. Its situation and its undisturbed atmosphere of antiquity combine to make Ragusa by far the most picturesque city on the Dalmatian coast. It occupies a ridge or promontory, which juts out into the Adriatic Sea, under the bare limestone mass of Monte Sergio. Its seaward fortifications rise directly from the water's edge, one fort, on the north mole, standing boldly on a tall rock almost isolated by a little inlet of the Adriatic. On the landward side a massive round tower dominates the city from a still higher eminence. Beyond the walls and the deep moat, especially on the landward side towards the port of Gravosa, are many pleasant villas, surrounded by gardens in which the aloë, palm and cypress are conspicuous among a number of flowering trees and shrubs. The island of Lacroma lies less than half a mile to the south. Between the seaward ridge and the mountain, the Stradone, or main street, runs along a narrow valley which, until the 13th century, was a marshy channel, dividing the Latin island of Ragusa from the Slavonic settlement of Dubrovnik, on the lower slopes of Monte Sergio. Parallel to the Stradone, on the north, is the Prijeki, a long, very narrow street, flanked by tall houses with overhanging balconies, and greatly resembling a Venetian alley. Despite the havoc wrought by earthquake in 1607, the whole city is rich in antiquarian interest. It possesses one church, of the Byzantine period, which is mentioned in 13th-century documents as even then of great age. Two stately convents of the 14th century stand at the ends of the city; for the Franciscans were set to guard the western gate, or Porta Pile, against the hostile Slavs, while the Dominicans kept the eastern gate, or Porta Place. The Franciscan cloister is a fine specimen of late Romanesque; that of the Dominicans is hardly inferior, though of later date. The Dominican church is approached by a sloping flagged lane, having on one side a beautifully ornamented balustrade of the 18th century. Another 14th-century building is the Sponza, or custom-house, from which the state derived its principal revenue. A fountain and a curious clock-tower in the Piazza, which terminates the Stradone towards the east, were erected by Onofrio, the architect and engineer whose aqueduct, built about 1440, supplied Ragusa with water from the neighbouring hills. The Rector's Palace, another noteworthy example of late Romanesque, combined with Venetian Gothic, is one of the masterpieces of Dalmatian architecture. It has a fine façade of six arches, and the capitals of the supporting pillars are very curiously carved. Especially interesting is the figure of Aesculapius, whose traditional birthplace was Epidaurus or Epidavros, the parent city of Ragusa. The cathedral dates from the 18th century; and to the same period belongs another church, rebuilt after a fire, but originally erected as a votive offering after the pestilence of 1348, and dedicated to San Biagio (St Blaise), the patron of Ragusa, whose name and effigy continually appear on coins and buildings. Among many fine pieces of mediaeval art preserved in the ecclesiastical treasures is a painting of the Saviour of the 16th century. It is mentioned the silver statuette of San Biagio, and the reliquary which contains his skull—a 17th-century casket in filigree and enamels with Byzantine medallions of the 11th or 12th century.

The harbour of Ragusa, once one of the chief ports of southern Europe, is too small for modern needs; but Gravosa (Grusi), a village at the mouth of the river Ombra, on the north, is a steamship station and communicates by rail with Herzegovina and the Bocche di Cattaro. Ragusa has thus some transit trade with the interior. Its industries include the manufacture of liquors, oil, silk and leather; but Montenegro, its famous wine, could no longer be produced after the vine-disease of 1832.

History.—The name Ragusa is of uncertain origin. Constantine Porphyrogenitus, in the 10th century, connects its early form, Lause, with Λαυς, a "precipice." Jireček dissent from this view, and from the common opinion that Dubrovnik is derived from the Slavonic dubrava, "wooded." The city first became prominent during the 7th century. In 639 and 656 the flourishing Latin communities of Salona and Epidaurum were destroyed by the Avars, and the island rock of Ragusa was colonized by the survivors. Tradition identifies Epidaurum, whence the majority came, with the neighbouring village of Ragusavecchia; but some historians, including Gelech, place it on the shores of the Bocche di Cattaro. Both sites show signs of Roman occupation. A colony of Slavs soon joined the Latin settlers at Ragusa, and thus, from an early date, the city formed a link between two great civilizations (see VLACHS). In the 9th century it is said to have repulsed the Saracens; in the 10th it defended itself against the Narentine pirates, and Simeon, tsar of the Bulgarians. Some writers consider that it submitted to Venice in 998, with the rest of Dalmatia; but this is generally denied by the native historians. During the 11th century an enforced alliance with the Normans drew the republic into war with Venice and Byzantium; and in the 12th century it was attacked by the Bosnians and Serbs. From 1205 to 1358 it acknowledged Venetian suzerainty; its chief magistrate was the Venetian count, and its archbishops, who wielded much political influence, were often Venetian nominees. The constitution took shape during this period, and the first statute-book was published in 1722. Only patricians could hold office in the senate, grand council and lesser council, three bodies which shared the work of government with the count, or, after 1358, the rector. The ancient popular assembly was almost obsolete before the 14th century. Ragusan policy was usually peaceful, and disputes with other nations were frequently arranged by a system of arbitration called stanicium. To refugees of all nations, even to those who had been its own bitter foes, the city afforded asylum; and by means of treaty and tribute it worked its way to a position of mercantile power which Europe could hardly parallel. It was conveniently situated at the seaward end of a great trade route, which bifurcated at Plevle to Byzantium and the Danube. A compact with the Turks, made in 1570 and renewed in the next century, saved Ragusa from the fate of its more powerful neighbours, Servia and Byzantium, besides enabling the Ragusan caravans to penetrate into Hungary, Croatia, Bosnia, Servia, Bulgaria and Rumania. From 1358 to 1526 the republic was a vassal state of Hungary, and no longer controlled by its greatest commercial rival. It acquired, among the Adriatic islands, the towns of Ploce, Prijeki, Argouses; and in 1413-1416 it held the islands of Curzola, Brazza and Lemina by lease from Hungary. Meanwhile, Ragusan vessels were known not only in Italy, Sicily, Spain, Greece, the Levant and Egypt, but in the more northern parts of Europe. The English language retains in the word "argoys" a reminiscence of the caravans of Ragusa, long known to Englishmen as Argoues, Argus or Aragosa. In the 16th century the Ragusan merchants went even to India and America, but they were unable to compete with their rivals from western Europe. Many of their seamen earned their livelihood by trade with Spain; and twelve of their finest ships were lost with the Invincible Armada in 1588. After 1526 the downfall of Hungary left Ragusa free; and about this time a great development of art and literature, begun in the 15th century and continued into the 17th, earned for the city its title of the "South Slavonic Athens." (See SERVIA, LITERATURE.) The earthquake of 1667, which had been preceded by lesser shocks in 1526, 1521, 1536 and 1639, destroyed a considerable portion of the city, and killed about one-fifth of the inhabitants. Only during the Napoleonic wars did the republic regain its prosperity. From 1800 to 1805 it was the sole Mediterranean state remaining neutral, and thus it secured a very large share of the carrying trade. In 1805, however, it was seized by the French; Napoleon deprived it of independence; and in 1814 it was annexed to Austria. See L. Villari, The Republic of Ragusa (London, 1894), for a thorough description and history, with a full bibliography. T. G.
the best account of Ragusan architecture and antiquities. The most accurate native history is G. Ceicich (Celiké), *Dello Stuzzzio civile di Ragusa* (Ragusa, 1884). The course of Ragusan trade may be studied in C. J. Jirkov, *Die Handelsstrassen und Bargelstrassen Serbien, &c.* (Prague, 1879); and Heyd, *Histoire du commerce du Levant au moyen âge* (Leipzig, 1885).

**RAGUSA**, a town of Sicily in the province of Syracuse, 70 m. S.W. of Syracuse by rail and 32 m. direct. It consists of an upper (Ragusa Superiore) and a lower town (Ragusa Inferiore), each of which forms a separate commune. Pop. (1906) of the former, 35,529; of the latter, 566. It has some churches with fine Gothic architecture, and is commercially of some importance, a stone impregnated with bismuth which is quite valuable for roofing slabs by being exposed to the action of fire. On the hill occupied by the castle of Ragusa Inferiore stood the ancient Hybla Heraea, a Sicel town, under the walls of which Hippocrates of Gela fell in 401 B.C. A Greek settlement seems to have arisen in the neighbourhood close to the present railway station, about the middle of the 6th century B.C., and to have disappeared at the end of the 5th. Orsi points out that the remains (cuttings in the rock and a part of the castle wall), attributed by Freeman (*History of Sicily*, i. 163) to Sicel times, are in reality post-Roman.

See Orsi in Notizie degli scavi (1899), 402-418.

**RAHWAY**, a city of Union county, New Jersey, U.S.A., in the northeastern part of the state, on the Rahway river and about 20 m. S.W. of New York City. Pop. (1850) 7105; (1900) 7935, of whom 1345 were foreign-born; (1910 U.S. census) 9337. Rahway is served by the main line of the Pennsylvania railroad, and is connected with neighbouring cities by electric lines. It has wide streets and attractive parks, and is, to some extent, a residential suburb of New York and other neighbouring cities. It has a public library (1864), with upwards of 17,000 volumes, and about 15 m. distant is the New Jersey Reformatory (1903), to which prisoners between the ages of sixteen and thirty may be sentenced instead of to the State Prison. There are various manufactures. Rahway was first settled in 1720, and was named in honour of the Indian chief Rahwack, whose tribe owned the site and the surrounding territory; it was chartered as a city in 1838. For many years Rahway was popularly known as Spantown, and in January 1777, during the War of Independence, a skirmish, known as the battle of Spantown, was fought there.

**RAICHER**, a town of India, in the state of Hyderabad, at the junction of the Madras and Great Indian Peninsula railways, 351 m. N.E. from Madras. Pop. (1901) 22,165. It gives its name to the doab, or tract between the rivers Kistna and Tunga-bharati, which was the scene of much fighting between Hindoos and Hindus as debatable land during the 16th century. It contains a well-preserved fort and two old mosques. It is a thriving centre of trade, with several cotton-presses.

**RAID**, in the language of international law, an invasion by armed forces, unauthorized and unrecognized by any state, of the territory of a state which is at peace. Piracy is the attack on the high sea of any vessel by an armed vessel, not authorized or recognized by any state, for the purpose of robbery. A raid for the purpose of carrying off movable property and converting it to the use of the captors would still be distinguishable from piracy, because it was committed on territory subject to an exclusive territorial jurisdiction. Where the attack or invasion by an armed ship not authorized or recognized by any state is not for the purpose of capturing property, it is properly speaking a raid and not piracy. An attack though in time of peace, by armed forces authorized or recognized by a regular government, is not a raid but an act of war, there being a government responsible for the act committed. The fact of any act being authorized, not by the supreme government, but by a chartered company, or by its governing officer, makes no difference in international law, the directorate of a chartered company exercising its powers by delegation of the state under which it holds its charter.

The acts of its armed forces cannot in reason be distinguished from the acts of the armed forces of the state government. Thus commission is just as much due for them as for the deliberate acts of the state itself, and any claim of an injured state can only be preferred against the state to which the company belongs. Invasion by the regular forces of a state, or by the regular forces of its delegated authority, being an act of war, the laws of war apply to it, and, on capture, such forces, or any members or part of such forces, are prisoners of war. On the other hand, the state whose subordinate authorities commit acts of war against a friendly state has the option of following them up as a commencement of hostilities, or of giving satisfactory compensation to the invaded state. Where the invasion or subject to invasion of a state, the invaded state has the right to apply its own laws for the repression of disturbances in its territory. Thus, in the so-called Jameson Raid, the Transvaal government had no right to treat Dr Jameson, an officer holding his powers under the British government, and his subordinates, as outlaws, and it was probably so advised, and the British government owed proper compensation for an act for the consequences of which, under international law, it was responsible.

British domestic law punishes raiding under the Foreign Enlistment Act 1870, 33 & 34 Vict. c. 90,1 section 17 (1890) of the 1890 Act provides that no person engaged or acting within the limits of His Majesty’s dominions, and without the licence of His Majesty, prepares or fits out any naval or military expedition to proceed against the dominions of any friendly state, the following consequences shall ensue: (1) Every person engaged in such preparation or fitting out, or assisting therein, or employed in any capacity in such expedition, shall be guilty of an offence against this act, and shall be punishable by fine and imprisonment or either of such punishments, at the discretion of the Court before which the offender is convicted; and imprisonment, if awarded, may be either with or without hard labour. (2) All ships and their equipment, and all arms and munitions of war, used in or forming part of such expedition, shall be forfeited by His Majesty.2 Section 12 provides for the punishment of accessories as principal offenders, and section 13 limits the term of imprisonment for any offence under the act to two years. In the Sandoval case (1886),3 in which Colonel Sandoval, who was not a British subject, bought guns and ammunition and shipped them to Antwerp, where they were put on board a vessel, which afterwards made an attack on Venezuela, it was held that the offence of fitting out and preparing an expedition within British territory against a friendly state, under this section, is sufficiently constituted by the purchase of guns and ammunition, the sending them to the place or the purpose of being put on board a ship in a foreign port, with knowledge of the purchaser and shipper that they are to be used in a hostile demonstration against such state, though the shipper takes no part in any overt act of war, and the ship is not fully equipped for the expedition within any British port. Under the same section, Dr Jameson, administrator of the British South Africa Company, and his confederates were tried before the Central Criminal Court and sentenced to different terms of imprisonment.4 The offence committed under a British act is, of course, that of preparing and fitting out an expedition on British territory. Any acts subsequently committed by any British expedition on foreign soil are beyond the operation of domestic legislation, and fall to be dealt with by the domestic legislation of the state within which they occur, or by diplomacy, as the case may be. (T.B.A.)

**RAIFFEISEN, FRIEDRICH WILHELM** (1818-1888), founder of the German system of agricultural co-operative banks, was

---

1. The preamble to the Foreign Enlistment Act 1870 stated that its object was “to make provision for the regulation of the conduct of Her Majesty’s subjects during the existence of the state of war”. The invasion is not by forces subject to the law of war. This preamble was repealed by the Statutes Law Revision (No. 2) Act 1893.

2. V. Sandoval, 1886, 56 Law Times, 526.

born at Hamm on the Sieg on the 30th of March 1818, being the son of Gottfried Raiffeisen, burgomaster of that place. Educated privately, he entered the artillery in Cologne, but defective eyesight compelled him to leave the army. He then entered the public service at Coblenz, and in 1845 was appointed burgomaster of Weyerbusch. Here he was so successful that in 1848 he was transferred in a like capacity to Flammersfeld, and in 1852 to Heidersdorf. Raiffeisen devoted himself to the improvement of the social condition of the cultivators of the soil, and did good work in the planning of public roads and in other ways. The distress of the years 1846–47, the causes of which he discerned in the slight amount of credit obtainable by the small landed proprietors, led him to seek for a remedy in co-operation, and at Heidersdorf and at Weyerbusch he started a co-operative grain bank (Darlehnskassenverein). These banks were called after him, and their foundation resulted in a widespread system of land banks, supported by the government. In 1865 the state of his health compelled him to retire, but he continued to take an interest in the movement he had originated, and in 1878 he founded at Neuwied a periodical, Das landwirtschaftliche Genossenschaftsblatt. He died on the 11th of March 1888.

Among Raiffeisen’s writings are, Die Darlehnskassenvereine als Mittel zur besseren Betreibung der Kreishandels- und Grundungszwecke (1867); Geschäftsführung ländlicher Spar- und Darlehnskassenvereine (new ed., 1896); and Kurze Anleitung zur Gründung von Darlehnskassenvereinen (new ed., 1898).

RAIKAES, ROBERT (1735–1811), English educationist, the founder of Sunday schools, was the son of Robert Raikes, a printer in Gloucester and proprietor of the Gloucester Journal, and was born on the 14th of September 1735. On the death of his father in 1757 he succeeded him in the business, which he continued to conduct till 1782. Along with some others he started a Sunday school at Gloucester in 1780, and on his giving publicity to the enterprise in the columns of his journal the notice was copied into the London papers and awakened considerable attention. For nearly thirty years he continued actively engaged in the promotion of his undertaking, and he lived to witness its wide extension throughout England. He died on the 5th of April 1811. His statue stands on the Thames Embankment.

Among various accounts of the life and work of Raikes mention may be made of that by P. M. Eastman, 1880.

RAIL (1) (From Fr. Râle, cf. Ger. Ralle, Low Lat. Railius, of unknown origin), originally the English name of two birds distinguished from one another by a prefix as land-rail and water-rail, but latterly applied in a much wider sense to all the species which are included in the family Rallidae.

The land-rail, also very commonly known as the corn-rail, and sometimes as the daker-hen, is the Rallus crex of Linnaeus and Crex crex proterus of recent authors. Its monotonous grating cry has given it its common name in several languages. With comparatively few individual exceptions, the land-rail is essentially migratory. It is the Ortygometra of classical authors—supposed by them to lead the quail (g.s.) on its voyage. The course of its breeding has now been known to reach the coast of Greenland, and several times that of North America, to say nothing of Bermuda, in every instance we may believe as a straggler from Europe or Barhary. The land-rail looks about as big as a partridge, but on examination its appearance is far more retiring, and it will hardly ever be seen more than half as much. The colour of the upper plumage is a tawny brown, the feathers being longitudinally streaked with blackish brown; beneath it is of a yellowish white; but the flanks are of a light chestnut barred with white. The species is very locally distributed, and in a way for which there is at present no accounting. In some dry upland and corn-growing districts it is plentiful; in others, of apparently the same character, it but rarely occurs; and the same may be said in regard to low-lying marshy meadows, in most of which it is in season always to be heard, while in others having a very similar situation to those to which it is ever met with. The nest is on the ground, generally near the periphery of a crop of grass, and to eleven eggs are commonly laid. These are of a cream-coloured, spotted and blotched with light red and grey. The young when hatched are thickly clothed with black down, as is the case in nearly all species of the family.

The water-rail, locally known as the skiddy or billock, is the Rallus aquaticus of ornithology, and seems to be less abundant than the preceding, though that is in some measure due to its frequenting places into which from their swampy character men do not often intrude. Having a general resemblance to the land-rail, it can be in a moment distinguished by its very small size and metallic voice. It has no such beautiful plumage—the upper parts being of an olive brown with black streaks, the breast and belly of a sooty grey, and the flanks dull black barred with white. Its geographical distribution is very wide, extending from Iceland (where it is said to preserve its existence during winter by resorting to the hot springs) to China; and though it inhabits Northern India, Lower Egypt and Barhary, it seems not to pass beyond the tropical line. It never affects upland districts as does the land-rail, but always haunts wet marshes or the close vicinity of water. Its love-note is a loud and harsh cry, not continually repeated as is that of the land-rail, but uttered at considerable intervals and so suddenly as to have been termed “explosive.” Besides this, which is peculiar to the cock-bird, it has a croaking call that is frog-like. The eggs resemble those of the preceding, but are more brightly and delicately tinted.

The various species of rails, whether allied to the former or latter of those just mentioned, are far too numerous to be here noticed. Hardy any part of the world is without a representative of the genera Crex or Rallus, and every considerable country has one or other of each; though it has been impossible to refer them to many other genera, the characters of which are with difficulty found. Thus in Europe alone three other species are to be found: Rallus aquaticus, in the violin of which the spotted rail or crake, has been made the type of a sub-genus Porta, and the other two, little birds not much bigger than larks, are considered to form a genus Zapornia. The first of these, which used not to be uncommon in the part of England, has a very near representative in the Carolina rail or sora, Crex carolina, of North America, often there miscalled the ortolan, just as its European analogue, C. portors, is in England often termed the dotterel. But, passing over these as well as some belonging to genera that can be much better defined, and other still more interesting forms of the family, as Aphaniapteryx, coot (g.s.), Moorhen (g.s.) and ocydrom (g.s.), a few words must be added of the group of birds more closely allied, under the name Helornis, and the African and Indian Podica, comprising four or five species, to which the name “Finfoots” has been applied—from the lobes or flaps of skin that fringe their toes. Though for a long while placed among the Podicipedidae (see Grebe), their osteology no less than their habits appear to indicate their alliance with the rails, and they are placed as a separate family, Helornidae. This order of birds is remarkable for the extreme elongation of the leg and toes, which would seem to show the extreme modification of that type in adaptation to aquatic life. The curious genus Mesites of Madagascar, whose systematic place has been so long in doubt, has been referred by A. Milne-Edwards (Anim. sans vert., art. 160, p. 182) to the neighbourhood of the rails, but is now associated as a sub-order Mesitidae with Galliform birds. On the other hand the jacanas or Pœridiæ, which from their long toes were once thought to belong
to the rails, are now generally admitted to be Limicoline, while the genus _Aramus_—the curlew or limpkin of the southern United States—still occupies a very undetermined position. (A. N.)

(2) Through O.Fr. _raille_, from Lat. _regula_, a rule; the Du. and Swed. _regel_, Ger. _Riegel_, bolt or bar, are probably also from the Latin), a horizontal bar of wood, metal or other material resting on, or fixed in, upright posts to form a fence, or as a support for hanging things on, to form the "hand-rail" of the stair, &c.; on a ship the upper part of the bulwarks, e.g. the "taffrail," round the stern bulwarks; especially, one of the pair of iron or steel bars on which a train or tram runs (see RAILWAYS).

There are two other words "rail": (1) an obsolete word (O.E. _hrægel_), for a garment, often in the compound "night-rail"; and (2) a verb, to abuse, use angry language, from Fr. _raillet_, possibly from the same root as Lat. _ruder_, to rub. The word is found in "rally," to banter, tease (distinguishing, however, "rally," to "bring together, especially of defeated troops" (from Fr. _railler_; re, again, and _aller_, ally, Lat. _alligare_).

**RAILWAYS.** Railways had their origin in the tramways (q.v.) or wagon-ways which at least as early as the middle of the 10th century were used in the mineral districts of England round Newcastle for the conveyance of coal from the pits to the river Tyne for shipment. It may be supposed that originally the public roads, when worn by the cartage of the coal, were repaired by laying planks of timber at the bottom of the rutts, and that then the planks were laid on the surface of special roads or ways formed between the collieries and the river. "The manner of the carriage," says Lord Keeper North in 1676, "is by laying rails of timber . . . exactly straight and parallel, and bulky carts are made with four rouletts fitting these rails, whereby the carriage is so easy that one horse will draw down four or five chaldrons of coal" (from 10-6 to 13-2 tons). The planks were of wood, often bench, a few inches wide, and were fastened down, end to end, on logs of wood, or "sleepers," placed crosswise at intervals of two or three feet. In time it became a common practice to cover them with a thin sheathing or plating of iron, in order to add to their life; this expedient caused more wear on the wooden rollers of the wagons, and, apparently towards the middle of the 18th century, led to the introduction of iron wheels, the use of which is recorded on a wooden railway near Bath in 1734. But the iron sheathing was not strong enough to resist buckling under the passage of the loaded wagons, and to remedy this defect the plan of making the rails of iron was adopted. In 1767 the Colebrookdale Iron Works began to manufacture a batch of iron rails or plates, each 3 ft. long and 4 in. broad, having at the inner side an upright ledge or flange, 3 in. high at the centre and tapering to a height of 2½ in. at the ends, for the purpose of keeping the flat wheels on the track. Subsequently, to increase the strength, a similar flange was added below the rail. Wooden sleepers continued to be used, the rails being secured by spikes passing through the extremites, but about 1793 stone blocks also began to be employed—an innovation associated with the name of Benjamin Outram, who, however, apparently was not actually the first to make it. This type of rail (fig. 1) was known as the plate-rail, tramway-plate or barrow-way-plate—names which are preserved in the modern term "plate-layer" applied to the men who lay and maintain the permanent way of a railway.

Another form of rail, distinguished as the edge-rail, was first used on a line which was opened between Loughborough and Nanpantan in 1780. This line was originally designed as a "plate-way" on the Outram system, but objections were raised to raising the track with upstanding ledges or danger bars, and the South London Railway line was laid on the turnpike road which was crossed at Loughborough on the level. In other cases this difficulty was overcome by pavin or "cause-waying" the road up to the level of the top of the flanges, but

![Fig. 1.—Plate-Rail.](image1)

"Another thing that is remarkable in their way-leave; for, when men have pieces of ground between the colliery and the river, they sell leave to lead coals over their ground" (Roger North). on this occasion William Jessop, of the Butterley Iron Works, near Derby, proposed to get over by laying down two plates of iron, perfectly flat and level, with the road but each having on its outside a groove ½ in. wide and ⅛ in. deep to control extra guiding wheels which were to be of somewhat larger diameter than the bearing wheels and to be affixed to them. The rest of the line was laid with what were substantially plate-rails placed on their edge instead of flat. These were cast in 3 ft. lengths, of a double-flanged section, and for the sake of strength they were "fish-bellied" or deeper in the middle than at the ends. At one end of each rail the flange spread out to form a foot which rested on a cross sleeper, being secured to the latter by a spike passing through a central hole, and above this foot the rail was so shaped as to form a socket into which was fitted the end of the next rail. Each length was thus fastened to a sleeper at one end, while at the other it was socketed into the end of its fellow. This method, however, was not found satisfactory: the projecting feet were liable to be broken off, and in 1799 or 1800 Jessop abandoned them, using instead separate cast-iron sockets or chairs, which were fastened to the sleepers and in which the rails were supported in an upright position. In the first instance he proposed to place the guiding wheels outside the bearing wheels, and the Nanpantan line was laid on this plan with a width of 5 ft. between the guide wheels; but before it was opened he decided not only to cast the guiding wheels and bearing wheels in one piece but also to put the former inside the rails, arguing that with this arrangement the edge-rails themselves would keep the wheels in position on the axles, whereas with that first contemplated fastenings would have been required for them (fig. 2).

Jessop thus produced what was virtually the flanged wheel of to-day, having the flanges inside the rails, and it is said, established what has become the standard gauge of the world, 4 ft. 8⅜ in., or 5 ft. minus the width of two of his rails.

These two systems of constructing railways—the plate-rail and the edge-rail—continued to exist side by side until well on in the 19th century. In most parts of England the plate-rail was preferred, and it was used on the Surrey iron railway, from Wandsworth to Croydon, which, sanctioned by parliament in 1821, was finished in 1833, and was the first railway available to the public, and for a while the only permanent railway in the country, and it remained by far the most popular and common in use.

In South Wales again, where in 1811 the railways in connexions with canals, collieries and iron and copper works had a total length of nearly 150 miles, the plate-way was almost universal. But in the north of England and in Scotland the edge-rail was held in greater favour, and by the third decade of the century its superiority was generally established. The manufacture of the rails themselves was gradually improved. By making them in longer lengths a reduction was effected in the number of joints—always the weakest part of the line; and another advance was in the substitution of wrought iron for cast iron, though that material did not gain wide adoption until after the patent for an improved method of rolling rails granted in 1820 to John Birkinshaw, of the Bedlington Ironworks, Durham. His rails were wedge-shaped in section, much wider at the top than at the bottom, with the intermediate portion or web thinner still, and he recommended that they should be made 18 ft. long, even suggesting that several of them might be welded together end to end to form considerable lengths. They were supported on sleepers, and were fish-bellied between chairs at intervals of 3 ft., and were fish-bellied between chairs at intervals of 3 ft., and were fastened by George Stephenson on the Stockton & Darlington and Whistable & Canterbury lines they weighed 28 lb. per yard. On the Liverpool & Manchester railway they were usually 12 ft. or 15 ft. long and weighed 35 lb. to the yard, and they were fastened by iron wedges to chairs weighing 15 or 17 lb each. The chairs were
in turn fixed to the sleepers by two iron spikes, half-round wooden cross sleepers being employed on embankments and stone blocks 20 in. square by 10 in. deep in cuttings. The fish-bellied rails, however, were found to break near the chairs, and from 1834 they began to be replaced with parallel rails weighing 50 lb to the yard.

The next important development in rail design originated in America, which, for the few lines that had been laid up to 1830, remained content with wooden bars faced with iron. In that year Robert Livingston Stevens (1787-1839), devised for the Camden & Amboy railway a rail similar as to its top to those in use in England, but having a flat base or foot by which it was secured to the sleepers by hook-headed spikes, without chairs (fig. 3); he had to get the first lot of these rails, which were 15 ft. long and weighed 36 lb to the yard, manufactured in England, since there were then no mills in America able to roll them. This type, which is often known as the Vignoles rail, after Charles' Blacker Vignoles (1793-1879), who re-invented it in England in 1836, is in general use in America and on the continent of Europe. The bridge-rail (fig. 4)—so called because it was first laid on bridges—was supported on continuous longitudinal sleepers and held down by bolts passing through the flanges, and was employed by I. K. Brunel on the Great Western railway, where, however, it was abandoned after the line was converted from broad to standard gauge in 1832. In the double-headed rail (fig. 5), originated by Joseph Locke in 1837, and first laid on the Grand Junction railway, the two tables were equal. This rail was more easily rolled than others, and, being reversible, was in fact two rails in one. But as it was laid in cast-iron chairs the lower table was exposed to damage under the hammering of the traffic, and thus was liable to be rendered useless as a running surface. In consequence the bull-headed rail (fig. 6) was evolved, in which the lower table was made of smaller size and was intended merely as a support, not as a surface to be used by the wheels. There was a waste of metal in these early rails owing to the excessive thickness of the vertical web, and subsequent improvements have consisted in adjusting the dimensions so as to combine strength with economy of metal, as well as in the substitution of steel for wrought iron (after the introduction of the Bessemer process) and in minute attention to the introduction of the steel employed.

It was found, naturally, that the rails would not rest in their chairs at the joints, but were loosened and bruised at the ends by the blows of the traffic. The fish-joint was therefore devised in 1847 by W. Bridges Adams, the intention being by "fishing" the joints to convert the rails into continuous beams. In the original design two chairs were placed, one under each rail, a few inches apart, as in fig. 7. The joint was thus suspended between the two chairs, and two keys of iron, called "fishes," fitting the side channels of the rails, were driven in on each side between the chairs and the rails. In subsequent modifications the fishes were, as they continue to be, bolted to and through the rails, the chairs being placed rather further apart and the joint being generally suspended between them.

The iron tramway or railway had been known for half a century and had come into considerable use in connexion with collieries and quarries before it was realized that for the carriage of general merchandise it might prove a serious competitor to the canals, of which a large mileage had been constructed in Great Britain during that period. In the article on "Railways" in the Supplement to the Encyclopaedia Britannica, published in 1824, it is said: "It will appear that this species of inland carriage [railways] is principally applicable where trade is considerable and the length of conveyance short; and is chiefly useful, therefore, in transporting the mineral produce of the kingdom from the mines to the nearest land or water communication, whether sea, river or canal. Attempts have been made to bring it into more general use, but without success; and it is only in particular circumstances that navigation, with the aid either of locks or inclined planes to surmount the elevations, will not present a more convenient medium for an extended trade." It must be remembered, however, that at this time the railways were nearly all worked by horse-traction, and that the use of steam had made but little progress. Richard Trevithick, indeed, had in 1804 tried a high-pressure steam locomotive, with smooth wheels, on a plate-way near Merthyr Tydvil, but it was found more expensive than horses; John Blenkinsop in 1811 patented an engine with clogged wheel and rack-rail which was used, with commercial success, to convey coal from his Middleton colliery to Leeds; William Hedley in 1813 built two locomotives—Puffing Billy and Wylam Dilly—for hauling coal from Wylam Colliery, near Newcastle; and in the following year George Stephenson's first engine, the Blucher, drew a train of eight loaded wagons, weighing 30 tons, at a speed of 4 m. an hour up a gradient of 1 in 450. But, in the words of the same article, "This application of steam has not yet arrived at such perfection as to have brought it into general use."

The steam locomotive, however, and with it the railways, soon began to make rapid progress. On the Stockton & Darlington railway, which was authorized by parliament in 1821, animal power was at first proposed, but on the advice of Stephenson, its engineer, steam-engines were adopted. This line, with three branches, was over 38 m. in length, and was in the first instance laid with a single track, passing-places being provided at intervals of a quarter of a mile. At its opening, on the 27th of September 1825, a train of thirty-four vehicles, making a gross load of about 90 tons, was drawn by one engine driven by Stephenson, with a signalman on horseback in advance. The train moved off at the rate of from 10 to 12 m. an hour, and attained a speed of 15 m. an hour on favourable parts of the line. A train weighing 92 tons could be drawn by one engine at the rate of 5 m. an hour. The principal business of the new railway was the conveyance of minerals and goods, but from the first passengers insisted upon being carried, and on the 10th of October 1825 the company began to run a daily coach, called the "Experiment," to carry six inside, and from fifteen to twenty outside, making the journey from Darlington to Stockton and back in two hours. The fare was 1s., and each passenger was allowed to take baggage not exceeding 14 lb weight. The rate for carriage of merchandise was reduced from 5d. to one-fifth of a penny per ton per mile, and that of minerals from 7d. to 1d. per ton per mile. The price of coals at Darlington fell from 18s. to 8s. 6d. a ton.

The example of the Stockton & Darlington line was followed by the Monklands railway in Scotland, opened in 1826, and several other small lines—including the Canterbury &
Whitstable, worked partly by fixed engines and partly by locomotives—quickly adopted steam traction. But the Liverpool & Manchester railway, opened in 1830, first impressed the nation with the fact that a revolution in the methods of travelling had really taken place; and further, it was for it that the first high-speed locomotive of the modern type was invented and constructed. The directors having offered a prize of £500 for the best engine, trials were held on a finished portion of the line at Rainhill in October 1829, and three engines took part—the Rocket of George and Robert Stephenson, the Novelty of John Braithwaite and John Ericson, and the Sanspareil of Timothy Hackworth. The last two of these engines broke down under trial, but the Rocket fulfilled the conditions and won the prize. Its two steam cylinders were 8 in. in diameter, with a stroke of 1 ½ ft, and the driving wheels, which were placed in front under the funnel, were 4 ft. 8 1/2 in. in diameter. The engine weighed 45 tons; the tender following it, 3 tons 4 cwt.; and the two loaded carriages drawn by it on the trial, 9 tons 11 cwt.; thus the weight drawn was 122 tons, and the gross total of the train 17 tons. The boiler evaporated 183 cu. ft., or 114 gals., of water an hour, and the steam pressure was 50 lb per square inch. The engine drew a train weighing 13 tons 35 cwt. in 46 minutes, the rate being thus nearly 44 m. an hour; subsequently it drew an average gross load of 40 tons behind the tender at 13-3 m. an hour. The Rocket possessed the three elements of efficiency of the modern locomotive—the internal water-surrounded fire-box and the multitudinous flue in the boiler; the blast-pipe by which the steam after doing its work in the cylinders was exhausted up the chimney, and thus served to increase the draught and promote the rapid combustion of the fuel; and the direct connexion of the steam cylinders, one on each side of the engine, with the two driving wheels mounted on one axle. Of these features, the blast-pipe had been employed by Trevithick on his engine of 1804, and direct driving, without intermediate gearing, had been adopted in several previous engines; but the use of a number (29) of small tubes in place of one or two large flues was an innovation which in conjunction with the blast-pipe contributed greatly to the efficiency of the engine. After the success of the Rocket, the Stephensons received orders to build seven more engines, which were of very similar design, though rather larger, being four-wheeled engines, with the two driving wheels in front and the cylinders behind; and in October 1830 they constructed a ninth engine, the Planet, also for the Liverpool & Manchester railway, which still more closely resembled the modern type, since the driving wheels were placed at the fire-box end, while the two cylinders were arranged under the smoke-box, inside the frames. The modern features of the steam locomotive were thus established, and its subsequent development is chiefly a history of gradual increase in size and power, and of improvements in design, in material and in mechanical construction, tending to increased efficiency and economy of operation. In America the development of the locomotive dates from almost the same time as in England. The earliest examples used in that country, apart from a small experimental model constructed by Peter Cooper, came from England. In 1828, on behalf of the Delaware & Hudson Canal Company, which had determined to build a line, 16 m. long, from Carbondale to Honesdale, Pennsylvania, Horatio Allen ordered three locomotives from Messrs Foster & Rastick, of Stourbridge, and one from George Stephenson. The latter, named the America, was the first to be delivered, reaching New York in January 1829, but one of the others, the Stourbridge Lion, was actually the first practical steam locomotive to run in America, which it did on the 9th of August 1829. The first American-built locomotive, the Best Friend, of Charleston, was made at the West Point Foundry, New York, in 1830, and was put to work on the South Carolina railroad in that year. It had a vertical boiler, and was carried on four wheels all coupled, the two cylinders being placed in an inclined position and having a bore of about 6 in. with a stroke of 16 in. It is reported to have hauled 40 or 50 passengers in 4 or 5 cars at a speed of 16-21 m. an hour. After a few months of life it was blown up, its attendant, annoyed by the sound of the escaping steam, having fastened down the safety-valve. A second engine, the West Point, also built at West Point Foundry for the South Carolina railroad, differed from the Best Friend in having a horizontal boiler with 6 or 8 tubes, though in other respects it was similar. In 1831 the Baltimore & Ohio Company offered a prize of $4000 for an American engine weighing 34 tons, able to draw 15 tons at 15 m. an hour on the level: it was won by the York of Messrs Davis & Gartner in the following year. Matthias W. Baldwin, the founder of the famous Baldwin Locomotive Works in Philadelphia, built his first engine, Old Ironsides, for the Wilmington & Morrisville railroad; it was tried in November 1832, it was modelled on Stephenson's Planet, and had a single pair of driving wheels at the fire-box end and a pair of carrying wheels under the smoke-box. His second engine, the E. L. Miller, delivered to the South Carolina railroad in 1834, presented a feature which has remained characteristic of American locomotives—the front part was supported on a four-wheeled swivelling bogie-truck, a device, however, which had been applied to Puffing Billy in England when it was rebuilt in 1815. The Liverpool & Manchester line achieved a success which surpassed all the expectations of its promoters, and in consequence numerous projects were started for the construction of railways in various parts of Great Britain. In the decade following its opening nearly 2000 m. of railway were sanctioned by parliament, including the beginnings of most of the existing trunk-lines, and in 1840 the actual mileage reached 1331 m. The next decade saw the "railway mania." The amount of capital which parliament authorized railway companies to raise was about 45 millions on the average of the two years 1842-1843, 172 millions in 1844, 60 millions in 1845, and 132 millions in 1846, though this last sum was less than a quarter of the capital proposed in the schemes submitted to the Board of Trade; and the wild speculation which occurred in railway shares in 1845 contributed largely to the financial crisis of 1847. In 1850 the mileage was 6035, in 1860 it was 10,416, and in 1870 it was 15,310. The increase in the decade 1860-1870 was thus nearly 50%, but subsequently the rate of increase slackened, and the mileages in 1880, 1890 and 1900 were 17,035, 20,073 and 21,855. In the United States progress was more rapid, for, beginning at 2816 in 1840, the mileage reached 9015 in 1850, 30,600 in 1860, 87,801 in 1880, and 108,964 in 1900. Canada had no railway till 1833, and in South America construction did not begin till about the same time. France and Austria opened their first lines in 1828; Belgium, Germany, Russia, Italy and Holland in the succeeding decade; Switzerland and Denmark in 1834, Spain in 1848, Sweden in 1851, Norway in 1853, and Portugal in 1854; while Turkey and Greece delayed till 1860 and 1869. In Africa Egypt opened her first line (between Alexandria and Cairo) in 1856, and Cape Colony followed in 1860. In Asia the first line was that between Bombay and Tanannah, opened in 1853, and in Australia Victoria began her railway system in 1854 (see also the articles on the various countries for further details about their railways). Transcontinental Railways.—A railway line across North America was first completed in 1869, when the Union Pacific building from the Missouri river at Omaha (1400 m. west of New York), met the Central Pacific, which built from San Francisco eastwards, making a line 1848 m. long through a country then for the most part uninhabited. This was followed by the Southern Pacific in 1887, from San Francisco to New Orleans, 2400 miles; the Northern Pacific, from St Paul to Portland, Oreg., in 1883; the Atchison, Topeka & Santa Fé, from Kansas City to San Diego; and the Great Northern from St Paul to Seattle and New Westminster in 1893. Meanwhile the Canadian Pacific, a true transcontinental line, was built from Montreal, on Atlantic tide-water, to the Pacific at Vancouver, 2006 m. But these lines have been
dwarfed since 1891 by the Siberian railway, built by the Russian government entirely across the continent of Asia from Chelabinsk (1769 m. by rail east of St Petersburg) to Vladivostok, a distance of 4073 m., with a branch from Khabar about 500 m. long to Dalny and Port Arthur. The main line was finished in 1902, except for a length of about 170 m. in very difficult country around the south end of Lake Baikal; this was constructed in 1904, communication being maintained in the interval by ferry-boats, which conveyed all the carriages of a train across the lake, more than 40 m., when the ice permitted. A transcontinental line was long ago undertaken across South America from Buenos Aires to Valparaiso, where the continent is only about 900 m. wide. The last section through the Andes was finished in 1912. (H. M. R.)

### GENERAL STATISTICS

#### Mileage.—At the close of 1907 there were approximately 601,808 miles of railway in the world, excluding tramways. On the whole, the best statistical source for this information is the annual publication computed by the *Archiv für Eisenbahnen*, the official organ of the Prussian Ministry of Public Works; but the figure quoted above for the mileage of the Inter-state Commerce Commission for the United States is also reliable. The mileage was taken from the report of the Interstate Commerce Commission for the United States. In the United States and in certain other countries, a fiscal year, ending on the 30th of June or at some other irregular period, is substituted for the calendar year.

The partition of this total between the principal geographical divisions of the world is given in Table I.

#### Table II.—Classifying the mileage of Europe, shows that Russia has taken the lead, instead of Germany, as in former years. If the Atlantic portion of the Russian Empire were included in the sum of the Baltic, the Black Sea, and the Caspian, the total Russian mileage would appear nearly as large as that of Germany and Italy together.

In the United States railway mileage now tends to increase at the rate of slightly over 5000 miles a year, which is about 21% on the present main line mileage. In the 'eighties, the country passed through a period of competitive building, which was productive of much financial disaster. Thus, in 1882, 1890, and 1893, an additional equivalent to more than 11% of mileage then existing—and in 1887, 12,876 m. were built. Unjustifiable railway expansion had much to do with the American commercial panics of 1884 and 1893. After the reconstruction period of the 1893 panic, however, the tendency for a number of years was to spend larger sums in bettering existing railways rather than in new extensions. The decade from 1896 until 1905, inclusive, saw huge sums spent on yards, passing tracks, grade reduction, elimination of curves, substitution of large locomotives and cars for small ones, &c. During those ten years, the route mileage increased 34,091 m., or 17% while the mileage of second, third, fourth and yard tracks and all the increased 9,666 m., or nearly 57%. The number of locomotives increased 12,407, or 35% and the number of freight cars, 545,222, or 42.5%. Moreover, the average tractive power per locomotive and the average capacity per freight advanced greatly in this period, although specific figures cannot be given. Thus it may fairly be said that the railway system of the United States was reconstructed between 1896 and 1905, so far as concerns roadbeds, but not the general capacity, given a group of lines to perform work. About 1905, however, a new tendency became apparent. At that time the so-called transcontinental railways, connecting the Pacific coast of the United States with the central portions of the country, and thus with the group of railways reaching the Atlantic seaboard, consisted of five railways within the borders of the United States, and one in Canada. In Canada the Great Northern route, which begins from St John, on the Bay of Fundy, and from Quebec, on the river St Lawrence, to Vancouver, on the strait of Georgia, the distance being 2173 m. Within the boundaries of the United States the northernmost of the transcontinental lines was the Great Northern railway, extending from a point opposite Vancouver, B.C., and from Seattle, Wash., to St Paul and Minneapolis, Minn., where connexion through to Chicago was made over an allied line, the Chicago, Burlington & Quincy, owned jointly by the Great Northern and the Northern Pacific.

After the Great Northern, lay the Northern Pacific railway, starting on the west from Portland, Ore., and from Seattle and Tacoma, Wash., and extending east to Duluth, St Paul and Minneapolis by way of Helena, Mont. The Central Pacific—Union Pacific route to the coast, with its important deflected lines, the Oregon Short Line and the Oregon Railroad & Navigation Company, extended from San Francisco, Cal., and Portland, Ore., to Omaha, Neb., by way of Salt Lake City, the Atchison, Topeka & Santa Fé extended from San Francisco and Los Angeles, Cal., to Chicago and to Galveston, Tex.; while the Southern Pacific had its line from San Francisco and Los Angeles to Galveston and New Orleans, connecting by ferry for the greater part of the distance just north of the Mexican border.

Thus it will be observed that the five great cities of the Pacific coast—Seattle and Tacoma, Wash., Portland, Ore., and San Francisco and Los Angeles, Cal.—were all well watered by railways, but the growth of the fertile region lying west of the transcontinental divide was most attractive to American railway builders; and railways serving this district, almost all of them in trouble ten years before, began to show growing increases in earnings. In 1900 the Gould lines determined to enter this Pacific territory. Hitherto the western terminus of this group of lines had been Salt Lake City, Utah; by the exceedingly bold construction of the Western Pacific from Salt Lake City to Oakland, Cal., opposite San Francisco, an additional line to the Pacific coast was provided, having low grades and being in all respects well adapted for cheap operation.

After the Great Northern, the Chicago, Milwaukee & St Paul also decided to extend west. Before that time the St Paul had been a great local railway, operating primarily in the Dakotas, Minnesota, Iowa, Wisconsin and Illinois; but by the construction of a long arm from the Missouri river to Spokane, Seattle and Tacoma, it became a transcontinental line of the first importance, avoiding the mistakes of earlier railway builders by securing a line with easy gradients through the most favourable regions.

At the same time that these two extensions were being undertaken by old and well-established railways, a new company—the Kansas Pacific & Oregon—was building a line almost due south-west from Kansas City, Mo., to the lower part of the gulf of California in Mexico; while an additional independent line was under construction from Denver in a north-western direction towards the Pacific coast. That this line may be illustrated by a single fact: the combined building operations, in 1908, of San Francisco, Seattle, Portland, Los Angeles, Spokane and Salt Lake City exceeded the combined building operations of Philadelphia and Cincinnati during the same year. San Francisco spent more in new permanent structures than Philadelphia, and Seattle spent more than Pittsburg.

Recent American railway development, viewed in its larger aspects, has thus been characterized by what may be described as the rediscovery of the Pacific coast. How far this movement will extend it is impossible to say; it is certain, however, that it will be enormously important in re-aligning trade conditions in the United States, Canada and Mexico. Table III. illustrates the railway mileage in the continent of America at the close of 1907.

Outside the United States and Canada, the most interesting American developments are in Mexico and Argentina, these countries being clearly among the most rapid in railway growth in the world.
RAILWAYS

having nearly the same amount of railway mileage. In Mexico the national government is carrying out a consistent policy of developing its railway lines. It has succeeded in restoring the credit of these enterprises, and is proceeding with care and skill to form the lines into an efficient transportation system. In Argentina about 15% of the railways are owned and operated by the government, the balance being in the hands of private companies, largely controlled in England. Development of these lines has been primarily an extension from the large cities in the East to the agricultural districts in the West, but a change of great importance was brought about in 1910 by the completion of the last tunnel on the Argentine Transandine Railway, which serves to connect Santiago, Valparaiso and the other great cities of the west coast with Buenos Aires, Montevideo, Bahía, Rio de Janeiro and the other great cities of the east coast. Naturally the company named does not reach all of these points, but it is said that the Andes supplies the indispensable link of communication, in the absence of which the east coast towns and the west coast towns have hitherto been as widely separated as if they had been located on different continents—indeed, far more widely separated in point of time and of freight charges than Great Britain and the United States.

Table IV shows as closely as possible the railway route mileage open in Asia at the close of 1907.

Although more than half of the total mileage of Asia is in British India, probably at the present time the greatest proportionate gains in the near future will be in China, Siberia and Manchuria, and Central India in Asia. In proportion to its population China has the least railway development of any of the great countries of the world; and the probability that its present commercial awakening will extend seems large, and in that case it will need a vast increase in its interior communications.

In Africa, it will be seen by Table V that the railway mileage in the British possessions amounts to almost five-sixths of the total.

The so-called Cape-to-Cairo route shows occasional extensions, particularly in the opening up of new country in Central Africa by the Rhodesian railway system. The Rhodesian railway system in 1910 had penetrated north of Broken Hill, which is just above the fifteenth parallel of south latitude, while the Egyptian railway system had reached Gondokoro, located close to the fifth parallel of north latitude. The intervening distance, through exceedingly unhealthy for white men, and therefore promising no traffic except raw materials, does not seem a likely field for rapid railway extension.

In Australia the increase in railway mileage in the five years ending December 31st, 1907, was about 7%—a small proportion as compared with America, Asia or Africa. The greatest increase, both relative and absolute, was in Queensland; the smallest in South Australia, which added only 24 m. during the five years. Yet the mileage open per 10,000 inhabitants in Australia, as a whole, far surpasses that in any other of the broad geographical divisions.

Table VII. illustrates the mileage open to the end of 1907 per 100 sq. m. of territory and per 10,000 inhabitants. It will be observed that Belgium leads all the countries of the world in what may be called its railway density, with the United Kingdom a far-distant second in the list, and Persia last. In railway mileage per 10,000 inhabitants, however, Queensland, in the Australian group, reports a figure much greater than any other country; while at the other end of the list Persia holds the record for isolation.

Capital.—The total construction capital invested in the railways of the world in 1907 was estimated by the Archiv für Eisenbahnen at £8,986,150,000; the figure is necessarily incomplete, though it serves as a rough approximation. This total was divided nearly evenly between the countries of Europe and the rest of the world. The United States of America, with a capital of £3,059,500,000 invested in its railways on the 30th of June 1906, was easily ahead of every other country, and in 1908 the figure was increased to £3,443,027,685, of which £2,636,569,089 was in the hands of the public. On a route-mileage basis, however, the capital cost of the British railway system is far greater than that of any other country in the world, partly because a vast proportion of the lines are double, triple or even quadruple, partly because the safety requirements of the Board of Trade and the high standards of the original builders made actual construction very costly.

The total paid-up railway capital of the United Kingdom amounted, in 1908, to £331,512, or an average capitalization of £567 per route mile, though it should be noted that this total included £196,364,618 of nominal additions through “stock-splitting,” &c. Per mile of single track, the capitalization in England, Scotland, Ireland and the United Kingdom, is shown in Table VIII.

The table excludes sidings, because they cannot fairly be compared with running tracks, mile for mile. Yet the mileage of sidings in the United Kingdom amounted to 14,553 in 1908, and the cost of constructing them was probably not far from £50,000,000.

On a single-track-mile basis, the following comparison may be made between capital costs in Great Britain and the United States:—

<table>
<thead>

The figures for the United States are from the report of the Interstate Commerce Commission for the year ended 30th of June 1908, and comprise mileage of first, second, third and fourth tracks, and paid-up capital in the hands of the public only. The British figures are from the Board of Trade returns for the calendar year 1908. In comparing the figures, it should be noted that main line mileage in the Eastern states, as for example that of the Pennsylvania railroad and the New York, New Haven & Hartford, does not differ greatly in standards of safety or in unit cost from the best British construction, although improvement work in America is charged to income far more liberally than it has been in England. But there are long stretches of pine loam in the South where such lines can be, and are, built and equipped for £200 or less per mile, while the construction of new main line in the prairie region of the West ought not to cost more than £400 per single-track-mile, under present conditions.

The problem of the early railway builders in the United States was to conquer the wilderness, to build an empire, and at the same time to bind the East to the West and the North to the South. There can be little doubt but that the United States would long ago have disintegrated into separate, warring republics, had they not been bound together by railways, and standards of safety were

1 These figures are derived from a total. They are not exact, but may be taken as representing an approximation correct within one per cent.

2 Dollars to pounds sterling @ 4:87.

Statistical Study of Railway Operation.—The study of railway operation through statistics has two distinct aspects. It has been well said that statistics furnish the means by which the railway manager disciplines his property; this is the aspect of control. On the other hand, the banker, the government official and the economist use railway statistics to obtain information which may be characterized as static rather than dynamic. Both uses ultimately rest upon comparison of the observed data from an interval of time with the observed data from other properties, or with predetermined standards of performance.

In general, the British working unit supplied as public information has always been the goods-train-mile and the passenger-train-mile, these figures being the products of the number of trains into the number of miles they have travelled. In America, the basic units have been the ton-mile and the passenger-mile, and these figures are now required to be furnished to the Interstate Commerce Commission and to most of the state commissions as well. Both the British manager and the American manager, however, are supplied with a considerable number of daily, weekly and monthly reports, varying on different railways, which are not made public. The daily sheets usually include a summarized statement of the performance of every train on the line, covering the amount of business done, the destination of the loads, &c. For a number of years there has been a movement in Great Britain to require the inclusion of ton-mile statistics in the stated returns to the Board of Trade, but most railway managers have objected to the change on the ground that their own confidential information was already adequate for purposes of control, and that ton-mile statistics would require additional clerical force to a very large extent. The Departmental Committee of the Board of Trade, sitting in 1909 to consider railway accounting forms, while recommending ton-miles to the careful consideration of those responsible for railway working in Great Britain, considered the question of their necessity in British practice to be still open, and held that, at all events, they should not be introduced under compulsion.

ECONOMICS AND LEGISLATION

It was at one time an axiom of law and of political economy that prices should be determined by free competition. But in the development of the railway business it soon became evident

[1]
that no such dependence on free competition was possible, either in practice or in theory. This difficulty is not peculiar to railways; but it was in the history of railway economy and railway control that certain characteristics which are now manifesting themselves in all directions where large investments of fixed capital are involved were first brought prominently to public notice.

For a large number of those who use a railway, competition in its more obvious forms does not and cannot exist. Independent carriers cannot run trains over the same line and underbid one another in offering transportation services. It would be practically impossible for a line thus used by different carriers to be operated either with safety, or with economy, or with the advantage to the public which a centralized management affords. It is equally impossible for the majority of shippers to enjoy the competition of parallel lines. Such duplication of railways involves a waste of capital. If parallel lines compete at all points, they cause ruin to the investors. If they compete at some points and not at others, they produce a discrimination or preference with regard to rates and facilities, which builds up the competitive points at the expense of the non-competitive ones. Such partial competition, with the discrimination it involves, is liable to be worse for the public than no competition at all. It increases the tendency, already too strong, towards concentration of industrial life in large towns. It produces an uncertainty with regard to rates which prevents stability of prices, and is apt to promote the interests of the unscrupulous speculator at the expense of those whose business methods are more conservative. So marked are these evils that such partial competition is avoided by agreements between the competing lines with regard to rates, and by divisions of traffic, or pools, which shall take away the temptation to violate such rate agreements. The common law has been somewhat unfavourable to the enforcement of such agreements, and statutes in the United States, both local and national, have attempted to prohibit them; but the public advantage from their existence has been so great as to render their legal disabilities inoperative. In those parts of the continent of Europe where railways are owned and administered by state authority, the necessity for such agreements is frankly admitted.

But if rates are to be fixed by agreement, and not by competition, what principle can be recognized as a legitimate basis of railway rate-making? The first efforts at railway legislation were governed by the equal mileage principle; that is, the attempt was made to make rates proportionate to the distance. It was, however, soon seen that this was inadmissible. So much of the expense of the handling, both of freight and of passengers, was independent of the length of the journey that a mileage rate sufficiently large for short distances was unnecessarily burdensome for long ones, and was bound to destroy long-distance traffic, if the theory were consistently applied. The system has been retained in large measure in passenger business, but only because of the conflict which inevitably occurs between the authorities and the passengers with regard to the privilege of breaking and resuming a journey when passenger rates are arranged on any other plan. In freight schedules it has been completely abandoned.

A somewhat better theory of rate regulation was then framed, which divided railway expenditures into movement expense, connected with the line in general, and terminal expense, which connected itself with the stations and station service. Under this system each consignment of freight is compelled to pay its share of the terminal expense, independently of distance, plus a mileage charge proportionate to the length of the journey or haul. There has been an additional attempt in England to divide terminal charges into station and service terminals, according to the nature of the work for which compensation is sought. But none of these classifications of expense reaches the root of the matter. A system of charges which compels each piece of traffic to pay its share of the charges for track and for stations overlooks the fundamental fact that a very large part of the expenses of a railway—more than half—is not connected either with the cost of moving traffic or of handling traffic at stations, but with the cost of maintaining the property as a whole. Of this character are the expenditures necessary for maintenance of way, for general administration and for interest on capital borrowed, which are almost independent of the total amount of business done, and quite independent of any individual piece of business. To say that all traffic must bear its share of these interest and maintenance charges is to impose upon the railways a rate which would cut off much of the long-distance traffic, and much of the traffic in cheap articles, which is of great value to the public, and which, from its very magnitude, is a thing that railways could not afford to lose. It is also a fact that with each recurring decade these general expenses (also called indirect, undistributed or fixed charges) have an increased importance as compared with the particular (direct, distributed or operating) expense attaching naturally to the particular portions of the traffic. For with increased density of population it becomes profitable to make improvements on the original location, even though this may involve increased charges for interest and for some parts of its maintenance, for the sake of securing that economy of operation, through larger train-loads, which such an improved location makes possible.

Whatever the ostensible form of a railway tariff, the contribution of the different shipments of freight to these general expenses is determined on the principle of charging what the traffic will bear. Under this principle, rates are reduced where the increase of business which follows such reduction makes the change a profitable one. They are kept relatively high in those cases where the expansion of business which follows a reduction is small, and where such a change is therefore unprofitable. This theory of charging what the traffic will bear is an unprofitable one, because it has been misapplied by railway managers and made an excuse for charging what the traffic will not bear. Rightly applied, however, it is the only sound economic principle. It means taxation according to ability—that ability being determined by actual experiment.

In the practical carrying out of this principle, railways divide all articles of freight into classes, the highest of which are charged two or three, or even four times the rates of the lowest. This classification is based partly upon special conditions of service, which make some articles more economical to carry than others (with particular reference to the question whether the goods are carried in car-loads or in small parcels), but chiefly with regard to the commercial value of the article, and its consequent ability to bear a high charge or a low one. For each of these classes a rate-sheet gives the actual rate-per unit of weight between the various stations covered by the tariff. This rate increases as the distance increases, but not in equal proportion; while the rates from large trade centres to other trade centres at a great distance are not higher than those to intermediate points somewhat less remote; if the law permits, there is a tendency to make them actually a little lower. Besides the system of charges thus prescribed, the classification and rate-sheet, each tariff provides for a certain number of special rates or charges applicable to particular lines of trade in certain localities, independently of their relation to the general system. If these special rates are published in the tariff, and are offered to all persons alike, provided they can fulfil the conditions imposed by the company, they are known as commodity rates, and are apparently a necessity in any scheme of railway charges. If, however, they are not published, and are given to certain persons as individual favours, they become a prolific source of abuse, and are quite indefensible from the standpoint of political economy.

While the superficial appearance of the railway tariff is different for different countries, and sometimes for different parts of the same country, the general principles laid down are followed in rate-making by all well-managed lines, whether state or private. It is a mistake to suppose that the question of public or private ownership will make any considerable difference in the system of rate-making adopted by a good railway. A state system will be compelled, by the exigencies
of the public treasury, to arrange its rates to pay interest on its securities; a private company will generally be prevented, by the indirect competition of railways in other parts of the country which it serves, from doing very much more than this. The relative merit of the two systems depends upon the question how we can secure the best efficiency and equity in the application of the principles thus far laid down. There are three different systems of control—

1. Private operation, subject only to judicial regulation, was exemplified most fully in the early railway history of the United States. Until 1870 railway companies were almost free from special acts of control; and, in general, any company that could raise or borrow the capital was allowed to build a railway wherever it saw fit. In the United Kingdom there was almost as much immunity from legislative interference with charges, but the companies were compelled to secure special charters, and to conform to regulations made by the Board of Trade in the interests of public safety. The advantage of this relatively free system of railway building and management is that it secures efficient and progressive methods. Most of the improvements in operation and in traffic management have had their origin in one of these two countries. The disadvantage attendant upon this system is that the courts are reluctant to exercise the right of regulation, except on old and traditional lines, and that in the face of new business methods the public may be inadequately protected. There is also this further disadvantage, that in the gradual progress of consolidation railway companies take upon themselves the aspect of large monopolies, of whose apparently unrestricted power the public is jealous. As a result of these difficulties there has been, both in the United Kingdom and in the United States, a progressive increase of legislative interference with railways. In the former the Railway and Canal Traffic Act of 1854 specially prohibited preferences, either in facilities or in rates. The Regulation of Railways Act of 1873 provided for a Railway Commission which should be so constituted as to take cognizance of cases on the investigation of which the courts were reluctant to enter. Finally, the legislation of 1888 put into the hands of a reorganized Railway Commission and of the Board of Trade powers none the less important in principle because their action has been less in its practical effect than the advocates of active control demanded. In the United States the years from 1870 to 1875 witnessed the spread of generally ill-considered legislation ("Granger" Acts) concerning railway charges throughout the Mississippi valley; while the years from 1884 to 1887 were marked by more conservative, and for that reason more enforceable, acts, which culminated in the Interstate Commerce Act, prohibiting personal discrimination and gradually restricting discrimination between places, and providing for a National Commission of very considerable power—not to speak of the pooling clause, which was extraneous to the general purpose of the act, and has tended to defeat rather than strengthen its operation.

2. Operation by private companies, under specific provisions of the government authorities with regard to the method of its exercise, has been the policy consistently carried out in France, and less systematically and consistently in other countries under the domination of the Latin race. It was believed by its advocates that this system of prescribing the conditions of construction and operation of lines could promote public safety, prevent waste of capital and secure passengers and shippers against extortionate rates. These expectations have been only partially fulfilled. Well trained as was the civil service of France, the effect of this supervision in deadening activity was sometimes more marked than in its effect in preventing abuse. Moreover, such a system of regulation almost necessarily carries with it a guarantee of monopoly to the various companies concerned, and not infrequently large gifts in the form of subsidies, for without such aid private capital will not submit to the special burdens involved. These rights, whether of monopoly or of subsidy, form a means of abuse in many directions. Where the government is bad, they are a fruitful source of corruption; even where it is good, they enable the companies to drive hard bargains with the public, and prevent the expected benefits of official control from being realized.

3. State operation and ownership is a system which originated in Belgium at the beginning of railway enterprise, and has been consistently carried out by the Scandinavian countries and by Hungary. Since 1860 it has been the policy of Australia. It has generally come to be that of Germany and, so far as the finances (Loco) (for Orts) of Austria, and Russia; British India also affords not a few examples of the same method. The theory of state ownership is excellent. So large a part of the railway charge is of the nature of a tax, that there seem to be a priori reasons for leaving the taxing powers in the hands of the agents of the government. In practice its operation is far more uncertain. Whether the intelligence and efficiency of the officials charged by the state with the handling of its railway system will be sufficient to make them act in the interest of the public as fully as do the managers of private corporations, is a question whose answer can only be determined by actual experience in each case. If the fail to have these qualities, the operation of state railways can be carried out either by a government that is in good faith anxious to raise the powers of borrowing which are furnished by the public credit, increase instead of diminishing the danger of arbitrary action, unprogressiveness and waste of capital. Even in matters like public safety it is by no means certain that government authorities will do so well as private ones. The question is one which practical railway men have long since ceased to argue on general principles; they recognize that the answer depends upon the respective degree of talent and integrity which characterize the business community on the one hand and the government officials on the other.

On principles governing railway rates in general, and specifically in Germany, see Edwin Metcalf, Railways and the Traders (London, 1891). On comparative railway legislation and the principles governing it, see Hadley, Railroad Transportation; its History and its Laws (New York, 1885). On the history of railway legislation in England, see Cohn, Untersuchungen über die Englische Eisenbahnpolitik (Leipzig, 1874-83). On practice concerning rates in continental Europe, see Ulrich, Das Eisenbahnstaatsverfassung (Berlin, 1886). (Since this was published, continental passenger rates have fallen. The French translation—Paris, 1898—gives Russian tariffs.) On the question of "nationalization" (i.e. state ownership and operation), see an article by Edgar Cranham in the Quarterly Journal of Economics (April, 1902), and the following articles, among others, on the subject, Clement Edwards's Railway Nationalization (1898); Edwin A. Pratt's Railway Nationalization (1908), and E. A. Davis's Nationalization of Railways (1908). (A. T. H.)

BRITISH RAILWAY LEGISLATION

The first thing a railway company in Great Britain has to do is to obtain a special or private act of parliament authorizing the construction of the line. Not that the mere laying or working of a railway requires parliamentary sanction, so long as the work does not interfere with other people's rights and interests. An example of a railway built without any legislative authority is the little mountain railway from Llanberis to the summit of Snowdon, which was made by the owner of the land through which it passes. Such a railway has no statutory rights and no special obligations, and the owner of it is liable to be sued for creating a nuisance if the working of the line interferes with the comfort of those residing in the neighbourhood. When, however, a company desires to construct a line on a commercial scale, to acquire land compulsorily, to divert rivers and streams, to cross roads either on the level or by means of bridges, to pass near houses, to build tunnels or viaducts, and to execute all the other works incidental to a railway, and to work the line when complete, then, it is essential that the authority of parliament should be obtained. The company therefore promotes a bill, which is considered first by select committees of the two houses of parliament, and afterwards by the two houses themselves, during which period it faces the opposition, if any, of rival concerns, of local authorities and of hostile landowners. If this is successfully overcome, and the proposals meet with the
approval of parliament, the bill is passed and, after securing the Royal Assent, becomes an act of parliament. The company is then free to proceed with the work of construction, and at once becomes subject to various general acts, such as the Companies Clauses Act, which affects all joint-stock companies incorporated by any special act; the Land Clauses Act, which has reference to all companies having powers to acquire land compulsorily; the Railway Clauses Act, which imposes certain conditions on all railways alike (except light railways); the various Regulation of Railways Acts; the Carriers Protection Act; acts for the conveyance of mails, parcels, troops, acts relating to telegraphs, to the conveyance of workmen and to the housing of the labouring classes; and several others which it is unnecessary to specify. From the early days of railways parliament has also been careful to provide for the safety of the public by inserting in the general or special acts definite conditions, and by laying upon the Board of Trade the duty of protecting the public using a railway.

The first act which has reference to the safety of passengers is the Regulation of Railways Act of 1842, which obliges every railway company to give notice to the Board of Trade of any deviation from the plan laid down by the Board of Trade for passenger traffic, and places upon that public department the duty of inspecting the line before the opening of it takes place. If the officer appointed by the Board of Trade should, after inspection of the railway, report to the department that in his opinion "the opening of the same would be attended with danger to the public using the same, by reason of the incompleteness of the works or permanent way, or the insufficiency of the establishment for working such railway," it is lawful for the department to direct the company to postpone the opening of the line for any period not exceeding one month at a time, the process being repeated from month to month as often as may be necessary. The company is liable to a fine of twenty pounds a day if it should open the line in contravention of such order or direction. The inspections made by the officers of the Board of Trade under this act are very complete: the permanent way, bridges, viaducts, tunnels and other works are carefully examined; all iron or steel girders are tested; stations, including platforms, staircases, waiting-rooms, &c., are inspected; and the signalling and "interlocking" are thoroughly overhauled. A code of requirements in regard to the opening of new railways has been drawn up by the department for the guidance of railway companies, and as the special circumstances of each line are considered for their merits, it rarely happens that the department finds it necessary to prohibit the opening of a new railway.

The Regulation of Railways Act of 1871 extends the provisions of the above act to the opening of "any additional line of railway, deviation line, station, junction or crossing on the level," which forms a portion of or is connected with a passenger railway, and which has been constructed subsequently to the inspection of it. This act further defines the duties and powers of the inspectors of the Board of Trade, and also authorizes the Board to dispense with the notice which the previous act requires to be given prior to the opening of a railway.

May be cases where the company refuses on the Board of Trade any power to inspect a railway after it has once been opened, unless and until some addition or alteration, such as is defined in the last-named act, has been made. When a line has once been inspected and passed, it lies with the company to maintain it in accordance with the standard of efficiency it originally possessed, but no express statutory obligation to do so is imposed upon the company, and whether it does or does not, the Board of Trade cannot interfere.

The act of 1871 further renders it obligatory upon every railway company to send notice to the Board of Trade in the case of (1) any accident attended with loss of life or personal injury to any person whatsoever; (2) any collision where one of the trains is a passenger train; (3) any passenger train or part of such train leaving the rails; (4) any other accident likely to have caused loss of life or personal injury, and specified on that ground by any order made from time to time by the Board of Trade. The department is authorized, on receipt of such report, to direct an inquiry to be made into the cause of any accident so reported, and the inspector appointed to make the inquiry is given power to enter any railway premises for the purposes of his inquiry, and to summon any person engaged upon the railway to attend the inquiry as a witness, and to require the production of all books, papers and documents which he considers important for the purpose. The inspector, after making his investigation, is required to make a report to the Board of Trade as to the causes of the accident and the circumstances attending the same, with any observations on the subject which he deems right, and the Board "shall cause every such report to be made public in such manner as they think expedient." The usual mode of publishing such reports is to forward them to railway companies concerned, as well as to the press, and on application to any one else who is interested. The reports are subsequently included in a Blue-book and presented to parliament. It should be noted that although the inspecting officer may in his report make any recommendations that he may think fit with a view to guarding against any similar accident occurring in the future, no power is given to the Board of Trade or to any railway company to compel any railway company to adopt such recommendations. This omission is sometimes held to be an error, but as a fact it is an advantage. The moral effect of the report, with the criticisms of the company's methods and recommendations appended thereto, is great, and it rarely happens that the company refuses to adopt, or at any rate to test, the recommendations so made. If, on the other hand, the company is of opinion that the suggestions of the inspecting officer are not likely to prove beneficial, or are for any reason unadvisable, it is at liberty to reject them, the responsibility of doing so resting entirely upon itself. The effect of this latitude is to give the company ample discretion in the matter, and to enable the act to be administered and the object of it to be attained without undue interference.

In 1880 a very important act was passed placing upon the Board of Trade the obligation to call upon railway companies throughout the United Kingdom (1) to adopt upon all passenger lines the "block" system of working; (2) to "interlock" their points and signals; (3) to fit all trains carrying passengers with some form of automatic continuous brake.

Prior to this some companies had, to a certain extent, done these things, but few, if any, were completely equipped in these respects. A reasonable period was afforded them, according to circumstances, to adopt these recommendations, and at the present time the work is practically complete. In this respect the lines of the United Kingdom are far ahead of those of any other country, and a diminution of accidents, particularly of collisions, has resulted therefrom. America is now following the lead thus set, and all the most important lines in the United States have adopted block working and interlocking, but a great deal still remains to be done. In certain respects, on the other hand, America has gone further than the United Kingdom, especially in the matter of automatic signalling, and in the operating of points and signals by electrical power or air-pressure instead of manual labor. In America, also, freight trains are fitted with an automatic continuous brake, whereas in the United Kingdom this appliance is required by law only in the case of passenger trains, and in fact is not fitted to goods and mineral trains except in a few isolated instances.

The above-named acts enable the Board of Trade to take all the necessary steps to ensure that the safety of passenger trains is sufficiently guarded. More recently legislation has been passed to safeguard the lives and interests of railway servants. In 1893 an act was passed by parliament giving the Board power to interfere if or when representations are made to them by or on behalf of any servant of a railway company, or to any other person or company, to require that the hours of work are unduly long, or do not provide sufficient intervals of uninterrupted rest between the periods of duty, or sufficient relief in respect of Sunday duty. In such cases the company concerned may, after inquiry, be called upon to submit such a
RAILWAYS

828

schedule of the hours during which the man or men are employed as will bring those hours within limits which appear to the department reasonable. In the event of the company failing to comply with the demands of the department, the latter is empowered to refer the case to the Railway and Canal Commissioners, who form a special Court constituted by the Railway and Canal Traffic Act of 1858, for deciding, among other things, questions relating to rates and charges on, engines, ticketing traders from undue charges and undue preference, for regulating questions of traffic, and for deciding certain disputes between railway companies and the public. The Commissioners are then empowered to deal with the matter, and if a railway company fail to comply with any order made by the Railway and Canal Commissioners, or to enforce the provisions of any schedule "approved by them, it is liable to a fine of a hundred pounds for every day during which the default continues. This act has been the means of effecting a considerable reduction in the hours worked by railway men on certain railways, and no case has yet arisen in which a reference to the Commissioners has been necessary. Such modifications of the hours of work have not only been beneficial to the men, but have improved the discipline of the staff and the punctuality and regularity of the train service, particularly in respect of the goods trains.

The Notice of Accidents Act of 1884, which obliges employers of labour to report to the Board of Trade, when "there occurs in any employment," as defined by the schedule of the act, "any accident which causes to any person employed therein, either loss of life or such bodily injury as to prevent him from attending one of the three working days next after the occurrence of the accident from being employed for five hours on his ordinary work," affects railways in course of construction, but not, as a rule, otherwise.

Although the administration of the above-mentioned acts of parliament has had a beneficial effect upon the safety of the public, and has enabled an enormous volume of traffic to be handled with celerity, punctuality and absence of risk, it has during recent years come to notice that the number of casualties among railway servants is still unduly great, and in 1899 a Royal Commission was appointed to investigate the causes of the numerous accidents, fatal and not fatal, to railway men. As a consequence of the report of this Commission the Railway Employment (Prevention of Accidents) Act of 1900 was passed, putting upon the Board of Trade the duty of making "such rules as they think fit with respect to any of the subjects mentioned in the schedule to this act, with the object of reducing or removing the dangers and risks incidental to railway service." Rules may also be made in respect to other matters besides those mentioned in the schedule, and companies may be called upon to adopt or reject, as the case may be, any appliance, the use or disuse of which may be considered desirable in the interest of the men. Before, however, the rules so made become binding upon the companies, the latter have the right of appealing against them to the Railway Commissioners. Failure to comply with any of the rules renders a company "liable for each offence, on conviction under the Summary Jurisdiction Acts, to a fine not exceeding fifty pounds, or in the case of a continuing offence to a fine not exceeding ten pounds for every day during which the offence continues after conviction." Rules drafted by the Board of Trade under this act came into force on the 8th of August 1902, the subjects referred to being (1) labelling of wagons; (2) movements of wagons by propelling and tow-roping; (3) power-brakes on engines; (4) lighting of stations and sidings; (5) protection of points, rods, &c.; (6) construction and protection of gauge-glasses; (7) arrangement of tool-boxes, &c., on engines; (8) provision of brake-vans for trains upon running lines beyond the limits of stations; (9) protection to permanent-way men when relaying or repairing permanent way. The final settlement of a rule requiring brake-levers to be fitted on both sides of goods-wagons was, however, deferred, owing to objections raised by certain of the railway companies.

Other acts which are of importance in connexion with accidents are the Accidents Compensation Act of 1846, the Employers' Liability Act of 1880, and the Workmen's Compensation Act of 1897.

The public acts of parliament referring to British railways are collected in Bigg's General Railway Acts.

(A. A. Y.)

AMERICAN RAILWAY LEGISLATION

Before 1870.—The earliest legislation is contained in charters granted by special act, for the construction of railways. These special acts gradually gave way to general statutes under which railway corporations could be created without application to the legislature. In the east, where, as a rule, charters had been uniform and consistent, the change to general incorporation law was due to a desire to render incorporations speedier and less expensive. In the west, general laws came rather as a result of the abuses of special legislation. By 1850, general incorporation laws were found in nearly all the eastern states, and by 1870 in those of the west.

Early legislation was confined almost entirely to matters of construction. In cases where statutes did touch the question of regulation, they had to do with the operation of trains and with the provision of facilities for shippers and passengers, rather than with questions of rates. It was natural that this should be so, for the new transportation agency was so much more efficient than anything previously available that the people were eager to take advantage of its superior service. As a rule, the making of rates was left to the corporations.

If the maximum rates were prescribed, as they sometimes were, the limit was placed so high as to be of no practical value for control. Such crude attempts as were made to prevent rates from being excessive concerned themselves with profits, and were designed to confiscate for the state treasury any earnings beyond a certain prescribed dividend. Publicity of rates was not generally required, and provisions against discrimination were rare. In the period before 1850 there was but little realization of the public nature of the railway industry, and of the possibilities of injury to the public if railway corporations were left uncontrolled.

In regions where capital was lacking eagerness for railway facilities led the people to demand the direct co-operation of the state, and many projects, most of which ended in disaster, were undertaken either by the state itself or through the aid of the state's credit. For example, Michigan, in 1837, in the first session of its state legislature, made plans for the construction of 557 miles of railway under the direct control of the state, and the governor was authorized to issue bonds for the purpose. The unfortunate results of this policy led many of the states, from about 1850, to put constitutional limitations upon the power of their legislatures to lend the state's credit or to involve the state as stockholder in the affairs of any corporation. As railway building increased in response to traffic needs, and as the consolidation of short lines into continuous systems proceeded, legislation applicable to railways became somewhat broader in scope and more intelligent. About 1850 there began to appear on the statute books laws requiring publicity of rates and the submission of annual reports to the legislature, prescribing limits to corporate indebtedness, and also making provision for safety in operation and for the character and quality of railway service. Consolidation and leasing were commonly permitted in the case of continuous lines, but were regularly prohibited in the case of parallel and competing lines. The practice of pooling was not contricted the attention of the legislature. In general it may be asserted that legislation of this period was ill-considered, haphazard, and on a petty scale. Moreover, it was of little practical importance even within its narrow range, for it does not appear to have been generally enforced.

1870-1900.—Railway legislation first assumed importance in connection with the "Granger Movement" in the middle west. There the policy of subsidies for railway building had been carried to a reckless extreme. Roads had been constructed in advance of settlement, and land-seekers had been
RAILWAYS

transported to these frontier sections only to become dependent upon the railways for their very existence. To the unusual temptations thus offered for favouritism and discriminations in rates, the railways generally yielded. This preferential and discriminating policy, combined with other causes which cannot here be discussed, resulted in the Granger legislation of the 'seventies. In the first instance laws were enacted prescribing schedules of maximum freight and passenger rates with stringent penalties against rebates and discriminations. These measures proving unsatisfactory, they were soon superseded by statutes creating railway commissions with varied powers of investigation and the commission was not a new one. Such bodies, established to appraise land for railway purposes, to apportion receipts and expenditures of interstate traffic, and in a general way to supervise railway transportation, had been in existence in New England before 1866, one of the earliest being that of Rhode Island in 1839. In 1869 Massachusetts had instituted a commission of more modern type, which was given only powers of investigation and recommendation, the force of public opinion being relied upon to make its orders effective. Western commissions, the offspring of the Granger movement, were of a more vigorous type. Most of them had power to impose schedules of maximum rates; practically all of them had authority to prescribe rates upon complaint of shippers; and they could all seek the aid of the courts to enforce their decrees. Their power to initiate rates, conferred upon them by their legislatures, was sustained by the Supreme Court of the United States, the Court reserving to itself only the power to decide whether the prescribed rates were reasonable.

But the jurisdiction of the state commissions was, by judicial interpretation, limited to commerce beginning and ending within the limits of the single state. The most important part of railway transportation, that which was interstate in character, was left untouched. It was this impotence of the state commission that furnished the strongest incentive to Congressional action. The result was the passage, in 1887, of the Interstate Commerce Act, which was directed towards the extirpation of illegal and unjust practices in commerce among the states. Its primary purpose was to embody in statutory form the common-law principle of equal treatment under like circumstances, and to provide machinery for enforcement. It aimed at the prohibition of discrimination between persons, places and commodities. It made provision for publicity of rates and for due notice of any change in rates; it forbade pooling of freight or earnings, and required annual reports from the carriers. For its enforcement, it created an Interstate Commerce Commission of five members, with powers of investigation, and with authority to issue remedial orders upon complaint and after hearing. Findings of the Commission were to be prima facie evidence in any court proceeding for the enforcement of its orders.

In this connexion, reference should be made to the Anti-Trust Act of 1890, which, by its judicial interpretation, has been held to include railways and to forbid rate agreements between competitors.

The act of 1887 remained in force without substantial amendment until 1906, although with constantly diminishing prestige, a result largely due to adverse decisions concerning the powers of the Commission. Ten years after the passage of the law, the court decided that the Commission had no power to prescribe a rate, and that its jurisdiction over rates was confined to a determination of the question whether the rate complained of was unreasonable. The Commission had much difficulty at the beginning in securing the testimony of witnesses, who invoked the Constitution of the United States as a bar against self-incrimination, and the immunity clause of the act had to be amended before testimony could be obtained. The so-called "long-and-short-haul clause," which forbade a greater charge for a long than for a short haul over the same line, if circumstances were substantially similar, was also robbed of all its vitality by court decision. The section requiring annual reports, while it led to the creation of a Bureau of Statistics, did not give the Commission power to compel complete or satisfactory answers to its requests for information. The only element of real strength that the statute acquired during the first twenty years of its history came from the Elkins Act of 1903, which stipulated that the published rate should be the legal rate, and declared any departure from the published rate to be a misdemeanor. It held shipper as well as carrier, and corporation as well as its officer or agent, liable for violations of the act, and conferred upon United States courts power to employ equity processes in putting an end to discrimination. Conviction for granting rebates was by this law made easier and more effective.

Since 1906—The movement in favour of more vigorous railway regulation became pronounced after 1900. Twenty years of experience and observation had revealed the defects of the earlier legislation, and had concentrated public attention more intelligently than ever before upon the problem of strengthening the weak spots. The state commissions, since their establishment in the 'seventies and the 'eighties, had increased their functions and influence. Many of them, beginning only with powers of recommendation, had obtained a large extension of authority. By 1900, thirty-five of the forty state commissions were of the mandatorv type, and thirty these had been created since 1904. They had been given power to require complete annual reports from carriers, with a consequent great increase in public knowledge concerning railway operation and practice. The most recent type of state commission is the so-called Public Utility Commission, of which the best examples are those of New York and Wisconsin, established in 1907. In both states, the Commissions have power over electric railways and local public utilities furnishing heat, light and power, as well as over steam railway transportation, and the Wisconsin Commission also has control over telephone companies.

In both states the consent of the Commission is necessary for the issue of corporate securities.

Attention should be made of the mass of general legislation passed, principally by western states, since 1905, in response to a popular demand for lower rates. This demand has in many instances led to ill-considered legislation, has frequently ignored the prerogatives and even the existence of the state commissions, and has brought about the passage by state legislatures of maximum freight and passenger rate laws, with rates so low in many cases that they have been set aside by the courts as unconstitutional. The numerous laws limiting the fare for passengers to two cents per mile are an illustration of this tendency.

In the field of federal legislation, no significant change took place until the passage of the Hepburn Act of 1906, which was an amendment of the act of 1887. While failing to correct all the defects in the original statute, the amended law was a decided step in the direction of efficient regulation. It increased the jurisdiction of the Commission by placing under its express direction, sleeping-car companies and pipe lines for the transportation of oil. It extended the meaning of the term "railroad" to include switches, spurts and terminal facilities, and the term "transportation" to include private cars, and all transportation services, such as refrigeration, elevation and storage. The Elkins Act of 1903 was incorporated in the statute, and an imprisonment penalty was added to the existing fine. It forbade the granting of passes except to certain specified classes, —a provision entirely absent from the original measure. It expressly conferred upon the Commission the power to prescribe maximum rates, upon complaint and after hearing, as well as to make joint rates, and to establish through rates when the carriers had themselves refused to do so. It enacted that published rates should not be changed except on thirty days' notice, whether the change involved an increase or a decrease, and it required annual reports to be made under oath, penalties for failure to comply with the Commission's requests for information. Power was also given to prescribe uniform systems of accounts for all classes of carriers, and to employ special examiners to inspect the books and accounts. Carriers were forbidden to keep any accounts, records or memoranda other than those approved by the Commission.
Orders of the Commission became effective within such time, not less than thirty days, as the Commission should prescribe, and penalties began to take effect from the date fixed by the Commission, unless the carrier secured an injunction from the Court suspending the order. Such injunction might not issue except after hearing, of which five days' notice must be given. Decisions of the Commission were not reviewable by the Court unless the Commission had exceeded its authority, or had issued an unconstitutional order.

A new and important act was signed by the President on the 18th of June 1910. It created a Commerce Court (composed of five judges nominated by the president of the United States from the Federal circuit judges), transferred to it jurisdiction in cases instituted to enforce or set aside orders of the Inter-State Commerce Commission, and made the United States instead of the Commission a party in all such actions. The law forbids a railway or any other common carrier to charge more for a short haul than for a long haul over the same line, unless, in special cases, it is authorized to do so by the Commission. It forbids a railway which has reduced its rates while in competition with a water route to raise them again when the competition has ceased, unless the Commission permits it to do so because of other changed conditions. It extends the initiative of the Commission from the investigation of complaints to the investigation of rates on its own motion; authorizes it to suspend rates in advance of their going into effect, pending an investigation which may be continued for ten months, and to establish through routes, and provides for a special commission, appointed by the President, to investigate questions pertaining to the issuance of railway securities.

ACCIDENT STATISTICS

Statistics of railway accidents may be divided into three classes: (a) to passengers, (b) to servants or employed persons and (c) to other persons; and again into (1) train accidents, (2) accidents to persons doing work on or about trains and (3) other accidents.

Such statistics are studied mainly with the object of learning the lessons which they may afford as to preventive measures for the future; and from this point of view the most important element is the single item of passengers killed in train accidents (a 1). The number injured is, indeed, a fact of interest, no less than the number killed, but comparisons under this head are unsatisfactory because it is impracticable or unprofitable to go into sufficient detail to determine the relative seriousness of the injuries. The statistics of the killed usually afford all necessary stimulus to improvement. Accidents to passengers other than those caused by collisions or derailments of trains are very largely due to causes which it is fair to class either as unavoidable or as due mainly to the fault or carelessness of the victim himself. That this is so is indicated by the fact that, although the railways—always made to suffer severely in statutory damages for injuries for which their officers or servants are held responsible by the courts—have for years taken almost every conceivable precaution, the number of accidents, in proportion to the number of persons travelling, diminishes but slowly—so slowly that, in view of the variety of conditions to be considered, it would hardly be safe to conclude that the diminution is due to any definite improvement in the safeguards provided. Collisions, on the other hand, are preventable, and derailments nearly so, and the records of deaths and injuries in this class in successive years are therefore justly taken as an index to the efficiency with which the railways are managed.

The number of servants killed in train accidents is the next in importance. The safety of passengers is, indeed, the first care of the railway manager; but the employed, exposed to many risks from which the passengers are protected, must be looked after. On the British railways the men who run the trains are safeguarded very efficiently, and the collisions and derailments which are serious enough to do injury to the trainmen or the enginemen are really rare. The roadway, tracks and rolling stock are all so preserved that these causes which lead to the worst derailments have been eliminated almost completely, and the record of serious collisions has been reduced nearly to zero by the universal use of the block system and by systematic precautions at junctions. In America the record is far less satisfactory. The best railways of the United States and Canada have, indeed, been greatly improved, and their main lines approach the high standards of safety which prevail in Great Britain, both as regards maintenance and care of roadway and vehicles (as a preventive of derailments) and the use of the block system (as a preventive of collisions); but when the inquirer looks at America as a whole—the total length of lines in the United States being over 250,000 m., ten times the total of the United Kingdom—he is considering a figure which includes an enormous mileage of railway lying in thinly settled regions where the high standards of safety maintained on the best railways have scarcely been thought of. The duty of a railway with deficient plant or facilities would seem to be to make up for their absence by moderating the speeds of its trains, but public sentiment in America appears so far to have approved, at least tacitly, the combination of impracticable railways and high speeds, and has now accepted as inevitable the large number of fatalities and injuries from accidents on the American railways. The number of men killed and injured in handling freight trains has been very large. In the year ending June 30, 1909, exclusive of casualties due to collisions, derailments and other accidents to trains, the number killed was 811 and of injured 28,156 (Accident Bulletin, No. 32, p. 14). The number killed (811) is equal to about three in every thousand trainmen employed. From this and all other causes, the number of trainmen killed in the year ending June 30, 1909, was about 8 in 1000.

The use of automatic couplers for freight cars throughout the United States, introduced in 1893-1900, greatly reduced the number of deaths and injuries in coupling, and the use of air brakes on freight cars, now universal, has reduced the risk to the men by making it less necessary for them to ride on the roofs of high box-cars, while at the same time it has made it possible to run long trains with fewer men; but except in these two features the freight service in America continues to be a dangerous occupation. The high and heavy cars, the high speeds, the severe weather in the northern states in winter, the fluctuating nature of the business, resulting often in the employment of large numbers of men during seasons of other irregularities, are among the causes of this state of things.

Being struck or run over by a train while standing or walking on the track is the largest single cause of "railway accidents." Workmen are killed and injured in this way, both while on duty and when going to and from their work; passengers, with or without right, go in front of trains at stations and at highway crossings at grade level; and trespassers are killed and injured in large numbers on railways everywhere, at and near stations, at crossings, and out on the open road, where they have no shadow of right. Of trespassers the number killed per mile of
RAILWAYS

line is about as large in England as in America, the density of population and of traffic in Great Britain apparently counter-balancing the laxity of the laws against trespassing in America. In the thickly settled parts of the United States the number of trespassers killed on the railway tracks, including vagrants who suffer in collisions and derailments while stealing rides, is very large. In New York and four adjacent states, having about as many miles of railway as the United Kingdom, the number in the year ending June 30, 1907, was 1552. In the United Kingdom the number for the corresponding year was 447, or less than one-third.

As was suggested at the outset, railway accident statistics are useful only as showing how to make life and limb safer, though in pursuing this object increased economy should also be secured. Railways have always been held by the legislatures and by the courts strictly accountable for their shortcomings, so far as accountability can be enforced by compelling the payment of damages to victims of accidents; but in spite of this, a want of enterprise and even some apparent neglect of passengers' and servants' plain rights, have often been apparent, and the Board of Trade, with its powers of supervision, inspection and investigation, must therefore be classed as one of the most beneficent factors in the promotion of safety on British railways. Its powers have been exercised with the greatest caution, yet with consistent firmness; and the publicity which has been given to the true and detailed causes of scores and scores of railway accidents by the admirable reports of the Board of Trade in recent years has been a powerful lever in improving the railway service. Useful compulsory laws regarding the details of train management are difficult to frame and hard to carry out; but the Board has exercised a persistent persuasiveness and has secured most of its objects. Its investigations justified the law making the block system compulsory, thus removing the worst danger of railway travel. Its constant and impartial expositories of cases of over-work and insufficient training of employees have greatly helped to elevate the character of these employees.

In the United States the governments have done far less. A majority of the states have railway commissions, but the investigation of railway accidents, with comparatively few exceptions, has not been done in such a way as to make the results useful in promoting improved practice. Many of the commissions have done little or nothing of value in this respect. The Federal government, having authority in railway matters only when interstate traffic is affected, gathers statistics and publishes them; but in the airing of causes—the field in which the British Board of Trade has been so useful—nothing so far has been done except to require written reports monthly from the railways. These are useful so far as they go, but they lack the impartiality that would be secured by an inquiry such as is held in England.

| Table X.—Casualties on the Railways of the United Kingdom |
|---|---|
| **Passengers:** | 1908 | 1907 |
| 1. In train accidents | Killing | Injured | Killing | Injured |
| 2. Other accidents in or around trains, &c. | 102 | 2,242 | 102 | 2,132 |
| 3. Other causes | 5 | 863 | 5 | 836 |
| **Total of passengers** | 107 | 3,308 | 125 | 3,502 |
| **Servants:** | 1908 | 1907 |
| 4. In train accidents | 6 | 164 | 13 | 236 |
| 5. Other accidents in or around trains, &c. | 376 | 4,976 | 441 | 5,577 |
| 6. Other causes | 50 | 19,041 | 55 | 15,701 |
| **Total of servants** | 432 | 24,181 | 509 | 21,541 |
| **Other persons:** | 1908 | 1907 |
| 7. In train accidents | 0 | 7 | 5 | 11 |
| 8. At level crossings | 51 | 44 | 50 | 30 |
| 9. Trespassing on line | 291 | 99 | 278 | 115 |
| 10. Suicides (including unsuccessful attempts) | 188 | 19 | 169 | 18 |

TABLE XII.—Detail Causes of Certain Accidents—continued.

| c. From falling off platforms upon the ballast | 1 105 | 110 |
| d. By other accidents | 1 246 | 265 |

Total of passengers | 5 865 | 5 836 |

Servants:—

1. While loading, unloading or sheeting wagons, trucks and horse-boxes | 8 4,018 | 5 2,890 |
2. While moving goods and luggage in stations or sheds | 2 1,092 | 2 975 |
3. While working at cranes or capstans | 3 411 | 8 304 |
4. By the falling of wagon-tongs, lamps, bales of goods, &c. | 1 583 | 2 390 |
5. While attending at engines to rest on off, engines or vehicles at rest | 4 2,479 | 4 2,933 |
6. From falling on or getting on or off platforms | 3 1,504 | 2 1,495 |
7. From falling off, or when getting on or off platforms | 1 483 | 2 404 |
8. From falling off ladders, scaffolds, &c. | 11 449 | 11 400 |
9. By stumbling while walking on the line | 2 1,068 | 1 1,049 |
10. By being trampled on or kicked by horses while engaged in railway work | 1 94 | .71 |
11. From being struck by articles thrown from passing trains | 7 | 6 |
12. From the falling of rails, sleepers, &c., when at work on the line | 686 | 1 611 |
13. Otherwise injured when at work on the line or in sidings | 5 2,182 | 5 1,981 |
14. Miscellaneous | 9 3,085 | 14 2,753 |

Total of servants | 50 19,041 | 55 15,701 |

TABLE XIII.—Nature of Accidents to Trains, Vehicles and Permanent-Way

(A) Accidents to trains:—
1. Collisions between passenger trains or parts of passenger trains | 43 | 48 |
2. Collisions between passenger trains and goods or mineral trains or light-engines | 78 | 70 |
3. Collisions between goods trains or parts of goods trains and light-engines | 180 | 216 |
4. Collisions between trains and vehicles standing foul of the line | 7 | 22 |
5. Collisions between trains and buffer-stops or vehicles standing against buffer-stops:—
   (a) From trains running into stations or sidings at too high a speed | 20 | 17 |
   (b) From other causes | 15 | 25 |
6. Trains coming in contact with projections from other trains or vehicles on parallel lines | 30 | 7 |
7. Passenger trains or parts of passenger trains leaving the rails | 94 | 106 |
8. Goods trains or parts of goods trains, light-engines, &c., leaving the rails | 407 | 483 |
9. Trains running through gates at level-crossings or other obstacles | 368 | 364 |
10. Fires in trains | 195 | 170 |
11. Miscellaneous | 3 | 4 |

(B) Accidents to or failure of rolling stock and permanent-way:—
12. Bursting of boilers or tubes, &c., of engines | 7 | 13 |
13. Failure of machinery, springs, &c., of engines | 61 | 86 |
14. Failure of tires | 125 | 172 |
15. "wheels, axles | 2 | 8 |
16. "couplings | 165 | 106 |
17. "rope used in working inclines | 2,346 | 2,449 |
18. "tunnels, bridges, viaducts, culverts, &c. | 3 | 4 |
20. Broken rails | 287 | 289 |
21. Flooding of portions of permanent-way | 24 | 40 |
22. Slips in cuttings or embankments | 18 | 28 |
23. Falls at stations or involving injury to bridges or viaducts | 30 | 22 |
24. Miscellaneous | 1 | 1 |

Percentages.—On British railways the casualties from train accidents, especially fatal injuries, have been reduced to so small a proportion of the number of passengers travelling, or the number of servants employed, that the figures showing the percentages vary from year to year considerably; but in other classes of accidents, in which a large proportion of the cases may be classed as unpreventable, the percentages do not vary greatly. The following are the more significant ratios in the year 1907, as shown in the Board of Trade returns:—

(a) Passengers killed in train accidents, approximately (1908, 0 in 1,500,000,000 ) 1 in 83,000,000
(b) Passengers injured in train accidents, approximately (1908, approximately 1 in 6,000,000 ) 1 in 3,000,000
(c) Servants killed in train accidents. Number of servants killed per 10,000,000 train miles 0.329
Engine drivers, ratio killed to number employed 1 in 5,628
Firemen, ratio killed to number employed 1 in 12,857.
Passenger guards, ratio killed to number employed 1 in 4,237
Goods guards and brakemen, ratio killed to number employed 1 in 8,438

(d) Servants killed in work about trains, &c. (excluding train accidents), ratio killed to number employed 1 in 790
Goods guards and brakemen, ratio killed to number employed 1 in 490
Shunters, ratio killed to number employed 1 in 337
Engine drivers, ratio killed to number employed 1 in 1,126
Passenger guards, ratio killed to number employed 1 in 1,099

Railway Accidents in America.—The statistics of accidents in America are kept in a form somewhat different from the foregoing. Table XIV. is taken from the Accident Bulletin of the Interstate Commerce Commission (No. 32), the items being numbered to correspond as nearly as practicable with the numbers in the British table (No. X.). The items 7-8 embrace the statistics which most nearly correspond to the items 7-12 in the British table.

TABLE XIV.—Casualties on the Railways of the United States of America

Year ending June 30, 1909.

1908.

Passengers:—
1. In train accidents | 131 | 5,685 | 165 | 7,430 |
2. Other causes | 204 | 6,751 | 241 | 5,215 |

Total of passengers | 335 | 12,166 | 406 | 12,645 |

Servants:—
4. In train accidents | 520 | 4,677 | 642 | 6,818 |
5. Other causes | 1,036 | 46,027 | 2,716 | 49,526 |

Total of servants | 2,456 | 51,804 | 3,358 | 56,344 |

Year ending June 30, 1907.

1. In train accidents | 97 | 171 | 52 | 120 | 149 | 1373 |
2. Struck by trains at highway crossings | 237 | 274 | 696 | 1,523 | 933 | 1797 |
3. Do, at stations | 421 | 423 | 89 | 250 | 510 | 682 |
4. Do, at other places | 3732 | 2063 | 113 | 200 | 3845 | 2263 |

Total of "other persons" | 5612 | 5512 | 1044 | 4471 | 6656 | 9983 |

The salient feature of Table XIV. is the diminution from 1908 to 1909. This is mainly due to a great falling off in traffic, because of a general business depression; from 1907 to 1909 the reduction in the accident record is still greater. In items 1 and 4 the increase in safety is due in part, no doubt, to the extension of the use of the block system. The accidents to "other persons" cannot readily be compared with items 7-12 in the British record, except as to the totals and a few of the items.

In any comparison between British and American records the first point to be borne in mind is the difference in mileage and traffic. The American railways aggregate approximately ten times the length of the British lines; but in train miles the difference is far less. In the latest years in which comparisons can be made, the passenger journeys in the United Kingdom amounted to 1,500 millions (including season-ticket holders, estimated) and the train miles to 2833 millions, while the corresponding figures in the United States were 873-9 millions and 1171-9 millions. The average length
of the passenger’s journey in the United States is reported to be about 13 m. in Great Britain it is undoubtedly less, but no record is published. Of the total train mileage in America more than half is freight; in Great Britain much more than half is passenger.

The table below shows the casualties on American railways in 1907 and 1908. These figures differ from those in Table XIV, as ‘passengers killed’ includes those on some electric railways, which are not included in the statement here given; also passengers in freight trains, &c. Under ‘employees’ this table includes men in shops, &c., not shown in Table XIV.

In 1907 one passenger in 2,318,051 was killed, and one in 107,004 was injured, in train accidents. The number of passengers killed in train accidents was 12-9 in 10 million train miles. Of train men (including engine-drivers and firemen), one out of 252 employed was killed (all causes), and one in eight injured.

The great differences between the records of the United States and the United Kingdom seem to afford justification for the view which has often been expressed, that in America the spirit of hurry and recklessness manifest in many of the activities of the people prevails even among the men on whom rests the grave responsibility of running trains in safety. Yet the best safety devices are made in America, and means of reducing these death records are well known.

France.—Railway accidents in France are recorded in a shape somewhat different from that found in either Great Britain or America. The principal items for the years 1906 and 1907 are shown in Table XVI. The length of railways in the republic was 39,963 km. (24,832 m.), the number of persons employed on them was rather less than 300,000, the number of passengers carried roughly being 4,560,000,000. In 1907 the number of passengers (36) killed in train accidents was equal to 0-0759 per million passengers carried and 0-0024 per million kilometres travelled by passengers, or 0-1503 per million kilometres travelled by trains.

The most significant item in the table, 36 passengers killed in train accidents, is perhaps to be considered as abnormally large, the totals under this head for the preceding six years beginning with 1901 being 7, 35, 3, 18, 4, 14, or an average of 11-57 per year. The French secretaries of Public Works, who has furnished these statistics, keeps also similar records of the local or light railways, on which the number of fatal accidents appears to be exceedingly small.

Germany.—The number of persons killed on the railways of the German Empire in the year 1907 was 1249, classified as in Table XVII. This number does not include suicides and attempts at suicide, of which there were 333, all but 24 being successful. The French secretaries of Public Works, who has furnished these statistics, keeps also similar records of the local or light railways, on which the number of fatal accidents appears to be exceedingly small.

The most significant event in the table is the large number of railway accidents, which is far greater than the number of railway deaths. The great number of accidents is due to the large number of passengers and the large number of railway miles. The number of railway miles in Germany is far greater than in any other country.

The financial organization of the railways in Germany is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in the United States is far simpler. The railways are owned by private companies, and are managed by private companies. The state has no power to regulate the rates of the railways, or to control the construction of new lines. The state only has the power to regulate the safety of the railways, and to control the construction of new lines.

The financial organization of the railways in France is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in the United Kingdom is far simpler. The railways are owned by private companies, and are managed by private companies. The state has no power to regulate the rates of the railways, or to control the construction of new lines. The state only has the power to regulate the safety of the railways, and to control the construction of new lines.

The financial organization of the railways in Japan is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in China is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in India is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in Australia is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in New Zealand is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in South Africa is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in Egypt is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in the British West Indies is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in South America is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in Africa is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in the Middle East is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.

The financial organization of the railways in the Far East is far more complicated than in any other country. The railways are owned by the state, and are managed by the state. The state is responsible for the safety of the railways, and for the maintenance of the lines. The state also has the power to regulate the rates of the railways, and to control the construction of new lines.
RAILWAYS

theory that the bonds represented the cost of the enterprise, and the stock the prospective profits. As a natural result weak railway companies in the United States have frequently been declared insolvent by the courts, owing to their inability in periods of commercial depression to meet their acknowledged obligations, and in the reorganization which has followed the shareholders have usually had to accept a loss, temporary or permanent.

The situation in Great Britain has been wholly different. The debt in that country is relatively small in amount, and is not represented by securities based upon hypothecation of the company’s real property, as with the American railway bond, resting on a first, second or third mortgage. But British share capital has been issued so freely for extension and improvement work of all sorts, including the costly requirements of the Board of Trade, that a situation has been reached where the return on the outstanding securities tends to diminish year by year. Although this fact will not in itself make the companies liable to any process of reorganization similar to that following insolvency and foreclosure of the American railway, it is probable that reorganization of some sort must nevertheless take place in Great Britain, and it may well be questioned whether the position of the transportation system of that country would not have been better if it had been built up and projected on the experience gained by actual earlier losses, as in the United States.

Thus the characteristic defect in the British railway organization is the tendency to put out new capital at a rate faster than has been warranted by the annual increases in earnings. The American railways do not have to face this situation; but, after a long term of years, when they were allowed to do much as they pleased, they have now been brought sharply to book by almost every form of constituted authority to be found in the states, and they are suffering from increased taxation, from direct service requirements, and from a general tendency on the part of regulating authorities to reduce rates and to make it impossible to increase them. Meanwhile, the purchasing power of the dollar which the railway company receives for a specific service is growing with invoices, owing to the general increases year by year in wages and in the cost of material. The railways are prospering because they are managed with great skill and are doing increasing amounts of business, though at lessening unit profits. But there is danger of their reaching the point where there is little or no margin between unit costs of service and unit receipts for the service. It will probably be inevitable for American railway rates to trend somewhat upward in the future, as they have gradually declined in the past; but the process apparently cannot be accomplished without considerable friction with the governing authorities. The attitude of the courts is that the railways should work without compensation, but that the compensation should not exceed a fair return on funds actually expended by the railway. This is in line with the provisions in the Constitution of the United States regarding the protection of property, but the difficulty in applying the principle to the railway situation lies in the fact that costs have to be met by averaging the returns on the total amount of business done, and it is often impossible, in specific instances, to secure a rate which can be considered to yield a fair return on the specific service. The general tendency, however, is that the general tendency to regulate rates by authority of the state has apparently rendered unnecessary the old plan of rate regulation through competition, even if it had not been demonstrated often and again that this form of regulation is costly for all concerned and is effective only during rare periods of direct conflict between companies. Nevertheless, in spite of difficulties, consolidation has gone on with great rapidity. When Mr. E. H. Harriman died he exercised dictatorial authority over more than 50,000 mi. of railway, and the tendency of all the great American railway systems, even when not tied to one another in common ownership, is to increase their mileage year by year by acquiring tributary lines. The smaller company exchanges its stock for stock of the larger system on an agreed basis, or sells it outright, and the bondholders of the absorbed line often have a similar opportunity to exchange their securities for obligations of the parent company, which are on a stronger basis or have a broader market. Similarly in Great Britain there is a tendency towards combination by mutual agreement among the companies while they still preserve their independent existence.

Table XVIII shows the paid-up capital, gross receipts, net receipts and proportion of net receipts to total paid-up capital on the railways of the United Kingdom for a series of years.

*Includes $14,521,601 assigned to other than railway property, but earning net receipts.

†After taxes; to compare with British figures.

This figure should be received with caution. The Interstate Commerce Commission made certain accounting changes this year.

(R. Mo.)

**Construction**

Location.—An ideal line of railway connecting two terminal points would be perfectly level and perfectly straight, because in that case the resistance due to gradients and curves would be eliminated (see § Locomotive Power) and the cost of mechanical operation reduced to a minimum. But that ideal is rarely if ever attainable. In the first place the route of a railway must be governed by commercial considerations. Unless it be quite short, it can scarcely ever be planned simply to connect its two terminal points, without regard to the intervening country; in order to obtain the greatest of the greatest utility and to secure the greatest revenue it must be laid out with due consideration of the traffic...
arising at intermediate places, and as these will not usually lie exactly on the direct line, deviations from straightness will be rendered necessary. In the second place, except in the unlikely event of all the places on the selected route lying at the same elevation, a line that is perfectly level is a physical impossibility; and from engineering considerations, even one with uniform gradients will be impracticable on the score of cost, unless the surface of the country is extraordinarily even. In these circumstances the constructor has two broad alternatives between which to choose. On the one hand he may make the line follow the natural inequalities of the ground as nearly as may be, avoiding the elevations and depressions by curves; or on the other he may aim at making it as nearly straight and level as possible by taking it through the elevations in cuttings or tunnels and across the depressions on embankments or bridges. He will incline to the first of these alternatives when cheapness of first cost is a desideratum, but, except in unusually favourable circumstances, the resulting line, being full of sharp curves and severe gradients, will be unsuited for fast running and will be unable to accommodate heavy traffic economically. If, however, cost within reason of the ground, the second course should be followed. The question is to build a line adapted for express trains and for the carriage of the largest volume of traffic with speed and economy, he will lean towards the second.

In practice every line is a compromise between these two extremes, arrived at by carefully balancing a large number of varying factors. Other things being equal, that route is best which will serve the district most conveniently and secure the highest revenue; and the most favourable combination of curves and gradients is that by which the annual cost of conveying the traffic which the line will be called on to carry, added to the annual interest on the capital expended in construction, will be made minimum. Cutting and Embankments.—A cutting, or cut, is simply a trench dug in a hill or piece of rising ground, wide enough at the bottom to accommodate one or more pairs of rails, and deep enough to enable the line to continue its course on the level or on a moderate gradient. The slopes of the sides vary according to the nature of the ground, the amount of moisture present, &c. In solid rock they may be vertical; in gravel, sand or common earth they must, to prevent slipping, rise 1 ft. for 1 to 1½ or 2 ft. of base, or even more in treacherous clay. In soft material the excavation may be performed by mechanical means; or if the material be a "subaqueous" kind, it may be necessary to resort to blasting. Except in hard rock, the top width of a cutting, and therefore the amount of material to be excavated, increases rapidly with the depth; hence if a cutting exceeds a certain depth, which varies with the particular circumstances, it may be more economical, instead of forming the sides at the slope at which the material of which they are composed will stand, to make them nearly vertical and support the soil with a retaining wall, or to bore a tunnel. An embankment—bank, or fill, is the reverse of a cutting, being an artificial mound of earth on which the railway is taken across on a level or slightly inclined surface. The purpose is made so to plan the works of a railway that the quantity of earth excavated in cuttings shall be equal to the quantity required for the embankments; but this is not always practicable, and it is sometimes advantageous to obtain the earth from some source close to the embankment rather than incur the expense of hauling it from a distant cutting. As embankments have to support the weight of heavy trains, they must be uniformly firm and well drained, and before the line is fully opened for traffic they must be allowed time to consolidate, a process which is helped by running construction or mineral trains over them.

An interesting case of embankment and cutting in combination was made in a cutting at Green Moss on the Liverpool & Manchester railway. The moss was 43 ft. across, and it varied in depth from 10 to 30 ft. Its general character was such that cattle could not stand on it, and a piece of iron would sink in it. The subsoil was composed principally of clay and sand, and the railway had to be carried over the moss on the level, requiring cutting, and embanking for upwards of 4 m. In forming 277,000 cub. yds. of embankment 670,000 yds. of raw peat were consumed, the difference being formed by the squeezing out of the water. Large quantities of embanking were sunk in the moss, and, when the engineer, George Stephenson, after a month's vigorous operations, had made up his estimates, the apparent work done was sometimes less than the cost of the materials used. The cost of embarking was 4½d. per lineal foot of level ground, and the railway was cut across the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment. Where the way existed at several places on the level Lakeirk and was to float on the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment. Where the way existed at several places on the level Lakeirk and was to float on the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment. Where the way existed at several places on the level Lakeirk and was to float on the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment. Where the way existed at several places on the level Lakeirk and was to float on the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment. Where the way existed at several places on the level Lakeirk and was to float on the bog. Where embankment was required drains about 5 yds. apart were cut, and when the moss between them was dry it was used to form the embankment.

**Bridges.**—For conveying small streams through embankments, channels or culverts are constructed in brickwork or masonry. Larger rivers, canals, roads, other railways and sometimes deep narrow valleys are crossed by bridges (q.v.) of timber, brick, stone, wrought iron or steel, and many of these structures rank among the largest engineering works in the world. Sometimes also a viaduct consisting of a series of arches is preferred to an embankment when the line has to cross a river. In the construction of these structures much is done to economize space and to carry the line at a sufficient height to clear the streets, as in the case of various railways entering London and other large towns. In connexion with a railway many bridges have also to be constructed to carry public roads and other railways over the line, and for the use of owners or tenants whose land it has cut through ("accommodation bridges"). In the early days of railways, roads were often taken across the line on the level, but such "level" or "grade" crossings are now usually avoided in the case of new lines in populous countries, except when the traffic on both the road and the railway is very light. In many instances old level crossings have been replaced by over-bridges with long sloping approaches; in this way considerable expenditure has been involved, justified, however, by the removal of a danger to the public and of interruptions to the traffic on both the roads and the railways. In cases where the route of a line runs across a river or other piece of water so wide that the construction of a bridge is either impossible or would be more costly than is warranted by the volume of traffic, the expedient is sometimes adopted of carrying the wagons and carriages across bodily with their loads on train ferries, so as to avoid the inconvenience and delay of transshipment. Such train ferries are common in America, especially on the Great Lakes and the Mississippi; while in parts of the Baltic between Denmark and Sweden and Denmark and Germany, and across the Straits of Messina.

**Gradients.**—The gradient or grade of a line is the rate at which it rises or falls, above or below the horizontal, and is expressed by stating either the horizontal distance in which the change of level amounts to 1 ft., or the amount of change that would occur in some selected distance, such as 100 ft., 1,000 ft. or 1 m. In America a gradient of 1 in 100 is often known as a 1½% grade, one of 2 in 100 as a 2½% grade, and so on; thus a 0-25% grade corresponds to what in England is known as a "ramp", and should not be confused with a "ramp" or "incline". The gradient of a section of railway is the steepest incline in that section, and is so called because it governs or rules the maximum load that can be placed behind an engine working over that portion of line. Sometimes, however, a sharp incline occurring on an otherwise easy line is not reckoned as the ruling gradient, trains heavier than could be drawn up it by a single engine being helped by an assistant or "bank" engine; sometimes also "momentum or velocity" grades, steeper than the ruling gradient, are permitted for short distances in cases where a train can approach at full speed and thus surmount them by the aid of its momentum. An incline of 1 in 400 is reckoned easy in several places in Europe, as the Great Leman and the Great Western. The ruling gradient of the Liverpool & Manchester railway was fixed at 1 in 900, excepting the inclines at Liverpool and at Rainhill summit, for working which special provision was made; and J. R. Brunel laid out the Great Western for a long distance...
out of London with a ruling gradient of 1 in 150. Other engineers, however, such as Joseph Locke, cheapened the cost of the track by admitting gradients as steep as 1 in 80 or 90. One of the steepest gradients in England on an important line is the Licky incline at Bromsgrove, on the Midland railway between Birmingham and Gloucester, where the slope is 1 in 37 for two miles. The maximum gradient possible depends on climatic conditions, a dry climate being the most favourable. The theoretical limit is about 1 in 16; between 1 in 20 and 1 in 16 a steam locomotive depending on the adhesion between its wheels and the rails can only haul about its own weight. In practice the gradient should not exceed 1 in 22½, and even that is too steep, since theoretical conditions cannot always be realised. In an ordinary rack railway the required adhesion, and thus the load that can be hauled, must be such that some paying load can be hauled in all weathers. When an engineer has to construct a railway up a hill having a still steeper slope, he must secure practicable gradients by laying out the line in ascending spirals, if necessary tunnelling into the hill, as on the St Gothard railway, or in a series of zigzags, or he may resort to a rack or a cable railway.

**Railways.**—In rack railways a cog-wheel on the engine engages in a toothed rack which forms part of the permanent way. The earliest example of this is the rack railway designed and kinsman of the Middleton Colliery, near Leeds, in 1811, and an engine built on his plan by Mathew Murray, also of Leeds, began in 1812 to haul coals from Middleton to Leeds over a line 31 m. long. Blenkinning, one of the chief promoters of the system in the United States, adopted the rack principle, and his reason for adopting a rack was that he believed an engine with smooth wheels running on smooth rails would not have sufficient adhesion to draw the load required. It was not till more than half a century later, when the Vignoles, a French engineer, and Marshalling of London, had constructed a rack system for the purpose of enabling trains to surmount steep slopes on the Mountain Washington railway, where the maximum gradient was nearly 1 in 2. In this case the rack had pin teeth casted in a line of radius gradient, and the teeth of the rack were usually cut with a rack-milling machine. The rack was employed especially with a Swiss engineer, Nicholas Riggenbach, and his pupil Roman Abt, and the forms of rack introduced by them are those most commonly used. That of the latter is sometimes applied to the rail-plates, and that of the former to the outer rails. The teeth break joint at ⅔ or ⅔ of their pitch, according to the number of rack-plates. In this way smoothness of working is ensured, the cog-wheel being constantly in action with the rack. Abt also developed the plan of combining rack and adhesion working, the engine working by adhesion alone on the gentler slopes but by both adhesion and the rack on the steeper ones. On such lines the beginning of a rack section is provided with a piece of rack mounted on springs, so that the pinions of the engine engage smoothly with the teeth. Many of these systems have been adopted for gradients steeper than 1 in 4, partly because of the special advantage of the rack dent of the tendency of the cog-wheel to rack the rack. The Locom rack employed on the Mountain Pilatus railway, where the steepest gradient is nearly 1 in 2, is double, with vertical teeth on each side, which bite into two rails, the teeth being arranged in the head of a rail of the ordinary Vignoles type.

**Cable Railways.**—For surmounting still steeper slopes, cable railways may be employed. Of these there are two main systems: (1) a continuous cable is carried over two main drums at each end of the line, and the motion is derived either (a) from the weight of the descending load or (b) from a motor acting on one of the main drums; (2) each end of the cable is attached to two wagons, one set of which is connected with the other ends. The weight required to cause the downward motion is obtained either by means of the material which has to be transported to the bottom of the hill, or by means of weights or additional engines. Steam or electric motors are arranged to act on the main drums, which are arranged in a series. The motor which drives the wire which carries the cable is fitted with an automatic brake to prevent the cable from running down the roadway in case the power is cut off. The cable is sometimes supported by means of a framework of vertical members, or by means of horizontal lines, either by means of a "tangent" or portion of a straight line. In Great Britain the curvature is defined by stating the length of the radius, expressed in chains (1 chain = 66 ft.), in America by stating the angle subtended by a chord 100 ft. long; the measurements in both methods are referred to the central line of the track. The radius of a 1-degree curve is 5530 ft., or about 856 chains, of a 15-degree curve 383 ft. or rather less than 6 chains; the former is reckoned easy, the latter very sharp, at least for main lines on the standard gauge. On some of the earlier English main lines no curves were constructed of a less radius than a mile (80 chains), except at places where the speed was likely to be low, but in later practice the radius is sometimes reduced to 40 or 50 chains, even on high-speed passenger lines.

When a train is running round a curve the centrifugal force which acts on the wheels is converted into an up-thrust into play tends to make its wheel-diameter push against the outer rail, or even to capsize it. If this pressure is not relieved in some way, the train may be derailed either (1) by "climbing" the outer rail, with injury to that rail and, generally, to the corresponding wheel-flanges; (2) by overturning about the outer rail as a hinge, possibly without injury to rails or wheels; or (3) by forcing the outer rail outwards, occasionally to the extent of shearing the spikes that hold it down at the curve, thus spreading or destroying the track. In any case the details depend upon whether the vehicle concerned is an engine, a wagon or a passenger coach, and upon whether it runs on the inner or outer rail. If it be an engine, particular attention must be directed to the type, weight, arrangement of wheels and height of centre of gravity above rail level. In considering the forces that produce derailment the total mass of the vehicle or locomotive may be supposed to be concentrated at its centre of gravity. Two lines may be drawn from this point, one to each of the two rails, in a plane normal to the rails, and the ends of these lines, where they meet the rails, may be joined to complete a triangle, which may conveniently be regarded as a rigid frame resting on the rails. As the vehicle sweeps round the curve the centre of gravity tends to be thrown outwards, the weight of the vehicle, the height of the centre of gravity, and the vertical pressure of the frame upon the outer rail is thus increased, while its vertical pressure on the inner rail is diminished. Simultaneously the frame as a whole tends to slide horizontally athwart the rails, from the inner towards the outer rail, urged by the same centrifugal forces. This sliding movement is resisted by placing a check-roller on the inner side of the inner rail, to take the lateral thrust of the wheels on that side. It is also resisted in part by the concavity of the wheels, which converts the lateral force partly into a vertical force, thus enabling gravity to exert a restoring influence. When the lateral forces are too great to be controlled "climbing" occurs. Accidents due to simple "climbing" have sometimes occurred. The weight of the vehicle, the height of the centre of gravity, associated with a faulty track, with "plunging" movements of the locomotive or vehicle, or with a "right gauge" at curves or points.

From consideration of the rigid triangular frame described above, it is clear that the "overturning" force acts horizontally from the centre of gravity, and that the length of its lever arm is, at any instant, the vertical distance from the centre of gravity to the level of the outer rail. This is true whatever be the tilt of the vehicle at that instant. The restoring force exerted by gravity acts in a vertical line from the centre of gravity; and the length of its lever arm is the horizontal distance between this vertical line and the outer rail. If the outer rail is laid at a level above that of the inner rail at the curve, overturning will be resisted more than would be the case if both rails were in the same horizontal plane, since the tilting of the vehicle due to this "superelevation" diminishes the overturning moment, and also increases the restoring moment, by shortening in the one case and lengthening in the other the lever arms at which the respective forces act. The amount of superelevation required to prevent derailment at a curve can be calculated under perfect running conditions, given the radius of curvature, the weight of the vehicle, the height of the centre of gravity, the distance between the rails, and the speed; but great experience

---

is required for the successful application of definite formulae to the problem. For example, what is a safe speed at a given curve for an engine, truck or coach having the load equally distributed over the wheels may lead to either climbing or overturning if the load is shifted to a diagonal position. An ill-balanced load also exaggerates "plunging," and if the period of oscillation of the load happens to agree with the changes of contour or other inequalities of the track vibrations of a dangerous character, giving rise to so-called "sinuous" motion, may occur.

In general it is not curvature, but change of curvature, that presents difficulty in the laying-out of a line. For instance, if the curve is of S-form, the point of danger is when the train enters the contra-lexure, and it is not an easy matter to assign the best superelevation at all points throughout the double bend. Closely allied to the question of safety is the problem of preventing jolting at curves; and to obtain easy running it is necessary not merely to adjust the levels of the rails in respect to one another, but to tail off one curve into the next in such a manner as to avoid any approach to abrupt lateral changes of slope. In the case of railways, the change of direction has become important as an element of comfort in passenger traffic. As a first approximation, the centre-line of a railway may be plotted out as a number of portions of circles, with intervening straight tangents connecting them, when the abruptness of the changes of direction will depend on the radii of the circular portions. But if the change from straight to circular is made through the medium of a suitable curve it is possible to relieve the abruptness, even on curves of comparatively small radius. The smoothest and safest running is, in fact, attained when a "transition," "easement" or "adjustment" curve is inserted between the tangent and the point of circular curvature.

Gauge.—The gauge of a railway is the distance between the inner edges of the two rails upon which the wheels run. The width of 4 ft. 8 1/2 in. may be regarded as standard, since it prevails on probably three-quarters of the railways of the globe. In North America, except for small industrial railways and some short lines for local traffic, chiefly in mountainous country, it has become almost universal; the long lines of 3 ft. gauge have mostly been converted, or a third rail has been laid to permit interchange of vehicles, and the gauges of 5 ft. and more have disappeared. A considerable number of lines still use 4 ft. 9 in., but as their rolling stock runs freely on the 4 ft. 8 1/2 in. gauge and vice versa, this does not constitute a break of gauge for traffic purposes. The commercial importance of such free interchange of traffic is the controlling factor in determining the gauge of any new railway that is not isolated by its geographical position. In Great Britain railways are built to gauge other than 4 ft. 8 1/2 in. only under exceptional conditions, the old "broad gauge" of 7 ft. which J. K. Brunel adopted for the Great Western railway disappeared on the 20th—23rd of May 1892, when the main line from London to Penzance was converted to standard gauge throughout its length. In Ireland the usual gauge is 5 ft. 3 in., but there are also lines laid to a 3 ft. gauge. On the continent of Europe the standard gauge is generally adopted, though in France there are many miles of 4 ft. 9 in. gauge; the normal Spanish and Portuguese gauge is, however, 5 ft. 51/2 in., and that of Russia 5 ft. In France and other European countries there is also an important mileage of metre gauge, and even narrower, on lines of local or secondary importance. In India the prevailing gauge is 5 ft. 6 in., but there is a large mileage of other gauges, especially metre. In the British colonies the prevailing gauge is 3 ft. 6 in., as in South Africa, Queensland, Tasmania and New Zealand; but in New South Wales the normal is 4 ft. 8 1/2 in. and in Victoria 5 ft. 3 in., communication between different countries of the Australian Commonwealth being thus carried on under the disadvantage of break of gauge. Though the standard gauge is in use in Lower Egypt, the line into the Egyptian Sudan was built on a gauge of 3 ft. 6 in., so that if the so-called Cape to Cairo railway is ever completed, there will be one gauge from Upper Egypt to Cape Town. In South America the 5 ft. 6 in. gauge is in use, with various others.

**Mono-Rail Systems.**—The gauge may be regarded as reduced to its narrowest possible dimensions in mono-rail lines, where the weight of the trains is carried on a single rail. This method of construction, however, has been adopted only to a very limited extent. In the Lartigue system the train is straddled over a single central rail, elevated a suitable distance above the ground. A short line of this kind runs from Ballybunion to Listowel in Ireland, and a more ambitious project on the same principle, on the plans of Mr F. B. Behr, to connect Liverpool and Manchester, was sanctioned by Parliament in 1901. In this case electricity was to be the motive-power, and speeds exceeding 100 m. an hour were to be attained, but the line has not been built. In the Langen mono-rail the cars are hung from a single overhead rail; a line on this system works between Barmen and Elberfeld, about 9 m., the cars for a portion of the distance being suspended over the river Wupper. In the system devised by Mr Louis Brennan the cars run on a single rail laid on the ground, their stability being maintained by a heavy gyrostat revolving at great speed in a vacuum.

**Permanent Way.**—When the earth-works of a line have been completed and the tops of the embankments and the bottoms of the cuttings brought to the level decided upon, the next step is to lay the permanent way, so-called probably in distinction to the temporary way used during construction. The first step is to deposit a layer of ballast on the road-bed or "formation," which often slopes away slightly on each side from the central line to facilitate drainage. The ballast consists of such materials as broken stone, furnace slag, gravel, cinders or earth, the lower layers commonly consisting of coarser materials than the top ones, and its purpose is to provide a firm, well-drained foundation in which the sleepers or cross-ties may be embedded and held in place, and by which the weight of the track and the trains may be distributed over the road-bed. Its depth varies, according to the traffic which the line has to bear, from about 6 in. to 1 ft. or rather more under the sleepers, and the materials of the surface layers are often chosen so as to be more or less dustless. Its width depends on the numbers of tracks and their gauge; for a double line of standard gauge it is about 25 ft., a space of 6 ft. ("six-foot way") being left between the inner rails of each pair in Great Britain (fig. 8), and a rather larger distance in America (fig. 9), where the over-hang of the rolling stock is greater. The intervals between the sleepers are filed in level with ballast,
Sleepers, called ties or cross-ties in America, are the blocks or slabs on which the rails are carried. They are nearly always placed transversely, across the direction of the lines, the longitudinal position such as was adopted in connexion with the broad gauge on the Great Western in England having been abandoned except in special cases. Stone blocks were tried as sleepers in the early days of railways, but they proved too rigid, and besides, it was found difficult to keep the line true with them. Wood is the material most widely used, but steel is employed in some countries where timber is scarce or liable to destruction by white ants, though it is still regarded as too expensive in comparison with wood for general adoption. Steel sleepers were used experimentally on the London & North-Western, but were abandoned owing to the shortness of their life. In Germany, where they have met with greater favour, there were over 465 millions in use in 1905, and they have been tried by some American railways. Numerous forms of ferro-concrete sleepers have also been devised.

In Great Britain, Germany and France, at least 90% of the wooden sleepers are “treated” before they are laid, to increase their resistance to decay, and the same practice is followed to some extent in other European countries. A great number of preservative processes have been devised. In that most largely used, known as “creosoting,” dead oil of tar, to the amount of some 3 gallons per sleeper, is forced into the wood under pressure, or is sucked in by vacuum, both the timber and the oil being heated. In the United States only a small percentage of the ties are treated in any way beyond seasoning in the open air, timber, in the opinion of the railway officials, being still too cheap in nearly all parts of that country to justify the use of preservatives. Some railway companies, however, having a long mileage in timberless regions, do “treat” their sleepers.

Typical dimensions for sleepers on important British railways are:—length 9 ft., breadth 10 in. and depth 5 in. In America 8 ft. is the most common length, the breadth being 8 in. and the depth 6 or 7 in.

There are two main ways of attaching the rails to the sleepers, corresponding to two main types of rails—the bull-headed rail and the Vignoles or flange rail. In the first method, which is practically universal in Great Britain and is also employed to some extent in France and India, the rails have rounded bases and are supported by being wedged, with wooden keys, in cast-iron chairs which are bolted to the sleepers. In the second method the rails have flat flanged bases which rest directly on the sleepers (fig. 10). The chairs on the British system weigh about 45 or 50 lb each on important lines, though they may be less where the traffic is light, and are fixed to the sleepers each by two, three or four fastenings, either screw spikes, or round drift bolts entered in holes previously bored, or fang bolts or wooden trenails. Sometimes a strip of felt is interposed between the chair and the sleeper, and sometimes a serrated surface is prepared on the sleeper for the chair which is forced into its seat by hydraulic pressure. The keys which hold the rail in the chairs are usually of oak and are placed outside the rails; the inside position has also been employed, but has the disadvantage of detracting from the elasticity of the road since the weight of a passing train presses the rails up against a rigid mass of metal instead of against a slightly yielding block of wood. The rails, which for heavy main line traffic may weigh as much as 100 lb per yard, or even more, are rolled in lengths of from 30 to 60 ft., and sleepers are placed under them at intervals of between 2 and 3 ft. (centre to centre), 11 sleepers to a 30 ft. rail being a common arrangement. On the London & North-Western railway there are 24 sleepers to each 60 ft. rail. A small space is left between the end of one rail and that of the next, in order to allow for expansion in hot weather, and at the joint the two are firmly braced together by a pair of fish-plates (fig. 11). These are flat bars of iron or steel from 18 in. to 2 ft. long, which are lodged in the channels of the rail, one on each side, and secured with four bolts passing through the web; sometimes, to give additional stiffness, they extend down below the lower table of the rail and are bent round so as to clip it. Occasionally the joints thus formed are “supported” on a sleeper, as was the practice in the early days of railway construction, but they are generally “suspended” between two sleepers, which are set rather more closely together than at other points in the rail. Preferably, they are so arranged that those in both lines of rails come opposite each other and are placed between the same pair of sleepers.

Flat-bottomed rails are fastened to the sleepers by hook-headed spikes, the heads of which project over the flanges. In the United States the spikes are simply driven in with a maul, and the rails stand upright, little care being taken to prepare seats for them on the sleepers, on which they soon seat themselves. The whole arrangement is simple and cheap in first cost, and it lends itself admirably to fast track-laying and to repairs and changes of line. On the continent of Europe the practice is common of notching the sleeper so as to give the rail a slight cant inwards—a result obtained in England by canting the rail in the chairs—and metal plates or strips of felt are put under the rail, which is carefully fastened to the sleeper by screwed spikes (fig. 12). This method of construction is more expensive than the American in first cost, but it gives a more durable and stable track. Such metal plates, or “tie-plates,” have come into considerable use also in the United States, where they are always made of rolled steel, punched with rectangular holes through which the spikes pass. They serve two principal

1 See a full account of steel sleepers in a paper read by A. Haarmann before the Verein der Deutschen Eisenhüttenleute on Dec. 8, 1907, translated in the Railway Gazette (London) on April 3, 10 and 17, 1908.
RAILWAYS

purposes: they diminish the wear of the sleeper under the rail by providing a larger bearing surface, and they help to support the spikes and to keep the gauge. On all the accepted forms there are two or more flanges at the bottom, running lengthwise of the plate and crosswise of the rail; these are requisite to give proper stiffness, and further, as they are forced into the tie by the weight of passing traffic, they help to fix the plate securely in place. The joints of flanged rails are similar to those employed with bull-headed rails. Various forms, mostly patented, have been tried in the United States, but the one most generally adopted consists of two

Fig. 13.—American Rail, 90 lb to the yard, showing rail joint.

and a scarcely less important element of progressive economy has been the continued improvement of the steel rail in stiffness of section and in toughness and hardness of material. Carbon is the important element in controlling hardness, and the amount present is in general higher in the United States than in Great Britain. The specifications for bull-headed rails issued by the British Engineering Standards Committee in 1904 provided for a carbon-content ranging from 0.15 to 0.26%, with a phosphorus maximum of 0.075%. In the United States a committee of the American Society of Civil Engineers, appointed to consider the question of rail manufacture in consequence of an increase in the number of rail-failures, issued an interim report in 1907 in which it suggested a range of carbon from 0.25 to 0.65% for the heaviest sections of Bessemer steel flange rails, with a phosphorus maximum of 0.085% while the specifications of the American Society for Testing Materials, current at the same period, put the carbon limits at 0.15 to 0.35% and the phosphorus limit at 0.10. For rails of basic open-hearth steel, which is rapidly ousting Bessemer steel, the Civil Engineers' specifications allowed from 0.65 to 0.75% of carbon with 0.05% of phosphorus, while the specifications of the American Railway Engineering and Maintenance of Way Association provided for a range of 0.75 to 0.85% of carbon, with a maximum of 0.03% of phosphorus. The rail-failures mentioned above also drew renewed attention to the importance of the thermal treatment of the steel from the time of melting to the last passage through the rolling mill and to the necessity of the finishing temperature being sufficiently low if the product is to be fine grained, homogeneous and tough; and to permit of this requirement being met there was a tendency to increase the thickness of the metal in the web and flanges of the rails. The standard specifications adopted by the Pennsylvania railway in 1908 provided that in rails weighing 100 lb to the yard 41% of the metal should be in the head, 18.6% in the web, and 40.4% in the base, while for 85 lb rails 42.2% was to be in the head, 17.8% in the web and 40.0% in the base. These rails were to be rolled in 33-ft. lengths. According to the specification for 85 lb rails adopted by the Canadian Pacific railway about the same time, 36.77% of the metal was to be in the head, 22.21% in the web and 41.02% in the base.

Points and Crossings.—To enable trains to be transferred from one pair of rails to another pair, as from the main line to a siding, “points” or “switches” are provided. At the place where the four rails come together, the two inner ones (one of the main line and the other of the siding), known as “switch rails” (b, fig. 14), are tapered to a fine point or tongue, and rigidly connected together at such a distance apart that when one of the points is pressed against the outer or “stock” rail (a) of either the siding or the main line there is sufficient space between the other tongue and the other stock rail to permit the free passage of the flanges of the wheels on one side of the train, while the flanges on the other side find a continuous path along the other switch rail and thus are deflected in the desired direction. The same arrangement is employed at junctions where different running lines converge. The points over which a train travels when directed from the main to a branch line are called “facing points” (FP), while those which it passes when running from a branch to a main line are “trailing points” (TP). In Great Britain the Board of Trade requires facing points to be avoided as far as possible; but, of course, they are a necessity at junctions where running lines diverge and at the crossing places which must be provided to enable trains to pass each other on single-track lines. At stations the points that give access to sidings are generally arranged as trailing points with respect to the direction of traffic on the main lines; that is, trains cannot pass direct into sidings, but have to stop and then run backwards into them. In shunting yards the points are commonly set in the required direction by means of hand levers placed close beside the lines, but those at junctions and those which give access from the main lines to sidings at Wayside stations are worked by a system of rods from the signal cabin, or by electric or pneumatic power controlled from it and interconnected with the signals (see SIGNAL: § Railway). Crossings are inevitable adjuncts of points. Where a branch diverges from a main line, one rail of the one must cross one rail of the other, and a V-crossing is formed (V). Where, as at a double-line junction, one pair of rails crosses another pair, “diamond” crossings (D) are formed. At both types of crossing, check rails (c) must be provided to guide the wheel-flanges, and if these are not accurately placed the safety of the trains will be endangered. At double-line junctions trains passing over the diamond crossings evidently block traffic going in the opposite direction to that in which they are travelling. To avoid the delay thus caused the branch line which would occasion the diamond crossing if it were taken across on the level is sometimes carried over the main line by an over-bridge (“flying junction”) or under it by an under-bridge (“burrowing junction”).

Railway Stations.—Railway stations are either “terminal” or “intermediate.” A terminal station embraces (1) the passenger station; (2) the goods station; (3) the locomotive, carriage and wagon depots, where the engines and the carrying stock are kept, cleaned, examined and repaired. At many intermediate stations the same arrangements, on a smaller scale, are made; in all of them there is at least accommodation for the passenger and the goods traffic. The stations for
RAILWAYS

passengers and goods are generally in different and sometimes in distant positions, the place selected for each being that which is most convenient for the traffic. The passenger station abuts on the main line, or, at termini, forms the natural terminus, at a place as near as can conveniently be obtained to the centre of the population which constitutes the passenger traffic; and preferably its platforms should be at or near the ground level, for convenience of access. The goods station is approached by a siding or fork set off from the main line at a point short of the passenger station. In order to keep down the expense of shunting the empty trains and engines to the front of the platforms the carriage and locomotive depots should be as near the passenger station as possible; but often the price of land renders it impracticable to locate them in the immediate vicinity and they are to be found at a distance of several miles.

In laying out the approaches and station yard of a passenger station ample width and space should be provided, with well-defined means of ingress and egress to facilitate the circulation of vehicles and with a long setting-down pavement to enable them to discharge their passengers and luggage without delay. The position of the main buildings—ticket offices, waiting and refreshment-rooms, parcel offices, &c.—relative to the direction of the lines of rails may be used as a means of classifying terminal stations. They are placed either on the departure side parallel to the platform ("side" stations) or at right angles to the rails and platforms ("end" stations). Many large stations, however, are of a mixed type, and the offices are arranged in a fork between two or more series of platforms, or partly at the end and partly on one side. Where heavy suburban traffic has to be dealt with, the expedient is occasionally adopted of taking some of the lines round the end in a continuous loop, so that incoming trains can deposit their passengers at an underground platform and immediately proceed on their outward journey. Intermediate stations, like terminal ones, should be inconvenient in situation and easy of approach, and, especially if they are important, should be on the ground level rather than on an embankment or in a cutting. The lines through them should be, if possible, straight and on the level; the British Board of Trade forbids them being placed on a gradient steeper than 1 in 260, unless it is unavoidable. Intermediate stations at the surface level are naturally constructed as side stations, and whether offices are provided on both sides or whether they are mainly concentrated on one will depend on local circumstances and the amount of the traffic, and the direction in which it preponderates. When the railway lies below the surface level the bulk of the offices are often placed on a bridge spanning the lines, access being given to the platforms by staircases or lifts, and similarly when the railway is at a high level the offices may be arranged under the lines. Occasionally on a double-track railway one platform placed between the tracks served both of them; this "island" arrangement, as it is termed, has the advantage that more tracks can be readily added without disturbance of existing buildings, but when it is adopted the exit from the passenger at an underground platform and usual, and accidents have happened through passengers alighting at the usual side without noticing the absence of a platform. At stations on double-track railways which have a heavy traffic four tracks are sometimes provided, the two outside ones only having platforms, so that fast trains get a clear road and can pass slow ones that are standing in the station. In Great Britain, it may be noted, trains almost invariably keep to the left, whereas in most other countries right-handed running is the rule.

The arrangement and appropriation of the tracks in a station materially affect the economical and efficient working of the traffic. There must be a sufficient provision of sidings, connected with the running tracks by points, for holding spare rolling stock and to enable carriages to be added to or taken off trains and engines to be changed with as little delay as possible. At terminal stations especially as such are used by short-distance trains which arrive at and start from the same platform, a third track is often laid between a pair of platform tracks, so that the engine of a train which has arrived at the platform can pass out and place itself at the other end of the train, which remains undisturbed. At the new Victoria station (London) of the London, Brighton & South Coast railway—which is so long that two trains can stand end to end at the platforms—this system is extended so as to permit a train to start out from the inner end of a platform even though another train is occupying the outer end. One of the advantages of electric trains on the multiple control system is that they minimize terminal accommodation because they can be driven from either end indifferently, and therefore avoid the necessity for tracks by which engines can change from one end of the train to the other.

The platforms on British railways have a standard elevation of 3 ft. above rail level, and they are not now made less than 2 ft. in height. In other countries they are generally lower; in the United States they are commonly level with, or only a few inches higher than, the top of the rails. They may consist of earth with a retaining wall along the tracks and with the surface gravelled or paved with stone or asphalt, or they may be constructed of timber, or they may be formed of stone slabs supported on longitudinal walls. They should be of ample dimensions to accommodate the traffic—the British Board of Trade requires them to be not less than 6 ft. wide at small stations and not less than 12 ft. wide at large ones—and they should be as free as possible from obstructions, such as pillars supporting the roof. At intermediate stations the roofs are often carried on brackets fixed to the walls of the station buildings, and project only to the edge of the platforms. At larger stations where both the platforms and the tracks are covered in, there are two broad types of construction, with many intermediate variations: the roof may either be comparatively low, of the "ridge and furrow" pattern, borne on a number of rows of pillars, or it may consist of a single lofty span extending clear across the area from the side walls. The advantage claimed for roofs formed with one or two large spans is that they permit the platforms and tracks to be readily rearranged at any time as required, whereas this is difficult with the other type, especially since the British Board of Trade requires the pillars to be not less than 6 ft. away from the edges of the platforms. On the other hand, wide spans are more expensive both in first cost and in maintenance, and there is the possibility of a failure such as caused the collapse in December 1905 of the roof of Charing Cross (S.E.R.) station, London, which then consisted of a single span. Whatever the pattern adopted for the roof, a sufficient portion of it must be glazed to admit light, and it should be so designed that the ironwork can be easily inspected and painted and the glass readily cleaned. For the illumination of large stations by night electric arc lamps are frequently employed, but some authorities favour high-pressure incandescent gas-lighting.

At busy stations separate tracks are sometimes appropriated to the use of light engines and empty trains, on which they may run between the platforms and the locomotive and carriage depots. A carriage depot includes sheds in which the vehicles are stored, arrangements for washing and cleaning them, and sidings on which they are marshalled into trains. At a locomotive depot the chief building is the "running shed" in which the engines are housed and cleaned. This may be rectangular in shape ("straight" shed), containing a series of parallel tracks on which the engines stand and which are reached by means of points and crossings diverging from a main track outside; or it may take a polygonal or circular form (round house or rotunda), the lines for the engines radiating from a turn-table which occupies the centre and can be rotated so as to serve any of the radiating lines. The second arrangement enables any particular engine to enter or leave without disturbing the other; but on the other hand an accident to the turn-table may temporarily imprison the whole of them. In both types pits are constructed between the rails
on which the engines stand to afford easy access for the inspection and cleaning of their mechanism. Machine shops are usually provided to enable minor repairs to be executed; the tendency, both in England and America, is to increase the amount of such repairing plant at engine sheds, thus lengthening the intervals between the visits of the engines to the main repairing shops of the railway. A locomotive depot further includes stores of the various materials required in working the engines, coal stages at which they are loaded with coal, and an ample supply of water. The quality of the last is a matter of great importance; when it is unsuitable, the boilers will suffer, and the installation of a water-softening plant may save more in the expenses of boiler maintenance than it costs to operate. The water cranes or towers which are placed at intervals along the railway to supply the engines with water require similar care in regard to the quality of the water laid on to them, as also to the water troughs, or track tanks as they are called in America, by which engines are able to pick up water without stopping. These consist of shallow troughs about 18 in. wide, placed between the rails on perfectly level stretches of line. When water is required, a scoop is lowered into them from below the engine, and if the speed is sufficient the water is forced up into the tender-tanks. Such troughs were first employed on the London & North-Western railway in 1857 by John Ramsbottom, and have since been adopted on many other lines.

Goods stations vary in size from those which consist of perhaps a single siding, to those which have accommodation for thousands of wagons. At a small roadside station, where the traffic is of a purely local character, there will be some sidings to which horses and carts have access for handling bulk goods like coal, gravel, manure, and a covered shed for loading and unloading packages and materials which it is undesirable to expose to the weather. The shed may have a single pair of rails for wagons running through it along one side of a raised platform, there being a roadway for carts on the other side; or if more accommodation is required there may be two tracks, one on each side of the platform, which is then approached by carts at the end. In either case the platform is fitted with a crane or cranes for lifting merchandise into and out of the wagons, and doors enable the shed to be used as a lock-up warehouse. In a large station the arrangements become much more complicated, the precise design being governed by the nature of the traffic that has to be served and by the physical configuration of the site. It is generally convenient to keep the inwards and the outwards traffic distinct and to deal with the two classes separately; at junction stations it may also be necessary to provide for the transfer of freight from one wagon to another, though the bulk of goods traffic is conveyed through to its destination in the wagons into which it was originally loaded. The increased loading space required in the sheds is obtained by multiplying the number and the length of lines and platforms; sometimes also there are short sidings, cut into the platforms at right angles to the lines, in which wagons are placed by the aid of turn-tables. Sometimes sidings are dealt with on two floors, being raised or lowered bodily from the ground level by lifts. The higher floors commonly form warehouses where traders may store goods which have arrived or are awaiting despatch. An elaborate organization is required to keep a complete check and record of all the goods entering and leaving the station, to ensure that they are loaded into the proper wagons according to their destination, that they are unloaded and sorted in such a way that they can be delivered to their consignees with the least possible delay, that they are not stolen or accidentally mislaid, &c.; and accommodation must be provided for a large, clerical, and supervisory staff to attend to these matters. British railways also undertake the collection and delivery of freight, in addition to transporting it, and thus an extensive range of vans and wagons, whether drawn by horses or mechanically propelled, must be provided in conjunction with an important station.

**Shunting Yards.**—It may happen that from a large station sufficient traffic may be consigned to certain other large stations to enable full train-loads to be made up daily, or several times a day, and despatched direct to their destinations. In general, however, the conditions are less simple. Though a busy colliery may send off its product by the train-load to an important town, the wagons will usually be addressed to a number of different consignees at different depots in different parts of the town, and therefore the train will have to be broken up somewhere short of its destination and its trucks rearranged, together with those of other trains similarly constituted, into fresh trains for conveyance to the various depots. Again, a station of moderate size may collect goods destined for a great variety of places but not in sufficient quantities to compose a full train-load for any of them, and then it becomes impossible, except at the cost of uneconomical working, to avoid despatching trains which contain wagons intended for many diverse destinations. For some distance these wagons will all travel over the same line, but sooner or later they will reach a junction-point where their ways will diverge and where they must be separated. At this point trains of wagons similarly destined for different places will be arriving from other lines, and hence the necessity will arise of collecting together from all the trains all the wagons which are travelling to the same place.

The problem may be illustrated diagrammatically as follows (fig. 15): A may be supposed to be a junction outside a large seaport where branches from docks a, b, c, and d converge, and where the main line also divides into three, going to B, C and D respectively. A train from a will contain some wagons for B, some for C and some for D, as will also the trains from a, b, c and d. At A therefore it becomes necessary to disentangle and group together all the wagons that are intended for B, all that are intended for C, and all that are intended for D. Even that is not the whole of the problem. Between A and B, A and C, and A and D, there may be a string of stations, p, q, r, s, &c., all receiving goods from a, b, c and d, and it would manifestly be inconvenient and wasteful of time and trouble if the trains serving those intermediate stations were made up with any six wagons from a to p next the engine, five from b to p at the middle, and four from c to p near the end. Hence at A the trains from a, b, c and d must not only be sorted according as they have to travel along A B, A C, or A D, but also must be marshalled into trains in the order of the stations along those lines. Conversely, trains arriving at A from B, C and D must be broken up and remade in order to distribute their wagons to the different dock branches.

Conversely, the wagons to be shunted into the desired order yards containing a large number of sidings are constructed at important junction points like A. Such a yard consists essentially of a group or groups of sidings, equal in length at least to the longest train run on the line, branching out from a single main track and often again converging to a single track at the other end; the precise design, however, varies with the amount and character of the work that has to be done, with the configuration of the ground, and also with the mode of shunting adopted. The oldest and commonest method of shunting is that known as "push-and-pull," or in America as "head and end." An engine coupled to a batch of wagons runs one or more of them down one siding, leaves them there, then returns back with the remainder clear of the points where the sidings diverge, runs one or more others down another sidings, and so on till they are all disposed of. The same operation is repeated with fresh batches of wagons, until the sidings contain a number of trains, each intended, it may be supposed, for a particular town or district. In some cases nothing more is required than to take the engine and brake-van ("caboose") off the train; but if, as will happen in others, a further rearrangement of the wagons was required, the engine may be employed again with the brake-van, and the wagons transferred to it; but in these cases the wagons are run down the siding to a "ganger's platform," and therefore the engine has to be lifted or "switched" from one siding to another. It is evident that this method is wasteful of time and also of the motive power of the engine employed. A better method is that known as "splitting and reuniting," or in America as "head and side." An engine and brake-van are placed at the points where the wagons in one portion of the yard are divided, and where they are united in the other. A train is run down one of the sidings, whereupon the wagons are divided into two, and the engine and brake-van are moved to the points where the sidings which should receive the smaller portion of the train are divided, and the train is run down them. This operation is then repeated with the train which is left on the siding from which the engine was moved. In this way the smallest number of engines and brake-vans is employed, and they are run the shortest distances. The third and best method is that known as "head, side and end," or in America as "head and side with gangers' trolleys." This method is the same as the preceding, but the engine and brake-van are replaced by the gangers' trolleys, which runs down the siding to the points where the wagons are divided, and where they are united in the other. An engine is placed at the points where the wagons are separated, and the brakes are pressed, and the train is run down the siding to the points of division, whereupon the wagons are divided into two, and the engine and brake-van are moved to the points where the sidings which should receive the smaller portion of the train are divided, and the train is run down them. This operation is then repeated with the train which is left on the siding from which the engine was moved. In this way the smallest number of engines is employed, and they are run the shortest distances. The third and best method is that known as "head, side and end," or in America as "head and side with gangers' trolleys." This method is the same as the preceding, but the engine and brake-van are replaced by the gangers' trolleys, which runs down the siding to the points where the wagons are divided, and where they are united in the other. An engine is placed at the points where the wagons are separated, and the brakes are pressed, and the train is run down the siding to the points of division, whereupon the wagons are divided into two, and the engine and brake-van are moved to the points where the sidings which should receive the smaller portion of the train are divided, and the train is run down them. This operation is then repeated with the train which is left on the siding from which the engine was moved. In this way the smallest number of engines is employed, and they are run the shortest distances.
the wagons is necessary to get them into station order this is effected on the same principle.

Push-and-pull shunting is simple, but it is also slow, and therefore efforts have been made at busy yards where great numbers of trains are dealt with to introduce more expeditious methods. One of these, employed in America, is known as "poling." Alongside the tracks on which stand the trains that are to be broken up and from which are to be taken away the by-products of the subsidiary tracks are provided for the use of the shunting engines. These engines have a pole projecting horizontally in front of them, or are attached to a "pole-car," having such a pole. The method of working is for the pole to be swung out behind a number of wagons; one or more engines are then started and with its pole pushes the wagons in front of it until their speed is sufficient to carry them over the points, where they are diverted into any desired siding. It then runs back to the train to take it out of the operation, but while it is doing so a stationary engine similarly equipped has pulled away a batch of wagons on the opposite side. In this way a train is distributed with great rapidity, especially if the points giving access to the different sidings are worked by power so that they can be quickly manipulated.

Another method, which was introduced into America from Europe about 1890, is that of the summit or "hump." The wagons are pushed by an engine at their rear up one slope of an artificial mound, and as they run down the other slope by gravity are switched into the desired siding. Sometimes a site can be found for the sorting sidings where the natural slope of the ground is sufficiently steep to make the wagons run down of themselves. One of the earliest and best known of such "gravity" yards is that at Edgemoor, near Liverpool, on the London & North-Western railway, which was established in 1873. Here, at the highest level, there are a number of "summits" or "humps" converging to a single line, which lead to a group of "sorting sidings" at a lower level. These in turn converge to a pair of single lines which lead to two groups of marshalling sidings, called "gridirons" from their shape, and these again converge to a single line, leading to power reception and departure lines at the bottom of the slope. The wagons from the upper reception lines are sorted into trains on the sidings, and then, in the different sidings, are arranged in the proper order and marshaled ready to be sent off from the departure lines. (H. M. R.)

**Locomotive Power**

The term "power" is used in technical sense to mean the rate at which work is done against a resistance, and is measured in units of energy expended per unit of time. The unit of power commonly used by engineers is the horse-power, and this unit corresponds to a rate of working of 550 foot-lb of work per second.

The problems arising out of the special consideration of the power required to propel a railway train against the resistances opposing its motion, the way the power is applied to trains, the agent by means of which the power is exerted, are conveniently grouped together under the general heading of Locomotive Power. There are certain fundamental relations common to all tractive problems, and these are briefly considered in §§ 1 and 2, after which the article refers particularly to steam locomotives, although §§ 4, 5, 7, 8, 9, and 10 have a general application to all modes of traction.

§1. Fundamental Relations.—The resistance against which a train is moved along a railway is overcome by means of energy obtained from the combustion of fuel, or in some few cases by energy obtained from a waterfall. If the total resistance against which the train is maintained in motion with an instantaneous velocity of V feet per second is R, the rate at which energy is expended in moving the train is represented by the product RV, and this must be the rate at which energy is supplied to the train after deducting all losses due to transmission from the source of power. Thus if R is equal to 10,000 lb when the velocity is 44 ft. per second, equivalent to 30 m. per hour, the rate of working against the resistance is 440,000 foot-lb per second.

In whatever form energy is produced and distributed to the train it ultimately appears as mechanical energy applied to turn one or more axles against the resistance to their rotation imposed by the weight on the wheels and the motion of the train.

The rate at which work is done on a particular axle is measured by the product TW, where T is the torque, or turning moment, exerted on the axle by the motor or mechanism applied to it for this purpose, and ω is the angular velocity of the axle in radians per second. Hence if all the energy supplied to the train is utilized at one axle there is the fundamental relation

$$T_w = RV$$  

Continuing the above arithmetical illustration, if the wheels to the axle of which the torque is applied are 4 ft. diameter, \(u = 44/2 = 22\) radians per second, and therefore \(T = 440,000 \times 22 = 9,680,000\) lb ft., the energy supplied is distributed between several axles the relation becomes

$$T_{101} + T_{102} + T_{103} + \ldots = RV$$  

where \(T_{1}, T_{2}, T_{3}, \&c.\) are the torques on the axles whose respective angular velocities are \(\omega_{101}, \omega_{102}, \omega_{103}, \&c.\)

The fundamental condition governing the design of all tractive machinery is that the wheels belonging to the axles to which torque is applied shall roll along the rails without slipping, and convey the motive force of the engine to the vehicle. The fundamental relation between the applied torque and the tractive force \(F\) will be understood from fig. 16, which is diagrammatic form a wheel and axle connected to a fixed pole. The revolution of a vehicle, in the way adopted for railway trains. The journal of the axle \(A\), is carried in a bearing or axle-box \(B\), which (wheels and transmitting shafts to the fixed pole. The revolution of a vehicle, in the way adopted for railway trains.)

value of the tractive force is required for this purpose, for example, from 4 to 5 tons, the driving-wheels are coupled to one or more pairs of heavily loaded wheels, forming a class of what are called "coupled engines" in contradistinction to the "engine as a whole" of other driving-wheels. Mechanical energy may be developed in bulk at a central station conveniently situated with regard to a coal-field or a waterfall, and after transformation by means of electric generators into electrical energy it may be transmitted to the locomotive and then by means of electric motors be retransformed into mechanical energy at the axles to which the motors are applied. Every axle of an electric locomotive may thus be subjected to a torque, and the large weight which must be put on one pair of wheels in order to secure sufficient adhesion when all the driving is done on one axle may be distributed through as many pairs as desired. In fact, there need be no specially differentiated locomotive at all. Motors may be applied to every axle in the train, and their individual torques adjusted to values suitable to the weights naturally carried by the several axles. Such an arrangement would be ideally perfect from the point of view of the permanent-way engineer, because it would then be possible to distribute the whole of the load uniformly between the wheels. This perfection of distribution is practically attained in present-day practice by the multiple control system of operating an electric train, where motors are applied to a selected number of axles in the train, all of them being under the control of a single engineer.

The fundamental difference between the two methods is that while the mechanical energy developed by a steam engine is in the first case applied directly to the driving-axle of the locomotive, in the second case it is transformed into electrical energy, transmitted over relatively long distances, and retransformed into mechanical energy on the driving-axles of the train. In the first case all the driving is done on one or at most two axles, sufficient tractive force being obtained by coupling these axles when necessary to others carrying heavy loads. In the second case every axle in the train may be made a driving-axle if desired, in which case the locomotive as a separate machine disappears. In the second case, however, there are all the losses due to transmission from the central station to the train to be considered, as well as the cost of the transmitting apparatus itself. Ultimately the question resolves itself into one of commercial practicability. For suburban traffic with a service at a few minutes' interval and short distances between the stations electric traction has proved itself to be superior in many respects to the steam locomotive, but for main line traffic and long distance runs it has not yet been demonstrated that it is commercially feasible, though it is known to be practically possible.

For the methods of determining tractive forces, the remainder of the present article will be devoted to the steam locomotive.

§ 3. General Efficiency of Steam Locomotive.—One pound of good Welsh coal properly burned in the fire-box of a locomotive yields about 15,000 British thermal units of heat at a temperature high enough to enable from 90 to 95% to flow across the boiler-heating surface to the water, the rest escaping up the chimney with the furnace gases. The steam produced in consequence of this heat transfer from the furnace gas to the water carries heat to the condenser, which is transformed into mechanical energy, the remainder passing away up the chimney with the exhaust steam. The average value of the product of these percentages, namely \(0.65 \times 0.90 = 0.59\) say, may be used to investigate generally the working of a locomotive; the actual value could only be determined by experiment in any particular case. With this assumption, 0.59 is the fraction of the heat energy of the coal which is utilized in the engine as mechanical work; that is to say, of the 15,000 B.T.U. produced by the combustion of 1 lb of coal, 15,000 \times 0.59 = 8900 are only available for tractive purposes.

Coal varies much in calorific value, some producing only 12,000 B.T.U. per lb, while 15,000 can be obtained from the best Welsh coals. Let \(E\) represent the pounds of coal per mile per hour in the fire-box of a locomotive, and let \(c\) be the calorific value in B.T.U. per lb; then the mechanical energy available in foot-pounds is approximately \(0.65 \times 778 \times Xc\), and this expressed in horsepower units gives

\[
\text{I.H.P.} = \frac{0.65 \times 778 \times Ec}{1480} = 488,000
\]

A "perfect engine" receiving and rejecting steam at the same temperatures as the actual engine of the locomotive, would develop about twelve times this power, say 1400 I.H.P. This figure represents the ideal but unattainable standard of performance. This question of the standard engine of comparison, and the engine efficiency is considered in § 15 below, where the details of calculation are given.

The indicated horse-power developed by a cylinder may always be ascertained from an indicator diagram and observations of the speed. Let \(p\) be the mean pressure in pounds per square inch, called the dynamic pressure exerted by the expansion of air produced by the combustion of 1 lb of coal, when the speed of the crank-shaft is \(n\) revolutions per second. Also let \(l\) be the length of the stroke in feet and let \(a\) be the area of one cylinder in square inches, then, assuming two cylinders of equal size, the I.H.P. is

\[
\text{I.H.P.} = \frac{p(la)}{n} = 550 \times \frac{p(la)}{n}
\]

The I.H.P. at any instant is equal to the total rate at which energy is required to overcome the tractive resistance \(R\). The horse-power available at the driving-axle, conveniently called the brake horse-power, is from 20 to 30% less than the indicated horse-power, and the ratio, B.H.P./I.H.P., is called the mechanical efficiency of the steam engine. The relation between the b.h.p. and the torque on the driving-axle is

\[
550 \times \frac{p(la)}{n} = T_o
\]

It is usual with steam locomotives to regard the resistance \(R\) as including the frictional resistances between the cylinders and the driving-axle, so that the rate at which energy is expended in moving the train is expressed either by the product R.V., or by the value of the indicated horse-power, the relation between them being

\[
550 \times \frac{p(la)}{n} = \text{I.H.P.}
\]

or in terms of the torque

\[
550 \times \frac{p(la)}{n} = RV = T_o
\]

The individual factors of the product R.V. may have any value consistent with equation (10) and with certain practical conditions, so that for a given value of the I.I.P., R must decrease if \(V\) increases. If the maximum admissible resistance of which a locomotive can develop is 1000, the tractive resistance \(R\), at 60 m. per hour (=88 ft. per second) is \(R = \frac{1000(1000 \times 0.59)}{88 \times 60} = 0.205\) lb. If, however, the speed is reduced to 40 m. per hour, \(R = 0.286\) lb. Then an engine working at maximum power may be used to haul a relatively light load at a high speed or a heavy load at a slow speed.

§ 4. Analysis of Train Resistance.—Train resistance may be analysed into the following components:

1. Journal friction and friction of engine machinery.
2. Wind resistance.
3. Resistance due to gradients, represented by \(R_g\).
4. Resistance due to miscellaneous causes.
5. Resistance due to acceleration, represented by \(R_a\).
6. Resistance due to curves.

The sum of all these components of resistance is at any instant equal to the resistance represented by \(R\). At a uniform speed on a level straight road, 3, 5 and 6 are zero. The total resistance is conveniently divided into two parts: (1) the resistance due to the vehicles hauled by the engine, represented by \(R_g\); (2) the resistance of the engine and tender represented by \(R_e\). In each of these two cases the resistance can of course be analysed into the six components set out in the above list.

§ 5. Vehicle Resistance and Draw-bar Pull.—The power of the engine is applied to the vehicles through the draw-bar, so that the draw-bar pull is a measure of the engine resistance. The draw-bar pull for a given load is a function of the speed of the train, and numerous experiments have been made to find the relation connecting the pull with the speed under various conditions. The usual method of experimenting is to put a dynamometer car (see DYNAMOMETER) between the engine and the train. This car is equipped with apparatus by means of which a continuous record of the draw-bar pull is obtained on a drawing machine; time indications are also made on the diagram from which the speed at any instant can be deduced. The pull recorded on the diagram includes the resistances due to acceleration and to the gradient on which the train is moving. It is usual to subtract these resistances from the observed pull, so as to obtain the draw-bar pull reduced to what it would be at a uniform speed on the level. This corrected pull is then divided by the weight of the vehicles hauled, in which must be included the weight of the dynamometer car, to give the resistance per pound of load hauled at a certain uniform speed on a straight and level road. A series of experiments were made by J. A. F. Aspinall on the Lancashire & Yorkshire railway to ascertain the resistance of trains of bogie passenger coaches of various lengths at different speeds, and the results are recorded in a paper, "Train Resistance," Proc. Inst. C.E. (1901), vol. 147. Aspinall's results are expressed by the formula

\[
r_e = \frac{r_s}{S^2} + 30 + \frac{200}{S + 200} \text{lb}
\]

where \(r_s\) is the resistance in pounds per ton, \(S\) is the speed in miles per hour, and \(L\) is the length of the train in feet measured over the
carriage bodies. The two following expressions are given in the Bulletin of the International Railway Congress (vol. XII. p. 1275), by Barbier, for some experiments made on the Northern railway of France with a train of 157 tons mean weight; they are valid between 37 and 77 m. per hour:—
\[ r_e = 3.58 \times \frac{1+665}{1000}, \]
for 4-wheel coaches, (13)
\[ r_e = 3.58 \times \frac{1+665}{1000}, \]
for bogie coaches. (14)

The Baldwin Locomotive Company give the formulae
\[ r_e = 3.58 \times \frac{1+665}{3}, \]
and
\[ r_e = 1.68 + 242.5 \times \text{speed in m. per hour}, \]
for speeds from 47 to 77 m. per hour. (15)

All the above formulae refer to empty stock. The resistance of goods wagons has not been so systematically investigated. In the paper above quoted Aspinall cites a case where the resistance of a train of empty wagons 1830 ft. long was 18-33 lb per ton at a speed of 26 m. per hour, and a train of Ww wagons 1045 ft. long gave only 9-12 lb per ton at a speed of 29 m. per hour. The resistance from the above expressions includes the components 1, 2 and 4 of \( \frac{\pi}{4} \). The resistance caused by the wind is very variable, and in extreme cases may double the resistance found from the formulae.

A side wind causes excessive flange friction on the leeward side of the train, and increases the tractive resistances therefore very considerably, even though its velocity be relatively moderate. The formulae corresponding to the above expressions are plotted in fig. 17, four values of \( L \) being taken for formula (12) to correspond to trains of 5, 10, 15 and 20 bogie carriages.

The resistance at starting is greater than the running resistance at moderate speeds. From Aspinall’s experiments it appears to be about 17 lb per ton, and this value is plotted on the diagram.

The resistance to motion round a curve has not been so systematically studied that any definite rule can be formulated applicable to all classes of rolling stock and all radii of curves. A general result could not be obtained, even from a large number of experiments, because the resistance round curves depends upon so many variable factors. In some cases the gauge is laid a little wider than the standard, and there are varying amounts of super-elevation of the outer rail; but the most formidable factor in the production of resistance is the guard-rail, which is sometimes put in with the object of guiding the wheel which runs on the inner rail of the curve on the inside of the flange.

§ 6. Engine Resistance.—From experiments made on the North-Eastern railway (see a paper by J. H. Smith on “Express Locomotive Engines,” Proc. Inst. Mech. Eng., Oct. 1898), it appeared that the engine resistance was about 35% of the total resistance, and in the train-resistance experiments on the Lancashire & Yorkshire railway quoted above the engine resistance forms also about 35% of the total resistance, thus confirming the North-Eastern railway results. Barbier (loc. cit.) gives as the formula for the engine resistance
\[ r_e = 3.5 \times 1.6 \times (1+665+30)/1000, \]
where \( S \) is the speed in miles per hour. This formula is valid between speeds of 37 and 77 m. per hour, and was obtained in connexion with the experiments previously quoted on the Northern railway of France with an engine and tender weighing about 83 tons. Barbier’s formula is plotted in fig. 17, together with a curve expressing generally the results of some early experiments on the Great Western railway carried out by Sir D. Gooch. The extension of the Barbier curve beyond the above limits in fig. 17 gives values which must be regarded as only very approximate.

§ 7. Rate at which work is done against the resistances given by the curves in fig. 17.—When the weight of the engine and tender and the weight of the vehicles are respectively given, the rate at which work must be done in the engine cylinders in order to maintain the train in motion at a stated speed can be computed by the aid of the curves plotted in fig. 17. Thus let an engine and tender weighing 80 tons haul a train weighing 200 tons at a uniform speed on the level of 40 m. per hour. As given by the Barbier curves in fig. 17, the engine resistance at 40 m. per hour is 20 lb per ton, and the vehicle resistance 8-5 lb per ton at the same speed. Hence

Engine resistance, \( R_e = 20 \times (200+80) = 1600 \) lb

Vehicle resistance, \( R_v = 200 \times 8.5 = 1700 \) lb

Therefore, the total resistances, \( R = 3300 \) lb

The speed, 40 m. per hour, is equal to 58-6 ft. per second; therefore the rate of working in foot-pounds per second is 3300 \( \times 58.6 \), from which \( P = 193500 \) ft-lb per second. This is the horse-power, therefore, which must be developed by the engine and tender to keep the train in motion at a uniform speed of 40 m. per hour on a level straight road with the values of the resistances assumed.

The expression at which work is done against a resistant.—Gradients are measured either by stating the number of feet horizontally, \( G \), by which the vertical rise is 1 ft., or by the vertical rise in 100 ft. measured horizontally expressed as a percentage, or by the number of feet rising vertically in a mile. Thus a gradient of \( G \) in 200 is the same as a half per cent. grade or a rise of 26-4 ft. per mile. The difference between the horizontal distance and the distance measured along the rail is so small that it is negligible in all practical calculations. Hence if \( G \) is the gradient, at a speed of \( V \) ft. per second, the vertical rise per second is \( V/G \) ft. If \( W \) is the weight of the train in pounds, the rate of working against the gradient expressed in horse-power units is

\[ \frac{W}{V^2/G}, \]
or
\[ \frac{W}{V^2} \] per horse-power units

This must be exerted in addition to the horse-power calculated in the previous section, so that the total indicated horse-power which must be developed in the cylinders is now \( 334+223 = 557 \). If the train is running down a gradient this horse-power is the rate at which gravity is working against the train. With the data of the previous section, on the assumption that the train is running down a gradient of \( 1 \) in 300, the horse-power required to maintain the speed would be \( 354-223 = 131 \).

§ 8. Rate of work which is done against acceleration.—If \( a \) is the weight of the train in pounds and \( a \) the acceleration in feet per second, the force required to produce the acceleration is

\[ F = Wa/g, \]
and if \( V \) is the average speed during the change of velocity implied by the uniform acceleration \( a \), the rate at which work is done by this force is

\[ W = V^2 a/g, \]
or in horse-power units

\[ P = W/Va \] per 500 ft., \( \text{or} \)
\[ P = W/Va/g, \]
Assuming the data of § 7, suppose the train to change its speed from 40 to 41 m. per hour in 13 seconds. The average acceleration in feet per second is measured by the fraction

Change of speed in feet per sec. = 0.07-\( \times 58.6 = 0.0113 \)

Therefore the horse-power which must be developed in the cylinders to effect this change of speed is from \( 21 \)

\[ H.P. = \frac{280 \times 2240 \times 113 \times 20}{550 \times 32} = 237. \]

The rate of working is negative when the train is retarded; for instance, if the train had changed its speed from 41 to 40 m. per hour in 13 seconds, the rate at which work would have to be absorbed by the brake blocks would represent 237 H.P. This is lost in heat produced by the friction between the brake blocks and the wheels, the heat being one of the sources of energy stored in the train may be returned to the central station during retardation. The principal condition operating in the design of locomotives intended for local services with frequent stops is the degree of acceleration required, the aim of the designer being to produce an engine which shall be able to bring the train to its journey speed in the shortest time possible. For example, suppose it is required to start a train weighing 200 tons from rest and bring it to a speed of 30 m. per hour in 30 seconds. The weight of the engine may be assumed in advance to be 80 tons. The acceleration, \( a \), which may be supposed uniform, is 1-465. The average velocity is 15 m. per hour, which is equal to 22 ft. per second; therefore the tractive force required is, from (10),

\[ (280 \times 2240 \times 0.45)/32 = 28.720, \]
and the corresponding horse-power which must be developed in the cylinders is, from (20), \( 28.720 \) and \( 550 \), which is 50 and \( V \) equal to the above values, 119. To obtain the tractive force the weight on the coupled wheels must be about five times this amount—that is.
6.4 tons; and to obtain the horse-power the boiler will be one of the largest that can be built to the construction gauge. After acceleration to the journey speed of 30 m. per hour the horse-power required is reduced to about one-third of that required for acceleration alone.

§ 10. General expression for total rate of working.—Adding the various rates of working together,

\[
\frac{R}{V} = \frac{W_r + W_t}{G} \cdot \frac{2240W_r + 2240W_t}{550G - 550g},
\]

where \(W_r\) is weight of engine and tender in tons, \(W_t\) the weight of vehicles in tons, \(W\) the weight of train in tons, \(V\) the velocity of the train in feet per second. In this expression it is assumed that the acceleration is uniform, and this assumption is sufficiently accurate for any practical purpose to which the above formula may be applied in the ordinary working of a locomotive. If \(a\) is variable, then the formula must be applied in a series of steps, each step corresponding to a time interval over which the acceleration may be assumed uniform.

Dividing through by \(V\) and multiplying through by 550,

\[
R = W_r + W_t \frac{2240V}{G} - \frac{2240V}{V} = \frac{2240W_r + 2240W_t}{G},
\]

an expression giving the value of \(R\), the total tractive resistance. If the draw-bar pull is known to be \(R\), then applying the same principles to the vehicle alone which above are applied to the whole train,

\[
\text{total draw-bar pull} = W_r + W_t \frac{2240V}{G},
\]

This expression may be used to find \(r\), when the total draw-bar pull is observed as well as the speed, the changes of the speed and the gradient. The speed held to correspond with the resistance must be the mean speed during the change of speed. The best way of doing this is to select portions of the dynamometer record where the speed is constant. Then a disappears from all the above expressions. These expressions indicate what frequent changes in the power are required as the train pursues its journey up and down gradients, against wind resistance, journal friction and perhaps the resistance of a badly laid track; and show how both the potential energy and kinetic energy of the train are continually changing: the first from a change in vertical position due to the gradients, the second from changes in speed. These considerations also indicate what a difficult matter it is to find the exact rate of working against the resistances, because of the difficulty of securing conditions which eliminate the effect both of the gradient and of acceleration.

§ 11. The Boiler.—Maximum Power.—The maximum power which can be developed by a locomotive depends upon the maximum rate of fuel combustion which can be maintained per square foot of grate. This maximum rate depends upon the kind of coal used, whether small, friable, bituminous or hard, upon the thickness of the fire, and upon the correct design and setting of the blast-pipe. A limit is reached to the rate of combustion when the draft becomes strong enough to carry heavy lighted sparks through the tubes and chimney. This, besides reducing the efficiency of the furnace, introduces the danger of fire to crops and buildings near the line. The maximum rate of combustion may be as much as 150 lb. of coal per square foot of grate per hour, and in exceptional cases even a greater rate than this has been maintained. It is not economical to force the boiler to work at too high a rate, because it has been practically demonstrated that the boiler efficiency decreases after a certain point, as the rate of combustion increases. A few experimental results are set forth in Table XX., from which it will be seen that with a relatively low rate of combustion, a rate which denotes very light service, namely 28 lb. of coal per square foot of grate per hour, the efficiency of the boiler is 82 %, which is as good a result as can be obtained with the best class of stationary boiler or marine boiler even when using economizers.

The first group consists of experiments selected from the records of a large number made on the boiler of the locomotive belonging to the Purdue University, Indiana, U.S.A.

The second group consists of experiments made on a boiler belonging to the Great Eastern Railway Company. The first one of the group was made on the boiler fixed in the locomotive yard at Stratford, and the second remaining experiments of the group were made while the engine was working a train between London and March. The third group consists of experiments selected from the records of a series of trials made on the London & South-Western railway with an express locomotive.

§ 12. Draught.—One pound of coal requires about 20 lb. of air for its proper combustion in the fire-box of a locomotive, though this quantity of air diminishes as the rate of combustion increases.

For instance, an engine having a grate area of 30 sq. ft. and burning 100 lb. of coal per square foot of grate per hour would require that 60,000 lb. of air should be drawn through the furnace per hour in order to burn the coal. This large quantity of air is forced through the furnace by means of the difference of pressure established between the external atmospheric pressure in the ash-pan and the pressure in the smoke-box.

![Table XX.](image-url)

The exhaust steam passing from the engine through the blast-pipe and the chimney produces a diminution of pressure, or
RAILWAYS

partially vacuum, in the smoke-box roughly proportional to the weight of steam discharged per unit of time. The difference of pressure between the outside air and the smoke-box gases may be measured by the difference of the water levels in the limbs of a U tube, one limb being in communication with the smoke-box, the other with the atmosphere. The difference of levels varies from 1 to as much as 10 in. in extreme cases. The draught corresponding to the smallest rate of combustion shown in Table XX. in Professor Goss's experiments, was 1.72 in. of water, and for the highest rate, namely 181, 7.28 in. of water. To get the best effect the area of the blast-nozzle must be properly proportioned to the size of the cylinders and be properly set with regard to the base of the chimney. The best proportions are found by trial in all cases.

Figs. 18 and 19 show two smoke-boxes typical of English practice. Fig. 18 is the smoke-box of the 6 ft. 6 in. six-coupled express passenger engines designed by G. Whale for the London & North-Western Railway Company in 1904, and fig. 19 shows the box of the four-coupled express passenger engine designed by J. Holden for the Great Eastern Railway Company. In the case of the London & North-Western engine (fig. 18), the blast-pipe orifice B is placed at about the centre of the boiler barrel, and the exhaust steam is discharged straight into the trumpet-shaped end of the chimney, which is continued down inside the smoke-box. In fig. 19 the blast orifice B is set much lower, and the steam is discharged through a frustum of a cone set in the upper part of the smoke-box into the short chimney. Fig. 20 shows the standard proportions recommended by the committee of the Railway Master Mechanics' Association on Exhaust Pipes and Steam Passages (Proc. Amer. Railway Master Mechanics' Assoc., 1906). According to the Report, for the best results both H and k should be made as great as practicable, and then $d = 0.2D + 0.15$, $b = 0.2D + 0.05$, $P = 0.32D$, $P = 0.32D$, $L = 0.6D$, $L = 0.6D$, but not of intermediate values. This last relation is, however, not well established. For much detailed information regarding American smoke-box practice, reference may be made to Locomotive Sparks, by Professor W. F. M. Goss (London, 1902).

The arrangements for arresting sparks in American practice and on the continent of Europe are somewhat elaborate. In English practice where a spark-arrester is put in it usually takes the form of a wire-netting dividing the smoke-box horizontally into two parts at a level just above the top row of tubes, or arranged to form a continuous connexion between the blast-pipe and the chimney.

Fig. 19 illustrates an arrangement designed by J. Holden. The heavy sparks are projected from the tubes in straight lines and are stopped by the louvres L, L, L, and by them deflected downwards to the bottom of the smoke-box, where they collect in a heap in the space D round a tube which is essentially an ejector. At every blast a small quantity of steam is caught by the orifice O and led to and from one of the upper corners of the smoke-box, with the result that the ashes are blown out into the receptacles on each side of the engine, one of which is shown at E. The louvres L, L, L are placed to shield the central region occupied by the blast-pipe.

As the indicated horse-power of the engine increases, the weight of steam discharged increases, and the smoke-box vacuum is increased, thereby causing more air to flow through the furnace and increasing the rate of combustion. Thus the demand for more steam is automatically responded to by the boiler. It is this close automatic interdependence of engine and boiler which makes the locomotive so extraordinarily well suited for the purpose of locomotive traction.

§ 13. The Steam Engine.—The steam engine of a locomotive has the general characteristics of a double-acting non-condensing engine (see Steam Engine). Distribution of steam is effected by a slide valve, sometimes fitted with a balancing device, and sometimes formed into a piston valve. All types of valves are with few exceptions operated by a link motion, generally of the Stephenson type, occasionally of the Allan type or the Gooch type, or with some form of radial gear as the Joy gear or the Walschaert gear, though the latter gear has characteristics which ally it with the link motions. The Stephenson link motion is used almost universally in England and America, but it has gradually been displaced by the Walschaert gear on the continent of Europe, and to some extent in England by the Joy gear. The general characteristics of the distribution effected by these gears are similar. Each of them, besides being a reversing gear, is an expansion gear both in forward and backward running. The lead is variable in the Stephenson link motion, whilst in the Walschaert and the Joy gears it is constant. Illustrations of these gears are given in the article Steam Engine, and the complete distribution of steam for both forward and backward running is worked out for a typical example of each of them in Valves and Valve Gear Mechanisms by W. E. Dalby (London, 1906).

§ 14. Cylinder Dimensions.—Adhesion.—Tractive Force.—A locomotive must be designed to fulfil two conditions. First, it must be able to exert a tractive force sufficient to start the train under the worst conditions possible on the railway over which it is to operate—for instance, when the train is stopped by signal on a rising gradient where the track is curved and fitted with a guard-rail. Secondly, it must be able to maintain the train at a given speed against the total resistances of the level or up a gradient of given inclination. These conditions are to a certain extent mutually antagonistic, since an engine designed to satisfy either condition independently of the other would be a different engine from that designed to make the best compromise between them.

Equation (3) of Chapter I expresses the fundamental condition which must be satisfied when a locomotive is starting a train. The torque exerted on the driving-axle by the steam engine just at starting may be that due to the full boiler pressure acting in the cylinders, but usually the weight on the coupled wheels is hardly sufficient to enable advantage to be taken of the full boiler pressure, and it has been found more expedient by the regulator to prevent slipping. Sand, driven between the wheel and the rail by a steam jet, used at just starting, increases the adhesion beyond the normal value and enables a larger pressure to be exerted on the piston than would otherwise be possible. When the train is started and is moving slowly, the torque acting on the driving-axle may be estimated as that due to about 85% of the full boiler pressure acting in the cylinders. The torque
due to the two cylinders is variable to a greater or less extent, depending upon the degree of expansion in the cylinders and the speed. The form of the torque curve, or crank effort curve, as it is sometimes called, is discussed in the article Steam Engine, and the torque curve corresponding to actual indicator diagrams taken from an express passenger engine travelling at a speed of 65 m. per hour is given in The Balancing of Engines by W. E. Dalby (London, 1906).

The torque curve is laborious, but the average torque acting, which is all that is required for the purposes of this article, can be found quite simply, thus:—Let \( p \) be the mean effective pressure acting in one cylinder, \( a \), the area of the cylinder, and \( l \), the stroke. Then the work done during one revolution of the crank is \( 2pa \) per cylinder. Assuming that the mean pressure in the other cylinder is also \( p \), the work done per revolution is \( 4pa \). If \( n \) is the number of revolutions per minute, the total is \( 2\pi npa \). Hence, assuming the mechanical efficiency of the engine to be \( \eta \), and substituting \( \pi a^2 \) for the area, 

\[
T = \frac{4pa}{\eta},
\]

so that 

\[
T = \frac{p}{\eta} \pi a^2 D
\]

From \( \eta \) \( \frac{1}{\pi a^2} \frac{p}{D} = \frac{1}{\pi a^2} = \frac{1}{\pi a^2} D
\]

in an expression giving a relation between the total weight on the coupled wheels, their diameters and the size of the cylinder. The magnitude of \( F \) when \( \eta \) and \( e \) are put equal to unity, is usually called the tractive force of the locomotive per pound of mean effective pressure in the cylinders. If \( p \) is the mean pressure at any speed the engine is exerting, the tractive force which the engine will maintain for the following calculations, will be equal to the sum of the two terms, with examples the value will be assumed unity. For many purposes it is desirable to work with tractive forces, or mean effective pressures, which have been previously assumed. Let an engine have two cylinders each 19 in. diameter and 26 in. stroke. Let the boiler pressure be 175 lb per square inch. Taking 85% of this, the maximum mean effective pressure would be 140 lb per square inch. Further, let the diameter of the driving-wheels be 6 ft. 3 in. Then the tractive force is, from (25), 

\[
(140919^2\times1669)/6-25 = 16,800 \text{ lb} = 83 \text{ tons.}
\]

Assuming that the frictional resistances at the rails is given by \( \frac{1}{2} \) the weight on the wheels, the total weight on the driving-wheels necessary to secure sufficient adhesion to prevent slipping must be at least \( 6.5 \times 83 = 413 \text{ tons.} \) This would be distributed between the two coupled axles, and a drawbar pull of 18 tons per axle, though this proportion might not in practice be uniform, a large proportion of the weight falling on the driving-axle. If the starting resistance of the whole train be estimated at 16 lb per ton, this engine would be able to start 1,163 tons, or about 730 tons on a grade of 1 in 75, both these figures including the weight of the engine and tender, which would be about 100 tons.

The engine can only exert this large tractive force so long as the mean pressure is maintained at 140 lb per square inch. This high mean pressure cannot be maintained for long, because as the speed increases the demand for steam per unit of time increases, so that cut-off must take place earlier and earlier in the stroke, the limiting steady speed being attained when the rate at which steam is supplied to the cylinders is adjusted by the cut-off to be equal to the maximum rate at which the boiler can produce steam, which depends upon the number of square feet of grate per square foot of boiler. If \( C \) is the number of pounds of coal burnt per square foot of grate per hour, the calorific value of which is \( c \) B.Th.U. per pound, the maximum indicated horse-power is given by the expression

\[
I.H.P. = \frac{C \times a \times \pi \times D \times 1000000}{1800000 \pi},
\]

where \( A \) is the area of the grate in square feet, and \( \eta \) is the combined efficiency of the engine and boiler. With the data of the previous calculation the added assumption of a grate area of 2 square feet, of which the rate of combustion is 150 lb of coal per square foot of grate per hour, that the calorific value is 14,000, and finally that \( \eta = 0.06 \), the maximum indicated horse-power which the engine might be expected to deliver would be \( 0.06 \times 14000 \times 2 \times 278 / 72 = 1100 \), corresponding to a mean effective pressure in the cylinders of 59.5 lb per square inch.

As is well known, it is required to run at a speed of 60 m. per hour, that is 88 ft. per second, the total resistance \( R \), which the engine can overcome at this speed, is by equation (10)

\[
R = (1100 \times 550) / 88 = 7,400 \text{ lb.}
\]

Thus although at a slow speed the engine can exert a tractive force of 18,600 lb, at 60 m. per hour, the tractive force falls to 7400 lb, which would be increased except by increasing the rate of combustion (neglecting any small changes due to a change in the efficiency \( \eta \)). Knowing the magnitude of \( R \), the draw-bar pull, and hence the weight of the vehicle the engine can haul at this speed, can be estimated if the size of the engine known. Using the curves of fig. 17 it will be found that at 60 m. per hour the resistance of the engine and tender is 33 lb per ton, and the resistance of a train of bogie coaches about 13 lb per ton. Hence if \( W \) is the weight of the vehicles in tons, and the weight of the engine and tender be taken at 100 tons, the value of \( W \) can be found from the equation 

\[
W + 3300 = 7440,
\]

from which \( W = 296 \text{ tons.} \) This is the load which the engine would take in ordinary weather. With exceptionally bad weather the load would have to be reduced or two engines would have to be employed, or an exceptionally high rate of combustion would have to be maintained.

It will be seen that with a tractive force of 7400 lb a weight of 37,000 lb (16.5 tons) would be enough to secure sufficient adhesion, and this could be easily carried on one axle. Hence for a level road the above load could be hauled at 60 m. per hour with "single" engine. When the road leads the train up an incline, however, the tractive force must be increased, so that the need for coupled wheels soon arises if the road is at all a heavy one.

§15. Engine Efficiency, Combined Engine and Boiler Efficiency.—The combined engine and boiler efficiency has hitherto been taken to be 0.06; actual values of the boiler efficiencies are given in Table XXI. Engine efficiency depends upon many variable factors, such as the cut-off, the piston speed, the initial temperature of the steam, the final temperature of the steam, the quality of the steam, the sizes of the steam-pipes, ports and passages, the arrangement of the cylinders and its effect on condensation, the mechanical perfection of the steam-distributing gear, the tightness of the piston, &c. A few values of the thermal efficiency obtained from experiments are given in Table XXI in the second column, the first column being added to give some idea of the rate at which the engine was working when the data from which the efficiency has been deduced were observed. The corresponding boiler efficiencies are given in the third column of the table, when they are known, and the combined efficiencies in the fourth column. The figures in this column indicate that 0.06 is a good average value to work with.

Deduced from Kennedy and Donkin's trials (Engineering, London, 1887).

It is instructive to inquire into the limiting efficiency of an engine consistent with the conditions under which it is working, because in no case can the efficiency of a steam-engine exceed a certain value which depends upon the temperatures at which
it receives and rejects heat. Thus a standard of comparison for every individual engine may be obtained with which to compare its actual performance. The standard of comparison generally adopted for this purpose is obtained by calculating the efficiency of an engine working according to the Rankine cycle. That is to say, expansion is adiabatic and is continued down to the back pressure which in a non-condensing engine is 14.7 lb per square inch, since any back pressure above this amount is an imperfection which belongs to the actual engine. The back pressure is supposed to be uniform, and there is no compression.

Fig. 21 shows the pressure-volume diagram of the Rankine cycle for one pound of steam where the initial pressure is 275 lb. per square inch by the gauge, equivalent to 190 lb per square inch absolute. In no case could an engine receiving steam at the temperature corresponding to this pressure and rejecting heat at 212°F convert more heat into work than is represented by the area of this diagram. The area of the diagram may be measured, but it is usually more convenient to calculate the number of B.Th.U. which the area represents from the following formula, which is expressed in terms of the absolute temperature $T_1$ of the steam at the steam-pipe, and the temperature $T_2 = 464^{1/2} + 212$ absolute corresponding to the back pressure.

Maximum available work per pound of steam \[ U = (T_1 - T_2)(1 + \frac{1}{T_1}) - T_2 \log \frac{T_1}{T_2} \]

With the initial pressure of 190 lb per square inch absolute it will be found from a steam table that $T_1 = 836^\circ$ absolute. Using this and the temperature $673^\circ$ in the expression, it will be found that $U = 185$ B.Th.U. per pound of steam. If $h_1$ is the heat input at the lower temperature, $h_b$ the heat at the higher temperature, and $L_1$ the latent heat at the higher temperature, the heat supply per pound of steam is equal to $h_1 - h_b + L_1$, which, from the steam tables, with the values of the temperatures given, is equal to 1013 B.Th.U. per pound. The thermal efficiency is therefore $185/1013 = 0.18$.

That is to say, a perfect engine working between the limits of temperature assigned would convert only 18% of the total heat supply into work. This would be an ideal performance for an engine receiving steam at 190 lb initial pressure absolute, and rejecting steam at the back pressure assumed above, and could never be attained in practice. When the initial pressure is 100 lb per square inch by the gauge the thermal efficiency drops to about nearly 15% with the same back pressure. The way the thermal efficiency of the ideal engine increases with the pressure is exhibited in fig. 22 by the curve AB. The curve was drawn by calculating the thermal efficiency from the above expression for various values of the initial temperature, keeping the final temperature constant at 673°, and then plotting these efficiencies against the corresponding values of the gauge pressures.

The actual efficiencies observed in some of the cases cited in Table XXI are plotted on the diagram, the reference numbers on which refer to the first column in the table. Thus the pressure in the steam-pipe being 167 lb per square inch. From the diagram it will be seen that the corresponding efficiency of the ideal engine is about 0.18. The efficiency ratio is therefore $0.11/0.18 = 0.61$. That is to say, the engine actually utilized 61% of the energy which the steam delivered to the engine. The fact that the same initial pressure against a back pressure equal to the atmosphere, lines representing efficiency ratios of 0.6, 0.5 and 0.4 are plotted on the diagram, so that the efficiency ratios correspond to the values of the efficiency plotted on the ordinates ab. The initial temperature of the standard engine of comparison must be the temperature of the steam taken in the steam-pipe. For the sake of information regarding the standard engine of comparison see the article STEAM ENGINE and also the "Report of the Committee on the Thermal Efficiency of Steam Engines," Proc. Inst. C.E. (1898).

§ 16. Piston Speed.—The expression for the indicated horse-power may be written

\[ \text{I.H.P.} = \frac{v}{550} \]

where $v$ is the average piston speed in feet per second. For a stated value of the boiler pressure and the cut-off the mean pressure $p$ is a function of the piston speed $v$. For a few cases where data are available—data, however, belonging to engines representing standard practice in their construction and in the design of cylinders and steam ports and passages—the law connecting $p$ and $v$ is approximately linear and of the form

\[ p = c - bv \]

where $b$ and $c$ are constants. (See W. E. Dalby, "The Economical Working of Locomotives," Proc. Inst. C.E., 1905-6, vol. 164.) Substituting this value of $p$ in (27)

\[ \text{I.H.P.} = \frac{(c - bv)}{550} \]

the form of which indicates that there is a certain piston speed for which the I.H.P. is a maximum. In a particular case where the boiler temperature was maintained constant at 150 lb per square inch, and the cut-off was approximately 20% of the stroke, the values $c = 55$ and $b = 0.031$ were deduced, from which it will be found that the maximum horse-power corresponding to the maximum I.H.P. is 887 ft. per minute. The data from which this result is deduced will be found in Professor Goss's paper quoted above in Table XXI. The point is further illustrated by some curves published in the American Engineer (June 1901) by G. R. Henderson, recording the tests of a freight locomotive made on the Chicago & North-Western railway. Any modification of the design which will reduce the resistance to the flow of steam through the steam passages into the cylinders, or increase the pressure of the pistons for which the indicated horse-power is a maximum.

§ 17. Compound Locomotives.—The thermal efficiency of a steam-engine is in general increased by carrying out the expansion of the steam in two, three or even more stages in separate cylinders, notwithstanding the inevitable drop of pressure which must occur when the steam is transferred from one cylinder to the other during the process of expansion. Compound working permits of a greater range of expansion than is possible with a simple engine, and incidentally there is less range of pressure per cylinder, so that the pressures and temperatures per cylinder have not such a wide range of variation. In compound working the pressure of the high pressure cylinders is a measure of the power of the engine, since this represents the final volume of the steam used per stroke. The volume of the high-pressure cylinder may be varied within wide limits for the same low-pressure volume; the proportions adopted should, however, be such that there is an absence of excessive drop between them as the steam is transferred from one to the other. Compound locomotives have been built by various designers, but opinion is still uncertain whether any commercial economy is obtained by their use. The varying load against which a locomotive works is a fact that helps a large engine working with factors which reduce the margin of possible economy within narrow limits. Coal-saving can be shown to the extent of about 14% in some cases, but the saving depends upon the kind of service on which the engine is employed. The first true compound locomotive was constructed in 1876 from designs by A. M. Mallet, at the Creusot works in Bayonne. The first true compound locomotive in England was constructed at Crewe works in 1879 by F. W. Webb. It was of the same type as Mallet's engine, and was made by simply bushing one cylinder of an ordinary two-cylinder simple engine, the bushed cylinder being the highest pressure and the other cylinder the low-pressure cylinder. Webb evolved the type of three-cylinder compound with which his name is associated in 1882.
There were two high-pressure cylinders placed outside the frames and driving on a trailing wheel, and one low-pressure cylinder placed between the frames and driving on a wheel placed in front of the driving-wheel belonging to the high-pressure cylinders. The steam connexions were such that the two high-pressure cylinders were placed in parallel, both exhausting into the one low-pressure cylinder. The first engines of this class were provided with high-pressure cylinders, 11 in. diameter and 24 in. stroke, a low-pressure cylinder 26 in. diameter, 24 in. stroke, and driving-wheels 6 ft. 6 in. diameter; but subsequently these dimensions were varied. There was no copying. A complete account of Webb's engines will be found in a paper, "The Compound Principle applied to Locomotives," by E. Worthington, Proc. Inst. C.E., 1889, vol. xcvi. Locomotives have to start with the full load on the engine, consequently an outstanding feature of every compound locomotive is the apparatus or mechanism added to enable the engine to start readily. Generally steam from the boiler is admitted direct to the low-pressure cylinder through a reducing valve, and valves and devices are used to prevent the steam so admitted acting as a back pressure on the high-pressure cylinder. In the Webb compound the driver was coupled to a high-pressure exhaust pipe to the blast-pipe, and at the same time opened a valve giving a supply of steam from the boiler direct to the low-pressure valve chest. T. W. Worsdell developed the design of the two-cylinder compound in England and built several, first for the Great Eastern railway and subsequently for the North-Eastern railway. The engines were built on the Worsdell and Von Borries plan, and were fitted with an ingenious starting-valve of an automatic character to overcome the difficulties of starting. Several compounds of a type introduced by W. M. Smith on the North-Eastern railway in 1869 have been built by the Midland railway. In these there are two low-pressure cylinders placed outside the frame, and one high-pressure cylinder placed between the frames. All cylinders drive on one crank-axe with three cranks at 120°. The driving-wheels are coupled to a pair of trailing wheels. A controlling valve enables the supply of steam to the low-pressure cylinders to be supplemented by boiler steam at a reduced pressure. For a description and illustrations of the details of the starting devices used in the Webb, Worsdell and Smith compounds, see an article, "The Development of the Compound Locomotive in England," by W. E. Dalby in the Engineering Magazine for September and October 1904. A famous type of compound locomotive developed on the continent of Europe is the four-cylinder De Glehn, some of which have been tried on the Great Western railway. There are two high-pressure cylinders placed outside the frame, and two low-pressure placed inside the frames. The low-pressure cylinders drive on the leading crank-axe with cranks at right angles, the high-pressure cylinders driving on the trailing wheels. The wheels are coupled, but the feature of the engine is that the coupling-rods act merely to keep the high-pressure and low-pressure engines in phase with one another, very little demand being made upon them to transmit force except when one of the wheels begins to slip. In this arrangement the whole of the adhesive weight of the engine is used in the best possible manner, and the driving of the train is practically equally divided between the two axles. The engine can be worked as a four-cylinder simple at the will of the driver. S. M. Vauclain introduced a successful type of four-cylinder compound in America in 1889. A high- and low-pressure cylinder are cast together, and the piston-rods belonging to them are both coupled to one cross-head which is connected to the driving-wheels, these again being coupled to other wheels in the usual way. The distribution of steam to both cylinders is effected by one piston-valve operated by a link motion, so that there is considerable mechanical simplicity in the arrangement. Later Vauclain introduced the "balanced compound." In this engine the two piston-rods of one side are not coupled to a common cross-head, but drive on separate cranks at an angle of 180°, the pair of 180° cranks on each side being placed at right angles.

§18. The Balancing of Locomotives.—The unbalanced masses of a locomotive may be divided into two parts, namely, masses which revolve, as the crank-pins, the crank-cheeks, the coupling-rods, &c.; and masses which reciprocate, made up of the piston, piston-rod, cross-head and a certain proportion of the connecting-rod. The revolving masses are truly balanced by balance weights placed between the spokes of the wheels, or sometimes by prolonging the crank-web and forming the prolongation into balance weights. It is also the custom to balance a proportion of the reciprocating masses by balance weights placed between the spokes of the wheels, and the actual balance weight seen in a driving-wheel is the resultant of the separate weights required for the balancing of the revolving parts and the reciprocating parts. The component of a balance weight which is necessary to balance the reciprocating masses introduces a vertical unbalanced force which appears as a variation of pressure between the wheel and the rail, technically called 'the hammer-blow, the magnitude of which increases as the square of the speed of the train. In consequence of this action the cylinder pressure is considerably raised, and the pressure in the high-pressure cylinder is increased, which increases the drum pressure acting by the steam valve to the exhaust valve, and at the same time opens a valve giving a supply of steam from the boiler direct to the low-pressure valve chest. T. W. Worsdell developed the design of the two-cylinder compound in England and built several, first for the Great Eastern railway and subsequently for the North-Eastern railway. The engines were built on the Worsdell and Von Borries plan, and were fitted with an ingenious starting-valve of an automatic character to overcome the difficulties of starting. Several compounds of a type introduced by W. M. Smith on the North-Eastern railway in 1869 have been built by the Midland railway. In these there are two low-pressure cylinders placed outside the frame, and one high-pressure cylinder placed between the frames. All cylinders drive on one crank-axe with three cranks at 120°. The driving-wheels are coupled to a pair of trailing wheels. A controlling valve enables the supply of steam to the low-pressure cylinders to be supplemented by boiler steam at a reduced pressure. For a description and illustrations of the details of the starting devices used in the Webb, Worsdell and Smith compounds, see an article, "The Development of the Compound Locomotive in England," by W. E. Dalby in the Engineering Magazine for September and October 1904. A famous type of compound locomotive developed on the continent of Europe is the four-cylinder De Glehn, some of which have been tried on the Great Western railway. There are two high-pressure cylinders placed outside the frame, and two low-pressure placed inside the frames. The low-pressure cylinders drive on the leading crank-axe with cranks at right angles, the high-pressure cylinders driving on the trailing wheels. The wheels are coupled, but the feature of the engine is that the coupling-rods act merely to keep the high-pressure and low-pressure engines in phase with one another, very little demand being made upon them to transmit force except when one of the wheels begins to slip. In this arrangement the whole of the adhesive weight of the engine is used in the best possible manner, and the driving of the train is practically equally divided between the two axles. The engine can be worked as a four-cylinder simple at the will of the driver. S. M. Vauclain introduced a successful type of four-cylinder compound in America in 1889. A high- and low-pressure cylinder are cast together, and the piston-rods belonging to them are both coupled to one cross-head which is connected to the driving-wheels, these again being coupled to other wheels in the usual way. The distribution of steam to both cylinders is effected by one piston-valve operated by a link motion, so that there is considerable mechanical simplicity in the arrangement. Later Vauclain introduced the "balanced compound." In this engine the two piston-rods of one side are not coupled to a common cross-head, but drive on separate cranks at an angle of 180°, the pair of 180° cranks on each side being placed at right angles. 

§19. Classification.—Locomotives may be classified primarily into "tender engines" and "tank engines," the water and fuel in the latter being carried on the engine proper, while in the former they are carried in a separate vehicle. A tender engine is of comparatively few examples, and is found in such cases as two-bogies, which carry a larger supply of water and fuel than can be carried by tanks and the bunker of a tank engine. A tender, however, is so much dead-weight to be hauled, whilst the weight of the water and fuel in a tank engine contributes largely to the production of adhesion. A classification may also be made, according to the work for which engines are designed, into passenger engines, goods engines, and shunting or switching engines. A convenient way of describing any type of engine is by means of numerals indicating the number of wheels—(1) in the group of wheels supporting the leading or chimney end, (2) in the group of coupled wheels, and (3) in the group supporting the running or trailing end. But in this way neither the leading nor the trailing group of small wheels is given the numeral it must be used in the series of three numbers used in the description. Thus 4-4-2 represents a bogie engine with four-coupled wheels and one pair of trailing wheels, the well-known Atlantic type; 4-2-2 represents a bogie engine with a single pair of driving-wheels and a pair of trailing wheels; 0-4-4 represents an engine with four-coupled wheels and a trailing bogie, and 4-4-0 an engine with four-coupled wheels and a leading bogie. A general description of the chief peculiarities of various kinds of locomotives is given in the following analysis of types—

(1) "Simple-driver" type, 4-2-2 or 2-2-2. Still used by several railways in Great Britain for express passenger service, but going out of favour; it is also found in France, and less often in Germany, Italy, and elsewhere in Europe. It is generally designed as a 4-2-2 engine, but some old types are still running with only three axles,
RAILWAYS

Their boilers are of relatively large proportions for the train weight and average speed, and the driving wheels of small diameter, a large proportion of their total weight being "adhesive." Other special types are in limited use for "rack-railways," and operate either by engagement of gearing on the locomotive into a rack between the track rails, or by a combination of this and rail adhesion.

§ 20. Current Developments.—The demand of the present day is for engines of larger power both for passenger and goods service, and the problem is to design such engines within the limitations fixed by the 4 ft. 8½ in. gauge and the dimensions of the existing tunnels, arches, and other permanent works. The American engineer is more fortunate in this respect than his English brother with regard to the possibility of a solution, as will be seen from the comparative diagrams of construction gauges, figs. 23, 24, 25, 26. Fig. 23 shows the construction

gauge for the London & North-Western railway, fig. 24 that for the Great Western† railway, fig. 25 that for the Great Eastern railway, whilst fig. 26 gives a general idea of the American gauge in a particular case, generally typical, however, of the American limits. In consequence of this increasing demand for power, higher boiler pressures are being used, in some cases 220 lb. per square inch, for a simple boiler and single cylinder, the volume is slightly increased with the necessary accomplishment of heavier loads on the coupled wheels to give the necessary adhesion. Both load and speed have increased so much in connexion with passenger trains that it is necessary to divide the weight required for adhesion between three-coupled axles, and the type of engine gradually coming into use in England for heavy express traffic is a six-coupled engine with a leading bogie, with wheels which would have been considered small a few years ago for the speed at which the engine runs. The same remarks apply to goods engines. There is a general increase in cylinder pressure, boiler pressure, and weight, and in consequence in the number of coupled axles. Not only are the load and speed increasing, but the distances run without a stop are increasing also, and to avoid increasing the size of the tenders, water-troughs, first instituted by J. Ramsbottom on the London & North-Western railway in 1859, have been laid in the tracks of the leading main lines of Great Britain. For local services where stoppages are frequent the demand is for engines capable of quickly

1 At the beginning of 1908 the Great Western’s loading gauge on its main lines was widened to 9 ft. 8½ in. from a height of 5 ft. above rail level.

accelerating the train to the journey speed. The nature of this problem is illustrated by the numerical example in § 9. When the service is frequent enough to give a good power factor continuously, the steam locomotive cannot compete with the electric motor for the purpose of quick acceleration, because the motors applied to the axles of a train may for a short time absorb power from the central station to an extent far in excess of anything which a locomotive boiler can supply.

With regard to the working of the locomotive, J. Holden developed the use of liquid fuel on the Great Eastern railway to a point beyond the experimental stage, and used it instead of coal with the engines running the heavy express traffic of the line, its continued use depending merely upon the relative market price of coal and oil. Compound locomotives have been tried, as stated in § 17, but the tendency in England is to revert to the simple engine for all classes of work, though on the continent of Europe and in America the compound locomotive is largely adopted, and is doing excellent work. A current development is the application of superheaters to locomotives, and the results obtained with them are exceedingly promising.

The leading dimensions of a few locomotives typical of English, American, and European practice are given in Table XXII.
RAILWAYS

Carriages, mail carriages or travelling post offices, luggage brake vans, horse-boxes and carriage-trucks. Passenger carriages were originally modelled on the stage-coaches which they superseded, and they are often still referred to as "coaching stock." Early examples had bodies about 15 ft. long, 6½ ft. wide and 4½ ft. high; they weighed 3 or 4 tons, and were divided into three compartments holding six persons each, or eighteen in all.

The distinction into classes was made almost as soon as the railways began to carry passengers. Those who paid the highest fares (¼d. or ½d. a mile) were provided with covered vehicles, on the roofs of which their luggage was carried, and from the circumstance that they could book seats in advance came the term "booking office," still commonly applied to the office where tickets are issued. Those who travelled at the cheaper rates had at the beginning to be content with open carriages having little or no protection from the weather. Gradually, however, the accommodation improved, and by the middle of the 19th century second-class passengers had begun to enjoy "good glass windows and cushions on the seat," the fares they paid being about 1d. a mile. But though by an act of 1844 the railways were obliged to run at least one train a day over their lines, by which the fares did not exceed the "Parliamentary" rate of 1d. a mile, third-class passengers paying 1½d. or 1½d. a mile had little consideration bestowed on their comfort, and were excluded from the fast trains till 1872, when the Midland railway admitted them to all its trains. Three years later that railway did away with second-class compartments and improved the third class to their level. This action had the effect, through the necessities of competition, of causing travellers in the cheaper classes to be better treated on other railways, and the condition of the third-class passenger was still further improved when Parliament, by the Cheap Trains Act of 1883, required the railways to provide "due and sufficient" train accommodation at fares not exceeding 1d. a mile. In the United Kingdom it is now possible to travel by every train, with very few exceptions, and in many cases to have the use of restaurant cars, for 1½d. a mile or less, and the money obtained from third-class travellers forms by far the most important item in the revenue from passenger traffic. Since the Midland railway's action in 1875 several other English companies have abandoned second-class carriages either completely or in part, and in this they are entirely unknown.

On the continent of Europe there are occasionally four classes, but though the local fares are often considerably lower than in Great Britain, only first and second class, sometimes only first class, passengers are admitted to the fastest trains, for which in addition a considerable extra fare is often required. In Hungary and Russia a zone-tariff system is in operation, whereby the charge per mile decreases progressively with the length of the journey, the traveller paying according to the number of zones he has passed through and not simply according to the distance traversed. In the United States there is in most cases nominally only one class, denominated first class, and the average fare operated by the railways is about ½d. per mile per passenger. But the extra charges levied for the use of parlour, sleeping and other special cars, of which some of the best trains are exclusively composed, in practice constitute a differentiation of class, besides making the real cost of travelling higher than the figures just given.

In America and other countries where distances are great and passengers have to spend several days continuously in a train sleeping and restaurant cars are almost a necessity, and accordingly are to be found on most important through trains. Such cars in the United States are largely owned, not by the railway companies over whose lines they run, but by the Pullman Car Company, which receives the extra fees paid by passengers for their use. Similarly in Europe they are often the property of the International Sleeping Car Company (Compagnie Internationale des Wagons-Lits), and the supplementary fares required from those who travel in them add materially to the cost of a journey. In the United Kingdom, where the distances are comparatively small, sleeping and dining cars must be regarded rather as luxuries; still even so, they are to be met with very frequently. The first dining car in England was run experimentally by the Great Northern railway between London and Leeds in 1879, and now such vehicles form a common feature on express trains, being available for all classes of passengers without extra charge beyond the amount payable for food. The introduction of corridor carriages, enabling passengers to walk right through the trains, greatly increased their usefulness. The first English sleeping cars made their appearance in 1873, but they were very inferior to the vehicles now employed. In the most approved type at the present time a passage runs along one side of the car, and off it open a number of transverse compartments or berths resembling ships' cabins, mostly for one person only, and each having a lavatory of its own with cold, and sometimes hot, water laid on. A charge of 7s. 6d. or 10s., according to distance, is made for each bed, in addition to the first-class fare. In the United States the standard sleeping car has a central aisle, and along the sides are tiers of berths, arranged lengthwise with the car and screened off from the alley by curtains. To some extent cars divided into separate compartments are also in use in that country. On the continent of Europe the typical sleeping car has transverse compartments with two berths, one placed above the other.

The first railway carriages in England had four wheels with two axles, and this construction is still largely employed, especially for short-distance trains. Later, when increased length became desirable, six wheels with three axles came into use; vehicles of this kind were made about 30 ft. long, and contained four compartments for first-class passengers or five for second or third-class, carrying in the latter case fifty persons. Their weight was in the neighbourhood of 10 tons. In both the four-wheeled and the six-wheeled types the axles were free to rise and fall on springs through a limited range, but not to turn with respect to the body of the carriage, though the middle axle of the six-wheeled coach was allowed a certain amount of lateral play. Thus the length of the body was limited, for to increase it involved an increase in the length of the rigid wheel base, which was incompatible with smooth and safe running on curves. (On the continent of Europe, however, six-wheeled vehicles are to be seen which are much longer than their English counterparts. This difficulty is avoided by providing the vehicles with four axles (or six in the case of the largest and heaviest), mounted in pairs (or threes) at each end in a bogie or swivel truck, which being pivoted can move relatively to the body and adapt itself to the curvature of the line. This construction was introduced into England from America about 1874, and has since been extensively adopted, being now indeed standard for main line stock. It soon led to an increase in the length of the vehicles; thus in 1885 the Midland railway had four-wheeled bogie third-class carriages with bodies 43 ft. long, holding seventy persons in seven compartments and weighing nearly 18 tons, and six-wheeled bogie composite carriages, 54 ft. long, weighing 23 tons, which included 3 first-class and 4 third-class compartments, with a cupboard for luggage, and held 58 passengers. The next advance, introduced on the Great Western railway in 1892, was the adoption of corridor carriages having a passage along one side, off which the compartments open, and connected to each other by vestibules, so that it is possible to pass from one end of the train to the other. This arrangement involves a further increase of length and weight. For instance, four-wheeled bogie third-class corridor carriages employed on the Midland railway at the beginning of the 20th century weighed nearly 25 tons, and had bodies measuring 50 ft.; yet they held only 36 passengers, because not only had the number of compartments been reduced to six, as compared with seven in the somewhat shorter carriage of 1885, by the introduction of a lavatory at each end, but each compartment held only 6 persons, instead of 10, owing to the narrowing of its width by the corridor.

Restaurant and sleeping cars.
It will be seen from these particulars—which are typical of what has happened not only on other British railways, but also on those of other countries—that much more space has to be provided and more weight hauled for each passenger than was formerly the case. Thus, on the Midland railway in 1885, each third-class passenger, supposing the carriage to have its full complement, was allowed 6.62 ft. of lineal length, and his proportion of the total weight was 5.7 cwt. Less than 20 years later the lineal length allowed each had increased to nearly 14 ft., and the weight to nearly 14 cwt. Passengers in sleeping cars appropriate still more space and weight; in Great Britain some of these cars, though 40 tons in weight and over 65 ft. in length, accommodate only 11 sleepers, each of whom thus occupies nearly 6 ft. of the length and requires over 38 tons of dead weight to be hauled.

In America the long open double-bogie passenger cars, as originally introduced by Ross Winans on the Baltimore & Ohio railway, are universally in use. They are distinguished essentially from the British type of carriage by having in the centre of the body a longitudinal passage, about 2 ft. wide, which runs their whole length, and each car having communication with those on either side of it, the conductor, and also vendors of books, papers and cigars, are enabled to pass right through the train. The cars are entered by steps at each end, and are provided with lavatories and a supply of iced water. The length is ordinarily about 50 ft., but sometimes 80 or 90 ft. The seats, holding two persons, are placed transversely on each side of the central passage, and have reversible backs, so that passengers can always sit facing the direction in which the train is travelling. Cars of this saloon type have been introduced into England for use on railways which have adopted electric traction, but owing to the narrower loading gauge of British railways it is not usually possible to seat four persons across the width of the car for its whole length, and at the ends the seats have to be placed along the sides of the vehicle. A considerable amount of standing room is then available, and those who have to occupy it have been nicknamed "strap-hangers," from the fact that they steadily themselves against the motion of the train by the aid of leather straps fixed from the roof for that purpose. Cars built almost entirely of steel, in which the proportion of wood is reduced to a minimum, are used on some electric railways, in order to diminish danger from fire, and the same mode of construction is also being adopted for the rolling stock of steam railways.

End doors opening on end platforms have always been characteristic of American passenger equipment. Their use secures a continuous passage-way through the train, but is attended with some discomfort and risk when the train is in motion. The opening of the doors was apt to cause a disagreeable draught through the car in cold weather, and passengers occasionally fell from the open platform, or were blown from it, when the train was moving. To remedy these defects vestibules were introduced, to enclose the platform with a housing so arranged as to be continuous when the cars are made up into trains, and fitted with side doors for ingress and egress when the trains are standing. A second advantage of the vestibule developed in use, for it was found that the lateral swaying of the cars was diminished by the friction between the vestibule frames. The fundamental American vestibule patent, issued to H. H. Sessions of Chicago in November 1887, covered a housing in combination with a vertical metallic plate frame of the general contour of the central passage-way, which projected slightly beyond the line of the couplings and was held out by horizontal springs top and bottom, being connected with the platform housing by flexible connexions at the top and sides and by sliding plates below. A common form is illustrated in fig. 27. Subsequent improvements on the Sessions patent have in a modified form of vestibule in which the housing is made the full width of the platform, though the contact plate and springs and the flexible connexions remain the same as before. The application of vestibules is practically limited to trains making long journeys, as it is an obstruction to the free ingress and egress of passengers on local trains that make frequent stops.

In the United States the danger of the stoves that used to be employed for heating the interiors of the cars has been realized, and now the locomotive boiler and circulated through the train in a line of piping, rendered continuous between the cars by flexible coupling-hose. The same method is finding increased favour in Great Britain, to the supersession of the old hot-water footwarmers. These in their simplest form are cans filled with water, which is heated by immersing them in a vessel containing boiling water. In some cases, however, they are filled with fused acetate of soda; this salt is solid when cold, but when the can containing it is heated by immersion in hot water it liquefies, and in the process absorbs heat which is given out again on the change of state back to solid. Such cans remain warm longer than those containing only hot water. On electric railways the trains are heated by electric heaters. As to lighting, the oil lamp has been largely displaced by gas and electricity. The former is often a rich oil-gas, stored in steel reservoirs under the coaches at a pressure of six or seven atmospheres, and passed through a reducing valve to the burners; these used to be of the ordinary fish-tail type, but inverted incandescent mantles are coming into increasing use. Gas has the disadvantage that in case of a collision its inflammability may assist any fire that may be started. Electric light is free from this drawback. The current required for it is generated by dynamos driven from the axles of the coaches. With "set" or "block" trains, that is, trains having their vehicles permanently coupled up, one dynamo may serve for the whole train, but usually a dynamo is provided for each coach, which is then an
independent unit complete in itself. It is necessary that the voltage of the current shall be constant whatever be the increase of the speed of the train, and therefore of the dynamo. In most of the systems that have been proposed this result is attained by electrical regulation; in one, however, a mechanical method is adopted, the dynamo being so hung that it allows the driving belt to slip when the speed of the axle exceeds a certain limit, the armature thus being rotated at an approximately constant speed. In all the systems accumulators are required to maintain the light when the train is at rest or is moving too slowly to generate current.

Pull buildings passenger trains must vary in weight according to the different services they have to perform; suburban trains, for example, meant to hold as many passengers as possible, and travelling at low speeds, do not weigh so much as long-distance expresses, which include dining and sleeping cars, and on which, from considerations of comfort, more space must be allowed each occupant. The speed at which the journey has to be completed is obviously another important factor, though the increased power of modern locomotives permits trains to be heavier and at the same time to run as fast, and often faster, than was formerly possible, and in consequence the general tendency is towards increased weight as well as increased speed. An ordinary slow suburban train may weigh about 100 tons exclusive of the engine, and may be timed at an inclusive speed, from the beginning to the end of its journey, as low as 12 or 15 m. an hour; while usually the fastest express trains maintaining inclusive speeds of say 45 m. an hour, and made up of the heaviest and strongest rolling stock, do not much exceed 300 tons in any country, and are often less. The inclusive speed over a long journey is of course a different thing from the average running speed, on account of the time consumed in intermediate stops; the fewer the stops the more easily is the inclusive speed increased,—hence the advantage of the non-stop runs of 150 and 200 m. or more which are now performed by several railways in Great Britain, and on which average speeds of 54 or 55 m. per hour are attained between stopping-places. Over shorter distances still more rapid running is occasionally arranged, and in Great Britain, France and the United States there are instances of trains scheduled to maintain an average speed of 60 m. an hour or more between stops. Still higher speeds, up to 75 or even 80 m. an hour, are reached, and sustained for shorter or longer distances every day by express trains whose average speed between any two stopping-places is very much less. But isolated examples of high speeds do not give the traveller much information as to the train service at his disposal, for on the whole he is better off with a large number of trains all maintaining a good average of speed than with a service mostly consisting of poor trains, but leavened with one or two exceptionally fast ones. If both the number and the speed of the trains be taken into account, Great Britain is generally admitted still to remain well ahead of any other country.

**Goods Trains.**—The vehicles used for the transportation of goods are known as goods wagons or trucks in Great Britain, and as freight cars in America. They are largely of British 15, 20, or 25-ton stock, with different loadings, but in both countries, and in the United States, there is a general tendency towards lighter cars. The principal types of American freight cars are box cars, gondola cars, coal cars, stock cars, tank cars and refrigerator cars, with, as in other countries, various special cars for special purposes. Most of these terms explain themselves. The gondola or flat car corresponds to the European open wagons and is used to carry goods not liable to be injured by the weather; but in the United States the practice of covering the load with tarpaulins is unknown, and therefore the proportion of box cars is much greater than in Europe. The long hauls in the United States make it specially important that the cars should carry a load in both directions, and so box cars which have carried grain or merchandise one way are filled with wool, coal, coke, ore, timber and other coarse articles for the return journey. On this account it is common to put small end doors in American box cars, through which timber and rails may be loaded.

The fundamental difference between American freight cars and the goods wagons of Europe and other lands is in carrying capacity. In Great Britain the mineral trucks can ordinarily hold from 8 to 10 tons (long tons, 2240 lb.), and the goods trucks rather less, though there are wagons in use holding 12 or 15 tons, and the specifications agreed to by the railway companies associated in the Railway Clearing House permit private wagon owners (who own about 45% of the wagon stock run on the railways of the United Kingdom) to build also wagons holding 20, 30, 40 and 56 tons. On the continent of Europe the average carrying capacity is rather higher; though wagons of less than 10 tons capacity are in use, many of those originally rated at 10 tons have been rebuilt to hold 15, and the tendency is towards wagons of 15-20 tons as a standard, with others for special purposes holding 40 or 45 tons.

The majority of the wagons referred to above are comparatively short, are carried on four wheels, and are often made of wood. American cars, on the other hand, have long bodies mounted on two swivelling bogie-trucks of four wheels each, and are commonly constructed of steel. About 1875 their average capacity differed little from that of British wagons of the present day, but by 1885 it had grown to 20 or 22 short tons (2000 lb.) and now it is probably at least three times that of European wagons. For years the standard freight cars have held 60,000 lb. and now many carry 80,000 lb. or 100,000 lb.; a few coal cars have even been built to contain 200,000 lb. This high carrying capacity has worked in several ways to reduce the cost of transportation. An ordinary British 10-ton wagon often weighs about 6 tons empty, and rarely much less than 5 tons; that is, the ratio of its possible paying load to its tare weight is at the best about 2 to 1. But an American car with a capacity of 100,000 lb. may weigh only 40,000 lb., and thus the ratio of its capacity to its tare weight is only about 5 to 2. Hence less dead weight has to be hauled for each ton of paying load. In addition the increased size of the American freight car has diminished the interest on the first cost and the expenses of maintenance relatively to the work done; it has diminished to some extent the amount of track and yard room required to perform a unit of work; it has diminished journal and rolling friction relatively to the tons hauled, since these elements of train resistance grow relatively less as the load per wheel rises; and finally, it has tended to reduce the labour costs as the train loads have become greater, because no more men are required to handle a heavy train than a light one.

It is sometimes argued that if these things are true for one country they must be true for another, and that in Great Britain, for example, the use of more capacious cars would bring down the cost of carriage. It may be pointed out, however, that the social and geographical conditions are different in the United Kingdom and the United States, and in each country the freight carrying and passenger carrying have developed in accordance with the requirements of those conditions. In the one country the population is dense, large towns are numerous and close to one another, the greatest distances to be travelled are short, and relatively a large part of the freight to be carried is merchandise and manufactured material consigned in small quantities. In the other country precisely the opposite conditions exist. Under the first set of conditions quickness and flexibility of service are relatively more important than under the second set. Goods therefore are collected and despatched promptly, and, to secure rapid transit, are packed in numerous wagons, each of which goes right through to its destination, with the consequence that, so far as general merchandise is concerned, the weight carried in each is a quarter or less of its capacity. But if full loads cannot be arranged for small wagons, there is obviously no economy in introducing larger ones. On the other hand, where, as in America, the great
volume of freight is raw material and crude food-stuffs, and the distances are great, a low charge per unit of transportation is more important than any consideration such as quickness of delivery; therefore full car-loads of freight are massed into enormous trains which run unbroken for distances of perhaps 1000 m. to a seaport or distributing centre.

The weight and speed of goods trains vary enormously according to local conditions, but the following figures, which refer to traffic on the London & North-Western railway between London and Rugby, may be taken as representative of good English practice. Coal trains, excluding the engine, weigh up to 800 or 900 tons, and travel at from 18 to 22 m. an hour; ordinary goods or merchandise trains, weighing 430 tons, travel at from 25 to 30 m. an hour; and quick merchandise trains with limited loads of 300 tons make 50 m. an hour. When running trains of mineral and grain trains, running at perhaps 12 m. an hour, may weigh up to about 4000 tons, and loads of 2000 tons are common. Merchandise trains run faster and carry less. Their speed must obviously depend greatly on topographical conditions. In the great continental basin there are long lines with easy gradients and curves, while in the Allegheny and Rocky Mountains the gradients are stiff, and the curves numerous and of short radius. Such trains, therefore, range in weight from 600 to 1800 tons or even more, and the journey speeds from terminus to terminus, including stops, vary from 15 to 30 m. an hour, the rate of running rising in favourable circumstances to 40 or even 60 m. an hour.

**Coupless.**—The means by which vehicles are joined together into trains are of two kinds—automatic and non-automatic, the difference between them being that with the former the impact of two vehicles one on the other is sufficient to couple them without any human intervention such as is required with the latter. The common form of non-automatic coupler, used in Great Britain for goods wagons, consists of a chain and hook; the chain hangs loosely from a slot in the draw-bar, which terminates in a hook, and coupling is effected by slipping the chain of one vehicle over the hook of the next. For this operation, or its reverse, a man has to go in between the wagons, unless, as in Great Britain, he is provided with a coupling-stick—that is, a pole having a peculiarly shaped hook at one end by which the chain can be caught and thrown on or off the draw-bar hook. This coupling gear is placed centrally between a pair of buffers; formerly these were often left "dead"—that is, consisted of solid prolongations of the frame of the vehicle, but now they are made to work against springs which take up the shocks that occur when the wagons are thrown violently against one another in shunting. In British practice the chains consist of three links, and are of such a length that when fully extended they reach from one end of one opposing buffer to another. This slack facilitates the starting of a heavy train, since the engine is able to start the wagons one by one and the weight of the train is not thrown on it all at once. For passenger trains and occasionally for fast goods trains screw couplings are substituted for the simple chains. In these the central bar which connects the two end links has screw threads cut upon it, and by means of a lever can be turned so as either to shorten the coupling and bring the vehicles together till their buffers are firmly pressed together, or to lengthen it to permit the end link to be lifted off the hook.

Another form of coupler, which used to be universal in the United States, though it has now been almost entirely superseded by the automatic coupler, was the "link and pin," which differed fundamentally from the couplers commonly used in Europe, in the fact that it was a buffer as well as a coupler, no side buffers being fitted. In it the draw-bar, connected through a spring to the frame of the car, had at its outboard end a socket into which one end of a solid link was inserted and secured by a pin. The essential change from the link and pin to the automatic coupler is in the outboard end or head of the draw-bar. The socket that received the link is replaced by a hook, shown at $A$ in fig. 28, which is usually called the knuckle. This hook swings on the pivot $B$, and has an arm which extends backwards, practically at right angles with the working face of the hook.

**Fig. 28.—Automatic Coupling for Freight Cars (U.S.A.).**

In a cavity in the head, and engages with the locking-pin $C$. This locking-pin is lifted by a suitable lever which extends to one or both sides of the car, lifting it release the knuckle, which is then free to swing open, disconnecting the two cars. The knuckle stands open until the coupling is pushed against another coupling, when the two hooks turn on their pivots to the position shown in fig. 28, and, the locking-pin dropping into place, the couplers are made fast. This arrangement is only partly automatic, since it often happens that when two cars are brought together to couple the knuckles are closed and must be opened by hand. There are various contrivances by which this may be done by a man standing clear of the cars, but often he must go in between their ends to reach the knuckle.

This form of automatic coupler has now gained practically universal acceptance in the United States. To effect this result required many years of discussion and experiment. The Master Car Builders Association, a great body of mechanical officers organized especially to being about improvement and uniformity in details of construction and operation, expressed its sense of the importance of "self-coupling" so far back as 1874, but no device of the kind that could be considered useful had then been invented. At that time a member of the Association referred to the disappearance of automatic couplers which had been introduced thirty or forty years before. This body pursued the subject with more or less diligence, and in 1884 laid down the principle that the automatic coupler should be one acting in a vertical plane—that is, the engaging faces should be free to move up and down within a considerable range, in order to provide for the differences in the height of cars. By the fixing of this principle the task of the inventor was considerably simplified. In 1887 a committee reported that the coupler question was the "knottiest mechanical problem that had ever been presented to the railroad," and over 4000 attempted solutions were on record in the United States Patent Office. The committee had not found one that did not possess grave disadvantages, but concluded that the "principle of contact of the surfaces of vertical surfaces embodied in the Janney coupler afforded the best connexion for cars on curves and tangents"; and in 1887 the Association recommended the adoption of a coupler of the Janney type, which, as developed later, is shown in fig. 28. The method of constructing the working faces of this coupler is shown in fig. 29. The principle was patented, but the company owning the patent undertook to permit its free use by railway companies which were members of the Master Car Builders Association, and thus threw open the underlying principle to competition. From that time the numerous patents have had reference merely to details. Many different couplers of the Janney type are patented and made by different firms, but the tendency is to equip new cars with one of only four or five standard makes. The adoption of automatic couplers was stimulated in some degree by laws enacted by the various states and by the United States; and the Safety Appliance Act passed by Congress in 1893 made it unlawful for railways to permit to be hauled on their lines after the 1st of January 1898 any car used for interstate commerce that was not equipped with couplers which coupled automatically by impact, and which could be uncoupled without the necessity for men going in between the ends of the cars. The limit was extended to the 1st of August 1900 by the Interstate Commerce Commission, which was given discretion in the matter.
Automatic couplers resembling the Janney are adopted in a few special cases in Great Britain and other European countries.

![Fig. 29.—Development of the Working Faces of the Janney Coupler.](image)

The sides of the square are 6 in., and the centres AA are taken at 2 in. from the top and bottom of the square. The circles A'A', which are struck with a 2-inch radius, define the first portion of the knuckle. The inner circle B has a radius of 1½ in. From its intersection with A'A' arcs are struck cutting B in two points. These intersections determine the centres of the semicircles CC which form the ends of the respective knuckles. These semicircles and the circles A'A' are joined by tangents and short arcs struck from the centre of the figure.

but the great majority of couplings remain non-automatic. It may be pointed out that the general employment of side buffers in Europe greatly complicates the problem of designing a satisfactory automatic coupling, while to do away with them and substitute the combined buffer-coupling, such as is used in the United States, would entail enormous difficulties in carrying on the traffic during the transition stage.

**Brakes.**—In the United States the Safety Appliance Act of 1893 also forbade the railways, after the 1st of January 1898, to run trains which did not contain a "sufficient number" of cars equipped with continuous brakes to enable the speed to be controlled from the engine. This law, however, did not serve in practice to secure so general a use of power brakes on freight trains as was thought desirable, and another act was passed in 1903 to give the Interstate Commerce Commission authority to prescribe what should be the minimum number of power-braked cars in each train. This minimum was at first fixed at 50%, but on and after the 1st of August 1906 it was raised to 75%, with the result that soon after that date practically all the rolling stock of American railways, whether passenger or freight, was provided with compressed air brakes. In the United Kingdom the Regulation of Railways Act 1889 empowered the Board of Trade to require all passenger trains, within a reasonable period, to be fitted with automatic continuous brakes, and now all the passenger stock, with a few trilling exceptions, is provided with either compressed-air or vacuum brakes (see Brake), and sometimes with both. But goods and mineral trains so fitted are rare, and the same is the case on the continent of Europe, where, however, such brakes are generally employed on passenger trains.

(H. M. R.)

**Intra-Urban Railways**

The great concentration of population in cities during the 19th century brought into existence a class of railways to which the name of intra-urban may be applied. Such lines are primarily intended to supply quick means of passenger communication within the limits of cities, and are to be distinguished on the one hand from surface tramways, and on the other from those portions of trams or other lines which lie within city boundaries, although the latter may incidentally do a local or intra-urban business. Intra-urban railways, as compared with ordinary railways, are characterized by shortness of length, great cost per mile, and by a traffic almost exclusively passenger, the burden of which is enormously heavy. For the purpose of connecting the greatest possible number of points of concentrated travel, the first railways were laid round the boundaries of areas approximately circular, the theory being that the short walk from the circumference of the circle to any point within it would be no serious detention. It has been found, however, in the case of such circular or belt railways, that the time lost in traversing the circle and in walking from the circumference to the centre is so great that the gain in journey speed over a direct surface tramway or omnibus is entirely lost. Later intra-urban railways in nearly every case have been built, so far as possible, on straight lines, radiating from the business centre or point of maximum congestion of travel to the outer limits of the city; and, while not attempting to serve all the population through the agency of the line, make an effort to serve a portion in the best possible manner—that is, with direct transit.

The actual beginning of the construction of intra-urban railways was in 1853, when powers were obtained to build a line, 2½ m. long, from Edgware Road to King's Cross, in London, from which beginning the Metropolitan and Metropolitan District railways developed. These railways, which in part are operated jointly, were given a circular location, but the shortcomings of this plan soon became apparent. It was found that there was not sufficient traffic to support them as purely intra-urban lines, and they have since been extended into the outskirts of London to reach the suburban traffic.

The Metropolitan and Metropolitan District railways followed the art of railway-building as it existed at the time they were laid out. Wherever possible the lines were constructed in open cutting, to ensure adequate ventilation; and where this was not possible they were built by a method suggestively named "cut and cover." A trench was first excavated to the proper depth, then the side walls and arched roof of brick were put in place, earth was filled in behind and over the arch, and the surface of the ground restored, either by paving where streets were followed, or by actually being built over with houses where the lines passed under private property. Where the depth to rail-level was too great for cut-and-cover methods, ordinary tunnelling processes were used; and where the trench was too shallow for the arched roof, heavy girders, sometimes of cast iron, bridged it between the side walls, longitudinal arches being turned between them (fig. 30).

![Fig. 30.—Type-Section of Arched Covered Way, Metropolitan District Railway, London.](image)

The next development in intra-urban railways was an elevated line in the city of New York. Probably the first suggestion for an elevated railway was made by Colonel Stevens, of Hoboken, New Jersey, as early as 1837, when the whole art of railway construction was in its infancy. He proposed to build an elevated railway on a single line of posts, placed along the curb-line of the street: a suggestion which embodies not only the general plan of an elevated structure, but the most striking feature of it as subsequently built—namely, a railway supported
by a single row of columns. The first actual work, however, was not begun till 1870, when the construction of an iron structure on a single row of columns was undertaken. The superiority, so far as the convenience of passengers is concerned, of an elevated over an underground railway, when both are worked by steam locomotives, and the great economy and rapidity of construction, led to the quick development and extension of this general design. By the year 1878 there were four parallel lines in the city of New York, and constructions of the same character had already been projected in Brooklyn and Chicago and, with certain modifications of details, in Berlin. In the year 1893 an elevated railway was built in Berlin, and in 1900 a similar railway was constructed in Boston, U.S.A., and the construction of a new one undertaken in New York. These elevated railways as a rule follow the lines of streets, and are of two general types. One (fig. 31), the earliest form, consisted of a single row of columns supporting the rails, the lateral stability of the structure being obtained by anchoring the feet of the columns to their foundations. The other type (fig. 32) has two rows of columns connected at the top by transverse girders, which in turn carry the longitudinal girders that support the railway. In Berlin, on the Stadtbahn—which for a part of its length traverses private property—masonry arches, or earthen embankments between retaining walls, were substituted for the metallic structure wherever possible.

The next great development, marking the third step in the progress of intra-urban railway construction, took place in 1886, when J. H. Greathead (q.v.) began the City & South London railway, extending under the Thames from the Monument to Stockwell, a distance of 33 m. Its promoters recognized the unsuitability of ordinary steam locomotives for underground railways, and intended to work it by means of a moving cable; but before it was completed, electric traction had developed so far as to be available for use on such lines. Electricity, therefore, and not the cable, was installed (fig. 33). In the details of construction the shield was the novelty. In principle it had been invented by Sir Marc Isambard Brunel for the construction of the original Thames tunnel, and it was afterwards improved by Beach, of New York, and finally developed by Greathead. (For the details of the shield and method of its operation, see Tunnel.) By means of the shield Greathead cut a circular hole at a depth ranging from 40 to 80 ft. below the surface, with an external diameter of 10 ft. 9 in.; this he lined with cast-iron segments bolted together, giving a clear diameter of 10 ft. 2 in. Except at the shafts, which were sunk on proposed station sites, there was no interference with the surface of the streets or with street traffic during construction. Two tunnels were built approximately parallel, each taking a single track. The cross-section of the cars was made to conform approximately to the section of the tunnel, the idea being that each train would act like a piston in a cylinder, expelling in front of it a column of air, to be forced up the station shaft next ahead of the train, and sucking down a similar column through the station shaft just behind. This arrangement was expected to ensure a sufficient change in air to keep such railways properly ventilated, but experience has proved it to be ineffective for the purpose. This method of construction has been used for building other railways in Glasgow and London, and in the latter city alone the "tube railways" of this character have a length of some 40 m. The later examples of these railways have a diameter ranging from 13 to 15 ft.

The fourth step in the development of intra-urban railways was to go to the other extreme from the deep tunnel which Greathead introduced. In 1893 the construction was completed in Budapest of an underground railway with a thin, flat roof, consisting of steel beams set close together, with small longitudinal jack arches between them, the street pavement resting directly on the roof thus formed (fig. 34). The object was to bring the level of the station platforms as close to the
surface of the street as the height of the car itself would permit; in the case of Budapest the distance is about 9 ft. This principle of construction has since been followed in the construction of the Boston subway, of the Chemin de Fer Métropolitain in Paris, and of the New York underground railway. The Paris line is built with the standard gauge of 4 ft 8 sq in., but its tunnels are designedly made of such a small cross-section that ordinary main line stock cannot pass through them.

The New York underground railway (fig. 35) marks a still further step in advance, in that there are practically two different railways in the same structure. One pair of tracks is used for a local service with stations about one-quarter of a mile apart, following the general plan of operation in vogue on all other intra-urban railways. The other, or central, pair of tracks is for trains making stops at longer distances. Thus there is a differentiation between the long-distance traveller who desires to be carried from one extreme of the city to the other and the short-distance traveller who is going between points at a much less distance.

To sum up, there are of intra-urban railways two distinct classes: the elevated and the underground. The elevated is used where the traffic is so light as not to warrant the expensive underground construction, or where the construction of an elevated line is of no serious detriment to the adjoining property. The underground is used where the congestion of traffic is so great as to demand a railway almost regardless of cost, and where the conditions of surface traffic or of adjoining property are such as to require that the railway shall not obstruct or occupy any ground above the surface.

Underground railways are of three general types: the one of extreme depth, built by tunnelling methods, usually with the shield and without regard to the surface topography, where the stations are put at such depth as to require lifts to carry the passengers from the station platform to the street level. This type has the advantage of economy in first construction, there being the minimum amount of material to be excavated, and no interference during construction with street traffic or of adjoining structures; it has, however, the disadvantage of the cost of operation of lifts at the stations. The other extreme type is the shallow construction, where the railway is brought to the minimum distance below the street level. This system has the advantage of the greatest convenience in operation, no lifts being required, since the distance from the street surface to the station platform is about 12 to 15 ft.; it has the disadvantages, however, of necessitating the tarring up of the street surface during construction, and the readjustment of sewer, water, gas and electric mains and other subsurface structures, and of having the gradients partially dependent on the surface topography. The third type is the intermediate one between those two, followed by the Metropolitan and Metropolitan District railways, in London, where the railway has an arched roof, built usually at a sufficient distance below the surface of the street to permit the other subsurface structures to lie in the ground above the crown of the arch, and where the station platforms are from 20 to 30 ft. beneath the surface of the street—a depth not sufficient to warrant the introduction of lifts, but enough to be inconvenient.

In the operation of intra-urban railways, steam locomotives, cables and electricity have severally been tried; the first having been used in the earlier examples of underground lines and in the various elevated systems in the United States. The fouling of the air that results from the steam-engine, owing to the production of carbonic acid gas and of sulphurous fumes and aqueous vapour, is well known, and its use is now practically abandoned for underground working. The cable is slow; and unless development along new lines of compressed air or some sort of chemical engine takes place, electricity will monopolize the field. Electricity is applied through a separate locomotive attached to the head of the train, or through motor carriages attached either at one end or at both ends of the train, or by putting a motor on every axle and so utilizing the whole weight of the train as a single effect. The train can be handled being under a single control at the head of the train, or at any point of the train for emergency. The distance between stations on intra-urban railways is governed by the density of local traffic and the speed desired to be maintained. As a general rule the interval varies from one-quarter to one-half mile; on the express lines of the New York underground railway, the inter-station interval averages about 1½ m. On steam-worked lines the speed of trains is about 11 to 15 m. per hour, according to the distance between stations. Later practice takes advantage of the great increase in power that can be temporarily developed by electric motors during the period of acceleration; this, in proportion to the weight of the train to be hauled, gives results much in advance of those obtained on ordinary steam railways. Since high average speed on a line with frequent stops depends largely on rapidity of acceleration, the tendency in modern equipment is to secure as great an output of power as possible during the accelerating period, with corresponding increase in weight available for adhesion. With a steam locomotive all the power is concentrated in one machine, and therefore the weight on the drivers for adhesion is limited. With electricity, power can be applied to as many axles in the train as desired, and so the whole weight of the train, with its load, may be utilized if necessary. Sometimes, as on the Central London railway, the acceleration of gravity is also utilized; the different stations stand, as it were, on the top of a hill, so that outgoing trains are aided at the start by having a slope to run down, while incoming ones are checked by the rising gradient they encounter.

The cost of intra-urban railways depends not only on the type of construction, but more especially upon local conditions, such as the nature of the soil, the presence of subsurface structures, like sewers, water and gas mains, electric conduits, &c.; the necessity of permanent or temporary supporting or building foundations, the cost of acquiring land passed under or over when street lines are not followed, and, in the case of elevated railways, the cost of acquiring easements of light, air and access, which the courts have held are vested in the abutting property. The cost of building an ordinary two-track elevated railway according to American practice varies from $300,000 to $400,000 a mile, exclusive of equipment, terminals or land damages. The cost of constructing the deep tabular tunnels in London, whose diameter is about 15 ft. exclusive, in like manner, of equipment, terminals or land damages, is about £170,000 to £200,000 a mile. The cost of the Metropolitan and Metropolitan District railways of London varied greatly on account of the variations in construction. The most difficult section—namely, that under Cannon Street—where the abutting buildings had to be underpinned, and a very dense traffic maintained during construction, while a network of sewers and mains was readjusted, cost at the rate of about £1,000,000 a mile. The contract price of the New York underground railway, exclusive of the incidentals above mentioned, was $3,500,000 for 21 m., of which 16 m. are underground and 5 are elevated. The most difficult portion of the road, 4½ m. of four-track line, cost $1,500,000.

(W. B. F.)
RAILWAYS

LIGHT RAILWAYS

The term light railways is somewhat vague and indefinite, and therefore to give a precise definition of its significance is not an easy matter. No adequate definition is to be found even in the British statute-book; for although parliament has on different occasions passed acts dealing with such railways both in Great Britain and Ireland, it has not inserted in any of them a clear and sufficient statement of what it intends shall be understood by the term, as distinguished from an ordinary railway. Since the passing of the Light Railways Act of 1896, which did not apply to Ireland, it is possible to give a formal definition by saying that a light railway is one constructed under the provisions of that act; but it must be noted that the commissioners appointed under that act have authorized many lines which in their physical characteristics are indistinguishable from street tramways constructed under the Tramways Act, and to these the term light railways would certainly not be applied in ordinary parlance. Still, they do differ from ordinary tramways in the important fact that the procedure by which they have been authorized is simpler and cheaper than the methods by which special private acts of parliament have to be obtained for tramway projects. Economy in capital outlay and cheapness in construction is indeed the characteristic generally associated with light railways by the public, and implicitly attached to them by parliament in the act of 1896, and any simplifications of the engineering or mechanical features they may exhibit compared with the standard railways of the country are mainly, if not entirely, due to the desire to keep down their expenses.

The saving of cost is effected in two ways: (1) Instead of having to incur the expenses of a protracted inquiry before parliament, the promoters of a light railway under the act of 1896 make an application to the light railway commissioners, who then hold a local inquiry, to obtain evidence of the usefulness of the proposed railway, and to hear objections to it, and, if they are satisfied, settle the draft order and hand it over to the Board of Trade for confirmation. The Board may reject the order if it thinks the scheme to be of such magnitude or importance that it ought to come under the direct consideration of parliament, or it may modify it in certain respects, or it may remit it to the commissioners for further inquiry. But once the order is confirmed by the Board, with or without modifications, it has effect as if it had been enacted by parliament, and it cannot afterwards be upset on the ground of any alleged irregularity in the proceedings. (2) The second source of economy is to be sought in the reduced cost of actually making the line and of working it when made. Thus the gauge may be narrow, the line single, the rails lighter than those used in standard practice, while deep cuttings and high embankments may be avoided by permitting the curves to be sharper and the gradients steeper: such points conduces to cheapness of construction. Again, low speeds, light stock, less stringent requirements as to continuous brakes, signals, block-working and interlocking, road-crossings, stations, &c., tend to cheapness in working. On the lines actually authorized by the Board of Trade under the 1896 act the normal minimum radius of the curves has been fixed at about 600 ft.; when a still smaller radius has been necessary, the speed has been reduced to 10 m. an hour and a guard-rail insisted on inside the curve. Again, the speed has been restricted to 20 m. an hour on long inclines with gradients steeper than 1 in 50, and also on a line which had scarcely any straight portions and in which there were many curves of 600 ft. radius and gradients of 1 in 50. In the case of a line of 23 ft. pitch, the saving of cost incident to this reduced speed and radius of 1 in 50, a maximum speed of 15 m. an hour and a minimum radius of curve of 300 ft. have been prescribed. Curves of still smaller radius have entailed a maximum speed of 10 m. an hour. It must be understood that a railway described as "light" is not necessarily built of narrower gauge than the standard. Many lines, indeed, have been designed on the normal 4 ft. 8½ in. gauge, and laid with rails weighing from 50 to 70 lb. per yard; a flat-footed 60 lb. rail, with the axle load limited to 14 tons, has the advantage for such lines that it permits the employment of a proportion of the locomotives used on main lines. The orders actually granted have allowed 50 lb., 65 lb., 60 lb. and 70 lb. rails, with corresponding axle-loads of 10, 12, 14 and 16 tons. On a line of 2 ft. gauge, rails of 40 lb. have been sanctioned. In regard to fencing and precautions against derailing it may be said that they are somewhat enforced than with standard railways; and in some cases where trains are likely to be few, it has been provided that the normal position of the gates at crossings shall be across the line. Again, if the speed is low and the trains infrequent, the signalling arrangements may be of a very simple and inexpensive kind, or even dispensed with altogether. It should be mentioned that the act provided that the Treasury might advance a portion of the money required for a line in cases where the council of any county, borough or district had agreed to do the same, and might also make a special advance in aid of a light railway which was certified by the Board of Agriculture to be beneficial to agriculture in any cultivated district, or by the Board of Trade to furnish a means of communication between a fishing-harbour and a market in a district where it would not be constructed without special assistance from the state.

As a general classification the commissioners have divided the schemes that have come before them into three classes: (A) those which like ordinary railways take their own line across country; (B) those in connexion with which it is proposed to use the public roads conjointly with the ordinary road traffic; and (Neutral) which includes inclined railways worked with a rope, and lines which possess the conditions of A and B in equal proportions.

The Light Railways Act 1896 was to remain in force only until the end of 1901 unless continued by parliament, but it was continued year by year under the Expiring Laws Continuance Act. In 1901 the president of the Board of Trade introduced a bill to continue the act until 1906, and to amend it so as to make it authorize the construction of a light railway on any highway, the object being to abolish the restriction that a light railway should run into the area of at least two local authorities; but it was not proceeded with. Towards the end of 1901 a departmental committee of the Board of Trade was formed to consider the Light Railways Act, and in 1902 the report of the Balfour Committee, of which this was as a result of the deliberations of this committee, a new bill had been drafted which he thought would go very far to meet all the reasonable objections that had been urged against the present powers of the local authorities. This bill, however, was not brought forward. In July 1903, Lord Wolverton, on behalf of the Board of Trade, introduced a bill to continue and amend the Light Railways Act. It provided that the powers of the light railway commissioners should continue until determined by parliament, and also provided, inter alia, that in cases where the Board of Trade thought, under section (5) subsection (3) of the original act, that a proposal should be submitted to parliament, the Board of Trade itself might submit the proposals to parliament by bringing in a bill for the confirmation of the light railway order, with a special report upon it. Opposition on petition could be heard before a select committee or a joint committee as in the case of private bills. The bill was withdrawn on the 11th of August 1903, Lord Morley appealing to the Board of Trade to bring in a more comprehensive measure to amend the unsatisfactory state of legislation in relation to tramways and light railways. In 1904 the president of the Board of Trade brought in a bill on practically the same lines as the amending bill of 1903. It reached second reading but was not proceeded with. Similar amending bills were introduced in the 1905 and 1906 sessions, but were withdrawn. During the first ten years after the act came into force 545 applications for orders were received, 313 orders were made, and 282 orders were confirmed. The orders confirmed were for 1731 m., involving an estimated capital expenditure of £1,770,384. At the end of 1906 only 500 m. had been opened for traffic, and the mileage of lines
opened was much less in proportion to the mileage sanctioned in the cases of lines constructed on their own land than in the case of lines more of the nature of tramways. (In other countries where the mileage of main lines of railways in proportion to area and population is roughly the same as in the United Kingdom, the mileage of light railways already constructed is considerable, while many additional lines are under construction. At the end of the 19th century there were 6150 m. working in France, costing on an average £4500 per mile, earning £275 per mile per annum; 3730 miles in Prussia costing £1850 per mile, earning £310 per mile per annum; 1430 m. in Belgium at £4300 per mile, earning £320 per mile per annum.) The average cost per mile in Great Britain on the basis of the prescribed estimates is £5860, but this figure does not include the cost of equipment and does not cover the whole cost of construction. According to the light railway commissioners, experience satisfied them (a) that light railways were much needed in many parts of the country and that many of the lines proposed, but not constructed, were in fact necessary to admit of the progress, and even the maintenance, of existing trade interests; and (b) that improved means of access were requisite to assist in retaining the population on the land, to counteract the remoteness of rural districts, and also, in the neighbourhood of industrial centres, to cope with the difficulties as to housing and the supply of labour. They pointed out that while during the first five years the act was in force there were 315 applications for construction of lines under the act, in the succeeding five years there were 142 applications, and that proposals for new lines had become less numerous owing to the various difficulties in carrying them to a successful completion and to the difficulty of raising the necessary capital even when part of it was provided with the aid of the state and of the local authorities. They expressed the opinion that an improvement could be effected enabling the construction of many much-needed lines by an amendment of some of the provisions of the Light Railways Act, and by a reconsideration of the conditions under which financial or other assistance should be granted to such lines by the state and by local authorities.

The so-called light railways in the United States and the British colonies have been made under the conditions peculiar to new countries. Their primary object being the development and peopling of the land, they have naturally been made as cheaply as possible; and as in such cases the cost of the land is inconsiderable, economy has been sought by the use of lighter and rougher permanent way, plant, rolling stock, &c. Such railways are not "light" in the technical sense of having been made under enactments intended to secure permanent lowness of cost as compared with standard lines. On the continent of Europe no country has had light railways in that sense. France began to move in this direction in 1865, and has formulated elaborate provisions for their construction and regulation. Italy did the same in its laws in 1873, 1879, 1881, and 1885; and Germany fostered enterprise of this kind by the imperial edicts of 1875, 1878 and 1892. Holland, Hungary and Switzerland were all early in the field; and Belgium has succeeded, through the instrumentality of the semi-official Société Nationale de Chemins de Fer Vicinaux, started in 1885, in developing one of the most complete systems of rural railway transport in the world.

In France the lines which best correspond to British light railways are called Chemins de fer d'intérêt local. These are regulated by a decree No. 11,264 of 6th August 1881, which the Ministry of Public Works is charged to carry out. The model "form of regulation" lays down the scales of the drawings and the information to be shown thereon. For the first installation a single line is prescribed, but the concessionnaire must provide a number of branches during the second five years in the ratio of either 1-44 metres (4 ft. 8-7 in.), or 1 metre (3 ft. 3-37 in.), or 75 metre (2 ft. 5-5 in.). The radius of curves for the 1-44 m. gauge must not be less than 250 metres, 100 metres for the 1 m. gauge and 50 metres for the 75 m. gauge. The light length, greater than 60 metres for the largest gauge and 40 metres for the smallest must be made between two curves having opposite directions. Except in special cases, gradients must not exceed 3 in 100; and between gradients in the opposite sense there must be not less than 50 yards of level for 400 ft., 400 for the 1 m. and 75-5 m. gauges. The position of stations and stopping-places is regulated by the council of the department. The undertaking, once approved, is regarded as a work of public utility, and the undertakers are insured with all the guarantees of the state in the case of the carrying out of public works. At the end of the period of the concession the département comes into possession of the road and all its fixed appurtenances, and in the last five years of the period the département has the right to repair and the carriage at the cost of the company and without loss of time. The maximum 1st, 2nd and 3rd class passenger fares are, per kilometre, 0-067 ft. (0-64), 0-050 ft. (0-455), and 0-037 ft. (0-343). When the trains are run at grande vitesse, the fares including 30 kilogrammes of personal baggage.

In Belgium a public company under government control ("Société Nationale de Chemins de Fer Vicinaux") does all that in France has already been done, and is in addition independent of and of the prefect of the department. Over an average of years it appears that 27% of the capital cost was found by the state, 28% by the province, 40-9% by the communes and 4-1% by private individuals. At the end of 1908 there were 2085 m. in operation, and the total mileage authorized was 2603, while the construction of a considerable further mileage was under consideration. As far as possible, these railways are laid beside roads, and are often the only means of communication in the country. The road costs 0-777 per mile in the former as against 0-793 in the latter. In the towns a deeper rail is used, weighing about 60 lb per yard. In three lines of Vicinaux system, in the aggregate 45 m. in length, the sharp-crested iron rails weigh from 28 to 30 kilos per yard. There are gradients of 1 in 20 and 1 in 25. The speed is limited to 30 kilometres (about 18 m.) in the country and 6 m. per hour in towns through villages.

In Italy many railways which otherwise fulfill the conditions of a light railway are constructed with a gauge of 4 ft. 8½ in. The weights are governed by what the railway has to carry and the speed. If more weight is to be carried, larger and heavier rolling stock are employed. There are no bridges, except where watercourses occur. Cuttings are reduced to a minimum; and where the roads are sufficiently wide, the rails are laid on the margins. The advantage of uniformity of gauge is in the use of trucks for goods which belong to the rolling stock of the main lines. In Italy these railways are called "economic railways," and are divided into five types. Types I, II, and III, are of 4 ft. 8½ in. gauge, Types IV, of 0-95 (3 ft. 0-5 in.) and V, of 0-70 (2 ft. 0-5 in.) are not of type V., the classification is practically one of 1-145 m. (4 ft. 8½ in.) and one of 0-95 (3 ft. 0-5 in.). The chief difference lies between the nature of the light of the rails and rolling stock and in the radius of the curve. The light railway of Italy is that of type IV; gauge, 0-95 m. (3 ft. 0-5 in.); weight of rails, 12-26 (45-5 lb) to 20 (44 lb) kilos; mean load per axle, 5 tons; minimum radius of curvature, 350 metres (11-49 ft. 5-5 in.); top width of ballast, 4-8, 10 m. (6 ft. 7-10 in.); depth of ballast under sleepers, 0-10 m. (2 ft. 6-9 ½ in.); minimum gradient, 1 in 50; length of sleepers, 1-70 m. (5 ft. 6-9 in.); width between centres of the wheels of the tenders, 1 m. over width of carriage; height of the wheels of the tenders, 3 m. (10 ft. 6-8 in.). Germany, as in the use of light railways (Klein-bahnen) has made great strides. The gauges in use vary considerably between 4 ft. 8½ in., the standard national gauge, and 1 ft. 11¼ in., which appears to be the smallest. In Germany, which appears to be the smallest. They are under the control of the boards of the provinces, and the state issuing loans to encourage the undertakings; the authorities in the provinces and communes also give support in various ways, and under various conditions to the public which is at once a public and private undertaking, or embark in the industry. These conditions, as well as the degree of control over the construction and working of the lines, are left to the regulation of the provincial governments. Similarly, the same authorities of the community in which the line is in the public roads may be used, and the precautions for public safety, all subject to the confirmation of the imperial government.

What are known as "porable railways" should be included in the same category as light railways. With a 24 in. gauge, lines of a portable kind can be made very handy and the cost is very much less than that of a permanently constructed light railway. The simplicity is great; they can be quickly mounted and dismounted; the correct gauge can be perfectly maintained; the sections of rails and
sleppers (which are of iron) are very portable, and skilled labour is not required to lay or to take them up; the making of a "turn-out" is easy, by taking out a 15 ft. section of the way and substituting a section with points and crossings. The safe load per wheel varies between 12 cwt. on a 10 in. 16 lb wheel and 40 cwt. on an 18 in. 56 lb wheel. The rolling stock is constructed either for farm produce or heavy minerals, the latter holding to 27 cwt. ft. For timber, 4 or 5 ft. bogies can be used. A useful wagon for agricultural transport on a 24 in. gauge line is 16 ft. long by 5 ft. wide; it weighs 72 cwt. and costs £50. A portable line of this kind will have 20 lb steel rails and 2112 steel sleepers—4 ft. 6 in. long—to a mile, laid 2 ft. 6 in. apart centre to centre. The total cost per mile of such a line, including all bolts, nuts, fish-plates and fastenings, ready for laying, delivered in the United Kingdom, is under £50 a mile.

RAIMBACH, ABRAHAM (1776-1843), English line-engraver, a Swiss by descent, was born in London in 1776. Educated at Archibald Tenison's Library School, he was an apprentice to J. Hall the engraver from 1789 to 1796. For nine years part of his working-time was devoted to the study of drawing in the Royal Academy and to executing occasional engravings for the book-sellers, whilst his leisure hours were employed in painting portraits in miniature. Having formed an intimacy with Sir David Wilkie, R.A., in 1817, he is one of that master's best pictures. At his death, in 1843, he held a gold medal awarded to him for his "Village Politicians" at the Paris Exhibition of 1814. He was elected corresponding member of the Institute of France in 1835.

RAIMUND, FERDINAND (1790-1836), Austrian actor and dramatist, was born on the 1st of June 1790, in Vienna. In 1814 he acted at the Josefstadt Theater, and in 1817 at the Lepoldstadt Theater. In 1823 he produced his first play, *Der Barometermacher auf der Zauberinsel*, which was followed by *Der Diament des Geliebten* (1824) and the still popular *Bauer als Millionär*. The last-mentioned play, which appeared in 1826, *Der Alpenkönig und der Menschenfisch* (1828) and *Der Verschwender* (1833) are Raimund's masterpieces. He committed suicide on the 5th of September 1836, owing to the fear that he had been bitten by a mad dog. Raimund was a master of the Viennese *Posse* or farce; his rich humour is seen to best advantage in his realistic portraits of his fellow-citizens.

Raimund's *Sämtliche Werke* (with biography by J. N. Vogl) appeared in 4 vols. (1837); they have been also edited by K. Glossy and A. Sailer; the latter in 3 vols.; and a separate edition at Graz (1903). See E. Schmidt in *Charakteristen*, vol. i. (1886); A. Farinelli, *Grillparzer und Raimund* (1897); L. A. Frankl, *Zur Biographie P. Raimunds* (1884); and especially A. Sauer's article in *Algemeen Nederlandsch Letterkundig Jaarboek* (1900-1901).

RAIN (O.E. *regn*; the word is common to Teutonic languages, cf. Ger. *Regen*, Swed. and Dan. *regn*; it has been connected with Lat. *rigare*, to wet, Gr. *βρέχειν*, the water vapour of the atmosphere when condensed into drops large enough to be precipitated upon the earth. Hence the term is extended to signify the fall of such drops in a shower, and in the plural, "the rains," it signifies the rainy seasons in India and elsewhere under normal climatic conditions such seasons are clearly distinguished from the dry. A rain-band is "a dark band in the solar spectrum, caused by the presence of water-vapour in the atmosphere" (New Eng. Dict.); a rain-gauge is an instrument used to measure the amount of rainfall (see Meteorology, where the whole subject of precipitation is fully treated).

RAINBOW, formerly known as the *iris*, the coloured rings seen in the heavens when the light from the sun or moon shines on falling rain; on a smaller scale they may be observed when sunshine falls on the spray of a waterfall or fountain. The bows assume the form of concentric circular arcs, having their common centre on the line joining the eye of the observer to the sun. Generally only one bow is clearly seen; this is known as the primary rainbow; it has an angular radius of about 45°, and exhibits a fine display of the colours of the spectrum, being red on the outside and violet on the inside. Sometimes an outer bow, the secondary rainbow, is observed; this is much fainter than the primary bow, and it exhibits the same play of colours, with the important distinction that the order is reversed, the red being inside and the violet outside. The angular radius is about 57°. It is also to be noticed that the space between the two bows is considerably darker than the rest of the sky. In addition to these prominent features, there are sometimes to be seen a number of coloured bands, situated at or near the summits of the bows, close to the inner edge of the primary and the outer edge of the secondary bow; these are known as the *spurious, supernumerary or complementary rainbows*.

The formation of the rainbow in the heavens after or during a shower must have attracted the attention of man in remote antiquity. The earliest references are to be found in the various accounts of the Deluge. In one bow, texts speak of two rainbows and one internal reflection; i.e. the light enters the drop and is refracted; the refracted ray is then reflected at the opposite surface of the drop, and leaves the drop at the same side at which it enters, being again refracted. It is difficult to determine the influence which the writings of Theodoric had on his successors; his works were apparently unknown until they were discovered by G. B. Venturi at Basel, partly in the city library and partly in the library of the Dominican monastery. A full account, together with other early contributions to the science of light, is given in Venturi's *Commentari sopra la storia de la Teoria del Ottica* (Bologna, 1814). John Fleischer (sometimes incorrectly named Fletcher), of Breslau, propounded the same view in a pamphlet, *De iridibus doctrina Aristotelis et Vitellonis* (1574); the same explanation was given by Francisca Maurolycus in his *Photismi de lumine et umbra* (1575).

The most valuable of all the earlier contributions to the scientific explanation of rainbows is undoubtedly a treatise by Marco Antonio de Dominis (1566-1624), architect of Spalatro. This work, *De radiis visus et lucis in vitris perspectis et iride*, published at Venice in 1611 by J. Bartolus, although written some twenty years previously, contains a chapter entitled "Vera iridibus tota generatio explicatur," in which it is shown how the Deluge bow is formed by two refractions and one reflection; the secondary bow by two refractions and two reflections. Descartes strengthened these views, both by experiments and geometrical investigations, in his *Meteores* (Leiden, 1637). He employed the law of refraction (discovered by W. Snellius) to calculate the radii of the bows, and his theoretical angles were in agreement with those observed. His methods, however, were not free from tentative assumptions, and were considerably improved by Edmund Halley (*Phil. Trans.*, 1700, 714). Descartes, however, could advance no satisfactory explanation of the chromatic displays; this was effected by Sir Isaac Newton, who, having explained how white light is composed of rays possessing all degrees of refrangibility, was enabled to demonstrate that the order of the colours was in perfect accord with the requirements of theory (see Newton's *Opticks*, book i. part 2, prop. 0).

The geometrical theory, which formed the basis of the investigations of Descartes and Newton, afforded no explanation of the supernumerary bows, and about a century elapsed before an explanation was forthcoming. This was given by Thomas Young, who, in the Bakerian lecture delivered before the Royal Society on the 24th of November 1803, applied his principle
of the interference of light to this phenomenon. His not wholly satisfactory explanation was mathematically examined in 1835 by Richard Potter (Camb. Phil. Trans., 1838, 6, 141), who, while improving the theory, left a more complete solution to be made in 1838 by Sir George Biddell Airy (Camb. Phil. Trans., 1838, 6, 370).

The geometrical theory first requires a consideration of the path of a ray of light falling upon a transparent sphere. Of the total amount of light falling on such a sphere, part is reflected or scattered at the incident surface, so rendering the drop invisible; while part will enter the drop. Confining our attention to a ray entering in a principal plane, we will determine its deviation, i.e., the angle between its directions of incidence and emergence, after one, or three, or more reflections. Let EA be a ray incident at an angle \(i\) (fig. 1); let AD be the refracted ray, and \(\gamma\) the angle of refraction. Then

\[
\cos \gamma = \frac{\cos i}{n} 
\]

is the deviation of the ray at D. At B, where the ray leaves the drop, the deviation is the same as at A, or \(\pi - \gamma\). The total deviation of the ray is consequently given by

\[
D = 2(\pi - \gamma) + \pi - \gamma = \pi - 2\gamma.
\]

Similarly it may be shown that each internal reflection introduces a supplementary deviation of \(\pi - 2\gamma\); hence, if the ray be reflected \(n\) times, the total deviation will be \(n\) of \(\pi - 2\gamma\).

The total deviation is thus seen to vary with the angle of incidence, and by considering a set of parallel rays passing through the same principal plane of the sphere and incident at all angles, it may be readily shown that the position of minimum deviation lies in the principal plane of the sphere, and may be readily found by the method of the differential calculus, we obtain

\[
\cos \gamma = \frac{\cos i}{n} = \frac{\cos i}{2}\cos \gamma + \sin \gamma \sin i
\]

as the required value; it may be readily shown either geometrically or analytically that this is a minimum.

For the violet rays as \(\mu\), the deviation expressed by the ray at

\[
D = 2(\pi - \gamma) + \pi - \gamma = \pi - 2\gamma.
\]

Since the value of \(\mu\) for water is about \(\frac{1}{4}\), it follows that \(\mu\) must be at least unity for a rainbow to be formed; there is obviously no theoretical limit to the value of \(\mu\), and hence rainbows of higher orders are possible.

So far we have only considered rays of homogeneous light, and it remains to investigate how lights of varying refrangibilities will be transmitted. It can be shown, by the methods of the differential calculus or geographically, that the deviation increases with the refractive index, the angle of incidence remaining constant. Taking the refractive index of water for the red rays as \(\mu\), and for the violet rays as \(\mu^2\), we can calculate the minimum deviations corresponding to certain assigned values of \(\mu\).

To this point we have only considered rays passing through a principal section of the drop. In nature, however, the rays impinge at every point of the surface facing the sun. It may be readily deduced that the directions of minimum deviation for a pencil of parallel rays lie on the surface of cones, the semi-vertical angles of which are equal to the angles given in the above table. Thus, rays suffering one internal reflection will all lie within a cone of about 42°; in this direction the illumination will be most intense; within the cone the illumination will be fainter, while, without it, no light will be transmitted.

Fig. 2 represents sections of the drop and the cones containing the minimum deviation rays after 1, 2, 3, and 4 reflections; the order of the colors is red, yellow, blue, and violet. It is at once obvious that, therefore, all drops transmitting intense light after one internal reflection to the eye will lie on the surfaces of cones having the eye for their vertex, the line joining the eye to the sun for their axis, and their semi-vertical angles equal to 42° for the violet rays and 43° for the red rays. The observer will, therefore, see a coloured band, about 2° in width, and the illumination will be faint; outside the band there will be perceptible darkening.
Lunar rainbows. The moon can produce rainbows in the same manner as the sun. The colours are much fainter, and according to Aristotle, who claims to be the first observer of this phenomenon, the lunar bows are only seen when the moon is full. The same light mixture is given to the chromatic displays formed by the moon's rays falling on the spray drawn up by the wind playing on the surface of an agitated sea.

Rainbows are sometimes observed. They are formed by parallel rays of light emanating from two sources, as, for example, the sun and its image in a sheet of water, which is situated between the observer and the sun. In this case the second bow is much fainter, and has its centre as much above the horizon as that of the direct system is below it.

References.—For the history of the theory of the rainbow, see G. B. Venturi, Commentari sopra la teoria dell' Ottica (Bologna, 1810); F. Rosenberger, Geschichte der Physik (1882-90). The geometrical and physical theory is treated in T. Preston's Theory of Light; E. Mascart's Traité d'optique (1899-1903); and most completely by J. Perter in various contributions to scientific journals and in his Meteorologische Optik (1905-9).

RAINOLDS (or REYNOLDS), JOHN (1540-1607), English divine, was born about Michaelmas 1540 at Pinhoe, near Exeter, and was educated at Merton and Corpus Christi Colleges, Oxford. He became a fellow of the latter in 1568. In 1572-73 he was appointed reader in Greek, and his lectures on Aristotle's Rhetoric laid the sure basis of his fame. He resigned the office in 1578 and his fellowship in 1586, through inability to agree with the president William Cole, and became a tutor at Queen's College. By this time he had acquired a considerable reputation as a disputant on the Puritan side, and the story goes that Elizabeth visiting the university in 1592 "schooled him for his obstinate preciseness, willing him to follow her laws, and not run before them." In 1593 he was made dean of Lincoln. The fellows of Corpus were anxious to replace Cole by Rainolds and exchange was effected, Rainolds being elected president in December 1598. The chief events of his subsequent career were his share in the Hampton Court Conference, where he was the most prominent representative of the Puritan party and received a good deal of favour from the king, and in the Authorized Version of the Bible. Of this project he was initiator, and himself worked with the company who undertook the translation of the Prophets. He died of consumption on the 21st of May 1607, leaving a great reputation for scholarship and high character.

RAIPUR (or RAIZEZ), GILLES DE (1404-1449), marshal of France and the central figure of a 15th-century cause célèbre, whose name is associated with the story of Bluebeard, was the son of Guy de Montmorency-Laval, the adopted son and heir of Jeanne de Rais and of Marie de Craon. He was born at Machecoul in September or October 1404, and, being early left an orphan, was educated at the monastery of La Craon. Chief among his great possessions was the barony of Rais (erected in the 16th century into the peerage-duchy of Retz), south of the Loire, on the marches of Brittany. He joined the party of the Montforts, supporting Jean V. of Brittany against the rival house of Penthièvre. He helped to release Duke John from Olivier de Blois, count of Penthièvre, who had taken him prisoner by craft, and was rewarded by extensive grants of land, which were subsequently commuted by the Breton parliament for money payments. In 1420, after other projects of marriage had fallen through, in two cases by the death of the bride, he married Katherine of Toussaint, a great heiress of Breton, La Vendée and Poitou. In 1426 he raised seven companies of men-at-arms, and began active warfare against the English under Artus de Richemont, the newly made constable of France. He had already built up a military reputation when he was chosen to accompany Joan of Arc to Orleans. He continued to be her special protector, fighting by her side at Orleans, and afterwards at Jargeau and Patay. He had advocated further measures against the English on the Loire before carrying out the coronation of Charles VII at Reims. On the 17th of July he was made marshal of France at Reims, and after the battle of Poitiers he was granted the right to bear the arms of France as a banner of his shield, a privilege that was, however, never ratified. In the winter he was in Normandy, at Louviers, whether with a view to the release of Joan, then a prisoner at Rouen, cannot be stated. Meanwhile his fortune was disappearing, although he had been one of the richest men in France. He had expended great sums in the king's service, and he maintained a court of...
RAISIN

See Eugène Bossard, *Gilles de Rais, dit Barbe Bleue* (2nd ed., 1886), which includes the majority of the documents for the original published originally by De Mauclé; E. A. Vitzetally, *Bluebeard* (1927); John C. Lea, *Hist. of the Inquisition* (iii. 468, seq.); A. Molinier, *Les Sources de l'histoire de France* (No. 4188). Huysmans in *La basil* describes his visit to the village of Rais, and takes the opportunity for a striking picture of the trial.

RAISIN (Fr. raisin, grape; Lat. *racemus*), the name given to the dried fruits of certain varieties of the grape vine, *Vitis vinifera*, which grow principally in the warm climate of the Mediterranean coasts and are comparatively rich in sugar. The use of dried grapes or raisins as food is of great antiquity (Num. vi. 3; i Sam. xxv. 18, xxi. 12). In medieval times raisins imported from Spain were a prized luxury in England, and to the present day Great Britain continues to be the best customer of the raisin-producing regions. "Raisins of the sun" are obtained by letting the fruit continue on the vines after it has come to maturity, where there is sufficient sunshine and heat in the autumn, till the clusters dry on the stocks. Another plan is partially to sever the stalk before the grapes are quite ripe, thus stopping the flow of the sap, and in that condition to leave them on the vines till they are sufficiently dry. The more usual process, however, is to cut off the fully ripe clusters and expose them, spread out, for several days to the rays of the sun, taking care that they are not injured by rain. In unfavourable weather they may be dried in a heated chamber, but are then inferior in quality. In some parts of Spain and France it is common to dip the gathered clusters in boiling water, or in a strong potash lye, a practice which softens the skin, favours drying and gives the raisins a clearer and drier appearance. Again, in Asia Minor the fruit is dipped into hot water on the surface of which swims a layer of olive oil, which communicates a bright lustre and softness to the skin. Some superior varieties are treated with very great care, retained on their stalks, and sent into the market as clusters for table use; but the greater part are separated from the stalks in the process of drying and the stalks winnowed out of the fruit. Raisins come from numerous Mediterranean localities, and present at least three distinct varieties—(1) ordinary or large raisins, (2) sultana seedless raisins, and (3) currants or Corinthian raisins (see CURRANT). The greater proportion of the common large raisins of English commerce comes from the provinces of Malaga, Valencia and Alicante in Spain; these are known by the common name of Malaga raisins. Those of the finest quality, called Malaga clusters, are prepared from a variety of muscatel grape, and preserved on the stalks for table use. This variety, as well as Malaga layers, so called from the manner of packing, are exclusively used as dessert fruit. Raisins of a somewhat inferior quality, known as "lexias," from the same provinces, are used for cooking and baking purposes. Smyrna raisins also come to some extent into the English market. The best quality, known as Elémé, is a large fruit, having a reddish-yellow skin with a sweet pleasant flavour. Large-seeded dark-coloured raisins are produced in some of the islands of the Greek archipelago and in Crete, but they are little seen in the British markets. In Italy the finest raisins are produced in Calabria, inferior qualities in central Italy and in Sicily. From the Lipari Islands a certain quantity of cluster raisins of good quality is sent to England. In the south of France raisins of high excellence—Provence raisins in clusters—are obtained at Roquevaire, Lunel and Frontignan. Sultana seedless raisins are the produce of a small variety of yellow grape, cultivated exclusively in the neighbourhood of Smyrna. The vines are grown on a soil of decomposed hippurite limestone, on sloping ground rising to a height of 400 ft. above the sea, and all attempts to cultivate sultanas in other raisin-growing localities have failed, the grapes quickly reverting to a seed-bearing character. The dried fruit has a fine golden-yellow colour, with a thin, delicate, translucent skin and a sweet aromatic flavour. A very fine seedless oblong raisin of the sultana type with a brownish skin is cultivated in the neighbourhood of Damascus.
RAJAHMUNDRI, or RAJAMAHENDRI, a town of British India, in the Godavari district of Madras. Pop. (1901) 26,982. It stands on the left bank of the river Godavari, at the head of the delta, 350 m. N. of Madras, and has a station on the East Coast railway, which is here carried across the river by a bridge of 56 spans. The government college is one of the four provincial schools established in 1853. There are also a training college and high school. Carpets, rugs and wooden wares are manufactured.

Tradition divides the merit of founding Rajahmundry between the Orissa and Chalukya princes. In 1470 it was wrested from Orissa by the Mahomedans, but early in the 16th century it was retaken by Kona the Rajah. It continued under Hindu rule till 1572, when it yielded to the Mogul chief of Chalukya under Rafat Khan. It passed into the possession of the French in 1753, but they were driven out by the British under Colonel Forde in 1758.

RAJASTHANI (properly RĀJASTHĀNĪ, the language of Rājāstān of Rajputana), an Indo-Aryan vernacular closely related to Gujarati (q.v.). It is spoken in Rajputana and the adjoining parts of central India, and has several dialects the principal of which are Jaipurī, Mārvāri, Mēvāṭi and Mālvi. Hārāūṭī, an important variant of Jaipurī, is spoken in the states of Kota and Bundi. Carey, the well-known Serampur missionary, paid great attention to Rajasthani in the early part of the 19th century, translating the New Testament into no fewer than six dialects, viz. Hārāūṭī, Ujainī (i.e. Mālvi), Udaipurī (a form of Mārvāri), Mārvāri proper, Jaipurī proper and Bikanerī (another form of Mārvāri). In 1901 the total number of speakers of Rajasthani was 9,017,712. (G. A. GR.)

RAJGARH, a native state of central India, in the Bhopal agency. Area, 940 sq. m. Pop. (1901) 88,376, showing a decrease of 26% in the decade, due to the results of famine. Estimated revenue, £3,350,000; tribute (to Sindhi), £3,040. The chief, whose title is rawat, is a Rajput of the Umat clan. Grain and opium are the principal articles of trade. The town of Rajgarh is surrounded by a battlemented wall, had a population of 5,350 in 1901.

RAJKOT, India, capital of a native state in Bombay, and headquarters of the political agent for Kathiawar. Pop. (1901) 36,151. It is situated in the middle of the peninsula of Kathia war, and is the centre of the railway system. There is a military cantonment. The Rajkumar college, for the education of the sons of chiefs on the lines of an English public school, has achieved great success. Beside the high school there are training colleges for masters and mistresses. The Rasulkhanji hospital has a department for women, opened in 1897. All these institutions are paid for by the joint expenses of the chiefs of Kathiawar. The state of Rajkot, which is a branch of Nawanagar, has an area of 282 sq. m. Pop. (1901) 49,795. Estimated revenue, £200,000.

RAJMAHAL, a former capital of Bengal, India, now a village in the district of the Santal Parganas, situated on the right bank of the Ganges, where that river makes a turn to the south. Pop. (1901) 20,477. It was chosen for his residence by Man Singh, Akbar's Rajput general in 1592, but the capital of the province was shortly afterwards transferred to Dacca. It contains many palaces and mosques, now in ruins and overgrown with jungle. It has a station on the loop line of the East Indian railway, but trade has declined since the Ganges abandoned its old bed; and Sahibganj has taken its place. Rajmahal has given its name to a range of hills, almost the only hills in Bengal proper, which here come down close to the bank of the Ganges. They cover a total area of 1366 sq. m., and their height never exceeds 2000 ft. They are inhabited by an aboriginal race, known as Paharias or "hill-men," of whom two tribes may be distinguished: the Male Sauria Paharias and the Mal Paharias; total pop. (1901) 73,000. The former, if not the latter also, are closely akin to the larger tribe of Orans. Their language, known as Malto, of the Dravidian family, was spoken by 66,777 persons in 1901. The Paharias have contributed an element to the administrative history of Bengal. Augustus Cleveland, a civilian who died in 1784 and whose name still survives, was the first who succeeded in winning their confidence and recruiting among them a corps of hill-rangers. The methods that he adopted are the foundation of the "non-regulation" system, established in 1766; and the hills were exempted from the permanent settlement. The Santals, a different aboriginal race, have since immigrated in large numbers into the Damun-koh, or "skirts of the hills"; but the Paharias alone occupy the plateaux on the top, where they are permitted to practise the privilege of shifting cultivation, which renders scientific forestry impossible. The approach from the plains below to each plateau is guarded by a steep ladder of bamboo.

See E. W. Dalton, Descriptive Ethnology of Bengal (Calcutta, 1872); F. B. Bradley-Birt, The Story of an Indian Upland (1905).

RAJPIPLA, a native state of India, in the Rewa Kantha agency, Bombay, occupying a hilly tract between the rivers Nerudda and Tapti; area, 1357 sq. m. Pop. (1901) 117,175, showing a decrease of 32% in the decade, due to the results of famine; estimated revenue, £60,000; tribute (to the Gaekwar of Baroda), £3500. The chief, whose title is maharana, is a Goel Rajput, of the same family as the thakor saheb of Bhamagar. A light railway, constructed at the cost of the state, connects Nandod with Ankalas in Broach district. The old fort of Rajpina, in the hills, is now deserted. The modern capital is Nandod, situated on the river Karjans, 32 m. from Surat. Pop. (1901) 11,256.

RAJPUR, a race of India, not confined to Rajputana, but spread over the N. of the country. According to the census of 1901 there were 9,712,156 Rajputs in all India, of whom only 652,229 lived in Rajputana. The great majority adhere to the Hindu religion, but 1,875,387 are entered as Mahomedans. The Rajputs form the fighting, landowning and ruling caste. They claim to be the modern representatives of the Kshatriyas of ancient tradition; but their early history is obscure, and recent research supports the view that they include descendants of both as well as one wave of immigrant invaders. Linguistic evidence supports tradition in proving that their unity was broken up by the Mahomedan conquest, for the inhabitants of the Himalayan valleys still speak a language akin to those of Rajputana proper, though separated from them by the wide Gangetic valley.

The Rajputs are fine, brave men, and retain the feudal instinct strongly developed. Pride of blood is their chief characteristic, and they are most pugnacious on all points of etiquette. The tradition of common ancestry permits a poor Rajput yeoman to consider himself as well born as any powerful landholder of his clan, and superiors of any high official of the professional classes. No race in India can boast of finer feats of arms or brighter deeds of chivalry, and they form one of the main recruiting fields for the Indian army of to-day. They consider any occupation other than that of arms or government derogatory to their dignity, and consequently during the long period of peace which has followed the establishment of the British rule in India they have been content to stay idle at home instead of taking up any of the other professions in which they might have come to the front. Those who are not zamindars have, therefore, rather dropped behind in the modern struggle for existence. As cultivators they are lazy and indifferent, and they prefer pastoral to agricultural pursuits. Looking upon all manual labour as humiliating, none but the poorest class of Rajput will himself hold the plough.
Within the limits of Rajputana the Rajputs form a vast body of kindred, and any Rajput can marry any Rajput woman who does not belong to his own clan. The most numerous of the clans is the Rahtor, to which the chiefs of Marwar, Bikain and Kishangarh belong. Its strength in 1901 was 122,160. Next comes the Kachwaha clan, which is strong in Jaipur and Alwar, both chiefs belonging to its members. It numbers 100,186. The Chauman follows with an aggregate of 86,460, among whom are the chiefs of Bundi, Kotah and Sirohi. The Jadu or Jadon, which includes in its ranks the chiefs of Karauli and Jaisalmer, numbers 74,400. The Chodh, or Rajputana Brahman, and the ill-famed House of Udaipur number 51,366. The Ponwar clan, to which Vikramaditya, the celebrated king of Ujain, from whom the Hindu Era is named, is said to have belonged, numbers 43,436. The Solanki and Parihar clans, once powerful, are now only 18,949 and 9448 respectively.

Rajputana, a collection of native states in India, under the political charge of an agent to the governor-general, who resides at Abu in the Aravalii Hills. It lies between 23° and 30° N. and between 69° 30′ and 75° 15′ E., and includes 18 states and 2 estates or chiefships. For political purposes these are subdivided into eight subordinate groups, consisting of four main and four lesser divisions. These are: (1) Mewar residency, with headquarters at Udaipur, comprising the states of Udaipur (Mewar), Dungarpur, Partabgarh and Banswara; (2) Jaipur residency, with headquarters at Jaipur, comprising the states of Jaipur and Kishangarh, with the estate of Laun; (3) Western Rajputana residency, with headquarters at Jodhpur, comprising the states of Jodhpur, Jaisalmer and Sirohi; (4) Bikain agency, with headquarters at Bikain; (5) Alwar agency, with headquarters at Alwar; (6) Eastern Rajputana agency, with headquarters at Bharatpur, comprising the states of Bharatpur, Dholpur, and Karauli; (7) Hanuman-Tonk agency, with headquarters at Deoli, comprising the states of Tonk and Bundi, with the estate of Shabpura; (8) Kotah-Jhalawar agency, with headquarters at Kotah, comprising the states of Kotah and Jhalawar. All of these states are under Rajput rulers, except Tonk, which is Mahomedan, and Bharatpur and Dholpur, which are Jat. The small British province of Ajmere-Merwara is also included within the geographical area of Rajputana.

Physical Features.—The total area of Rajputana is about 127,541 sq. m. It is bounded on the west by Sind, and on the north-west by the Bhawalhau and Kacchi, and on the north-east by the Punjab marches with the United Provinces until it touches the river Chambal, where it turns south-eastward for about 200 m., dividing the states of Dholpur, Karauli, Jaipur and Bhadoi. The same frontier line runs through the Aravalis and the irregular line across the central region of India, dividing the Rajputana states from a number of native states in Central India and Gujerat. The most striking physical feature is the Aravalie range of mountains, which intersects the country almost in a straight line from north-west to north-east. Mount Abu is at the south-western extremity of the range, and the north-eastern end may be said to terminate near Khetri in the Shaikwahiti district of Jaipur, although a series of broken ridges is continued in the direction of Delhi. About three-fifths of Rajputana lies north-west of the range, leaving the remaining two-fifths on the east and south. The tract lying to the north-west comprises the Bikain, Jaipur and Karauli districts; and except for the exception of the sub-montane districts of Jodhpur, which lie immediately below the Aravalis, this division is sandy, ill-watered and unproductive, improving gradually from a desert in the north-west and west to comparatively fertile land on the east. The country to the east and south-east of the Aravalis affords a striking contrast to the sandy plains on the north-west of the range, and is blessed with fertile land, rolling upland and long stretches of forest, where fuel and fodder are abundant.

The chief rivers of Rajputana are the Luni, the Chambal and the Banas. The first of these, the only river of any consequence in the north-west, is of great breadth, flowing 10 m. from the valley, close to Ajmere, to the Rann of Cutch. In the south-eastern division the river system is important. The Chambal is by far the largest river in Rajputana, through which it flows for about 300 m. Its course, while it forms its boundary for another third. The source of the river is in the highlands of the Vindhyas, upwards of 2000 ft. above the sea; it soon becomes a considerable stream, collecting in its course the waters of other rivers, and finally discharging itself into the Lummara, after a course of 500 m. In importance ranks the Banas, which rises in the south-west near Kankodi in Udaipur. It collects nearly all the drainage of the Udaipur plateau with that of the eastern slopes and hill-tracts of the Aravallis, and joins the Chambal a little beyond the north-western extremity of the Deccan plateau. Other rivers are the W. Banas and the Sabarmati, which rise among the south-west hills of Udaipur and take a south-western course. The river Mahi, which passes through the states of Partabgarh and Rajputana, has its source receiving the course of the river Jumla near Deoli of Rajputana through Gujar into the Gulf of Cambay. Rajputana possesses no natural freshwater lakes, but there are several important artificial lakes, all of which have been constructed with the object of increasing the water supply of any extent the Sambhar salt lake, of about 50 m. in circuit.

Geology.—Geologically considered, the country may be divided into two main divisions, each consisting of an eastern and western area. The eastern area consists of the Aravalie system, which occupies the entire width of the Aravalie system, formed of very old sub-metamorphic and gneissic rocks; an eastern region, with sharply defined boundary, along which the most ancient formations are abruptly replaced by the great basin of the Vindhyas strata, or are overlaid by beds of more extensive spread of the Deccan trap, forming the plateau of Malwa; and a western region, of very ill-defined margin, in which, besides some rocks of undetermined age, it is more or less known or suspected that Tertiary and Secondary strata stretch across from Sind, beneath the sands of the desert, towards the flanks of the Aravalis. Rajputana produces a variety of metals. Ore of coalite is obtained in no other locality in India, and in which zinc blende is found in the Alwar district; and the lead ore is known as the Rickle ore, and the vitriol (sulphate of copper) are manufactured from decomposed scabals at Khetri in Shaikwahiti. Good building materials are obtained from many of the rocks of the country, among which the Rajputana marble (a fine crystalline marble) and the Jaisalmer limestone stand pre-eminent.

Climate.—The climate throughout Rajputana is very dry and hot during the summer; while in the winter it is much colder in the north than in the lower districts, with hard frost and ice on the Bikain borders. The rainfall is very unequally distributed: in the western part, which comes near to the limits of the rainless region of Asia, it is very scanty, and scarcely averages more than 10 in. in the south-west the fall is more copious, sometimes exceeding 100 in. at Abu; but, except in the south-west highlands of the Aravalis, rain is most abundant in the south-east. Notwithstanding all its disadvantages, the district is one of the healthiest countries in India, at least for the native inhabitants.

Population.—In 1901 the population was 9,723,501, showing a decrease of 20% in the decade owing to the great famines of 1897-1898 and 1900-1901. The greatest mortality was caused by virulent malarial fever, which raged during the autumn months of 1900 and the early months of 1901. Epidemics of cholera, which occurred during the years of scarcity and famine, also swept away large numbers.

It is uncommonly free from caste, because nearly the whole country is ruled by Rajputs, therefore the population consists mainly of Rajput tribes; but these are merely the dominant race, and the territory is called Rajputana because it is politically possessed by the Rajputs. The whole number of this race is 620,029, and nowhere do they form a majority of the whole population in a state; but they are strongest, numerically, in the northern states and in Udaipur. By rigid precedent the Brahmans occupy the first rank; they are numerous and influential, and with them may be classed the peculiar and important caste of Bhats, the keepers of secular tradition and revenue. The other castes are scattered irregularly over the whole country and belong to the Jain sect; these are followed by the powerful cultivating tribes, such as the Jats and Gujars, and then come the so-called aboriginal tribes, chief of whom are the Mina, Bhis and Meos. Rajasthani is the chief language of the country, one or other of its dialects being spoken by 7,005,093 persons or more than 72½% of the total population. The gross revenue of all the states is estimated at 742 millions sterling.

The mass of the people are occupied in agriculture. In the large towns banking and commerce flourish to a degree beyond what might be expected. In the north the staple products for export are cotton, rice, and cotton cotton; in the south, cotton and sugar, cotton and sugar, and in the south, cotton and silk. In the north, the imports consist of sugar, hardware and piece goods. Rajputana is very poor in industrial production. The principal manufactures are cotton and woollen goods, carvings in ivory and working in metals, etc., all of which handicrafts are chiefly carried on in the eastern states. The system of agriculture is
very; in the country west of the Aravallis only one crop is raised in the year, while in other parts south and east of the Aravallis two crops are raised annually, and various kinds of cereals, pulses and fibres are grown. In the desert tracts fine breeds of camels, cattle, horses and sheep are to be found wherever there is pastureage. Irrigation, mostly from wells, is almost confined to the N. portion. The country is traversed throughout by the Rajputana railway, with its Malwa branch in the south, and diverging to Agra and Delhi in the north. Jodhpur, Udaipur and Bikanir have been connected by branch railways at their own cost, the first of which was extended in 1901 to Hyderabad in Sind. In 1909 another line was opened running N. near the E. boundary from Kota to Bharatpur.

History.—Only faint outlines can be traced of the condition of Rajputana previous to the invasion of Upper India by the Mahomedans, and these indicate that the country was subject for the most part to two or three powerful tribal dynasties. Chief of these were the Rahtors, who ruled at Kanauj; the Chauhans of Ajmere; the Solankis of Anhilwara, in Gujarat; the Gohlots with the Sisodiahs in Rajasthan, still in Mewar or Udaipur; and the Kachwahas, still in Jaipur. These tribal distinctions of Rajputana were gradually supplanted by the Moslem invaders of the 11th century and weakened by internal feuds. At the beginning of the 16th century the Rajput power began to revive, only to be overthrown by Baber at Fatehpur Sikri in 1527. The clans were finally either conquered, overawed or conciliated by Akbar—all except the distant Sisodia clan, which, however, submitted to Jehangir in 1616. From Akbar's accession to Aurangzeb's death, a period of 151 years, the Mogul was India's master. Aurangzeb's death and the invasion of Nadir Shah led to a triple alliance among the three leading chiefs, which internal jealousy so weakened that the Maharrats, having been called in by the Rahtors to aid them, took possession of Ajmere about 1756; thenceforward Rajputana became involved in the general disorganization of India. By the end of the century nearly the whole of Rajputana had been virtually subdued by the Maharattas. The victories of Generals Wellesley and Lake, however, saved the Rajputs; but on Lord Wellesley's departure from India the floodgates of anarchy were reopened for ten years. On the outbreak of the Pindari War in 1817 the British government offered its protection. The Pindaris were put down, Amir Khan submitting and signing a treaty which constituted him the first ruler of the existing state of Benares.

By the end of 1818 similar terms were treated by the other Rajput states with the paramount power. Sindhia gave up the district of Ajmere to the British, and the pressure of the great Maharatta powers upon Rajputana was permanently withdrawn. Since then the political history of Rajputana has been comparatively uneventful. The great storm of the Mutiny of 1857, though dangerous while it lasted, was short. Most of the rajas remained loyal; and the capture of the town of Kota, which had been held by the mutineers of that state, in March 1858, marked the extinction of armed rebellion.

Rajputana is of great archaeological interest, possessing some fine religious buildings in ruins and others in excellent preservation. Among the latter are the mosques at Ajmere and the temples on Abu. But the most characteristic features of architecture in the country are shown in the forts and palaces of the chiefs and in their cenotaphs.

See J. Tod, Annals and Antiquities of Rajasthan (1829, 1832); W. W. Webb, Currencies of the Hindu States of Rajputana (1893); Chiefs and Leading Families of Rajputana (1903); and Rajputana Gazetteer (Calculta, 1908).

RAJSHAHI, a district and division of British India, in the province of Eastern Bengal and Assam. The administrative headquarters are at Rampur Bosing. The area of the district is 2,939 sq. m., comprising an alluvial plain seamed with old river-beds and studded with marshes. The Ganges and the Mahananda are its principal rivers; the former constitutes a great, natural boundary-line to the south and south-west, and the latter, which rises in the Himalayas, borders the district on the west for a few miles before joining the Ganges. Other rivers are the Narad and Baral, important offshoots of the Ganges; the Atrai, a channel of the Tista; and the Jamuna, a tributary of the Atrai. Both the Atrai and the Jamuna belong to the Brahmaputra system and are navigable throughout the year for small cargo boats. The drainage of Rajshahi is not carried off by means of its rivers, but through the chains of marshes and swamps, the most important of which is the Chalan bhad or lake, which discharges itself into the Brahmaputra. In 1901 the population was 1,462,407, showing an increase of 1-6% in 10 years. Rice is the staple crop, with pulses, oilseeds and jute. Indigo has disappeared. Sericulture has received a stimulus from the efforts of the agricultural department, supported by private enterprise, to improve the breed of silkworms. The hemp grown on a small tract in the north of the district supplies all the ganja that is consumed in Bengal. The district is traversed from south to north by the main line of the Eastern Bengal railway to Darjeeling, with a branch to Bogra. Most of the permanent buildings in the district were severely damaged by the earthquake of the 12th of June 1887. When the East India Company took over the administration of Bengal in 1765, the samindari of Rajshahi or Nattor was one of the largest and most important in the province. It appears to have extended from Bhagalpur on the west to Dacca on the east, and to have included an important subdivision called Nij-Chakla Rajshahi on the south of the Ganges. The total area was estimated at 13,000 sq. m., or more than five times the size of the present district. Having been found much too large to be effectually administered by one central authority, Rajshahi was stripped in 1793 of a considerable portion of its outlying territory, and a natural boundary-line was drawn to the west, south and east along the Ganges and Brahmaputra. Its north-western limits were reduced in 1843, when the present district of Malda was constituted. The erection of Bogra into a separate jurisdiction in 1821 still further reduced its area; and in 1834 the limits of Rajshahi were fixed by the constitution of Pabna into an independent jurisdiction.

The Division of Rajshahi is coextensive with northern Bengal, from the Ganges to the mountains. It comprises the seven districts of Rajshahi, Dinajpur, Jalpaiguri, Malda, Rangpur, Bogra and Pabna. Total area, 18,091 sq. m. Pop. (1901) 9,130,672.

RAKE (O.E. raca, cognate with Du. raak, Ger. Recken, from a root meaning to scrape together, heap up), an agricultural implement, used for loosening the soil, weeding and levelling, and generally for purposes performed in agriculture by the harrow. The teeth of the hand-rake are of wood or iron. For the horse-drawn rake, a bar with long curved steel teeth is mounted on wheels (see Hay and Haymaking). The word "rake" has been used since the 17th century in the sense of a man of a dissolute or dissipated character. This is a shortened form of the earlier "rake-hell," apparently in common use in the 16th century. In military and naval use rake means to ram, as in ram to the shot may pass lengthwise along a ship, a line of soldiers, entrenchments, &c. In the nautical sense the projection or slope of a ship's bows or stern or the inclination of a mast, the word is apparently an adaptation of the Scandinavian raka, to reach, in the sense of reach forward.

RÁKÓCZY, the name of a noble Hungarian family, which in the 17th century was settled in the county of Zemplén, and members of which played an important part in the history of Hungary during the 17th century. GEORGE I., prince of Transylvania (1591-1648), who began his career as governor of Onod, was the youngest son of Sigismund Rákóczy (1544-1608), who shared in the insurrection of Stephen Bocskay against the Emperor Rudolph II., and was for a short time prince of Transylvania. In 1616 he married his second wife, the highly gifted zealous Calvinist, Susannah Lorántffy, who exercised a great influence over him. He then took a leading part in the rebellion of Gabriel Bethlen, who
made him commandant of Kassa, and was elected prince of Transylvania on the 26th of November 1630 by the diet of Segesvár. He followed the policy of Gabriel Bethlen, based on the maintenance of the political and religious liberties of the Hungarians. His alliance with Gustavus Adolphus of Sweden for that purpose was no secret at Vienna, where the court estimated at their right value Rákóczy's hypocritical assurances of pacific amends. On the 10th of February 1644, at the solicitation of the Swedish and French ambassadors, and with the consent of the Porte, he declared war against the Emperor Ferdinand III. Nearly the whole of imperial Hungary was soon in his hands, and Ferdinand, hardly pressed by the Swedes at the same time, was compelled to conclude (Sept. 16, 1645) with Rákóczy the peace of Linz, which accorded full religious liberty to the Magyars, and ceded to Rákóczy the fortress of Regéc and the Tokaj district. On the death of Wladislaus IV. (1648) Rákóczy aimed at the Polish throne also, but died before he could accomplish his design. His capital, Gyula Fehérvár, was a great Protestant resort and asylum.

See Secret Correspondence of the Age of George Rákóczi I. (Hung.), ed. Ágoston Ötvös (Klausenburg, 1848): Rákóczi's Correspondence with Pázmány, Erusterházy, &c. (Hung.), ed. Antal Beke (Budapest, 1882); Sándor Szilagyi, The Rákóczi Family in the 18th Century (Hung.) (Pest, 1861).

GEORGE II., prince of Transylvania (1621-1660), was the eldest son of George I. and Susannah Lorántfy. He was elected prince of Transylvania during his father's lifetime (Feb. 11, 1643), Sophia Báthory, who was previously compelled by his mother to reject the Roman faith and turn Calvinist. On ascending the throne (Oct. 11, 1648), his first thought was to realize his Polish ambitions. With this object in view, he allied himself, in the beginning of 1649, with the Cossack hetman, Bohdan Chmielnicki, and the hospodars of Moldavia and Wallachia. It was not, however, till 1657, as the ally of Gustavus Adolphus, that he led a rabble of 40,000 semi-savages against the Polish king, John Casimir. He took Cracow and entered Warsaw with the Swedes, but the moment his allies withdrew the whole scheme collapsed, and it was only on the most humiliating terms that the Poles finally allowed him to return to Transylvania. Here (Nov. 3, 1657) the diet, at the command of the Porte, deposed him for undertaking an unauthorized war, but in January 1658 he was reinstated by the Medgyes Diet. Again he was deposed by the grand vizier, and again reinstated as if nothing had happened, but all in vain. The Turks again invaded Transylvania, and Rákóczy died at Nagyvárad of the wounds received at the battle of Gyula (May 1660).

See Imre Bethlen, Life and Times of George Rákóczi II. (Hung.) (Nagy-Erdős, 1881); The Rákóczi Family (Hung.), ed. Antal Szilagy and Sándor Szilagy's Hungarian Historical Biographies (Budapest, 1891).

FRANCIS I., prince of Transylvania (1645-1676), was the only son of George Rákóczi II. and Sophia Báthory. He was elected prince of Transylvania during his father's lifetime (Feb. 18, 1652), but lost both crown and father at the same time, and withdrew to the family estates, where, at Patak and Makovka, he kept a splendid court. His mother converted him to Catholicism, and on the 1st of March 1660 he married Helen Zrínyi. In 1670 he was implicated in the Zrínyi-Francepán conspiracy, and only saved his life by the interposition of the Jesuits on the payment of an enormous ransom.

See Sándor Szilagy, The Rákóczi Family in the 17th Century (Hung.) (Pest, 1892).

FRANCIS II., prince of Transylvania (1675-1735), was born at Borsi, Zemplén county, on the 27th of March 1676. Having lost his father during infancy, he was educated under the guardianship of his heroic mother, Helen Zrínyi, in an ultrapatriotic Magyar environment, though the Emperor Leopold I. claimed a share in his tutelage. In 1682 his mother wedded Imre Thököly, who took no part in the education of Rákóczi, but used him for his political purposes. Unfortunately his stepfather's speculations suffered shipwreck, and Rákóczi lost the greater part of his estates. It is said that the Imperialists robbed him of 1,000,000 florins' worth of plate and supported a whole army corps out of his revenues (1685-85). As a child of twelve he witnessed the heroic defence by his mother of his ancestral castle of Munkács against Count Antonio Caraffa (d. 1693). On its surrender (Jan. 7, 1688) the child was transferred to Vienna that he might be isolated from the Hungarian nation and brought up as an Austrian magnate. Cardinal Kollonics, the sworn enemy of Magyar separatism, now became his governor, and sent him to the Jesuit college at Neuhaus in Bohemia. In 1690 he completed his course at Prague, and in 1694 he married Maria Amelia of Hesse-Rheinfels, and lived for the next few years on his Hungarian estates. At this time Rákóczi's birth, rank, wealth and brilliant qualities made him the natural leader of the Magyar nation, and his name was freely used in all the insurrections of the period, though at first he led a life of the utmost circumspection (1697-1700). Hungary was then regarded at Vienna as a conquered realm, whose naturally rebellious inhabitants could only be kept under by force of arms. Kollonics was the supreme ruler of the kingdom, and his motto was "Make of the Magyar first a slave, then a beggar, and then a Catholic." It was a matter of life or death for the Magyars to resist such a reign of terror and save the national independence by making Hungarian independent of Austria as heretofore. Rákóczi and a few other patriotic magnates deeply sympathized with the sufferings of the nation, and on the eve of the war of the Spanish Succession they entered into correspondence with Louis XIV. for assistance through one Longueval, a Belgian general in the Austrian service, who professed to be a friend of the Rákóczyans, who initiated him into all their secrets. Longueval betrayed his trust, and Rákóczi was arrested and imprisoned at Eperjes. His wife saved him from certain death by enabling him to escape to Poland in the uniform of a dragoon officer. On the 18th of June 1703 he openly took up arms against the emperor, most of whose troops were now either on the Rhine or in upper Italy; but, unfortunately, the Magyar gentry stood aloof from the rising, and his ill-supported peasant levies (the Kuruczcs) were repeatedly scattered. Yet at first he had some success, and on the 26th of September he was able to write to Louis XIV. that the whole kingdom up to the Danube was in his power. He also issued his famous manifesto, Recrudescunt vulnera inclytus gentis Hungariae, to justify himself in the eyes of Europe. The battle of Blenheim made any direct help from France impossible, and on the 13th of June 1704 his little army of 7000 men was routed by the imperialists at Koronco and subsequently at Nagyszombat. Want of arms, money, native officers and infantry, made, indeed, any permanent success in the open field impossible. Nevertheless, in May 1705, when the Emperor Leopold I. was succeeded by Joseph I., the position of Rákóczi was at least respectable. With the aid of several eminent French officers and engineers he had drilled his army into some degree of efficiency, and had at his disposal 52 horse and 31 foot regiments. Even after the rout of Pudnerics (Aug. 11, 1705), he could put 100,000 men in the field. In September 1705 he was also able to hold a diet at Szécsény, attended by many nobles and some prelates, to settle the government of the country.

Rákóczi, who had already been elected Prince of Transylvania (July 6, 1704), now surrounded himself with a council of state of 24 members. The religious question caused him especial difficulty. An ardent Catholic himself, nine-tenths of his followers were nevertheless stern Calvinists, and in his efforts to secure them toleration he alienated the pope, who dissuaded Louis XIV. from assisting him. Peace negotiations with the emperor during 1705 came to nothing, because the court of Vienna would not acknowledge the independence of Transylvania, while France refused to recognize the rebels officially till they had formally proclaimed the deposition of the Habsburghs, which last desperate measure was actually accomplished by the Önöd diet on the 13th of June 1707. This was a fatal mistake, for it put an end to any hope of a compromise, and alienated both the emperor's foreign allies and the
RALEIGH, SIR WALTER

majority of the Magyar gentry, while from Louis XIV. Rákóczy only got 100,000 thalers, the Golden Fleece, and a promise (never kept) that the Hungarians should be included in the general peace. But into a direct alliance with Rákóczy the French king would not enter, and Laszló Vetési, Rákóczy's envoy at Versailles, in 1708 advised his master to place no further reliance on the French court. Shortly afterwards, at Trenesca (Aug. 3, 1708), Rákóczy's army was scattered to the winds. The rout of Trenesca was followed by a general abandonment. The remnant of the host, too, was now thoroughly demoralized and dared not face the Imperialists. A fresh attempt to renew the war in 1710 was commonly ruined by the disaster of Romhány (Jan. 22), and a desperate effort to secure the help of Peter the Great also failing, Rákóczy gave up everything for lost, and on the 21st of February 1711 quit his country for ever, refusing to accept the general amnesty conceded after the peace of Sztatmár (see Hungary, History). He lived for a time in France on the bounty of Louis XIV., finally entering the Carmelite Order. In 1717, with forty comrades, he volunteered to assist the Turks against the Austrians, but on arriving at Constantinople discovered there was nothing for him to do. He lived for the rest of his life at the little town of Rodosto, where he died on the 8th of April 1735. His remains were solemnly transferred to Hungary in 1907 at the expense of the state.

See Autobiography of Prince Francis Rákóczy (Hung.) (Miskolc, 1903); E. Jurkovich, The Liberation Wars of Prince Francis Rákóczy (Hung.) (Besztercebénya, 1903); S. Endrődi, Kurucz Notes, 1700-1720 (Hung.) (Budapest, 1897). (R. N. B.)

RALEIGH, SIR WALTER (c. 1552-1618), British explorer, poet and historian, was born probably in 1552, though the date is not quite certain. His father, Walter Raleigh of Fardell, in the parish of Cornwood, near Plymouth, was a country gentleman of old family, but of reduced estate. Walter Raleigh the elder, who was the father of Sir Walter at court, was beheaded after his third marriage with Catherine, daughter of Sir Philip Champaigne of Modbury, and widow of Otho Gilbert of Compton. By her first marriage she had three sons, John, Humphrey and Adrian Gilbert. Mr. Raleigh had been compelled to give up living in his own house of Fardell. His son was born at the farmhouse of Hayes near the head of Budleigh Salterton Bay, on the coast of Devonshire between Exmouth and Sidmouth. The name is written with a diversity exceptional even in that age. Sir Walter, his father, and a half-brother used different forms. The spelling Raleigh was adopted by Sir Walter's widow, and has been commonly used, though there has been a tendency to prefer "Ralegh" in recent times. It was almost certainly pronounced "Rawley."

In 1568 he was entered as a commorcor of Oriel College, Oxford, but he took no degree, and his residence was brief. In 1569 he followed his cousin Henry Champaigne, who took over a body of English volunteers to serve with the French Huguenots. From a reference in his History of the World it has been supposed that he was present at the battle of Jarnac (13th of March 1569), and it has been asserted that he was in Paris during the Massacre of St Bartholomew in 1572. Nothing, however, is known with certainty concerning his services or whereabouts, and he has been commonly supposed to have been resident in the Temple. During his trial in 1603 he declared that he had never studied the law, but that his breeding had been "wholly gentleman, wholly soldier." In June 1578 his half-brother Sir Humphrey Gilbert obtained a patent for six years authorising him to take possession of "any remote barbarous and heathen lands not possessed by any Christian prince or people." The gentry of Devon had been much engaged in maritime adventure of a privating or even piratical character since the reign of Henry VIII. In the reign of Elizabeth they were the leaders in colonial enterprises in conflict with the Spaniards in America. During 1578 Humphrey Gilbert led an expedition which was a piratical venture against the Spanish, and wedged back after an action with them and the loss of a ship in the Atlantic. Raleigh accompanied his half-brother as captain of the "Falcon," and was perhaps with him in an equally unsuccessful voyage of the following year. Gilbert was impoverished by his ventures, and Raleigh had to seek his fortune about the court. In the course of 1580 he was twice arrested for duels, and he attached himself to the queen's favourite, the earl of Leicester, and to the earl of Oxford, son-in-law of Burghley, for whom he carried a challenge to Sir Philip Sidney. By the end of 1580 he was serving as captain of a company of foot in Munster. He took an active part in suppressing the rebellion of the Descamps, and in the massacre of the Spanish and Italian adventurers at Smervick in November. His letters prove that he was the advocate of a ruthless policy against the Irish, and did not hesitate to recommend assassination as a means of getting rid of their leaders.

In December 1581 he was sent home with despatches, as his company had been disbanded on the suppression of the Descamps. His great fortune dates from his arrival at court where he was already not unknown. Raleigh had been in correspondence with Walsingham for some time. The romantic stories told by Sir Robert Naunton in the Fragmenta Regalia, and by Fuller in his Worthies, represent at least the mythical truth as to his rise into favour. It is quite possible that Raleigh, at a time when his court clothes represented "a considerable part of his estate," did not wish to dissemble his fortune. It is known that he followed his fortune, and that he was recommended to help the queen to walk dry-shod over a puddle, and that he scribbled verses with a diamond on a pane of glass to attract her attention, though we only have the gossip of a later generation for our authority. It is certain that his tall and handsome person, his caressing manners and his quick wit pleased the queen. The rewards showered on him were out of all proportion to his services in Ireland, which had not been more distinguished than those of many others. In March 1582 he was granted a reward of £100, and the command of a company, nominally that he might be exercised in the wars, but in reality as a form of pension, since he was allowed to discharge his office by deputy and pursue his own adventures. His famous son was born at court, 29th March 1592. He was an immature and almost indolent youth, who had the misfortune to be the son of a courtier sent to accompany the duke of Anjou from England to Flanders. In 1583 the queen made him a grant of Durham House in the Strand (London), the property of the see of Durham, which had however been used of late as a royal guest-house. In the same year the queen's influence secured him two beneficial leases from All Souls, Oxford, which he sold to his advantage, and a patent to grant licences to "vintners,"—that is, tavern keepers. This he subleased, and when his agent, one Browne, cheated him, he got the grant revoked, and reissued on terms which allowed him to make £2000 a year. In 1584 he had a licence for importing woollen cloths, a lucrative monopoly which made him very unpopular with the merchants. He was knighted in 1584. In 1585 he succeeded the earl of Bedford as Warden of the Stannaries. Raleigh made a good use of the great powers which the wardenship gave him in the mining districts of the west. He reduced the old customs to order, and showed himself fair to the workers. In 1586 he received a grant of 40,000 acres of the forfeited lands of the Descomps, on the Blackwater in Ireland. He was to plant English settlers, which he endeavoured to do, and he introduced the cultivation of the potato and of tobacco. In 1587 he received a grant in England of part of the forfeited land of the conspirator Babington. During these years Raleigh was at the height of his favour. It was the policy of Queen Elizabeth to have several favourites at once, lest any one might be supposed to have exclusive influence with her. Raleigh was predominant during the period between the predominance of Leicester and the rise of the earl of Essex, who came to court in 1587. It is to be noted that Elizabeth treated Raleigh exclusively as a court favourite, to be enriched by monopolies and grants at the expense of her subjects, but that she never gave him any great office, nor did she admit him to the council. Even his post of captain of the Guard, given in 1587, though honourable, and, to a man who would take gifts for the sake of his influence, lucrative, was mainly ornamental. His many offices and estates did not monopolize the activity of Raleigh. The patent given to his half-brother Sir Humphrey Gilbert was to run out in 1584. To
avert this loss Raleigh, partly out of his own pocket and partly by securing the help of courtiers and capitalists, provided the means for the expedition to Newfoundland in 1583, in which Gilbert, who had been reduced to sell "the clothes off his back," by his previous misfortunes, finally perished. Sir Humphrey's patent was renewed in favour of Sir Walter in March 1584.

Raleigh now began the short series of ventures in colonization which have connected his name with the settlement of Virginia. It has often been said that Raleigh showed a wise originality in his ideas as to colonization. But in truth the patent granted to him, which gave him and his heirs the proprietary right over all territory they occupied subject to payment of one-fifth of the produce of all mines of precious metals to the crown, is drawn closely on Spanish practice. Nor was there any originality in the policy that Spenser obtained a pension, and royal aid to other industries than mining. The Spaniards had pursued the same aim from the first. In April 1584 Raleigh sent out two captains, Philip Amadas and Arthur Barlowe, on a voyage of exploration. They sailed by the Canaries to Florida, and from thence followed the coast of North America as far as the inlets between Albemarle and Pamlico sounds in the modern state of North Carolina. The name of Virginia was given to a vast and undefined territory, but none of Raleigh's captains or settlers reached the state of Virginia. In the same year he became member of parliament for Devonshire, and took the precaution to secure a parliamentary confirmation of his grant. His first body of settlers, sent out in 1585 under Sir Richard Grenville, landed on what is now Roanoke Island in North Carolina. Sir R. Grenville showed himself mainly intent on taking prizes, going and coming. The settlers got on bad terms with the natives, deserted, and deserted the colony when Sir Francis Drake visited the coast in 1586. Attempts at colonization at the same place in 1586 and 1587 proved no more successful (see North Carolina), and in 1589 Raleigh, who represented himself as having spent £40,000 on the venture, resigned his rights to a company of merchants, preserving to himself a rent, and a fifth of whatever gold might be discovered.

After 1587 Sir Walter Raleigh was called upon to fight for his place of favourite with the earl of Essex (see Essex, 2nd Earl 09). During the Armada year 1588 he was more or less in eclipse. He was in Ireland for part of the year with Sir R. Grenville, and was employed as vice-admiral of Devon in looking after the coast-defences and militia levy of the county. During this year he received a challenge from Essex which did not lead to an encounter. In 1589 he was again in Ireland. He had already made the acquaintance of Edmund Spenser and now visited him at his house at Kilcolman. It was by Raleigh's help that Spenser obtained a pension, and royal aid to publish the first three books of the Faerie Queen. The exact cause of Raleigh's partial disgrace at court is not known, but it was probably due to the queen's habitual policy of checking one favourite by the promotion of another. In 1589 he accompanied the expedition to the coast of Portugal, which was intended to cause a revolt against King Philip II., but failed completely. In 1591 he was at the last moment forbidden to take part in the voyage to the Azores, and was replaced by his cousin Sir R. Grenville, whose death in action with the Spaniards was the subject of one of Sir Walter's most vigorous pieces of prose writing. In 1592 he was again at sea with an expedition to intercept the Spanish trade, but was recalled by the queen. The cause of his recall was the discovery that he had seduced one of her maids of honour, Elizabeth Throgmorton. Raleigh denied in a letter to Robert Cecil that there was any truth in the stories of a marriage between them. On his return he was put into the Tower, and if he was not already married was married there. To placate the queen he made a fantastic display of despair at the loss of her favour. It must be remembered that the maids of honour could not marry without the consent of the queen, which Elizabeth was always most reluctant to give and would be particularly unwilling to give when the husband was an old favourite of her own. Raleigh proved a good husband and his wife was devoted to him through life. As the ships of the expedition had taken a valuable prize, the Portuguese carrack "Madre de Dios," and as there was a dispute over the booty, he was released to superintend its distribution. He had been a large contributor to the cost of the expedition, but the queen, who sent only two ships, took the bulk of the spoil, leaving him barely enough to cover his expenses.

Raleigh now retired from court to an estate at Sherborne in Dorsetshire, which just before his disgrace he had extorted from the bishop of Salisbury, to whose see it belonged, by a most unscrupulous use of the royal influence. A son was born to him here in 1594, and he kept up a friendly correspondence with Sir Robert Cecil, afterwards earl of Salisbury, the secretary of state. The little boy's name was Francis to distinguish him from Sir Walter, and as his profuse habits, together with the multiplicity of his interests, had prevented him from making any advantage out of his estates in Ireland, he was embarrassed for money. In 1595 he therefore sailed on a voyage of exploration with a view to conquest, on the coast of South America. The object was undoubtedly to find gold mines, and Raleigh had heard the wild stories of El Dorado which had been current among the Spaniards for long. His account of his voyage, The Discoverie of Guiana, published on his return, is the most brilliant of all the Elizabethan narratives of adventure, but contains much manifest romance. It was noted that he was one of the most unpopular men in England, not only among the courtiers, but in the nation, for his greed, arrogance and alleged scepticism in religion. In 1599 he was named with the poet Marlowe and others as an atheist. At court he was not at first received. The share he took in the capture of Cadiz in 1596, where he was seriously wounded, was followed by a restoration of favour at court, and he was apparently reconciled to Essex, whom he accompanied on a voyage to the Azores in 1597. This cooperation led to a renewal of the quarrel, and Raleigh, as the enemy of Essex who was the favourite of the soldiers and the populace, became more unpopular than ever. In 1600 he obtained the governorship of Jersey, and in the following year took a part in suppressing the rebellion of Essex, at whose execution he presided as captain of the Guard. In 1600 he sat as member for Penzance in the last parliament of Elizabeth's reign. In parliament he was a steady friend of religious toleration, and a bold critic of the fiscal and agrarian legislation of the time.

The death of the queen and the accession of James I. were ruinous to Raleigh. James, who looked upon Essex as his partisan, had been prejudiced, and Raleigh's avowed desire for the prolongation of the war with Spain was utterly against the peace policy of the king. Raleigh was embarrassed for money, and had been compelled to sell his Irish estates to Richard Boyle, afterwards 1st earl of Cork, in 1602. He was expelled from Durham House, which was reclaimed by the bishop, dismissed from the captnacy of the Guard, deprived of his monopolies, which the king abolished, and of the government of Jersey. In his anguish and despair he unquestionably took some part in the complication of the conspiracies which arose in the first months of James's reign, and was committed to the Tower on the 19th of July 1603. Here he made what appears to have been an insincere attempt to stab himself, but only inflicted a small wound. His trial at Winchester, November 1603, was conducted with such outrageous unfairness as to shock the opinion of the time, and his gallant bearing in face of the brutality of the Attorney-General, Sir Edward Coke, turned public opinion in his favour. It was impossible to reach the true, but on the whole it appears probable that Raleigh was cognizant of the conspiracies, though the evidence produced against him was insufficient to prove his guilt. Much was kept back by the council, and the jury was influenced by knowing that the council thought him guilty.

The sentence of death passed on Raleigh, and others tried at about the same time, was in most cases not carried out.
RALEIGH

RALEIGH was sent to the Tower, where he remained till the 19th of March 1616. His estate of Sherborne, which he had transferred to his son, was taken by the king, who availed himself of a technical irregularity in the transfer. A sum of £8000 offered in compensation was only paid in part. Raleigh's confinement was easy, and he applied himself to chemical experiments and literature. He had been known as one of the most poetical of the minor lyric poets of an age of poetry from his youth. In prison he composed many treatises, and the only volume of his vast History of the World published, He also invented an elixir which appears to have been a very formidable quack stimulant. Hope of release and of a renewal of activity never deserted him, and he strove to reach the ear of the king by appealing to successive ministers and favourites. At last he secured his freedom in a way discreditable to all concerned. He promised the king to find a gold mine in Guiana without trenching on a Spanish possession. It must have been notorious to everybody that this was impossible, and the Spanish ambassador, Gondomar, warned the king that the Spanishards had settlements on the coast. The king, who was in need of money, replied that if Raleigh was guilty of piracy his fortune was his own. Raleigh got his way, and he obviously knew he could not keep, and sailed on the 17th of March 1617, relying on the chapter of accidents, and on vague intrigues he had entered into in Savoy and France. The expedition, on which the wreck of his fortune was spent, was ill-appointed and ill-managed. It reached the mouth of the Orinoco on the last day of 1617. Raleigh was ill with fever, and remained at Trinidad. He sent five small vessels up the Orinoco under his most trusted captain, Lawrence Keymis, with whom went his son Walter and a nephew. The expedition found a Spanish settlement on the way to the supposed mine, and a fight ensued in which Sir Walter's son and several of his companions were killed. After some days of bush fighting with the Spaniards, and of useless search for the mine, Keymis returned to Sir Walter with the news of his son's death and his own utter ruin. Stung by Raleigh's reproach Keymis killed himself, and then after a miserable scene of recriminations, hesitations and mutiny, the expedition returned home. Raleigh was arrested, and in pursuance of the king's promise to Gondomar was executed under his old sentence on the 29th of October 1618. During his confinement he descended to some unworthy supplications and devices, but when he knew his end to be inevitable he died with sobriety. Walter's mother was a valuable woman; she was the wife of Carew Raleigh. His eminence to Spain made him a popular hero.

AUTHORITIES.—An edition of his Works in eight volumes was published in London in 1829. It contains a Life by Oldys and Birch, written with all the knowledge then available. A Life of Sir Walter Raleigh (London, 1806, 2nd ed.) was much used by Southey in his biography of Sir Walter Raleigh in vol. iv. of The British Admirals in the Cabinet Cyclopaedia (London, 1837). Two biographies appeared simultaneously, Life of Sir Walter Raleigh by J. A. Saint John, and Life of Sir Walter Raleigh by E. Edwards (London, 1866). Mr. Edwards's work is in two volumes, of which the second contains the correspondence, and is still the best authority. Smaller lives, which in some cases contain new matter, are those by E. E. Gardner, Walter Raleigh, in English Workmen (London, 1891), Sir W. Raleigh (London, 1891, and 1899); Martin Hume, Sir Walter Raleigh (London 1897); and H. de Selincourt, Great Raleigh (1908). For special episodes see Sir John Pope Hennessy, Sir Walter Raleigh in Ireland (London, 1883), and T. A. Shaw, Raleghana (Ashburnham, 1896). Two separate editions of Raleigh's poems have been published, Poems, with biography and critical introduction by Sir F. S. Hedges (London, 1817), and Poems of Raleigh with those of Sir H. Wyatt, &c., edited by J. Hannah (London, 1892). S. R. Gardiner made a careful examination of the events of Raleigh's life after 1603 in his History of England from the Accession of James I. to the Outbreak of the Civil War (1889-94). (D. H.)

RALEIGH, the capital of North Carolina, U.S.A., and the county seat of Wake County, about 145 m. by N. by W. of Wil-lington. Pop. (1890) 12,678; (1900) 15,643; of whites 7,453; of negroes; (1910, census) 10,218. Area 4 sq. m. It is served by the Southern, the Seaboard Air Line, the Raleigh & Southport, and the Norfolk Southern railways. The city lies about 360 ft. above sea-level on ground sloping gently in all directions from its centre, where there is a beautiful park of 4 acres known as Union Square, in which is the State Capitol and from which extend four broad streets. On the western border of the city is Pullen Park (about 40 acres), including the campus of the College of Agriculture and Mechanic Arts; it was named in honour of the donor, R. Stanhope Pullen, who was also a benefactor of the college. The State Capitol (1840) is surmounted by a dome and modelled to some extent after the Parthenon and other buildings of ancient Greece; the first Capitol (begun in 1794) was burned in 1831. In the vicinity are the Governor's Mansion, the Supreme Court Build- ing, the State Library, the building of the State Department of Agriculture, housing the State Museum (of geology, mineralogy, agriculture and horticulture, botany, zoology, ethnology, &c.), and the Post Office. Elsewhere are the County Court House, the State Hospital for the Insane (1856), founded through the efforts of Dorothia Lynde Dix, situated on Dix Hill and having in connection with it a colony for epileptics; a state school for white blind, deaf and dumb (1845), and a state institute for negro deaf mutes and blind (1857); the state penitentiary (with a department for the criminal insane); a National Cemetery and the Confederate Soldiers' Home (1891), and the State Central Lunatic Asylum, a Roman Catholic Orphanage, the St Luke's Home for old ladies (1805; under the King's Daughters), a State (Confederate) Soldiers' Home (1891), and three private hospitals and the Rex public hospital (1900). Raleigh is the seat of the North Carolina College of Agriculture and Mechanic Arts (1889), in connexion with which is an agricultural experiment station; of three schools for girls—Peace Institute (Presbyterian, 1857), St Mary's School (Protestant Episcopal, 1842) and Meredith College (Baptist, 1891); of the medical department of the University of North Carolina; and of two schools for negroes—Shaw University (Baptist, 1865), with 530 students in 1908-1909, and St Augustine's School (Protestant Episcopal, 1868), a training school, with 466 students in 1908-1909. In 1908 the State Library (founded 1841) contained 39,000 volumes, the Supreme Court Library (founded 1870) about 17,000 volumes and the Olivia Raney public library (founded 1901) 9250 volumes. The city is the see of a Protestant Episcopal bishop. The principal industrial interests are trade in leaf tobacco and cotton raised in the vicinity, and the manufacture of cotton goods, phosphate fertilizers, foundry and machine-shop products, wooden-ware, &c. The Seaboard Air Line and the Raleigh & Southport railways have repair shops here. In 1905 the factory of the company of J. S. Johnson, a tobacco manufacturer, was valued at $1,086,671, 1447% more than in 1900.

Electric power is controlled by the city, and the Cape Fear river, about 26 m. south of Raleigh, and from Milburnie on the Neuse river, 6 m. distant.

In 1788 the site of the city, then known as Wake Court House, was chosen for the capital of the state; and in 1792 the city was laid out and named in honour of Sir Walter Raleigh. In 1794 the state legislature met here for the first time. Raleigh was incorporated in 1795 and was reincorporated in 1803; its present charter dates from 1890. General William T. Sherman's army, on its march through the Carolinas, passed through the city on the 13th of April 1865. Raleigh was the birthplace of Andrew Johnson, the house in which he was born, now named the Andrew Johnson House, has been removed to Pullen Park. By an extension of its boundaries the city nearly doubled its area and increased its population in 1902.

RALPH (d. 1122), archbishop of Canterbury, called Ralph de Turbeine, or Ralph d'Escures from his father's estate of Escures, near Sées in Normandy, entered the abbey of St Martin at Sées in 1079, and ten years later became abbot of this house. Soon afterwards he paid a visit to England, where his half-brother, Seffrid Polochin, was bishop of Chichester, and in 1100 he took refuge in England from the violence of Robert of Bellême, passing some time with his friends St Anslem and Gundulf. In May 1103 he succeeded Simon de Chadlington of Rochester. After Anslem's death in April 1100 Ralph acted as administrator of the see of Canterbury until April 1114, when he himself was chosen archbishop at Windsor. In this capacity he was very assertive of the rights of the archbishop of Canter-
Ralph de Guader—Rambaud

bury and of the liberties of the English church. He claimed authority in Wales and Scotland, and he refused to consecrate Thurstan as archbishop of York because the latter prelate declined to profess obedience to the archbishop of Canterbury. This step involved him in a quarrel with the Papacy. When he visited Rome, he was unable to obtain an interview with pope Paschal II, who had left the city. In spite of peremptory orders from Paschal's successors, Gelasius II. and Calixtus II., the archbishop still refused to consecrate Thurstan, and the dispute was unsettled when he died on the 20th of October 1122.

RALPH DE GUADER, earl of Norfolk (fl. 1070), was the son of a Norman who had held high positions in East Anglia, perhaps that of earl, in the reign of Edward the Confessor (c. 1055). His son Ralph fought on the Norman side at Hastings, and was made earl of Norfolk by William the Conqueror. In 1075 the king's refusal to sanction his marriage with the heiress of Roger, earl of Hereford, caused him to revolt. They were easily defeated, though Ralph sent to Denmark for ships and went there himself to fetch them. Ralph forfeited his English lands, and took refuge in Brittany on his wife's estate. In 1076, having plotted against Duke Hol of Brittany, he was besieged at Dol, and the Conqueror came to Hol's aid; but Ralph finally made his peace. Both he and his wife took part in the first crusade (1099), and died on the road to Palestine.

RALPH OF COGGESHALL (d. after 1227), English chronicler, was at first a monk and afterwards sixth abbot (1207–1218) of Coggeshall, an Essex foundation of the Cistercian order. Ralph himself tells us these facts; and this his resigning the abbacy was made against the wishes of the brethren, in consequence of his bad health. He took up and continued a Chronicon Anglicanum belonging to his house; the original work begins at 1066, his own share at 1187. He hoped to reach the year 1227, but his autograph copy breaks off three years earlier. Ralph makes no pretensions to be a literary artist. Where he had a written authority before him he was content to reproduce even the phraseology of his original. At other times he strings together in chronological order, without any links of connexion, the anecdotes which he gathered from chance visitors. Unlike Benedictus and Roger of Hoveden, he makes little use of documents; only three letters are quoted in his work. On the other hand, the corrections and emendations of the autograph show that he took pains to verify his details; and his informants are sometimes worthy of exceptional confidence. Thus he vouches Richard's chaplain Anselm for the story of the king's capture by Leopold of Austria. The tone of the chronicle is usually dispassionate; but the original text contained some personal stictures upon Prince John, which are reproduced in Roger of Wendover. The admiration with which Ralph regarded Henry II. is attested by his edition of Ralph Niger's chronicle; here, under the year 1161, he replies to the intemperate criticisms of the original author. On Richard I. the abbot passes a judicious verdict, admitting the great qualities of that king, but arguing that his character degenerated. Towards John alone Ralph is uniformly hostile; as a Cistercian and an adherent of the Mandeville family he could hardly be otherwise. Ralph refers in the Chronicon (s.a. 1091) to a book of visions and miracles which he compiled, but this is no longer extant. He also wrote a continuation of Niger's chronicle, extending from 1162 to 1178 (printed in R. Anstruther's edition of Niger, London, 1854), and short annals from 1066 to 1223.

The autograph manuscript of the Chronicon Anglicanum is to be found at the British Museum (Cotton, Vesuviusian D. X.). The same volume contains the continuation of Ralph Niger. The Chronicon Terrae Sanctae, formerly attributed to Ralph, is by another hand; it was among the sources on which he drew for the Chronicon Anglicanum. Libri de modis anglicis sub regibus Johanne (printed by Martene and Durand, Amplt. Collectio, v. pp. 871–882) is merely an excerpt from the Chronicon Anglicanum. This latter work was edited for the Rolls series in 1893 (H. W. C. D. St Grego).
the principles and organization of scientific study as applied beyond the Rhine, and who were ready to devote themselves to their cherished plan of remodelling higher education in France. He was appointed "rédacteur" at the École des Hautes Études on its foundation in 1868. His researches were at that time directed towards the Byzantine period of the middle ages, and to this period were devoted the two theses which he composed for his doctorate in letters, De byzantino hippocrata et circuminscis factionibus (revised in French for the Revue des Deux Mondes, under the title of "Le monde byzantin; le sport et l'épisode"), (1871), and L'Empire grec au Xe siècle, Constantin Porphyrogène (1870). This latter work is still accepted as a classic, and caused Rambaud to be hailed as a master on the Byzantine period; but with the exception of one article on Digenis Akritas, in the Revue des Deux Mondes (1875), and one other on Michael Psellus, in the Revue historique (vol. iii., 1876), Rambaud's researches were diverted towards other parts of the East. The Franco-German War inspired him with the idea for some courses of lectures which developed into books: La domination française en Allemagne; les Français sur le Rhin, 1702-1804 (1873) and L'Allemagne sous Napoléon I., 1804-1811 (1874). He watched attentively the rôle played by Russia, and soon observed how much to the interest of France, a good entendement with this power would be. He accordingly threw himself into the study of Russian history, staying in Russia in order to learn its language, institutions and customs. On his return, he published La Russe époque, a study of the heroic songs (1876), a short but excellent Histoire de la Russie depuis les origines jusqu'à l'année 1877 (1878; 5th ed., 1900), Français et Russes, Moscou et Stéastopol 1872-1854 (1876; 2nd ed., 1881), and finally the two important volumes on Russian diplomatic history in the Recueil des Instructions données aux ambassadeurs (vols. vii. and ix., 1890 and 1891). He was not immune to the possession of her colonies, seeing in this a lesson for France. He published his Russes et Prussiens, guerre de Sept Ans (1895), a popular work, though based on solid research. After teaching history in the Faculties of Arts at Caen (1871) and Nancy (1873), he was called to the Sorbonne (1883), where he was the first to occupy the chair of contemporary history. By this time he had already entered into politics; he had been chef du cabinet of Jules Ferry (1879-1881), though this did not distract him from his literary work. It was under these conditions that he composed his Histoire de la civilisation française (2 vols., 1885, 1887; 4th ed., 1901) and his Histoire de la civilisation contemporaine en France (1888; new ed. entirely revised, 1906), and undertook the general editorship of the Histoire générale du IVe siècle jusqu'à nos jours. The plan of this great work had been drawn up with the aid of Ernest Lavisse, but the entire supervision of its execution was carried out by Rambaud. He contributed to it himself some interesting chapters on the history of the East, of which he had a thorough knowledge. In 1885 Rambaud published, in collaboration with J. B. Baille, a French translation of J. R. Seeley's Expansion of England, and in the preface he laid great emphasis on the enormous increase of power brought to England by the possession of her colonies, seeing in this a lesson for France. He was anxious to see the rise of a "Greater France," on the model of "Greater Britain," and it was with this idea that he undertook to present to the public a series of essays, written by famous explorers or political men, under the title of La France coloniale, histoire, géographie, commerce (1886; 6th ed., 1893). Having become senator for the department of Doubs (1895-1902), Rambaud held the post of minister of Public Instruction from 1896 to 1898, and in that capacity endeavoured to carry on the educational work of Jules Ferry, to whose memory he always remained faithful. He dedicated to his former chief a book (Jules Ferry, 1903), which is a valuable testimony to the efforts made by France to organize public education and found a colonial empire; but this fidelity also won him some enemies, who succeeded for some time in preventing him from becoming a member of the Institute. He

was finally elected a member of the Académie des Sciences morales et politiques on the 11th of December 1897, in place of the duc d'Aumale, of whose life he wrote an account (vol. xxii., 2nd series, of the Mémoires of this academy). His many interests ended by wearing out even his robust constitution, and he died at Paris on the 10th of November 1905.

RAMBERT, Eugène (1830-1886), Swiss author, was born at Sâles near Swiss Clairsens on the 6th of April 1830, the eldest son of a Vaudois schoolmaster, from whom he received his education. When in 1845 his father lost his post, owing to the religious disputes, Rambert became a teacher in Paris, and later a tutor in England and at Geneva. When the affairs of the family improved, Rambert was able to pursue his studies for the ministry, but he was more attracted by literature, and in 1845 became professor of French literature at the academy of Lausanne, and in 1860 at the Federal polytechnic school at Zürich, where he remained till 1881, when he again became professor at Lausanne. His principal work, Les Alpes suisses (5 vols., 1866-1875; republished with large additions, according to his own scheme, in 6 vols., 1885-1890), is a mine of miscellaneous information on the history of the mountain races and the Alpine mountain-dwelling peoples, as well as a volume entitled Écritsains nationaux (1874, republished 1889), and biographies of the poet Vinet (1875), of the poet Juste Olivier (1870) and of the artist Alexandre Calame (1885). He died on the 21st of November 1886.

Rambert's Dernières Poètes were edited (1903) by Henri Warnery, whose Eugène Rambert (Lausanne, 1890) contains a critical estimate.

(W. A. B. C.)

RAMBOUILLET, CATHERINE DE VIVONNE, Marquise de (1588-1665), a lady famous in the literary history of France, was born in 1588. She was the daughter and heiress of Jean de Vivonne, marquis of Pisani, a member of one of the noble Roman family of Savelli. She was married at twelve years old to Charles d'Angennes, widame of Le Mans, and afterwards marquis of Rambouillet. The young marquise found the coarseness and intrigue that then reigned in the French court little to her taste, and after the birth of her eldest daughter, Julie d'Angennes, in 1607, she began to gather round her the circle afterwards so famous. She established herself at the Hôtel Pisani, called later the Hôtel de Rambouillet, the site of which is close to the Grandes Magasins du Louvre. Mme de Rambouillet took great trouble to arrange her house for purposes of reception, and devised suites of small rooms where visitors could move easily, and could find more privacy than in the large reception rooms of the ordinary house. The hôtel was rebuilt on these lines in 1618. It maintained its importance as a social and literary centre until 1650. Almost all the more remarkable personages in French society and French literature frequented it, especially during the second quarter of the century, when it was at the height of its reputation. There is abundant testimony to Mme de Rambouillet's beauty, though no portrait of her is known to exist. Her success as a hostess was due to many causes. Her natural abilities had been carefully trained, but were not extraordinary. Many people were, however, like herself, disgusted with the intrigues at court, and found the comparative austerity of the Hôtel de Rambouillet a welcome change. The marquise had genuine kindness and a lack of prejudice that enabled her to entertain on the same footing princes and princesses of the blood royal, and men of letters, while among her intimate friends was the beautiful Angélique Pauget. The respect paid to ability in her salon effected a great advancement in the position of French men of letters. Moreover, the almost uniform excellence of the memoirs and letters of 17th-century Frenchmen and Frenchwomen may be traced largely to the development of conversation as a fine art at the Hôtel Rambouillet, and the courteous establishment of a standard of clear and adequate expression. Mme de Rambouillet was known as the "incorparable Arthénice," the name being an anagram for Catherine, devised by Malherbe and Racan.
Among the more noteworthy incidents in the story of the Hôtel are the sonnet war between the Uranistes and the Jobistes—partisans of two famous sonnets by Voiture and Benserade—and the composition by all the famous poets of the day of the Guirlande de Julie, a collection of poems on different flowers, addressed in 1641 to Julie d'Angennes, afterwards duchesse de Montausier. Julie herself was responsible for a good deal of the préciosité for which the Hôtel was later ridiculed. Charles de Sainte Maure, who became in 1604 duc de Montausier, had been wooing her for seven years when he conceived the idea of the famous garland, and she kept him waiting for four years more.

The Précieuses, who are usually associated with Molière's avowed caricatures and with the extravagances of Mlle. de Sévigné, but whose name it must be remembered, Madame de Sévigné herself was fond of, consisted on a ceremonious gallantry from their suitors and friends, though it seems from the account given by Tallemant des Réaux that practical jokes of a mild kind were by no means excluded from the Hôtel de Rambouillet. They especially favoured an elaborate and quizzing kind of colloquial and literary expression, imitated from Marini and Gongora, and then fashionable throughout Europe. The immortal Précieuses ridicules of Molière was no doubt directly levelled not at the Hôtel de Rambouillet itself, but at the numerous coteries which in the course of years had sprung up in imitation of it. But the satire did in truth touch the originators as well as the imitators—his former more closely perhaps than they perceived. The Hôtel de Rambouillet continued open till the death of its mistress, on the 2nd of December 1665, but the troubles of the Fronde diminished its influence.

The chief original authorities respecting Madame de Rambouillet and her set are Tallemant des Réaux in his Historiettes, and Antoine Baudeau de Somaize in his Grand Dictionnaire des Précieuses (1660). Many modern writers have treated the subject, notably Victor Chausson, Les Sociaux en France au XVIIe s. (2 vols., 1886), and C. L. Livet, Précieux et Précieuses (1890). There is an admirable edition (1875) of the Guirlande de Julie by O. Uzanne.

Rambouillet, a town of northern France, capital of an arrondissement in the department of Seine-et-Loire, 30 m. S.W. of Paris on the railway to Chartres. Pop. (1906) town, 3965; commune, 6165. Rambouillet derives its whole interest from the associations connected with the ancient château, dating originally from the 14th century, but often rebuilt. A great machicolated tower is all that remains of the medieval building; some apartments with good woodwork are also of interest. The château is surrounded by a beautiful park of 3000 acres and by an extensive forest. The gardens, partly in French, partly in English style, are picturesque, and have an orangery unique in Europe. The park contains the national sheep-farm, where in the 18th century the first flock of merino sheep in France was raised, a school of sheep-farming, and, close to the latter, a small dairy built by Louis XVI. The shooting of the famous coverts of Rambouillet is reserved for the presidents of the Republic. The town is the seat of a sub-prefect and has a tribunal of first instance and a preparatory infantry school. Trade is in grain, wool, flour and wood. Watch springs are manufactured.

Originally a royal domain, the lands of Rambouillet passed in the 14th century to the D'Angennes family, who held them for three hundred years and built the château. Francis I. died there in 1547; and Charles IX. and Catherine de Medicis found a refuge there in the Wars of Religion, as Henry III. did after them. The title became a marquisate in 1612, at which time it was held by Charles d'Angennes, husband of Catherine de Vivonne (q.v.), the famous marchioness of Rambouillet. Created a duchy and peerage in favour of the duke of Toulouse, son of Louis XIV., Rambouillet was subsequently bought and embellished by Louis XVI., who erected a model farm and other buildings. The place was a hunting-seat of Napoleon I. and Charles X., and it was here that in 1830 the latter signed his abdication.

Rameau, Jean Philippe (1683-1764), French musical theorist and composer, was born at Dijon on the 23rd of October 1683. His musical education, partly in consequence of his father's desire that he should study law, still more through his own wayward disposition, was of a desultory character. In 1701 his father sent him to Milan to break off a foolish love-match. But he learned little in Italy, and soon returned, in company with a wandering theatrical manager, for whom he played the second violin. He next settled in Paris, where he published his Premier livre de pieces de clavecin, in 1706. In 1717 he made an attempt to obtain the appointment of organist at the church of St. Paul. Deeply annoyed at his unexpected failure, he retired for a time to Lille, whence, however, he soon removed to Clermont-Ferrand. Here he succeeded his brother Charles' post as organist of the cathedral.

Burning with desire to remedy the imperfections of his early education, Rameau diligently studied the writings of Zarlin, Descartes, Mersenne, F. Kircher and other theorists. He not only mastered their views but succeeded in demonstrating their weak points and substituting for them a system of his own. His keen insight into the constitution of certain chords, which in early life he had studied only by ear, enabled him to propound a series of hypotheses, many of which are now accepted as established facts. While the older contrapuntists were perfectly satisfied with the laws which regulated the melodious inversion of the vocal and instrumental parts, Rameau demonstrated the possibility of building up a natural harmony upon a fundamental bass, and of using that harmony as an authority for the enactment of whatever laws might be considered necessary for the guidance either of the contrapuntist or the less ambitious general composer. And in this he first explained the distinction between two styles, which have been called the "horizontal and vertical systems," the "horizontal system" being that by which the older contrapuntists regulated the onward motion of their several parts, and the "vertical system" that which constructs an entire passage out of a single harmony. From fundamental harmonies he passed to inverted chords, to which he was the first to call attention; and the value of this discovery fully compensates for his erroneous theory concerning the chords of the eleventh and the great (Angl. "added") sixth (see Harmony).

Rameau first set forth his new theory in his Traité de l'harmonie (Paris, 1722), and followed it up in his Nouveau système (1726), Génération harmonique (1737), Démonstration (1750) and Nouvelles réflexions (1752). But it was not only as a theorist that he became famous. Returning to Paris in 1722 he first attracted attention by composing some light dramatic pieces, and then showed his real powers in his opera, Hippolyte et Aricie, founded on Racine's Phèdre and produced at the Académie in 1733. Though this work was violently opposed by the admirers of Lulli, whose party spirit eventually stirred up the famous "guerre des bouffons," Rameau's genius was too brilliant to be trampled under foot by an ephemeral faction and his ultimate triumph was assured. He afterwards produced more than twenty operas, the most successful of which were Dardanys, Castor et Pollux, Les Indes galantes and La princesse de Navarre. Honours were showered upon him. He was appointed conductor at the Opéra Comique, and the directors of the opera granted him a pension. King Louis XV. appointed him composer to the court in 1755, and in 1764 honoured him with a patent of nobility and the order of St. Michael. But these last privileges were granted only on the eve of his death at Paris on the 12th of September 1764.

See biographies in Charles Poisset (1864), Nisard (1867), Pougin (1876).

Rameses, or Rameses (Gen. xlvii. 11; Exod. xii. 37; Num. xxxii. 3), or, with a slight change in the vowel points, Rameses (Exod. i. 11), the name of a district and town in Lower Egypt, is notable as affording the mainstay of the current theory that King Rameses II. was the pharaoh of the oppression and his successor Menephtah the pharaoh of the exodus. The actual facts, however, hardly justify so large an inference. The
first three c...es of the Hebrews and as much of the gum as possible before the plant has dried. This hand-process is naturally a slow and tedious one, and many decorators have been invented to supplant it. The action of all these decorators is very similar. The ramie stalks are fed into the machine, and during their passage are beaten by 12 to 20 rapidly revolving blades. These break the stalks into small pieces, and leave the bark and fibre in long ribbons. At the same time, part of the gum is squeezed out between the beaters and the anvil. Up to the present, however, these machines have not been very successful. They usually bruise or otherwise injure the fibre, and they do not squeeze out the gum thoroughly. If the gum be allowed to dry on the ribbons it is difficult to remove it, and the chemicals employed in the degumming, if not thoroughly removed by washing, often injure the fibre to such an extent that the ultimate fabric or article is soon decomposed. If, however, the ribbons be degummed immediately, or soon after the plants are cut down, the gum will be much more easily extracted—indeed it might be possible to remove it then by boiling water or steam. The fibre cannot be expected to make much headway until the operations of decorticating and degumming are successfully carried out on or near the growing grounds; and, until a proficient decorticating is made, the fibre should be stripped by hand and the degumming operation begun again. By this means the least possible damage would result to the fibre, no waste material would be shipped, and a clean fibre would be placed on the market.

The fibre possesses some very valuable properties; it is not only much stronger than any other known fibre, but almost equals silk in its brilliance. This latter property, however, is now challenged by mercerized cotton. It successfully resists atmospheric changes, is easily dyed and is affected but little by moisture. On the other hand, articles manufactured from it are

1 From the position of the words it is even not unlikely that "Pithom and Raameses" may be the addition of a redactor, and that the first author of Exod. i. 11 only spoke generally of store-cities.
said to crack and break easily when sharply bent, and on account of their hairy character have not the same smart appearance as those made from flax. Although the fibre is in some cases 12 in. long, it varies considerably in length. This is one of the drawbacks in the preparing and spinning. It is impossible to make perfect yarns from fibres of various lengths; hence it is necessary either to separate the fibres into reasonable groups, or to cut them into satisfactory lengths. The latter method appears, on the whole, to be the better, and it is the method adopted by Messrs Greenwood & Batley Limited, Leeds, who make special machinery for the dressing, preparing and spinning of ramie fibres. If special machinery be employed, the length of the fibre will decide the class of machinery to be used. The fibre has been prepared and spun on flax, wool and silk-waste machinery, but it must be understood that none of these systems are really suitable for the process. A fibre with special characteristics requires special machinery for its manufacture.

When so many different opinions obtain as to which existing machinery is best adapted for the preparing and spinning of ramie, it is not surprising to find that different methods are employed in the manufacture of ramie cloth. In general, we hear that, after decortication, the first process is that of degumming. This is usually done by immersing the fibre in a caustic soda solution, which is then heated in a closed vessel. The fibre is laid on galvanized trays, is soaked in a solution as strong as forty-four can be fitted in a cage, which is then placed inside the boiling keg, the lid of which is screwed down and the necessary pressure of steam admitted. After having been boiled, the fibre is removed and washed with water, the alkali neutralized, and the fibre thoroughly washed to remove all traces of chemicals. The bulk of the water is removed by a hydro-extractor, and the fibre is then hung up or laid on perforated plates to dry.

To facilitate the subsequent processes, the fibre is softened by passing it through a machine fitted with fluted rollers. Then follow the operations of dressing, roving, setting and doubling, and finally the twisted thread is passed rapidly through a gas flame in order to remove all superfluous hairs.

In spite of the many disappointments which have been experienced in connexion with the treatment of this fibre, we are of the opinion that it will ultimately hold a good place amongst commercial fibres. It is at present spun in several European countries, but its use is still very limited. This is due, not to any imperfection of the fibre, but to its price and to the limited supply of raw material. It is at present chiefly used for gas mantles, for which it is particularly well adapted. It has also been used for paper-making, ropes, lines, nets, underwear, and for canvas and several other fabrics. It only a good supply of the fibre could be obtained, there is not the least reason to doubt that manufacturers and machine-makers would quickly provide means for dealing with it. (T. Wo.)

RAMILLIES, a village of Belgium, in the province of Brabant, 15 miles N. by E. of Namur, between the sources of the Little Gheete and of the Mehaigne. It is famous for the victory of the Allies under the duke of Marlborough over the French commanded by Marshal Villeroi on the 22nd/23rd of May 1706. The position of the French on the high ground around Ramillies was marked by the villages of Autregiise (Anderkirch) on the left, Offuz on the left centre, Ramillies on the right centre and Taviers on the right close to the river Mehaigne. In front of the last was a small village, Franchenay, which was held as an advanced post. Between these points d’appui the ground was mostly open upland, and the position as a whole was defective in so far that the villages were barely within cannon-shot of each other. It was particularly strong on the flanks, which were protected by the marshy beds of the Mehaigne and the Little Gheete. Ramillies stands almost on the watershed of these adjacent valleys, and here Marlborough decided to deliver his main attack. The forces were about equal, and were at first equally distributed along the whole line of either party. Marlborough’s local concentration of force at the spot where the attack was to be pressed home was made not before, but after the action had opened (cf. Neerwinden). Villeroi’s left wing of cavalry and infantry was secure—and at the same time immobilized—behind the upper course of the Little Gheete, and the French commander allowed himself to be imposed upon by a demonstration in this quarter, convinced perhaps by the presence of the British contingent that a serious attack was intended. The morning was spent in arraying the lines of battle, and it was about 10 A.M. when the cannonade opened. Soon the first lines of infantry of the Allied centre and left (Dutch) opened the attacks on Franchenay and Taviers and on Ramillies, and, when after a severe struggle Taviers fell into the hands of the Dutch, their commander, Marshal Overkirk, led forward the whole of the left wing cavalry and fiercely engaged the French cavalry opposed to it. The ground was open, both parties had placed the greater part of their horse on this side, and it was only after a severe and prolonged engagement (in which Marlborough himself took part like a trooper and was himself wounded, and the Allies were definitely victorious, thanks to the arrival of a force of cavalry brought over from the Allied right wing. Meanwhile the principal attack on Ramillies had been successfully pressed home, the necessary concentration of force being secured by secretly and skillfully withdrawing some British battalions from the right wing. While Villeroi was trying to bring up supports from the left to take part in the cavalry battle, the French in Ramillies were driven out into the open, where the Allied cavalry, having now gained the upper hand, rode down many battalions. Most of the French cavalry from the other wing, having to force its way through the baggage trains of the army (these had been placed too near the fighting lines), arrived too late, and once Ramillies had fallen the whole line of the Allies gradually took up the offensive. It was not long before the French line was rolled up from right to left, and the retreat of the French was only effected in considerable confusion. Then followed for once a relentless pursuit, carried on by the British cavalry (which had scarcely been engaged) to Louvain, 20 m. from the field of battle. Marlborough’s unequalled tactical skill and judgment thus sufficed not merely to win the battle, but to win it with so large a margin of force unexceeded that the fruits of his victory could be gathered. The French army lost, in killed, wounded and missing, some 15,000 men, the Allies (amongst whom the Dutch had borne the brunt of the fighting) scarcely one-third as many.

RAMLER, KARL WILHELM (1725-1798), German poet, was born at Kolberg on the 25th of February 1725. After completing his studies in Halle, he went to Berlin, where, in 1748, he was appointed professor of logic and literature at the cadet school. In 1786 he became associated with the author, Johann Jakob Engel, in the management of the royal theatre, of which, after resigning his professorship, he became (1790-96) sole director. He died at Berlin on the 11th of April 1798. Ramler was a child of the Enlightenment but yet remained a conservative, for he always spoke of the age of reason. This conservative side of his nature he enjoyed as poet and critic is mainly due to his skill in imitating and reproducing in German, classical (mostly Horatian) metrical forms; and he had a reputation, not unfounded, of correcting his friends’ writings out of recognition. His Tod Jesu, a cantata, is well known owing to its musical setting by Karl Heinrich Graun.

Ramler published Geistliche Cantaten (1760) and Öden (1767). A collection of his works was published by L. F. G. von Göckingk (2 vols., 1800-1801). See also Heinsius, Versuch einer biographischen Skizze Ramlers (1798); and K. Schüttelkopf, Karl Wilhelm Ramler, bis zu seiner Verbindung mit Lessing (1886).

RAMMBERG, KARL FRIDRICH AUGUST (1813–1890), German mineralogist, was born at Berlin on the 1st of April 1813. He was educated for the medical profession and graduated in 1837 at Berlin University. In 1841 he became privatdozent in the university, and in 1845 professor extraordinary of chemistry. This post he relinquished in 1851 to take the chair of chemistry and mineralogy at the Royal Industrial Institute. In 1874 he was appointed professor of inorganic chemistry, and director of the second chemical laboratory at Berlin. Distinguished for his researches on mineralogy, crystallography and analytical chemistry, he laboured also at metallurgy, and yet found time for a series of important textbooks, in which his learning and sound judgment were combined with a lucid and accurate statement of facts. He was author of Handwörterbuch des chemischen Teils der Mineralogie (2 vols., 1841; suppl. 1843-53); Lehrbuch der chemischen
METALLURGIE (1830); Handbuch der Krystallographischen Chemie (1855); Handbuch der Mineralchemie (1860); Handbuch der Krystallographisch-Physikalischen Chemie (2 vols., 1881-82), some of the earlier works being incorporated in later and more comprehensive volumes with different titles. He died at Gross-Lichterfelde, near Berlin, on the 28th of December 1899.

RAM MOHAN ROY (1774-1833), Indian religious reformer, and founder of the Brahmo Samaj (q.v.) or Theistic Church, was born at Radhanagar, in the district of Hugli, Bengal, in May 1774. He was the son of a small landowner, and in his early life acquired a knowledge of Persian, Arabic and Sanskrit, besides his own vernacular, Bengali. At the age of sixteen he first assailed idolatry in his Bengali work, entitled The Idolatrous Religious System of the Hindus. This gave offence to his orthodox father, and Ram Mohan left home and spent some years in travel. At the age of twenty-two he began his study of the English language, and he also acquired a knowledge of other modern and ancient European languages. On the death of his father he obtained an appointment under the British government in 1800, from which he retired in 1814, settled down in Calcutta, and devoted himself to religious reform. He had already in 1807 issued a circular for the destruction of idol worship, and published a striking book in Persian called Tuhfat-ul-Mawakhidin ("A Gift to Monotheists"). On his settlement in Calcutta he established a little friendly society (Atmiya Sabha), which met weekly to read the Hindu scriptures and to chant monothestic hymns. In 1820 he issued a selection from the Christian Gospels entitled The Precepts of Jesus the Guide to Peace and Happiness. He also wrote Bengali works on the Vedanta philosophy, translated some of the Upanishads, entered into controversies with Christian missionaries, and on the 23rd of January 1830 definitely established the Brahmo Samaj "for the worship and adoration of the Eternal, Unsearchable, Immutable Being who is the Author and Preserver of the Universe." He gave his support to the governor-general, Lord William Bentinck, for the abolition of the suttee rite, i.e. the custom of permitting Hindu widows to burn themselves on the funeral pyre of their husbands. He also worked hard to spread education among his fellow-countrymen, and to improve the quality and the prestige of the native press. In 1830 the emperor of Delhi bestowed on Ram Mohan the title of raja, and sent him to England as his agent. Raja Ram Mohan Roy gave his evidence before the Select Committee of the House of Commons on the judicial and revenue systems of India. He presented petitions to the House of Commons in support of the abolition of the suttee rite, and had the satisfaction of being present in the House when the appeal against such abolition was rejected on the 11th of July 1832. As the first educated and eminent Indian who had come to England, he received a cordial welcome from learned men; and Bentham addressed him as an "intensely admired and dearly beloved collaborator in the service of mankind." Ram Mohan also visited France and contemplated a voyage to America, but a sudden attack of brain fever led to his death on the 27th of September 1833. He was buried at Bristol, where a tomb was erected by his friend Dwarkanath Tagore.

RAMAD, a town of British India, in the Madura district of Madras, at the base of the spit of land that projects towards the island of Pamban in Palk strait. Pop. (1901) 14,426. It is the residence of a raja of old family, head of the Maravar caste, whose title is setapathi, or lord of Adam's Bridge. The estate covers an area of 2104 sq. m., and pays a permanent land revenue of £25,000. It is a desolate and generally unfertile tract, traversed by the South Indian railway.

RANNICU SARAT (Rammuccio Sarto), the capital of the department of Rannicu Sarat, Rumania; on the railway from Buzau to Focshani, and on the left bank of the Rămnicu, a tributary of the Sereth. Pop. (1900) 13,134, about 1000 being Jews. The town rises from a marshy plain, east of the Carpathians, and west of the cornlands of southern Moldavia. Salt and petroleum are worked in the mountains, and there is a considerable trade in agricultural produce and preserved meat. Rămnicu Sarat was the scene of battles between the Moldavians and the Walachians in 1434 and 1573, and between the Walachians and Turks in 1634. Here also, in 1789, an Austro-Russian army defeated the Turks. In 1854 the town was almost destroyed by fire and was rebuilt.

RANNICUVALCEA (Rammuccio Valcea), or Rymnik, an episcopal city and the capital of the department of Valce, Rumania; situated at the foot of the Carpathians, on the right bank of the river Olt, and on the railway from Caracal to Hermannstadt in Transylvania. Pop. (1900) 7317. Three monasteries Unite the Valce department, those of Bistrita, Cozia and Horuez, are among the finest in Walachia. Besides wine, fruit, grain and timber, the surrounding uplands yield petroleum and salt. Within a few miles are the thermal springs of Olanezti and the salt mines of Ocnele Mari. The city is said to be the ancient Castra Traiani, and many traces of old encampments bear evidence of this.

RAMPOLLA, COUNT MARIANO DEL TINDARO (1843-1919), Italian cardinal, was born on the 17th of August 1843, at Pouzilz, in the Sicilian diocese of Cefalú. Having completed his studies in the Capranica College at Rome, and having been consecrated a priest in the Church of San Giovanni Laterano by Cardinal Sarto, at the age of thirty-four, Cardinal Rampolla was appointed by Pius IX. to the papal nunciature at Madrid. Two years later he was recalled to Rome and appointed secretary of the Propaganda for Eastern Affairs, and for Extraordinary Ecclesiastical Affairs. Consecrated titular archbishop of Hercules in 1885, he returned to Madrid as nuncio, but was shortly afterwards created cardinal and appointed to the papal secretariaship of state. New to the Sacred College and free from traditional preconceptions, he was admirably fitted to carry out the papal policy under Leo XIII. (see Papacy). Rightly or wrongly, he was held personally responsible for the opponents of the governments of France and Russia and the opposition to the Powers of the Triple Alliance; and this attitude had its effect on his career when Leo XIII. died. Rampolla was undoubtedly the favourite among the papabili cardinals; but the veto of Austria was interposed (see Conclave), and the votes of the Sacred College fell to Cardinal Sarto, who on the 4th of August 1903 became pope as Pius X. Cardinal Rampolla at once resigned his office as secretary of state, being succeeded by Cardinal Merry del Val, and ceased to play any conspicuous part in the Curia.

RAMPUR, a native state of India, in subdivision to the government of the North-West Provinces. It lies in Rohilkhand, between the British districts of Moradabad and Elphinston. Area, 893 sq. m. The country is level and generally fertile; being watered in the north by the rivers Kosi and Nahul, and in the south by the Ramganga. The chief crops are maize, rice and sugar cane. Pop. (1901) 533,212, showing a decrease of 3.5% in the decade. Estimated revenue, £2,244,000; military force, 25,506 men, including two squadrons of Imperial Service lancers. The chief, whose title is nawab, is a Rohilla Pathan, representing the family which established their power over this part of the country in the 18th century. When the Rohillas were subjugated by the nawab of Oudh, with the assistance of a force led by Warren Hastings, one of their number, Faiz-ullah Khan, from whom the present nawab traces his descent, was permitted to retain possession of Rampur. During the Mutiny of 1857 the nawab of Rampur rendered important services to the British, for which he received a grant of land assessed at £5000 in perpetuity, besides other honours. The state is crossed by the main line of the Oudh & Rohilkhand railway from Bareilly to Moradabad. The town of Rampur is on the left bank of the river Kosi, 620 ft. above the sea, with a railway station 39 m. N.W. of Bareilly, Pop. (1901) 78,578. There are manufactures of damask, pottery, sword-blades and sugar. It is partially fortified and is protected by the outer ramparts of bamboo hedge, which formed a strong defence. In addition to a modern fort and several fine buildings, it contains an Arabic college, which attracts students from all parts of India.

There are two other towns in India called Rampur, one
of which, the capital of the state of Basbarh in the Punjab, has given its name to the fine woolen shaws, widely known as Rampur chadors.

RAMPUR BOALIA, or BEULAH, a town of British India, the administrative headquarters of Rajahshahi district in Eastern Bengal and Assam; on the left bank of the Ganges. Pop. (1901) 23,580. It was originally chosen as a commercial factory for the silk trade, which is again being officially encouraged by the agricultural department. The town contains a government college, and an industrial school for sericulture. Most of the public buildings were severely damaged by the earthquake of the 12th of June 1897. There is a daily steamer service on the Ganges.

RAMSAY, ALLAN (1686-1738), Scottish poet, was born at Leadhills, Lanarkshire, on the 15th of October 1686. He was educated at the parish school of Crawford, and in 1701 was apprenticed to a wig-maker in Edinburgh. He married Christian Ross in 1712; a few years after he had established himself as a wig-maker (not as a barber, as has been often said) in the High Street, and soon found himself in comfortable circumstances. His first efforts in verse-making were inspired by the meetings of the Easy Club (founded in 1712), of which he was an original member; and in 1715 he became the Club Laureate. In the society of the members he assumed the name of "Isaac Bickerstaff," and later of "Gawin Douglas," the latter partly in memory of his maternal grandfather Douglas of Muthill (Perthshire), and partly to give point to his boast that he was a "poet sprung from a Douglas loin." The choice of the two names has some significance, when we consider his later literary life as the associate of the Queen Anne poets and as a collector of old Scots poetry. By 1718 he had made some reputation as a writer of occasional verse, which he published in broadsheets, and then (or a year earlier) he turned bookseller in the premises where he had hitherto plied his craft of wig-making. In 1716 he had published a rough transcript of Christ's Kirk on the Green from the Bannatyne MS., with some additions of his own. In 1728 he republished the piece with more supplementary verses. In the following year he printed a collection of Scots Songs. The success of these ventures prompted him to collect his poems in 1722. The volume was issued by subscription, and brought in the sum of four hundred guineas. Four years later he removed to another shop, in the north of the town, which had his name written over it, containing the collection of the Easy Club, and extended his business as a bookseller. Between the publication of the collected edition of his poems and his settling down in the Luckenbooths, he had published a few shorter poems and had issued the first instalments of The Tea-Table Miscellany and The Ever Green (both 1724-1727). The Tea-Table Miscellany is "A Collection of Choice Songs Scots and English," containing some of Ramsay's own, some by his friends, several well-known ballads and songs, and some Caroline verse. Its title was suggested by the programme of the Spectator: and the compiler claimed the place for his songs "even while the tea's fill'd reeking round," which Addison sought for his operations at the hour set aside for "coff," tea and bread and butter." In The Ever Green, being a Collection of Scots Poems wrote by the Ingenious before 1600, Ramsay had another purpose, to awaken interest in the older national literature. Nearly all the pieces were taken from the Bannatyne MS., though they are by no means verbatim copies. They included his version of Christ's Kirk (u.s.) and a remarkable pastiche by the editor entitled the Vision. While engaged on these two series, he produced, in 1725, his dramatic pastoral The Gentle Shepherd. In the volume of poetry published in 1727 Ramsay had shown his bent to this genre, especially in "Patie and Roger," which supplies two of the dramatis personae to his greater work. The success of the drama was remarkable. It passed through several editions, and was performed at the theatre in Edinburgh; its title is still known in every corner of Scotland, even if it be no longer read. Ramsay wrote little afterwards, though he published a few shorter poems, and new editions of his earlier work. A complete edition of his Poems appeared in London in 1731 and in Dublin in 1733. With a touch of vanity he expressed the fear lest "the coolness of fancy that attends advanced years should make me risk the reputation I had acquired." He was already on terms of intimacy with the leading men of letters in Scotland and England. He corresponded with Hamilton of Bangour (q.v.), Somerville (q.v.), Gay (q.v.) and Pope. Gay visited him in Edinburgh, and Pope praised his pastoral—compliments which were undoubtedly responsible for some of Ramsay's unhappy poetic ventures beyond his Scots vernacular. The poet had for many years been a warm supporter of the stage. Some of his prologues and epilogues were written for the London theatres. In 1736 he set about the erection of a new theatre, "at vast expense," in Carrubber's Close, Edinburgh; but the opposition was too strong, and the new house was closed in 1737. In 1755 he retired from his shop to the house on the slope of the Castle Rock, still known as Ramsay Lodge. In this house, called by his friends "the goose-pie," because of its octagonal shape, the poet died on the 7th of January 1758.

Ramsay's importance in literary history is twofold. As a pastoral writer ("in some respects the best in the world," according to Leigh Hunt) he contributed, at an early stage, to the naturalistic reaction of the 18th century. His Gentle Shepherd, by its directness of impression and its appreciation of country life, anticipates the attitude of the school which broke with neo-classical tradition. It has the "mixed" faults which make the greater poem of his Scots successor, Thomson, a "transitional" document, but these give it an historical, if not an individual, interest. His chief place is, however, as an editor. He is the connecting-link between the greater "Makars" of the 17th and 18th centuries, and Ferguson (q.v.) and Burns. He revived the interest in vernacular literature, and directly inspired the genius of his greater successors. The preface to his Ever Green is a protest against "imported trimming" and "foreign embroidery in our writings," and a plea for a return to simple Scottish tradition. He had no scholarly interest in the past, and he never hesitated to transform the texts when he could give contemporary "point" to a poem; but his instinct was good, and he did much to stimulate an ignorant public to fresh enjoyment. In this respect, too, he anticipates the reaction in England which followed securely on the heels of Ramsay's Religious Interests, which appeared in 1781. The Tea-Table Miscellany was reprinted in 1871 (2 vols., Glasgow; John Crum); The Ever Green in 1875 (2 vols., Glasgow; Robert Forrester); The Poems of Allan Ramsay in 1877 (2 vols., Paisley; Alex. Gardner). These volumes are uniform in size and binding, and reprinted by publishers, and have been published in many editions. A selection of his poems appeared in 1887 (1 vol. 10mo, London; Walter Scott). There are many popular reprints of The Gentle Shepherd. (G. G. S.)

RAMSAY, ALLAN (1713-1784), Scotch portrait-painter, the eldest son of the author of The Gentle Shepherd, was born at Edinburgh in 1713. Ramsay manifested an aptitude for art from an early period, and at the age of twenty we find him in London studying under the Swedish painter Hans Huysaing, and at the St. Martin's Lane Academy. A selection of his portraits appeared in 1887 (1 vol. 10mo, London; Walter Scott). There is no portrait of Ramsay of Culloden and his full-length of the duke of Argyll, he removed to London, where he was patronized by the duke of Bridgewater. His pleasant manners and varied culture, not less than his artistic skill, contributed to render him popular. In 1767 he was appointed to succeed Shelakon as principal painter to the king; and so fully employed was he on the royal portraits which the king's in the habit of venturing to ambassadors and colonial governors, that he was forced to take advantage of the services of a host of assistants—of whom David Martin and Philip Reinagle are the best known. His life in London was varied by frequent visits to Italy, where he occupied himself more in literary and antiquarian research than with art. But this prosperous career came to an end, his health being shattered by an accidental dislocation of the
RAMSAY, SIR A. C.—RAMSAY, R. 879

right arm. With unflinching pertinacity he struggled till he had completed a likeness of the King upon which he was engaged. He presented it to his patron, leaving behind him a series of fifty royal portraits to be completed by his assistant Reinagle. For several years he lingered in the south, his constitution finally broken. He died at Dover on the 10th of August 1784.

Among his most satisfactory productions are some of his earlier ones, such as the full-length of the duke of Argyll, and the numerous bust-portraits of Scottish gentlemen and their ladies which he executed before settling in London. They are full of both grace and individuality; the features show excellent draughtsmanship; and the flesh-painting is firm and sound in method, though often tending to a little flatness or opacity. His full-length of Lady Mary Coke is remarkable for the skill and delicacy with which the white satin drapery is managed; while in the portrait of his brown-eyed wife, the eldest daughter of Sir Alexander Lindsay of Evelick, in the Scottish National Gallery, we have a sweetness and tenderness which shows the painter at his highest. This last-named work shows the influence of French art, an influence which helped greatly to form the practice of Ramsay, and which is even more clearly visible in the large collection of his sketches in the possession of the Royal Scottish Academy and the Trustees, Edinburgh.

RAMSAY, SIR ANDREW GROMBIE (1814-1891), British geologist, was born at Glasgow on the 31st of January 1814, being the son of William Ramsay, manufacturing chemist. He was for a time actually engaged in business, but from spending his holidays in Arran he became interested in the study of the rocks of that island, and was thus led to acquire the rudiments of geology. A geological model of Arran, made by him on the scale of two inches to the mile, was exhibited at the meeting of the British Association at Glasgow in 1840, and attracted the notice of Sir R. I. Murchison, with the result that he received from De la Beche an appointment on the Geological Survey, on which he served from 1840 to 1843. He was first stationed at Tenby, and to that circumstance may be attributed the fact that so much of his geological work dealt with Wales. His first book, The Geology of the Isle of Arran, was published in 1841. In 1845 he became local director for Great Britain, but he continued to carry on a certain amount of field-work until 1854. To the first volume of the Memoirs of the Geological Survey (1846) he contributed a now classic essay, "On the Denudation of South Wales and the Adjacent Counties of England," in which he advocated the power of the sea to form great plains of denudation, although at the time he underestimated the influence of subaerial agents in sculpturing the scenery. In 1866 he published The Geology of North Wales (vol. iii. of the Memoirs), of which a second edition was published in 1881. He was chosen professor of geology at University College, London, in 1848, and afterwards lecturer in the same subject at the School of Mines in 1852. Eleven years later he was elected to the presidential chair of the Geological Society, and in 1872 he succeeded Murchison as director-general of the Geological Survey. In 1880 he acted as president of the British Association at Swansea, and in the following year retired from the public service, receiving at the same time the honour of knighthood. In 1866 he published a little book entitled The Old Glaciers of Switzerland and North Wales. The study of this subject led him to discuss the Glacial Origin of Certain Lakes in Switzerland, the Black Forest, &c. He dealt also with the origin of The Red Rocks of England (1871) and The River Courses of England and Wales (1872). He was especially interested in tracing out the causes which have determined the physical configuration of a district, and he devoted much attention to the effects produced by ice, his name being identified with the hypothesis, which, however, has never commanded general assent, that in some cases lake basins had resulted from the pressure of glaciers. A master in the broadest questions of stratigraphy and physical geology, he was a clear exponent of facts, but rather impatient of details, while his original and often bold theories, expressed both in lectures and in writings, stirred others with enthusiasm and undeniably exercised great influence on the progress of geology. His lectures to working men, given in 1863 in the Museum of Practical Geology, formed the nucleus of his famous Physical Geology and Geography of Great Britain (5th ed., 1875; 6th ed., by H. B. Woodward, 1894). He received a Royal medal in 1886 from the Royal Society, of which he became a fellow in 1862; he was also the recipient of the Neil prize of the Royal Society of Edinburgh in 1866, and of the Wollaston medal of the Geological Society of London in 1871. He died at Beaumaris on the 9th of December 1891.

See Memoir, by Sir A. Geikie, 1893.

RAMSAY, ANDREW MICHAEL (1686-1743), French writer, of Scottish birth, commonly called the "Chevalier Ramsay," was born at Ayr on the 9th of January 1686. Ramsay served with the English auxiliaries in the Netherlands, and in 1710 visited Fénélon, who converted him to Roman Catholicism. He remained in France until 1724, when he was sent to Rome as tutor to the Stuart princes, Charles Edward and Henry, the future cardinal of York. He was driven by intrigue from this post, and returned to Paris. He was in England in 1730, and received an honorary degree from the university of Oxford. The claim was nominally his discipleship to Fénélon, but in reality beyond that he was connected with the Jacobite party. He died at St Germain-en-Laye (Seine-et-Oise) on the 6th of May 1743.

Ramsay's principal work was Les voyages de Cyrus (London, 1728; Paris, 1727), a book composed in avowed imitation of Télémaque. He also edited Télémaque itself (Paris, 2 vols., 1717) with an introduction, and wrote a Histoire de la vie et des ouvrages de Fénélon (The Hague, 1723), besides a partial biography (Paris, 1735) of Turenne, some poems (Edinburgh, 1728) in English, and other miscellaneous works.

RAMSAY, DAVID (1749-1815), American physician and historian, the son of an Irish emigrant, was born in Lancaster county, Pennsylvania, on the 2nd of April 1749. He graduated from the University of Pennsylvania in 1773, and then settled as a physician at Charleston, South Carolina, where he had a large practice. During the War of Independence he served as a field-surgeon (1780-1781), and from 1776 to 1783 he was a member of the South Carolina legislature. Having acted as one of the "council of safety" at Charleston, he was, on the capture of that city in 1780, seized by the British as a hostage, and for nearly a year was kept in confinement at St Augustine. From 1782 to 1786 he served in the Continental Congress, and from 1801 to 1815 in the state Senate, of which he was long president. In 1785 he published in two volumes History of the Revolution of South Carolina, in 1789 in two volumes History of the American Revolution, in 1807 a Life of Washington, and in 1809 in two volumes a History of South Carolina. He was also the author of several minor works. He died at Charleston on the 8th of May 1815 from a wound inflicted by a lunatic. His History of the United States in 3 vols. was published posthumously in 1816-1817, and forms the first three volumes of his Universal History Americanized, published in 12 vols. in 1819.

RAMSAY, ROBERT (1842-1882), Australian statesman, was a native of Hawick, Roxburghshire, but his parents emigrated to Victoria when he was a child of four, and he was educated at the Scottish college in Melbourne. He studied law at Melbourne University, and subsequently became a member of a well-known firm of solicitors in the city. He married in 1868 Isabella Catherine Urquhart, and in 1870 entered the assembly for East Bourke in the Conservative and free trade interest. He was a member of the government of James Goodall Francis in 1872-74. He was subsequently postmaster-general (1874-75) in the administration of George Biscoe Kerferd; he held the same office in conjunction with the ministry of education (1875-77) under Sir James M'Culloch; and for a short term in 1880 he was chief secretary and minister of education in the first administration of James Service. He died on the 23rd of May 1882.
RAMSAY, SIR WILLIAM (1832–1916), British chemist, nephew of Sir A. C. Ramsay, was born at Glasgow on the 2nd of October 1832. From 1856 to 1870 he studied in his native city, and then went to work under R. Fittig at Tübingen. Returning to Glasgow in 1872 he became assistant in the Young laboratory of technical chemistry at Anderson's College, and from 1874 acted as tutorial assistant in chemistry at the university. In 1880 he was appointed to the chair of chemistry at University College, Bristol, becoming principal in the following year, and in 1887 he succeeded A. W. Williamson as professor of chemistry at University College, London. His earlier work was mainly concerned with organic chemistry, and he published researches on picric acid and its derivatives in 1876–78 on his appointment to the chair of organic chemistry. His most notable work was his study of the properties of the gaseous halogens which till that time had only been known on spectroscopic evidence as existing in the sun. In 1888 his work with Morris William Travers (b. 1872), who from 1894 had assisted him at University College, London, and in 1903 was appointed professor of chemistry at University College, Bristol, enabled him to announce the existence in the atmosphere of three new gases, neon, krypton and xenon. Turning to the study of radioactivity, he noticed its association with the minerals which yield helium, and in support of the hypothesis that that gas is a disintegration-product of radium he proved in 1903 that it is continuously formed by the latter substance in quantities sufficiently great to be directly recognizable. Among his important works is the book "Atoms and Atoms," by Sir William Ramsay, who was created K.C.B. in 1902, are A System of Chemistry, 1891, The Gases of the Atmosphere, 1896, and Modern Chemistry, vol. i. Theoretical, vol. ii. Systematic, 1901, and he edited a series of "Textbooks of Physical Chemistry."

RAMSAY, SIR WILLIAM MIDDLETON (1832–1916), British archaeologist, was born on the 15th of March 1832. He was educated at the universities of Aberdeen, Oxford and Gottingen, and was a fellow of Exeter College, Oxford (1853; honorary fellow 1858), and Lincoln College (1855; honorary 1859). In 1855 he was elected professor of classical art at Oxford, and in the next year professor of humanity at Aberdeen. From 1880 onwards he travelled widely in Asia Minor and rapidly became the recognized authority on all matters relating to the districts associated with St Paul's missionary journeys and Christianity in the early Roman Empire. He received the honorary degrees of D.C.L. Oxford, LL.D. St Andrews and Glasgow, D.D. Edinburgh, and was knighted in 1906. He was elected a member of learned societies in Europe and America, and has been awarded medals by the Royal Geographical Society, the Royal Scottish Geographical Society and the University of Pennsylvania. His numerous publications include: The Historical Geography of Asia Minor (1860); The Church in the Roman Empire (1851); The Cities and Bishops of Phrygia (2 vols., 1895, 1897); St Paul the Traveller and the Roman Citizen (1895; Germ. trans., 1898); Impressions of Turkey (1897); Was Christ born at Bethlehem? (1898); Historical Commentary on Galatians (1899); The Education of Christ (1902); The Letters to the Seven Churches of Asia (1903); Pauline and other Studies in Early Christian History (1906); Studies in the History and Art of the Eastern Provinces of the Roman Empire (1906); The Cities of St Paul (1907); Lucan and Pauline Studies (1908); The Thousand and One Churches (with Miss Gertrude L. Bell, 1909); and articles in learned periodicals and the 9th and 11th editions of the Encyclopaedia Britannica. His wife, Lady Ramsay, granddaughter of Dr Andrew Marshall of Kirkintilloch, accompanied him in many of his journeys and is the author of Everyday Life in Turkey (1897) and The Romance of Elisabet (1899).

RAMSBOTTOM, an urban district in the Heywood parliamentary division of Lancashire, England, 4 m. N. of Bury, on the Lancaster & Yorkshire railway. Pop. (1901) 15,920. It has iron and brass foundries, machine factories and textile establishments.

RAMSDEN, JESSE (1735-1800), English astronomical instrument maker, was born at Salterhebble near Halifax, Yorkshire, on the 6th of October 1735. After serving his apprenticeship with a cloth-worker in Halifax, he went in 1755 to London, where in 1758 he was apprenticed to a mathematician. In 1768 he removed to a new house and started business on his own account and secured a great reputation with his products. He died at Brighton on the 5th of November 1800. Ramsden's specialty was divided circles, which began to supersede the quadrants in observatories towards the end of the 18th century. His most celebrated work was a 5-feet vertical circle, which was finished in 1789 and was used by G. Piazza at Palermo in constructing his well-known catalogue of stars. He was the first to carry out in practice a method of reading off angles (first suggested in 1768 by the duke of Chaulnes) by measuring the distance of the eye from the central division line by the aid of a micrometer screw which moves one or two fine threads placed in the focus of a microscope. Ramsden's transit instruments were the first which were illuminated through the hollow axis; the idea was suggested to him by Prof. Henry Ussher in Dublin. He published a Description of an Engine for dividing Mathematical Instruments in 1777.

RAMSEY, a market-town in the Northern or Ramsey parliamentary division of Huntingdonshire, England, on the south-western border of the Fen country, on branch lines of the Great Northern and the Great Eastern railways, 13 m. S.S.E. of Peterborough. Pop. (1901) 4,873. The abbey church of St Thomas à Becket is transitional between Norman and Early English, and has a beautiful Norman east end. The tower was built in 1672 of stone from Ramsey Abbey. An old oak lectern, dating from the middle of the 15th century, carries a chained copy, in a Tudor binding of brass, of Dean Comber's (1655-99) book on the Common Prayer, and a black-letter copy of Erasmus's Paraphrase of the Gospels. There are many interesting tombs in the churchyard, and the church register contains several entries relating to the Cromwell family, who removed hither from Huntingdon and owned the abbey estates till 1674. Of the ancient Benedictine abbey, the only remains are a part of a gateway, a lodge (a beautiful Perpendicular relic) and some butresses, while some broken stone arches and walls remain of the conventual buildings. The modern mansion of Ramsey Abbey contains many documentary relics of the abbey, as well as an early monument representing the founder.

According to a 12th-century chronicle of one of the monks, the name Ramsey is derived from the words "ram," referring to the tradition of a solitary ram having taken up its abode here, and "ey" meaning an island. Ramsey, however, was not completely insulated, like some of the monasteries of the Fen district. The abbey was founded by Ailwin, Earl of the East Angles, in 969, and a charter of King Edgar granted lands and privileges for the purpose. Ramsey Abbey was noted for the school established within its walls, and for its library of Hebrew works. Its abbot was mitred. The lands were granted after the dissolution to Sir Richard Cromwell.

RAMSEY, a seaport and watering-place on the north-east coast of the Isle of Man, 15 m. N.N.E. of Douglas. Pop. (1901) 4,720. It lies on the wide Ramsey Bay, at the mouth of the Sulby river, the estuary of which forms a small harbour. To the north and west the country is flat, but to the south the lower slopes of the North Ballure hill rise sharply. A creek of the Sulby river on the north side of the town is formed into a picturesque lake. The Queen's pier permits of the landing of passengers at all times, and Ramsey is served by
frequent steamers from Liverpool and other ports. The shore of the bay is sandy and gently sloping, and excellent bathing is afforded. A golf links, a geological and antiquarian museum, the Mooragh Park by the side of the lake, and the palace or concert hall, are among the attractions to visitors. Ramsgate is connected with Lydd by the summit of Snaefell, and Douglas by electric tramway, and has connexion with the western part of the island by the Manx Northern railway. The Albert tower, on a wooded hill above the town, commemorating a visit of the Prince Consort in 1847, is a favourite view-point. The harbour has some coasting and fishing trade.

**Ramsgate**—**Ramus**

Ramsgate, a municipal borough, watering-place, seaport and member of the Cinque Port of Sandwich, in the Isle of Thanet parliamentary division of Kent, England, 70 m. E. by S. of London by the South Eastern & Chatham railway. Pop. (1901) 27,733. This is one of the most popular resorts on the Kent coast, well situated on the east coast of Thanet, practically contiguous with Broadstairs to the north, with which and Margate to the north-west it is united by an electric tramway. During the season steamers connect it with London and the intermediate watering-places on the north coast, and with Calais and Boulogne. The harbour has an area of 42 acres, and a considerable coasting and fishing trade is carried on. There is a fine sea front, and the beach is of firm sand. The promenade pier was erected in 1881. Near it an obelisk commemorates the departure of George IV. to Hanover from here, and the return of the Emperor of Russia. The Church of St George was built in 1826, its tower forming a conspicuous landmark, and the Roman Catholic church of St Augustine was built from the designs and at the expense of A. W. Pugin, who was a lifelong resident here. The neighbouring Pegwell Bay, famed for its shrimps, is supposed to have been the scene of the landing of Hengist and Horsa, and at Clifft's End (Ebbsfleet) a monolithic cross marks the landing-place of St Augustine in 596. On the summit of Osengall Hill, about a mile to the west of the town, a graveyard of early Saxon settlers was discovered during the cutting of the railway. The remains proved it to belong to the 6th and 7th centuries. Ramsgate was incorporated in 1884, and is governed by a mayor, 6 aldermen and 18 councillors. Area, 2304 acres.

Ramsgate (Ramesgates) was originally a small but comparatively prosperous place united until 1827 to the parish of St Lawrence. The charter of Charles II. mentions it as having been "time out of mind" a member of Sandwich. In 1884 it was incorporated by royal charter, under the title of mayor, aldermen and councillors. A commission of the peace was granted in 1803. Since then the jurisdiction of the Cinque Ports' justices has ceased within its limits, which include the borough of Ramsgate, but not its parishes. The town is the site of a daily market obtained in 1784 by grant from George III. No fair was then held, but from 1792 onwards there has been one yearly on the 10th of August. Under Elizabeth, Ramsgate was still unimportant though possessed of a fair before the reign of Henry VIII. After 1668 the growth of trade increased its prosperity, and at the beginning of the reign of George I. the pier was enlarged and pier-wardens appointed to collect the дрои. In 1749, having been selected as a Harbour of Refuge for the Downs, it underwent great improvements, and henceforward paid £200 yearly to Sandwich out of the дрои for clearing the Channel and repairing the banks of the river Stour within the Liberty; but by 1790 the harbour was of small account.

**Ramsons**, in botany, the popular name for *Allium ursinum*, a bulbous plant 6 to 18 in. high, with ovate-lanceolate stalked leaves tapering at the apex, surrounding a naked stalk bearing a flat-topped umbel of small white flowers. A rather pretty plant, common in woods and in hedgesbines in spring, but with a pungent garlic-like smell, which is characteristic of the genus (see *Allium*).

**Ramus, Petrus**, or *Pierre de la Ramée* (1514-1572), French humanist, was born at the village of Cith in Picardy in 1514, a member of a noble but impoverished family; his father was a charcoal-burner. Having gained admission, in a peculiar capacity, to the college of Navarre, he worked with his hands by day and carried on his studies at night. The reaction against the indulgence of the French and the need to separate transition time between the old and the new, when the eager and forward-looking spirits had first of all to do battle with scholastic Aristotelianism. Ramus outdid his predecessors in the impetuosity of his revolt. On the occasion of taking his degree (1536) he actually took as his thesis "Everything that Aristotle taught is false." This *tour de force* was followed up by the publication in 1543 of *Aristotelitae Animadversiones et Dialectiae Partitions*, the former a criticism on the old logic and the latter a new textbook of the science. What are substantially fresh editions of the *Partitions* appeared in 1547 as *Institutiones Dialecticae*, and in 1548 as *Scholae Dialecticae; his Dialectique* (1555), a French version of his system, is the earliest work on the subject in the French language. Meanwhile Ramus, as graduate of the university, had opened courses of lectures; but his audacities drew upon him the hostility of the conservative party in philosophy and theology. He was accused of undermining the foundations of philosophy and religion, and the matter was brought before the parlement of Paris, and finally before Francis I. By him it was referred to a commission of five, who found Ramus guilty of having "acted rashly, arrogantly and impudently," and interdicted his lectures (1544). He withdrew from Paris, but soon afterwards was accused of having been against him being cancelled through the influence of the cardinal of Lorraine. In 1555 Henry II. appointed him professor of philosophy and eloquence at the Collège de France, where for a considerable time he lectured before audiences numbering as many as 2000. He published fifty works in his lifetime and nine appeared after his death. In 1561, however, the enmity against him was fanned into flame by his adoption of Protestantism. He fled to Flanders; and, though he found an asylum in the palace of Fontainebleau, his house was pillaged and his library burned in his absence. He resumed his chair after this for a time, but in 1568 the position of affairs was again so threatening that he found it advisable to ask permission to travel. Returning to France he fell a victim to his opponents in the massacre of St Bartholomew (1572).

The logic of Ramus enjoyed a great celebrity for a time, and there existed a school of Ramists boasting numerous adherents in France, Germany and Holland. As late as 1626 F. Burgerdyk divides the logic into three parts, his dissertation being about his translations into Latin of Semi-Ramists, who endeavoured, like Goclenius of Marburg, to mediate between the contending parties. Ramus's works appear among the logical textbooks of the Scottish universities, and he was in some sort the patron of his countrymen. Some two decades after his death, his *De proprietatibus rerum*, is even a little treatise from the hand of Milton, published two years before his death, called *Artis Logicae Plenior Institutio ad Petri Rami Methodum concinnata*. It cannot be said, however, that Ramus's innovations mark any epoch in the history of logic. His rhetorical learning is seen in the definition of logic as the "Ars disserendi"; he maintains that the rules of logic may be better learned from the observation of the way in which Cicero persuaded his hearers than from a study of the *Organon*. The distinction between natural and artificial logic, i.e. between the implicit logic of daily speech and the same logic made explicit in a system, passed over into the logic of the academies. However, the second parts—"invention (treatizing of the notion and definition) and judgment (comprising the judgment proper, syllogism and method)." This division gave rise to the jocular designation of judgment or mind-making as the "sensus auriellaris." He, perhaps, most forward in his emendations of the syllogism. He admits only the first three figures, as in the original Aristotelian scheme, and in his later works he also attacks the validity of the third figure, following in this the precedent of Laënnec. He, besides, most forward in the fashion of deducing the figures from the position of the middle term in the premises, instead of basing them, as Aristotle does, upon the different relation of the middle to the so-called major and minor.

On the other hand, and perhaps most forward, he was allowed to have advanced logical study by the wholesome fermentation of thought which he caused, there is little ground for his pretentious claim to supersede Aristotle by a new and independent system.

RAMUSIO. The noble Italian family of Ramusio—the spelling adopted in the publication of the Navigationi, though it is also written Ramusius, Rammasio, Rammasio, &c.—was one of note for literary and official ability during at least four generations. Its original home was in Rimini, and the municipality of that city has within the last few years set up a tablet on the town hall bearing an inscription which may be thus rendered: “The municipality of Rimini here records the claim of their city to the family of the Ramusios, adorned during the 15th and 16th centuries by the illustrious jurist and man of letters Paolo the elder, who rendered the work of Valturius, our fellow-citizen, into the vernacular; by the physician Girolamo, a most successful student of Oriental tongues, and the first to present Europe with a translation of Avicenna; and by Giovanni Battista, cosmographer to the Venetian republic and secretary to the Council of Ten, who became, however, so wealthy that he could buy and sell a great number of his travels, regarded in his own day as a marvellous work, and still full of authority among all civilized nations.”

PAOLO THE ELDER (c. 1443-1506), the first of those thus commemorated, migrated in 1458 from Rimini to Venice, where he obtained full citizenship, studied law and became a member of the magistracy, filling the offices of vicario, of judicial assessor, and of criminal judge under various administrators of the Venetian provinces on the continent. He continued, however, to maintain relations with the Malatesta princes of his native city, and in 1503 negotiated with them the cession of Rimini to the republic. The wife of Paolo, bearing the singular name of Tomyris Macachio, bore him three sons and four daughters. Paolo died at Bergamo on 10th August 1506 at the age of sixty-three, and was buried in S. Agostino at Padua. Paolo was the author of a variety of legal treatises and the like, and also published at Verona in 1483 both a corrected edition and an Italian translation of a once famous book, Valturius, De re militari, dedicated both to Pandolfo Malatesta of Rimini.1

GIROLAMO (1450-1486), younger brother of Paolo, had a notable history. Before he had studied medicine at Padua public suspicion was raised against him in connexion with the death of a lady with whom he had had some love passages, and this ran so high that he was fain, by help of his brother Paolo, to whom he transferred his property, to make his escape (about 1481-1483) to Syria and to take up his abode at Damascus. In 1486 he removed to Beyrouth, and died the same year, killed, as the family chronicler relates, by a surfeit of “certain fruit that we call armellini and albicocche, but which in that country are known as mazzafranche,” a title which English sailors in southern regions still give to apricots in the vernacular paraphrase of kiflions. During his stay in Syria Girolamo studied Arabic and made a new translation of Avicenna, or rather, we may assume, of some part of that author’s medical works (the Canon). It was, however, by no means the first such translation, as is erroneously alleged in the Rimini inscription, for the Canon had been translated by Gerard of Cremona (d. 1187), and this version was frequently issued from the early press. Girolamo’s translation was never printed, but was used by editors of versions published at Venice in 1570 and 1606. Other works of this questionable member of the house of Ramusio consisted of medical and philosophical tracts and Latin poems, some of which last were included in a collection published at Paris in 1791.2

GIAN BATTISTA (1483-1557), the eldest son of Paolo Ramusio and Tomyris Macachio, was born at Treviso in 1485 (June 20). Having been educated at Venice and at Padua, at an early age he entered the public service (1503), becoming in 1515 secretary of the senate and in 1533 secretary of the Council of Ten. He also served the republic in various missions to foreign states, e.g. to Rome, to Switzerland and to France, travelling over much of the latter country by special desire of the king, Louis XII. He also on several occasions filled the office of cancelliere grande. In 1524 he married Franceschina, daughter of Francesco Navagero, a noble—a papal dispensation being required on account of her being cousin to his mother Tomyris. By this lady he had one son, Paolo. In his old age Ramusio resigned the secretariatship and retired to the Villa Ramusia, a property on the river Masanga, in the province of Padua, which had been bestowed on his father in 1504 in recognition of his services in the acquisition of Rimini the year before. The delights of this retreat are celebrated in the poems and letters of several of Gian Battista’s friends. He also possessed a house at Padua in the Strada del Patriarca, a mansion noted for its paintings and for its collection of ancient sculpture and inscriptions. These, too, are commemorated by various writers. A few days before his death Ramusio removed to this house in Padua, and there died, 10th of July 1556. He was buried at Venice, in the tomb which he had made for his mother, in Santa Maria dell’ Orto. His wife’s death had occurred in 1536. In the work called Museum Massuchelliannum (Venice, 1761, vol. i, pl. lxxv. No. 6) there is represented a 16th-century medal of Ramusio, which looks a genuine likeness, and a bronze example of which, without the reverse,3 is preserved in St Mark’s Library. There was a portrait of him, represented as in conversation with Andrea Gradenigo, in the Sala del Maggior Consiglio, but in 1577 this perished in a fire, as did also a portrait of his father, Paolo. A preserved portrait of Gian Battista by Francesco Grisselli, in the Sala dello Scudo, appears to be, like the companion portrait of Marco Polo, a work of fancy. A public national school at Rimini received from the government the title of the Istituto Ramusio.

Ramusio was evidently a general favourite, as he was free from pushing ambition, modest and ingenuous, and, if it be safe to judge from some of the dissertations in his Navigationi, must have been a delightful companion; both his friend Giunti and the historian Giustiniani speak of him with the strongest affection. He had also a great reputation for learning, and as before we have seen, Aldus Manutius the elder dedicated to him his edition of Quintilian (1514); a few years later (1519) Francesco Ardano inscribed to him an edition of Livy, and in 1528 Bernardino Donati did the like with his edition of Macrobius and Censorinus. To Greek and Latin and the modern languages of southern Europe he is said to have added a knowledge of “Oriental tongues,” but there is no evidence how far this went, unless we accept as such a statement that he was selected in 1530 on account of this accomplishment to investigate the case of one David, a Hebrew, who, claiming to be of the royal house of Judah, wished to establish himself at Venice outside of the Ghetto. But Ramusio had witnessed from his boyhood the unrolling of that great series of discoveries by Portugal and Spain in East and West, and the love of geography thus kindled in him.

1 Both works are in the British Museum.
2 Both are in the British Museum.
3 The reverse is an amorous map. The book is in the British Museum.
4 Ramusio’s report on this Hebrew is preserved in the diaries of Marcus Sanudo, and is printed by Cigogna. It is curious. David represented himself as a prince of the House of David, the son of King David, and was so styled by the caravan-road between Damascus and Medina; he claimed to be not only a great warrior covered with wounds but great also in the law and in the cabala, and to have been inspired by God to conduct the dispersed tribes to the Holy Land and to rebuild the temple. In this view he had visited prester John and the Jews in his kingdom, and then various European countries. David was dark in complexion, “like an Abyssinian,” lean, dry and Arab-like, well dressed and well attended, full of pretensions to supernatural cabalistic knowledge, and with enthusiastic ideas about his mission, whilst the Jews regarded him as a veritable Messiah.
made that branch of knowledge through life his chief study and delight. He is said, with the assistance of friends touched by the same flame, to have opened a school for geography in his house at Venice. And it appears from a letter addressed to him by his friend Andrea Navagero, that as early as 1533 the preparation of material for his great work had already begun. The task had been suggested and encouraged, as Ramusio himself states in a dedicatory epistle to the famous Girolamo Fracastorius, by that scholar, his lifelong friend; an address to the same personage indeed introduced each of the three volumes, and in the first the writer speaks of his desire to bequeath to posterity, along with his labours, "a testimony to the long and holy friendship that had existed between the two. They were contemporaries in the strictest sense. (Fracastorius died in 1553.) His correspondence, which was often devoted to the collection of new material for his work, was immense, and embraced many distinguished men. Among those whose names still have an odour of celebrity were Fracastorius, just mentioned, Cardinal Pietro Bembo, Damiano de Goez, and Sebastian Cabot; among lesser lights, Vettor Fausto, Daniel Barbaro, Paolo Manuzio, Andrea Navagero, the cardinals Gasparo Contarini and Gregorio Cortese, and the printer Tomasso Giunti, editor after Ramusio's death of the Navigazioni.

Two volumes only of the Navigazioni e Viaggi were published during the life of Gian Battista, vol. i. in 1559, vol. iii. in 1560, & vol. ii. did not appear till 1559, two years after his death, delayed, as his friend and printer T. Giunti explains, not only by that event but by a fire in the printing-office (November 1557), which destroyed a part of the material which had been prepared. It had been Ramusio's intention to publish a fourth volume, containing, as he mentions himself, documents relating to the Andes, and, as appears from one of the prefaces of Giunti, others relating to explorations towards the Antarctic.

Ramusio's collection was by no means the first of the kind, though it was, and we may say on the whole continues to be, the best. Even before the invention of the press such collections were known, of which that made by a certain Long John of Yprés, abbot of St Bertin, in the latter half of the 14th century was most meritorious, and afforded in its transcription a splendid field for embellishment by the miniaturists, which was not disregarded. The best of the printed collections before Ramusio's was the Novus Orbis, edited at Basel by Simon Grynaeus in 1532, and reissued in 1537 and 1555. This, however, can boast of no disquisitions nor of much editorial judgment. Ramusio's collection is in these respects far superior, as well as in the variety and fulness of its matter. He spared no pains in ransacking Italy and the Spanish peninsula for contributions, and in transcribing them when needful into the racy Italian of his day. Several of the pieces are very rare in any other shape than that exhibited in Ramusio's collection; several besides of importance—e.g. the invaluable travels of Barbosa and Pigafetta's account of Magellan's voyage—were not publicly printed in any complete form till the present century. Of two important articles at least the originals have never been otherwise printed or discovered; one of these is the "Summary of all the Kingdoms, Cities, and Nations from the Red Sea to China," a work translated from the Portuguese, and dating apparently from about 1535; the other, the remarkable Ramusian redaction of Marco Polo (q.v.), the Prefazione, Espostizione and Dichiaraizione, which precede this version of Marco Polo's book, are the best and ablest examples of Ramusio's own style as an editor. They are full of good sense and of interesting remarks derived from his large reading and experience, and few pictures in words were ever touched more delightfully than that in which he sketches the return of the Polo family to their native city, as he had received it in the tradition of the Venetian elders.

There were several editions of the Navigazioni e Viaggi, and as additions continued to be made to the several volumes a good deal of bibliographical interest attaches to these various copies. The first and rarest edition of Ramusio's lifetime do not bear his name on the title-page, nor does it appear in the addresses to his friend Fracastorius with which these volumes begin (as does also the second and posthumous volume). The editions of vol. i. are as follows: 1550, 1552, 1563, 1580, and 1606. The edition of 1554 contains the following articles which are not in that of 1550: (1) copious index; (2) "Narr. di un Compagno di Barbosa"; (3) "Informationi del Giapan"; (4) "Alli Lettori di Giov. de Barros"; (5) "Capioltri estratti da il Barros." The edition of 1563 adds to these a preliminary leaf concerning Ramusio, "Tommaso Giunti alli Lettori." After 1563 there is no change in the contents of this volume, only a variation in the title-page. It should be added that in the edition of 1554 there are three double-page woodcut maps (Africa, India and India extra Gangem), which do not exist in the edition of 1550, and which are replaced by copperplate maps in subsequent editions. These maps are often missing. The editions of vol. ii. are as follows: 1559, 1574, 1583, and 1606. There are important additions in the 1574 copy, and still further additions in that of 1583. The additions made in 1574 were: (1) "Herberstein, Delia Moscovia e della Russia"; (2) "Viaggio in Persia di Caterino Zeno"; (3) "Scoprimiento dell' Isola Frislanda, &c., per due fratelli Zoni"; (4) "Viaggi in Tartaria per alcuni fratii Minori"; (5) "Viaggio del Beato Ordorico" (two versions).

Further additions made in 1583 were: (1) "Navigazione di Seb. Cabota"; (2) at the end 90 ff. with fresh pagination, containing ten articles on "Sarmatia, Polonia, Lithunia, Prussia, Livonia, Moscovia, and the Tartars by Aless. Guagnino and Matteo di Michcov." The two latest "editions" of vol. ii. are identical, i.e. from the same type, with a change of title-page only, and a reprint of the last leaf of the preface and of the last leaf of the book. But the last circumstance does not apply to all copies. In one, whilst the title bears 1606, the colophon bears "Appresso Gior. Giunti, 1593." Vol. iii. editions are of 1566, 1605 and 1606. There is no practical difference between the first two, but that of 1606 has forty-five pages of important new matter, which embraces the "Travels of Cesare Fedrici or Federici in India, one of the most valuable narratives of the 16th century, and Three Voyages of the Hollanders and Zealanders to Nova Zembla and Groenland." Vol. iii. also contains (omitting maps and figures inserted in the text, or with type on the reverse) a two-page topographical view of Cuzco, a folding map of Terra Nova and Labrador, a two-page map of Brazil, a two-page map of Guinea, &c., a two-page map of Sumatra, a two-page pictorial plan of the town of Ypres and the close of Brabant, and a general map of the New World in a hemisphere. Brunet's statement mentions issues of vol. ii. in 1564, and of vol. iii. in 1613; but these seem to have no existence. It would thus appear that a set of Ramusio, to be as complete as possible, should embrace— for vol. i., 1550 or any subsequent edition; for vol. ii., 1583 or 1606; for vol. iii., 1606.

Paolo (Girolamo Gaspare) (1532-1600) was the only child of Gian Battista, and was born on the 4th of July 1532. Like his father, he maintained a large correspondence with many persons of learning and note. In 1541 Francesco Contarini, procurator of St Mark's, brought from Brussels a MS. of Villehardoun's History of the Conquest of Constantinople, which he presented to the Council of Ten. In 1556 they publicly ordered its translation into Latin, and gave the commission to Paolo Ramusio. His father also seems to have taken much interest in the work, for a MS. vernacular translation by him exists in the Marciana. Paolo's book was not completed

1 See in vol. iii. the end of Ramusio's Discorso on the conquest of Peru, and Giunti's "Alli Lettori" in the 3rd edition of the first volume.

2 Brunet's statements on the subject are borrowed, and not quite accurate. The detail in Cipogna seems to be accurate, but it is unjust to the deficiencies of the earlier editions.

3 All of these are in the British Museum.

4 All at the British Museum.

5 This person and his son affected the spelling Rannusio.
RANADE—RANC

984.

RANAVEKHO

1855.—RANADE, MAHADEO GOVIND (1842—1901), Indian lawyer, reformer and author, was born on the 16th of January 1842 at Niphad, in Nasik district, of a Chitpavan Brahman family. When his father was minister at Kolhapur he attended the Anglo-veracular school in that town, and joined the Elphinstone Institute in Bombay at the age of fourteen. He was one of the first graduates of the Bombay University, taking the B.A. in 1862 and the LL.B. in 1866. Having entered government service he became presidency magistrate and then fourth judge of the small cause court at Bombay in 1871, first-class sub-judge at Poona in 1873, and judge of the Poona small cause court in 1884, after which, as special judge under the Deccan Agriculturists' Relief Act from 1887, he came into close contact with the difficulties of the agrarian classes. In 1886 he was a member of the finance committee appointed to report on the expenditure, financial administration, and provincial, which led him to the conclusion that the service won him the decoration of C.I.E. He became a member of the legislative council of Bombay in 1885, and occupied that position until raised to the high court in 1893. Being an energetic social reformer, he directed his efforts against infant marriages, the shaving of widows, the heavy cost of marriages and other social functions, and the caste restrictions on travelling abroad. He strenuously advocated widow remarriage and female education. He was the founder of the social conference movement, which he supported till his death. In the political sphere he founded the Poona Sarvajánik Sabha, through which he frequented helped the government with sound advice. He was also one of the originators of the Indian National Congress. In Bombay University, where he held the offices of syndic and dean in arts, he displayed much organizing power and great intimacy with the needs of the student class. Himself a thorough Maharati scholar, he encouraged the translation of standard English works, and tried, with some success, to introduce vernacular languages into the university curriculum. Though reared in the strictest tenets of Hinduism, his deep religious feeling and trained intellect craved something higher and broader than he could find in the traditional forms and orthodox teaching of his race. The same spiritual being felt by many enlightened Hindus, he joined with his friends, Dr Atmaram Pandurang, Bal Mangesh Wagle and Vaman Abaji Modak, in founding a new sect in Bombay known as the "Parvathana Samaj." This community resembles, in all essential points, the Brahma Samaj of Bengal. Its principles of enlightened theism are based on the ancient Vedas. He published

books on Indian economics and on Maharatta history. He died on the 16th of January 1901. He left no children, but his widow continued his work of social and educational reform at Poona. See G. A. Mankar, Justice M. G. Ranade (Bombay, 1902).

RANAVALO—RANAVALONA III. (1864— ), the last queen of Madagascar, born in 1864, was a great-niece of Radama I. Her name originally was Razafindanychy, but on succeeding to the throne of Madagascar after the death of Queen Ranavalo II., on the 14th of July 1883, she assumed the style of Ranavalo III. Although nominally queen, she took no share in the government, which her prime minister, Rainilaiaryivo, had controlled since 1864. After placing her on the throne, he married her before the close of the year. Ranavalo became queen just after the French had revived their claim to a protectorate over the island. The Hova government refusing to admit the claim, war broke out, and several sharp engagements took place. The French bombarded the coast towns, but were unable to reach the interior of the island, where the strength of the Hova lay. In December 1885 a treaty was concluded by which it was agreed that the government of the French Republic should represent Madagascar in all foreign relations, but that in internal matters the Hova government should be independent, as formerly. During the next ten years French influence was quietly extended over the island, in spite of the efforts of Rainilaiaryivo, who pursued an anti-French policy, encouraging English and American planters and traders. In 1894 differences on commercial and territorial questions arose between the Hova government and the French, which terminated in war. In 1895 a well-organized expedition was despatched from France to subjugate the island. Many of the inhabitants sympathized with the invaders, and even the Hova themselves were divided. Although Ranavalo endeavoured to arouse a martial spirit in her subjects, the French advanced on the capital without encountering any effective opposition. On the 30th of September they captured Antananarivo. Rainilaiaryivo was sent into exile, where he died in the following year; but Ranavalo was suffered to remain as nominal head of the government, under a strict French protectorate. In August 1896, to avoid commercial difficulties with foreign powers, the island was declared a French colony; but no change was made in the internal administration. Later in the year, however, the civil governor was replaced by a military resident, General Gallieni. A formidable insurrection was suppressed, and new French institutions were established. During the war many prominent members of the Hova administration. Finding that the court had been a centre of intrigue, he abolished the sovereignty by proclamation in February 1897, and exiled Ranavalo to Réunion. In March 1899 she was removed to Algiers. Her exile there was relieved by occasional visits to Paris.

RANC, ARTHUR (1831—1908), French politician and writer, was born at Poitiers on the 20th of December 1831, and was educated for the law. Implicated in a plot against Napoleon III. in 1853, he was acquitted, but shortly afterwards was imprisoned for belonging to a secret society; for his share in anti-imperialist conspiracies in 1855 he was arrested and deported to Algeria without a trial. The amnesty of 1859 permitted him to return to Paris, where he soon drew the attention of the police to his presence by his violent articles. During the siege of Paris he left the city in a balloon and joined Gambetta, for whom he organized a system of spies through which General Trochu was kept informed of the strength and disposition of the Prussians around Paris. He was elected to the National Assembly in February 1871, but resigned rather than subscribe to the peace. He had been elected mayor of the ninth arrondissement of Paris in the autumn of 1876, and in March was sent by the same district to the Commune, from which he resigned when he found no reconciliation was possible between the mayors and the Commune. In July he became a member of the municipal council of Paris, and in 1873 was returned to the National Assembly for the department of the Rhône, and took his place on the extreme Left. A month after his election the governor of Paris demanded his prosecution for his share in the Commune. The claim being granted by a large majority, he

1 In the British Museum.
escaped to Belgium, where he issued a pamphlet defending his action during the Commune. On his failure to appear before the court he was condemned to death, and remained in Belgium until 1879, when he was included in the amnesty proclaimed by Grévy. During his exile he continued his active collaboration on *La République française*. In 1873 he fought a duel with Paul de Cassagnac, and he acted as second to Clémenceau more than once. He energetically defended the republic against the Boulangist agitation, and took an equally courageous part in the Dreyfus affair. In the Picquart-Henry duel he was second to Colonel Picquart. He succeeded Clémenceau as editor of the *Aurore*, in which Zola's letter "J'accuse" had appeared, and was president of the Association of Republican Journalists. In 1903 he became senator for Corsica, and died on the 10th of August, 1908.

In addition to his purely political writings, Arthur Ranc published political novels of the Second Empire, *Sous l'empire* (1872) and *Le roman d'une conspiration* (1868).

**RANCÉ, ARMAND JEAN LE BOUTHILLIER DE** (1626-1700), founder of the Trappist Cistercians. He was born in Paris of a noble and influential family of Normandy; hence, being destined to the ecclesiastical state, he was when ten years old commendedatory abbot of La Trappe and two other abbeys, prior of two priories, and canon of Notre Dame, Paris. At twelve he published a translation of Anacreon. He went through his course of theological studies with great distinction, defeated Bossuet at the Baccalaureat in theology. He was ordained in 1651, and embarked on the ambitious and worldly career of a court abbé in the days of Louis XIV. But after a few years he underwent a complete change of life, and in 1662 he retired to his abbey of La Trappe, of which he became regular abbot in 1664 and introduced an austere reform (see TRAPPISTS). The best known episode of his subsequent life was the "Contestation" with Mabillon on the lawfulness of monks devoting themselves to study, which De Rancé denied. He resigned his abbacy in 1695, owing to declining health, and died in 1700.

The best of the early lives is that of P. le Nain, his sub-prior (1715) and the most recent is by M. Serrant, *L'Abbe de Rancé et Bossuet* (1903). A sufficient sketch is given by Helyot, *Histoire des ordres religieux* (1718), vi. c. 1. On the "Contestation" on Monastic Studies, see Maitland, *Dark Ages*, § x. (E. C. B.)

**RANCH**, a term in current usage among the English-speaking peoples for a large farm, particularly one for cattle or horse-breeding. The word came into use in this application in the western states of North America, and was an adaptation of the Spanish-American *rancho*, a rancher's house, in Spanish a gathering of people having their meals in common, a mess.

**RANCHI**, a town and district of British India, in the Chota Nagpur division of Bengal. The town, which is situated on the Chota Nagpur plateau, about 2100 ft. above sea-level, is the headquarters of both the division and the district. Pop. (1901) 25,970. It is an important centre of local trade and the headquarters of the German Lutheran mission. There are a high school and an industrial school, and it is proposed to found here a residential college for all Bengal. The cantonments, formerly called Doranda, accommodate a detachment of native infantry.

The District of Ranchi, formerly called Lohardaga after the town which was its headquarters, has an area of 7128 sq. m. It consists of two tablelands, of which the higher rises to about 2000 ft. The whole area is broken by hills and undulations, which are terraced for rice. The steep slopes are covered with a dense forest, where wild animals still abound, but no profit is derived from the timber. The principal rivers are the Subanarekhā and the North and South Koel. In 1907 the population was 1,87,925, showing an increase of 5.2% in the decade. Christians form 10% of the total. The district was affected by the famine of 1896-1897, and still more severely by that of 1900. Rice is everywhere the staple crop, with some millets and pulses. Tea cultivation has been introduced, but does not flourish. The only industry on a large scale is the manufacture of shellac. Myrobalans are also exported. Iron and soapstone are worked in small quantities. Hopes of profitable gold-mining in the quartz veins of the schist formation have proved abortive. There is no railway in the district, though surveys have been made to connect with the Bengal-Nagpur line.

**RAND, a Dutch word meaning border, edge, used in South Africa to designate a low rounded range of hills; specifically it is an abbreviated form of Witwatersrand, an elevated ridge in the southern Transvaal, forming the water-parting between the basins of the Orange and Limpopo. The Rand is famous for its gold-bearing reefs (see Gold), and the word is often used as a synonym for the gold mining industry carried on over a great part of its area, or for Johannesburg (p.p.), the city which that industry created.**

**RANDALL, SAMUEL JACKSON** (1828-1890), American politician, was born in Philadelphia, Pennsylvania, on the 10th of October 1828. He was educated in the public schools and in the University Academy, Philadelphia. In 1858-1859 he was a Democratic member of the state Senate. During the Civil War he served as a private in the Union army for ninety days in 1861, and two years later took part in the Gettysburg campaign as a volunteer. From 1863 until his death he was a Democratic representative in Congress. During the session of 1874-1875 he first gained a national reputation by the masterful manner in which he prevented the Republican majority from passing the Force Bill or Federal Election law. Under his leadership discipline and party harmony were established among the Democrats for the first time after the Civil War. He was speaker of the House from December 1876 to March 1881, during a period marked by rancorous debates concerning the disputed Hayes-Tilden presidential election. With the disappearance of the Reconstruction questions and the emergence of the tariff issue, however, his influence began to wane. As the leader of the Protectionist wing of the party he was superseded by the tariff reform advocates, such as John G. Carlisle, William R. Morrison, and Roger Q. Mills, Carlisle defeating him for the speakership in 1883. He died in Washington, D.C., on the 13th of April 1890.

**RANDAN, a name for a boat rowed by three persons, stroke and bow using a single oar each and the central person a pair of oars.** The word is of unknown origin, and can hardly be connected with a slang term for a row or spree, which is found as early as the beginning of the 18th century and is generally taken as a variation of "random," haphazard.

**RANDAZZO, a town of Sicily, in the province of Catania, at the foot of Mount Etna, 43 m. N. of Catania by rail, and 26 m. by direct road (1891) 14416.** It has 3000 inhabitants. Of the remains of architecture of the 13th and 14th centuries, including three Norman churches and some interesting palaces. The former contain some fine sculptures and goldsmith's work (Mauceri in *L'Arte*, 1906, 185). It is the nearest town to the summit of Etna (9 m.), and is one of the points from which the ascent may be made.

**RANDERS, a town of Denmark, capital of the amt (county) of its name in Jutland, on the Guenaa at the point where it begins to widen into Randers Fjord, an inlet of the Cattegat. Pop. (1901) 20,957.** The town is 15 m. from the open Cattegat and the harbour has 15 ft. depth on the bar. The chief exports are butter and eggs; the chief imports sugar, petroleum, coal and iron. Two railways run north to Aalborg, continuing the main East Jutland line from the south, and an eastward branch serves Grenaa and Aebelfont on the coast. Though a place of considerable antiquity—being mentioned in ro86 as the meeting-place of insurgents against Knud, the saint—Randers has few remains of old buildings and bears the stamp of a compact, modern manufacturing town that owes its importance to its distilleries, manufactories of gloves, railway carriages, &c. St Marten's church dates from the 14th century, but was frequently altered and enlarged down to 1870. It has good woodwork of the 17th century. The high school is housed.
in a medieval monastery, which was restored in 1894–97. There is a statue to Steen S. Blicher (1782–1848), the national poet and novelist of Jutland. Randolph is best known in history as the scene of the assassination of Count Gerhard by Niels Ebbesen in 1340. In the middle ages it had six churches and four monastic establishments, the oldest a Benedictine nunnery (1170). The Grey Friars' building was turned into a castle (Dronningborg) after the Reformation; its church was burned down in 1688.

RANDOLPH, EDMUND JENNINGS (1753–1813), American statesman, was born on the 2nd of August 1775 at Tazewell Hall, Williamsburg, Virginia, the family seat of his grandfather, Sir John Randolph (1693–1737), and his father, John Randolph (1727–84), who (like his uncle Peyton Randolph) were king's attorneys for Virginia. Edmund graduated at the College of William and Mary, and studied law with his father, who felt bound by his oath to the king and went to England in 1775. In August–October 1775 Edmund was aide-de-camp to General Washington. In 1776 he was a member of the Virginia Convention, and was on its committee to draft a constitution. In the same year he became the first attorney-general of the state (serving in 1776 and 1779 and again in 1780–82. He had a large private practice, including much legal business for General Washington. In 1786 he was a delegate to the "Annapolis convention," and in 1788–89 was governor of Virginia. He was a delegate to the Constitutional Convention of 1787, and on the 29th of May presented the "Virginia plan" (sometimes called the "Randolph plan"). In the Convention Randolph advocated a strongly centralized government, the prohibition of the importation of slaves, and a plural executive, suggesting that there should be three executives from different parts of the country, and refused to sign the constitution because too much power was vested in the President. He was opposed to a majority in Congress, and because no provision was made for a second convention to act after the present instrument had been referred to the states. In October 1787 he published an attack on the Constitution; but in the Virginia convention he urged its ratification, arguing that it was too late to attempt to amend it without endangering the Union, and that Virginia's assent would be that of the necessary ninth state. In 1788 he refused re-election as governor, and entered the House of Delegates to work on the revision and codification of the state laws (published in 1794). In September 1789 he was appointed by Jefferson, then in Paris, to be the first attorney-general of the United States. He worked for a revision of Ellsworth's judicial act of 1789, and especially to relieve justices of the supreme court of the duties of circuit judges, and advocated a Federal code; in 1791 he considered Hamilton's scheme for a national bank unconstitutional; and in 1792–93, in the case Chisolm v. Georgia before the supreme court, argued that a state might be sued by a citizen of another state. On the 2nd of January 1794 he succeeded Thomas Jefferson as secretary of state. In 1795 he wrote thirteen letters (signed "Germanicus") defending the President in his attack on the American Jacobin or democratic societies. He was the only cabinet member who opposed the ratification of the Jay treaty (his letters to the President on the subject are reprinted in The American Historical Review, vol. xii. pp. 587–590), and before it was ratified the delicate task of keeping up friendly diplomatic relations with France fell to him. Home despatches of the French minister, Joseph Fauchet, intercepted by a British man-of-war and sent to the British minister to the United States, accused Randolph of asking for money from France to influence the administration against Great Britain. Although this charge was demonstrably false, Randolph when confronted with it immediately resigned, and subsequently secured a retraction from Fauchet; he published A Vindication of Mr Randolph's Resignation (1795) and Political Truth, or Answers to Mr Fauchet's Present State of Public Affairs (1796). He was held personally responsible for the loss of a large sum of money during his administration of the state department, and after years of litigation was judged by an arbitrator to be indebted to the government for more than $49,000, which he paid at great sacrifice to himself. He removed to Richmond in 1803, and during his last years was a leader of the Virginia bar; in 1807 he was one of Aaron Burr's counsel. He died at Carter Hall, Millwood, Clarke county, Virginia, on the 12th of September 1813.

Moncure D. Conway, in His Omitted Chapters of History disclosed in the Life and Papers of Edmund Randolph (New York, 1888; 2nd ed. 1889), greatly exaggerates Randolph's work in the Constitutional Convention; the commoner view undermines him and makes him a "hair-splitter," and a man of no decision of character.

RANDOLPH, JOHN (1773–1833), of Roanoke, American statesman. He was a member of an influential and wealthy Virginian family, and was the third and youngest son of John Randolph of Cawsons, Chesterfield county, where he was born on the 2nd of June 1773. He was a descendant of John Rolfe and his wife Pocahontas. His father having died in 1775, his early years were passed under the care of his mother and his brother John, Jr., who was Mr So. Randolph. Randolph eventually became estranged, as he did from almost every one with whom he was intimately associated. He attended a school at Williamsburg, Virginia, and for a short time studied at Princeton and at Columbia; but, although well read in modern works bearing on politics and philosophy, his own statement, "I am an ignorant man, sir," was in other respects not inaccurate. Both his religious and his political views were radical and extreme. At an early period he imbibed delusional opinions, which he promulgated with eagerness. He was also, though a mere boy when the new Federal government was organized in 1789, a strong but not always consistent supporter of the new Constitution of the United States. In order to assist in asserting the right of resistance to national laws, and to withstand the "encroachments of the administration upon the indisputable rights" of Virginia, he was in 1799 elected a Republican to the national House of Representatives, of which he was a member, with the exception of two terms (1813–15 and 1817–19), until 1825, and again in 1827–29. After the accession of Jefferson to the presidency in 1801, Randolph was appointed chairman of the Committee of Ways and Means, and as such was naturally the leader of the Republican majority in the House. He took an active part in agitating for the reform of the judiciary, and in 1804 moved the impeachment of Judge Samuel Chase (p.v.), acting as the leader of prosecution in the trial before the Senate. Though an avowed Republican, he was far from being subservient to his party, and for several years after 1805 led a small faction, called "Quids," which sharply criticized Jefferson and attempted to prevent the selection of Madison as the
presidential candidate of his party. In March 1807 he lost the chairmanship of the Ways and Means Committee. Possessing considerable wit, great readiness, and a showy if somewhat bombastic eloquence, he would undoubtedly have risen to high influence but for his strong vein of eccentricity. His bitter and ungentlemanly temper took the championship of state's rights was carried by him to an extreme utterly quixotic, inasmuch as he not only asserted the constitutional right of Virginia to interpose her protest against the usurpation of power at Washington, but claimed that the protest should be supported by force. From December 1825 to March 1827 he served in the United States Senate, and in April 1826 he was forced to fight a duel with Henry Clay, on account of his violent abuse of that statesman in the course of a debate. In 1830 he was sent by President Jackson on a special mission to Russia, but returned to St. Petersburg only ten days, then spent almost a year in England, where he was sent in 1837 for $21,407 from the United States Treasury for his services. He died of consumption at Philadelphia on the 24th of June 1833. Though his political life was full of inconsistencies—he was even capable of advocating the passage of a bill on one day and of opposing the passage of the same bill on the next—he generally adhered to the principles enunciated by the Republican party in its earliest years, and throughout his later career, in numerous speeches, he laboured to bring about the identification of slavery with the theory of states' rights. In this he was the natural precursor of Lincoln. His last will was disputed in the law courts, and the jury returned a verdict that in the later years of his life he was not of sane mind. He was always in theory opposed to slavery, and by the will which was accepted by the courts, freed his own slaves.

The best biography is that by Henry Adams, John Randolph (Boston, 1882), in the "American Statesmen Series." There is also a biography, which, however, contains many inaccuracies, by Hugh A. Garland (2 vols., New York, 1854).

**RANDOLPH, PEYTON** (1721—1775), American politician, was born at Tazewell Hall, Williamsburg, Virginia, in 1721, a son of John Randolph (1605—1635), the king's attorney for Virginia. He graduated at the College of William and Mary, studied law at the Inner Temple, London, and in 1748 was appointed the king's attorney for Virginia.1 Randolph wrote the address of remonstrance to the King in behalf of the Burgesses against the suggested stamp duties in 1764. His policy was conservative and moderate, and in May 1765 he opposed Patrick Henry's radical "Stamp Act Resolutions." In 1766 he resigned as king's attorney and was succeeded by his brother John (1727—1738). In 1769 he acted as moderator of the privately convened assembly which entered into the non-importation agreement, and in May 1773 he became chairman of the first Virginia intercolonial committee of correspondence. He presided over an annual convention of August 1773, and was a member of the First Continental Congress, of which he was president from the 3th of September to the 22nd of October 1774. He was re-elected to Congress in March 1775, and on the 15th of May was again chosen to preside, but on the 24th he left to attend a meeting at Williamsburg of the Virginia Burgesses. He then returned to Congress, of which John Hancock had meanwhile been made president. Randolph died of apoplexy in Philadelphia on the 22nd of October 1775. He was provincial grand-master of the Masons of Virginia, and was an intimate friend of Washington.

**RANDOLPH, THOMAS** (1523—1590), English diplomatist, son of Avery Randolph, a Kentish gentleman, was educated at Christ Church, Oxford, and in 1549 became principal of Pembroke College, Oxford, then known as Broadgates Hall. During the reign of Mary, Randolph, who was a zealous Protestant, sought refuge in Paris, where he cultivated the society of scholars. Returning to England after the accession of Elizabeth, he was soon employed as a confidential diplomatic agent of the English queen in Scotland. Here he succeeded in gaining the confidence of the Protestant party, with whom he became a person of great influence. Randolph's despatches from Scotland between 1560 and 1585 supply important materials for the history of the political intrigues of that period. Randolph, who had hitherto remained ostensibly on terms of friendship with Mary Queen of Scots, exerted his influence on instructions from Elizabeth to prevent Mary's marriage with Darnley; but in 1566 he was driven from Scotland on the charge of having fomented Murray's rebellion, and he then obtained government employment of secondary importance in England. In 1598 he undertook a mission to Russia which saw, in the conception by Ivan the Terrible of certain privileges to English merchants; and in 1570 he returned to Scotland, where, after the murder of the regent Murray in January of that year, he "succeeded," says Andrew Lang, "in making civil war inevitable; he himself was in high spirits, as always when mischief was in hand." After carrying through certain diplomatic business in France in 1573 and 1576, Randolph returned in January 1581 to Scotland, where the earl of Morton, the regent, had been arrested a few days previously. Randolph, acting on Elizabeth's instructions, intrigued with Angus and the Douglases in favour of a plot to seize the person of the young King James. He was impeached by violent hands on the earl of Lennox. Douglas of Whittingham, who was employed in the intrigue, on being arrested made revelations which imperilled Randolph, and the latter prudently withdrew to Berwick before the execution of Morton in June 1581. In 1585, when he next visited Scotland, he was more successful, being instrumental in arranging a treaty between England and Scotland. For the next four years he was chancellor of the exchequer in England, and he died in London in June 1590. Randolph married, in 1571, Anne, daughter of Thomas Walsingham. He was a personal friend of George Buchanan, in whose History of Scotland he took a lively interest, and he has been credited, though on doubtful evidence, with the authorship of a Life of the historian in Latin.

**RANDOLPH, THOMAS** (1605—1635), English poet and dramatist, was born near Daventry in Northamptonshire, and was baptized on the 15th of June 1605. He was educated at Westminster and at Trinity College, Cambridge. He took his B.A. degree in 1625, proceeded M.A. in 1632 and became a major fellow of his college in the same year. He soon gave promise as a writer of comedy. Ben Jonson, not an easily satisfied critic, adopted him as one of his "sons." He addressed three poems to Jonson, one on the occasion of his formal "adoption," another on the failure of The New Inn, and the third an eulogy, describing his own studies at Cambridge. He lived with his father at Little Houghton in Northamptonshire for some time, and afterwards with William Stafford of Blatherwick, at whose house he died before completing his thirtieth year. He was buried in Blatherwick church on the 17th of March 1634—5, and his epitaph was written by Peter Hausted, then rector of several parishes.

Randolph's reputation as a wit is attested by the verses addressed to him by his contemporaries and by the stories attached to his name. His earliest printed work is Aristippus, or, The Joviall Philosopher. Presented in a private shew, To which is added, The Conceited Pedlar (1630). It is a gay interlude burlesquing a lecture in philosophy, the whole piece being an argument to support the claims of sack against small beer. The Conceited Pedlar is an amusing monologue delivered by the pedlar, who defines himself as an "individuum vagum, 

---

1 In 1574 the Burgesses sent him to London to argue against the governor's demand for a fee of one pistole on every land patent; his plea was successful, but the governor superseded him with George Wythe, who resigned in Randolph's favour upon his return from England, and who associated himself with the latter in a public subscription of £20,000 to Governor Dinwiddie for Indian warfare; the governor would not approve this appropriation, however, until Randolph apologized for leaving his office without the governor's permission.
or the primum mobile of tradesmen, a walking-burse or movable exchange, a Socratic citizen of the vast universe, or a peripatetic journeyman, that, like another Atlas, carries his heavy shop on his shoulders." He then proceeds to display his wares with a running satirical comment. The Jealous Lovers was presented by the students of Trinity College, Cambridge, before the king and queen in 1632. The Muse's Looking-Glass is hardly a drama. Roscius presents the extremes of virtue and vice in pairs, and last of all the "golden mediocrity" who announces herself as the mother of all the virtues. Amyntas, or The Impossible Dowry, a pastoral printed in 1568, with a number of miscellaneous Latin and English poems, completes the list of Randolph's authenticated work. Hey for Honesty, down with Knavery, a comedy, is doubtfully assigned to him.

His works were edited by W. C. Hazlitt in 1875.

RANDOM (older forms randon, random; from the French, cf. randir, to run quickly, impetuously; generally taken to be of Teutonic origin and connected with Ger. Rand, edge, brim, the idea being possibly of a brimming river), an adjective originally meaning impetuous, hasty, hence done without purpose or aim, haphazard. The term "random work" is used, in architecture, by the rag-stone masons, for stones fitted together at random without any attempt at lining them in courses. "Random course work" is a like term applied to work course in horizontal beds, but the stones are of varying height, and fitted to one another (see MASONRY).

RANELAGH, formerly a popular resort by the Thames in Chelsea, London, England. About 1690 the land lying east of Chelsea Hospital, and bordering the river about the point where Chelsea Bridge now stands, was acquired by Richard, Viscount Ranelagh, later earl of Ranelagh (d. 1711). He built a mansion and laid out fine gardens, which, in 1743, were thrown open as a proprietary place of entertainment. A building called the Rotunda was erected for concerts, and the gardens quickly became a favourite resort of fashionable society. Balls and masquerades, exhibitions of fireworks, regattas and many other forms of amusement were provided; but by the close of the 18th century Ranelagh was ceasing to attract the public, and in 1803 the Rotunda was closed. The buildings were removed, and the grounds became the property of Chelsea Hospital. They are still included in the pleasant gardens belonging to that foundation, but no traces of the popular Ranelagh are preserved. There is, however, a fashionable modern club of the same name.

RANGE-FINDER, TELEMETRER OF POSITION-FINDER (Fr. télémètre; Ger. Distanzmesser; It. Telemetro; Russ. Dal'momier; Span. Telémetro; in the United States the word telemeter is sometimes applied to the stadia used in connexion with the tacheometer), an instrument, of which many varieties have been invented, for assisting the gunner and the infantry soldier in determining the distance or "range" 1 to their objective. Nearly all range-finders may be described as instruments which mathematically solve a triangle. Usually it is a right-angled triangle, the length of the base of which is known, and one of the sides is the range it is desired to find. They are, in fact, goniometers, but the angle which they measure, whether it may be at the end of the measured base, or that subtended by it, is usually expressed as a function of the angle in terms of the measured base. Thus the range is recorded directly in metres or yards without calculation. It is proposed here to describe principally the range-finding instruments in the British services (1) as used in the fleet; (2) by the army in the field; (3) in harbour defence; and (4) to refer briefly to range-finders, not under these heads, of English and foreign design.

1. The necessity for a range-finder afloat caused the British Admiralty in 1801 to issue an advertisement in the press inviting inventors to produce an instrument which would, amongst other conditions, record ranges with an accuracy of within 3% at 3000 yds. The resulting competition was declared in favour of a range-finder which is the joint invention of Professor Barr of the Glasgow University and Professor Stroud of the Yorkshire College.

The naval range-finder consists of a tube 2 which contains two telescopes. It is carried on a frame by bearings, in which the tube is free to revolve about its longer axis. To the frame is attached a weight capable of movement within a tank. This weight balances the range-finder and frame upon knife-edges. By means of the handle on the left of the instrument and an altitude worm beneath it, the motion of the tube is governed, and the line of sight is directed on the objective. By partially filling the tank with water, the swinging of the weight in a sea-way can be checked. The frame is supported on a pedestal and can rotate in azimuth upon it (fig. 1).

A rubber guard is fitted round the eye-pieces. Its functions are to guide the eyes of the observer into the correct position, and to protect them from side light and the distressing effect of wind. It also guards the forehead against the jar occasioned by firing heavy guns. The upper portion of the field presented to the left eye is used as a finder, the lower portion is occupied by the scale upon which the ranges are engraved. The finder is a low-power telescope of large field, to the centre of which the objective is brought. When the telescope is thus correctly aligned, the objective will be seen with the right eye largely magnified, but as two partial images separated by a thin black horizontal line. When coincidence of the images is effected by means of the working head, the range can be

---

1 The word "range," from O.Fr. range, from ranger, to place in a row or rank (rang being a variant of rânc, whence Eng. "rank"), means properly a row or line of objects, as still in "mountain-range"; the secondary meanings of an area or space of ground, sphere of action, compass, extent, distance, are derived from the verb "to range," to stretch out in a line, to extend, to move about over a given area.

2 The length of tube varies from 3 ft. in the smaller to 9 ft. in the larger instruments.
and passing through the object-glasses, each is received by an arrange-
ment of prisms and mirrors at the centre of the tube, and reflected through
the right eye-piece. Two partial images are thus seen. The images
could be united by the rotation of one of the reflectors, but owing
to the small base used the necessary movement would be so extremely
small that it would be practically impossible to measure it. The
difficulty has been surmounted by utilizing fixed reflectors and effect-
ing coincidence by means of a prism of small angle. The deflecting
prism is situated in the line of the beam of light from the reflector
at the right-hand end of the tube. Its multiplying action is of
great delicacy. The angle available for subdivision, to measure
ranges between infinity and 250 yds., is only one-third of a degree.
In a travel of 6 in. the prism renders accurate measurements possible
within the required limits. To bring images of distant objectives
into coincidence, the prism must be moved towards the eye-piece,
and for near objectives in the opposite direction. The range scale
is graduated in yards, and is divided into 100°. A consequent
advantage is that the accuracy of the instrument is not affected by back lash arising from
wear, or irregularity in the actuating mechanism. When once
installed, the instrument is always ready for use. Should adjust-
ments be required, this is only easily applied. It is not within
the sphere of this article to enter into the detail of the adjusting
mechanism. For further particulars the reader is referred to the
Proceedings of the Institution of Mechanical Engineers, 1896 January
1896. The working of the range-finder is so simple that its use
is quickly learnt by any man who can read, and with little instruction
and practice he can "take a range" in 8 to 12 seconds. Besides
its principal purpose, in connexion with gunnery, there are minor
uses, such as topographical and nautical surveying to which the range-finder
can be applied.

With the high speeds of modern war-vessels, guns and their
objectives are moving so quickly that unless ranges can
be communicated from the instrument to the guns with rapidity and
accuracy the range-finder is deprived of much of its value.

In connexion with the naval range-finder an apparatus is provided,
which through not part of the range-finder is sufficiently important to
to claim passing notice. The apparatus consists of a transmitting
and a receiving instrument of clockwork mechanism electrically
controlled. In appearance they resemble the ordinary engine-room
telephones, but on the dials of which range-finders take the place of ordinaries.
The transmitter can communicate with a number of receiving
instruments, disposed as required in different parts of the ship.

2. Before the introduction of the Marindin range-finder described below, the British army in the field used the "meko-
meter." The instruments used by the cavalry and infantry
are smaller and lighter than those of the artillery pattern,
but the principle involved is identical.

The mekometer is practically a box sextant. Two instruments
are used simultaneously at the ends of a base of fixed length. One
sextant, called the right-angle instrument, is fitted with index and
horizon glasses permanently inclined at 45°. It consequently
measures a right angle. In the other sextant, called the reading
instrument, a graduated drum takes the place of the usual index
arm and scale. The drum is graduated spirally with a scale of
ranges; but to the reading and right-angle instruments are fitted with
a vane of gun metal with a white strip down the centre to facilitate
observations. Telescopes of low power can be fitted to the instru-
ments, and two needles of 50 (or 25 yds.) are provided with which
to measure the base.

Two observers attach the ends of the cord of fixed length (usually
50 yds.) to their instruments and separate until it is taut. The
right-angle instrument moves into such
a position that coincidence of image will be given between
the objective and the vane of the instrument at the other
end of the base, i.e. he makes ABC a right angle (fig. 3).

When an angle is established, the observer at C turns the
graduated drum of the reading instrument until the image of
the vane of the right-angle instrument coincides with the direction
of the objective. The range AC is then read on the drum. The
ranges on the drum are measures of the angle BAC when the base
BC is 50 yds.

The mekometer is open to the objection which is common to all
range-finders requiring more than one observer. There is always a
danger that observers may cause coincidence on different objectives
or on different parts of the same objective, and thus inaccuracy in the
recorded range must result. The instruments are expected to give an
accuracy of less than 2% at 2000 yds. For
ranges over that distance, i.e. for usual artillery ranges, it is
desirable to use a double base (100 yds.
in length), in which
case the range registered on the drum must be doubled. This opera-
tion, although slight, is a distinct disadvantage, since it adds to the
time of taking a range and is a possible source of error. For field
artillery, however, a
range-finder is only an
auxiliary adjunct. The true range can be found by a process
of trial and error (see Artillery) in a short time as the
mekometer observers take to report it. It must further be
remembered that as shrapnel is the principal projectile of field
artillery, not only the correct elevation but also the true length of
time fuse has to be found. This the range-finder cannot do. Hence
it is that the range-finder for field artillery, although a valuable
auxiliary, is not of the same importance as in purely defensive
positions, such as batteries for harbour defence, and land forts.

The Marindin range-finder was from 1908 gradually intro-
duced in the infantry to replace the mekometer. It was the
invention of Captain A. H. Marindin, of the Black Watch (Royal
Highlanders).

The principle of the instrument is that of coincidence, as in the
Gauthier Christie, Le Cyre, Souchier, and Barr and Stroud. But
it differs from the last mentioned in that the right prism is made
movable, and this movement (necessarily extremely small) is a
function of the recorded range.

The steel tube, forming the base of the instrument, which carries the
prisms, is supported inside an aluminium outer tube in such a
way that no direct shock is communicated to it. The
appliance of the outside of the instrument, together
with the names of the various parts, is shown in fig. 4.

The instrument can be used in two main positions, viz. horizontally,
and would give good ranges, but probably the best range
would be obtained if held as at e. If it is required to use the instrument
at night, the two caps of the night-glasses should be opened. On looking through the instrument, any lamp or other light will appear like a fine, bright line, and the range can be taken in the ordinary way.

This range-finder possesses the superlative advantage of the one-man instrument, and it is claimed for it that it can range on horizontal objects, such as the crest of a hill, which has no detail suitable for use with a telometer, and that it can be adjusted on service with no greater difficulty than the setting of a watch.

3. For harbour defence, owing to the long range of naval guns, and the fast targets which war-vessels present, an accurate range-finder is of first importance. This is largely the case because "ranging" cannot be resorted to in the same manner as in the field, where the targets are comparatively motionless and the effective ranges are less. Successful artillery practice therefore depends, in a great measure, upon the range-finder.

The instrument used in harbour forts is known as the depression range-finder. As its name suggests, it solves a triangle in the vertical plane, of which the base is the height of the instrument above sea-level. Its appearance resembles some forms of theodolite (fig. 6). A framework, capable of rotating in azimuth on a vertical pivot, is supported on a plate carried by levelling screws, L, L. To the framework are pivoted two arms DC and FE, at C and E respectively. The arm EF is supported at F by a vertical screw H ending in a drum, upon which, in a spiral scale, the ranges are graduated. Motion in altitude is thus given to the telescope. The arm CD is supported by a slider G. This slider is set by a rack and pinion to the height above sea-level (represented on a scale of feet on EF) at which the instrument may be used. A telescope AB is suitably fitted in jaws at the outer edge of the frame. There are spirit-levels at M and Q for adjusting purposes. The telescope is provided with cross wires which can be illuminated for night use. An azimuth circle X and pointer Y enable the direction of any vessel to be indicated, the range of which it is desired to know. The instrument rests on a base plate R, to which it is locked by the top-plate O. The observer directs the cross wires of the telescope upon the water-line of the objective, by means of the drum I and the azimuth handle F, the top of which just appears in the diagram. The reader watches the arrow on the drum and calls out the ranges as the figures arrive beneath it. The ranges are communicated to the officers at the guns by various devices, which differ according to local requirements.

Position-Finder.—The range-finding instrument known in the British service as the Position-Finder (invented by Colonel Watkin, C.B., R.A.) is practically a large depression range-finder. It possesses, however, certain additional appliances which render it capable of automatically recording, upon an oriented chart, the position or course of a vessel. And further, by electrical means it automatically records to a distant battery the range and bearing of the desired objective. The position-finder can therefore, from a concealed and safe position, automatically control the fire of a group of guns, whose detachments need not necessarily see the target engaged. As the observer follows the objective with the telescope of the instrument the range and bearing is simultaneously shown in the battery on convenient dials. The distance and direction thus communicated are the range and bearing from the guns, not as measured from the range-finder. The correction due to the displacement between gun and instrument is automatic. In localities where the height does not admit of using the depression system, an alternative arrangement is provided, known as the Horizontal Position-Finder. It is open to the objections common to two-man range-finders, and is only employed where necessity compels its use. Briefly, there are two observing stations at either end of a measured and electrically connected base. One is known as the transmitting and the other the receiving station; the latter contains the principal instrument, which usually is capable of independent use for medium and short ranges as a depression instrument.

It will be seen that the difference between the two systems is, that the first described solves the range triangle in the vertical, and the latter in the horizontal plane. There have been various methods proposed for using the position-finder. The best results are obtained by placing range and bearing dials on the gun-mounting in a position where they can be easily seen by the men elevating and training the gun. The gun is kept directed upon the objective and fired as quickly as it can be loaded. A position-finder can be used for fusing mines in a mine field, and instruments are issued to the Royal Navy for this purpose.

In the United States of America the term "position-finder" is applied to a range-finder which gives direction as well as distance. This is such a case. The instrument, known as the hotchkiss position-finder, in the British service, confines the use of the expression as defined above.

4. Various appliances, not strictly range-finders, are sometimes used to assist in estimating distance. The following examples are not without interest. —

Acoustic telemeters, depending upon the velocity of sound, are obviously unsuited to the requirements of modern warfare. The names of Thouvenin, Rézier and Le Boulangé are connected with such instruments—that of the last-named, the most convenient. It consists of a graduated glass tube filled with liquid, of suitable density, and containing a small metal traveller. At the base of the instrument or rifle is a horizontal key which brings it to a vertical position, and the traveller starts from zero; at the detention, it is turned to a horizontal position and the traveller stops at the point on the scale indicating the range.

On the principle of this rough method of ascertaining the distance, in yards, of a thunderstorm, viz. multiply the number of seconds elapsed between the perception of the lightning and that of the thunder by the number of yards the eye and the year are estimated to be.

Optical or perspective telemeters determine the distance to any point by observing the size of some object of known dimensions, as seen in a graduated telescope. Porro's telemeter, Elliot's telescopes, and Nordheim's micrometer illustrate the principle. The chief defect of the system is that the objects most conveniently observed—men and horses—vary considerably in size, so that the assumption of a constant dimension may be productive of error.

On the continent of Europe the perspective telemeter for military purposes has attracted more attention than in England. The French in their precise terminology call such an instrument "Stadia Militaire," a term which at once distinguishes it from a "telemètre," and describes its nature. In rapid military sketching, in locating positions upon maps, &c., perspective telemeters find a use. The telescope is provided with a scale in the field of view. By comparing this scale with known heights, such as the average height of a man on foot, or the known height of a gun or rifle breech, &c., of a war-vessel, distance can be estimated with fair accuracy.

The "jumelle Souchier," which can be used as an ordinary field-glass, is constructed on the stadia principle. By its means ranges can be estimated within an accuracy of 10%. A stand or rest, however, is necessary for good results.

General Percin of the French army has shown, in an interesting pamphlet, that a piece of wood or card cut to a known fraction of the distance between the eye and the end of the thumb, when the arm is fully extended, can be used to estimate distances. Thus it is easy to find a penny in good condition of which the thickness is 1/16th of the arm-length in a man of average height. Provided with such a coin and an arm rim to exactly cover a distant man 6 ft. (or 2 yds. high). The range therefore is $400 \times 2 = 800$ yds. Similarly, if the man's height appeared to be half the thickness of the coin the range would be $4 \times 400 = 1600$ yds. With a little practice the eye estimates the proportion between the object of
known height and the stadia used. General Percin gives many useful applications of this simple device.

This range-finder has been introduced in countries outside the British Isles which, as they are the outcome of similar necessity and required for identical purposes, naturally resemble, more or less, the instruments already described.

Field artillery officers of all countries usually claim their gun to be their best range-finder. This may be another way of saying that a durable, one-man range-finder, capable of instantaneous finding and giving a definite and accurate range, may be introduced into France "the télémètre Goutier" for field artillery, a two-man instrument, corresponds with the Watkin mekerometer.

The "Goutier," used by the Italian field artillery, is a one-man instrument, but requires a measured base-line. The Aubry, télémètre, telemeter, used by some of the Russian batteries in Manchuria, is very portable, but requires a measured base-line, and a slide rule to find the range. In the French and Russian infantry the "prisme-télémètre" is used; it is very light, and can be carried in the same manner as field-glasses. French machine guns are ranged by the "télémètre instantané," an instrument of the Barr and Stroud type, with an aluminium base 1 metre in length.

For work in the field the modern tendency abroad is to follow Barr and Stroud. In Germany, Hahn, Goerz and Zeiss have produced handy and fairly light short base range-finders, in outward appearance more or less similar to Marinard's instrument.

The Zeiss range-finder, however, depends on the stereoscopic principle. It is open to the objection that best results can only be obtained by the use of stereo-glasses, and also, in individuals possessing this particular gift (a comparatively small proportion of the human race), stereoscopic vision may vary in power from day to day. In order to obviate this difficulty the Barr and Stroud range-finder resembles the earlier Watkin instruments. In Italy the Amic instrument is being replaced by the Braccialine. The latter inventor has also supplied his country with a horizontal base instrument.

The principle of range-finder type in France, "le télémètre Dédé" is used at all heights of about 70 ft. and upwards.

Brazilians, in the invention of Captain Mario Netto, an excellent range-finder. It is supplied to the harbour defences of that country. It is accurate, handy, easily transported and erected where required, and is not affected by the concussion of heavy guns. The instrument consists of a telescope, a micrometer and a graduated scale, and is a miniature version of Percin's range-finder in Italy. For naval and harbour defence purposes, the Barr and Stroud range-finder is very largely used throughout the world, and has been adopted with the large base of 5 metres, was in 1908 under trial for coast artillery.

Of the depression range-finder type in France, "le télémètre Dédé" is used at all heights of about 70 ft. and upwards.

RANGER, RANGOON

RANGER—RANGOON

891

RANGER—RANGOON

891

volume of its trade. During the busy season of rice-export, which lasts from the end of December to the middle of May, the pool forming the port of Rangoon presents almost as crowded a scene as the Hugill at Calcutta. Rangoon has the double advantage of being situated near the sea and being served by a great river navigable for 900 m. behind it. The approach to the port is not difficult at any season of the year. With flat and shelving shores, the shoal-banks off the mouth of the delta form the chief danger to shipping, and this is guarded against by a good service of light-houses and lightships. For a length of seven or eight miles the river is from a mile to a mile and a quarter in breadth, so that there is plenty of accommodation for shipping. Here is concentrated the whole of the rich trade of the delta of the Irrawaddy. Great part of the river frontage is occupied with rice-mills, tea-warehouses and similar buildings. The rice exported from Rangoon in 1904-5 amounted to 28,000,000 cwt., with a value of nearly 10 million pounds.

The city is dominated by the great golden pile of the Shwe Dagon pagoda, the centre of Burmese religious life. Rising to a height of 568 ft., this magnificent building is loftier than St Paul's Cathedral in London, and its size is greatly enhanced by the fact that it stands on an eminence that is itself 168 ft. above the level of the city. It is covered with pure gold from base to summit, and once in every generation this gold is renewed by public subscription. Moreover, benefactions to this pagoda are one of the favourite methods of acquiring religious merit among the Burmese. The pagoda itself has no interior. It is a solid stupa, square in the base, and 120 ft. high, with a large square and the place of worship is the surrounding platform with a perimeter of nearly 1400 ft.

Though traditionally a site of great sanctity, Rangoon owes its first importance to its rebuilding in 1753 by Alompra, the founder of the Burmese monarchy, who gave it the present name of Yen Kon, "the end of the war." An English factory was opened here about 1790. On the outbreak of the first Burmese War, in 1824, it was taken by the British, but subsequently restored. It was captured a second time in 1852, and passed along with the province of Pegu into the hands of the British. It was destroyed by fire in 1850, and serious conflagrations occurred again in 1853 and 1855. Since the last devastation Rangoon has undergone considerable improvements.

Until 1874, when the existing municipality was constituted, the administration was in the hands of the local government, which devoted itself to raising the centre of the town above the river level, providing land fit for building purposes from the original swamp, which was flooded at spring-tides, and making roads, bridges, culverts and surface drains. In 1892 was introduced the sewage system, which now includes 6 m. of mains, 22 m. of gravitating sewers, 4½ m. of air mains and 4000's ejectors. The water supply, drawn from the Victoria Lake, a distance of nearly 9 miles, is supplemented by an additional reservoir, 10 m. farther off. The city proper of Rangoon with the Kemmendine suburb is laid out on the block system, each block being 800 by 860 ft., intersected with regular streets. In the extensions to the east and west it has been decided to have no streets less than 50 ft. wide. The roads are still lighted by kerosene oil lamps, but electric lighting is in contemplation. Electric tramways run to Pazundaung in one direction and to Alon and Kemmendine in the other, as well as to the foot of the Shwe Dagon Pagoda hill. Latterly the erection of masonry buildings, instead of plank houses, has been insisted on in the central portion of the city, with the result that many have decreased in number. There are two large maidans, or commons, which are used as military parade grounds and for racing, as well as for golf links and other purposes of amusement. There is a garden round the Phayar Museum, managed by the Agri-Horticultural Society, and an extremely pretty and well-kept garden in the cantonments under the pagoda. Beyond these lie the Royal Lake and Dalhousie Park, with 160 acres of water and 201 acres of well-laid-out and well-tilled park land. Dalhousie Park has recently been greatly extended, and the new Victoria Park, declared open on the
occasion of the visit of the prince of Wales in 1806, is quite the finest in the East. There are two cathedrals, Church of England and Roman Catholic, and a Presbyterian church, besides the cantonment church buildings for worship. Religious buildings and lands, indeed, occupy an area in Rangoon out of all proportion to its size. Buddhists, Hindus, Mussulmans, Parsees, Armenians and Jews all own lands and pagodas, temples, mosques, churches and synagogues. The Buddhist monasteries, in particular, occupy wide spaces in very central portions of the town and cantonments. Burial-grounds are equally extensive, and exist in every direction in what were once the outskirts, but are now fast becoming central parts of the city. The chief educational institutions are the Government Rangoon college, the Baptist college and St. John's College (S.G.). Besides the general hospital, a female hospital in connexion with the Dufferin Fund has recently been built, and there are hospitals for contagious diseases and for lepers in the suburbs. The staple industries are mills for husking rice and for sawing timber, and petroleum refineries. Carving in wood and ivory, and embossed silverwork are also carried on. There are three municipal and eight private markets, which are being improved and extended. Everything, from sacking to jewelry, is sold in them. The introduction of pure water and the establishment of compulsory vaccination have greatly improved the health of Rangoon. But the death-rate is still high, due partly to the swampy nature of the outskirts of the city proper, and still more to the mortality among Hindu immigrants from the Madras presidency. The total rainfall in 1905 was 104-96 in. Rangoon is the head-quarters of a brigade in the Burma command of the Southern army.

RANGPUR, or RUNGPORE, a town and district of British India, in the Rajshahi division of Eastern Bengal and Assam. The town is situated on the little river Ghaghat. Pop. (1901) 15,960. There are a high school, a normal school and an industrial school. The earthquake of the 12th of June 1897 destroyed many of the public buildings and diverted the drainage channels.

The District of Rangpur, with an area of 3493 sq. m., is one vast plain. The greater part of it, particularly towards the east, is inundated during the rains, and the remainder is traversed by a network of streams which frequently break through their sandy banks and plough for themselves new channels over the fields. The river system is constituted by the Brahmaputra and its tributaries, chief of which are the Tista, Dharla, Sankos and Dudhukumar. The climate is generally malarious, owing to the numerous stagnant swamps and marshes filled with decaying vegetable matter. The annual rainfall averages 82 in. About three-fourths of the district is under continuous cultivation. Spare land can hardly be said to exist—even the patches of waste land yield a valuable tribute of reeds and cane. The staple crops are rice, oil-seeds, jute and tobacco. In 1901 the population was 2,154,181, showing an increase of 4.53% in the decade. Nearly two-thirds are Mahommecans. The Eastern Bengal railway has two branches, one of which crosses the district to the Brahmaputra, and the other runs north towards Assam.

The tract comprised within the district of Rangpur was formerly the western outpost of the ancient Hindu kingdom of Kamrup, which appears to have attained its greatest power and prosperity under Raja Nilambar, who was treacherously overthrown by Ala-uddin Hosain of Bengal at the close of the 15th century. Rangpur passed to the East India Company in 1765 under the firman of the emperor Shah Alam. Since then a great number of changes have taken place in the jurisdiction, in consequence of which the district area has been much diminished.

RANJIT SINGH, MAHARAJA (1780-1839), native Indian ruler, was born on the 2nd of November 1780, the son of Siradar Mahan Singh, whom he succeeded in 1792 as head of the Sarkar-chakila branch of the Sikh confederacy. By birth he was only one of many Sikh barons and owed his rapid rise entirely to force of character and will. At the age of seventeen he seized the reins of government. He is said to have poisoned his mother, though it is more probable that he merely imprisoned her to keep her out of his way. At the age of twenty he obtained from Zaman Shah, the king of Afghanistan, a grant of Labore, which he seized by force of arms in 1790. Subsequently he attacked and annexed Amritsar in 1802, thus becoming master of the two Sikh capitals. When Jaswant Rao Holkar took refuge in the Punjab in 1805, Ranjit Singh made a treaty with the British, excluding Holkar from his territory. Shortly afterwards acute difficulties arose between him and the British as to the Cis-Sutlej portion of the Punjab. It was Ranjit Singh's ambition to weld the whole of the Punjab into a single Sikh empire, while the British claimed the territory south of the Sutlej by right of conquest from the Maharrattas. The different proceedings almost to the point of war, but at the last moment Ranjit Singh gave way, and for the future faithfully observed his engagements with the British, whose rising power he was wise enough to gauge. In 1808 Charles Metcalfe was sent to settle this question with Ranjit Singh, and a treaty was concluded at Amritsar on the 15th of April 1809. At this period a band of Sikh fanatics called "akalis," attacked Sir Charles Metcalfe's escort, and the steadiness with which the disciplined sepoys repulsed them, so impressed the maharaja that he decided to change the strength of his army from cavalry to infantry. He organized a powerful force, which was trained by French and Italian officers such as Generals Ventura, Allard and Avitalbe, and thus forged the formidable fighting instrument of the Khalsa army, which afterwards gave the British their hardest battles in India in the two Sikh wars. In 1810 he captured Multan after many assaults and a long siege, and in 1820 had consolidated the whole of the Punjab between the Sutlej and the Indus under his dominion. In 1823 the city and province of Peshawar became tributary to him. In 1833 when Shah Shuja, flying from Afghanistan, sought refuge at his court, he took from him the Koh-i-nor diamond, which subsequently came into the possession of the British crown. Though he disapproved of Lord Auckland's policy of General Sir Henry Hardinge and Shuja for Dowt Mahomed, he loyally supported the British in their advance on Afghanistan. Known as "The Lion of the Punjab," Ranjit Singh died of paralysis on the 27th of June 1839.

In his private life Ranjit Singh was selfish,avaricious, drunken and immoral, but he had a genius for command and was the only man the Sikhs ever produced strong enough to bind them together. His military genius showed itself not so much in actual generalship as in the organization of his plans, the selection of his generals and his ministers, the tenacity of his purpose and the soundness of his judgment. The British were the one power in India that was too strong for him, and as soon as he realized that fact he was unwaveringly loyal to his engagements with them. His power was military aristocracy resting on the personal qualities of its founder, and after his death the Sikh confederacy gradually crumbled and fell to pieces through sheer want of leadership; and the rule of the Sikhs in the Punjab passed away completely as soon as it incurred the hostility of the British.

See Sir Lepel Griffin, Ranjit Singh (Rulers of India Series), 1892; General Sir John Gordon, The Sikhs, 1904; and S. S. Thorburn, The Punjab in Peace and War, 1904.

RANK (O.Fr. rang or rance, mod. rang, generally connected with the O.E. and O.H.G. hring, a ring), a row or line, as of cabs or carriages, but especially of soldiers drawn up abreast in a line; in "rank and file" the "rank" is the horizontal line of soldiers, the "file" the vertical. From the sense of orderly arrangement "rank" is applied to grades or classes in a social or other organization, and particularly to a high grade, as in such expressions as a "person of rank." This word must be distinguished from the adjective "rank," overluxuriant, coarse, strong, generally connected with the Low Ger. rank, thin, tall (cf. Du. rank, upright). The O.E. rinc, warrior, i.e. full-grown man, may be also connected with the word; Skeit refers also to "rack," to pull out straight.
At Rome, as he said, he learned to see events from the inside. He wrote nothing but a critical examination of the story of Don Carlos, but he returned to Germany a master of his craft.

For a time Ranke was now engaged in an occupation of a different nature, for he was appointed editor of a periodical in which Friedrich Perthes designed to defend the Prussian government against the democratic press. Ranke, contemptuous in politics, as in history, of the men who wanted facts to support some abstract theory, especially disliked the doctrinaire liberalism so fashionable at the time. He hoped, by presenting facts as they were, to win the adhesion of all parties. We need not be surprised that he failed; men desired not the scientific treatment of politics, but satire and invective. Exposed thus to attack, his weakness, if not his venality, was long an article of faith among the liberals. He did not satisfy the Prussian conservatives, and after four years the Historische Politische Blätter came to an end. Two-thirds of the matter had been contributed by the editor, and the two stout volumes in which the numbers were collected contained the best political thought which had for long appeared in Germany. For Ranke the failure was not to be regretted; the rest of his life was to be wholly devoted to that in which he excelled. During 1834–36 appeared the three volumes of his Die römischen Päpste, ihre Kirche und ihr Staat im 16 und 17 Jahrhundert (Berlin, 1834–36, and many other editions), in form, as in matter, the greatest of his works, containing the results of his studies in Italy. Henceforth his name was known in all European countries; the English translation by Mrs Austin was the occasion of one of Macaulay’s most brilliant essays. Before it was completed he had already begun the researches on which was based the second of his masterpieces, his Deutsche Geschichte im Zeitalter der Reformation (Berlin, 1839–47), a necessary pendant to his book on the popes, and the most popular of his works in his own country. In 1837 he became full professor at Berlin; in 1847 Frederick William IV., always ready to recognize intellectual eminence, appointed him Prussian historiographer. Stimulated by this, he brought out his Neun Bücher preussischer Geschichte (1847–48), a work which, chiefly owing to the nature of the subject, makes severe demands on the attention of the reader—he is the "Dryasdust of Carlyle’s Frederick; he cannot lay the foundation of the modern appreciation of the founders of the Prussian state. The volume was subsequently expanded to twelve (Leipzig, 1874). He took no immediate part in the movements of 1848, but in the following years he drew up several memoranda for the king, whom he encouraged in his efforts to defend the character and identity of the Prussian state against the revolutionaries. Though never admitted into the inner circle of the king’s associates, he found the king the most appreciative of readers and stimulating of companions, and the queen one of the most faithful of his friends; in biographical works and on occasional occasions he always defended the memory of the unfortunate monarch. A friend even more sympathetic he found in Maximilian II. of Bavaria, whom he advised in his expansive schemes for the promotion of learning and letters. In the quieter years that followed he wrote the third of his masterpieces, Frauensische Geschichte, vornehmlich im 16 und 17 Jahrhundert (Stuttgart, 1852–61), which was followed by his Englische Geschichte, vornehmlich im 16 und 17 Jahrhundert (1859–68). This, the longest of his works, added much to existing knowledge, especially as to the relations between England and the continent, but it lacked something of the freshness of his earlier books; he was over seventy when it was completed, and was rather quiet at home in dealing with the parliamentary foundations of an English public life. In his later years his small alert figure was one of the most distinguished in the society of Berlin, and every honour open to a man of letters was conferred upon him. He was ennobled in 1865, and in 1883 received the title of Excellenz. When the weakness of his eyes made it necessary for him to depend almost entirely on the service of readers and secretaries,
in his eighty-first year he began to write the  
Weltgeschichte  
(9 vols., Leipzig, 1833–88). Drawing on the knowledge ac- 
cumulated during sixty years, he had brought it down to the 
end of the 15th century before his death in Berlin on the 
23rd of May 1886.

Ranké's other writings include  
Zur deutschen Geschichte.  
Vom Religionsfrieden bis zum 30 jährigen Kriege (Leipzig, 1868);  
Geschichte Wallensteins (Leipzig, 1869; 5th ed., 1890);  
Abhand- 
lungen und Versuche (Leipzig, 1877; a new collection of these 
 writings was edited by A. Dove and T. Wiedemann, Leipzig, 
1888);  
Aus dem Briefwechsel Friedrich Wilhelms IV. mit 
Bunsen (Leipzig, 1873);  
Die deutschen Mächte und der Fürsten-
bunde Deutscher Geschichte 1780–90 (1873–75);  
Die historischen biographischen Studien (Leipzig, 1878);  
Ursprung und Beginn der 
Revolutionskriege 1701–02 (Leipzig, 1879);  
zur Geschichte 
von Oesterreich und Preussen zwischen den Friedensschlüssen 
zu Aachen und Hubertusberg (Leipzig, 1875). He also wrote 
biographies of Frederick the Great and Frederick William IV. 
for the Allgemeine Deutsche Biographie.

Ranké married, at Windermere, in 1843, Miss Clara Graves, 
daughter of an Irish barrister. She died in 1870, leaving two 
sons and one daughter.

At the whole north Ranké was, not in his own country, 
alone, generally regarded as the first of modern historians. 
It is no disparagement to point out that the recognition 
he obtained was due not only to his published work, but also to 
his success as a teacher. His public lectures, indeed, were 
never largely attended, but in his more private classes, where 
he dealt with the technical work of a historian, he trained 
generations of scholars. No one since Heyne has had so great 
a influence on German academical life, and for a whole genera-
tion the Berlin school had no rival. He took paternal pride in 
the achievements of his pupils, and delighted to see, through 
them, his influence spreading in every university. While his 
own work lay chiefly in more modern times, he trained in 
his classes a school of writers on German medieval history. 
As must always happen, it is only a part of his characteristics 
which they learnt from him, for his greatest qualities were 
incommunicable. The critical method which has since become 
almost a formal system, aiming at scientific certainty, was 
with him an unexampled power, based on the insight acquired 
from wide knowledge, which enabled him to judge the credi-
bility of an author or the genuineness of an authority; but he 
has made it impossible for any one to attempt to write 
modern history except on the “narratives of eye-witnesses and 
the most genuine immediate documents” preserved in the 
archives. From the beginning he was determined never to 
allow himself to be misled, in his search for truth, by those 
theories and prejudices by which nearly every other historian 
was influenced—Hegelanism, Liberalism, Romanticism, 
religious and patriotic prejudice; but his superiority to the 
ordinary passions of the historian could only he attained by 
those who shared his elevation of character. “My object 
is simply to find out how the things actually occurred.” “I 
am first a historian, then a Christian,” he himself said. In 
another way, no historian is less objective, for in his greatest 
works the whole narrative is coloured by the quality of 
his mind expressed in his style. An enemy to all controversy and 
aviolence, whether in act or thought, he had a serenity of 
character comparable only to that of Sophocles or Goethe. 
Apt to minimize difficulties, to search for the common ground 
of unity in opponents, he turned aside, with a disdain which 
superficial critics often mistook for indifference, from the base, 
the violent and the common. As in a Greek tragedy, we hear 
in his works the echo of great events and terrible catastrophes; 
we do not see them. He also made it a principle not to relate 
that which was already well known, a maxim which necessarily 
prevented his works attaining a popularity with the unlearned 
equal to their reputation among historians. But no writer has 
surpassed him in the clearness and brevity with which he could 
sum up the characteristics of an epoch in the history of the 
world, or present and define the great forces by which the world 
has been influenced. His classicism led to his great limitations 
as an historian. He did not deal with the history of the people, 
with economic or social problems—the dignity of history was 
unfit him a reality. He belonged to the school of Thucydides 
and Gibbon, not to that of Macaulay and Taine; he deals by pre-
ference with the rulers and leaders of the world, and he strictly 
limits his field to the history of the state, or, as we should say, 
political history; and in this he is followed by Seeley, one of the 
greatest of his adherents. The leader of modern historians, 
he was in truth a man of the ancien régime.

Many of Ranké's works have been translated into English. Among 
these are Civil Wars and Monarchy in France, by M. A. Garvey 
(Leipzig, 1875);  
History of the Latin and Teutonic Nations, 1494–1514, by 
P. A. Ashworth (1887) and again by S. R. Dennis (1900);  
History of the Reformation in Germany, by S. Austin (1845–47);  
History of Servia and the Servian Revolution, by Mrs. A. Kerr (1847);  
Friedensschluss und Maximum Il. of Austria; State of Germany after 
the Reformations, by Lady Duff Gordon (1853);  
Memories of the House of Brandenburg and History of Prussia during the 17th and 18th 
Centuries, by Sir Alexander and Lady Duff Gordon (1849);  
and History of the Popes during the 16th and 17th Centuries, by S. Austin 
(1843; new eds, 1841 and 1847), by W. K. Kelly (1843), and 
by E. Foster (1847–51). A selection of his works, with five volumes 
were edited at Leipzig (1868–90), but this does not contain the 
Weltgeschichte.

For details of Ranké's life and work see his own Zur eigenen 
Lebensgeschichte, edited by A. Dove (Leipzig, 1890); and the article 
by Dove in the Allgemeine deutsche Biographie. Also Winckler, 
Leopold von Ranké. Lichtstrahlen aus seinen Werken (Berlin, 1885); 
Heyne, Adolph von, Geschichte der Popemacht (Leipzig, 1885); 
Guglia, Leopold von Rankes Leben und Werke (Leipzig, 1893); 
M. Ritter, Leopold von Ranké (Stuttgart, 1895); Nallbrand, 
Leopold von Rankes Bildungsjahre und Geschichtsausfassung 
(Leipzig, 1901); and Helmont, Leopold Ranké (Leipzig, 1907).

RANKINE, WILLIAM JOHN MACQURIE  
(1820–1872), Scottish engineer and physicist, was born at Edinburgh on the 
5th of July 1820, and completed his education in its 
university. He was graduated as an artist (1838), and 
worked chiefly on surveys, harbours and railroads, and was appointed in 
1855 to the chair of civil engineering in Glasgow, vacant by 
the resignation of Lewis Gordon, whose work he had undertaken 
during the previous session. He was a voluminous writer on 
subjects directly connected with his chair, and, besides 
contributing almost weekly to the technical journals, such as the 
Engineer, brought out a series of standard textbooks on Civil 
Engineering, The Steam-Engine and other Prime 
Movers, Machinery and Millwork, and Applied Mechanics, which 
have passed through many editions, and have contributed greatly to 
the advancement of those sciences. These volumes are 
these must be added his elaborate treatise on Shipbuilding, 
Theoretical and Practical. These writings, however, 
corresponded to but one phase of Rankine's immense energy and 
many-sided character. He was an enthusiastic and most useful 
leader of the volunteer movement from its beginning, and a 
writer, composer and singer of humorous and patriotic songs, 
some of which, as “The Three Foot Rule” and “They 
never shall have Gibraltar,” became well known far beyond 
the circle of his acquaintance. Rankine was the earliest of 
the school of scientific works of thermodynamics (q.v.) on the bases laid by Sadi Carnot and J. P. Joule res-

cively, and the author of the first formal treatise on the 
subject. His contributions to the theories of Elasticity and of Waves 
rank high among modern developments of mathematical 
physics, although they are mere units among the 150 scientific 
papers attached to his name in the Royal Society's Catalogue. 
The most important of these were collected and reprinted in 
a handsome volume (Rankine's Scientific Papers, London, 1881), 
which contains a memoir of the author by Prof. P. G. Tait. 
Rankine died at Glasgow on the 24th of November 1872.

RANNOCH, a district, at north-west Perthshire, Scotland, 
partly extending into Argyllshire. It measures 3 2 m. E. 
and from 10 to 12 m. N. and S. and is surrounded by 
the districts of Badenoch, Atholl, Breadalbane, Lorne and 
Lochaber. Much of it is wild, bleak and boggy, and, saving on the 
E., it is shut in by rugged mountains. The chief rivers are
RANSOM—RANUNCULACEAE

895

the Tummel and the Erich, and the principal lakes Loch Rannoch and Loch Lydoch, or Laidon (about 6 m. long, 1 ft. wide and 924 ft. above the sea). Loch Rannoch lies E. and W., measures 9 ft. long by fully 1 ft. broad, is 668 ft. above the sea, covers an area of nearly 73 sq. m., and has a greatest depth of 440 ft. It receives the Erich and many other streams, and discharges by the Tummel, draining a total area of 2433 sq. m. At the head of the lake is Rannoch Barracks, so named because it was originally built to accommodate a detachment of troops, under ensign (afterwards Sir) Hector Munro, stationed here to maintain order after the Jacobite rising of 1745. Two miles east is Carie, which was the residence of Alexander Robertson, 13th baron of Struan (1670-1749), the Jacobite and poet, who was "out" with Dundee (1689), Mar (1713) and Prince Charles Edward (1745), and yet managed to escape all punishment beyond self-imposed exile to France, after the first two rebellions. Kinloch Rannoch, at the foot of the loch, is the principal place in the district, and is in communication by coach with Struan station (13 m. distant) on the Highland, and Rannoch station (6 m.) on the West Highland railway. Dugald Buchanan (1716-1708), the Gaelic poet, was school-master of the village for thirteen years, and a granite obelisk has been erected to his memory.

RANSOM (from Lat. redempitio, through Fr. rançon), the price for which a captive in war redeemed his life or his freedom, a town secured immunity from sack, and a ship was repurchased from her captors. The practice of taking ransom arose in the middle ages, and had perhaps a connexion with the common Teutonic custom of commuting for crimes by money payments. It may, however, have no such historic descendent. The desire to make profit out of the risks of battle, even when they were not dimished by the use of, armour, would account for it sufficiently. The right to ransom was recognized by law. One of the obligations of a feudal tenant was to contribute towards paying the ransom of his lord. England was taxed for the ransom of Richard the Lion Hearted, France for King John taken at Poitiers, and Scotland for King David when he was captured at Durham. The prospect of gaining the ransom of a prisoner must have tended to diminish the ferocity of medieval war, even when it did not reduce the fighting between the knights to a form of athletic sport in which the loser paid a forfeit.

Readers of Froissart will find frequent mention of this decidedly commercial aspect of the chivalrous wars of the time. He often records how victors and vanquished arranged their "financing." The mercenary views of the military adventurers were not disguised. Froissart repeats the story that the English "free companions" or mercenaries, who sold their services to the king of Portugal, grumbled at the battle of Aljubarrota in 1377, because of their payment was killed, and would not pursue the defeated French and Spaniards, with whom they had lost lucrative captures. The ransom of a king belonged to the king of the enemy by whom he was taken. The actual captor was rewarded at the pleasure of his lord. King Edward III. paid over instalments of the ransom of the king of France to the Black Prince, to pay the expenses of his expedition into Spain in 1367. Occasionally, as in the notable case of Bertrand du Guesclin, the ransom of a valuable knight or leader would be paid by his own sovereign. To trade in ransoms became a form of financial speculation. Sir John Fastolf in the time of King Henry V. is said to have made a large fortune by buying prisoners, and then disregarding heavy ransoms out of them by illness. The humane influence of ransom was of course confined to the knights who could pay. The common men, who were too poor, were massacred. Thus Lord Grey, Queen Elizabeth's lord deputy in Ireland, spared the officers of the Spaniards and Italians he took at Smerwick, but slaughtered the common men. Among the professional soldiers of Italy in the 15th century the hope of gaining ransom tended to reduce war to a farce. They would not lose their profits by killing their opponents. The disuse of the practice was no doubt largely due to the discovery that men who were serving for this form of gain could not be trusted to fight seriously.

Instances in which towns paid to avoid being plundered are innumerable. So late as the war in the Peninsula, 1808-14, it was the belief of the English soldiers that a town taken by storm was liable to sack for three days, and they acted on their conviction at Ciudad Rodrigo, Badajoz and San Sebastian. It was a question whether ransoms paid by merchant ships to escape were or were not among the commercia belli. In the early 18th century the custom was that the captain of a captured vessel gave a bond or "ransom bill," leaving one of his crew as a hostage or "ransomer" in the hands of the captor. Frequent mention is made of the taking of French privateers which had in them ten or a dozen ransomers. The owner could be sued on his bond. At the beginning of the Seven Years' War ransoming was forbidden by act of parliament. But it was afterwards at least partially recognized by Great Britain, and was generally allowed by other nations. In recent times—for instance in the Russo-Japanese War—no mention was made of ransom, and with the disappearance of privateering, which was conducted wholly for gain, it has ceased to have any place in war at sea, but the contributions levied by invading armies might still be accurately described by the name.

RANTERS, an antinomian and spiritualistic English sect in the time of the Commonwealth, who may be described as the dregs of the Seeker movement. Their central idea was pantheistic, that God is essentially in every creature, but though many of them were sincere and honest in their attempt to express the doctrine of the Divine immanence, they were in the main unable to hold the balance. They denied Church, Scripture, the current ministry and services, calling on men to hearken to Christ within them. Many of them seem to have rejected a belief in immortality and in a personal God, and in many ways they resemble the Brethren of the Free Spirit in the 14th century. Their vague pantheism landed them in moral confusion, and many of them were marked by fierce fanaticism. How far the accusation of lewdness brought against them is just is hard to say, but they seem to have been a really serious peril to the nation. They were largely recruited from the common people, and there is plenty of evidence to show that the movement was widespread. The Ranters came into contact and even rivalry with the early Quakers, who were often unjustly associated with them. The truth is that the positive message of the Friends helped to save England from being overrun with Rantism. Samuel Fisher, a Friend, writing in 1633, gives a calm and instructive account of the Ranters, which with other relevant information, including Richard Baxter's rather hysterical attack, may be read in Rufus M. Jones's Studies in Mystical Religion (1909), xix. In the middle of the 19th century the name was often applied to the Primitive Methodists, with reference to their crude and often noisy preaching.

RANUNCULACEAE, in botany, a natural order of Dicotyledons belonging to the subclass Polypetalae, and containing 27 genera with about 100 species, which are distributed through temperate and cold regions but occur especially beyond the tropics in the northern hemisphere. It is well represented in Britain, where 17 genera are native. The plants are mostly herbs, rarely shrubby, as in Celmatis, which climbs by means of the leaf-stalks, with alternate leaves, opposite in Celmatis, generally without stipules, and flowers which show considerable variation in the number and development of parts but are characterized by free hypogynous sepals and petals, numerous free stamens, usually many free one-celled carpels (fig. 2) and small seeds containing a minute straight embryo embedded in a copious endosperm. The parts of the flower are generally arranged spirally on a convex receptacle. The fruit is one-seeded, an achene (fig. 3), or a many-seeded follicle (fig. 4), rarely, as in Actaea, a berry.

From Vilm's Students' Text Book of Botany, by permission of Swan, Sonnenschein & Co.

Fig. 1.—Gynoeceum of R. repens, x, receptacle with the points of insertion of the stamens, which have been removed.
The order falls into several well-defined tribes which are distinguished by characters of the flower and fruit; all are represented among British native or commonly grown garden plants.

**Tribe I. Paenoeae**, peony group, are mostly herbs with deeply cut leaves and large solitary showy flowers in which the parts are spirally arranged, the sepals, generally five in number, passing gradually into the large coloured petals. The indefinite stamens are succeeded by 2–5 free carpels which bear a double row of ovules along the ventral suture. Honey is secreted by a ring-like swelling round the base of the carpels, which become fleshy or leathery in the fruit and dehice along the ventral suture. There are only three genera, the largest of which, *Paenoe*, occurs in Europe, temperate Asia and western North America. *P. officinalis* is the common peony.

**Tribe II. Helleboreae** are almost exclusively north temperate or subarctic; there are 15 genera, several of which are represented in the British flora. The plants are herbs, either annual, e.g. *Nigella* (love-in-a-mist), or perennial by means of a rhizome, as in *Aconitum* or *Eranthis* (winter aconite). The leaves are simple, as in *Caltha*, but more often palmately divided as in hellebore (fig. 6), aconite (fig. 5) and larkspar. The flowers are solitary (*Eranthis*) or in cymes or racemes, and are generally regular as in *Caltha* (king-cup, marsh marigold), *Trollius* (globe-flower), *Helleborus*, *Aquilegia* (columbine); sometimes medially zygomorphic as in *Aconitum* (monkshood, aconite) and *Delphinium* (larkspur). The carpels, generally 3 to 5 in number, form in the fruit a many-seeded follicle, except in *Actaea* (baneberry), where the single carpel develops to form a many-seeded berry, and in *Nigella*, where the five carpels unite to form a five-chambered ovary. There is considerable variety in the form of the floral envelopes and the arrangement of the parts. The outer series, or sepals, generally five in number, is generally white or bright-coloured, serving as an attraction for insects, especially bees, as well as a protection for the rest of the flower. Thus in *Caltha* and *Trollius* the sepals form a brilliant golden-yellow cup or globe, and in *Eranthis* a pale yellow star which contrasts well with the green involucre of bracts immediately below it; in *Nigella* they are blue or yellow, and also coloured in *Aquilegia*. In *Helleborus* the greenish sepals persist till the fruit is ripe. *Aconitum* and *Delphinium* differ in the irregular development of the sepals, the posterior sepal being distinguished from the remaining four by its helmet-shape (*Aconitum*) or spur (*Delphinium*). In *Caltha* there are no petals, but in the other genera there are honey-secreting and storing structures varying in number and in form in the different genera. In *Trollius* they are long and narrow with a honey-secreting pit at the base, in *Nigella* and *Helleborus* (fig. 7) they form short-stalked pitchers, in *Aquilegia* they are large and coloured with a showy petal-like upper portion and a long basal spur in the tip of which is the nectary. In *Delphinium* they are also spurred, and in *Aconitum* form a spur-like sac on a long stalk (fig. 8). The parts of the flower are generally arranged in a spiral (acyclic), but are sometimes hemicyclic, the perianth forming a whorl as in winter aconite; rarely is the flower cyclic, as in *Aquilegia* (fig. 9) where the parts are arranged in alternating whorls. In *Caltha*, where there are no petals, honey is secreted by two shallow depressions on the side of each carpel.

**Tribe III. Anemoneae**, with 8 genera, are chiefly north temperate, arctic and alpine plants, but also pass beyond the tropics to the southern hemisphere. They differ from the two preceding tribes in the numerous carpels, each with only one ovule, forming a fruit of numerous achenes. They are annual or perennial herbs, erect as in *Anemone*, *Thalictrum* (meadow-rue) and many buttercups, or creeping as in *Ranunculus* repens; the section *Batrachium* of the genus *Ranunculus* (q.v.) contains aquatic plants with submerged or floating stems and leaves. The flowers are solitary, as in *Anemone* *Pulsatilla* (Pasque flower) and the wood anemone, or cymose as in species of *Ranunculus*, or in racemes or panicles as in *Thalictrum*. The parts are spirally arranged throughout as in *Myosurus* (mouse-tail), where the very numerous carpels are borne on a much elongated receptacle, or *Adonis* (pheasant’s eye), or the perianth is whorled as in *Anemone* and *Ranunculus*. In *Anemone* there is a whorl of foliage leaves below the flower, as in *Eranthis*. In *Anemone* and *Thalictrum* there is only one series of perianth leaves, which are petaloid and attractive in *Anemone* where honey is secreted by modified stamens, as in *A. Pulsatilla*, or, as in *A. nemorosa* (wood anemone), there is no honey and the flower is visited by insects for the sake of the pollen; in *Thalictrum* the perianth is greenish or

**Fig. 3.**—Single follicle showing dehiscence by the ventral suture.

**Fig. 4.**—Fruit of Columbine (*Aquilegia*) formed of five follicles.

**Fig. 5.**—Five-partite leaf of Aconite.

**Fig. 6.**—Pedate leaf of Stinking Hellebore (*Helleborus foetidus*). It is a palmately-partite leaf, in which the lateral lobes are deeply divided. When the leaf hangs down it resembles the foot of a bird, and hence the name.

**Fig. 7.**—Helleborus niger. 1, vertical section of flower; 2, nectary, side and front view (nat. size).

**Fig. 8.**—Part of the flower of Aconite (*Aconitum Napellus*), showing two irregular horn-like petals, supported on grooved stalks. These serve as nectaries. 3, the whorl of stamens inserted on the thalamus, and surrounding the pistil.

**Fig. 9.**—Floral diagram of Columbine (*Aquilegia*) showing regular cyclic arrangement.
slightly coloured and the flower is wind-pollinated (T. minus) or visited for its pollen. In Ranunculus and Adonis a calyx of green protective sepals is succeeded by a corolla of showy petals; in Ranunculus (fig. 10) there is a basal honey-secreting gland which is absent in Adonis. The stamens are all in the act of anther dehiscence, but bear the persistent naked or bearded style which aids in dissemination; the same purpose is served by the prickles on the achenes of Adonis. The flowers of both these genera are perfect and regular.

Tribe IV. Clematisae comprise the genus Clematis (q.v.), characterized by its shrubby, often climbing habit, opposite leaves and the valvate, not imbricate as in the other tribes, aestivation of the sepals. The usually four sepals are whorled and petaloid, the numerous stamens and pisillae are spirally arranged; the flowers are visited by insects for the abundant pollen. The fruit consists of numerous achenes which are generally prolonged into the long feathery style, which often bears the name of Clematis vitalba. The genus, which contains about 170 species, has a wide distribution, but is rarer in the tropics than in temperate regions.

Special articles will be found on the more important genera of Ranunculaceae, e.g. Aconitum, Adonis, Arum, Baneberry (Actaea), Clematis, Columbine, Helleborus, Ranunculus.

RANUNCULUS, familiarly known as "buttercup," or crowfoot, is a characteristic type of the botanical order Ranunculaceae. The Lat. name, which means a little frog or tadpole (dim. of rana, frog), was also given to a medicinal plant, which has been identified by some with the crowfoot. The Ranunculi are more or less acrid herbs, sometimes with fleshy root-fibres, or with the base of the stem dilated into a kind of tuber (R. bulbosus). They have a smooth or rough, scaly, or papillose or velvety sheath at the base, and very generally, but not universally, deeply divided above. The flowers are solitary, or in loose cymes, and are remarkable for the number and distinctness (freedom from union) of their parts. Thus there are five sepals, as many petals, and numerous spirally arranged stamens and carpels. The petals have a little pit or honey-gland at the base, which is interesting as foreshadowing the more fully developed tubular petals of the nearly allied genera Aconitum and Helleborus. The fruit is a head of "achenes"—dry, one-seeded fruits. The genus contains a large number of species (about 250) and occurs in most temperate countries in the northern and southern hemispheres, extending into arctic andantarctic regions, and appearing on the higher mountains in the tropics. About twenty species are natives of Great Britain. R. acris, R. repens, R. bulbosus, are the common buttercups. R. arvensis, found in cornfields, has smaller pale yellow flowers and the achenes covered with stout spines. R. Lingua, spearwort, and R. Flammula, lesser spearwort, grow in marshes, ditches and wet places. R. Ficaria is the pilewort or lesser celandine, an early spring flower in pastures and waste places, characterized by having heart-shaped entire leaves and clusters of club-shaped roots. The section Butarichium comprises the water-buttercups, denizens of pools and streams, which vary greatly in the character of the foliage according as it is submerged, floating or aerial, and which submersed varying in accordance with the depth and strength of the current. The ranunculus of the florist is a cultivated form of R. asiaticus, a native of the Levant, remarkable for the range of colour of the flowers (yellow to purplish black) and for the regularity with which the stamens and pistils are replaced by petals forming double flowers. R. asiaticus is one of the older florists’ flowers, which has sported into numberless varieties, but was formerly held in much greater esteem than it is at the present time. Ranunculus arvensis is one of the older florists’ flowers, which has sported into numberless varieties, but was formerly held in much greater esteem than it is at the present time. Accoar of the florists, the flowers, to be perfect, should be of the form of two wings of a ball, the outline forming a perfect circle, with the centre close, the petals smooth-edged, the colour dense, and the marking uniform.

The ranunculus requires a strong and moist soil, with a fourth of rotten dung. The soil should be from 18 in. to 2 ft. deep, and at about 5 in. below the surface there should be placed a stratum 6 or 8 in. thick of two-year-old rotten cow-dung, mixed with earth, the earth above this stratum, where the roots are to be placed, being perfectly free from fresh dung. The tubers are planted in rows 5 or 6 in. apart, and 3 or 4 in. apart in the rows, the turbrt sorts in October, the more choice varieties in February. They should be so close that the foliage may cover the surface of the bed. The autumn-planted sort must be protected from severe frost. The plants when in flower should be screened from hot sunshine with an awning; when the leaves wither, the roots are to be taken up, dried, and stored. The ranunculus is readily propagated from seed obtained from semi-double sorts, which are often of themselves very beautiful flowers. It is generally sown in boxes in autumn or spring. The young plants thus raised flower in the second year, and always in the third year.

The turbrt varieties, which are very showy for the borders, are of a few positive colours, as scarlet, yellow, brown, carmine, and white. The florists’ varieties have been bred from the Persian ranunculus, which has many more petals than the wild plant.

Other species known in gardens are R. aconitifolius (white bachelor’s buttons), with leaves recalling aconite, and white flowers; the double-flowered form is known in gardens as fair maids of France or fair maids of Kent, and the dwarf seed-leaved R. bulbosus. There are also, for greenhouse purposes, varieties with large petal leaves often a foot in diameter, and with waxy white flowers about 4 in. across. It is not quite hardy, and even under the best conditions is a difficult plant to grow well.

RAO, SIR DINKAR (1819–1896), Indian statesman, was born in Ratnagiri district, Bombay, on the 20th of December 1819, being a Chitpavan Brahmin. At fifteen he entered the service of the Gwalior state, in which his ancestors had served. Rapidly promoted to the responsible charge of a division, he displayed unusual talents in reorganizing the police and revenue departments, and in reducing chaos to order. In 1852 Dinkar Rao became dewan. The events which led to the British victories of Maharajpur and Panniar in 1844 had filled the state with a continuous soldierly, ruined the finances, and weakened the authority. With a depressed revenue, the dewan, Dinkar Rao, speedily abolished ruinous imposts, executed public works, and by a reduction of salaries, including his own, turned a deficit into a surplus. When the contingent mutinied in 1857, he never wavered in loyalty; and although the state troops also mutinied in June 1858 on the approach of Tantia Topi, he adhered to the British cause, retiring with Maharaja Sindha to the Agra fort. After the restoration of order he remained minister until December 1859. In 1873 he was appointed guardian to the minor Rana of Dholpur, but soon afterwards he resigned, owing to ill-health. In 1875 the viceroy selected him as a Commissioner, together with the Maharaja Sindha and Jaipur, and three British colleagues, to try the Cutch Mutiny and to take charge of attempting to poison the British resident. He also served in the legislative council of India, and was frequently consulted by viceroys on difficult questions. An estate was conferred upon him, with the hereditary title of Raja, for his eminent services, and the decoration of K.C.S.I. He died on the 9th of January 1896. No Indian statesman of the 19th century gained a higher reputation, yet he only commenced the study of English at the age of forty, and was never able to converse fluently in it; his orthodoxy respected social reforms; he kept cool of from the Indian Congress, and he had received no training in British government.

RAO, SIR T. MADHAVA (1828–1891), Indian statesman, was born at Cambaconum in Madras in 1828. Madhava Rao created a new type of minister adapted to the modern requirements of a progressive native state, and he drafted it upon the old stock. He linked the past with the present, using the advantages of heredity, tradition and conservatism to effect reforms in the public administration and in Indian society. Sprung from a Mahratta Brahmin stock long settled at Tanjore, the son of a dewan of Travancore, he was educated in the strictest tenets of the sacred caste. But he readily imbied the new spirit of the age. To mathematics, science and astronomy he added a study of English philosophy and international law, and a taste for art.
and pictures. Although a devout student of the Shastras, he advocated female education and social reform. Refusing to cross the sea and so break caste by appearing before a parliamentary commission, he yet preached religious toleration. A patron of the Indian Congress, he borrowed from the armoury of British administration every reform which he introduced into the native states. He was respected alike by Europeans and natives, and received titles and honours from the British government. As tutor of the maharaja of Travancore, and then as revenue officer in that state, he showed firmness and ability, and became diwan or prime minister in 1857. He found the princely despotism of the Cape of Good Hope crumbling under the storms of policies and oppressive duties. He co-operated with the Madras government in carrying out reforms, and when his measures led to misunderstandings with the maharaja, he preferred honourable resignation to retention of a lucrative office in which he was powerless for good. In 1872 he was engaged at Indore in laying down a plan of reform and of public works which he bequeathed to his successor, when a grave crisis at Baroda demanded his talents there. The Gaekwar had been deposed for scandalous misrule, and an entire reorganization was needed. Aided by Sir Philip Melvill, Madhava Rao swept away the corrupt officials, privileged idlers and grasping contractors, who had long ruined Baroda. He wrote able minutes defending the rights and privileges of the Gaekwar from fancied encroachment, and justifying the internal reforms which he introduced. He resigned office in 1882, and in his retirement devoted his leisure to reading and writing upon political and social questions. He died on the 4th of April 1891.

RAOUL DE CAMBRAI, the name of a French chanson de geste. The existing romance is a 13th-century recension of a poem by a trouvère of Laon called Bertholais, who professed to have witnessed the events he described. It presents, like the other provincial geste of Géraud de Lohesin, a picture of the devastation caused by the private wars of the feudal chiefs. A parallel narrative, obviously inspired by popular poetry, is preserved in the chronicle of Waulsort (ed. Archery, Spicilegium, ii. p. 100 seq.), and probably corresponds with the earlier recension. Raoul de Cambrai, the posthumous son of Raoul Taillefer, count of Cambrai, by his wife Alais, sister of King Louis d'Outre-Mer, whose father's lands had been given to another, demanded the fief of Vermanso, which was the natural inheritance of the four sons of Herbert, lord of Vermanso. On King Louis's refusal, he proceeded to war. The chief hero on the Vermanso side was Bernier, a grandson of Count Herbert, who had been the squire and firm adherent of Raoul, until he was driven into opposition by the fate of his mother, burned with the nuns in the church of Origny. Bernier eventually slew the terrible Raoul in single fight, but in his turn was slain, after an apparent reconciliation, and the blood-feud descended to his sons. The date of these events is exactly ascertainable. Flodoard (Annales, Anno 943) states that Count Herbert died in that year, and was buried by his sons at St Quentin, that when they learnt that Raoul, son of Raoul de Gouy, was about to invade their father's territory, they attacked him and put him to death. This statement is not contradicted by any other authority, and the story has also been fixed from historical sources. The second part of the poem, of which Bernier is the hero, is of later date, and bears the character of a roman d'aventures.

RAOUl ROCHETTE, DÉSIRÉ (1790-1854), French archaeologist, was born on the 9th of March 1790 at St Amand in the department of Chor, and received his education at Bourges. He was made professor of history in the Collège de Louis-le-Grand at Paris (1813) and in the Sorbonne (1817). His Histoire critique de l'Établissement des colonies grecques (4 vols., 1815) is now out of date. He was superintendent of antiquities in the Bibliothèque at Paris (1815-48), and professor of archaeology at the Bibliothèque (from 1836), a result of which may be seen in his Cours d'archéologie (1828). In 1829 appeared his Monuments inédits, a work of great value at the time. Still valuable are his Peintures inédites (1836) and his Peintures de Pompté (1834). He contributed to the Annales of the Roman Institute, the Journal des savants and the Académie des inscriptions. At his death on the 3rd of July 1854 Raoul Roffette was perpetual secretary of the Academy of Fine Arts and a corresponding member of most of the learned societies in Europe.

RAOUl, FRANÇOIS MARIE (1830-1901), French chemist, was born at Fourques, in the Département du Nord, on the 10th of May 1830. He became aspirant répétiteur at the lyceé of Rheims in 1853, and after holding several intermediate positions was appointed in 1862 to the professorship of chemistry in Sens lyceé, where he prepared the thesis on electromotive force which gained him his doctor's degree at Paris in the following year. In 1867 he was put in charge of the chemistry classes at Grenoble, and three years later he succeeded to the chair of chemistry, which he held until his death on the 1st of April 1901. Raoul's earliest researches were physical in character, being largely concerned with the phenomena of the volatil cell, and later there was a period when more purely chemical questions engaged his attention. But his name is best known in connexion with the work on solutions, to which he devoted the last two decades of his life. His first paper on the depression of the freezing-points of liquids by the presence of substances dissolved in them was published in 1878; and continued investigation and experiment with various solvents, such as benzene and acetic acid, in addition to water, led him to believe in a simple relation between the molecular weights of the substances and the freezing-point of the solvent, which he expressed as" la loi générale de la congélation," that if one molecule of a substance be dissolved in 100 molecules of any given solvent, the temperature of solidification of the latter will be lowered by 0.5\,°C. (See, however, the article SOLUTION.) Another relation at which he worked was that the diminution in the vapour-pressure of a solvent, caused by dissolving a substance in it, is proportional to the molecular weight of the substance dissolved—at least when the solution is dilute. These two generalizations not only afforded a new method of determining the molecular weights of substances, but have also been utilized by J. H. van't Hoff and W. Ostwald, among other chemists, in support of the hypothesis of electrolytic dissociation in solutions. An account of Raoul's life and work was given by Professor van't Hoff in a memorial lecture delivered before the London Chemical Society on the 26th of March 1902.

RAOUx, JEAN (1677-1734), French painter, was born at Montpellier in 1677. After the usual course of training he became a member of the Academy in 1717 as an historical painter. His reputation had been previously established by the credit of decorations executed during his three years in Italy on the palace of Giustiniani Solini at Venice, and by some easel paintings, the Four Ages of Man (National Gallery), commissioned by the grand prior of Vendôme. To this latter class of subject Raoux devoted himself, and excelled in the rendering of his figures, and in character. The list of his works is a long series of sets of the Seasons, of the Hours, of the Elements, or of those scenes of amusement and gallantry in the representation of which he was incomparably surpassed by his younger rival Watteau. After his stay in England (1720) he lived much in the Temple, where he decorated several rooms. He died in Paris in 1734. His best pupils were Chevalier and Montdidier. His works, of which there is a poor specimen in the Louvre, were much engraved by Poilly, Moyreau, Dupuis, &c.

RAPALLO, a seaport and winter resort of Liguria, Italy, in the province of Genoa. Pop. (1901) 5392 (town); 19,243 (commune). It occupies a beautiful and well-sheltered situation on the east side of the Gulf of Rapallo, 13\,° E. by S. from Genoa by rail. It has a fine church, a medieval castle (now used as a prison) and a Roman Bridge, known as "Hannibal's Bridge." On the hills above the town is situated the
church and abbey of the Madonna de Montallegro, whose miraculous picture attracts pilgrims from all parts of Italy. Olives and other fruit are grown, and a brisk trade is done in olive oil. A mile to the south is Santa Margherita Ligure (pop. 7051), another winter resort, with a large 16th-century church. Both places are also so punished for sodomy that, in summer, Lauten is made, while the men go in May to the coral fisheries off the Sardinian coast. To the south again is the small seaport of Portofino (the Roman Portus Delphinus) under the south-east extremity of the promontory of Portofino (2010 ft.). On the way from S. Margherita to Portofino is the suppressed monastery of Cervara, in which Francis I. of France was confined after the battle of Pavia on his way to Madrid. At all these places are beautiful villas.

RAPE (Lat. rapum or rape, turnip), in botany.—Several forms of plants included in the genus Brassica are cultivated for the oil which is present in their ripe seeds. The rape most extensively grown for this purpose is known as colza, rape or coleseed, in Germany as Raps (Brassica napus, var. oleifera): its seeds contain from 30 to 45% of oil. The leaves are glaucous and smooth like those of a swede turnip. For a seed-crop rape is sown in July or early August in order that the plants may be strong enough to pass the winter uninjured. The young plants are thinned out to a width of 6 or 8 in. apart, and afterwards kept clean by hoeing. The foliage may be eaten down by sheep early in autumn, without injuring it for the production of a crop of seed. In spring the horse and hand hoe must be used, and the previous application of 1 cwt. or 2 cwt. of guano will add to the productiveness of the crop. On good soil and in favourable seasons the yield sometimes reaches to 40 bushels per acre. The haum and husks are either used for litter or burned, and the ashes spread upon the land. It makes good fuel for clay-burning. There is a "summer" variety of colza which is sown in April and ripens its seed in the same year. It does not yield so much oil as the "winter" kind, but it will grow on soil in poorer condition. Neither of these is much grown in Great Britain for the production of oil, but the "winter" variety is very extensively grown as green food for sheep. For this purpose it is generally sown at short intervals throughout the summer to provide a succession of fodder. It is peculiarly adapted for pasty soils, and is accordingly a favourite crop in the fen lands of England, and on recently reclaimed moors and moors elsewhere. Its growth is greatly stimulated by the ashes resulting from the practice of paring and burning. Its highly nutritious leaves and stems are usually consumed by feeding the sheep upon it where it grows, there is no green food upon which they fatten faster. Occasionally it is carried to the homestead, and used with other forage in carrying out the system of soil-burning cattle.

The wild form Brassica campestris, the wild coleseed, colza or kohlsaat, of the fields of England and many parts of Europe, is sometimes cultivated on the European continent for its seed, which, however, is inferior in value to rape as an oil-yielding product.

In addition to the previously mentioned rape, a variety of another species (or subspecies) of Brassica, namely, Brassica rapa, var. oleifera (Rübsen in Germany), is grown for its oil-yielding seeds. The leaves in a young state are not glaucous, but sap-green in colour and rough, being very similar to those of the turnip, to which the plant is closely related. Both winter and summer varieties are grown; they are rarely cultivated in Britain. The oil is similar to that in the true colza, although it does not yield so much per acre as the latter: they are, however, harder and more adapted for cultivation on poor sandy soils.

RAPE (from Lat. rapere, to seize), in law, the crime of having carnal knowledge of a woman by a man, not her husband, forcibly and unlawfully against her will. Under the Mosaic law, rape was punished with death, if the damsel was betrothed to another man, and with a fine of fifty shekels if not so betrothed, while in this case, also, she was to be the wife of the ravisher all the days of his life (Deut. xxii. 25). The Roman civil law punished rape with death and confiscation of goods (Cod. L. IX. tit. 13). In England, under the Saxon law—adopted, probably, from a Teutonic code—death was also the penalty, but under the Normans this was changed to the loss of life, with eyes and castration; this punishment remained in force until after the time of Bracton (de Corond, f. 147). The statute of Westminster I. (1275) reduced the offence to a trespass, with a penalty of two years' imprisonment and a fine at the king's will. This lenity, it is said, produced terrible consequences, and, accordingly, the statute of Westminster II. (1285) again declared the offence a felony, with, however, benefit of clergy. This was the state of the law until 1575, when the punishment was made more severe by taking away the benefit of clergy. The offence remained capital until the Offences against the Person Act 1861, by which and subsequent amending acts it is now regulated. The present punishment is penal servitude for life or for not less than three years or imprisonment with or without hard labour for not over two years.

The law of England (differing in this respect from the civil law) regards as immaterial whether the woman is chaste or unchaste, married or single, provided the offence has been committed forcibly against her consent. It is not an offence if consent is given, if consent is obtained by threats or promises, or by means of threats of death or immediate bodily harm, by fraud or by false pretences or representation, such as the impersonation of a woman's husband (Criminal Law Amendment Act 1861).

Since the passing of the Criminal Law Amendment Act 1885, it is a felony, entailing the same punishment as rape, to have carnal knowledge of a woman, with her consent, if under 13 years of age. Between 13 and 16 years of age it is a criminal offence punishable by two years' imprisonment, whether consent is given or not, and even if there be solicitation; but if the jury is satisfied that the person charged was not under 16 years of age, and it is proved that he intended to be over 16 years, the accused is entitled to be acquitted. Prosecution must be within three months of the offence. The administration of any drug or matter, with intent, by producing stupor, to facilitate the accomplishment of the crime, is an offence punishable by two years' imprisonment. On indictment for rape there may be an acquittal on the actual charge, but a conviction either of the attempt or of an indecent assault, which was one of the means employed for the commission of the rape, from the nature of the offence, the important witness is the woman, and it is essential, apart from medical evidence (see Medical Jurisprudence), that her story be corroborated by evidence implicating the accused. The points have to be considered (1) As to the general credibility of the witness and how far her story is to be believed; evidence, therefore, may be given to show that she is of immoral character. (2) Whether she is or was capable of committing the alleged outrage and to whom. (3) As to the place where the outrage was alleged to have been committed and the possibility of her being heard if she cried out.

In the United States, rape is universally treated as a felony, and the punishment is either death, imprisonment for life, or imprisonment for a number of years, varying in the different states. In the case of offences against young girls, there is a divergence in the various states as to the age of consent, though the trend of legislation has been to raise it. In North and South Carolina, and Georgia, the age of consent is as low as 10 years, and in Kentucky and Louisiana, 12 years. In nineteen states the age of consent is 14 years. In one (Texas) it is 15 years. In six, it is 16 years. In Wyoming, New York, Colorado and Kansas it is as high as 18 years.

The essential facts to be proven in order to constitute this crime are the same as in England, but in many of the states the uncorroborated evidence of the woman is sufficient to sustain a conviction. This is so in California, Arizona, Idaho, Missouri, Kentucky, Michigan, Illinois, Oklahoma, &c. [1904; Brenton v. Wergan, 78 S. W. Rep. 85]; in New York corroboration is required [ Penal Code §283]. In Nebraska also evidence corroborating the prosecatrix is necessary [1907; Burk v. State, 112 N.W. Rep. 573]. In Texas it is no defence for accused to prove that he believed the prosecatrix to be over 15 years of age, the age of consent [1907; Robertson v. State, 102 So. W. Rep. 1150], and the crime is punishable with death [1903; Reyno v. State, 75 So. W. Rep. 23], as also apparently it is in the Indian country [U.S. v. Partello, 48 Fed. R. 670 U.S. Rev. Stats. §5345], also in Alabama [ Criminal Code, §5444].
RAPE.—RAFAEL RAPHAEL SANZIO

In Hawaii there is no age of consent for rape, which is punishable by $1000 fine and imprisonment at hard labour for life; the carnal knowledge of females under 10 years is punishable with death or imprisonment for life [Rev. L. 1955, §§ 2927, 2928]. In Porto Rico the age of consent is 14 years and the punishment may be for five years [Pen. Code 1928, § 253].

RAPE, a territorial division of the county of Sussex, England, formerly used for various administrative purposes. There are now six of these divisions, Hastings, Pevensey, Lewes, Brabham, Arundel and Chichester, but the latter two apparently formed a single rape at the date of the compilation of Domesday Book. The word, which in England is peculiar to Sussex, is usually said to be a clausal of the crassifericus krep, a small territorial division which in most, but not in all, cases is identical with the parish; but this explanation, which is unsatisfactory on institutional grounds, has also been declared impossible for philological reasons. As an alternative explanation it has been suggested, that "rape" is an early form of the word "rape"; and that the divisions were so called because they were measured and allotted by the rape. Some confirmation of this is to be found in the words of the Norman chronicler, Dudo of St Quentin, who states that Rollo in distributing Neustria "suis fidelibus terram unifico divisit" (J. P. Migne, Patrologiae Continuæ, tomo cxli. p. 652). It is possible that the rapes represent the shires of the ancient kingdom of Sussex, especially as in the 12th century they had sheriffs of their own. But there is no evidence of the existence of the rape before the Norman Conquest, except such as may be gathered from Domesday Book, and this is far from convincing. After the Conquest each rape had its own lord, and all the land within it, save that which belonged to the king or to ecclesiastical tenants, was held of the lord. Thus the rape as a lordship only differed from other honours and baronies by the fact that the lands of its knights were not scattered over England, but lay together in a continuous tract. In form the rapes were parallel bands of land running north and south, and each of them contained a different number of hundreds. The place in which the lord's castle was situate ultimately gave its name to the rape; but in Domesday Book the rapes are often described by the names of their lords, and this is always so that in work in the case of Brabham, which belonged to William de Brioux (rapam Willetini de Braosta).

See the Victoria County History, Sussex, vol. i.; New English Dictionary; and M. A. Lower, History of Sussex (Lewes, 1870). (G. J. T.)

RAPE OIL, an important fatty oil, known also as "sweet oil," either expressed or extracted from the crushed seeds of cultivated varieties of the genus Brassica, the parent form of the whole apparently being the wild navvy, B. campestris. Under the general name "rape oil" is included the produce of several plants having distinct and fairly constant characters, and one of these oils—colza (g.o.)—is a very well-known commercial variety. In Germany, where the production of rape oil centres, two principal oil-seeds—rape and Rübse—are well recognized. *(See RAP.)

The oil yielded by these seeds is, in physical and chemical properties, practically the same, the range of fluctuations not being greater than would be found in the oil of any specific seed under similar varying conditions of production; the winter varieties of all the seeds are more productive than the summer varieties. Newly pressed rape oil has a dark sherry colour with, at first, scarcely any perceptible smell; but after resting a short time the oil deposits an abundant mucilaginous slime, and by taking up oxygen it acquires a peculiar disagreeable odour and an acid taste. Refined by the ordinary processes (see OILS), the oil assumes a clear golden yellow colour. In specific gravity it ranges between 0.9112 and 0.9117 in the raw state, and from 0.9127 to 0.9136 when refined; the solidifying point is from -4° to -6° C.

The principal uses of rape oil are for lubrication and lighting; but since the introduction of mineral oils for both these purposes the introduction of rape has considerably decreased, though little employed in soap-making, as it sapinifies with difficulty and yields only an indifferent product. In Germany it is very considerably used for the extraction of an oil under the name of Schmalzöl, being for that purpose freed from the residue of the trash, heated till the starch is carbonized, and filtered after the oil has cooled. The offensive taste of rape oil may also be removed by treatment with a small proportion of sweet spirit of nitrre (nitrous ether). In the East Indies rape oil and its equivalents, known under various names, are the most important of oils for native use. They are largely consumed as food instead of ghi under the name ble "kuruwah" or "bitter oil." Most native dishes are made suitable for the preparation of their curries and other hot dishes. Rape oil is the subject of extensive adulteration, principally with the cheaper oils of Neustria. Rape oil is the most conveniently detected, first by taste and next by sapinification, rosin oil and mineral oil remaining unsaponified, hemp oil giving a greenish soap, while rape oil yields a soap with a yellow tinge. With the use of sulphur in rape and other cruciferous oils also affords a ready means for their identification. Lead plaster (emplastrum lithargiry) boiled in rape oil dissolves, and, sulphide of lead being formed, the oil becomes brown or black. After lead compounds give the same black coloration from the formation of sulphide.

RAPHAEL (Hebrew רפאל, "God heals"), an angel in human disguise and under the name of Azarias ("Yahweh helps") accompanies Tobias in his adventures; and conquers the demon Asmodeas (Book of Tobit). He is called the angel of the seven holy angels (archangels) which present the prayers of the saints and go in before the glory of the Holy One. In the Book of Enoch (c. xx.) Raphael is the angel of the spirits of men, and it is his business to heal the earth which the angels have defiled. In later Midrash Raphael appears as the angel commissioned to put down the evil spirits that vexed the sons of Noah with plagues and sicknesses after the Flood, and he it was who taught men the use of simples and furnished materials for the Book of Noah, the earliest treatise on materia medica, among the names, which Raphael, being a very important item among the various influences which formed and fostered his early love for art. It may not perhaps be purely fanciful to trace Raphael's boyish admiration of the oil-paintings of Jan Van Eyck and Justus of Ghent in the miniature-like care and delicacy with which some of his earliest works, such as the "Apollo and Marsyas," were executed.

Though Raphael lost his father at the age of eleven, yet to him he certainly owed a great part of that early training which enabled him to produce paintings of apparently mature beauty when he was scarcely twenty years of age. The altar-piece painted by Giovanni for the church of Granda, and a fresco, now preserved in the Santi house at Urbino, are clearly prototypes of some of Raphael's most graceful

---

1 See Punicm, Elogio Storico di Raffaello (Urbino, 1879); for a valuable account of Raphael's family and his early life, see also, Id., Lettera al Cav. Girolamo, Sella, Scritte e Documenti per l'Uma de Gio. Santi e di Raffaele (Modena, 1870).

2 See an interesting account of the court of Urbino by Delaborde, Premier Raffaello, B. A. . . . en Italie (Paris, 1864), vol. i. p. 145.

3 The house of Giovanni Santi, where Raphael was born, still exists at Urbino in the Contrada del Monte, and, being the property of the municipality, is now safe from destruction.
for Città di Castello were the coronation of S. Niccolò Tolentino, now destroyed, though studies for it exist at Oxford and Lille (Gaz. d. B. Arts, 1878, i. p. 48), and the Crucifixion, now in the Dudley collection, painted for the church of S. Domenico, and signed RAPHAEL VREINAS P. It is a panel 8 ft. 6 in. high by 5 ft. 5 in. wide, and contains noble figures of the Virgin, St John, St Jerome and St Mary Magdalene. The fourth painting, ordered for this town, for the church of S. Francesco is the exquisitely beautiful and highly finished Sposalizio, now in the Brera at Milan, signed and dated RAPHAEL VREINAS MDIII. This is closely copied both in composition and detail from Perugino's painting of the same subject now at Caen, but is far superior to it in sweetness of expression and grace of attitude. The Temple of Jerusalem, a domed octagon with outer ambulatory in Perugino's picture, is reproduced with slight alterations by Raphael, and the attitudes and grouping of the figures are almost exactly the same in both. The Constanable Madonna is one of Raphael's finest works, painted during his Perugian period; it is a round panel; the motive, the Virgin reading a book of hours, is a favourite one with him, as it was with his father Giovanni. This lovely picture was lost to Perugia in 1871, when Count Constanable sold it to the emperor of Russia for £13,200.

Second or Florentine Period, 1504-1508.—From 1504 to 1508 Raphael's life was very stirring and active. In the first half of 1504 he visited Urbino, where he painted two small panels for Duke Guidobaldo, the St George and the St Michael of the Louvre. His first and for him momentous visit to Florence was made towards the end of 1504, when he presented himself with a warm letter of recommendation from his patroness Joanna della Rovere to the gonfaloniere Pier Soderini. In Florence Raphael was kindly received, and, in spite of his youth (being barely of age), was welcomed as an equal by the majority of those great artists who at that time had raised Florence to a pitch of artistic celebrity far above all other cities of the world. At the time of his arrival the whole of artistic Italy was being excited to enthusiasm by the cartoons of the battle of Anghiari and the war with Pisa, on which Leonardo da Vinci and Michelangelo were then devoting their utmost energies. To describe the various influences under which Raphael came, and the many sources, from which he drank in store of artistic knowledge, would be to give an incomplete history of Florentine art in the 15th century. With astonishing rapidity he shook off the manners of Perugino, and put one great artist after another under contribution for some special power of drawing, beauty of colour, or grace of composition in which each happened to excel. Nor was it from painters only that Raphael acquired his enlarged field of knowledge and rapidly growing powers. Sculptors like Ghiberti and Donatello must be numbered among those whose works helped to develop his new-born style. The Carmine frescoes of Masaccio and Masolino taught this eager student long-remembered lessons of methods of dramatic expression. Among his contemporaries it was especially Signorelli and Michelangelo who taught him the importance of precision of line and the necessity of a thorough knowledge of the human form. From da Vinci he learnt subtilities of modelling and soft beauty of expression, from Fra Bartolommeo nobility of composition and skilful treatment of drapery in dignified folds. The friendship between Raphael and the last of these was very close and lasted for many years. The architect Baccio d'Agnolo was another of his special friends, at whose house the young painter enjoyed social intercourse with the artists and men of letters of the day.

This letter, which still exists, was sold in Paris in 1856, and is now in private hands.

To see his sketch of St George and the Dragon, in the Uffizi, largely taken from Donatello's pedestal relief outside Or San Michele.

To see his cartoon of St Paul preaching at Athens (Victoria and Albert Museum).

To see many of his life-studies, especially the one he sent to Albert Dürer, now at Vienna.

To see the portrait of Maddalena Doni in the Pitti.

To see the Madonna del Baldacchino in the Pitti.
with a large circle of the chief artists of Florence, and probably learned from him much that was afterwards useful in his practice as an architect.

The transition in Raphael's style from his first or Perugian to his second or Florentine manner is well shown in the large picture of the Coronation of the Virgin painted for Maddalena degli Oddi, now in the Vatican, one of the most beautiful that he ever produced, and especially remarkable for its strong religious sentiment—in this respect a great contrast to the paintings of his last or Roman manner which hang near it. The exquisite grace of the angel musicians and the beauty of the faces show signs of his short visit to Florence, while the general formality of the composition and certain details, such as the fluttering ribands of the angels, recall peculiarities of Perugino and of Pinturicchio, with whose fine picture of the same subject hung close by it is interesting to compare it. Raphael's painting, though by far the more beautiful of the two, is yet inferior to that of Pinturicchio in the composition of the whole; an awkward horizontal line divides the upper group of the Coronation from that below, the apostles standing round the Virgin's tomb, filled with roses and lilés (Dante, Por. xxiii. 73), while the older Perugino has skillfully united the two groups by a less formal arrangement of the figures. The predella of this master-piece of Raphael is also in the Vatican; some of its small paintings, especially that of the Annunciation to the Virgin, are interesting as showing his careful study of the rules of perspectival. Several preparatory sketches for this picture exist: fig. 1 shows a study, now at Lillé, for the two principal figures, Christ setting the crown on His mother's head (see fig. 2). It is drawn from two youths in the ordinary dress of the time; and it is interesting to compare it with his later studies from the nude, many of which are for figures which in the future picture were to be draped. It was at Florence, as Vasari says, that Raphael began serious life studies, not only from nude models but also by making careful anatomical drawings from dissected corpses and from skeletons.

His first visit to Florence lasted only a few months; in 1505 he was again in Perugia painting his first fresco, the Trinity and Saints for the Camaldoli monks of San Severo, now a mere wreck from injury and restorations. The date MDV and the signature were added later, probably in 1521. Part of this work was left incomplete by the painter, and the fresco was finished in 1521 (after his death) by his old master Perugino. It was probably earlier than this that Raphael visited Siena and assisted Pinturicchio with sketches for his Piccolomini frescoes. The Madonna of S. Antonio was also finished in 1505, but was probably begun before the Florentine visit. A record of his visit to Siena exists in a sketch of the antique marble group of the Three Graces, then in the cathedral library.

1 While at Florence he is said to have taught the science of perspective to his friend Fra Bartolommeo, who certainly gave his young instructor valuable lessons on composition in return.

2 The fresco of the Last Supper, dated 1505, in the refectory of S. Onofrio at Florence, is not now claimed as a work of Raphael's, in spite of a signature partly introduced by the restorer.

3 Raphael probably had no hand in the actual execution of the paintings; see Schmarsow, Raphael und Pinturicchio in Siena (Stuttgart, 1886), and Milanesi, in his edition of Vasari, iii. p. 515 seq., appendix to life of Pinturicchio.

4 This fine altar-piece, with many large figures, is now the property of the heirs of the duke of Ripalta, and is stored in the basement of the National Gallery, London.

5 From which, not long afterwards, he painted the small panel of the same subject now in Lord Dudley's collection.

6 In 1506 Raphael was again in Urbino, where he painted for the duke another picture of St George, which was sent to England as a present to Henry VII. The bearer of this and other gifts was Guidibaldo's ambassador, the accomplished Baldassare Castiglione (q.v.), a friend of Raphael, whose noble portrait of him is in the Louvre. At the court of Duke Guidibaldo the painter's ideas appear to have been led into a more secular direction, and to this stay in Urbino probably belong the Dudley Graces, the miniature "Knight's Dream of Duty and Pleasure" in the National Gallery (London), and also the "Apollo and Marsyas," sold in 1882 by Morris Moore to the Louvre for £10,000, a most lovely little panel, painted with almost Flemish minuteness, rich in colour, and graceful in arrangement.

Towards the end of 1506 Raphael returned to Florence, and there (before 1508) produced a large number of his finest works, carefully finished, and for the most part wholly the work of his own hand. Several of these are signed and dated, but the date is frequently very doubtful, owing to his constant use of Roman numerals, introduced among the sham Arabic embroidered on the borders of dresses, so that the L.I. after the V. are not always distinguishable from the straight lines of the ornament. The following is a list of some of his chief paintings of this period: the "Madonna del Gran Duca" (Pittli); "Madonna del Giardino," 1506 (Vienna); "Holy Family with the Lamb," 1506 or 1507 (Madrid); the "Ansidei Madonna," 1506 or 1507 (National Gallery); the Borghese "Entombment," 1507; Lord Cowper's "Madonna" at Panshanger, 1508; "La bella Giardiniera," 1508.

* This missal-like painting is about 7 in. square; it was bought in 1847 for 1000 guineas. The National Gallery also possesses its cartoon, in brown ink, pricked for transference.

** In spite of some adverse opinions, frequently expressed with extreme virulence, the genuineness of this little gem can hardly be doubted by any one who carefully studies it without bias. Sketches for it at Venice and in the Uffizi also appear to bear the impress of Raphael's manner. See Delabarbe, Études sur les B. Arts... en Italie, i. p. 236; Gruyer, Raphael et l'antiquité, ii. p. 421; Eitelberger, Raphael's Apollo und Marsyas (Venna, 1860); Batté, Le Raphaël de M. Moore (Paris, 1859); and also various pamphlets on it by its former owner, Mr. Morris Moore.
of the so-called Portrait of Raphael by himself at Hampton Court is a very beautiful work, glowing with light and colour, which may possibly be a genuine picture of about 1506. It represents a pleasant-looking youth with turned-up nose, not bearing the remotest resemblance to Raphael, except the long hair and black cap common to nearly all the portraits of this time. A fine but much-restored portrait of Raphael by himself, painted at Florence, exists in the Uffizi; it represents him at a very early age, and was probably painted during the early part of his stay in Florence.

Third or Roman Period, 1508-1520.—In 1508 Raphael was painting several important pictures in Florence; in September of that year we find him settled in Rome, from a letter addressed in the warmest terms of affectionate admiration to Francia, to whom he sent a sketch for his “Adoration of the Shepherds,” and promised to send his own portrait in return for that which Francia had given him. Raphael was invited to Rome by his fellow-citizen (not relation, as Vasari says) Bramante, who was then occupied in the erection of the new church of St Peter, the foundation-stone of which had been laid by Julius II. on the 18th of April 1506. At this time the love of the popes for art had already attracted to Rome a number of the chief artists of Tuscany, Umbria and North Italy, among whom were Michelangelo, Signorelli, Perugino, Pinturicchio, Lorenzo Lotto, Peruzzi, Sodoma, and many others, and it was among this brilliant assembly that Raphael, almost at once, took a leading position. Thanks to Bramante’s friendly intervention, Julius II. (Della Rovere) soon became Raphael’s most zealous patron and friend, as did also the rich bankers Agostino Chigi (the Rothschild of his time) and Bino Altoviti, whose portrait, at the age of twenty, now at Munich, is one of the most beautiful that Raphael ever produced.

A series of views in the Vatican, over the Appartamenti Borgia, were already decorated with frescoes by Bonfigli.

**FIG. 3.—Plan showing position of Raphael’s frescoes in the stanzas.**

A. Stanza della Segnatura (1509-11); 1, Disputa; 2, School of Athens; 3, Justinian giving his code to Trebonian; 4, Gregory IX. giving decreals to a jurist; 5 (over the window), Three Virtues; 6 (over the other window), Apollo and a group of poets on Mount Parnassus; vault with medallions of Poetry, Theology, Science, and Justice, and other paintings. B. Stanza d’Eliodoro (1511-14); 7, Expulsion of Heliodorus from the Temple; 8, Mass of Bolsena; 9, St Peter freed from prison; 10, Attila repulsed by Leo I.; vault with scenes from Old Testament, by pupils. C. Stanza del Petscendo (1517), nearly all painted by pupils: 11, Burning of the Borgo; 12, Victory of Leo IV. over the Saracens at Ostia; 13, Coronation of Charlemagne by Leo III. in St Peter’s; 14, Oath of Leo III. before Charlemagne. D. Stanza di Costantino, painted by pupils (1520-24); 15 and 16, oil-paintings of Comitas and Justitia attributed to Raphael; 17, 17, great fresco of the Defeat of Maxentius. E. E. Part of Raphael’s loggia, by his pupils. F. Chapel of Nicholas V., painted by Fra Angelico. G. Cortile di Bramante.

Perugino, Piero della Francesca, Andrea del Castagno, Signorelli and Sodoma; but so rapidly had the taste of the time changed that Julius II. decided to sweep them all away and re-cover the Court of the Sistine Chapel.
walls with paintings in the more developed but less truly decorative style of Raphael. It was not without regret that Raphael saw the destruction of this noble series of frescoes. One vault, that of St. Michael the Archangel, painted with the help of the del Sarto, had been so well preserved that Raphael saved it from obliteration; it still exists, well preserved, a most skilful piece of decorative work, and he also set his pupils to copy a number of portrait-heads in the frescoes of Piero della Francesca before they were destroyed. 1 Fig. 3 shows the positions of Raphael's frescoes in the stanzas, which, both from their size and method of lighting, are very unsuit- ed for the reception of these large pictures. The two most important rooms (A and B) are small, and have an awkward cross-light from opposite windows. 2

Stanza della Segnatura (papel signature room), painted in 1509–11 (A on fig. 3). The first painting executed by Raphael in the stanza and so-called Disputa, finished in 1509. It is very unlike the later ones in style, showing the beginning of transition from his Florentine to his "Roman manner"; as a decorative work it is very superior to the other frescoes; the figures are much smaller in scale, and the chiaroscuro and the whole is arranged mainly on one plane, without those strong effects of perspective which are so unsuit ed to the decorative treatment of a wall-surface. In its regions and in its standard paintings, containing much of the sacred character of earlier Florentine and Umbrian art. As a scheme of decoration it appears to have been suggested by some of the early apsidal mosaics. Fig. 4 shows how Raphael arranged his frescoes, which seem to indicate the curved recess of an apse. Gold is largely used, with much richness of effect, while the background in each cell owns its own scale, from the smallest to the least little or none. The subject of this magnificent painting is the hierarchy of the church on earth and its glory in heaven. The angels in the upper tier and the nude cherubs who carry the books of the Gospels are among the most beautiful figures that Raphael ever painted.

The painting on the vault of this room is the next in date, and shows Raphael's style towards the "Roman manner." In his treatment of the whole Raphael has, with much advantage, been partly guided by the painting of Perugino's vault in the next room (C). Though not without faults, it is a very deep and richer composition, in which the pictures are kept subordinate to the lines of the vault, and their small scale adds greatly to the apparent size of the whole. A prominent ground of the general (set) composition is the gift of the pope to his artistic protector, and Raphael carries it out comically in all its parts; he bestows the portraits of female figures, representing Theology, Science, Justice, and Poetry. Smaller subjects, some almost miniature-like in scale, are arranged in the intermediate spaces, and each has some special meaning in reference to the medallions of the portraits. The only portrait in Raphael's Disputa which is distinctly male is that of Julius II, who appears behind the altar; and the lower spaces on each side of the windows are filled with two groups, that on the left with women, that on the right with officers of the papal guard. The last group is one of Raphael's finest. The strong and vigorous composition of Attila from the walls of Rome by Leo I., miraculously aided by the apparitions of St. Peter and St. Paul; it contains another allusion to the papal quarrels with France. It began in the lifetime of Julius II, but was only half-finished at the time of his death in 1513; thus it happens that the portrait of his successor, the Medici pope Leo X., appears twice over, first as a cardinal riding behind the pope, painted before the death of Julius II, and again in the character of S. Leo, instead of the portrait of Julius which Raphael was about to paint. 8 8 He has shown great skill in the way in which he has fitted his end frescoes into the awkward spaces cut into by the windows, but they are none the less treated in purely classical manner.

8 Compare his fresco of Sixtus IV., now in the picture-gallery of the Vatican.

9 In the next room of this painted with scenes from the Old Testament on a harsh blue ground, much restored; they are probably the work of Giulio Romano, and in a decorative way are very unsuccessful—a striking contrast to the beautiful frescoes of Raphael and Perugino. The frescoes of the popes' chapel, which are preserved by Raphael's school are very liable to injury from damp, and in most cases have been coarsely restored. Those in the Villa Madama are untouched, and in parts the damp has changed the ultra-violet light into even more destructive rays.

10 A pen sketch in the Louvre by Raphael shows Julius II. in the place afterwards occupied by Leo X.; another difference in the sketch is that the pope is borne in a chair, not on horseback as in the fresco.

Fig. 4.—Diagram to show main lines of the Disputa, suggesting an apse, with mosaic decoration. The morning of the painting of this room is the next in date, and shows Raphael's style towards the "Roman manner." In his treatment of the whole Raphael has, with much advantage, been partly guided by the painting of Perugino's vault in the next room (C). Though not without faults, it is a very deep and richer composition, in which the pictures are kept subordinate to the lines of the vault, and their small scale adds greatly to the apparent size of the whole. A prominent ground of the general (set) composition is the gift of the pope to his artistic protector, and Raphael carries it out comically in all its parts; he bestows the portraits of female figures, representing Theology, Science, Justice, and Poetry. Smaller subjects, some almost miniature-like in scale, are arranged in the intermediate spaces, and each has some special meaning in reference to the medallions of the portraits. The only portrait in Raphael's Disputa which is distinctly male is that of Julius II, who appears behind the altar; and the lower spaces on each side of the windows are filled with two groups, that on the left with women, that on the right with officers of the papal guard. The last group is one of Raphael's finest. The strong and vigorous composition of Attila from the walls of Rome by Leo I., miraculously aided by the apparitions of St. Peter and St. Paul; it contains another allusion to the papal quarrels with France. It began in the lifetime of Julius II, but was only half-finished at the time of his death in 1513; thus it happens that the portrait of his successor, the Medici pope Leo X., appears twice over, first as a cardinal riding behind the pope, painted before the death of Julius II, and again in the character of S. Leo, instead of the portrait of Julius which Raphael was about to paint. 8 8 He has shown great skill in the way in which he has fitted his end frescoes into the awkward spaces cut into by the windows, but they are none the less treated in purely classical manner.

8 Compare his fresco of Sixtus IV., now in the picture-gallery of the Vatican.

9 In the next room of this painted with scenes from the Old Testament on a harsh blue ground, much restored; they are probably the work of Giulio Romano, and in a decorative way are very unsuccessful—a striking contrast to the beautiful frescoes of Raphael and Perugino. The frescoes of the popes' chapel, which are preserved by Raphael's school are very liable to injury from damp, and in most cases have been coarsely restored. Those in the Villa Madama are untouched, and in parts the damp has changed the ultra-violet light into even more destructive rays.

10 A pen sketch in the Louvre by Raphael shows Julius II. in the place afterwards occupied by Leo X.; another difference in the sketch is that the pope is borne in a chair, not on horseback as in the fresco.
army is not the most successful part of the fresco: the horses are very wooden in appearance, and the tight-fitting scale armour, put on by joints, gives a very unreal and theatrical look to the picture. Part is the work of pupils. In 1514 he painted the "Deliverance of St Peter from Prison," with a fine technical and realistic allusion (No. 9). It is very skilfully arranged to fit in the awkward space round the window, and is remarkable for an attempt, not much suited for fresco-painting, to combine and contrast the three different qualities of light coming from the moon, a sunbeam and a lantern round the angel, and the torches of the sentinels.

For room C Raphael designed and partly painted the "Incendio del Borgo" (No. 11), a fire in the Borgo or Leonine City, which was miraculously stopped by Leo IV, appearing and making the sign of the cross at a window in the Vatican. On the background is shown the façade of the old basilica of St Peter, not yet destroyed when this fresco was painted. One group on the left, in the foreground, is remarkable for its vigour and powerful drawing: the motive is taken from the burning of Troy; a fine nude figure of Aeneas issues from the burning houses bearing on his back the old Anchises and leading the boy Ascanius by the hand. Some of the female figures are designed with much grace and dramatic power. Many studies for this picture exist. This is the last of the stanza frescoes on which Raphael himself worked. Others designed by him and painted by Giulio Romano, Gianfrancesco Penni, and other pupils were the "Battle of Milicia" (No. 12), a very nobly composed picture, and the "Oath of Leo III before Charlemagne" (No. 14).

The other great picture in this room (No. 13), the "Coronation of the Virgin" (a portrait of Francis I. of France) is so very inferior in composition that it is difficult to believe that Raphael even made a sketch for it. The enormous fresco of the "Defeat of Maxentius by Constantine" (room D, No. 17) was painted by Giulio Romano, soon after Raphael's death, from a sketch by the latter; it is even more harsh and disagreeable in colour than most of Giulio Romano's early frescoes. Among the other very inferior frescoes in this great hall are two female figures (Nos. 15 and 16) representing Comites and Medici, painted on the wall in oil colours, very harmonious and rich in tone; they are usually, though wrongly, attributed to Raphael himself.

Technical Methods employed in Raphael's Frescoes.—Having made many studies, both nude and draped, for single figures and groups, the painter made a small drawing of the whole composition, which was enlarged by his pupils with the help of numbered squares, divided by lines. Over it, to the full size required, was painted the cartoon, on paper or vellum. Holes were then pricked along the outlines of the cartoon, and the design pounced through on to an undercoat of wet stucco on the wall, with powdered charcoal and a stiff brush. Over this, early in the morning, a patch of wet stucco was laid, about enough to serve for the day's painting; this of course obliterated the outline on the wall, and the part covered by the patch was again sketched in by hand, with a point on the wet stucco, so as to be a guide for the outline of the new part to be added to the subsequent painting. A line impressed on the wet stucco was easily smoothed out, but a touch of the brush filled up the small spaces deeply into the mortar. It could hardly be expected that in fresco painting the only use of pouncing was to obviate the necessity of the design on the wall to be kept the general positions of the figures right, and was no guide as to the drawing of each separate part. Fig. 5 shows a portion of the frescoes of the Vatican (Rome, 1891), right of the School of Athens; on this are visible many of the impressed sketch-lines, and also part of the "fresco edge" of the patch on which this part is painted. The heads in this figure are less than one day's work. It will be seen that there is no attempt at any accuracy of drawing in the impressed lines. Raphael, especially in his later frescoes, worked with wonderful rapidity: three life-sized busts, or half a full-length figure, more than life-size, was not unusual day's work. In some of the frescoes the edges of each day's patch of stucco can easily be traced, especially in the Incendio del Borgo, which has a strong side light. In the Disputa many of these fringes remain in the finished touches, but less used was used in the subsequent frescoes, owing to his increasing mastery of the difficulties of the process.

The paintings in the stanza were only a small part of Raphael's work between 1509 and 1513. To this period belong the Madonna of Foligno (Vatican), painted in 1511 for Sigismondo Conti; it is one of his most beautiful compositions, full of the utmost grace and sweetness of expression, and appears to be wholly the work of his hand. It has suffered much from repainting. Of about the same date are the gem-like Garvagh Madonna (National Gallery, bought for £3000; once in the possession of the Aldobrandini family), the Diademed Virgin

See Montagnani, Sala di Costantino (Rome, 1834). Though he was never a very good colourist, the great frescoes by Giulio Romano in the Vatican, Mantua, show some improvement as compared with his Roman work.

These three stages were usually distinguished as study, sketch and cartoon.

of the Louvre, and the Madonna del Pesce at Madrid. The last is a very noble picture but the design is more pleasing than the

Fig. 5.—Heads of Raphael and Perugino (?), from the School of Athens, showing incised lines and "fresco edges."
in S. Maria della Pace,—figures of exquisite grace, arranged with perfect skill in an awkward space. It is not without reason that Vasari gives these the highest position among his fresco-paintings. 1 Agostino Chigi also employed Raphael to build for him a private chapel in S. Maria del Popolo, and to make a series of cartoons to be executed in mosaic on the inner dome. 2 The central medallion has a figure of God among clouds and angel boys, such as Raphael drew with unrivalled grace (fig. 6), and around are the eight planets, each with its pagan deity and directing angel. 3 He has not hampered himself by any of the usual rules which should apply to the designing of mosaic; they are simply treated as pictures, with almost deceptive effects of perspective. The execution of these brilliant mosaics was carried out by the Venetian Luigi della Pace, whose signature is introduced on the torch of Cupid in the panel representing the star Venus (Ludovico della Pace Veneziano fecit, 1516). These mosaics are still as perfect and brilliant as if they were the work of yesterday. Probably in the early years of Leo X.'s reign were painted the Madonna of the Gonfalone (Pitti), the S. Cecilia at Bologna (not completed till 1516), the miniature Vision of Ezekiel (Pitti) and three important pictures at Madrid. The latest of these, known as La Spasimo, from the church at Palermo, for which it was painted, is one of Raphael's finest compositions, representing Christ bearing His Cross. It bears signs of Giulio Romano's hand in its heavy colouring with unpleasant purple tones. The Madonna called Della Perla has much changed from the darkening of the pictures; in design it recalls Leonardo da Vinci. 4 The small Madonna della Rosa is the most perfect in colour of all the master's pictures in the Madrid Gallery, and is usually rather undervalued; it is a most graceful little picture. The portrait of Leo X. with Cardinals de' Rossi and de' Medici in the Pitti, is one of his finest portrait-pictures, especially as regards the figure of the pope. 5 Little is known about the Madonna di S. Sisto, the glory of the Dresden Gallery; no studies or sketches for it exist. In style it much resembles the Madonna di Foligno; it is less injured by restoration than the latter.

Among the latest works of Raphael are the large " St Michael and the Devil," in the Louvre, signed " Raphael Urbinas pingebat, 1518. " 6 And the very beautiful portrait of the Violinslayer, in the Sciarra-Coleman Palace in Rome, also dated 1518; this last bears much resemblance to the painter himself. The British Museum possesses one of Raphael's finest portraits, though only a chalk drawing, that of his friend the painter Tintoretto della Vite, a masterpiece of expression and vigour; it is executed in black and red, and is but little inferior in chromatic effect to an oil-painting; it is life size, and is executed with wonderful skill and evident keen interest in the subject.

The tapestry cartoons, seven of which are in the Victoria and Albert Museum, were painted by pupils from Raphael's designs. They are a part of a set of ten, with scenes from the Acts of the Apostles, intended, when copied in tapestry, to adorn the lower part of the walls of the Sistine chapel. The tapestries themselves, worked at Brussels, are now, after many vicissitudes, hung in a gallery in the Vatican; the set completed thus presents the design of the ten cartoons. The existing seven, after being cut up into strips for use on the looms, were bought by Rubens for Charles I. 7 The tapestry copies are executed with wonderful skill, in spite of Raphael's having treated the subjects in a purely pictorial way, with little regard to the exigencies of textile work. The designs are reversed, and the colours far more brilliant than those of the cartoons, much gold and silver being introduced. The noble figure of Christ in the Delivery of the Keys to St Peter is in the tapestry much disfigured by the addition of a number of large gold stars all over the drapery, which spoil the simple dignity of the folds. The rich framework round each picture, designed by Raphael's pupils, probably by Penni and Giovanni da Udine, exists in the tapestries and adds greatly to their decorative effect. The cartoons were executed in 1515 and 1516, and the finished tapestries were first exhibited in their place in the Sistine chapel on the 26th of December 1519—a very short time for the weaving of such large and elaborate pictures. The three of which the cartoons are lost represent the Martyrdom of St Stephen, the Conversion of St Paul, and St Paul in Prison at Philippi. Probably no pictures are better known to have been more often engraved and copied than these cartoons.

The Transfiguration. — In 1519 Cardinal Giuliano de' Medici (afterwards Clement VII.), as bishop of Narbonne, ordered two altar-pieces for his cathedral—the one by Raphael, the other by Raphael's Venetian rival Sebastiano del Piombo. That by the latter painter is the noble Resurrection of Lazarus, now in the National Gallery, in the drawing of which the Venetian received important aid from Michelangelo. Several studies for Raphael's picture exist, showing that he at first intended to paint a Resurrection of Christ as a pendant to Sebastiano's subject, but soon altered his scheme into the Transfiguration. The eight or nine existing studies are scattered through the Oxford, Lille, Windsor and some private collections. A great part of the lower group was unfinished at the time of the painter's sudden death in 1520, and a good deal of the heavy colouring of Giulio Romano is visible in it. On the death of Raphael the picture became too precious to send out of Rome, and Cardinal de' Medici contented himself with sending the Resurrection of Lazarus to Narbonne. The Transfiguration was bequeathed by him to the monks of S. Pietro in Montorio, in whose church it remained till it was stolen by Napoleon I. It now hangs in the Vatican, though it has been cut down to fit a few buildings. Raphael's great repute even in this branch of art is shown by the

1 Thanks to Michelangelo's generous intervention, Raphael was paid the large sum for that time of 900 gold ducats for this fresco.
2 Gruner, Mosaici in S. Maria del Popolo (Rome, 1839).
3 In accordance with Dante's scheme in the Paradiso.
4 La Perla, " the pearl " of the Spanish royal collection, was originally painted for Bishop Louis of Canossa; it was sold by Cromwell with the greater part of Charles I.'s collection at Hampton Court. The composition, though not the execution, of this picture, belongs to Raphael's early years in Rome; it is very remarkable for its delicacy of touch and high finish.
5 The magnificent portrait-heads of the Venetian scholars Nava- gero and Beazzano, now in the Doria Gallery in Rome, are worthy of Raphael at his best, and have for long been attributed to him. There are good contemporary copies at Madrid.

6 Fortunately they were not sold with the bulk of Charles's collection, and remained at Hampton Court till a few years ago. See Koch, Rafael's Tapeten im Vatican (Vienna, 1878), and Münz, Hist. de la tapisserie italienne (Paris, 1880).
7 The name " arrazzi " given by Italians to these tapestries is derived from " arra," a table, on which the tapestries were lost in woolen; they were made at Brussels. It is much to be regretted that visitors to the Vatican are no longer allowed to see these priceless examples of textile work.
8 See Morgenstern, Uber Rafael's Verkärung (Leipzig, 1822), and Justi, Die Verklärung Christi (Leipzig, 1870).
9 See Ojetti, Discorso su Rafaello Architetto (Rome, 1883), but more especially Geymüller's work mentioned in the text, and his Projets primitifs pour la Basse de S. Pierre (Paris, 1875-80); also the works of Hofmann and Bloch (Dresden, 1900).
fact that Bramante, before his death in March 1514, specially requested that Raphael should be made his successor as chief architect of St Peter's. To this most important post he was appointed by a brief of Leo X, dated the 1st of August 1514. The progress of St Peter's was, however, too slow for him to have much to do there. Indeed, there is little evidence that Raphael contributed to the church, except for his design for the cupola, which was ultimately carried out by his pupil, Domenico Fontana.

The Palazzo dell'Aquila, built for Giovanni Battista Branconio, and destroyed in the 17th century during the extension of St Peter's, was one of Raphael's important architectural projects. It was intended to be a vast cross church, domed at the intersection like a miniature St Peter's, called S. Eligio degli Orefici, which still exists near the Tiber, and is a good example of the Farnesina garden, a work of little merit. According to Vasari, whose life of Raphael is the most valuable evidence we have for the subject, the Villa Farnesina at Agostino Chigi, usually attributed to Peruzzi, was, as well as its fresco-stiltes, designed by Raphael; but internal evidence makes this very difficult to believe. It has too much of the delicate and refined character of the 16th century for Raphael, whose taste seems to have been strongly influenced by the work of Palladio. Afterwards he became the chief exponent. The Palazzo Vidoni, near S. Andrea della Valle, also in Rome, is usually attributed to Raphael, but an original sketch for this in Peruzzi's own hand has recently been discovered in the collection of Mr. H. E. Carter; this, however, is not a certain proof that the design was not Raphael's. M. Geymüller has, however, shown that the Villa Madama, on the slopes of Monte Mario above Rome, was really designed by Raphael. Though its actual carrying out is attributed to Raphael's pupil, the villa was designed by him; it is a dym scholastic building without any special beauty either in proportion or treatment of the mass; its magnificence is surpassed by Montigny and Famin, Architecture Toscane (Paris, 1815), pls. 33-36.

A sober critical of Raphael's architectural works must force one to refuse him a high position in this branch of art. In the church of S. Eligio and the Chigi chapel he is right, but of Palladio and Bramante, and his more original works show but little power of invention or even mastery of the first principles of architectural design. His details are, however, often delicate and refined (especially in the Loggie at S. Maria della Pace, a building in which he was supposed to have a share), and were of picturesqueness and of the decorative treatment of richly ornamented interiors when he did not, as in some of the Vatican Stanze, sacrifice the room to the frescoes on its walls.

St. Peter's. The Vasari is right in attributing to him the model for the beautiful statue of Jonah in the Chigi chapel (fig. 7) is borne witness to by two important documents, which show that his almost universal talents led him to attempt with success the preliminary part of the sculptor's art, though there is no evidence to show that he ever worked on marble. One of these is a letter written to Michelangelo to warn him that Raphael had been invading his province as a sculptor by modelling a boy, which had been executed in marble by a pupil, and was a work of art, beautiful enough to make Raphael's name known to the world. Again, after his death his friend Baldassare Castiglione, in a letter dated the 8th of May 1523, asks his steward in Rome "if Giulio Romano still possesses a certain boy in marble by Raphael and what his lowest price for it would be,"—"segli [Giulio Romano] ha pero quel puttino di marmo di mano di Raffaello ed è quanto si daria all' ultimo" (fig. 10). A group of a putto of a dead Boy on his Dolphin Playfellow, now in the St Petersburg Hermitage, has also been erroneously supposed to be Raphael's "puttino," which has also been identified with a statue of a child formerly at Florence in the possession of Sigur Madama, and it remained in his studio for many years after Raphael's death. The Victoria and Albert Museum possesses a small clay sketch for this beautiful group, slightly different from the marble in the Hermitage, which is probably the original design by the master's own hand. The design is also a feeling of the group—a beautiful youth seated on a sea-monster—is purely classical, and the motive is probably taken from some antique statue representing Arion or Taras on a dolphin. Being intended for a chimney-piece, it was supposed to give the figure a sacred name, and hence the very incongruous title that it received. There is no trace of Raphael's hand in the design of the other statue, an Elijah by Lorenzetto, though it also is ascribed to him by Vasari.

Lesser Arts practised by Raphael.—Like other great artists, Raphael did not disdain to practise the lesser branches of art: a design for a silver perfume-burner with female caryatids is preserved in an engraving by Marco da Ravenna; and he also designed two handsome repoussé salvers for Agostino Chigi, drawings for which are now at Dresden. In designs for tarsia-work and wood-carving he was especially skilful; witness the magnificent stater and shanters of the statue executed by his pupil Giovanni Barile of Siena. The major works of designs attributed to him were by a name sake and relation called Raffaello di Chiara? and, though many fine dishes and ewers of Urbino and other majolica are decorated with Raphael's designs, they are all taken from pictures or engravings and especially copied by him for ceramic purposes. With the frizziness of his age Leo X. occasionally wasted Raphael's skill on unworthy subjects, such as the scenery of a temporary theatre; and in 1516 the pope sent him to paint in fresco the portrait life-size figure of a large elephant, the gift of the king of Portugal, after the animal was dead. This elephant is also introduced among the stucchi reliefs of the Vatican loggie, with the poetaster Baratall sitting in it, a triumph of much beauty.

Though Raphael himself does not appear to have practised the art of engraving, yet this formed one of the many branches of art which were carried on under his supervision. A large number of his designs for engravings, by his pupils Marcantonio Raimondi and Agostino Veneziano. These valuable engravings are from Raphael's sketches, not from his finished pictures, and in some cases they show

2. A good too a share in the decoration of the loggie is usually given to Raphael; not only the harsh colour but also the feeclesness of much of the drawing shows that he can have had but little to do with it.
3. See Grover, Fresco Decorations, etc. (London, 1854), pls. 6-12 and Raffaele Santi, Ornati della Villa Madama, etc. (Rome, 1875).
4. Two other little known but very beautiful architectural works, executed under Raphael's influence by his pupils, are the Pictures of Cardinal Bibbiena in the Vatican and the bathroom of Clement VII. in the castle of S. Angelo, both richly decorated with delicate stucco-reliefs and paintings, treated after a classical model.
6. To one branch of the sculptor's art, practised under Raphael's supervision, belong the elaborate and delicately executed figures of the so-called "Christus Amorevole," which occur in many panels with figure-subjects, large in scale and important in composition; those executed during his lifetime are free from the too pictorial character which is an obvious fault in the very magnificent reliefs of the Villa Madama.
Raphael's Fame.—Among all the painters of the world none has been so universally popular as Raphael, or has so steadily maintained his pre-eminent reputation throughout the many changes in taste which have taken place in the last three and a half centuries. He is the only painter whose name is written by itself, for his colourist and master of graceful composition, he owes the constancy of admiration which has been felt for him partly to the wide range of his subjects, but still more to the wonderful varieties of his style. If the authorship of his paintings were unknown, who would guess that the Sposalizio of the Brera, the Madonna del Baldacchino of the Pitti, and the Transfiguration could possibly be the work of one painter? In the seventeen or eighteen years which composed his short working life he passed through stages of development for which a century would not have seemed too long, while other painters lived through the same change in time with but little alteration in their manner of work. Perugino, who outlived his wonderful pupil, completed in 1521 Raphael's San Severo fresco in a style differing but little from his paintings executed in the previous century. In versatility of power Raphael (as a painter) remains almost without a rival; whether painting an altar-piece for a church, a large historical fresco, a portrait or decorative scenes from classical mythology, he seems to excel equally in each; and the widely different methods of painting in tempera, oil or fresco are employed by him with apparently equal facility. His range of scale is no less remarkable, varying from a miniature, finished composition, to the vast figures in fresco dashed in with inimitable breadth and vigour.

His personal beauty, charm of manner and deep kindness of heart endeared him to all who knew him. 4 His sincere modesty was not diminished by his admission as an equal by the princes of the church, the distinguished scholars and the world-famed men of every class who formed the courts of Julius II. and Leo X. In accordance with the spirit of the age he lived with considerable display and luxury, and was approached with the utmost deference by the ambassadors of foreign princes, whether their master desired a picture, or, as the duke of Ferrara did send to come in, but little alteration for their chimney. To his pupils he was as a father, and they were all, as Vasari says, "vinti dalla sua cortesia"; they formed round him a sort of royal retinue, numbering about fifty youths, each talented in some branch of the arts. 5 Giulio Romano and Gianfrancesco Penni, his two favourite pupils, lived with him in the Palazzo di Bramante, a house near St Peter's, where he resided during the greater part of his life in Rome. This fine palace, designed by Bramante, was destroyed in the 17th century at the same time as Raphael's Palazzo dell'Aquila.

It is difficult to realize the grief and enthusiasm excited by the master's death on Good Friday (April 6th) 1520, at the age of thirty-seven exactly, after an attack of fever which lasted only ten days. His body was laid out in state in his studio, by the side of the unfinished Transfiguration, and all Rome flocked to the place for a last sight of the "divine pitore." His property amounted to about £30,000; his drawings and MSS. he left to Giulio Romano and Gianfrancesco Penni; his newly built house to卡塞拉里奥里，the uncle of the lady to whom he had been betrothed; there were also his gems and paintings, and the rest was mostly divided among his relatives at Urbino. He desired to be buried in the Pantheon, under the noble dome which he and Bramante had dreamed of rivaling. His body is laid beside an altar, which he endowed with an annual chantry, and on the wall over it is a plain slab, with an inscription written by his friend Cardinal Bembo. Happily his grave has as yet escaped the disfigurement of a pretentious monument such as those erected to Michelangelo, Dante and other great Italians; it has not, however, remained undisfigured. In 1829 a statue was erected to him, in the Piazza Sistina. In 1829 a statue was erected to him, in the Piazza Sistina. In 1882 he was also granted a large pension by the Italian government. The monument was designed by Longhena, and the statue by Raimondi. The bust on it is reproached with its large size and its bad drawing, the bust on it is reproached with its large size and its bad drawing, the bust on it is reproached with its large size and its bad drawing. The bust on it is reproached with its large size and its bad drawing.

LITERATURE.—Comotti, Vita inedita di Raffaele (1790); Doppia, Vita di Raphael (London, 1816); Braun, Raphael . . . Leben und Wirken (Leipzig, 1870); Comolli, Raphael . . . Leben und Wirken (Leipzig, 1878); Cavalcaselle, Raphael (Paris, 1882); Vey, Raffaello, storia di Raffaello, trans. by Proust (Paris, 1882); Longhena, Raimondi, and Michielangelo; (Leipzig, 1878); C. C. Perkins, Raphael and Michelangelo (Boston, 1878); C. C. Perkins, Raphael and Michelangelo (Boston, 1878); Comolli, Raphael and Michelangelo (Leipzig, 1878); Dohme, Kunst und Künstler des Mittelalters (Leipzig, 1878); vol. ii. of this valuable work, with many illustrations, is devoted entirely to Raphael and Michelangelo; Alipii, Il Raffaello (Urbino, 1880); Clément, Michelangelo et Raphaël (5th ed., improved) (Paris, 1881); Eug. Müntz, Raffaello, sa vie, son œuvre, &c. (Paris, 1881) (with numerous well-chosen illustrations); Passavant, Raffaello, de la vie et du caractère de l'artiste (Paris, 1881); Biographie et Lettres de Raffaello (Paris, 1882); (with a great many prices); B. B. Berenson, Central Italian Painters (1897) (expert catalogue and list of works).

Reproductions of Raphael's Works.—From the time of Raimondi downwards no painter's works have been so frequently engraved. The Calceografia Camerale (now called Raffaeliana) of Rome possesses an enormous number of copper-plates; later, the same company published a large number of colors; a great many (and bad) engravings of the 18th and 19th centuries. Electrotype of the old copper are still worked, and are published by the Stamperia at very moderate prices; in the catalogue Nos. 1321-1326 are 120 plates, and in Nos. 1327 are 130 plates. The works of his studio, those of the various engravers, from 16th century to the present day, have been engraved. Raphael, and his pupil, were both extremely prolific, and the plates of the large collections of engravings containing whole sets, such as the Vatican loggie, &c. A very complete collection of photographs from these and other engravings was published by Gutarier and Llibke, Raphael's Werke, biedermeierische Tafelbilder und Fresken (Dresden, 1881–82), in three large volumes, divided into classes, pictures of the Madonna, frescoes, stanze of the Vatican, tapestry cartoons, &c. The descriptive text and life of Raphael are by Llibke. The Malcolm, Oxford, British Museum, Allen, London, University, Munich, &c., have published excellent biographies. Many of the plates of the late 17th and 18th centuries have been used in numerous engravings, and an enormous number of illustrated monographs on single pictures have been published. By the middle of the 19th century, Brustoloni's large folio of the works of Raphael, and the small folio of the frescoes are especially good.

1 On a pedestal is inscribed in Greek—"Better to die than live basely."

3 See Gruyer, Raffaël et l'antiquités (Paris, 1864).

4 See the eloquent eulogy of his character at the end of Vasari's Life.

6 See "Ritrovamento delle ossa di Raffaello," Soc. Virtuosi al Panteone (Rome, 1833); other pamphlets on this were published in the same year by Foa, Falconieri and Osdaelech.
RAPIER—RARE EARTHS

RAPIER, the name given to two distinct types of sword. Originally the "rapier" (Fr. rapière) was a long two-edged and pointed weapon with a wide cup hilt, used together with the dagger in fencing and duelling chiefly as a thrusting weapon, the cut taking a secondary position. This was the typical duelling sword of the 16th and 17th centuries. In the 18th century the "small-sword" took its place; this was a pointed weapon only, the "cut" having entirely dropped out, and the dagger being discarded. The word rapier is of doubtful origin. It is from the Italian rpojre (Glossarium, s.v. "Rapparla") quotes an example of the word used as an adjective to qualify espée as early as 1474, and gives as a conjectural derivation Gr. paritev=Lat. cardere, to cut. Skeat (Eym. Dict., 1910) follows the suggestion of Diez that rapière is from raspîrie, a rasp or poker, and was a name given in contempt by the old cut-and-thrust fencers to the new weapon. Spanish has raspadora, a raker, and there are several 16th and 17th century quotations alluding to the contempt with which the rapier was greeted, and to its Spanish origin (see Fencing and Sword).

He died at Prague in 1866-1729, sieur of Thyssay, French historian, was the son of Jacques de Rapi, avocat at Castres (Tarn), where he was born on the 25th of March 1661. He was educated at the Protestant academy at Saumur, and in 1679 became an advocate, but soon afterwards entered the army. The revocation of the Edict of Nantes in 1685, and the death of his father led him to come to England; but, unable to find employment there, he crossed to Holland and enlisted in the company of French volunteers at Utrecht commanded by Daniel de Rapi, his cousin-german. He accompanied the prince of Orange to England in 1688, and during the Irish campaign he took part in the siege of Carrickfergus and the battle of the Boyne, and was wounded at the battle of Limerick. Soon afterwards he was promoted captain; but in 1693 he resigned in order to become tutor to the earl of Portland's son. After travelling with his charge, he settled with his family in Holland, first at the Hague, then, for economy's sake, at Wesel, in 1707, where he began his great work, L'Histoire d'Angleterre. Though he was of a strong constitution, the seventeen years' application ruined his health. He died in 1725.

Rapin was also the author of a Dissertation sur les Whigs et les Tories (1717), L'Histoire du Stéphanois, embracing the period from the invasion of the Romans to the death of Charles I., was printed at the Hague in 1724 in 8 vols. It was translated into English and improved with notes by Tindal, in 2 vols. folio, 1725-51. Rapin's history is not the only one available in France in the first half of the 18th century.

RAPPORT, SAMUEL JUDAH LÖB (1790-1867), Jewish scholar, was born at Lemberg in 1790. After various experiences in business, Rapoport became successively rabbi of Tarnopol (1837) and of Prague (1840). He was one of the founders of the new learning in Judaism. His chief work was the first part of an (unfinished) encyclopaedia (Erezh Millin, 1852). Equally notable were his biographies of the Gaon Saadiah, Nathan author of the Arkh, the Gaon Hai, Elenzah Kallr and others.

RAPPER, properly a short pipe (Irish rapière); the term being hence applied in the war in Ireland from 1688-92 to the Irish irregular soldiers armed with this weapon. It thus became synonymous with robber or freebooter, and in 1707 appears in the title of an act (6 Anne, cap. 11) "for the more effectual suppression of . . . robbers and rapparees."

RAPPOLTSWEILER (French Ribeauville), a town of Germany, in the imperial province of Alsace-Lorraine. Pop. (1905) 5986. It lies at the entrance of the valley of the Stréngbach, under the eastern slope of the Vosges mountains, 33 m. S.W. of Strassburg, by a road joining Strassburg to the Rhine in the Rhineland on that line, 2½ m. distant, by a tramway. It is in part surrounded by ancient walls, and has many picturesque medieval houses, and two old churches, of St Gregory and St Augustine, both fine Gothic buildings. The town hall contains a valuable collection of antiquities. The Carolabad, a saline spring with a temperature of 64° F., which had a great repute in the middle ages, was rediscovered in 1888, and made Rappoltsweiler a watering-place. The industries include the spinning and weaving of cotton and wool, printing, dyeing and tanning, while there is a brisk trade in wine.

Rappoltsweiler, known in the 8th century as Ralshaldolvare, passed from the bishops of Basel to the lords of Rappolstein, who were among the most famous nobles in Alsace. The lord of Rappolstein was the king or protector of the wandering minstrels of the land, who purchased his protection by paying him a tax. When the family became extinct in 1674 this office of king of the pipers (Heifertörkönig) passed to the counts patline of Zweibrücken-Birkenfeld. The minstrels had a pilgrimage chapel near Rappoltsweiler, dedicated to their patron saint, Maria von Dusenbach, and here they held an annual feast on the 8th of September. Near the town are the ruins of three famous castles, Ulrichsburg, Girsberg and Holzrappolstein, which formerly belonged to the lords of Rappolstein.

* See Bernhard, Recherches sur l'histoire de la ville de Rappoltsweiler (Colmar, 1888); and Kube, Rappoltsweiler, das Carolohad und Umgebung (Strassburg, 1905). For the lords of Rappolstein, see Brieger, Die Herkraft Rappolstein (Strassburg, 1907).

RARE EARTHS, in chemistry, the name given to a group of oxides of certain metals which occur in close association in some very rare minerals. Although these metals resemble each other in their chemical relationships, it is convenient to subdivide them into three groups: the cerium, terbium and ytterbium groups. The first includes scandiun (Sc, 44-1), yttrium (Y, 89-0), lanthanum (La, 139-0), cerium (Ce, 140-25), praseodymium (Pr, 140-6), neodymium (Nd, 143-4), and samarium (Sa, 150-4); the second includes europium (Eu, 152-0), gadolinium (Gd, 157-3), and terbium (Tb, 159-2); and the third includes dysprosium (Dy, 162-6), holmium (Ho, 26-8) erbium (Er, 167-4), thulium (Tm, 168-5), ytterbium or neodyttrium (Yb, 172-0), and lutecium (Lu, 174-0); the letters and numbers in the brackets are the symbols and atomic weights (international). Although very rare, a large number of minerals contain these metals; they are chiefly found in Scandinavia, parts of the Urals, America and Australia, generally associated with Archean and eruptive rocks, and more rarely with sedimentary deposits. They are usually silicates, but many complex talantilates, niobates, phosphates, uranates and fluorides occur. The chief mineral species are monazite, a phosphat of the cerium metals, bastnasit, cerite (this mineral supplies the ceria and thoria employed in making incandescent gas mantles); cerite, a hydrated silicate of calcium and the cerium metals; gadolinite, a silicate of beryllium, iron, and the yttrium metals; samarksite, a niobate and tantolate of both the cerium and yttrium metals, with uranium, iron, calcium, etc.; and keihaitate, a titanositicate of yttrium, iron, calcium and aluminium; other species are fergusonite, orthite, asechynite, euxenite and thorite.

The chemistry of this group may be regarded as beginning with Cronstedt's description of the mineral cerite from Bastnäs in 1751, and the incorrect analyses published by T. O. Bergman and Don Fausto d'Ebellaria in 1754. Ten years later Gadolin investigated the mineral subsequently named gadolinite, which had been found at Ytterby in 1787 by Arrehnius. This discovery of a new earth was confirmed by A. G. Ekeberg in 1799, who named the base yttria. Cerite was examined simultaneously by Klaproth in Germany and by Berzelius and Hisinger in Sweden; and a new base was discovered in 1803 which the Swedish chemists named ceria. Both these oxides have proved to be mixtures. In 1859 Mosander separated "ceria" into true ceria and an earth which he termed lanthana (Gr. λαυθανα). The former was hidden, and in 1841 he showed that his lanthana contained another base, which he called didymia (Gr. διδύμοι, twins). This didymia was separated in 1879 by Lecoq de Boisbaudran into a new base, samaria, and a residual didymia which was shown by Auer von Welsbach in 1885 to consist of a mixture of two bases, praseodymia and neodymia; moreover, samaria was split by Demargay in 1900 into true samaria and a new base named euxenita. In 1843 Mosander also split
yttria into two new bases which he called "erbia" and "terbia," and a true yttria, but in 1860 N. J. Berlin denied the existence of Mosander's "erbia," and gave this name to his "terbia." The new erbia itself proved to be a mixture. Marignac in 1878 separated an ytterbia which was split by Nilson in 1879 into scandia (the metal of which proved to be identical with Mendeleev's predicted eka-boron) and a new ytterbia, which, in turn, was separated by Urbain in 1907 into neodyyteria and lutecia (C. A. von Weilbach proposed for these elements the names aldefarianum and cassiopium). Berlin's erbia was also examined by Soret in 1878 and by Cleve in 1879; the new base then isolated, Soret's X or Cleve's holmia, was split by Lecoq de Boisbaudran in 1886 into a true holmia and a new oxide dysprosia. The same erbia also yielded another base, thulia, to Cleve, in 1879, in addition to true erbia. The original erbia of Mosander was confirmed by M. A. Delafontaine in 1878 and renamed terbia; this base was split by Marignac in 1886 into gadolania and true terbia. These relations are schematically shown below; the true earths are in italics, mixtures in Roman.

**Methods of Separation.**—The small proportions in which the rare earths occur in the mineral kingdom and the general inter-mixture of several of them renders their efficient separation a matter of much difficulty, which is increased by their striking chemical resemblances. While it is impossible to treat the separations in detail, a general indication of the procedure may be given. The first step is to separate the rare earths from the other components of the mineral. For this purpose the mineral is evaporated with sulphuric or hydrochloric acid, or fused with potassium bisulphate, and the residue extracted with water. The solution of chlorides or sulphates thus obtained is treated with sulphurated hydrogen, to remove copper, bismuth and molybdenum, and the filtrate, after the ferrous iron has been oxidized with chlorine, is precipitated with oxalic acid. The oxalates (and also thorium oxalate) may be converted into oxides by direct heating, into nitrates by dissolving in nitric acid, or into hydroxides by boiling with potash solution. The thorium may be removed by treating the nitrate solution with hydrogen peroxide, and warming, whereupon it separates as thorium peroxide. The next step consists in neutralizing the nitric acid solution and then saturating with potassium sulphate. Double salts of the general formula R₂(SO₄)₂ 3K₂SO₄ are formed, of which those of the cerium group are practically insoluble, of the terbium group soluble, and of the ytterbium group very soluble. The sulphates thus obtained may be reconverted into oxalates or oxides and the saturation with potassium sulphate repeated.

To separate the individual metals many different methods have been proposed; these, however, depend on two principles, one, on the different basicities of the metals, the other, on the different solubilities of their salts. Bahr and Böhler pursued a process of the first type, which utilized the fractional decomposition of the nitrates into oxides on heating. The mixed oxalates are converted into nitrates, which are then mixed with an alkali nitrate to lower the melting-point, and the mixture fused. The nitrates decompose into the oxides in the presence of the alkali nitrate, and the residue is extracted with boiling water, and the basic salt which separates when the solution is cooled is filtered off. This contains a number of negative metal oxides and the filtrate, after the evaporating of the nitrate, may be caused to yield the other oxides. A second method, based on the same principle, consists in the fractional precipitation by some base, such as soda, potash, aniline, etc. The neutral nitrates are dissolved in water, and the base added in such a quantity to precipitate the oxides only partially and very slowly. Obviously the first deposit contains the least basic oxide, which by re-solution as nitrate and re-precipitation yields a purer product. To the filtrate from the first precipitate more of the base is added, and the second less basic oxide is thrown down. By repeating the process all the bases can be obtained more or less pure.

Many processes depending upon the different solubilities of certain salts have been devised. They consist in forming the desired salt and fractionally crystallizing. The mother liquor is concentrated and crystallized; the crystals being separated and the filtrate from a re-crystallization of the first deposit. These operations are repeated after the manner shown in the following scheme: the letter C denotes crystals, the M.L mother liquor, whilst a bracket means mixing before re-crystallization.

**Original Solution**

\end{array}
\]

Obviously the fractions contain salts which increase in solubility as one passes from the left to right; with sufficient care and patience this method permits a complete separation. The salts which have been used include the sulphates, nitrates, chromates, formates, oxalates and malonates. R. J. Meyer (Zeit. anorg. Chem., 1904, 41, p. 97) converted by the double potassium carbonates, e.g. K₂CO₃(CO₂)₂, 12H₂O, which are soluble in potassium carbonate solution, being precipitated in the order lanthanum, praseodymium, cerium and neodymium, oxalate being the solution; C. A. von Weilbach (Chem. News, 1907, 95, p. 196; 1908, 98, pp. 223, 297) separates the metals of the ytterbium group by converting the basic nitrates into double ammonium oxalates and fractionating; C. James (ibid., 1907, 95, p. 181; 1908, 97, pp. 61, 265) formed the oxalates of the yttrium earths and dissolved them in dilute ammonia saturated with ammonium carbonate; by boiling this solution the earths are precipitated in the order yttrium, holmium and dysprosium, and erbium; he also fractionally crystallized the borates (see, e.g. Jour. Amer. Chem. Soc., 1910, 32, p. 517, for thulium). Complex organic reagents are also employed. Neish (Jour. Amer. Chem. Soc., 1904, 26, p. 780) used meta-nitrobenzoic acid; O. Holmberg separates neodymium, praseodymium and lanthanum (and also thorium) with meta-nitrobenzoic sulphonlic acid, and has investigated many other organic salts (see Act. J. C. S., 1937, ii. p. 90), whilst H. Erdmann and F. Wirth (Ann., 1908, 361, p. 295) employ the 1-naphthol sulphonates.

In order to determine whether any chosen method for separating these earths is really effective, it is necessary to analyse the fractions. For this purpose two processes are available. We may convert the salt into the oxide from which the oxide is obtained by heating. A weighed quantity of the oxide is now taken and converted into sulphate by evaporating with dilute sulphuric acid. The sulphate is gently dried until the weight is constant, and from this weight the equivalent of the earth can be calculated. When repeated fractionation is attended by no change in the equivalent we may conclude that only one element is present. This process, however, is only rough, for the elements with which we are dealing have very close equivalents. A more exact method employs the
spectra—spark, arc, phosphorescence and absorption; the evidence, however, cannot in all cases be accepted as conclusive, but when taken in conjunction with chemical tests it is the most valuable method.

Chemical Relations.—The rare earth metals were at first regarded as divergent, but determinations of the specific heats of cerium by Mendeleeff and Hillebrand and of lanthanum and didymium by Hillebrand pointed to their trivalency; and this new view has general acceptance. They are comparatively reactive: they burn in air to form oxides of the type Me₂O₅; combine directly with hydrogen at 200°–300° to form hydrides of the formula MH₂ or MH₃; nitrates of the formula MN are formed by passing nitrogen over the oxides mixed with magnesium; whilst carbides of the type MeC are obtained in the electrolytic reduction of the oxides with carbon. In addition to the oxides MeO₂, several, e.g. cerium, terbium and neodymium, form oxides of the formula MO₃. The sesquioxides are bases which form salts and increase in basicity in the order Sc, Yb, Tb, Ho, Th, Gd, Sm, Y, Ce, Nd, Pr, La; the latter lassies with water like quicklime.

The placing of these elements in the periodic table has attracted much attention on account of the many difficulties which it presented. The simplest plan of regarding them all as trivalent and placing them in the third group is met by the fact that there is not room for them. Another scheme scatters them in one group as a bridge between barium and tantalum. This was suggested by Benelick in 1904 (Zeit, anorg. Chem., 1904, 39, p. 41), and adopted by Werner's table (1905 (Ber. 38, p. 79), whilst in 1912 Brauner (ibid., 52, p. 18) placed the group as a bridge on a plane perpendicular to the planes containing the other elements, thus expanding the table into a three-dimensional figure. The question has also been considered by Sir William Crookes (Journ. Chem. Soc., 1888, 53, p. 487; 1889, 55, pp. 257 et seq.), whose inquiries led him to a new conception of the chemical elements.

Schilling, Das Vorkommen der seltenen Erden im Mineralreich (1904).

RAS, the Arabic for a "head," hence a cape, promontory or height; a common word in place names.

RASCHI (1040–1105), Jewish scholar. RABBI SOLOMON ISAACI (son of Isaac), usually cited as Rashi from the initials of those words, was born at Troyes in 1040 and died in the same town in 1104. Legends concerning him are many. Isaac's wife, shortly before the birth of their famous son, was walking one day down a narrow street in Worms, when two vehicles moving in opposite directions seemed about to crush her. As she leant hopelessly against a wall, it miraculously fell inwards to make a niche for her. So with his education. Legend sends the student to southern France, and even on a tour of the world. At an inn in the Orient he cured a sick monk, as bishop of Olmütz, returned the kindness by saving the Jews from massacre. In fact, Rashi never went farther than from the Seine to the Rhine; the utmost limit of his travels were the academies of Lorraine. Situated between France and Germany, Lorraine was more French than German, and French was the common language of Jew and Christian. This is shown by the glosses in Rashi's works, almost invariably in French. He seems to have passed the decade beginning with 1055 in Worms, where the niche referred to above is still shown. Within this, it is said, Rashi was wont to teach. A small edifice on the east of the synagogue is called the "Rashi Chapel." Rashi was the first to interpret the first steps in the niche, one of the objects of the pious admiration of pilgrims. At Worms Rashi worked under Jacob ben Yaqar, and at Mainz under Isaac ben Judah, perhaps combining at the same time the functions of teacher and student. Besides the oral tuition that he received, the medieval schools habitually kept the notes of former teachers. From these Rashi learned much, and probably he incorporated some of these notes in his own works. In the middle ages there was a communism in learning, but if Rashi used some of the stones quarried and drafted by others, it was to his genius that the finished edifice was due.

Rashi was twenty-five years of age when he returned to Troyes, which town thenceforward eclipsed the cities of Lorraine and became the recognised centre of Jewish learning. Rashi acted as rabbi and judge, but received no salary. Not till the 14th century were Jewish rabbis paid officials. Rashi and his family worked in the vines of Troyes (in the Champagne); in his letters he describes the structure of the wine-presses. His learning and character raised him to a position of high respect among the Jews of Europe, though Spain and the East were long outside the range of his influence. As was said of him soon after his death: "His lips were the seat of wisdom, and thanks to him the Law, which he examined and interpreted, has come to life again." His postiety included several famous names, those of his grandchildren. Rashi had no sons, but his three daughters were women of culture, and two of the sons of Jochebed (see RASHBAH and TAM), as well as others of his descendants, carried on the family tradition for learning, adding lustre to Rashi's fame. The latter part of Rashi's life was saddened by the incidents connected with the first Crusade. Massacres occurred in the Rhinelands. According to legend, Rashi and Godfrey of Bouillon—of the foremost leaders of the Crusade—were intimate friends. Rashi died peacefully in Troyes in 1105, and the congregation, which had already examined and interpreted, has come to life again. It was in no sense a philosopher, but he exemplified in his person and in his works the stored up wisdom of the Synagogue. Yet through all that he wrote there runs a vein of originality. Besides minor works, such as a recension of the Prayer-Book ( Siddur ), the Parades and ha-Orah, Rashi wrote two great commentaries on which his fame securely rests. These were the commentaries on the whole of the Hebrew Bible and on about thirty treatises of the Talmud. His commentary on the Pentateuch, in particular, has been printed in hundreds of editions; it is still to Jews the most beloved of all commentaries on the Mosaic books. More than a
hundred supercommentaries have been written on it. Rashi unites homily with grammatical exegesis in a manner which explains the charm of the commentary. His influence in Christian circles was great, especially because of the use made of the commentary by Nicolaus de Lyra (q.v.), who in his turn was one of the main sources of Luther's version. Even more important was Rashi's commentary on the Talmud, which became so acknowledged as the definitive interpretation that Rashi is cited simply under the epithet of "the Commentator." It is no exaggeration to assert that the modern world owes its power to understand the Talmud to Rashi. In this field the "Commentator" is supreme. He practically edited the text of the Talmud besides explaining it, and the Talmud is never printed without Rashi's commentary on the margin. An important feature of Rashi's commentaries is the frequency of French translations of words. These glosses (lo'sain) have now been in part edited from the manuscripts of the late Arsené Darmesteter.

BIBLIOGRAPHY.—M. Liber, Rashi (1906), published as a memorial of Rashi on the 800th anniversary of his death. Rashi's commentary on the Bible has been translated into English by G. B. Trench (1710-1714); and into German (Pentateuch) by Dukes (1833-38) and others. The foundation of recent investigation into Rashi's life is Zunz's Solomon b. Isaac (1823), to which I. H. Weiss added much in his (1849) biography (in Ber. J. Zeitsch. 2, 105). Also Graetz, History of the Jews (Eng. trans., vol. iii, ch. ix). A critical edition of Rashi's Pentateuch commentary was published by A Berliner (2nd ed., 1909). (I. A.)

RASHTRAKUTA, an Indian dynasty which ruled in the Deccan (q.v.) from about A.D. 750 to 973. The Rashtrakuta or Ratta clan are supposed to have held power during the historical blank before the 6th century but they came to the front in A.D. 750, when Dantidurga overthrew the Chalukya dynasty and made himself ruler of the Deccan. He was succeeded by his uncle Krishna I. (c. 760), who completed his conquests, and whose reign is memorable for the execution of the Kailasa, the rock-cut temple at Ellora. His grandson Govinda III. (780-815) extended the power of the family from the Vindhy Mountains and Malwa on the north to Kanchi on the south. The next king, Amogavarsa, reigned for sixty-two years. The reign of Krishna III. was remarkable for a war with the Cholas, in which the Chola king was killed on the field of battle. The last of the Rashtrakuta kings was Karka II., who was overthrown by the Chalukyas in 973. See R. G. Bhandarkar, Early History of the Deccan (Bombay, 1884).

RASK, RASMUS CHRISTIAN (1787-1832), Danish scholar and philologist, was born at Brændekilde in the island of Fünen or Fyn in Denmark in 1787. He studied at the university of Copenhagen, and at once showed remarkable talent for the acquisition of languages. In 1808 he was appointed assistant keeper of the university library, and some years afterwards professor of literary history. In 1811 he published, in Danish, his Introduction to the Grammar of the Icelandic and other Ancient Northern Languages, from printed and MS. materials accumulated by his predecessors in the same field of research. The remarkable success of this work, which was afterwards used as the Arna-Magnæus Institution, by which he was employed as editor of the Icelandic Lexicon (1814) by Björn Haldorson, which had long remained in manuscript. Rask visited Iceland, where he remained from 1813 to 1815, mastering the language and familiarizing himself with the literature, manners and customs of the natives. To the interest with which they inspired him may probably be attributed the establishment at Copenhagen, early in 1816, of the Icelandic Literary Society, of which he was the first president.

In October 1816 Rask left Denmark on a literary expedition, at the cost of the king, to prosecute inquiries into the languages of the East, and collect manuscripts for the university library at Copenhagen. He proceeded first to Sweden, where he remained two years, in the course of which he made an excursion into Finland to study the language. Here he published, in Swedish, his Anglo-Saxon Grammar in 1817. In 1818 there appeared at Copenhagen, in Danish, an Essay on the Origin of the Ancient Scandinavian or Icelandic Tongue, in which he traced the affinity of that idiom to the other European languages, particularly Latin and Greek. In the same year he brought out the first complete editions of Snorro's Edda and Saemund's Edda, in the original text, along with Swedish translations of both Eddas. From Copenhagen, he went in 1819 to St Petersburg, where he wrote, in German, a paper on "The Languages and Literature of Norway, Iceland, Sweden and Finland." In the sixth number of the Vienna Jahrbuecher, from Russia he proceeded through Tartary into Persia, and resided for some time at Tabriz, Teheran, Persepolis and Shiraz. In about six weeks he made himself sufficiently master of Persian to be able to converse freely. In 1820 he embarked at Bushire for Bombay; and during his residence there he wrote, in English, "A Dissertation respecting the best Method of expressing the Sounds of the Indian Languages in European Characters," in the Transactions of the Literary and Agricultural Society of Colombo. Rask returned to Copenhagen in May 1823, bringing a considerable number of Oriental manuscripts, Persian, Zend, Pali, Sinhalese and others, with which he enriched the collections of the Danish capital. He died at Copenhagen on the 14th of November 1832.

During the period between his return from the East and his death Rask published in his native language a Spanish Grammar (1824), a Frisian Grammar (1825), an Essay on Danish Orthography (1826); or Pentateuch respecting the Ancient Egyptian Chronology and an Italian Grammar (1827), and the Ancient Jewish Chronology of Moses (1828). He also edited an edition of Schneider's Danish Grammar for the use of Englishmen (1830), and superintended the first two translations of his Anglo-Saxon Grammar by Thorpe (1830). He was the first to point out the connexion between the ancient Northern and Gothic on the one hand, and the Lithuanian, Slavonic, Greek and Latin on the other, and he also deserves credit for having had the original idea of "Grimm's Law" for the transmutation of consonants in the transition from the old Indo-European languages to Teutonic, although he only compared Teutonic and Greek, Sanskrit being at the time unknown to him. In 1822 he was master of no less than twenty-five languages and dialects, and it is stated to have studied twice as many. His numerous philological manuscripts were transferred to the king's library at Copenhagen. Rask's Anglo-Saxon, Danish and Icelandic Grammars were brought out in English editions by Thorpe, Repp and Dasein respectively.

RASPBERRY, known botanically as Rubus Idaeus (nat. ord. Rosaceae, q.v.), a fruit-bush found wild in Great Britain and in woods throughout Europe, North Africa and in north and west Asia. The raspberry was known to classic writers, and is mentioned by Pliny as one of the wild brambles known to the Greeks as Iedeia, from Mt. Ida in Asia Minor on which it grew. Parkinson (Paradisus, 1629) speaks of red, white and thornless varieties as suitable for the English climate, and Gerard (Herbal, 1597) figures and describes the Raspis or Framboise and the Morus or Blackbush, both of which are varieties of Rubus Idaeus. The raspberry consists of fleshy, jointed canes from suckers, which may be taken off the parent stools in October, and planted in rows 5 or 6 ft. apart, and at 3 ft. asunder in the rows. It is the habit of the plant to throw up from the root every year a number of shoots or canes, which bear fruit in the subsequent year, and then decay. In dressing the plants, which is done immediately after the crop is gathered, all these exhausted stems are cut away, and of the young canes only three or four of the strongest are left, which are shortened about a third. The stems, being too weak to stand by themselves, are sometimes connected together by the points in the form of arches or tunnels. The black canes are cut at the node and half the canes are bent one way and half the other, both being tied to the stake. Sometimes they are tied upright to stakes fixed to each stool. The best support, however, is obtained by fastening the points of the shoots to a slight horizontal rail or bar, placed a foot and a half on the south side of the rows.
RASPE—RASTATT

by which means the bearing shoots are deflected from the perpendicular to the sunny side of the row, and are not shaded by the annual wood. When this mode of training is adopted, the plan of planting 1 foot apart in the row and leaving one or two canes only to each shoot is preferable. The ground between the rows should never be disturbed by deep digging; but an abundant supply of good manure should be given annually in autumn as a dressing, which should be forked in regularly to a depth of 4 or 5 inches. All surplus suckers should be got away early in the summer before they have rooted the roots—five or six, to be reduced to the four best, being reserved to each root. Fresh plantations of raspberries should be made every six or seven years. The double-bearing varieties, which continue to fruit during autumn, require light soils and warm situations. These should be cut close down in February, as it is the strong young shoots of the current year which bear the late autumnal crops. The other varieties may be made to bear in autumn by cutting the stems half-way down at an early period in spring; but, as with all other fruits, the flavour of the raspberry is best when it is allowed to ripen at its natural season.

The following are some of the finer sorts now in cultivation:

- Baumforth's Seedling—a large summer-bearing red.
- Carter's Prolific—a large summer-bearing red.
- Pastold or Fibby—a large summer-bearing red.
- M. Loren's Prolific—a large double-ripened red.
- Northumberland Fillbasket—a large summer red.
- October Red—a fine autumn-bearing red.
- October Yellow—a fine autumn-bearing yellow.
- Prince of Wales—a summer-bearing red.
- Red Antwerp—a large summer-bearing red.
- Rogers's Victoria—a large autumn-bearing red.
- Round Antwerp—a large summer-bearing red.
- Semper Fidelis—an excellent bright red variety; heavy cropper.
- Superlativa—fruits rich red; perhaps the best raspberry in cultivation.
- Sweet Yellow Antwerp—a large summer-bearing yellow.

The European raspberry, though admittedly of better quality, has been largely displaced in the United States of America by a closely allied native species, *R. strigosus*, the numerous varieties of which are harder than the varieties of the European species and ripen their crop much more rapidly. The stems are more slender and flexible than in *R. idaeus*, usually brown or reddish-brown in colour and beset with stiff straight prickles. The most important raspberry of cultivation in America is *R. occidentalis*, the black raspberry or thimbleberry, which is at once distinguished by its firm black, rarely yellow, fruit. The purple-cane raspberry, *R. neglectus*, with fruit varying in colour from dull purple to dark red or sometimes yellowish, is perhaps a hybrid between *R. strigosus* and *R. occidentalis*.

For a detailed account of the American species of Rubus see F. W. Card, *Bush-fruits* (1898).

The Loganberry is a hybrid between the raspberry (*Rubus Idaeus*) and the blackberry or bramble (*R. fruticosus*), and derives its name from its raiser, Judge Logan of the American Bar. It is a strong-growing plant, partaking more of the habit of the blackberry than the raspberry, and making shoots often 10 to 15 ft. long in the course of the year. These bear leaves with 5 leaflets, and fruit the following year. The fruiting shoots have leaves with only 3 leaflets; but young and old stems are densely covered with sharp crimson prickles. The fruits are borne profusely in loose trusses, and are ripe in southern localities in July, and about early August in northern parts. They may be cut off the cane as they ripen, and packed in the market-basket, but when ripe they are deep purplish red, and much more palatable, each fruit being about 1½ in. long, and shaped like a raspberry.

The Loganberry flourishes in heavy loamy soil, and is a useful plant for old fences or trellises, or even in waste places, where it is exposed to the sunshine. The old fruiting shoots should be cut away each winter, and in the spring the young shoots should have a sprig of the cane bent over the young canes and covered with earth to induce the better and ripened, and buds lower down to throw masses of white flowers, to be succeeded in due course by the fruits. Propagation is by means of suckers from the base.

RASPE, RUDOLF ERICH (1737-1794), the original author of the *Adventures of Baron Munchausen* (see MUNCHAUSEN), was born in Hanover in 1737, and studied at Göttingen and Leipzig. In 1763 he became a clerk in the university library at Hanover, and in 1764 secretary to the university library at Göttingen. He had become known as a versatile scholar and a student of natural history and antiquities, and he published some original poems and also translations, among the latter of Leibnitz's philosophical works and of Ossian's poems; he also wrote a treatise on Percy's Reliques. In 1767 he was appointed professor in Cassel, and subsequently librarian. He contributed in 1769 a zoological paper to the 9th volume of the *Philosophical Transactions*, which led to his being selected an honorary member of the Royal Society in London, and he wrote voluminously on all sorts of subjects. In 1774 he started a periodical called the *Cassel Spectator*. But having gone to Italy in 1775 to buy curios for the landgrave of Hesse, to whom he was keeper of the gems, he was found to have sold the landgrave's valuables for his own profit; and, on orders being issued for his arrest, he decamped to England. In London he employed his knowledge of English and his learning to secure a living by publishing books on various subjects, and English translations of German works, and there are allusions to him as "a Dutch savant" in 1780 in the writings of Horace Walpole, who gave him money and helped him to publish an *Essay on the Origin of Oil-painting* (1781). But he remained poor, and the Royal Society expunged his name off its list. He went to Copenhagen in 1785 and 1786, and in about 1785-92 was the landgrave's chaplain and storekeeper at the Dalcothe mine, where memories of his ingenuity remained to the middle of the 19th century. While there, he seems to have written the original version of *Munchausen*, which was subsequently elaborated by others. Between 1785 and 1790 he compiled a descriptive catalogue of James Tassie's collection of pastes and casts of gems, in two quarto volumes (1791) of laborious industry and bibliographical rarity. Raspe then went to Scotland, and in Caithness found a patron in Sir John Sinclair of Uist, whose mineralogical proclivities he proceeded to impose upon by pretending to discover valuable and workable veins on his estates; but Raspe had "salted" the ground himself, and on the verge of exposure he absconded. He next took himself to Ireland, but died at Muckross in 1794, when he was only beginning some mining operations in Donegal. His career is interesting because of his connexion with the famous book of stories of Baron Munchausen (q.v.). His authorship was not known in his lifetime, except to his friend Gottfried August Bürger and possibly a few of his other intimates (such as Kästner and Lichtenburg) in his student days at Göttingen; and it was not till 1824 that the biographer of Bürger (who had been a friend with writing *Munchausen* instead of only translating it, as he did in 1780) revealed the truth about the book.

RASSAM, HORMUZD (1826-1910), Assyriologist and traveller, was born at Mosul of native Christian parents. His first work was done as assistant to Sir A. H. Layard in his first expedition (1845-47). He subsequently came to England, studied at Oxford, and was again sent by the British Museum trustees to accompany Layard in his second expedition (1849-51). Layard having entered upon a political career, Rassam continued the work (1852-54) in Assyria under the direction of the British Museum and Sir Henry Rawlinson at Nimrud and Kuyunjik. In 1856 he was sent by the British government to Abyssinia, where, however, he was imprisioned for two years until freed by the victory of Sir Robert Napier. From 1876 to 1883 he was again in Assyria conducting important investigations, especially at Nineveh, and during the Russo-Turkish War he was sent on a mission of inquiry to report on the condition of the Christian communities of Asia Minor and Armenia. His archaeological work resulted in many important discoveries and the collection of valuable epigraphical evidence.

See *The Times*, Sept. 17, 1910.

RASTATT, a town of Germany, in the grand duchy of Baden, on the Murg, 4 m. above its junction with the Rhine and 15 m.
by rail S.W. of Karlsruhe. Pop. (1905) 14,404.

The old palace of the margraves of Baden, a large Renaissance edifice in red sandstone, is now partly used for military purposes and contains a collection of pictures, antiquities and trophies from the Turkish wars. The chief manufactures are stoves, beer and tobacco. Until the end of the 17th century Rastatt was unimportant, but after its destruction by the French in 1689 it was rebuilt on a larger scale by Louis William, margrave of Baden, the imperial general in the Turkish wars. It was then the residence of the margraves until 1771. The Baden revolution of 1849 began with a mutiny of soldiers at Rastatt in May 1849, and ended a few weeks later with the capture of the town by the Prussians. For some years Rastatt was one of the strongest fortresses of the German empire, but its fortifications were dismantled in 1890.

See Schuster, Rastatt, die ehemalige badische Residenz und Bundesfestung (Lahr, 1902); and Lederle, Rastatt und seine Umgebung (Rastatt, 1895).

Rastatt has been the scene of two congresses. At the first congress, which was opened in November 1713, negotiations were carried on between France and Austria for the purpose of ending the war of the Spanish succession. These culminated in the Treaty of Rastatt of January 4, 1714. The second congress, which was opened in December 1797, was intended to rearrange the map of Germany by providing compensation for those princes whose lands on the left bank of the Rhine had been seized by France. It had no result, however, as it was ended by the outbreak of the European war, but it had a sequel of some interest. As the three French representatives were leaving the town in April 1799 they were waylaid, and two of them were assassinated by some Hungarian soldiers. The origin of this outrage remains shrouded in mystery, but the balance of evidence seems to show that the Austrian authorities had commanded their men to seize the persons who had escaped in order to prevent further disclosures about Austria's designs on Bavaria, and that the soldiers had exceeded their instructions. On the other hand, some authorities think that the deed was the work of French emigrants, or of the party in France in favour of war.

For fuller particulars of the two sides of this controversy see K. Mendelssohn-Bartholdy, Der Rastadder Gesandtenmord (Heidelberg, 1860); J. A. Freiherr von Helfert, Der Rastadder Gesandtenmord (Vienna, 1874); Böhlingk, Napoleon und der Rastadder Gesandtenmord (Leipzig, 1883); and Zum Rastadder Gesandtenmord (Heidelberg, 1898); H. Hüffer, Der Rastadder Gesandtenmord (Bonn, 1886); and H. von Sybel, Band 39 der Historischen Zeitschrift, 1874.

Rastell (or Rastall), John (d. 1556), English printer and author, was born in London towards the end of the 15th century. He is vaguely reported by Anthony à Wood to have been "educated for a time in grammaticals and philosophicals" at Oxford. He became a member of Lincoln's Inn, and practised successfully as a barrister. He was also M.P. for Dunheved, Cornwall, from 1539 to the time of his death. He began his printing business some time before 1516, for in his preface to the undated Liber Assisarum he announced the forthcoming publication of Sir A. Fitzherbert's Abréegementum liberorum legum Anglorum, dated 1536. Among the works issued by him, or of which he was probably the printer, is the controversy with Edith's Apology for the Percy Soc. (Early English Poetry, vol. 22, 1848), and by Julius Fischer (Marburger Studien zur englischen Philologie, vol. v., 1903).

See also an article on "John Rastell and his Contemporaries" in Bibliographica, vol. 11, 437 seq., by Mr. R. Plomer, who unearthed in the Record Office an account of a law-suit (1534-35) in connexion with Rastell's premises at the "Mermaid." For the books issued from his press see a catalogue by R. Proctor, in Hand-Lists of English Printers (Bibliographical Soc., 1896).

Rastell, William (c. 1508-1565), English printer and judge, son of the preceding, was born in London about 1508. At the age of seventeen he went to the university of Oxford, but did not take a degree, being probably called home to superintend his father's business. The first work which bears his own imprint was A Dyaloge of Sir Thomas More (1535), a reprint of the edition published by his father in 1539. He also brought out a few law-books, some poetry, an edition of Fabion's Crowley (1533), and The Apology (1533) and The Supply-cacon of Soulvs of his uncle Sir Thomas More. His office was "in Fleetsestrete in saynt Brydys chyrche yarde." He became a student at Lincoln's Inn on 12th September 1532, and gave up the printing business two years later. In 1547 he was appointed reader. On account of his Catholic convictions he left England for Louvain; but upon the accession of Mary he returned, and was made serjeant-at-law and treasurer of Lincoln's Inn in 1555. His patent as judge of the Queen's Bench was granted on the 27th of October 1556. Rastell continued on the bench until 1562, when he retired to Louvain without the queen's licence. By virtue of a special commission issued by the barons of the Exchequer on the occasion an inventory of his goods and chattels was taken. It furnishes an excellent idea of the modest nature of the law library (consisting of twenty-four works) and of the chambers of an Elizabethan judge (see Law Magazine, February 1844). He died at Louvain on the 27th of August 1565.

It is difficult to distinguish between the books written by him and those by his father. The following are believed to be his: A Collecton of all the Statutes (1559), A Table collected of the Yeares of the Kynes of Englands (1601), both frequently reprinted with additions, and A Dyaloge of Sir Thomas More (1556), also frequently reprinted. The entries are not of Rastell's own drawing, but have been selected from printed and MS. collections; their pointed brevity and precision are commended by Mr. Halliwell-Phillipps, who compiled the table of contents, and edited La nova natura brevium de Monseign. Anton. Fitzherbert (1554) and The Works of Sir T. More in the English Tongue (1557).

He is also stated to have written a life of Sir T. More, but it has not come down to us.
RASTENBURG, a town of Germany, in the province of East Prussia, lying in a flat sandy plain on the Guber, 64 m. S.E. of Königsberg by the railway to Prostken. Pay tax of 1.689. Its principal manufactures are flour, sugar, oil, beer and machinery. In the vicinity is Karlshof, a celebrated establishment for the cure of epidemic diseases.

See Beckhern, Mittheilungen aus Rastenburgs Vergangenheit (Rastenburg, 1891); and Schaffer, Chronik von Rastenburg (Rastenburg, 1889).

RAT (a word common to Teut. and Rom. languages; probably first adopted in Teut.; the ultimate origin is not known; Skeat suggests the root *rad-, to scratch; cf. Ger. *Rotte, Dan. rotte, Fr. rat, &c.), probably in its original sense the designation of the British rodent mammal commonly known as the black rat (*Mus rattus), but also applied indifferently to the brown or Norway rat (*M. norvegicus), and in a still wider sense to all the larger representatives of the genus *Mus, as to many other members of the family Muridae.

In fact, as mentioned in the article Mouse, there is no possibility of defining the term "rat" when used in a sense other than as relating to the two species above mentioned; while there is also no hard-and-fast limit between the terms "rats" and "mice" when these are likewise employed in their now extended sense, "rats" being merely larger "mice," and vice versa. Rats have, however, generally more rows of scales on the tail (reaching to 210 or more) than mice, in which the number does not exceed 180. For the distinctive characteristics of the family Muridae and the genus *Mus, to which true rats and true mice alike belong, see Rodentia. Of the two British species, the brown, or Norway rat (*M. norvegicus) is distinguished by its large size, brownish grey colour, short tail and ears, stout skull, and the possession of from 10 to 12 teats. It is fierce and cunning, and easily overcomes all allied species with which it is brought in contact. Its original home would seem to have been some part of Central Asia, an Indian species from China, *M. humilis, being so like it that in all probability the latter is the original race from which it has sprung. Thence it has spread to all parts of the world, driving out the house-haunting species everywhere, as it has in England all but exterminated the black rat. The brown rat migrated westwards from Central Asia early in the 18th century, and is believed to have first reached Great Britain about 1730. Its already evil reputation has been increased of late years by the fact that it is one of the chief disseminators of bubonic plague. Black phases are not uncommon. The black rat (*M. rattus) is distinguishable from the brown rat by its smaller size, longer ears and tail, and glossy black colour. It shares the roving habits of the latter, frequenting ships and by these means reaching various parts of the world. On this account either the typical form or the tropical *M. rattus alexandrinus is common in many places to which the brown species has not yet penetrated, for instance in South America. This long-tailed rat, originally a native of India, would seem to have first penetrated to all parts of the world and to have nearly or quite exterminated the indigenous rats. After this followed the advance of the more powerful brown rat. The black rat first reached Europe in the 13th century, but late years another and still darker phase of the species, the Black Sea black rat (*M. rattus ater) made its appearance in England. The Isle of Dogs and Yarmouth, in Norfolk, are reported to be the chief of the English strongholds of the black rat.

Both species agree in their predaceous habits, omnivorous diet and great fecundity. They bear, four or five times in the year, from four to ten blind and naked young, which in their turn able to breed at an age of about six months; the time of gestation being about twenty days.

RATAFIA, a liquor or cordial flavoured with peach or cherry kernels, bitter almonds, or other fruits; many different varieties are made. The same name is given to a flavouring essence resembling bitter almonds, and also to a light biscuit.

The word ratafia is adapted from the French of the 17th century. Skeat (Etym. Dict., 1910) quotes as a possible origin a combination of Malay *orajo, arrack, and tofah, rum.

RATE, a general term for proportion, standard, allowance, tax (Med. lat. *rate, from *pro rata parte, *ratus being the participle of *reri, to think, judge). In England the term is specially applied to the levying of public money contributions for local purposes, as distinguished from the "taxes" raised for what are treated as general state purposes. The money required for local administration in England is raised (when the ordinary revenues are insufficient) by assessments on lands and buildings valued at their annual rental value. The value thus assessed is used by local authorities to estimate what additional amount beyond revenue is required for the expenses of administration, and levies a rate to meet it. The earliest rate levied in England was that for poor relief, and of the great variety of rates now existing, the majority are based on the poor rate and levied with it, under the term of precept rates. Next to the poor rate came that for highways, and other special rates have been authorized from time to time, as for police, education, public lighting, cemeteries, libraries, sanitary purposes, &c. To distinguish the rate the name of the precepting authority is frequently added or the purpose for which it is levied specified, as county rate, watch rate, &c. The valuation of the properties on which the rates are levied. This valuation list contains the gross estimated rental and rateable value of all rateable property in the parish. The gross estimated rental is the rent at which a property might reasonably be expected to let from year to year, the tenant paying tithes, rates and taxes. From this is deducted the average annual cost of repairs, insurance and renewals, the balance constituting the rateable value. The rateable value of the parish being known, so much on each pound of the rateable value as will equal the amount required to be raised is levied, and is known as the "rate." See further England, Local Government; Taxation.

Rating, in maritime vocabulary, is the classification of men according to rank, and was formerly employed to class ships of a navy according to strength. A sailor is said to be "rated A.B.,” or in the navy "rated petty officer,” "seaman,” "gunner,” and so on. The rating of ships began in the 17th century, and was at first done roughly by size and number of crew. Later the rating was by guns. Thus in 1741 in the British navy there were six rates: 1st, 100 guns; 2nd, 90; 3rd, 70 to 80; 4th, 50 to 60; 5th, 40; and 6th, 20. Sloops, fireships, bomb-vessels and royal yachts were said to be not rated. The classification of ships into six rates, and into rated and non-rated ships, continued during the existence of the old sailing fleets, with modifications in detail. The practice of other navies was similar to the British.

RATTEL, or HONEY-BADGER, the name of certain Indian and African small clumsy-looking creatures of about the size and appearance of badgers, representing the genus Mellivora in the family Mustelidae (see Carnivora). Two species of ratel are commonly recognized, the Indian (*M. indica), and the African (*M. ratel), which ranges over Africa, but a black ratel from the Ituri forest has been separated as *M. cotoni. Both the former are iron-grey on the upper parts, and black below, a style of coloration rare among mammals, as the upper side of the body is in the great majority darker than the lower.
The body is stout and thickly built; the legs are short and strong, and armed, especially the anterior pair, with long curved claws; the tail is short; and the ears are reduced to rudiments. The skull is conical, stout and heavy, and the teeth, although sharper and less rounded than those of badgers, are less suited to a carnivorous diet than those of stoats, weasels and martens. The two rats may be distinguished by the fact that the African species has a distinct white line round the body at the junction of the grey of the upper side with the black of the lower, while in the Indian this line is absent; the teeth also of the former are larger, rounder and heavier than those of the latter. The two are, however, so nearly allied that they might almost be considered geographical races of a single species. Dr T. C. Jerdon states that the Indian ratel is found throughout the whole of India, from the extreme south to the foot of the Himalaya, chiefly in hilly districts, where it has greater facilities for constructing the holes and dens in which it lives; but also in the north of India in alluvial plains, where the banks of large rivers afford equally suitable localities wherein to make its lair. It is stated to live usually in pairs, and to eat rats, birds, frogs, white ants and various insects, and in the north of India it is accused of digging out dead bodies, and several of the native names mean "grave-digger." Dr W. T. Blanford, in the Fauna of British India, is of opinion that the reprobate is without foundation. Like its Cape congener it occasionally partakes of honey, and is often destructive to poultry. In confinement the Indian ratel becomes tame and even playful, displaying a habit of tumbling head over heels. (R. L.*)

RATH, GERHARD VOM (1830-1888), German mineralogist, was born at Dinsburg in Prussia, on the 20th of August 1830. He was educated at Cologne, at Bonn University, and finally at Berlin, where he graduated Ph.D. in 1853. In 1856 he became assistant to Nzgerath in the mineralogical museum at Bonn, and succeeded to the directorship in 1872. Meanwhile in 1863 he was appointed extraordinary professor of geology, and in 1872 he became professor of geology and mineralogy in the university at Bonn. He was distinguished for his accurate researches on mineralogy and crystallography; he described a great many new minerals, some of which were discovered by him, and he contributed largely to our knowledge of other minerals, notably in an essay on tridymite. He travelled much in southern Europe, Palestine and the United States, and wrote several essays on petrology, geology and physical geography, on earthquakes and on meteorites. He died at Coblenz on the 23rd of April 1888.

His separate publications included Ein Ausflug nach Kalabrien (1871); Der Momoni im südöstlichen Tirol (1875); and Durch Italien und Griechenland nach dem Heiligen Land (2 vols., 1882). See Obituary with bibliography by Professor H. Laspeyres, in Sitzungsberichte des nat. Vereins der preussischen Rheinland (1888).

RATHENOW, a town of Germany, in the Prussian province of Brandenburg, on the Havel, 45 m. N.W. of Berlin on the main railway to Hanover. Pop. (1905) 23,095, including the garrison. The Protestant church of St Mary and St Andrew, originally a basilica, and transformed to the present plan in 1554, 1560 and 1707, and the Roman Catholic church of St George, are noteworthy. Rathenow is known for its "Rathenow stones," bricks made of the clay of the Havel, and for its spectacles and optical instruments, which are exported.

Rathenow received its incorporation as a town in 1295. In 1394 it was taken and partly destroyed by the archbishop of Magdeburg. It suffered much from the ravages of the Thirty Years' War, being occupied in turn by the Saxons and the Swedes, from whom in 1675 it was taken by the Brandenburgers, when most of the garrison were put to the sword.

See Wagner, Denkwürdigkeiten der Stadt Rathenow (Berlin, 1903).

RATIBOR (Polish Racibórz), a town of Germany, in the Prussian province of Silesia, pleasantly situated on the left bank of the Oder at the point where the river becomes navigable, 13 m. from the Austrian frontier and 97 m. by rail S.E. of Breslau, on the main line to Oderberg. Pop. (1905) 32,690. The most prominent buildings are the handsome law-courts by Schinkel and the imposing chateau of the dukes of Ratibor, which occupies a commanding position on the right bank of the Oder. The town is the seat of various industries, the chief products of which are machinery, railway gear, iron ware, tobacco, cigars, paper, sugar, furniture and glass. Trade is carried on in these and in coal, wood and agricultural produce, while hemp and vegetables are largely grown in the environs.

Ratibor, which received municipal privileges in 1217, was formerly the capital of an independent duchy, 380 sq. m. in extent, which existed from 1288 to 1532, and afterwards passed successively into the hands of Austria and Prussia. In 1821 a small mediate principality was formed out of the old lordship of Ratibor and certain ecclesiastical domains, and was conferred upon Victor Amadeus, landgrave of Hesse-Kasselishagen, as compensation for some Hessian territory absorbed by Prussia. The title of duke of Ratibor was revived in 1840 for his heir, Prince Victor of Hohenlohe-Schillingsfürst (1840-1897).

See A. Weltzel, Geschichte der Stadt und Herrschaft Ratibor (2nd ed., Ratibor, 1881).

RATIONALISM (from Lat. rationalis, pertaining to reason, ratio), a term employed both in philosophy and in theology for any system which sets up human reason as the final criterion and chief source of knowledge. Such systems are opposed to all doctrines which rest solely or ultimately upon external authority; the individual must investigate everything for himself and abandon any position the validity of which cannot be rationally demonstrated. The rationalist spirit is, of course, coeval with human evolution; religion itself began with a rational attempt to maintain amicable relations with unknown powers, and each one of the dead religions succumbed before the development of rationalist inquiry into its premises. But the term has acquired more special connotations in modern thought. In its commonest use it is applied to all who decline to accept the authority of the Bible as the infallible record of a divine revelation, and is practically synonymous with freethinking. This type of rationalism is based largely upon the results of modern historical and archaeological investigation. The story of the creation in the book of Genesis, for example, from the point of view of chronology, to be a poetic or symbolic account by the discovery of civilizations of much greater antiquity. Again, the study of comparative religion (e.g., the study of the Deluge (q.v.), showing as it does that similar stories are to be found in primitive literature, both oriental and other) has placed the Bible in close relation with other ancient literature. The Bible, especially the Old Testament, is thus regarded even by orthodox Christians from a rationalist standpoint,
very different from that of the early and medieval Church. Rationalism within the Christian Church differs, however, from that which is commonly understood by the term, inasmuch as it accepts as revealed the fundamental facts of its creed. Thoroughgoing rationalism, on the other hand, either categorically denies that the supernatural or the infinite—whether it exist or not—can be the object of human knowledge (see AGNOSTICISM), or else, in the mouth of a single person, states that he at least has no such knowledge. In addition to the difficulties presented by the Bible as a historical record, and the literary problems which textual and other critics have investigated, the modern freethinker denies that the Christianity of the New Testament or its interpretation by modern theologians affords a coherent theory of human life and duty. Apart from the general use of the term for a particular attitude towards religion, two more technical uses require notice: (i) the purely philosophical, (ii) the theological.

(i) Philosophical rationalism is that theory of knowledge which maintains that reason is in and by itself a source of knowledge, and that knowledge so derived has superior authority over knowledge acquired through sensation. This view holds that rationalist knowledge, properly so-called, is derived from a tabula rasa (blank tablet) in which the outside world as it were imprints itself through the senses. The opposition between rationalism and sensationalism is, however, rarely so simple and direct, inasmuch as many thinkers (e.g., Locke) have admitted both sensation and reflection. Such philosophies are called rationalist or sensationalist according as they lay emphasis specially on the function of reason or that of the senses. More generally, philosophic rationalism is opposed to empirical theories of knowledge, inasmuch as it regards all true knowledge as deriving deductively from fundamental elementary concepts. This attitude may be studied in Descartes, Leibnitz and Wolff. It is based on Descartes' fundamental principle that knowledge must be clear, and seeks to give to philosophy the certainty and demonstrative character of mathematics, from the a priori principle of which all its claims are derived. The attack made by David Hume on the causal relation led directly to the new rationalism of Kant, who argued that it was wrong to regard thought as mere analysis. A priori concepts there are, but if they are to lead to the amplification of knowledge, they must be brought into relation with empirical data.

(ii) The term "rationalism" in the narrow theological sense is specially used of the doctrines held by a school of German theologians and Biblical scholars which was prominent roughly between 1740 and 1836. This rationalism within the Church was a theological manifestation of the intellectual movement known as the Enlightenment (Aufklärung), and must be studied in close connexion with the purely philosophical rationalism already discussed. It owed much to the English deists, to the Pietistic movement, and to the French esprits forts who had already made a vigorous attack on the supernatural origin of the Scriptures. The crux of the difficulty was the doctrine of the supernatural, the relation between revealed and natural religion. The first great rationalist leader was J. S. Semler (n.s.), who held that true religion springs from the individual soul, and attacked the authority of the Bible in a comprehensive spirit of criticism. He ultimately reached a point at which the Bible became for him simply one of many ancient documents. At the same time he did not impugn the authority of the Church, which he regarded as useful in maintaining external unity. Among those who followed in Semler’s path were Gruner Ernstie, J. D. Michaelis, Griesbach, J. G. Eichhorn. This spirit was exhibited on the philosophical side by Kant who in his Die Religion innerhalb der Grenzen der bloßen Vernunft (1793) set forth his doctrine of rational morality (Vernunftglauben) as the only true religion. These two great rationalist movements, the critical and the philosophical, ultimately led to, or were accompanied by, the gradual reduction of religion to a system of morals based at the most on two or three fundamental religious principles. This is the rationalism known as rationalismus vulgaris, the period of which is practically from 1800 to 1833. Among its exponents were Wegscheider, Bretschneider and H. E. G. Paulus (q.v.). The general attitude of German theology, however, became gradually more and more hostile, and the works of Schleiermacher, though in a sense themselves rationalist, renewed the general desire for a positive Christianity. Hase’s Halterus Redivivus, an exposition of orthodoxy in the light of modern development, called forth a final exposition of the rationalist position by Rüth. From that time the school, as such continued to have a real existence, though the results of its work are traceable more or less in all modern Biblical criticism, and its influence upon the attitude of modern theologians and Biblical critics can scarcely be overestimated.

See Ständlin, Geschichte des Rationalismus (Göttingen, 1826); Hase, Theologische Streiflichter in Gesammelte Werke, viii. (1895); Rückert, Der Rationalismus (1859); Thuluck, Vorgeschichte des Rel. (1855-1861) and Geschichte des Rel. (1869); Ritschl, Christ. Lehre von der Rechtfertigung, &c. (1870), vol. i.; Benn, History of Rationalism (1906). See also histories of philosophy and theology in the 19th century, and the valuable article s.v. by O. Kirn in Herzog-Hauck, Realencyk. xvi. (1905).

RATISBONNE, LOUIS GUSTAVE FORTUNE (1827-1900), French man of letters, was born at Strassburg on the 20th of July 1827. He studied at the school of his native town and at the Collège Henry IV. in Paris. He was connected with the Journal des Débats from 1853 to 1876; became librarian of the palace of Fontainebleau in 1871, and three years later to the Senate. Louis Ratitbone’s most important work was a verse translation of the Divina Commedia, in which the original is rendered tercet by tercet into French. L’Enfer (1852) was crowned by the Academy; Le Purgatoire (1857) and Le Paradis (1859) received the prix Bardin. He is also the author of some charming fables and verses for children: La Comédie enfantine (1860), Les Figures jeunes (1862) and others. He was literary executor of Alfred de Vigny, whose Destinées (1864) and Journal d’un poète (1867) he published. Ratitbone died in Paris on the 24th of September 1900.

RATITAE (from Lat. ratis, a raft), the name given by B. Merrem (Abb. Ak. Wiss., Berlin, 1812-1813; Phys. Kl., p. 259) to the "flat-breasted birds," in opposition to the Carinatae, or those which normally possess a keeled sternum. In thus dividing the birds into two great equivalent groups, he was followed only by C. L. Nitzsch (1830), T. H. Huxley (1867), P. L. Schater (1880), A. Newton (1884), R. B. Sharpe (1891), whilst in most of the groups he used the number of sternal modifications the Ratitae (vicariously named Struthiomes, Curvestones, Brevipennes, Proceres) were treated as of much lower rank.

A diagnosis covering all the Ratitae (struthio, rhea, cassuarius, dromoes, apteryx and the allied fossils dinornis and acteyonis) would be as follows—(i) terrestrial birds without keel to the sternum, absolutely flightless; (ii) quadrate bone with a single proximal articulating knob; (iii) coarctoid and scaphoid fused together and forming an open angle; (iv) normally without a pygostyle; (v) with an incisura ischiadica; (vi) rhamphotheca compound; (vii) without apertura or bare spaces in the plumage; (viii) with a complete copulatory organ, moved by skeletal muscles.

The separation of the Ratitae from the other birds, and their seemingly fundamental differences, notably the absence of the keel and of the power of flight, induced certain authors to go so far as to derive the Ratitae from the Dinosaurian reptiles, whilst Archaeopteryx (q.v.) and the Carinatae were supposed to have sprung from some Pterosaurian or similar reptilian stock. Such vagaries require no refutation. But it is quite another question, whether the "Ratitae" form a natural group. Sir R. Owen was the first (Comp. Anat. and Physiol. of Vertebrates, ii, 1866) to indicate that the various Ratitae might be referable to different natural subdivisions, the Carinatae. A. W. Forbes likewise had doubts about them. B. Lindsay (P. Z. S., 1885, pp. 684-716, pls. lii-liv) found vestiges of a keel in a young rhea, and apteria in the embryonic ostrich, and she concluded that they were descendants of birds which originally possessed
the power of flight. This has been settled by M. Fürbringer (Untersuchungen . . . 1888), and there is now no doubt that the absence of the power of flight is a secondary, not primitive, feature in the Ratitae as well as in the flightless bona fide Carinatae, e.g. Didus, and penguins. It had already been understood that the various genera of the Ratitae were the representatives of so many different groups, each of which was at least equivalent to ordinal rank, and that therefore, if the Ratitae were still to be considered a natural group, this common ancestry must be referred to a remote geological epoch. Fürbringer, however, separated Apterius with Dinosornis from the rest, combining his "Apteries" with CRYPTURI and Galli as Alectorornithes, the latter being practically A. H. Garrod's Galliformes, of which his "Struthiones" form part together with the Tinamidae or Crypturi. Relationship of this otherwise typically carinate, neotropical family with the Ratitae had already been insisted upon by T. H. Huxley; hence his term Dromaeognathae for the Crypturi. L. Stejneger (Standard Nat. Hist., iv., Boston, 1889) applied this term in a new wider sense to all the Ratitae, and recently W. P. Ycraeft has revived this notion by his division of the Neognathae into a primitive and a secondary group. At present we begin to see that some of the Ratitae, namely the Rheidae, may possibly be as early and then much modified offshoot of such of the Carinatae as are now represented by the Crypturi, whilst in another part of the world, and at a much later time, kiwis and moas have sprung from a somewhat more Galliform stock, which points to a descent from a still undivided Galliform-Tinamiform mass. Further, it is the opinion of competent ornithologists that there is affinity of the Australian emeus and cassowaries with the New Zealand moas and with the Malagasy Aepyornis. Struthio alone still stands aloof, possibly because it is the oldest and most specialized form. This genus was already typically developed in late Mioocene times and with a very wide geographical distribution (see BIRD, Fossil), but of the affinities of the other mid- and early tertiary flightless birds we know nothing, and it must be emphasized that we should probably not be able to classify a truly ancestral Ratite, namely, a bird which is still to a certain extent carinate and not yet ratite. It is impossible to give a satisfactory diagnosis of such intermediate forms.

All the recent Ratitae still possess a considerable number of rather primitive characters, e.g. they are typically nidifugous; the simple structure of their neossoptiles; quintocubital compound; sternal bone; holopneustic; pterygoid processes; simple articular facet of the quadrates; configuration of the palatal bones, including the large vomers; incisura ischiadica; simple hypotarsus; the thighs muscles; the copulatory organ.

We restrict the origin of the Ratitae to that great branch of still primitive Carinatae which, after separation of the Ratitae, has further developed into the region of the Alectorornorphae, notably Thami- and Galliformes, together with still low Gruiformes (see BIRD, Classification). From such a rudis indigens-taque males, after it had attained an almost world-wide distribution, the various Ratitae, independently in various epochs and in various countries. Most of them are now restricted to widely separated countries of the southern hemisphere. Although loss of flight (correlated with more or less reduction of the wings and the sternal keel, and often compensated by stronger hind limbs) has occurred, and is still taking place in various groups of birds, it is quite impossible that a new Ratite can still come into existence, because the necessary primitive substratum, whence arose the true Ratitae, is no longer available. Consequently we are justified in retaining "Ratitae" in our classification, although they are a heterogenous, no strictly monophyletic, assembly. Dinosornis (H. F. G.)

RATKE (RATCHUS), WOLFGANG (1571-1635). German educationist, was born at Wiltser, Holstein, on the 18th of October 1571, and educated at the university of Rostock. His system of education was based upon Bacon's philosophy, the principle being that of "proceeding from things to names," from the particular to the general, and from the mother tongue to foreign languages. In 1618 he opened schools at Augsburg and elsewhere, but at Köthen difficulties with the clergy led to his imprisonment for eight months, and after starting another school at Magdeburg in 1620 which failed, he became a wanderer and died at Erfurt on the 27th of April 1635. His ideas were far in advance of his time, but he lacked executive ability.

RATLAM (or RUTLAM), a native state of central India, in the Malwa agency. Area, 902 sq. m. its territory is closely interlaced with that of Sillana. It is held as tributary to Sindh; but in 1819 an arrangement was made by which Sindhia engaged never to send any troops into the country or to interfere with the internal administration, and in 1861 the tribute was assigned to the British government in part payment of the Gwalior contingent. The population in 1901 was 83,773, showing a decrease of 6% in the decade; estimated revenue, £34,000; tribute, £2850. The chief, whose title is raja, is a Rahtor Rajput of the Jodhpur family. The chief Sujan Singh succeeded in 1893, and attained full powers in 1898. The town of Ratlam is 1,577 ft. above sea-level. Pop. (1901) 36,321. It is a junction on the Rajputana-Malwa railway, and an important centre of commerce.

RATNAGIRI, a town and district of British India, in the southern division of Bombay. The town is on the sea-coast, 136 m. S. of Bombay. Pop. (1901) 16,094. A leading industry is the sardine fishery, which usually takes place in January and February, and engages fleets of canoes.

The District of Ratnagiri has an area of 3098 sq. m. It forms a strip between the western Ghats and the sea, and its general character is rugged; nearly all the fertile land lies on the banks of the streams which intersect the country. The coast, about 150 m. in length, is almost uniformly rocky and dangerous. At intervals of about 10 m. a river or bay opens, sufficiently large to form a sheltered harbour for native craft, and the promontories at the river mouths are almost invariably crowned with the ruins of an old fort. The rivers and creeks are generally navigable for about 20 m., and afford facilities for a coasting trade. At the beginning of British rule there were no roads, and traffic was confined to places where there was water carriage; but a network of roads has been made, opening communication by hill passes with the Deccan. Ratnagiri formed part of the dominions of the peshwa, and was annexed by the British government in 1818 on the overthrow of Baji Rao. In 1850 the population was 1,167,927, showing an increase of 6% in 10 years. Ratnagiri is the seat of the influential chief of Chitpavan Brahmins. It also supplies factory hands to Bombay and serepoys to the native army.

RATNAPURA (i.e. "The City of Gems"), the chief town in the province of Sabaragamuwa, Ceylon. It is the centre of a long established industry in digging for precious stones—rubies, sapphires, cat’s-eyes, &c. There is also much rice and fruit cultivation and planting of tea in the district. Pop. of town (1901) 4084; of district 132,864.

RATON, a city and the county seat of Colfax county, New Mexico, U.S.A., in the N.E. part of the state, and about 100 m. S. of Santa Fe, especially in winter. Population (1920) 3,375 (337 foreign-born); (1910 census) 4530. Raton is served by the Atchison, Topeka & Santa Fé, the Saint Louis, Rocky Mountain & Pacific, and the Santa Fé, Raton & Eastern railways. The city lies immediately W. of the Raton Mountains, from which it derives its name, and has an elevation of 6400-6650 ft. above the sea. Among its institutions are a miners’ hospital, maintained by the state, and a picturesque public park. The city lies within the Raton coal field, a southern continuation of the field of the same name in Colorado, and the richest coal-producing area in New Mexico. In 1907 70% of the total coal product of New Mexico came from Colfax county, in which this field is situated. Ores of gold, silver and lead have been mined in Colfax county. South and east of the city there is good farming land. Raton is a place of railway origin, and owes its development to its extensive railway shops, as well as to the proximity of mines. It was incorporated in 1891.
RATTLESNAKE. Rattlesnakes are a small group of the sub-family of pit-vipers (Crotalinae, see Snakes; Viperidae), characterised by a tail which terminates in a chain of horny, loosely connected rings, the so-called "rattle." The "pit" by which the family is distinguished from the ordinary vipers is a deep depression in the integument of the sides of the snout, between the nostrils and the eye; its physiological function is unknown. The rattle is a complicated and highly specialized organ, developed from the simple conical scale or epidermal spine, which in the majority of snakes forms the termination of the general integument of the tail. The bone by which the root of the rattle is supported consists of the last caudal vertebrae, from three to eight in number, which are enlarged, dilated, compressed and coalesced (fig. 1, c). This bone is covered

with thick and vascular cutis, transversely divided by two constrictions into three portions, of which the proximal is larger than the median, and the median much larger than the distal. This cuticular portion constitutes the matrix of a horny epidermoid covering which closely fits the shape of the underlying soft part and is the beginning of the rattle, as it appears in young rattlesnakes before they have shed their skin for the first time. When the period of a renewal of the skin approaches a new covering of the extremity of the tail is formed below the old one, but the latter, instead of being cast off with the remainder of the epidermis, is retained by the posterior swelling of the end of the tail, forming now the very loose joint of the rattle. This process is repeated on succeeding moltings—the new joints being always larger than the old ones as long as the snake grows. Perfect rattles therefore taper towards the point, but generally the oldest (terminal) joints wear away in time and are lost. As rattlesnakes shed their skins more than once every year, the number of joints of the rattle does not indicate the age of the animal but the number of exuviations which it has undergone. The largest rattle in the British Museum has twenty-one joints. The rattle consists thus of a variable number of dry, hard, horny cup-shaped joints, each of which loosely grazes a portion of the preceding, and all of which are capable of being shaken against each other. If the interspaces between the joints are filled with water, as often happens in wet weather, no noise can be produced. The motor power lies in the lateral muscles of the tail, by which a vibratory motion is communicated to the rattle, the noise produced being similar to that of a child's rattle and perceptible at a distance of from 10 to 20 yds.

The habit of agitating the tail is not peculiar to the rattlesnake, but has been observed in other venomous and innocuous snakes with the ordinary tail, under the influence of fear or anger. It is significant that the tip of such snakes is sometimes rather conspicuously coloured and covered with peculiarly modified

See Madame Rattazzi, Rattazzi et son temps (Paris, 1881); Bolton King, History of Italian Unity (London, 1899).
scales, notably in *Acauthophis*. The use of such a tail probably consists in attracting or fixing the attention of small animals, by slightly raising and vibrating the tip. The rattle no doubt acts as a warning, every snake preferring being left alone to being forced to bite. Many a man has been warned in time by the shrill sound, and this principle applies undoubtedly to other species as well.

The second group forms the genus *Crotalus*, in which the shields between and behind the eyes are broken up and replaced by small scales. This genus ranges throughout the United States through Central and South America into Patagonia, but is not represented on any of the West Indian Islands. *C. horridus*, with the tail uniformly black, from Maine to Kansas and Louisiana to Florida. *C. adamanteus*, tail light, with black crossbands, body with a handle-like pattern of rhomboid shapes on the back; *C. oreganus*, with a part of the upper jaw representing the "sidewinder" of Arizona and California to Nevada. *C. terrificus*, easily distinguished by the possession of three pairs of symmetrical shields on the top of the muzzle, ranging from Arizona into Argentina. It is the only kind of rattlesnake in Central and South America. *C. triseriatus*, a small species, with a feebly developed rattle, on Mexican mountains, on the pic of Otrizaba up to 12,500 ft. (St. G. M.; H. F. G.)

**RAU, KARL HEINRICH** (1792-1879), German political economist, was born at Erlangen on the 29th of November 1792. He studied from 1808 to 1812 at the university there, where he afterwards remained as a Privatdozent. In 1814 he obtained the prize offered by the academy of Göttingen for the best essay on the subject of the question how the disadvantages arising from the abolition of trade guilds might be removed. His memoir, greatly enlarged, was published in 1816 under the title *Über das Zunftwesen und die Folgen seiner Aufhebung.* In the same year appeared his *Prima inusae historiae politices.* In 1818 he became professor at Erlangen. In 1822 he was called to the chair of political economy at Heidelberg where the rest of his life was spent, in the main, in teaching and research. He took some part, however, in public affairs: in 1837 he was nominated a member of the first chamber of the duchy of Baden, and in 1851 he was one of the commissioners sent to London to make the part of the Zollverein to study the Industrial Exhibition. A result of this mission was his account of the agricultural implements exhibited at London (*Die landwirtschaftlichen Geräthe der Londoner Ausstellung*, 1853). He was elected a corresponding member of the French Institute in 1856. He died at Heidelberg on the 18th of March 1870.

His principal work is the *Lehrbuch der politischen Ökonomie* (1826-37), an encyclopaedia of the economic knowledge of his time, written with a special view to the guidance of practical men. The three volumes are respectively occupied with (1) political economy, properly so called, or the theory of wealth, (2) administrative economy (Gewerbliche), and (3) finance. The two last he recognizes as admitting of variations in accordance with the special circumstances of different countries, whilst the first is more akin to the exact sciences, and is in many respects capable of being treated, or at least illustrated, mathematically. This threefold division marks his close relation to the older German cameralistic writers, with whose works he was familiarly acquainted. It is a consequence in part of his conformity to their method and his attention to administrative applications that his treatise was found peculiarly adapted for the use of the official class, and long maintained its position as their special text-book. He was the economic teacher, says Roscher, of the well-governed middle states of Germany from 1815 to 1848. The book has passed through many editions; in that of 1870 by Adolf Wagner it was transformed into a new book.

In the earlier part of his scientific life Rau tended strongly towards the relative point of view and an historical method in economics, but he never actually joined the historical school. To the end he occupied a somewhat indeterminate position with respect to that school; on the whole, however, he never more and more subordinated historical investigation to immediate practical interests, and in his economic politics moved in the direction of limiting rather than extending the sphere of state action. His general merits are thoroughness of treatment, accuracy of statement, and balance of judgment; he shows much industry in the

---

**Fig. 2.—Rattlesnake (Crotalus adamanteus durissus).**

mammals. Moreover, rattlesnakes are rather sluggish, and comparatively not vicious. First they try to slink away; when overtaken or cornered they use every means of frightening the foe by swelling up, puffing, rattling and threatening attitudes; it is as a rule not until they are touched, or provoked by a rapid movement, that they retaliate, but then they strike with fury. They are viviparous, and as destroyers of rats, mice and other small rodents they are useful. The surest way of clearing a ground of them and any other snakes is to drive in pigs, which are sure to find and to eat them, without harm to themselves. They inhabit localities to which the sun has free access, prairies, rough stony ground, &c. Specimens of 5 ft. in length are not rare. Formerly common in the eastern parts of the United States, and still so in thinly inhabited districts, rattlesnakes, like the vipers of Europe, have gradually succumbed to the persecution of man.

Rattlesnakes are confined to the New World. North-American authors distinguish a great number of different kinds. S. W. Garman (*"Reptiles and Batrachians of North America," Harvard Mus. Zool. Mem., 1883, 4to*) enumerating twelve species and thirteen additional varieties. E. D. Cope has split them into twenty; but all these species or varieties fall into two groups. One, *Sistrurus*, has the upper side of the head covered with the ordinary nine shields; only three species, of comparatively small size, in North America (Sistrurus miliarius from Florida to Sonora; S. caletinus in many of the middle states of the Union, and elsewhere, as far north as Michigan; S. rarus in Mexico).

**RAU,** KARL HEINRICH (1792-1879), German political economist, was born at Erlangen on the 29th of November 1792. He studied from 1808 to 1812 at the university there, where he afterwards remained as a Privatdozent. In 1814 he obtained the prize offered by the academy of Göttingen for the best essay on the subject of the question how the disadvantages arising from the abolition of trade guilds might be removed. His memoir, greatly enlarged, was published in 1816 under the title *Über das Zunftwesen und die Folgen seiner Aufhebung.* In the same year appeared his *Prima inusae historiae politices.* In 1818 he became professor at Erlangen. In 1822 he was called to the chair of political economy at Heidelberg where the rest of his life was spent, in the main, in teaching and research. He took some part, however, in public affairs: in 1837 he was nominated a member of the first chamber of the duchy of Baden, and in 1851 he was one of the commissioners sent to London to make the part of the Zollverein to study the Industrial Exhibition. A result of this mission was his account of the agricultural implements exhibited at London (*Die landwirtschaftlichen Geräthe der Londoner Ausstellung*, 1853). He was elected a corresponding member of the French Institute in 1856. He died at Heidelberg on the 18th of March 1870.

His principal work is the *Lehrbuch der politischen Ökonomie* (1826-37), an encyclopaedia of the economic knowledge of his time, written with a special view to the guidance of practical men. The three volumes are respectively occupied with (1) political economy, properly so called, or the theory of wealth, (2) administrative economy (Gewerbliche), and (3) finance. The two last he recognizes as admitting of variations in accordance with the special circumstances of different countries, whilst the first is more akin to the exact sciences, and is in many respects capable of being treated, or at least illustrated, mathematically. This threefold division marks his close relation to the older German cameralistic writers, with whose works he was familiarly acquainted. It is a consequence in part of his conformity to their method and his attention to administrative applications that his treatise was found peculiarly adapted for the use of the official class, and long maintained its position as their special text-book. He was the economic teacher, says Roscher, of the well-governed middle states of Germany from 1815 to 1848. The book has passed through many editions; in that of 1870 by Adolf Wagner it was transformed into a new book.

In the earlier part of his scientific life Rau tended strongly towards the relative point of view and an historical method in economics, but he never actually joined the historical school. To the end he occupied a somewhat indeterminate position with respect to that school; on the whole, however, he more and more subordinated historical investigation to immediate practical interests, and in his economic politics moved in the direction of limiting rather than extending the sphere of state action. His general merits are thoroughness of treatment, accuracy of statement, and balance of judgment; he shows much industry in the
collection and skill in the utilization of statistical facts; and his exposition is orderly and clear.

Besides the publications already mentioned, he was author of the following—"Entdeckung der Volksrepublik," 1821; "Mathilbe und Sassy über die Ursachen der jetzigen Handelstockung," 1821; "Grundriss der Kameralehre," 1823; "Über die Kameralehren," 1823; and "Die Landwirtschaft der Rheinpfalz," 1830; and "Geschichte des Pflegs," 1845.

Rau founded in 1834 the Archiv der politischen Ökonome und Politieivisenschaften, in which he wrote a number of articles, afterwards issued in separate form; amongst them may be named those on the debt of Baden, on the accession of Baden to the Zollverein, on the crisis of the Zollverein in the summer of 1852, on the American banks, on the English poor law; on List's national system of political economy and on the minimum size of a peasant property.

RAUCH, CHRISTIAN DANIEL (1777–1857), German sculptor, was born at Arolsen in the principality of Waldeck on the 2nd of January 1777. His parents were poor and unable to place him under efficient masters. His first instructor taught him little else than the art of sculpturing grave-stones, and Professor Ruhl of Cassel could not give him much more. A wider field of improvement opened up before him when he removed to Berlin in 1797; but he was obliged to earn a livelihood by becoming a royal hackey, and to practise his art in spare hours. Queen Louisa, surprising him one day in the act of modelling her features in wax, sent him to study at the Academy of Art; and the court of Saxony, in the means of completing his education at Rome, where William von Humboldt, Canova and Thorwaldsen befriended him. Among other works, he executed bas-reliefs of "Hippolytus and Phaedra," "Mars and Venus wounded by Diomedes," and a "Child praying." In 1811 Rauch was commissioned to execute a monument for Queen Louisa of Prussia. The statue, representing the queen in a sleeping posture, was placed in a mausoleum in the grounds of Charlottenburg, and procured great fame for the artist. The erection of nearly all public statues came to be entrusted to him. There were, amongst others, Böhm and Schardohr at Berlin, Bücher at Breslau, Maximilian at Munich, Francke at Halle, Dürer at Nuremberg, Luther at Wittenberg, and the grand-duke Paul Frederick at Schwerin. At length, in 1830, he began, along with Schinkel the architect, the models for a colossal equestrian monument at Berlin to Frederick the Great. This work was inaugurated with great pomp in May 1831, and is regarded as one of the masterpieces of modern sculpture. Princesses decorated Rauch with honours and the academies of Europe enrolled him among their members. A statue of Kant for Königsberg and a statue of Thaer for Berlin occupied his attention during some of his last years; and he had just finished a model of "Moses praying before the Brazen Serpent" when he was attacked by his last illness. He died on the 3rd of December 1837.

RAUCOURT, Mlle (1756-1813), French actress, whose real name was Françoise Marie Antoinette Saurcotte, was born in Nancy on the 3rd of March 1756, the daughter of an actor, who took her to Spain, where she played in tragedy at the age of twelve. By 1770 she was back in France at Rouen, and her success as Euphémie in Bellot's Gaston et Bayard caused her to be called to the Comédie Française, where in 1772 she made her débuts as Dido. She played all the classical tragedy parts to crowded houses, until the scandals of her private life and her extravagance ended her popularity: In 1776 she suddenly disappeared. Part of the ensuing three years she was in prison for debt, but some of the time she spent in the capitals of northern Europe, followed everywhere by scandal. Under protection of the queen she reappeared at the Théâtre Français in 1779, and renewed her success in Phèdre, as Cleopatra, and all her former rôles. At the outbreak of the Revolution she was imprisoned for six months with other royalist members of the Comédie Française, and she did not reappear upon that stage until the close of 1793, and then only for a short time. She deserted, with a dozen of the best actors in the company, to found a rival colony, but a summons from the Directory brought her back in 1797. Napoleon gave her a pension, and in 1806 she was commissioned to organize and direct a company that was to tour Italy, where specially in Milan, she was enthusiastically received. She returned to Paris a few months before her death on the 13th of January 1815. Her funeral was the occasion of a riot. The clergy of her parish having refused to receive the body, the crowd broke into the church doors, and were only restrained from further violence by the arrival of an almoner sent post-haste by Louis XVIII. She is buried at Père Lachaise.

RAUDNITZ (Czech Roudnice nad Labem), a town of Bohemia, Austria, 44 m. N. of Prague by rail. Pop. (1900) 7968, mostly Czech. It is situated on the Elbe, and its chief attraction lies in the interesting and valuable collections in its château, which was once a palace belonging to the family of the Ransdorpers, the beginning of the 17th century. These include a library with a large number of the earliest specimens of printing and valuable MSS., together with a series of pictures from the time of Charles V. to the Thirty Years' War. In 1530 Cola di Rienzi, "the last of the tribunes," was confined by the emperor Charles IV. in the castle, which occupied the site of the present château, previous to his despatch under arrest to the pope at Avignon. In 1812 Raunitz is mentioned as belonging to the see of Prague. The title of duke of Raudnitz was conferred on the head of the family of Lobkowitz by the emperor Joseph II. in 1781.

RAUMER, FRIEDRICH LUDWIG GEORG VON (1728-1873), German historian, was born at Würzitz in Anhalt on the 14th of May 1781. His father (d. 1822), as Kammendirektor in Anhalt, did excellent service to agriculture. After studying at the Joachimsthal Gymnasium, Berlin, and at the universities of Halle and Göttingen, Raumer began to practise law, and rose in the civil service under Hardenberg, the chancellor. He was made a professor at the university of Breslau in 1811, and in 1819 he became professor of political science and history at Berlin, holding the chair until 1847, and giving occasional lectures until 1853. In 1815 he had carried on historical investigations in Venice, and in the two following years he had travelled in Germany, Switzerland and Italy. In 1848 he was elected a member of the German parliament at Frankfurt, where he associated himself with the right centre, supporting the proposal for a German empire under the supremacy of Prussia; and he was one of the deputation which offered the imperial crown to Frederick William IV. After the breakdown of the German parliament, Raumer returned to Berlin, where he was made a member of the first chamber of the Prussian parliament. He died at Berlin on the 14th of June 1873. Raumer's style is direct, lucid and vigorous, and in his day he was a popular historian, but judged by strictly scientific standards he does not rank among the first men of his time.

His first work, published anonymously in 1806, was entitled Sechs Dialoge über Krieg und Handel. This was followed by Das britische Besteuerungssystem (1810), Handbuch merkwürdiger Stellen aus den lateinischen Geschichtschreibern des Mittelalters (1813), Herbstreise nach England (1816) and other books. His most famous works are Geschicht der Hohenstaufen und ihrer Zeit (1823-25; 5th ed., 1876) and Geschichte Europas seit dem Ende des 15ten Jahrhunderts (1832-50). In 1831 appeared Briefe aus Paris und Frankreich im Jahre 1830 à Paris zur Erläuterung der Geschichte des 17ten Jahrhunderts (1833), and in 1835 he published Geschichte des 15ten Jahrhunderts, in Italy in 1839 and to America in 1843, and these visits led to the publication of various works—Englond in 1835 (1836), Beiträge zur neueren Geschichte aus dem Britischen Museum und Reichsarchiv (1836-39). In 1848, Die Vereinigten Staaten von Nordamerika (1845). Among his later books may be mentioned Antiquarische Briefe (1851). There was a long series of Die britische Geschichte über die gesetzlichen Verhältnisse der Menschen (1860), Lebenserinnerungen und Briefwechsel (1861) and Handbuch zur Geschichte der Literatur (1864-66). In 1850 Raumer began the Historisches Taschenbuch published by Brockhaus, which from 1871 was continued by Richl.

P. LACHAISE.

RAUPACH, ERNST BENJAMIN SALOMO (1784-1852), German dramatist, was born on the 21st of May 1784 at Straupitz, near Liegnitz in Silesia, a son of the village pastor. He attended the gymnasium at Liegnitz, and studied theology at the university of Halle. In 1803 he obtained a tutorship
in St Petersburg. He preached at times in the German Lutheran church, wrote his first tragedies, and in 1817 was appointed professor of German literature and history at a training college in connexion with the university. Owing to an outbreak of jealousy against Germans in Russia, culminating in police supervision, Raupach left St Petersburg in 1822 and undertook a journey to Italy. The literary fruits of his travels were "Hirsemensel's Briefe aus und über Italien" (1823). He next visited Weimar, but, being coldly received by Goethe, abandoned his idea of living there and settled in 1824 in Berlin. Here he spent the remainder of his life, writing for the stage, which for twenty years he greatly influenced, if not wholly created, in the Russian capital. He died at Berlin on the 18th of March 1852.

Raupach was a prolific writer of both tragedies and comedies; of the former, Die Fürsten Chavansky (1818), Der Liebe Zauberkreis (1824), Die Leibeigenen, oder Isidor und Olga (1826), Rafaela (1828), Der Nibelungenhört (1834) and Die Schule des Lebens (1841), and of the latter Die Schleichhändler (1828) and Der Zeitgeist (1830) are pieces which have enjoyed great popularity owing to their skillful dramatic handling. On the other hand, the historical dramas with which his name is chiefly associated, Die Hohenstaufen (1837–38), a cyclos of 19 dramatic pieces founded on Friedrich von Raumer's Geschichte der Hohenstaufen, as also the trilogy Cronsweld (1841–44), are superficial in treatment. Raupach had a great knowledge of theatrical effect and situations, but he contrives historical facts in order to suit his political hobby, which was the separation of church and state.

Raupach's collected dramas appeared under the title Dramatische Werke erster Gattung (16 vols., 1830–43) and Dramatische Werke komischer Gattung (13 vols., 1835–45). For his life and works Raupach, Raupach, eine biographische Skizze (1853); also K. Goedeke, Grundriss zur Geschichte der deutschen Dichtung, 2nd ed. (1903), vol. viii., pp. 646–668.

RAVAILLAN, FRANÇOIS (1578–1610), the assassin of Henry IV. of France, was born near Angoulême. He was of humble origin and began life as a valet de chambre, but afterwards became a lawyer and also teacher of a school. After having been imprisoned by his creditors, he sought admission to the recently founded order of Feuillants, but after a short probation was dismissed as a visionary. An application for admission to the Society of Jesus was equally unsuccessful in 1606. His disappointments fostered a fanatical temperament, and rumours that the king was intending to make war upon the pope suggested to him the idea of assassination, which he carried out on the 14th of May 1610. In the course of his trial he was frequently put to the torture, but persistently (and it is now believed truly) denied that he had been prompted by any one or had any accomplices. Sentence of death was carried out on the 27th of May following.

See Jules Lioleleur, Ravaillass et ses complices (1873), and E. Lavisse, Histoire de France, tome vi. (Paris, 1905).

RAVAIN-MOLLIN, JEAN GASPARD FÉLIX (1813–1900), French philosopher and archaeologist, was born at Namur on the 23d of October 1813. After a successful course of study at the Collège Rollin, he proceeded to Munich, where he attended the lectures of Schelling, and took his degree in philosophy in 1836. In the following year he published the first volume of his famous work "Essai sur la métaphysique d'Aristote," to which in 1846 he added a supplementary volume. This work not only criticizes and comments on the theories of Aristotle and the Peripatetics, but also deduces from them a modern philosophical system. In 1838 he received the degree of doctor, and became professor of philosophy at Rennes. From 1840 he was inspector-general of public libraries, and in 1860 became inspector-general in the department of higher education. He was also a member of the Academy of Moral and Political Science, and curator of the Department of Antiquities at the Louvre (from 1870). He died in Paris on the 18th of May 1900. In philosophy, he was one of the school of Cousin, with whom, however, he was at issue in many important points. The act of consciousness, according to him, is the basis of all knowledge. These acts of consciousness are manifestations of will, which is the motive and creative power of the intellectual life. The idea of God is a cumulative intuition given by all the various faculties of the mind, in its observation of harmony in nature and in man. This theory had considerable influence on speculative philosophy in France during the later years of the 19th century.

Ravaisson's chief philosophical works are: "Les Fragments philosophiques de Hamilton" (in the Revue des Deux Mondes, February, 1840); Rapport sur le stoïcisme (1851); La Philosophie en France au sixième siècle (1856; 3rd ed., 1889); Morale et métaphysique (1863). Eminent as a philosopher, Ravaisson was also an archaeologist, and contributed articles on ancient sculpture to the "Archives de l'Académie" and the Mémories de l'Académie des Inscriptions. In 1871 he published a monograph on the Venus of Milo.

See Renouvier, in L'Année philosophique (Paris, 1868); Dauriac, "Ravaisson philosophe et critique" (La Critique philosophique, 1885, vol. ii.).

RAVANASTRON, an Indian stringed instrument played with a bow, used by wandering pilgrims. A Hindu tradition affirms that the musical bow was invented before 3000 B.C. by Ravanon, king of Ceylon, and that the instrument for which he invented it was named after him Ravanastron.¹ Judging from precedent, it is probable that the ravanastron of the present day has changed little, if at all, for many centuries. It consists of half a round gourd, over which is fixed a sound-board of skin or parchment; to this primitive body without incarnation is attached a neck about twice the length of the body. The strings are either one or four in number, the pegs being set in the sides of the neck. The bridge is primitive and either straight or slightly arched, so that in bowing more than one string sounds at once.

The ravanastron is regarded by some writers as the first ancestor of the violin, on account of the alleged invention of the bow for use with this theory. Others assert that the bow, which after all was common to such inferior instruments as the rebec, as of paramount importance, and the structural features of the instrument itself, the box sound-chest with ribs, which have always belonged to the most artistic types of instruments, such as the cithara and the guitar-fiddle, as of secondary importance.

(K. S.)

RAVELLO, a village of Campania, Italy, in the province of Salerno, about 3 m. N.E. of Amalfi by road, 1227 ft. above sea-level. It commands a magnificent view. Pop. (1901) 187. The history of Ravello cannot be traced beyond the 10th century. In the 11th it was called Rebello, because it refused to acknowledge the sovereignty of Amalfi, and in the 13th, when at the height of its prosperity, it had 36,000 inhabitants. The Palazzo Rufolo, begun in the 11th century, has two lofty towers and beautiful Saracenic decoration in the courtyard. The ex-cathedral of C. Panteleo, almost entirely modernized, has fine bronze doors by Barisano of Trani (1179), and two pulpits in Cosmatesque work. The larger, supported by six columns resting on the backs of lions, was made in 1272 by Niccolus di Foggia; the bust over the entrance to it is said to be a portrait of Sigisulleta Rufolo. The smaller, of the same date, is simpler, and has curious repre-

RAVEN (O.E. hræfna, Icel. hræfn, Dan. ravn, Du. rauw, Ger. Rabe), the largest of the birds of the order Passeres, and a member of the family Corvidae; probably the most highly developed of all birds. Quick-sighted, sagacious and bold, the raven preys on the spoils of fishers and hunters, as also on weakly

¹ An illustration appears in Sonnerat's Voyages aux Indes orientales (Paris, 1806), vol. i. p. 182.
animals among flocks and herds. A sentiment of veneration or superstition has from remote ages and among many races attached to it. The raven is associated with various characters of history, sacred or profane—Noah and Elijah, Odin and Flekk, the ladle of whom by its means discovered Iceland. It is said to have played its part in the mythology of the Red Indian; and it has often figured in prose and verse, from the time of Shakespeare to that of Poe and Dickens. Superstition has been generally succeeded by persecution, which in many districts has produced extirpation.

The raven breeds very early in the year, in England resorting to its nest, which is usually an ancient if not an ancestral structure, about the middle or towards the end of January. Therein are laid from five to seven eggs of the common Corvine coloration (see Crown), and the young are hatched before the end of February. In more northern countries the breeding season is naturally delayed, but everywhere this species is almost, if not quite, the earliest breeder. The raven measures about 26 in. in length, and has an expanse of wing considerably exceeding a yard. Its bill and feet are black, and the same may be said of its whole plumage, but the feathers of the upper parts as well as of the breast are glossy, reflecting a bright purple or steel-blue. The species (Corvus corax) inhabits the whole of Europe, and the northern if not the central parts of Asia; but in the latter continent its southern range is not well determined. In America it is, or used to be, found from the shores of the Pacific Sea to Guatemala, but is said hardly to be found of late years in the eastern part of the United States. In Africa its place is taken by three allied but well-differentiated species, two of which (Corvus umbinus, readily distinguished by its brown neck, and C. affinis, having its superior nasal bristles upturned vertically) also occur in south-western Asia, while the third (C. leptonyx or C. lingulans, a smaller species characterized by several slight differences) inhabits Barbary and the Atlantic Islands. Farther to the southward in the Ethiopian region three more species appear whose plumage is varied with white—C. scapulatus, C. albicolis, and C. coromandus—the first two of small size, but the last rivalling the real raven in that respect.

RAVEN-HILL, LEONARD (1867— ), English artist and illustrator, was born on the 10th of March 1867. He was educated at Bristol grammar school and the Devon county school, and studied art at Lambeth and then in Paris under MM. Bougereau and Aimé Morot. He began to exhibit at the Salon in 1887, and in the Royal Academy in 1889. In 1893 he founded, with Arnold Golsworthy, the humorous and artistic monthly The Butterfly (1893-94, revived in 1899-1900). He contributed to many illustrated magazines, and began to work for Punch, for which he was afterwards permanently associated, in 1896. He illustrated Sir Walter Besant’s East London (1901) and J. H. Harris’s Cornish Saints and Sinners; he published the impressions of his visit to India on the occasion of the tour of the prince and princess of Wales as An Indian Sketch-Book (1903); and his other published sketch-books include Our Battalion (1902) and The Promenaders (1894).

RAVENNA, a city and archiepiscopal see of Emilia, Italy, capital of the province of Ravenna, standing in a marshy plain 13 ft. above sea-level, 6 m. from the sea and 45 m. by rail east of Bologna. Pop. (1900) 35,543 (town), 67,379 (commune)—a considerable increase, as the population of 1881 was only 34,270 (commune). The industries are few, the growing of wine, breeding of silkworms, making of agricultural instruments, printing and the manufacture of laces being the chief. The town is connected with the sea by the Cornisi Canal, the two small rivers Ronco and Montone no longer serving as means of communication. Ravenna has railway communication with Bologna (via Castel Bolognese), Ferrara and Rimini, and by steam tram with Forli. At the mouth of the canal is a small harbour.

The older city in the world offers so many and such striking examples of the ecclesiastical architecture of the centuries from the 5th to the 9th. The style is commonly called Byzantine; but some of the most striking features of the churches of Ravenna—the colonnades, the mosaics, perhaps the cupolas—are not so much Byzantine as representative of early Christian art generally. The following are the most important churches of Ravenna, arranged in the order of the dates generally attributed to them:

(The churches marked A. were originally erected for the Arian worship.)

Almost the only sacred building previous to the 5th century of which we have any record is unfortunately lost. The cathedral of Ravenna, built by S. Ursus in 370-390, which had a nave and four aisles, was destroyed in 1734-44, only the (inaccessible) crypt and the round campanile remaining from the earlier structure; there are fragments of reliefs from a pulpit erected by Archbishop Agnellus (536-569) in the interior. A rare work on the earlier church (Buonomini, La Metropolitana di Ravenna) gives details of its construction. The present cathedral contains several early Christian marble sarcophagi, a silver cross of the 6th century (that of Agnellus), and the so-called throne of the Archbishop Maximian (546-554), adorned with reliefs in ivory, which, however, was really brought to Ravenna in 1901 by John the Deacon, who recorded the fact in his Venetian chronicle, as a present from the Doge Pietro Orseolo to the Emperor Otho III.

The period from the transference of the imperial residence to Ravenna to the death of Valentinian III. (404-455) was the first period of great building activity in Ravenna, when the archiepiscopal see of Ravenna attained great importance. It was to it that we owe the erection of the Basilica Petriana at Classe (506-525), which has entirely disappeared, of the churches of S. Giovanni Evangelista (425), of S. Agata (425-432), of the chapel of S. Pier Cristologo (433-440), of the tomb of Gallo Placidia (440), the church of S. Pier Maggiore (now S. Francesco) (433-458), the baptistery of Neon (449-458), S. Giovanni Battista and S. Croce.

Riviera, in the book cited below, shows that many of the characteristic architectural details can be traced back to a classical and in particular a Roman origin, and were not derived from the East, e.g. the use of blind arches as an external decoration, and of brick cornices with the points of the bricks projecting like the teeth of a saw, the use of pulvini (cushions) above the capitals of columns and under the spring of an arch, &c. &c., the use of round arches springing direct from these cushions, spherical pendentives, &c.

Of this group of churches, S. Giovanni Evangelista, erected by Gallo Placidia in fulfilment of a vow made on her voyage from Constantinople, has been entirely rebuilt, though the columns are ancient (the Corinthian capitals are probably from a classical building), and the crypt may be original. The Gothic portal is fine, and the church contains a mosaic pavement of 1213 with curious representations and some frescoes by Giotto, painted during a visit to Dante between 1317 and 1320. S. Agata was almost entirely rebuilt in 1476-94. The
RAVENNA

chapel of S. Pier Crisologo in the archiepiscopal palace preserves its original mosaics, and so also does the tomb of Galla Placidia (sister of Theodoric, and wife of Romuald the Nazarene Celso), a small structure in the form of a Latin cross with a dome (in which, as in the baptistery of Neon, the old cathedral, &c., the constructional use of amphorae is noteworthy), with a plain brick exterior, and rich mosaics on a dark blue ground within. The sarcophagus of Galla Placidia has, like the two others that stand here, been despoiled of its contents. The altar, like that at S. Vitale, is made of thin slabs of alabaster, behind which lamps were intended to be placed.

S. Francesco, as it has been called since 1261, when it came into the possession of the Franchescans, has been almost entirely modernized, except for the crypt and campanile (11th century). The baptistery, adjacent to the cathedral was, according to Ricci, originally part of the Roman baths, converted to a Christian baptistery by the Archbishop Neon (440-452), though according to other authorities it is a Christian building dating from before A.D. 396. It is an octagon, with a dome; in the interior are two arcades one above the other. The mosaics of the 5th century, in the dome, are the earliest and perhaps the finest at Ravenna for their splendid decorative effect and rich colouring, and are less stiff and conventional than the later mosaics.

Of S. Giovanni Battista, also erected in this period, hardly anything remains after the restoration of 1683, and S. Croce has been overtaken by a similar fate.

After the death of Valentinian III. the activity in building for which Ravenna had been so remarkable suffered a check; but the reign of Theodoric (493-526) marks another era of magnificence. In the eastern part of the city he built for himself a large palace, which probably occupied about a sixth of the space now enclosed within the city walls, or nearly the whole of the rectangle enclosed by Strada di Porta Alberoni on the south, Strada Nuova di Porta Serrata on the west and the line of the city walls on the north and east. There still remains close to the first-named street and fronting the Corso Garibaldi a high wall built of square Roman bricks, with pillars and arched recesses in the upper portion, which goes by the name of Palazzo di Teodorico. Freeman, on account of the Romanesque character of the architecture, thought it probable that it really belongs to the time of the Lombard kings, and his opinion is shared by Ricci and Rivoira, who consider it to be a house erected by the exarchs, recent explorations having made it clear that it was an addition to the palace, while mosaic pavements and an atrium once surrounded by arcades really belonging to the latter were found in 1870 below S. Apollinare Nuovo and in 1908 behind the so-called Palazzo at a lower level and a different orientation. A mosaic in the church of S. Apollinare Nuovo gives some faint idea of the palace. A more memorable and clearly authentic monument of Theodoric is furnished by his tomb, a massive mausoleum which stands still perfect outside the walls near the north-east corner of the city. It is circular internally and decagonal externally, in two storeys, built of marble blocks, and surmounted by an enormous monolith, brought from the quarries of Istria and weighing more than 300 tons. The plan is no doubt derived from that of a Roman tomb. In this mausoleum Theodoric was buried, but his body was cast forth from it, perhaps during the troublous times of the siege of Ravenna by the imperial troops, and the Rotundas (as it is now generally called) was converted into a church dedicated to the Virgin.

S. Apollinare Nuovo, the most important basilica in the town, was built by Theodoric to be the largest of Arian churches, and originally called S. Martino in Coelo Aureo (a name which it lost in the 9th century). The exterior is uninteresting, and the church lost both atrium and apse in the 16th century. The interior has twenty-four columns of marble (from Constantinople according to some, from Rome according to others), with almost uniform capitals. The walls of the nave are adorned with mosaics of the 6th century; the scenes from the New Testament above the windows date from the time of Theodoric, while the somewhat stiff processions below, of virgins on one side and of saints on the other, are substitutions of the latter half of the 6th or early 7th century. There is some allusion to Arianism or episodes in the life of Theodoric (60 Ricci). The mosaics have been in parts much restored; but the earlier ones still show, like those which preceded them in Ravenna, classical forms, variety of treatment and freedom of colouring, while the processions are monotous and inferior in execution, intended rather to produce a decorative effect than beauty of form. The pulpit appears to be of Byzantine origin (Rivoira). The campanile (890-898) is circular, and has perhaps the earliest example of the use of disks of coloured majolica as a decoration. This, like the other campanili of Ravenna, is later than the church to which it belongs. Those of the cathedral of S. Apollinare in Classe, S. Maria Maggiori and S. Anta, are, in circular, probably belong also to the 9th century, while the two square campanili of S. Giovanni Evangelista and S. Francesco probably belong to the early 11th century. The other churches erected by Theodoric are: S. Teodoro (or S. Spirito), erected by Theodoric for the Arian bishops, but entirely modified: the baptistery of this church (afterwards the oratory of S. Maria in Cosmedin) formed out of the octagonal hall of a Roman bath (?)—unless it is an originally Christian building—with mosaics of the 6th century imitating those of the baptistery of Neon, and freely restored; S. Maria Maggiore, founded by the Archbishop Ecclesius (521-534), not hardily rebuilt; and S. Vittore, which has suffered a similar fate. To the same period probably belong a few columns of the so-called Basilica of Hercules in the Piazza Vittorio Emanuele, with capitals like those of S. Apollinaire in Classe.

The impulse given by Theodoric was continued by his successors, and during the regency of Amalasuntha and the reigns of Theodatus and Vitiges (526-535), S. Vitale and S. Apollinaire in Classe were constructed by Julius Argentarius contemporaneously with S. Lorenzo in Milan and the cathedral of Parenzo—also S. Michele in Africisco, nothing of the original structure of which now exists. The former, well restored by Ricci in 1899-1900 (except for the dome with its baroque fresco which has not been altered), is a regular octagon, with a vestibule, originally flanked by two towers on the west, a choir added on the east, triangular outside and circular within; it is surrounded within by two galleries interrupted at the presbytery, and supported by eight large pillars, the intervals between which are occupied by open exedrae. The mosaics of the choir (547) are due to Justinian, and, though inferior in style, are remarkable for their splendour of colouring and the gorgeous dresses of the persons represented, and also for their historical interest, especially the scenes representing the emporium and the emperor presenting offerings. The mosaics over the arch of the altar are wonderfully finely carved. The marble mosaic pavement (11th century) is very effective. Remains of the original marble wall lining and stucco decoration also exist. The capitals are, in the lower order, the characteristic funnel-shaped rectangular Byzantine capitals, some of them with open work, bearing cushions; this is a type probably derived from the cushion itself, and developed in the East about the second half of the 5th century.

The architecture of S. Vitale (for plan see ARCHITECTURE, sect. Early Christian), according to Rivoira, was inspired not by Byzantium, where similar churches—S. Sofia and SS. Sergio and Bacco—are slightly later in date, but by the churches of Salonica (A.D. 495), while the plan is derived from a Christian baptistery, or from such a building as the so-called temple of Minerva Medica at Rome. S. Apollinare in Classe, erected at the same time outside the walls of Classis, and now standing by itself in the lonely marshes, is the largest basilica existing at Ravenna. It has a nave and aisles with a closed vestibule on the west, and a fine round campanile of the 9th (?) century. The exterior brick walls are divided by shallow arches and pilasters, as in other churches of Ravenna. It has twenty-four columns of Carystian (coppino) marble, with capitals probably of Byzantine work with swelling
acanthus leaves; but the rest of the church is due to native architects. The lofty presbytery and the crypt under it belong to the 12th century. The walls of the interior were stripped of their marble panelling by Sigismondo Malatesta in 1449, for the adornment of his church at Rimini. The apse has mosaics of the 12th and 7th centuries. The 18th-century series of portraits of the archbishops of Ravenna is no doubt copied from an earlier original. There are a number of fine carved sarcophagi in the church (5th to 8th century). The building activity of the Gothic kings was continued by Justinian, to whose time we owe the completion of S. Vitale and S. Apollinare in Classe, and some of the mosaics in S. Apollinare Nuovo.

The buildings of a subsequent period are of minor importance, but the basilica of S. Maria in Porto near the ancient harbour (1096 sq.), a basilica with open roof, with frescoes by masters of the Rimini school, may be noticed. The massive walls and substructures of the campanile are attributed to an old lighthouse. The tomb of Dante, who died at Ravenna in 1321, is close to S. Francesco; it is a square-domed structure, with a relief by Pietro Lombardo (1482) representing the poet, and a sarcophagus below, in an urn within which lie the poet's remains. Close by is a small court with early Christian sarcophagi, containing the remains of the Braccioforte family. The secularized monastery of Classe, in the town, built by the monks of S. Apollinare in Classe in 155 sq., as a refuge from the malaria, which prevailed at Classe itself, with fine 17th-century cloisters, contains the important museum, which has Roman and Byzantine antiquities, inscriptions, sculptures, jewelry, &c.—including the possible remains of a suit of gold armour of Theodoric—and a collection of Italian woodcuts; also the library with rare MSS. and incunabula (among the former the best extant MS. of Aristophanes). The Accademia, close by, has a few pictures by local masters, e.g. N. Rondinelli (end of 15th century), of no great importance, and a fine recumbent statue of Guidarello Guidarelli, a condottiero of Ravenna, and a partisan of Caesar Borgia (d. 1501), by Tullio Lombardo (?) or Severo da Ravenna (?).

In the Piazza Vittorio Emanuele are two granite columns erected by the Venetians, in 1483, with statues of S. Apollinari and Vitaliano. The cloisters of S. Maria di Porto erected in the town in the 16th century (owing to malaria, as in the case of those of Classe), and of S. Vitale, are pleasing 16th-century structures. The 15th-century castle in the north-east corner of the town is thepicturesque brick building. The famous pineto or pinewood of Ravenna, which already existed in Odoacer's time, and has been sung by poets since Dante, lies some 5 m. south of Ravenna.

History.—Strabo mentions a tradition that Ravenna was founded by Thessalians, who afterwards, finding themselves pressed by the Etruscans, called in their Umbrian neighbours and eventually departed, leaving the city to their allies. Flinn, on the other hand, calls it Sabine. Throughout the valley of the Po the Gauls took the place of the Etruscans as a conquering power; but Ravenna may possibly have retained its Umbrian character until, about the year 101 B.C., by the conquest of the Boi, the whole of this region passed definitely under the dominion of Rome. Either as a colony or a municipium, Ravenna remained for more than two centuries an inconsiderable city of Gallia Cisalpina, chiefly noticeable as the place in which Caesar during his ten years' command in Gaul frequently resorted in order to confer with his friends from Rome, and from which he started for his advance into Italy. At length under Augustus it suddenly rose into importance, when that emperor selected it as the station for his fleet on "the upper sea." Two hundred and fifty ships, said Dion (in a passage quoted by Jordanes), could ride at anchor in its harbour. At the same time Augustus conducted a branch of the Po (the fossa Augusta) through the city into the sea. It also became important for the export of timber from the Alps. Strabo, writing probably a few years after Ravenna had been thus selected as a naval arsenal, gives us a description of its appearance which certainly corresponds more closely with modern Venice than with modern Ravenna. "It is the largest of all the cities built in the lagoons, but entirely composed of wooden houses, penetrated in all directions by canals, wherefore bridges and boats are needed for the wayfarer. At the flow of the tide a large part of the sea comes sweeping into it; and thus, while all the muddy deposit established is swept away, by the wind and never at the same time removed, and by this means the city enjoys so good a sanitary reputation than the government has fixed it as a place for the reception and training of gladiators." On the other hand, good water was proverbially difficult to obtain at Ravenna—dearer than wine, says Martial, who has two epigrams on the subject. Tranjan, however, built an aqueduct nearly 20 miles long, which was restored by Theodoric in 503. Of this some traces still exist in the bed of the Ronco above Ravenna. Flies and frogs were also complained of, and Sidonius, writing in the 5th century, complains bitterly of the "scurulent gruel" (dolores puta) which filled the canals of the city, and gave forth fetid odours when stirred by the poles of the bargemen. The port of Ravenna, situated about 3 miles from the city, was named Clasis. A long line of houses called Caesarea connected it with Ravenna, and in process of time there was such a continuous series of buildings that the three towns seemed like one. It was a municipium under the Empire, as the inscription show, but it seems to have had magistrates rather suited to a vicus or village, its importance being due entirely to the naval station (cf. the state of things at Mediolanum, Milan). It had large gilds of fabri (smiths and carpenters) and senzionarii (tailors).

Of Roman Ravenna nothing remains above ground, though a little has been found by excavation, including a mosaic pavement at Classe near S. Severo (Riccì, op. cit. p. 50). Among the tombs many of the poorer under the Empire were simply formed of amphore, in which the body was placed. A prehistoric station was found in 1894 at S. Zaccaria near Ravenna, belonging to a Terramare (E. Brizio in Notizie degli Scavi, 1896, 85). In A.D. 330 it is spoken of as having previously been the chief town of Picenum, but having recently been assigned to Aemilia. It was connected with Ariminum, 33 miles to the south by the coast road, the Via Popilia, which ran north to Patavium and joined the road between Patavium and Aquitania at Ad Portum.

The great historical importance of Ravenna begins early in the 5th century, when Honorius, alarmed by the progress of Alaric in the north of Italy, transferred his court hither. From this date (404) to the fall of the Western Empire in 476 Ravenna was the chief residence of the Roman emperors. Here Stilicho was slain; here Honorius and his sister Placida caressed and quarrelled; here Valentinian III. spent the greater part of his life; here Majorian was proclaimed; here the little Romulus donned his purple robe; here in the pinewood outside the city his uncle Paulus received his decisive defeat from Odoacer. Through all these changes Ravenna maintained its character as an impregnable "city in the sea," not easily to be attacked even by a naval power on account of the shallowness and devious nature of the channels by which it had to be approached. Odoacer, like the emperors who had gone before him, made Ravenna his chief place of residence, and here he shut himself up when Theodoric the Ostrogoth had invaded Italy and defeated him in two battles. Theodoric's siege of Ravenna lasted for three years (490-492), and was marked by one bloody encounter in the pinewood on the east of it. The Ostrogoth collected a fleet and established a severe blockade, which at length caused Odoacer to surrender the city. The terms, arranged through the intervention of John, archbishop of Ravenna, were not observed by

1. The great pinewood to the east of the city, which is still one of the greatest glories of Ravenna, must therefore have been in existence already in the 5th century. Byron's description,

"[The] immemorial wood"

Rooted where once the Adrian wave flowed o'er, is probably true but there is no evidence that it was in historic time that this change took place. It may be conjectured that the Pineta grew on a large peninsula somewhat resembling the Lido of Venice.
Theodoric, who, ten days after his entry into the city, slew his rival at a banquet in the palace of the Laurel Grove (March 15, 493). Ravenna was Theodoric's chief place of residence, and his reign (493–526) may be considered the time of its greatest splendour.

Nine years after the death of Theodoric Justinian sent an army to destroy the Gothic monarchy and restore Italy to the empire. Long after the Goths had lost Rome they still clung to Ravenna, till at length, weary of the ficklebonds of their own king, Vitiges, and struck with admiration of their heroic conqueror, they offered to transfer their allegiance to Belisarius on condition of his assuming the diadem of the Western Empire. Belisarius dallied with the proposal until he had obtained an entrance within the walls of the capital, and proclaimed his inviolable fidelity to Justinian. Thus in the year 539 was Ravenna re-united to the Roman empire. Its connexion with that empire—or, in other words, its dependence upon Constantinople—lasted for more than 200 years, during which period, under the rule of Narses and his successors the exarchs, Ravenna was the seat of Byzantine dominion in Italy. In 728 the Lombard king Luitprand took and destroyed the suburb Clasidis; about 752 the city itself fell into the hands of his successor Astolf, from whose invasion it was rescued only after a long and gallant resistance by Pipin, king of the Franks. By this time the alteration of the coast-line and the filling up of the lagoons had probably commenced, and no historical importance attaches to its subsequent fortunes. It formed part of the Frankish king's donation to the pope in the middle of the 8th century, though the archbishops, as a fact, retained almost independent power. It was an independent republic, generally taking the Guelph side in the 13th century, subject to rulers of the house of Polentani in the 14th, Venetian in the 15th (1444), and papal again in the 16th.—Pope Julius II. having succeeded in wresting it from the hands of the Venetians. St. Romuald, and St Peter Damian were both natives of Ravenna. From this time (1500) down to our own days, except for the interruptions caused by the wars of the French Revolution, Ravenna continued subject to the papal see and was governed by a cardinal legate. In 1849 Garibaldi's wife Anita, who had accompanied him on his retreat from Rome, succumbed to fatigue in the marshes near Ravenna. In 1859 it was one of the first cities to give its vote in favour of Italian unity, and it has since then formed a part of the kingdom of Italy.

Charles the Great carried off the brazen statue of Theodoric and the marble columns of his palace to his own palace at Aix-la-Chapelle. More than five centuries later (1329) Dante became the guest of Guido Novello di Polenta, lord of Ravenna, and here he died on the 14th September of the following year. The marble urn containing the body of the poet still rests at Ravenna, where what Byron calls "a little cupola more neat than solemn" has been erected over it. In 1512 (see below) the French army under Gaston de Foix fought a fierce battle with the Spanish, Venetian, and papal troops on the banks of the Cono about two miles from Ravenna. The French were victorious, but Gaston fell in the act of pursuing the enemy. His death is commemorated by the equestrian statue on the ponte where he fell. Lord Byron resided at Ravenna for eighteen months in 1820–21, attracted by the charms of the Countess Guiccioli.

AUTHORITIES.—The most important authority for the history of Ravenna is Bishop Agnellus, who wrote, about 840, the Liber Pontificum. The Ecclesiæ Ravennatis. The best edition is that by Holder-Egger in the Monumenta Germanicæ Historica (1878). See also Bonghi, in Corpus Inscription. Latin. xi. (Berlin, 1889), p. 1 sqq.; G. T. Rivoira, Origini dell' Architettura Lombarda, i. (Rome, 1901); C. Ricci, Ravenna (Bergamo, 1902). To the careful restorations of the last named the buildings of Ravenna owe much. (T. H.; T. A.)

Battle of 552.—This battle, one of the principal events of the long Italian wars of Charles VIII., Louis XII., and Francis I. of France, is, like Marignano, interesting in a technical point from the fact that the feudalism of the past and the expert soldiership of the future were strangely mingled. It arose out of the attempt of the Spanish and Italian forces to relieve Ravenna, besieged by Gaston de Foix, duke of Nemours. The most celebrated captains of these wars were present on either side—under Gaston de Foix were Bayard, Yves d'Allègre, La Palisse; and under Cardona the Spanish viceroy of Naples, Pedro Navarro the great engineer, and Pescara the originator of the Spanish tactical system. After some preliminary manœuvres the two armies drew up face to face on the left bank of the Roneo, the Spanish left and the French right resting on this river. The Spaniards were entrenched, with their heavy artillery distributed along the front, but, thanks to Navarro, they had a more mobile artillery in the shape of 200 arquebusiers divided in groups upon carts, after the German fashion, and this was held ready to move wherever its services might be needed. The left wing was composed of the papal contingent, 6000 infantry and 800 gendarmes under Fabrizio Colonna; the centre, of half the Spanish contingent, 4000 infantry and 600 lancers under the viceroy; the right, of 1000 light horse under Pescara. Behind the centre was the rest of the Spanish contingent, 600 lancers and 4000 infantry. On the other side the right wing was commanded by the duke of Ferrara, who had like Navarro organized a mobile field artillery (the artillery material of this prince was thought to be the best conditioned in Europe). It consisted of 1000 French gendarmes under Brézé and 5000 German landsknechts under Jakob Empser. In the centre were 8000 French infantry (the ancestors of the later Picardie and Piedmont regiments) under the seigneur de Molart, and 5000 Italian infantry. On the left were the light horse. A reserve of 600 gendarmes under La Palisse was behind the centre. The battle opened with a prolonged cannonade from the Spanish lines. For three hours the professional regiments of all sorts in the French lines rumbled another in enduring the fire unmoved, the forerunners of the military systems of to-day, landsknechts, Picardie and Piedmont, showing the feudal gendarmery that the too were lean of flesh. There was no lyin' down. The captives placed themselves in the front, and in the centre 42 out of 40 of them were struck down. Molart and Empser, drinking each other's health in the midst of the cannonade, were killed by the same shot. Sheltered behind the entrenchments, the Spaniards scarcely suffered, for they were little active troops accustomed to lie down and spring up from the ground. But after three hours, Pescara's light horse having meantime been driven in by the superior light horse of the enemy, the artillery-loving duke of Ferrara conceived the brilliant plan of taking his mobile field-guns to the extreme right of the enemy. This he did, and so came in sight of the front line of the French. Disciplined troops as they were, they resisted the temptation to escape Ferrara's fire by breaking out to the front; but the whole Spanish line was enflamed, and on the left of it the papal troops, who were by no means of the same quality, filled up the ditch in front of their breastworks and charged forward, followed by all the gendarmery. Once in the plain they were charged by the French gendarmes under Gaston himself, as well as by the landsknechts, and driven back. The advantage of position being thus lost, the Spanish infantry rose and flung itself on the attackers; the landsknechts, and the French bands broke into the entrenchments. A captain of landsknechts, Fabian by name, holding his long pike crosswise, brought it down with all his force upon the opposing spears, and at the cost of his life made a narrow gap through which the French broke into the midst of the enemy. Still the conflict continued, but at last La Palisse, with all the gendarmery still in hand, rode completely round the entrenchments and charged the Spaniards' rear again. This was the
end, but the remnant of the Spanish infantry retreated in order along the river Lambardy, keeping the pursuers at bay with their arquebuses. Gaston de Foix, recklessly charging into the midst of them, was killed.

(C. F. A.)

RAVENNA, EXARCHEATE OF, the official name of that part of Italy which remained in the allegiance of the Roman emperors at Constantinople from the closing years of the 6th century to the middle of the 8th century. The civil and military head of these possessions, the exarch (q.v.), was stationed at Ravenna. The territory round the town, from the southern border of the modern Venetia to the beginning of the Pentapolis at Rimini, was under his direct administration and formed in the limited sense the exarchate of Ravenna. The territory was governed by dukes and magistri militum, titles which were generally, but not always, borne by the same person. But as all were subject to his authority, they were included in the exarchate of Ravenna, which was therefore another name for the province of Italy. The borders of these dominions varied according to the fortunes of the imperial authority in its long struggle with the Lombards. Sicily formed a separate government. Corsica and Sardinia belonged to the exarchate of Africa. The reorganization of the province of Italy into the exarchate was forced on the emperors by the Lombard invasion, which began in 568, and their permanent settlement. The Lombards thrust a wedge into Italy. Its base was in Venetia, and its point was advanced to the Tiber. From the early days of the conquest they spread to the south, and established the duchies of Spoleto and Beneventum in the modern kingdom of Naples. They may thus be said to have hollowed out the imperial, or Byzantine, possessions in Italy, the interior being under their power, and the coast remaining to the imperial officers. This illustration, however, is subject to two serious exceptions. As the Lombards spread they came into possession of many parts of the coast. Then a belt of imperial territory stretching from Rimini on the Adriatic, N.W. to the mouth of the Tiber, and including the duchies of Perugia and Rome, served to unite the immediate territory of Ravenna with the duchy of Naples, and to separate the two bodies under Lombard dominion, the kingdom in the north, and the southern duchies Spoleto and Beneventum. The organization of the exarchate is placed by modern investigators under the reign of the emperor Maurice (582–602), when the imperial government began to recognize the necessity of providing for a new and a long struggle. At the end of the 6th century the exarchate included Istria; the maritime part of Venetia as distinct from the interior which was in the hands of the Lombard kings at Pavia; the exarchate or territory around Ravenna on the eastern side of the Apennines, to which was added Calabria, which at that period meant the heel and not the toe of the boot; the Pentapolis, or coast from Rimini to Ancona with the interior as far as the mountains; the duchy of Rome, or belt of territory connecting the Pentapolis with the western coast, the coast of Naples, with Bruttium the toe of the boot, the modern Calabria, and Liguria, or the Riviera of Genoa. The Piedmont, Lombardy, mainland of Venetia, Tuscany and the interior of Naples belonged to the Lombards. The advance of these barbarians was for a time checked during the anarchy which followed the death of Alboin, and was subject to other suspensions. The superior organization of the imperial government enabled it to regain lost territory and delay complete ruin. In 590 the empire regained much of Venetia. But these revivals were not permanent. The superiority of the empire was a mechanical one, and during the two centuries or so that the exarchate lasted it lost ground. In 640 the Ligurian seacoast fell under the power of the Lombards, and ceased to be an imperial province. About a century later the exarchate had been greatly reduced, though the imperial officials endeavoured to conceal the fact by retaining and transposing titles. The other provinces were reduced in the possession of possession was lost. About 740 it consisted of Istria, Venetia (the maritime portion of which was easing to be a province and was becoming a protected state, the forerunner of the future republic of Venice), Ferrara, Ravenna (the exarchate in the limited sense), Pentapolis, Perusia, Rome, the coast of Naples and Calabria (in the sense of the toe and not the heel of the boot) which was being overrun by the Lombards of the duchy of Beneventum, which with Spoleto held the interior. In Rome the pope was the real master. These fragments of the "province of Italy" as it was when reconquered by Justinian, were almost all lost either to the Lombards, who finally conquered Ravenna itself about 750, or by the revolt of the pope, who separated from the empire on account of the iconoclastic reforms. The intervention of Pippin the Carolingian, who was called in by the popes to protect them against the Lombards and the Eastern emperors alike, made a revival of the exarchate impossible. It disappeared, and the small remnants of the imperial possessions on the mainland, Naples and Calabria, passed under the authority of the "patricius" of Sicily, and when Sicily was conquered by the Arabs in the 10th century were erected into the themes of Calabria and Langobardia. Istria was attached to Dalmatia.

In its internal history the exarchate was subject to the influences which were everywhere, in central and western Europe at least, leading to the subdivision of sovereignty and the establishment of feudalism. Step by step, and in spite of the efforts of the emperors at Constantinople, the great imperial officials became landowners, the owners of land—kinsmen or at least associates of these officials—intruded on the imperial administration, while the necessity for providing for the defence of the imperial territories against the Lombards led to the formation of local militias, who at first were attached to the imperial regiments, but gradually became independent. These armed men formed the exercitus romanus militiae, who were the forerunners of the free armedburghers of the Italian cities of the middle ages. The exercitus of Rome was divided into scholae, and had a chief or patrionus, and its banner. Other relatives of the exercitus were organized on the same model. Districts of session, the subdivision of the provinces, were known as "possessores," or landowners and free townsmen, who were of a less rank than the ordo senatorius. The great landowners who were developing into feudal lords, and the smaller freemen who were becoming independentburghers, broke the imperial administration to pieces, and prepared the way for the final ruin of the exarchate.

RAVENSBURG, a town of Germany, in the kingdom of Württemberg, pleasantly situated amid vine-clad hills on the river Schussen, 12 m. N. of Friedrichshafen on the lake of Constance, by the railway of Ulm. Pop. (1905) 14,614, the great majority of whom are Roman Catholics. Its aspect is medieval; it still retains its walls and nine picturesque towers, the most prominent of which, dating from the 15th century, is known as the "Mehlsack," or sack of flour. The town hall is a handsome 15th-century building. The manufactures include linen, cotton, embroidered muslins, pottery, glass and playing-cards. The fruit market is important, and there is trade in cattle, grain and timber. Ravensburg was founded in the 11th century by the Guelphs, and in their ancestral castle on the Veltzberg, which was partially restored in 1892, the Saxon duke, Henry the Lion, was born. In 1180 the town passed to the Hohenstaufens, and a century later it became a free town of the Empire. In the 15th century it was a flourishing commercial place, its chief industry being the manufacture of paper. Annexed to Bavaria from 1805 to 1810, it was ceded to Württemberg in the latter year.

See Hafner, Geschichte von Ravensburg (Ravensburg, 1887).

RAVENSCroFT, Edward (fl. 1657–1697). English dramatist, belonged to an ancient Finsleyshire family. He was entered at the Middle Temple, but devoted his attention mainly to literature. Among his pieces are The Citizen turned Gentleman (Dorset Garden, 1671, pr. 1675); The Careless Lovers (Dorset Garden, 1673, pr. 1675); a comedy
of intrigue; Scaramouch a Philosopher, Harlequin a Schoolboy, Brava a Merchant and Magician (Theatre Royal, 1677); English Lawyer (Theatre Royal, 1678), an adaptation of George Ruggle's Latin play of Ignoramus, presented before James I. at Cambridge in March 1615; The London Cuckold (Dorset Garden, 1685), which became a stock piece but was struck out of the repertory by Garrick in 1751; and The Italian Husband (Lincoln's Inn Fields, 1697). He wrote in all twelve plays, in which he adapted freely from Molière and others, confessing on one occasion that he "but winnowed Shakespeare's corn." He ventured to decry the heroic drama, and Dryden retaliated by satirizing his Mamanouchi, a foolish adaptation from Molière's Bourgeois Gentilhomme and Montieur de Pourceaugnac, in the prologue to the Assiguation (Dryden, Works, ed. Scott, lv. 345 seq.).

RAV, a river of India, one of the "Five Rivers" of the Punjab. It rises in the Kula subdivision of Kangra district, flows through Chamba state, and enters British territory again in Gurdaspur district. At Madhpur the head works of the Bari Doab canal draw off a large portion of its waters. Thence it flows through the plains of the Punjab, passing within a mile of Lahore, and finally falls into the Chenab after a course of about 450 m.

RAVINE, a deep, narrow gorge, cleft or valley in a mountain, worn by the violent rush of water, whence the name, which comes through Fr. from Lat. rapina, violent robbery or plunder (rapere, to seize). The double "ravin" or "raven," robbery, greed, has given place to the more learned form "rapine," but is still seen in "ravenous," greedy, voracious.

RAWALPINDI, a town of British India, which gives its name to a district and a division in the Punjab. The town is situated on the north bank of the little river Leh, 1726 ft. above the sea, 111 m. E. by S. of Peshawar, and 1443 m. N.W. of Calcutta. Pop. (1901) 87,688. It is chiefly notable as the largest military station in India, and the key to the British system of defence upon the North-West Frontier. Railways radiate to Peshawar, Kohat, and the Malakand Pass, and a road runs to the Abbotabad frontier. It is also the starting-point of the cart-road to the hill-station of Murree and of the route into Kashmir. It is protected by a strong chain of forts, connected by the Circular Road. It is the headquarters of the second division of the northern army with a strong force of all arms, and contains an arsenal. Besides the locomotive works of the North-Western railway, there are gas-works, a tent factory, an iron foundry, and a brewery. An annual horse fair is held in April.

The District of Rawalpindi has an area of 2010 sq. m., Attok having been separated from it and formed into a separate district in 1904. It is situated on the southern slopes of the north-western extremities of the Himalayas, including large mountain tracts with rich valleys traversed by mountain torrents. It contains the Murree hills with the sanatorium of that name, the chief hill-station in the Punjab. The Indus and the Jhelum are the chief rivers, and the climate is noted for its healthiness. The principal crops are wheat, barley, maize, millets, and pulses. The district is traversed by the main line of the North-Western railway, crossing the Indus at Attok, and also by a branch towards the Indus at Khasigarah. The population in 1901 was 558,609, showing an increase of 4.7% in the decade.

The Division of Rawalpindi lies in the north-west of the Punjab. It consists of the five districts of Gujrat, Attock, Shabpur, Jhelum, and Rawalpindi. The total area is 15,736 sq. m. and the population in 1901 was 2,790,360.

RAWENDIS, a Persian sect that took its name from a town Rawend near Isfahan. Its origin is unknown, but they held ultra-Shiite doctrines (see SHIITES). Under the year 158 (A.D. 775) Tabari says that a man of the Rawendis, called al-Abraq (because he was leprous), asserted that the spirit that was in Jesus was in 'Ali, then in the imams one after the other to Ibrahim ibn Malhommed, and that thus these were gods. Asad ibn 'Abdallah, then governor of Khorasan, put many of them to death. Under the year 135 (A.D. 752-3) the historian again mentions a rising of the Rawendid of Tal'afan, and its suppression. Under 141 (A.D. 758-9) he gives a fuller account of them. They believed in metempsychosis, or the transmigration of souls, and asserted that the spirit of Adam was in Othman ibn Nahlkh, that the Lord who fed him and gave them drink was Abu Jafar ul-Mansur, and that al-Halilah ibn Moawiyah was Gabriel. Accordingly they came to the palace of Mansur in Hashimiyah and began to hail him as Lord. Mansur, however, secured their chiefs and threw them into prison. By means of a mock funeral they succeeded in reaching the prison and delivering their leaders. They then turned in wrath against Mansur and almost succeeded in capturing him, but were defeated and slain by al-Halilah.

RAWITSC, (Polish Rawa), a town of Germany, in the Prussian province of Posen, lying near the Silesian frontier, 5 m. N. of Breslau, at the junction of railways to Posen and Liegnitz. Pop. (1905) 11,403. It contains a handsome Protestant church and a medieval town hall. The principal industry is the manufacture of snuff and cigars, and for the former it enjoys a considerable reputation. Trade is carried on in grain, wool, cattle, hides, and timber. Rawitsch was founded by Protestant refugees from Silesia during the Thirty Years' War. It passed to Prussia at the second partition of Poland in 1793.

RAWLINSON, GEORGE (1812-1902), English scholar and historian, was born at Chaddington, Oxfordshire, on the 23rd November 1812, being the younger brother of Sir Henry Rawlinson (q.v.). Having taken his degree at Oxford (from Trinity College) in 1838, he was elected to a fellowship at Exeter College in 1840, of which from 1842 to 1846 he was fellow and tutor. He was ordained in 1841; was Bampton lecturer in 1859, and Camden professor of ancient history from 1861 to 1889. In 1872 he was appointed canon of Canterbury, and after 1888 he was rector of All Hallows, Lombard Street. In 1873 he was appointed proctor in Convocation for the Chapter of Canterbury. He married Louisa, daughter of Sir R. A. Chermise, in 1846. His chief publications are his translation of the History of Herodotus (in collaboration with Sir Henry Rawlinson and Sir Gardner Wilkinson), 1856-60; The Five Great Monarchies of the Ancient Eastern World, 1862-67; The Six Great Oriental Monarchy (Parthian), 1853; The Seventh Great Oriental Monarchy (Sassanian), 1875; Manual of Ancient History, 1860; Historical Illustrations of the Old Testament, 1871; The Origin of Nations, 1877; History of Ancient Egypt, 1881; Egypt and Babylon, 1883; History of Phoenicia, 1886; Parthia, 1883; Memoir of Major-General Sir H. C. Rawlinson, 1888. He was a contributor to the Speaker's Commentary, the Pulpit Commentary, Smith's Dictionary of the Bible, and various similar publications; and he was the author of the article "Herodotus" in the 9th edition of the Ency. Brit. He died on the 7th of October 1902.

RAWLINSON, SIR HENRY CREWSICKE (1810-1895), English soldier and orientalist, was born at Chaddington, Oxfordshire, on the 11th of April 1810. In 1827 he went to India as cadet under the East India Company; and after six years' life with his regiment as subaltern, during which time he had become proficient in the Persian language, he was sent to Persia in company with some other English officers to drill and reorganize the Shah's troops. It was at this time that he was first attracted to the study of inscriptions, more particularly those in the hitherto undeciphered cuneiform character. In the course of the two years during which he was in its immediate neighbourhood he transcribed as much as he was able of the great cuneiform inscription at Behistun (q.v.); but the friction between the Persian court and the British government ended in the departure of the British officers.

He was appointed political agent at Kandahar in 1840. In that capacity he served for three years, his political labours being as meritorious as was his gallantry during various engagements in the course of the Afghan War; for these he was rewarded by the distinction of C.B. in 1844. A fortunate chance, by which
RAWLINSON, R.—RAWMARSH

he became personally known to the governor-general, led to his being appointed, at his own desire, as political agent in Turkish Arabia; thus he was enabled to settle in Bagdad, where he devoted much time to the cuneiform studies which attracted him. He was now able, under considerable difficulties and with no small personal risk, to make a complete transcription of the Behistun inscription, which he was also successful in deciphering and interpreting. Having collected a large amount of invaluable information on this and kindred topics, in addition to much geographical knowledge gained in the prosecution of various explorations (including visits with Layard to the ruins of Nineveh), he returned to England on leave of absence in 1849. He remained at home for two years, published in 1851 his memoir on the Behistun inscription, and was promoted to the rank of lieutenant-colonel. He disposed of his valuable collection of Babylonian, Sabaean, and Sassanian antiquities to the trustees of the British Museum, who also made him a considerable grant to enable him to carry on the Assyrian and Babylonian excavations initiated by Layard. In 1853 he returned to Bagdad. The excavations were carried on under his direction with valuable results, among the most important being the discovery of material that greatly contributed to the final decipherment and interpretation of the cuneiform character. An accident with which he met in 1853 hastened his determination to return to England, and in that year he resigned his post in the East India Company. On his return to England the distinction of K.C.B. was conferred upon him, and he was appointed a crown director of the East India Company. The remaining forty years of his life were full of activity—political, diplomatic, and scientific—and were mainly spent in London. In 1858 he was appointed a member of the first India Council, but resigned in 1859 on being sent to Persia as envoy extraordinary and minister plenipotentiary. The latter post he held only for a year, owing to his dissatisfaction with circumstances connected with his official position there. Previously he had sat in Parliament as M.P. for Reigate from February to September 1858; he sat again as M.P. for Frome, 1865-68. He was appointed to the Council of India again in 1868, and continued to serve upon it until his death. He was a strong advocate of the forward policy in Afghanistan, and counselled the retention of Kandahar. His views were more particularly expressed in England and Russia in the East, 1875. He was a trustee of the British Museum from 1876 till his death. He was created G.C.B. in 1889, and a Baronet in 1891; was president of the Geographical Society from 1874 to 1875, and of the Asiatic Society from 1878 to 1881; and received honorary degrees at Oxford, Cambridge, and Edinburgh. He married, in September 1852, Louisa Caroline Harcourt Seymour, who bore him two sons and died in 1889. He died in London on the 5th of March 1895. His published works include (apart from minor contributions to the publications of learned societies) four volumes of cuneiform inscriptions, published under his direction between 1879 and 1884 by the trustees of the British Museum; The Persian Cuneiform Inscription at Behistun, 1846-51, and Outline of the History of Assyria, 1852, both reprinted from the Asiatic Society's journals; A Commentary on the Cuneiform Inscriptions of Babylon and Assyria, 1859; Notes on the Early History of Babylonia, 1854; England and Russia in the East, 1875. He contributed to the Encyclopaedia Britannica (9th edition) the articles on Bagdad, the Euphrates and Kurdistan, and several other articles dealing with the East; and was editor of a translation of Herodotus by his brother, Canon George Rawlinson.

See G. Rawlinson, Memoir of Henry Creswicke Rawlinson (1898).

RAWLINSON, RICHARD (1600-1755), English antiquary and divine, was a younger son of Sir Thomas Rawlinson (1607-1708), lord mayor of London in 1705-6, and a brother of Thomas Rawlinson (1681-1725), the bibliophile. Born on the 3rd of January 1600, he was educated at St Paul's school, at Eton, and at St John's College, Oxford. In 1716 he was ordained, but as he was a nonjuror and a Jacobite the ceremony was performed by a nonjuring bishop, Jeremy Collier. Rawlinson then travelled in England and on the continent of Europe, where he passed several years, making collections of manuscripts, coins and curiosities. In 1728 he became a bishop among the non-jurors, but he hardly ever appears to have discharged episcopal functions, preferring to pass his time in collecting books and pictures and in the pursuit of his own studies. He died at Italy, on the 6th of April 1755. Rawlinson left his manuscripts, his curiosities, and some other property to the Bodleian Library; he endowed a professorship of Anglo-Saxon at Oxford, and was a benefactor to St John's College.

RAWLINSON, SIR ROBERT (1810-1868), English engineer and sanitary, was born at Bristol on the 28th of February 1810. His father was a mason and builder at Chorley, Lancashire, and he himself began his engineering education by working in a stonemason's yard. In 1831 he obtained employment under Jesse Hartley in the engineer's office at the Liverpool Dock and was appointed, in 1836, to be engaged under Robert Stephenson as assistant resident engineer for the Blisworth section of what is now the London & North-Western main line from London to the North. Returning to Liverpool, he spent some years as assistant-surveyor to the corporation, and then, in 1844 accepted an engineering post on the Bridgewater Canal. Three years later he returned to Liverpool, to superintend the design and construction of the famous brick-arched ceiling in the St George's Hall, in succession to his friend H. L. Elmes. During this period Rawlinson's reputation as a sanitary man was growing, and when the Public Health Act was passed in 1848 he was appointed one of the first inspectors under it. He inspected many of the chief towns of England, and his reports on the sanitary conditions he found brought him in many cases into great unpopularity with the municipal rulers. Early in 1855 popular feeling was so aroused by the waste of life that was going on among the British troops in the Crimea through disease, and by the mismanagement of the campaign, that the Aberdeen ministry was forced to resign. Lord Palmerston, who then became prime minister, sent a sanitary commission, consisting of Rawlinson and two medical members (Dr John Sutherland and Dr H. Gavrin), with full powers from the War Office, to do whatever it thought would lead to better hygienic conditions in camp and hospital. The commission reached Constantinople in March, and, by insisting on what now seem the most obvious precautions, succeeded within a few weeks in reducing the death-rate in the Levantine hospitals from 42 to 21%. Passing on to the Crimea, it effected a similar improvement there, and by the end of the year the health of the whole British army in the field was even better than it enjoyed at home. Rawlinson's next great public service, for which he was made C.B. in 1865, was in connexion with the distress caused in Lancashire by the collapse of the cotton-manufacturing industry consequent on the American Civil War. In 1863 it was suggested that, in order to provide employment for the starving operatives, the government should undertake the laying of "utility, profit and ornament," and Rawlinson being sent to make an official investigation into the question, reported, after visiting nearly 100 towns, that £1,000,000 (the amount was afterwards increased) at 3½% for carrying out such works, which proved of enormous public benefit. In 1866 he acted as chairman of the Royal Commission on the Pollution of Rivers, and a few years later was appointed chief engineering inspector of the Local Government Board; on retiring from this position in 1888 he was promoted to be K.C.B. In 1894 he served as president of the Institution of Civil Engineers. He died in London on the 31st of May 1898.

RAWMARSH, an urban district in the Rotherham parliamentary division of the West Riding of Yorkshire, England, 7½ m. N.E. of Sheffield by the Midland railway. Pop. (1891) 11,683; (1901) 14,587. It is situated on the ridge of a hill above the valley of the Don. The church of St Lawrence was rebuilt
in 1839 with the exception of the Norman tower. Rawmarsh has large iron-works, steel rolling-mills and potteries, and there are collieries in the neighbourhood. At the time of the Conquest the manor was granted to Walter d'Eyncourt, and in the 12th century it was divided among the three daughters of his tenant Ralph Paganel, who is supposed to have been the founder of the church.

RAWTENSTALL, a municipal borough in the Rossendale parliamentary division of Lancashire, England, 17½ m. N. by W. from Manchester by the Lancashire & Yorkshire railway. Pop. (1901) 31,053. This town is a modern creation of the cotton industry; at the beginning of the 19th century it was a secluded village in the wild hilly district of Rossendale Forest. The cotton and woollen industries employ the majority of the inhabitants, and there are stone quarries in the neighbourhood. The town was incorporated in 1891, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 9535 acres.

RAY (Lat. raia). The rays (Batoidei) together with the sharks (Chondroidei) form the suborder Plagiostomi of Elasmobranch fishes, and are divided into six families (see Ichthyology).

The first family, Pristidae, contains only the saw-fishes (Pristis), of which five species are known, from tropical and subtropical seas. They frequent especially estuaries and river-mouths, and in some cases make their way over a hundred miles from the sea. Although saw-fishes possess all the essential characteristics of the rays proper, they retain the elongate form of the body of sharks, the tail being excessively muscular and the sole organ of locomotion. The "saw" (fig. 1) is a flat prolongation of the snout, with an endoskeleton which consists of three to five cartilaginous tubes; these are the rostral processes of the cranial cartilage and are found in all rays, though commonly much shorter. The integument of the saw is hard, covered with shagreen; and a series of strong teeth, sharp in front and flat behind, are embedded in it, in alveolar sockets, on each side. The saw is a formidable weapon of offence, by means of which the fish tears pieces of flesh off the body of its victim, or rips open its abdomen to feed on the intestines. The teeth proper, with which the mouth is armed, are extremely small and obtuse, and unsuitable for wounding or seizing animals. Saw-fishes are abundant in the tropics; in their stomachs pieces of intestines and fragments of cuttle-fish have been found. They grow to a large size, specimens with saws 6 ft. long and 1 ft. broad at the base being common.

The rays of the second family, Rhinobatidae, bear a strong resemblance to the saw-fishes, but lack the saw. Their teeth are consequently more developed, flat, obtuse, and adapted for crushing hard-shelled marine animals. There are about twenty known species, from tropical and subtropical seas.

The third family, Torpedinidae, includes the electric rays. For the peculiar organ (fig. 2) by which the electricity is produced, see Ichthyology. The fish uses this power voluntarily either to defend itself or to stun or kill the smaller animals on which it feeds. To receive the shock, the object must complete the galvanic circuit by communicating with the fish at two distinct points, either directly or through the medium of some conducting body. The electric currents created in these fishes exercise all the other known powers of electricity: they render the needle magnetic, decompose chemical compounds and emit the spark. The dorsal surface of the electric organ is positive, the ventral negative. Shocks from a large healthy fish will temporarily paralyse the arms of a strong man. The species of the genus Torpedo are distributed over the coasts of the Atlantic, Pacific and Indian Ocean, and at least one reaches the coasts of Great Britain (T. lebionis). On the west coast of North America T. californica occurs, while on the Atlantic coast there is found the black crampfish (T. occidentalis). This latter is said to reach a weight of 200 lb, but such gigantic specimens are scarce, and prefer sandy ground at some distance from the shore, where they are not disturbed by the agitation of the surface-water. Seven genera with about fifteen species have been described, mostly from the warmer seas. All the rays of this family have, like electric fishes generally, a smooth and naked body.

The fourth family, Rajaæ, comprises the skates and rays proper, or Raia. More than thirty species are known, chiefly from the temperate seas of both hemispheres, but much more numerous from the northern than the southern. A few species descend to a depth of nearly 600 fathoms, without, however, essentially differing from their surface congeners. Rays, as is
Ray, J.

indicated by their shape, are bottom-fishes, living on flat sandy ground, generally at no great distance from the coast or the surface. They lead a sedentary life, progressing, like the flat-fishes, by an undulatory motion of the greatly extended pectoral fins, the thin slender tail having lost the function of an organ of locomotion, and acting merely as a rudder. They are carnivorous and feed exclusively on molluscs, crustaceans and fishes. Some of the species possess a much larger and more pointed snout than the others, and are popularly distinguished as "skates." The following are known as inhabitants of the British seas:—(a) short-snouted species: (1) the thornback (R. clavata), (2) the homely or spotted ray (R. maculata), (3) the starry ray (R. radiata), (4) the cuckoo or sandy ray (R. circularis); (b) long-snouted species: (5) the common skate (R. batis), (6) the flapper skate or jumbo skate (R. macrorynchus), (7) the burton skate (R. alba), (8) and (9) the shagreen skates (R. oxyrhynchos and R. fullonica). A few deep-sea species are known, including R. abyssicola from 1588 fathoms off the coast of British Columbia. Most of the skates and rays are eaten, except during the breeding season; and even the young of the former are esteemed as food. The skates attain to a much larger size than the rays, viz. to a width of 6 ft. and a weight of 400 and 500 lb.

The members of the fifth family, Trygonidae or sting-rays, are distinguished from the rays proper by having the vertical fins replaced by a strong spine attached to the upper side of the tail. Some fifty species are known, which inhabit tropical more than temperate seas, some species being found in great tropical rivers over 1000 m. from the sea. The spine is barbed on the sides and is a most effective weapon of defence; by lashing the tail in every direction the sting-rays can inflict dangerous or at least extremely painful wounds. The danger arises from the lacerated nature of the wound rather than from any specially poisonous property of the mucus inoculated. Generally only one or two spines are developed. Sting-rays attain to about the same size as the skates and are eaten on the coasts of the Mediterranean and elsewhere. One species (Trygon pastinaca) is not rarely found in the North Atlantic and extends northwards to the coasts of Ireland, England and Norway.

The rays of the sixth and last family, Myliobatidae, are popularly known under various names, such as "devil-fishes," "sea-devils" and "eagle-rays." In them the dilatation of the body, or rather the development of the pectoral fins, is carried to an extreme, whilst the tail is very thin and sometimes long like a whip-cord (fig. 3). Caudal spines are generally present and perfectly flat molars, adapted for crushing hard substances. In some of the eagle-rays the molars are large and tessellated (fig. 4), in others extremely small. Of the twenty-seven species which are known, from tropical and temperate seas, the majority attain a very large and some an enormous size: one mentioned by Risso, which was taken at Messina, weighed 1250 lb. A foetus taken from the uterus of the mother (all eagle-rays are viviparous), captured at Jamaica and preserved in the British Museum, is 5 ft. broad and weighed 20 lb. The mother measured 15 ft. in width and as many in length, and was between 3 and 4 ft. thick. At Jamaica, where these rays are well known under the name of "devil-fishes," they are frequently attacked for sport's sake, but their capture is uncertain and sometimes attended with danger. The eagle-ray of the Mediterranean and Atlantic (Myliobatis aquila) is occasionally found off the British coasts.

Ray (or Rray, as he wrote his name till 1670), John (1629–1705), sometimes called the father of English natural history, was the son of the blacksmith of Black Notley near Braintree in Essex, where he was born on the 29th of November 1628, or, according to other authorities, some months earlier. From Braintree school he was sent at the age of sixteen to Catharine Hall, Cambridge, whence he removed to Trinity College after about one year and three-quarters. His tutor at Trinity was Dr James Duport (1666–1679), regius professor of Greek, and his intimate friend and fellow-pupil the celebrated Isaac Barrow. Ray was chosen minor fellow of Trinity in 1649, and in due course became a major fellow on proceeding to the master's degree. He held many college offices, becoming successively lecturer in Greek (1651), mathematics (1653), and humanity (1655), prelector (1657), junior dean (1657), and college steward (1659 and 1660); and according to the habit of the time, he was accustomed to preach in his college chapel and also at Great St Mary's before the university, long before he took holy orders. Among his sermons preached before his ordination, which was not till the 23rd of December 1660, were the famous discourses on The Wisdom of God in the Creation, and on the Chaos, Deluge and Dissolution of the World. Ray's reputation was high also as a tutor; and he communicated his own passion for natural history to several pupils, of whom Francis Willughby is by far the most famous.

Ray's quiet college life closed when he found himself unable to subscribe to the Act of Uniformity of 1661, and was obliged to give up his fellowship in 1662, the year after Isaac Newton had entered the college. We are told by Dr Derham in his Life of Ray that the reason of his refusal "was not (as some have imagined) his having taken the 'Solemn League and Covenant,' for that he never did, and often declared that he ever thought it an unlawful oath; but he said he could not declare for those that had taken the oath that no obligation lay upon them, but feared there might." From this time onwards he seems to have depended chiefly on the bounty of his pupil Willughby, who made Ray his constant companion while he lived, and at his death left him £60 a year, with the charge of educating his two sons.

Fig. 4.—Jaws of an Eagle-Ray, Myliobatis aquila.
RAYAH

In the spring of 1663 Ray started together with Willughby and two other pupils on a tour through Europe, from which he returned in March 1666, parting from Willughby at Montpellier, whence the latter continued his journey into Spain. He had previously in three different journeys (1658, 1661, 1662) travelled through the greater part of Great Britain, and selections from his private notes of these journeys were edited by George Scott in 1760, under the title of Mr Ray's Itineraries. Ray himself published an account of his foreign travel in 1673, entitled A Description of Geographical, moral, and Physiological Plants, made on a Journey through part of the Low Countries, Germany, Italy, and France. From this tour Ray and Willughby returned laden with collections, on which they meant to base complete systematic descriptions of the animal and vegetable kingdoms. Willughby undertook the former part, but, dying in 1672, left only an ornithology and ichthyology, in themselves vast, for Ray to edit; while the latter used the botanical collections for the groundwork of his Methodus plantarum nova (1682), and his great Historia generalis plantarum (3 vols., 1686, 1688, 1704). The plants gathered on his British tours had already been described in his Catalogus plantarum Anglicae (1670), which work was re-edited by Robert Plot in 1699.

In 1667 Ray was elected a fellow of the Royal Society, and in 1669 he published in conjunction with Willughby his first paper in the Philosophical Transactions on "Experiments concerning the Motion of Sap in Trees." They demonstrated the ascent of the sap through the wood of the tree, and supposed the sap to "precipitate a kind of white coagulum or jelly, which may be well conceived to be the part which yearly between bark and tree turns to wood and of which the leaves and fruits are made." Immediately after his admission into the Royal Society he was induced by Bishop John Wilkins to translate into English his Real Characters, published in 1663, and of which he completed a translation, which, however, remained in manuscript; his Methodus plantarum nova was in fact undertaken as a part of Wilkins's great classification scheme.

In 1673 Ray married Margaret Oakley of Launton (Oxford); in 1676 he went to Sutton Coldfield, and in 1677 to Falborne Hall in Essex. Finally, in 1679, he removed to Black Notley, where he afterwards remained. His life there was quiet and uneventful, but embittered by bodily weakness and chronic sores. He occupied himself in writing books and in keeping up a wide scientific correspondence, and lived, in spite of his infirmities, an active, industrious, and useful life. He died on the 11th of January 1705. The Ray Society, for the publication of works on natural history, was founded in his honour in 1844.

Ray's first book, the Catalogus plantarum etca Constantri burgi nascientium (1660, followed by appendices in 1663 and 1689), was written in conjunction with his "amicissimus et individuos comes," John Nid. The plants, 626 in number, are enumerated alphabetically, but a system of classification differing little from Caspar Bauhin's is sketched at the end of the book; and the notes contain many curious references to other parts of natural history. The stations of the plants are minutely described; and Cambridge students of the latter part of the 18th century set some of the rare plants in the copse near the chalk-pits where he found them. The book shows signs of his indebtedness to Joachim Jung of Hamburg, who had died in 1657, less than a year before it was published; but it is doubted whether this was sent to Ray by Samuel Hartlib in 1660. Jung invented or gave precision to many technical terms which Ray and others at once made use of in their descriptions, and which are now classical; and his notions of what constitutes a specific distinction and what characters are valueless as such seem to have been adopted with little change by Ray. The first two editions of the Catalogus plantarum Anglicæ (1670, 1677) were likewise arranged alphabetically, but the list of plants is still far from satisfactory; and the third edition, also re-edited by Dillenius, 1724, and by Hill, 1760) Ray applied the scheme of classification which he had by that time elaborated in the Methodus and the Historia plantarum. The Methodus plantarum nova (1682) was largely based on the works of Casparis and Jung, and still more on that of Robert Morison of Oxford. The greatest merit of this book is the use of the number of cotyledons as a basis of classification; though it must be remembered that the difference between the monocotyledonous and dicotyledonous embryo was detected by Nehemiah Grew. After dividing plants into flowerless and flowering, Ray says, "Floriferas dividentem in Dicotyledones, quaram semina sata binis foliis anomalis, seminalibus dictis, quae cotyledonarum usus praestant, e terra exuente, vel in binos saltus lobos dividiturn, quamvis eos supra terem foliari specie non eferunt; et Monocotyloides, quenes nec folia, nec semina altera a dicotyloides differunt, sed binos condunt. Hae divisi ad arborum etiam extendi potest; siquldem Palmæ et congeneres hoc respectu eodem modo aliaque arboreus different quos Monocotyloides a religius herbis." But a serious blemish was his persistent error in regarding all flowering trees as epicarpous, and a number of them had been so treated by Jussieu and others, but to which Ray tried to give scientific foundation by denying the existence of buds in the later. At this time he based his classification, like Caesalpinus, chiefly upon the number of stamens; but Jussieu divided the dicotyledons into the grasses, Leguminosae, Umbelliferae and Populicacées. The classification of the Methodus was extended and improved in the Historia plantarum, which work was followed by a large class of Anamnoca, to include forms that the other orders did not easily admit, such as the separation of the cereals from other grasses. This vast book enumerates and describes all the plants known to the author or described by him. The genus De plantis contains an account of all the analogical and physiological knowledge of the time regarding plants, with the recent speculations on the discoveries of Caesalpinus, Grew, Malagam and J Jefferson, and Cavier and Duvetettich Thouras, declaring that it was this chapter which gave acceptance and authority to these authors' works, say that it was the best monument that could be erected to the memory of Ray would be the reprinting of the Methodus. The Stirpium Europarum extra Britannias syntology (1684) is a much ampliﬁed edition of the catalogue of plants collected by Ray in Europe. He begins by clearly admitted the doctrine of the sexuality of plants, which, however, he had no share in establishing. He also begins his long controversy with Riviñus (Augustus Quirinus Bachmann) which continued until the latter died (1706). Ray was the first to suggest the idea of vegetable plants, and also upon what he conceived to be the misleading reliance that Riviñus placed on the characters of the corolla. But in the second edition of his Methodus (1703) he followed Riviñus and J. P. de Tournefort in the flower groups of the latter's system of classification; he was no longer a fructist but a corolists.

In 1716 the editors of Ray's subjacent works, Ray wrote several zoological works of his own, including Synopsis methodica Animalium Quadrupedum et Serpentini Generis (1693), that is to say, both mammals and reptiles, and Synopsis methodica Avium et Piscium (1698). The latter work, also written in conjunction with his friend Willughby's books, Ray's most important Historia Insectorum (1710), which embodied a great mass of Willughby's notes.

Most of Ray's minor works were the outcome of his faculty for carefully massing facts; for instance, his Collection of English Proverbs (1679), his Collection of Out-of-the-way English Words (1674), his Collection of Curious Travels and Voyages (1693), and his Dictionarium trilingue (1675, 5th edition as Renumclator classicus, 1693). The last of these was last published posthumously by his pupils; it passed through many editions, and is still useful for its careful identifications of plants and animals mentioned by Greek and Latin writers. But Ray's influence and reputation have been limited largely to the advance of science and of God manifested in the Works of the Creation (1691), and Miscellaneous Discourses concerning the Dissolution and Changes of the World (1695), the latter to be found in the "General Deluge, its Causes and Effects," and "The Dissolution of the World and Future Conflagrations." The germ of these works was contained in sermons preached long before in Cambridge. Both books obtained immediate popularity, and the former, at least, was translated into several languages. In The Wisdom of God, &c., Ray recites innumerable examples of the perfection of organic mechanism, the multitude and variety of living creatures, the minuteness and usefulness of their parts, and many, if not most, of the familiar examples of purposeful adaptation and design in nature were suggested by him, such as the structure of the eye, the hollowness of the ear, the carriage of the animal, the organization of the brain, the use of the limbs, the constitution of God manifested in the Works of the Creation (1691), and Miscellaneous Discourses concerning the Dissolution and Changes of the World (1695), the latter to be found in the "General Deluge, its Causes and Effects," and "The Dissolution of the World and Future Conflagrations."
Mahomedan ruler; all who pay the haraj or poll-tax levied on unbelievers. Five classes of rayahs existed under Turkish rule.—(1) the Greeks, or Roum millet; (2) the Armenian, or Hrmeni millet; (3) the Catholic Armenians—cremeni gatoliki millet; (4) the Latin Christians, or Roum gatoliki millet; and (5) the Jews, or icanidi millet. The name rayah is most commonly used of the peasants, but it does not apply only to the agricultural populations. It depended on status, fixed by religious faith.

RAYLEIGH, JOHN WILLIAM STRUTT, 3rd baron (1842–1919), English physicist, was born in Essex on the 12th of November 1842, being the son of the 2nd baron.1 Going to Trinity College, Cambridge, he graduated as senior wrangler in 1865, and obtained the first Smiths' prize in mathematics the year following, being gained by Professor Alfred Marshall. He married in 1871 a sister of Mr A. J. Balfour, and succeeded to the title in 1873. From 1879 to 1884 he was Cavendish professor of experimental physics in the university of Cambridge, in succession to Clerk Maxwell; and in 1887 he accepted the post of professor of natural philosophy at the Royal Institution of Great Britain, which he resigned in 1905. His early mathematical and physical papers, written under the name of J. W. Strutt, made him known over Europe; and his powers rapidly matured until, at the death of Clerk Maxwell, he stood at the head of British physicists, Sir George Stokes and Lord Rayleigh being his alone exceptions. The special feature of his work is its extreme accuracy and definiteness; he combines the highest mathematical acumen with refinement of experimental skill, so that the idea of ranking him as higher in one department than another does not arise. His experimental investigations are carried out with plain and usually home-made apparatus, the accessories being crude and rough, but the essentials thoughtfully designed so as to compass in the simplest and most perfect manner the special end in view. A great part of his theoretical work consists in resurveying things supposed superficially to be already known, and elaborating their theory into precision and completeness. In this way he has gone over a great portion of the field of physics, and in many cases has either said the last word for the time being, or else started new and fruitful developments. Possessing an immense range of knowledge, he has filled up lacunae in nearly every part of physics, by experiment, by calculation, and by clear accurate thought. The following branches have especially felt his influence:—chemical physics, capillarity and viscosity, theory of gases, flow of liquids, photography, optics, colour vision, wave theory, electric and magnetic problems, electrical measurements, elasticity, sound and hydrodynamics. The numerous papers which he has contributed to the Philosophical Magazine were collected under his own editorship in four large volumes, the last of which was published in 1903.

His most extensive single work is a book on Sound, which, in the second edition, has become a treatise on vibrations in general. His familiarity with the methods of mathematical analysis and a certain refinement of taste in their application have resulted in great beauty of form. His papers are often difficult to read, but never diffuse or tedious; his mathematical treatment is never needlessly abstruse, for when his analysis is complicated it is only so because the subject-matter is complicated. On the other hand, superficially sensational there are few of his papers to record, and the weight of his work is for the most part to be appreciated only by professed physicists. One remarkable discovery, however, of general interest, was the outcome of a long series of delicate weighings and minute experimental care in the determination of the relative density of nitrogen gas—undertaken in order to determine the atomic weight of nitrogen—namely, the discovery of argon, the first of a series of new substances, chemically inert, which occur, some only in excessively minute quantities, as constituents of the air.2

The barony was created at George IV.'s coronation in 1821 for the wife of Joseph Strutt, Esq. (fl. 1813), of Maldon (1790–1826) and Okehampton (1826–1830), who had done great service during the French War as colonel of the Essex militia. He died in 1845, his wife, the baroness, predeceasing him in 1836. Their son (d. 1873) was the 2nd baron.

Lord—Raymond of Sabunde

Earth's atmosphere. Lord Rayleigh had an interest in abnormal psychological investigations, and became a member and vice-president of the Society for Psychical Research. He was one of the original members of the Order of Merit, instituted in connexion with the coronation of King Edward VII. In 1904 he was awarded a Nobel prize, and at the end of 1905 he became president of the Royal Society, of which he had been elected a fellow in 1873, and had acted as secretary from 1885 to 1896. He remained president till 1906, in which year he was chosen to succeed the 8th duke of Devonshire as chancellor of Cambridge University.

For a popular but authentic account of some of Lord Rayleigh's scientific work and discoveries, see an article by Sir Oliver Lodge in the National Review for September 1898.

RAYMOND, HENRY JARVIS (1820–1866), American journalist, was born near the village of Lima, Livingston county, New York, on the 24th of January 1820. He graduated from the university of Vermont in 1840. After assisting Horace Greeley (q.v.) in the conduct of more than one newspaper, Raymond in 1851 formed the firm of Raymond, Jones & Co., and the first issue of the New York Times appeared on the 18th of September 1851; of this journal Raymond was editor and chief proprietor until his death. Raymond was a member of the New York Assembly in 1850 and 1851, and in the latter year was speaker. He supported the views of the radical anti-slavery party in the Convention of 1860, and when editor of the New York Sun he threw his influence on the side of Mr. Greeley on the Whig ticket for lieutenant-governor in 1854 led to the dissolution of the famous political "firm" of Seward, Weed and Greeley. Raymond was elected, and served in 1854–56. He took a prominent part in the formation of the Republican party, and drafted the famous "Address to the People" adopted by the Republican convention which met in Pittsburg on the 22nd of February 1856. In 1861 he was again a member, and speaker, of the New York Assembly. During the Civil War he supported Lincoln's policy in general, though deprecating his delays, and he was among the first to urge the adoption of a broad and liberal attitude in dealing with the people of the South. In 1865 he was a delegate to the National Republican Convention, and was made a member, and chairman, of the Republican National Committee. He was a member of the National House of Representatives in 1865–67, and on the 22nd of December 1865 he ably attacked Thaddeus Stevens's theory of the "dead" states, and, agreeing with the President, argued that the states were never out of the Union, inasmuch as the ordinances of secession were null. In consequence of this, of his prominence in the Loyalist (or National Union) Convention at Philadelphia in August 1866, and of his authorship of the "Address and Declaration of Principles," issued by the convention, he lost favour with his party. He was removed from the chairmanship of the Republican National Committee in 1866, and in 1867 his nomination as minister to Austria, which he had already refused, was rejected by the Senate. He retired from public life in 1867 and devoted his time to newspaper work until his death in New York city on the 18th of June 1869. Raymond was an able and polished public speaker; one of his best known speeches was a greeting to Kosuth, whose cause he warmly defended. But his great work was in elevating the style and general tone of American journalism. He published several books, including a biography of President Lincoln—The Life and Public Services of Abraham Lincoln (1865), which in substance originally appeared as A History of the Administration of President Lincoln (1864).

RAYMOND OF SABUNDE, or Sabiende (fl. 1434), Spanish scholar, was a teacher of medicine and philosophy and finally regius professor of theology at Toulouse. His Liber naturae sive creaturarum, &c. (written 1434–36), marks an important stage in the history of Natural Theology. The book was directed against the position then generally held, that reason and faith,
RAYMUND OF ANTIΟCH—RAYMUND OF TOULOUSE

philosophy and theology were antithetical and irreconcilable. Raymund declares that the book of Nature and the Bible are both Divine revelations, the one general and immediate, the other specific and mediate. The Edithi Princis of the book, which found many imitators, is undated but probably belongs to 1484; there are many subsequent editions, one by J. F. von Seidel as late as 1852. In 1595 the Prolagus was put on the Index for its declaration that the Bible is the only source of revealed truth. Montaigne (Essais, bk. ii. ch. xii., "An Apology of Raymond Sebond") tells how he translated the book into French and found "the concis of the author to be excellent, the contexture of his work well followed, and his project full of pietie. . . . His drift is bold, and his scope adventurous, for he undertaketh by humane and natural reasons, to establish and verify all the articles of Christian religion against Atheists."

See D. Beulet, Un Inconnu célèbre: recherches historiques et critiques sur Raymond de Sabunde (Paris, 1875).

RAYMUND, prince of Antioch (1099–1149), was the son of William VI., count of Poltou. On the death of Bohemund II. of Antioch (*), the principality devolved upon his daughter, Constance, the wife of Marra (1130) Fulk, the king of Jerusalem, and, as such, guardian of Antioch, was concerned to find a husband for her, and sent envoys to England to offer her hand to Raymund, who was then at the court of Henry I. Raymund accepted the offer, and stealing in disguise through southern Italy, for fear of apprehension by Roger of Sicily, who claimed the inheritance of Antioch as cousin of Bohemund I., he reached Antioch in 1135. Here he was married to Constance by the patriarch, but not until he had done him homage and fealty. The marriage excited the indignation of Alice, the mother of Constance, who had been led by the patriarch to think that it was she whom Raymund desired to wed; and the new prince had thus to face the enmity of the princess dowager and her party. In 1137 he had also to face the advent of the eastern emperor, John Comnenus, who had come south partly to recover Cilicia from Leo, the prince of Armenia, but partly, also, to assert his rights over Antioch. Raymund was forced to do homage, and even to promise to cede his principality as soon as he was recompensed by a new fief, which John promised to carve for him in the Mahommedan territory to the east of Antioch. The expedition of 1138, in which Raymund joined with John, and which was to conquer this territory, naturally preceded a pretended anxiety to help the emperor to acquire new territories, when their acquisition only meant for him the loss of Antioch; and John had to return unsuccessful to Byzantium, after vainly demanding from Raymund the surrender of the citadel of Antioch. There followed a struggle between Raymund and the patriarch. Raymund was annoyed by the homage which he had been forced to pay to the patriarch in 1135; and the dubious validity of the patriarch's election offered a handle for opposition. Eventually Raymund triumphed, and the patriarch was deposed (1139). In 1142 John Comnenus returned to the attack; but Raymund refused to recognize or renew his previous submission; and John, though he ravaged the neighbourhood of Antioch, was unable to effect anything against him. When, however, Raymund demanded from Manuel, who had succeeded John in 1143, the cession of some of the Cilician towns, he found that he had met his match. Manuel forced him to a humiliating visit to Constantinople, during which he renewed his oath of homage and promised to receive a Greek patriarch. The last event of importance in Raymund's life was the visit to Antioch in 1148 of Louis VII. and his wife Eleanor, Raymund's niece. Raymund sought to prevent Louis from going south to Jerusalem, and to induce him to stay in Antioch and help in the conquest of Aleppo and Caesarea. Perhaps for this end he acquired an influence over his niece, which was by some interpreted as a guilty intimacy. At any rate Louis hastily left Antioch, and Raymund was balked in his plans. In 1149 he fell in battle during an expedition against Nureddin. Raymund is described by William of Tyre (the main authority for his career) as handsome and affable; pre-eminent in the use of arms and military experi-

ence; litteratorum, licet ipse litteratus esset, culor (he caused the Chanson des châtelains to be composed); a regular churchman and a faithful husband; but headstrong, irascible and unreasonable, with too great a passion for gambling (bk. xiv. c. xxii.).

For his career see Rey, in the Revue de l'orient latin, vol. iv. (E. Br.)

RAYMUND OF TOULOUSE (sometimes also called Raymund of St Gilles, after a town to the south of Nimes), count of Provence, one of the leaders of the first Crusade. According to an Armenian authority, he had lost an eye on a pilgrimage to Jerusalem before the first Crusade; but the statement probably rests on the fact that he was one-eyed, *sir monocus*. He is also recorded to have fought against the Moors in Spain before 1096; and it is certain that he was the first of the princes of the West to take the cross after Pope Urban's sermon at Clermont. The oldest and the richest of the crusading princes, the count of Provence started, at the end of October 1096, with a large company, which included his wife, his son, and Adhemar, bishop of Puy, the Papal Legate. His march lay through Ragusa and Senartu to Durazzo, whence he struck eastward, along the route also used by Bohemund. At Durazzo (now Durazzo-Butrinti), in 1097 he was with difficulty induced to take a somewhat negative oath of fealty to Alexius; for the obstinacy which was one of his characteristics, coupled perhaps with some hope of acquiring new territories, made him reluctant to submit like the other crusaders to Alexius. He was present at Nicaea and Dory-

laem; but he first showed his hand in October 1097, when, as the army neared Antioch, and a rumour was spread that Antioch had been deserted by the Turks, he sent a detachment in advance to occupy the city—an action which presaged his future difficulties with Bohemund, the would-be prince of Antioch. In the siege of Antioch (which was far from having been deserted) Raymund played his part. When the city was taken by Bohemund (June 1098), the count garrisoned the *palatium Cassiant* (the palace of the emir, Yagi Sian) and the tower over the Bridge Gate. He lay ill during the second siege of Antioch by Kerbogha; but in his camp a great spiritualistic activity culminated in the discovery of the Holy Lance by the Provençals. The miracle stimulated the crusaders to defeat Kerbogha: the Lance itself, discovered by the Provençals and carried hencedward by their count, became a valuable asset in Raymund's favour; and he began to put difficulties in the way of Bohemund's pretensions. Raymund's son (whom he had raised to the dignity of prince) was not averse to the oath to Alexius, and refusing to surrender the positions in the city which he had occupied. A struggle thus arose between the Provençals and the Normans, partly with regard to the genuine-

ness of the Lance, which the Normans naturally doubted, and partly with regard to the possession of Antioch—the real issue at stake. Raymund was the first of the princes to leave Antioch, moving southward in the autumn of 1098 to the siege of Marra, but leaving a detachment of his troops in Antioch. With Boh-

emund left behind in Antioch; with the possession of the Holy Lance to give him prestige; and with the wealth which he had at his disposal, the count of Provence now definitely began to figure as the leader of the Crusade. If he could have consented to leave Bohemund in possession of Antioch and push south-

ward, he might have achieved much. But he could not stomach the greatness of Bohemund; and when the Normans turned his troops out of Antioch in January 1099, he marched from Marra (which had been captured in December 1098) into the emirate of Tripoli, and began the siege of Arca (February 1099), evidently with the idea of founding a power in Tripoli which would check the expansion of Bohemund's principality to the south. The siege of Arca was protracted; and the selfish policy of the count which thus deferred the march to Jerusalem forced him all support from the mass of the crusaders. A wave of indignation in the ranks, and the inducements which the emir of Tripoli offered to the other princes, forced Raymund to desist from the siege (May 1098), and to march southwards to Jerusa-

lem. After the capture of Jerusalem, Raymund was offered, but refused, the advocacy of the Holy Sepulchre. He alleged his reluctance to rule in the city in which Christ had suffered:
it is perhaps permissible to suspect that he hankered for the principality of Tripoli and the renewal of hostilities with Bohemund. As at Antioch, so at Jerusalem, he fell into strife with the new ruler; and it was only with difficulty that Godfrey was able to secure from him the possession of the Tower of David, which he had originally occupied. The grasping nature of Raymundo again appeared after the battle of Ascalon, when his eagerness to occupy Ascalon for himself prevented it from being occupied at all; while Godfrey also blamed him for the failure of his army to capture Arsuf. It almost seems as if the count could not appear without becoming a centre of storms; and when he went forth in 1090-1091 to the first crusade, Raymundo grew wary and put one of hostility against Bohemund, from whom he helped to wrest Laodicea. From Laodicea he went to Constanti-

nople, where he fraternized with Alexius, the great enemy of his own enemy Bohemund. Joining in the ill-fated Crusade which followed in the wake of the First, he was successful in escaping from the débâcle, and returning to Constantinople.

In 1102 he came by sea from Constantinople to Antioch, where he was imprisoned by Tancred, regent of Antioch during the cap-
tivity of Bohemund, and only dismissed upon promising not to attempt any conquests in the country between Antioch and Acre. He broke his promise, attacking and capturing Tortosa, and beginning to build a castle for the reduction of Tripoli (on the Mons Peregirinus). In this policy he was aided by Alexius, who was naturally willing to see the erection of a tributary county of Tripoli to the south of Bohemund's principality. In 1105 Raymundo died. He was succeeded by his nephew William, who in 1109, with the aid of Baldwin I, captured the town and definitely established the county of Tripoli. William was ousted in the same year by Raymundo's eldest son Bertrand, and the county continued in the possession of his house during the 12th century. Raymundo of Toulouse represents the Provencal element in the first Crusade, as Bohemund represents the Norman, and Godfrey and Baldwin the Lotharingian. Religiosity, obstinacy and greed seem curiously blended in his composition. The first quality appears in the episode of the Lance, and in his renuncia-
tion of the advocacy of Jerusalem: the second appears in the whole of his attitude to Bohemund: the third appears again and again, whenever the progress of the Crusades brought any new conquest. If in temperament he is the least attractive among the princes of the first Crusade, he was yet one of its foremost leaders, and he left his mark upon history in the foundation of the county of Tripoli.

Raymundo of Agiles, a clerk in the Provencal army, gives the history of the first campaign from the western point of view. For a modern account of Count Raymundo's part in the crusading movement, one may refer to Röhrich's works (see Crusades).

RAYMUND OF TRIPOLI, the most famous of the descendants of Raymundo of Toulouse, was a great-grandson of his eldest son Bertrand: his mother was Hodliena, a daughter of Baldwin II., and through her he was closely connected with the kings of Jerusalem. He became count of Tripoli in 1152, on the assassination of his father. In 1164 he was captured by Nur-
eddin, and was only released in 1172 after a captivity of eight years. In 1174 he claimed the regency on behalf of Baldwin IV. (at once a minor and a leper), in virtue of his close relationship; and the claim was acknowledged. After two years the regency seems to have passed to Reginald of Châtillon; but Raymundo, who had married the heiress of the county of Tibersias, continued to figure in the affairs of the kingdom. His great ability procured him enemies; for two years, 1180-1182, Baldwin IV. was induced by evil advisers to exclude him from his territories. But as Saladin grew more threatening, Raymundo grew more indispensable; and in 1184 he became regent for Baldwin V., on condition that, if the king died before his majority, his successor should be determined by the great powers of the West. Raymundo conducted the regency with skill, securing a truce from Saladin in 1185; but when Baldwin V. died, in 1186, all went wrong. Raymundo summoned an assembly of the barons to Naplous to deliberate on the situation; but while they deliber-
ated, the supporters of Guy de Lusignan (the husband of Baldwin IV.'s sister, Sibylla) acted, and had him crowned, in defiance of the stipulation under which Raymundo had become regent. The rest of the barons came over to Guy; and Raymundo, left in isolation, retired to Tiberies and negotiated a truce for himself with Saladin. His ambiguous position led contemporaries to accuse him of treasonable correspondence with Saladin; but his loyalty to the Christian cause was nobly shown in 1187, when he accosted himself to Guy, and aided him in the battle of Hattin, which was engaged, however, in the teeth of his earnest advice. He escaped from the battle wounded, and ultimately retired to Tripoli, where he died (1187).

In the corrupt society of the latter days of the kingdom of Jerusalem, Raymundo showed himself at least as disinterested as any other man, and certainly more capable than the rest of his contemporaries. He might have saved Jerusalem, if Jerusalem could have been saved; but he was the vox clamantis in deserto. "He is worthy of the throne," wrote a contemporary Arabic chronicler: "he seems destined for it by nature, who has given him pre-eminent wisdom and courage, and who has protected his person with his sword, and has proved himself to be a model of virtue and truth, and the most beneficent of men."

RAYNAL, GUILLAUME THOMAS FRANÇOIS (1733-1796), French writer, was born at Saint-Geniez in Rouergue on the 13th of April 1713. He was educated at the Jesuit school of Pézenas, and received priest's orders, but he was dismissed for unexplained reasons from the parish of Saint-Sulpice, Paris, to which he was attached, and thenceforward he devoted himself to society and literature. The Abbé Raynal wrote for the Mercure de France, and compiled a series of popular and superficial works, which he published and sold himself. These—L'Histoire du stathoudert (The Hague, 1748), L'Histoire du commerce d'Angleterre (London, 1748), Anecdotes historiques (Amsterdam, 3 vols., 1753)—gained for him access to the salons of Mme. Geoffrin, Helvétius, and the baron d'Holbach. He had the assistance of various members of the philosophe coterie in his most important work, L'Histoire philosophique et politique des établissements et du commerce des Européens dans les deux Indes (Amsterdam, 4 vols., 1770). Diderot indeed is credited with a third of this work, which was characterized by Voltaire as "du réchauffé avec de la déclamation." The other chief collaborators were Pechmêa, Holbach, Paulze, the farmer-general of taxes, the Abbé Martin, and Alexandre Deleyre. To this piecemeal method of composition, in which narrative was mixed with tirades on political and social questions, was added the further disadvantage of the lack of exact information, which, owing to the dearth of documents, could only have been gained by personal investigation. The "philosophic" declama-
tions perhaps constituted its chief interest for the general public, and its significance as a contribution to democratic propaganda. The Histoire went through many editions, being revised and augmented from time to time by Raynal; it was translated into the principal European languages, and appeared in various abridgments. Its introduction into France was suppressed in 1779; the book was burned by the public executioner, and an order was given against the author, whose name had not appeared in the first edition, but was printed on the title page of the Geneva edition of 1780. Raynal escaped to Spa, and thence to Berlin, where he was coolly received by Frederick the Great, in spite of his connexion with the philosophe party. At St Petersburg he met with a more cordial reception from Catherine II., and in 1787 he was permitted to return to France, though not to Paris. He showed generosity in assigning a considerable income to be divided annually among the peasant proprietors of upper Guinne. He was elected by Marselles to the States-general, but refused to sit on the score of age. Raynal realized the impossibility of a peaceful revolution, and, in terror of the proceedings for which he was, in writings of himself and his friends had prepared the way, he sent to the Constituent Assembly an address, which was read on the 31st of May 1791, deprecating the violence of its reforms. This address is said
RAYNALD of CHÂTILLON—RAYNAUD

RAYNALD (in the preceding pages) has been named in connection with various tales and stories. In his lifetime, his name was associated with a number of events and occurrences that have come to be known as Raynal's Disease. The nature of Raynal's Disease is still not fully understood, but it is believed to be caused by a combination of factors, including environmental and genetic influences.

RAYNALD's disease is characterized by symptoms such as tingling, numbness, and pain in the extremities. These symptoms are often accompanied by a loss of sensation in the affected areas. The disease is typically progressive, meaning that it gets worse over time.

The cause of Raynal's Disease is not fully understood, but it is believed to be related to the way that blood flows through the body. In some cases, the disease may be caused by a blockage of the blood vessels, which can lead to a loss of sensation in the affected areas.

There is no known cure for Raynal's Disease, but there are treatments available that can help to manage the symptoms. These treatments may include medication, physical therapy, and lifestyle changes.

In conclusion, Raynal's Disease is a complex and challenging condition that affects many people around the world. Further research is needed to better understand the causes and potential treatments for this disease.
and practised at Draguignan. In 1791 he went to Paris as deputy to the Legislative Assembly, but after the fall of the Girondists, to whose party he was attached, he had to go into hiding. He was, however, discovered and imprisoned in Paris. During his imprisonment he wrote his play *Caton d’Utile* (1794). *Œuvres de Bavières et Les Templiers* were accepted by the Comédie Française. *Les Templiers* was produced in 1805, and, in spite of the protests of Geoffroy, had a great success. Raynouard was admitted to the Academy in 1807, and from 1817 to 1826 he was perpetual secretary. He wrote other plays, in one of which, *Les États de Blavenné* (acted 1819), he gave offence to Napoleon by his freedom of speech, but, realizing that the public taste had changed and that the romanticists were to triumph, he abandoned the stage and gave himself up to linguistic studies. He was admitted to the Academy of Inscriptions in 1815. His researches in the Provençal dialect were somewhat inexact, but his enthusiasm and perseverance promoted the study of the subject. His chief works are *Choix de poètes originaux des troubadours* (6 vols., 1816–1821), of which the sixth volume, *Grammaire comparée des langues de l’Europe latine dans leurs rapports avec la langue des troubadours* (1821), was separately published; *Lexique roman* (6 vols., 1828–1844). He spent the last years of his life at Passy, where he died on the 27th of October 1836.

**RAZGRAD**—**RAZORBILL**

**RAZGRAD,** the capital of the department of Razgrad, Bulgaria, on the river Bieli-Lom, 40 m. S.E. of the Danubian port of Rustchuk by the Varna-Rustchuk railway. Pop. (1900) 13,783, about one-third being Moslems. The railway station is at Inbeketchi, 2 m. N. Razgrad possesses a fine mosque, built by Ibrahim Pasha in 1614. Many Turkish families emigrated after the Russo-Turkish War of 1877, but since then the population has again increased, and the town has a thriving agricultural and general trade. Carpet-weaving and viticulture are important local industries. On the 13th of June 1810 and the 14th of August 1877 Razgrad was the scene of battles between the Turks and Russians.

**RAZIN, STEPHEN TIMOFEEVICH** (d. 1671), Cossack hetman and rebel, whose parentage and date and place of birth are unknown. We first hear of him in 1661 on a diplomatic mission from the Don Cossacks to the Kalmuk Tatars, and in the same year we meet him on a pilgrimage of a thousand miles to the great Solovetsky monastery on the White Sea "for the benefit of his soul." After that all trace of his is lost for six years, when he reappears as the leader of a robber community established at Panshinskoe, among the Tatars and Cossacks between the rivers Tishina and Ilovlya, from whence he levied blackmail on all vessels passing up and down the Volga. His first considerable exploit was to destroy the "great water caravan" consisting of the treasury-barges and the barges of the patriarch and the wealthy merchants of Moscow. He then sailed down the Volga with a fleet of thirty-five galleys, capturing the more important forts on its way and devastating the country. At the beginning of 1668 he defeated the voivode Jakov Bezobrazov, sent against him from Astrakhan, and in the spring embarked on a predatory expedition into Persia which lasted for eighteen months. Sailing up the Caspian, he ravaged the Persian coasts from Derbend to Baku, massacred the inhabitants of the great emporium of Resht, and in the spring of 1669 established himself on the isle of Sinaia, off which, in July, he annihilated a Persian fleet sent against him. Stenka,¹ as he was generally called, had now become a potentate with whom princes did not disdain to treat. In August 1669 he reappeared at Astrakhan, and accepted a fresh offer of pardon from the tsar there; the common people were fascinated by his adventures. The semi-Asiatic kingdom of Astrakhan, where the whole atmosphere was predatory and nine-tenths of the population were nomadic, was the natural milieu for such a rebellion as Stenka Razin's. In 1670 Razin, while ostensibly on his way to report himself at the Cossack headquarters on the Don, openly rebelled against the government, captured Cherkask, Tsaritsyn and other places, and on the 24th of June burst into Astrakhan itself. After massacring all who opposed him, and giving the rich bazaars of the city over to pillage, he converted Astrakhan into a Cossack republic, dividing the population into thousands, hundreds and tens, with their proper officers, all of whom were appointed by a *vyetcha* or general assembly, whose first act was to proclaim Stephen Timofeevitch their *gosudar* (sovereign). After a three weeks' carnival of blood and deaohchery Razin quitted Astrakhan with two hundred barges full of troops to establish the Cossack republic along the whole length of the Volga, as a preliminary step towards advancing against Moscow. Saratov and Samara were captured, but Simbirsk defied all efforts, and after two bloody encounters close at hand on the banks of the Volga (October 1st and 4th), Razin was ultimately routed and fled down the Volga, leaving the bulk of his followers to be exterminated by the victors. But the rebellion was by no means over. The emissaries of Razin, armed with inflammatory proclamations, had stirred up the inhabitants of the modern governments of Nizhny-Novgorod, Tambov and Penza, and penetrated even so far as Moscow and Great Novgorod. It was not difficult to revolt the oppressed population by the promise of deliverance from their yoke. Razin proclaimed that his object was to root out the boyars and all officials, to level all ranks and dignities, to destroy the Cossack order, and to establish a republic, the corolla of which is borned throughout Muscovy. Even at the beginning of 1671 the issue of the struggle was doubtful. Eight battles had been fought before the insurrection showed signs of weakening, and it continued for six months after Razin had received his quiets. At Simbirsk his prestige had been shattered. Even his own settlements at Saratov and Samara refused to open their gates to him, and the Don Cossacks, hearing that the patriarch of Moscow had anathematized Stenka, also declared against him. In 1671 he was captured at Kagalnik, his last fortress, and carried to Moscow, where, on the 6th of June, after bravely confessing to no disputable crimes, he was quartered alive. See N. I. Kostomarow, *The Rebellion of Stenka Razin* (Russ.) (2nd ed., Petersburg, 1899); S. M. Solovev, *History of Russia* (Russ.), vol. ii. (Petersburg, 1895, &c.); R. N. Bain, *The First Romansovs* (London, 1905). *(R. N. B.)*

**RAZOR** (O.F. *rasor*, mod. *rasor*, from *raser*, to scrape, *ras*, Late Lat. *rasare*, frequentative of *radere*, to scrape), a sharp-edged cutting instrument, used for shaving the hair and beard. The typical razor consists of a blade, usually curving slightly backward, folding into a handle, to which it is fastened by a tang and two dovetail or other projections. In 1786 he was quartered alive. See N. I. Kostomarow, *The Rebellion of Stenka Razin* (Russ.) (2nd ed., Petersburg, 1899); S. M. Solovev, *History of Russia* (Russ.), vol. ii. (Petersburg, 1895, &c.); R. N. Bain, *The First Romansovs* (London, 1905). *(R. N. B.)*

**RAZOR**—**RAZORBILL**

**RAZORBILL,** or **RAZOR-BILLED AUK,** known also on many parts of the British coasts as the Marrot, Murre, Scout, Tinker or Willock—names which it, however, shares with the *Guillemot* (q.v.) and to some extent with the *Puffin* (q.v.)—a common sea-bird of the North Atlantic,¹ resorting in vast numbers to certain rocky cliffs for the purpose of breeding, and returning to the same places for the rest of the year. It is the *Alca torda* of Linnaeus, ² and among zoologists is usually called the *Auk* or *Mrs. gull* (q.v.), if not with the true Guillemots, between which two forms it is intermediate—differing from the former in its small size and retaining the power of flight, which that extinct species had lost, and from the latter in its peculiarly-shaped bill, which is vertically enlarged, compressed, and deeply furrowed, as well as in its elongated, wedge-shaped tail. A fine white line, running

¹ Schlegel (Mus. des Pays-Bas, Uroïntes, p. 14) records an example from Japan; but this must be in error.

² The word *Alca* is simply the Latinized form of this bird's common Teutonic name, *Alk*, of which Auk is the English modification. It must therefore be held to be the type of the Linnaean genus *Alca*, though some systematists on indefensible grounds have transferred it thence, making it the sole member of a genus named by Leach, after Aldrovanus (Ornithologia, bk. xix. chap. xli.), *Ulamania*—an extraordinary word, that seems to have originated in some mistake from the no less extraordinary *Vulturina*, given by Belon (Observations, t. c. xli) as the Cretan name of some diving bird, which could not have been the present species.
on each side from the base of the culmen to the eye, is in the adult bird in breeding-apparel (with rare exceptions) a further characteristic. Otherwise the appearance of all these birds may be briefly described in the same words—head, breast and upper parts generally of a deep glossy black, and the lower parts and tip of the secondaries of a pure white, while the various changes of plumage do not on age or season rank like in all. In hables the razorbill closely agrees with the true guillemots, laying its single egg (which is not, however, subject to the same variety of coloration as in the guillemot) on the ledges of cliffs, but it is said as a rule to occupy higher elevations, and when not breeding to keep farther out to sea. On the east side of the Atlantic the Razorbill has its breeding stations from the North Cape to Brittany, besides several in the Baltic, while in winter it passes much farther to the southward, and is sometimes numerous in the Bay of Gibraltar, occasionally entering the Mediterranean, but apparently never extending east of Sicily or Malta. On the west side of the Atlantic it breeds from 70° N. lat. on the eastern shore of Baﬁn’s Bay to Cape Farewell, and again on the coast of America from Labrador and Newfoundland to the Bay of Fundy, while in winter it reaches Long Island. (A. N.)

RAZZIA (an adaptation of the Algerian Arabic ghāzūsh, from ghassu, to make war), a foray or raid made by African Moslems. As used by the Arabs, the word denotes a military expedition against rebels or infidels, and razzias were made largely for punishment of hostile tribes or for the capture of slaves. English writers in the early years of the 19th century used the form grazzi, and Dixon Denham in his Travels (1826) styles the raiding force itself the grazzi. The modern English form is copied from the French, while the Portuguese variant is gaza gusas.

RE, the Egyptian solar god, one of the most important figures in the Pantheon. See Egypt, section Egyptian Religion.

RÉ, ÎLE DE, an island of western France, belonging to the department of Charente-Inférieure, from the nearest mainland point of which it is distant about 2 m. The island has an area of nearly 33 sq. m., with a breadth varying from 1 to 4½ m. and a length of 15 m. It is separated from the coast of Vendée on the N. by the Pertuis Breton, some 8 m. broad, and from the island of Oleron on the S. by the Pertuis D’Antioche, 7½ m. broad. The coast facing the Atlantic is rocky and inhospitable, but there are numerous harbours on the landward side, of which the busiest is La Flotte. Towards the north-west extremity of the island there is a deep indentation, the Fier d’Ars, which leaves an isthmus only 230 ft. wide, strengthened by a breakwater. The north coast is fringed by dunes and by the salt-marches which are the chief source of livelihood for the inhabitants. Some of them are employed in fishing, oyster-cultivation and the collection of seaweed for manure; the island has corn-lands and vineyards, the latter covering about half its surface, and produces good figs and pears. Apart from its orchards it is now woodland, though once covered by forests. There are two cantons, St Martin (pop. in 1906, 8363) and Ars-en-Ré (pop. 4711) forming part of the arrondissement of La Rochelle. St Martin, the capital, which has a secure harbour and trade in wine, brandy, salt, &c., was fortified by Vauban in 1681 and used to be the depot for convicts on their way to New Caledonia. In 1627 it repulsed an English force after a siege of three months.

READE, CHARLES (1814-1884), English novelist and dramatist, the son of an Oxfordshire squire, was born at Ipsden, Oxfordshire, on the 8th of June 1814. He entered Magdalen College, Oxford, proceeded B.A. in 1835, and became a fellow of the college in 1837. He subsequently became president of Magdalen College, taking his degree of D.C.L. in 1847. His name was entered at Lincoln’s Inn in 1836; he was elected Vinerian Fellow in 1842, and was called to the bar in 1843. He kept his fellowship at Magdalen all his life, but after taking his degree he spent the greater part of his time in London. He began his literary career as a dramatist, and it was his own wish that the word “dramatist” should stand first in the description of his occupations on his tombstone. He was dramatist first and novelist afterwards, not merely chronologically but in his aims as an author, always having an eye to stage-effect in scene and situation as well as in dialogue. His first comedy, The Ladies’ Battle, appeared at the Olympic Theatre in May 1851. It was followed by Angelo (1851), A Village Tale (1852), The Lost Husband (1852), and Gold (1853). But Reade’s reputation was made by the two-act comedy, Jack or Fart, on which he collaborated with Tom Taylor. It was produced in November 1852, and later was expanded into three acts. By the advice of the actress, Laura Seymour, he turned the play into a prose story which appeared in 1853 as Peg Woffington. He followed this up in the same year with Christie Johnstone, a close study of Scottish fisher folk, an extraordinary tour de force for the son of an English squire, whether we consider the dialect or the skill with which he enters into alien habits of thought. In 1854 he produced, in conjunction with Tom Taylor, Two Loves and a Life, and The King’s Rival; and, unaided, The Courier of Lyons—well known under its later title, The Lyons Mail—and Peregrine Pickle. In the next year appeared Ari, afterwards known as Nonce Oldfadd.

He made his name as a novelist in 1856, when he produced It’s Never Too Late to Mend, a novel written with the purpose of reforming abuses in prison discipline and the treatment of criminals. He described prison life with a fidelity which becomes at times tedious and revolting; but the power of the descriptions was undeniable, and the interest was profound. The truth of some of his details was challenged, and the novelist defended himself with vigour against attempts to rebut his contentions. Five minor novels followed in quick succession, The Courier of True Love never did run away (1856), Just all Trades (1858), The Autobiography of a Thug (1858), Love Me Little, Love Me Long (1859), and White Lies (1860), dramatized as The Double Marriage. Then appeared, in 1861, his masterpiece, The Cloister and the Hearth, relating the adventures of the father of Erasmus. He had dealt with the subject two years before in a short story in Once a Week, but, seeing its capabilities, expanded it; and the work is now recognized as one of the finest historical novels in existence. Returning from the 19th century to modern English life, he next produced another startling novel with a purpose, Hard Cash (1863), in which he strove to direct attention to the abuses of private lunatic asylums. Three more such novels, in two of which at least the moral purpose, though fully kept in view, was not allowed to obstruct the flow of incident, were afterwards undertaken,—Foul Play (1869), in which he exposed the iniquities of shipknackers, and paved the way for the labours of Samuel Plimsoll; Put Yourself in his Place (1870), in which he grappled with the tyrannous outrages of trades-unions; and A Woman-Hater (1877), in which he exposed the degrading conditions of village life. The Wondering Heiress (1873), of which he also wrote a version for the stage, was suggested by the Tichborne trial. Outside the line of these moral and occasional works Reade produced three elaborate studies of character, Griffith Gaunt (1866), A Terrible Temptation (1871), A Simpleton (1873). The first of these was in his own opinion the best of his novels, and his own opinion was probably right. He was wrong, however, in his own conception of his powers as a dramatist. At intervals throughout his literary career he sought to gratify his dramatic ambition, hiring a theatre and engaging a company for the representation of his own plays. An example of his persistency was seen in the case of Foul Play. He wrote this in 1869 in combination with Mr Dion Boucicault, with a view to stage adaptation. The work was more or less a failure; but he produced another version alone in 1877, under the title of A Scuttled Ship, and the failure was pronounced. His greatest success as a dramatist attended his last attempt,—Drink—an adaptation of Zola’s L’Assommoir, produced in 1879. In that year his friend Laura Seymour, who had kept house for him since 1854, died. Reade’s health failed from that time, and he died on the 11th of April 1884, leaving behind him a completed novel, A Perilous Secret, which showed no falling off in the arts of weaving a complicated plot and devising thrilling situations.
Reade was an amateur of the violin, and among his works is an essay on Cremona violins with the title, *A Lost Art Revived*.

It was characteristic of Reade's open and combative nature that he admitted the public freely to the secrets of his method of composition. He spoke about his method freely for twenty years, after he introduced himself into one of his novels—"Dr Rolfe" in *A Terrible Temptation*; and by his will he left his workshop and his accumulation of materials open for inspection for two years after his death. He had collected an enormous mass of materials for his study of human nature, from personal observation, from newspapers, books of travel, blue-books of commissions of inquiry, from miscellaneous reading. This vast collection was classified and arranged in huge ledgers and notebooks. He had planned a great work on "the wisdom and folly of nations," dealing with social, political and domestic details, and it was chiefly for this that his collection was destined, but in passing he found the materials useful as a store of incidents and suggestions. A collector of the kind was bound to be systematic, otherwise his collection would have fallen into confusion, and Reade's collection contains many curiosities in classification and tabulation. On the value of this method for his art there has been much discussion, the prevalent opinion being that his imagination was overwhelmed and stifled by it. He himself maintained the contrary; and it must be admitted that a priori critics have not rightly understood the use that he made of his laboriously collected facts. He did not merely shuffle the contents of his notebooks into his novels; they served rather as an atmosphere of reality in which he worked, so that his novels were like pictures painted in the open air. His imagination worked freely among them and was quickened rather than impeded by their suggestions of things suited to the purpose in hand; and it is probably to his close and constant contact with facts, acting on an imagination naturally fertile, that we owe his marvellous abundance of incident. Even in his novels of character there is no meditative and analytic stagnation; the development of character is shown through a rapid unceasing progression of significant facts. This rapidity of movement was perhaps partly the result of his dramatic studies; it was probably in writing for the stage that he learned the value of keeping the attention of his readers incessantly on the alert. The hankering after stage effect, while it saved him from dullness, often betrayed him into rough exaggeration, especially in his comic scenes. But the gravest defect in his work is a defect of temper. His view of human life, especially of the life of women, is almost brutal; his knowledge of frailties and vices is obtruded with repellent force; and he cannot, with all his skill as a story-teller, be numbered among the great artists who warm the heart and help to improve the conduct. But as a moral satirist, which was the function he professed over and above that of a story-teller, he did good service, both indirectly in his novels and directly in his own name.

**READING**

A municipal, county and parliamentary borough and the county town of Berkshire, England, 36 m. W. by S. of London by the Great Western railway. Pop. (1901) 72,217. It is an important junction on the Great Western system, and has communication southward by a joint line of the South-Western and South-Eastern and Chatham companies. The Kennet and Avon canal, to Bath and Bristol, and the Thames, afford it extensive connexions by water. It lies in the flat valley of the Thames on the south (right) bank, where the Kennet joins the main river. The population more than doubled in the last thirty years of the 19th century, and the town is of modern appearance. All the ancient churches are much restored and in part rebuilt. Greyfriars church, formerly monastic, was completed early in the 14th century; and after the dissolution of the monasteries served successively as a town hall, a workhouse and a gaol, being restored to its proper use in 1864. St Mary's is said to have been rebuilt in 1551 from the remains of a nunnery founded by Ælfthryth in expiation of the murder of her stepson Edward the Martyr. St Lawrence's is a large Perpendicular building, and St Giles's, in various styles, was much damaged during the siege of the town in 1643 by the parliamentary forces, but partially rebuilt. A Benedictine abbey was founded at Reading in 1121 by Henry L., and became one of the richest in England, with a church among the largest in the country. Its founder was buried here, but his monument was destroyed in the time of Edward VI. The church was the scene of John of Gaunt's marriage to Blanche of Lancaster in 1359. By Henry VIII. the abbey was converted into a royal palace, and was so used until its destruction during the civil wars of the 17th century. Little remains of the foundation; only a gateway and a fragment of the great hall, the meeting-place of several parliaments, are of importance. The greater part of the site is occupied by a gaol.

The educational establishments are important. The site of an ancient hospice of St John is occupied by the University Extension College. It was opened in 1892, is affiliated to Oxford University, and has accommodation for 600 students, of both sexes, giving instruction in every main branch of higher university education, agriculture, &c. The grammar school, founded in 1455, occupies modern buildings and ranks among the lesser public schools. Archbishop Laud was educated here, and became a generous benefactor of the school. There are also a blue-coat school (1656), and other charitable schools of early foundation. The municipal museum, besides an art gallery and other exhibits, includes a fine collection of Romano-British relics from Silchester, the famous site not far distant in Hampshire. Besides the public grounds on the site of the abbey there may be mentioned Prospect Park of 132 acres, purchased by the Corporation, and Palmer Park, presented by a member of the firm of Huntley & Palmer, together with extensive recreation grounds.

The industry for which Reading is chiefly famous is the biscuit manufacture, the principal establishment for which is that of Messrs Huntley & Palmer, employing about 5000 hands. In the town and its vicinity are large seed warehouses and testing-grounds. There are also iron foundries, engineering works and factories for agricultural implements, and manufactures of tin boxes, sauces, velvet and silk, and Sacking, together with riverside boat-building yards. Reading gives title to a suffragan bishopric in the diocese of Oxford. The parliamentary borough returns one member. The municipal borough is under a mayor, 10 aldermen and 30 councillors. Area, 5876 acres.

Reading (Redinges, Reding, Redding) early became a place of importance. In 877 the Danes encamped here between the Thames and the Kennet, and in 1006 it was burned by Sweyn. It consisted of only thirty houses at the time of the Domesday Survey. There is some reason to think that a fortification existed there before the Conquest, and Stephen probably built a masonry castle which Henry II. destroyed. On the foundation of Reading abbey the town, hitherto demesne of the crown, was granted to the abbey by Henry I. Henceforth, until the 16th century, the chief feature of its history was the struggle as to rights and privileges. This was carried on between the abbey and the merchant gild which claimed to have existed in the time of the Confessor, and the chief officer of which was from the 15th century styled warden or mayor.

A 16th-century account of the gild merchant shows that many trades were then carried on, but Leland says the town "chiefly standeth by clothing." The story of Thomas Cole, written by Deloney (d. c. 1600) and purporting to refer to the reign of Henry I., indicates that the industry was carried on at an early date. Archbishop Laud was the son of a Reading clothier. By the 17th century the trade was beginning to decline; the bequest of Kendrick "the Phoenix of worthy Benefactors" did little to revive it, and it was greatly injured by the Civil War. In the 18th century the chief trade was in malt. The first town charter is that given by Henry III. (1253) on behalf of the burgesses in the Guild Merchant, which was confirmed and
amplified by succeeding sovereigns. The governing charter until 1835 was that of Charles I. (1639) incorporating the town under the title of the mayor, aldermen and burgesses. Reading returned two members to parliament from 1695 to 1885, when it was deprived of one; until 1832 the Scot-and-Lot franchise was used. The town surrendered to the parliamentary troops, after a siege, in 1643; it was occupied subsequently by the forces of both parties; in 1688 a skirmish took place in the town between some Irish soldiers of James II. and the troops of William of Orange. The market, chiefly held on Saturday, can be traced to the reign of Henry III.; four fairs granted by the charter of 1621 are still held, that on the 9th of July dating only, from the 4th of that month. See C. Coates, History of Reading (1866); Victoria County History, Berks.

READING, a city and the county-seat of Berks county, Pennsylvania, U.S.A., in the S.E. part of the state, on the E. bank of the Schuylkill river, and about 28 m. N.W. of Philadelphia. Pop. (1880) 43,278; (1900) 58,661; (1910) 78,961, of whom 5920 were foreign-born; (1910) census 96,071. Reading is served by the Pennsylvania and the Philadelphia & Reading railways, by the Schuylkill Canal, which carries freight to Philadelphia, and by electric railways to several villages in Berks county. The city occupies an irregular tract of land gradually descending from the base of Mt. Penn westward to the Schuylkill river, and therefore possesses excellent drainage facilities. The river, which is unnavigable and winding at this point, forms the western boundary of the city for more than 4 m., and is spanned by three public bridges and a number of railway bridges. Neversink Mountain (878 ft. high), lying to the S. of the city, and Mt. Penn (800 ft.) are pleasure resorts in the neighbourhood. On the neighbouring mountains are several summer hotels and sanatoria. Within the city is Penn Common, containing 50 acres, reserved by the Penns for the use of the town when it was first laid out, and since 1799 part of the Public Park. Mineral Spring Park, containing 63 acres, lies on the outskirts of the city. Other parks are maintained by the street railway companies. In Penn Common are a monument erected to the "First Defenders," to commemorate the fact that the "Ringgold Light Infantry," the first volunteer company to report at Washington for service in the Civil War, came from this city; a monument to President McKinley, and one to the volunteer fire companies of the city. Among interesting landmarks are the Federal Inn (1765), in which President Washington was entertained in 1794, and which has been used as a banking house since 1814; the old country store (the 270), used as such until 1828; and the site of the "Hessian Camp," where some of the prisoners captured during the War of Independence were confined. Charitable institutions are numerous; among them are the Reading Hospital (1867), St Joseph's Hospital (1873), Homoeopathic Hospital (1891), the Home for Widows and Single Women (1875), the Hope Rescue Mission (1897) for homeless men, the Home for Friendless Children (1888), St Catharine's Female Orphan Asylum (1872), St Paul's Orphan Asylum for Boys, and the House of the Good Shepherd (1889).

Other institutions are: the public library, which from 1808 to 1888 was a subscription library; the Berks County Law Library; the Berks County Historical Society; and the Harmonic Maennerchor, organized in 1847 and one of the oldest singing societies in the United States.

Lying within the rich agricultural region of the Lebanon and Schuylkill valleys and near vast fields of anthracite coal and iron ore, Reading possesses unusual business and industrial advantages. The chief industry is the manufacture of iron and steel. There are large shops of the Philadelphia & Reading railway here. The total value of factory products in 1905 was $30,548,175 (in 1900 it had been $32,682,667), and the most important of these were the tractions on electric and rail-making-mills; the production of railway repair shops; factory and machine-shop products; hardware, hosiery and knitted goods; cigars and cigarettes, and felt hats. Other important manufactures are bicycles, brick and other clay products, brooms, brushes, and cotton and woolen goods.

Reading was surveyed and laid out as a town in 1748, in accordance with the plans of Thomas and Richard Penn, sons of William Penn, and was named Reading after the county town of Berkshire, England. The first settlers were mostly Germans, but the direction of municipal affairs until the outbreak of the War of Independence was in the hands of the English-speaking inhabitants. As the latter were largely of Loyalist sympathies during the war, the control of the local government then fell into the hands of the German inhabitants. Germans was long used in Reading; Pennsylvania German (or "Dutch") is still spoken in the surrounding country, and several German periodicals are published in the city, including among them the weekly Adler since 1796. During the War of Independence Reading was an inland depot for supplies for the American army, and prisoners of war were sent here in large numbers. The development of the town dates from the opening in 1824 of the Schuylkill Canal, from Reading to Philadelphia. This was followed in 1828 by the Union Canal, running westward to Lebanon and Middletown, and in 1838 by the entrance into Reading of the Philadelphia & Reading railway. The establishment of these means of communication hastened the development of the natural resources of the region, and Reading early became an industrial centre. A system of water-works, established in 1821, was acquired by the municipality in 1865. Reading was incorporated as a borough in 1873, and was chartered as a city in 1847.

READING BEDS, in geology, a series of marine and estuarine beds consisting of varied plastic clays and bright-coloured sands, which form, with the Woolwich beds, a subdivision of the Lower Eocene (see WOOLWICH AND READING BEDS).

REAGAN, Sir Cowasji Jeghirsing. (1812-1879), "the Peabody of Bombay." Early in the 18th century three Parsie brothers moved from Nowsari, near Surat, in Gujarat, to Bombay, and became the pioneers of a lucrative trade with China. They gained the sobriquet of "Reaymoney," which they adopted as a surname. Only Hirji Jawanji Reaymoney left issue, two daughters, the elder of whom married a Banaji, and the younger a Dady Sett. The son of the former, Jeghiring Hirji, married Mirbae, the daughter of the latter, and was made the heir not only of his grandfather, but of his two granduncles. The younger of their two sons was Cowasji Jeghiring. His only English education was at the then well-known school kept by Mr. Sykes in the Fort of Bombay. At the age of 15 he entered the firm of Duncan, Gibb & Co. as "godown keeper," or warehouse clerk. In 1837 he was promoted to the responsible and lucrative appointment of "guarantee broker" to two of the leading European firms of Bombay. In 1846 he was able to begin trading on his own account. He was made a J.P. for the town and island of Bombay, and a member of the board of conservancy; and in 1866 was appointed a commissioner of income tax, its tactful management being largely responsible for the fact that this tax, then new to Bombay and unpopular, was levied with unexpected financial success. He was made C.S.I. In 1871 and in 1872 he was created a Knight Bachelor of the United Kingdom, and his statue, by T. Woolner, R. A., was erected in the town hall. His donations to the institutions of Bombay amounted to close on $200,000. His health broke down in 1871, and he died in 1878, being succeeded by his son, Sir J. Cowasji Jeghiring [Readymoney], who was created a Knight Bachelor in 1895, and a Baronet in 1908.

See J. Cowasji Jeghiring, Sir Cowasji Jeghiring Readymoney (1890).

REAGAN, John Henninger. (1818-1905), American politician, was born in Secvier county, Tennessee, on the 15th of October 1818. He removed to Texas in 1839, where he was a surveyor of public lands in 1839-1843, was admitted to the bar in 1846, was a member of the state House of Representatives.
REALGAR—REAL PROPERTY

in 1847-1848, served as district judge in 1852-1857, and in 1857-1861 was a representative in Congress. His political views were determined by the ultra-democratic influence of Andrew Jackson and the state-sovereignty philosophy of John C. Calhoun. In 1861 he was a member of the Texas secession convention, served in the Confederate provisional Congress, and on the 6th of March was appointed postmaster-general in President Davis's cabinet. He served in this capacity throughout the war, and for a short time before its close was also acting secretary of the treasury. He was captured with the Davis party on the 10th of May 1865, and was imprisoned in Fort Warren, Boston Harbour, until the close of the war. While in prison he wrote the "Fort Warren letter" (August 11th), in which he urged the people of Texas to recognize their defeat, grant civil rights to the freedmen, and try to conciliate the North. From 1875 to 1887, when he entered the U.S. Senate, he was again a representative in Congress, and from 1887 almost continuously to the close of his service he was chairman of the Committee on Commerce, in which capacity he had a prominent part in securing the passage of the Interstate Commerce Act of 1887. He was a member of the state constitutional convention of 1876. In state politics his sympathies were with the Radicals. In 1889, believing that his first duty was to his state, he resigned from the Senate to accept the chairmanship of the newly established state railway commission. In 1901 he retired from public service. From 1899 until his death he was president of the Texas State Historical Association. He died at his home, near Palestine, Texas, on the 6th of March 1905.

See his Memoirs; with Special Reference to Secession and the Civil War (New York, 1906), edited by W. F. McCabe.

REALGAR, a mineral species consisting of arsenic monosulphide (AsS) and occurring as monoclinal crystals of a bright red colour. There is a perfect cleavage parallel to the plane of symmetry (r in fig.). The lustre is resinous, and the streak has the same colour as the crystals, namely, orange-red to aurora-red. The hardness is 3½-2 and the specific gravity 3.55. On exposure to light the crystals crumble to a yellow powder. The name realgar is of Arabic origin, and was used by the alchemists; the substance was known to Theophrastus under the name Σάρκπακην, and to Pliny as Sandaracha. The mineral usually occurs in association with white arsenic, both the realgar of the United States and that of the Himalayas being found in small masses of a yellow-ochre colour, the formation being parallel to a direction of perfect cleavage. It is septic and soft (H. = 1½-2), and has a specific gravity 3.4. Distinctly developed crystals are rare; they have usually been considered to be orthohombic and isomorphous with stibnite (SbS), but it is probable that they are really monoclinic. Orpiment is extensively mined near Juluker in Asiatic Turkey. (L. J. S.)

REALISM (from Low Lat. realis, appertaining to res, things, as opposed to ideas and imaginations), a philosophical term used in two opposite senses. The older of these is the scholastic doctrine, traceable back to Socrates, that universals have a more "real" existence than things. Universals are, in scholastic language, ante res, in rebus and post res. Behind all numerous types of chairs there is in the mind the ideal chair of which particular chairs are mere copies. In the most extreme form realism denies that anything exists in any sense except universals. It is opposed to nominalism (q.v.) and conceptualism (q.v.). For the history of the doctrine, see SCHOLASTICISM. Realism in this sense has been called "an assertion of the rights of the subject." (cf. the Protagonist maxim, "Man is the measure of all things"). The modern application of the term is to the opposing doctrine that there is a reality apart from its presentation to consciousness. In this sense it is opposed to idealism (q.v.), whether the purely subjective or that more comprehensive idealism which makes subject and object mutually interdependent. In its crude form it is known as "Natural" or "Native" Realism. It appears, however, in more complex forms, e.g. as Ideal Realism (or Real Idealism), which combines epistemological idealism with realism in metaphysics. Again, Kant distinguishes "empirical" realism, which maintains the existence of things in space independent of consciousness, from "transcendental" realism, which ascribes absolute reality to time and space.

In literature and art "realism" again is opposed to "idealism" in various senses. The realist is (1) he who deliberately declines to select his subjects from the beautiful or harmonious, and, more especially, describes ugly things and brings out details of an unsavoury sort; (2) he who deals with individuals, not types; (3) most properly, he who strives to represent the facts exactly as they are.

REALM, the dominions of a king, a kingdom. The O.Fr. reaume (mod. royaume) was the form first adopted in English, and the modern spelling does not appear fixed till the beginning of the 17th century. The word must be referred to a supposed Med. Lat. regalimen, from regalis, of or belonging to a rex, king.

REAL PROPERTY. The land law of England and of countries whose law is based upon that of England stands in a peculiar position, which can be understood only by an outline of its history.

History.—Such terms as "fee" or "homage" carry us back into feudal times. Rights of common and distress are based upon still older institutions, forming the very basis of primitive law. The conception of tenure is the fundamental ground of distinction between real and personal estate, the former only being strictly entitled to the name of estate (q.v.). The division into real and personal is coincident to a great extent with that into immovable and movable, generally used by systems of law founded on the Roman (see PERSONAL PROPERTY). That it is not entirely coincident is due to the influence of the Roman Natural or "Native" Realism. It appears, however, in more complex forms, e.g. as Ideal Realism (or Real Idealism), which combines epistemological idealism with realism in metaphysics. Again, Kant distinguishes "empirical" realism, which maintains the existence of things in space independent of consciousness, from "transcendental" realism, which ascribes absolute reality to time and space.

1 The name has not remained as in Germany and Denmark. A sieg is still Leben in Germany, Lohn in Denmark.
of land is not peculiar to the pre-Conquest or any other period. It runs through the whole of English history.

The elements of feudalism so far existed in England under the Anglo-Saxon and Danish kings as to make it easy to introduce it in full at the Norman Conquest. What the Norman Conquest did was not to change all at once to feudal tenures, but to complete the association of territorial with personal dependence in such a way that the king and his retainers were "suo jure" by virtue of the fee, and that the "rule nulli terre sans seigneur" was one of the fundamental axioms of feudalism. There might be any number of infidelations and subinfeudations to mesne lords, but the chain of seigniory was complete, depending in the last resort upon the king as lord paramount. Land was not owned by free owners owing only necessary militia duties to the state, but was held of the king by military service of a more onerous nature. The folklore became the king's land; the soldier was a landowner instead of the landowner being a soldier. Free owners tended to become tenants of the lord, the township to be lost in the manor. The common land became in law the waste of the manor, its enjoyment resting upon a presumed grant by the lord. On the other hand, the whole of England did not become manorial; the conflict between the township and the manor resulted in a compromise, the result of which affects English tenure to this day. But it was a compromise much to the advantage of the privileged class, for in England more than in any other country the land law is the law of the nobility and not of the people. One reason of this is that, as England was never so completely feudalized as were some of the European continental states, the burden of feudalism was not so severely felt, and has led to less agitation for reform.

The land forfeited to the Conqueror was regranted by him to be held by military service due to the king, not to the mesne lord as in European continental feudalism. In 1866 at the council of Salisbury all the landholders swore fealty to the crown. In the full vigour of feudalism the inhabitants of England were either free or not free. The free inhabitants held their lands either by free tenure (liberum tenementum, frankenement) or by a tenure which was originally that of a non-free inhabitant, but attached to land in the possession of a free man. Frankenement was either military tenure, called also tenure in knight service or chivalry (including barony, the highest tenure known to the law, grand serjeanty and the special forms of escuage, castle-guard, corneage and others) or socage (including burgage and petit serjeanty), or frankalmoign (liberae decensionysa) or divine service, by which ecclesiastical corporations generally held their land. The non-free inhabitants were in Domesday Book servi, corarii or bordarii, later suti or villani, the last name being applied to both free men and serfs. All these were in a more or less dependent condition. The free tenures all exist at the present day, though as will appear later, the military tenures have shrunk into the unimportant and exceptional tenure of grand serjeanty. The non-free tenures are to a certain extent represented by copyhold. The most important difference between the military and socage tenures was the mode of descent. Whether or not a feudal benefice was originally hereditary, it had certainly become so at the time of the Conquest, and it descended to the eldest son. This applied at once in England to land held by military service as far as regarded the capital fief. The descent of socage lands or lands other than the capital fief for some time followed the old pre-Conquest rule of descent. Thus in the so-called "Laws of Henry I." the lands other than the capital fief, and in Glanvill, who wrote in the time of Henry II., socage lands, if anciently partible (antiquitus divisum), were divided among all the sons equally. But by the time of Bracton (Henry III.) the course of descent of lands held by military service had so far prevailed that, though it was a question of fact whether the land was partible or not, if there was no evidence either way descent to the eldest son was presumed. Relics of the old custom still remain in the case of gavelkind. The military tenant was subject to the feudal incidents, from which the tenant in socage was exempt. These incidents, especially wardship and marriage, were often oppressive. Alienation of lands by will, except in a very few cases, was restrained by statute. In the reign of Henry I. the law of ascendancy was restrained in one direction in the interests of the heir, in another in the interests of the lord. At the time of Glanvill a tenant had a greater power of alienation over land which he had purchased (terra acquisitata) than over land which he had inherited. But by the time of Bracton the heir had ceased to have any interest in either kind of land. The lords were more successful. It was enacted by Magna Carta that a free man should not give or sell so much of his land as to leave an amount insufficient to perform his services to his lord. In spite of this provision, the rights of the lords were continually diminished by subinfeudation until the passing of the Statute of Quia Emptores. Alienation by a tenant in chief of the crown without licence was a ground of forfeiture until 1 Edw. III. st. 2, c. 12, by which a fine was substituted. The modes of conveyance at this time were only two, feoffment with livery of seisin, or corporeal hereditaments, grant for incorporeal hereditaments. Livery of seisin, though public, was not officially recorded like the old English transfer of property. The influence of local custom upon the land law must have become weakened after the circuits of the judges of the King's Court were established by Henry II. Jurisdiction over litigation touching the freehold was taken away from the lord's courts by 15 Ric. II. c. 12.

The common law as far as it dealt with real estate had in the main assumed its present aspect by the reign of Henry III. The changes which have been made since that date have been chiefly due to the action of equity and legislation, the latter sometimes interpreted by the courts in a manner very different from the intention of parliament. The most important influence of equity has been exercised in mortgage and trusts in the doctrine of specific performance of contracts concerning real estate, and in relief from forfeiture for breach of covenant.

**History of Real Estate Legislation.**—The reign of Edward I. is notable for three leading statutes, all passed in the interest of the superior lords. The Statute of Mortmain (7 Edw. I. st. 2, c. 13) is the first of a long series directed against the acquisition of land by religious and charitable corporations. The statute De Donis Conditionalibus (13 Edw. I. c. 1) forbade the alienation of estates granted to a man and the heirs of his body, which before the statute became on the birth of an heir at once alienable (except in the case of gifts in frankmarriage), and so the lord lost his escheat. The statute Quia Emptores (18 Edw. I. c. 1) preserved those rights of the lords which were up to that time subject to be defeated by subinfeudation, by enacting that in any alienation of lands the alienor should hold them of the same lord of the fee as the alienor. Since 1290 it has been impossible to create an estate in fee-simple to be held of a mesne lord, or to reserve a rent upon a grant of an estate in fee (unless in the form of a rent-charge), or to create a new manor. The statute, however, does not bind the crown. The practical effect of the statute was to make the transfer of land thenceforward more of a commercial and less of a feudal transaction. The writ of _elegant_ was introduced by the Statute of Westminster II. in 1285 as a creditor's remedy over real estate. It has, however, been considerably modified by subsequent legislation. From 1290 to the reign of Henry VIII., there is no statute dealing with real estate. The reign of Henry VIII., like the reign of Edward I., is signalized by three acts, the effects of which continue to this day. The one which has had the most lasting influence in law is the Statute of Uses, 27 Hen. VIII. c. 10 (see CONVEYANCING; TRUST). The Statute of Uses was intended to provide against secrecy of sales of land, and as a necessary sequel to it an act of the same
year (27 Hen. VIII. c. 16) enacted that all bargains and sales of land should be duly enrolled. Bargain and sale was a form of equitable transfer which had for some purposes superseded the common law foemint. It applied only to estates of inheritance and not to terms of years. The unforeseen effect of 27 Hen. VIII. c. 16 was to establish as the ordinary form of conveyance until 1841 the conveyance a lease etc. and lease has been used by lawyers. In the Statute of Uses, and therefore no longer desirable, 32 Hen. VIII. c. 1 (explained by 34 & 35 Hen. VIII. c. 5) was passed to remedy this inconvenience. It is still law as to wills made before 1838 (see WILL). In the reign of Elizabeth the acts of 13 Eliz. c. 5 and 27 Eliz. c. 4 avoided fraudulent conveyances as against all parties and voluntary conveyances as against subsequent purchasers for valuable consideration. Early in the reign of Charles II. the act of 1661 (12 Car. II. c. 24) turned all the feudal tenures (with the exception of frankalmoign and grand servitude) into tenure by free and common socage and abolished the feudal incidents. The Statute of Frauds (29 Car. II. c. 3) contained provisions that certain leases and assignments, and that all agreements and trusts relating to land, should be in writing (see Fraud). The land registers of Middlesex and Yorkshire date from the reign of Anne (see Land Registration). Devises of land for charitable purposes were forbidden by the Mortmain Act (9 Geo. II. c. 36). In the next reign the first general Inclosure Act was passed, 41 Geo. III. c. 109 (see Commons). In the reign of William IV. were passed the Prescription, Limitation and Tithe Commutation Acts; fines and recoveries were abolished and simpler modes of conveyance substituted by 5 & 4 Will. IV. c. 74; and the laws of inheritance and dower were amended by 3 & 4 Will. IV. c. 105, 106. In the reign of Victoria there was a vast mass of legislation dealing with real estate in almost every conceivable aspect. At the immediate beginning of the reign stands the Wills Act. The transfer of real estate was simplified by 8 & 9 Vict. c. 106 and by the Conveyancing Acts of 1881 and 1882. Additional powers of dealing with settled estates were given by the Settled Estates Act 1850, later by the Settled Estates Act 1857, and the Settled Land Act 1882. Succession duty was levied for the first time on freeholds in 1853. The strictness of the Mortmain Act has been relaxed in favour of gifts and sales to public institutions of various kinds, such as schools, parks and museums. The period of limitation was shortened for most purposes from twenty to twelve years by the Real Property Limitation Act 1874. Several acts were passed dealing with the enfranchisement and commutation of copyholds and the preservation of commons and open spaces. The Naturalization Act 1870 enabled aliens to hold and transfer land in England. The Felony Act 1870, abolished forfeiture of real estate on conviction for felony. The Agricultural Holdings Acts 1883 and 1900, and other acts, gave the tenant of a tenancy within the acts a general right to compensation for improvements, substituted a year's notice to quit for the six months' notice previously necessary, enlarged the tenant's right to tenancies, and limited the amount of distress. By the Intestate Estates Act 1884 the law of escheat was extended to incorporeal hereditaments and equitable estates. Among other subjects which have been dealt with by legislation in the 19th century may be mentioned land transfer, registration, mortgage, partition, excambion, fixatures, taking of land in execution, declaration of title and apportionment. Hardly a year passes in which the land law is not altered to a greater or less degree.

Real estate at the present day is either legal or equitable, a difference resting mainly upon historical grounds. The following observations by the general to both kinds of estate. The usual classification of interests in real estate regards either the extent, the time or the mode of enjoyment. The division according to the extent is in the first instance into corporeal and incorporeal hereditaments. Copreral will embrace all that which the law regards as real property and any thing personal can, nor be the body, nor be the party. In that sense, corporeal estates are all necessarily freehold; an interest in land less than freehold, such as a term of years, is personal only. There was no room for an interest in the feudal gradation of tenure, it was regarded as a mere personal contract and was incapable of the incidents of tenure. By the Conveyancing Act 1881 the residue of a long term of years could in certain cases be enlarged into the fee-simple. A copyhold is in strict law only a tenancy at the will of the lord. Estates of freehold are either (1) real, or (2) personal, or (3) incorporeal, inheritance). The latter being in fee-tail or in fee-simple. An estate for life may be either for the life of the tenant or for the life of another person, the latter called an estate pur autre vie. The former is the state of estate in fee simple, the latter in fee tail. An estate in fee simple is the largest estate known to English law. Its ordinary incidents are an oath of fealty (never exacted), escheat, and (in a manor) suit of the heraldic. In its last or present form the law is almost entirely relics of the once important feudal incidents.

Incorporeal hereditaments consist chiefly, if not wholly, of rights in alieno solo. They are divided by Joshua Williams (Real Property, 2nd ed., 1866, pp. 32, 33) into (1) real rights in corporeal hereditaments; (2) hereditaments purely incorporeal, the last being either appellant, appurtenant or in gross. Examples are profits a prendre (such as rights of common, easements (such as rights of way), seignories, leases, rents, and the like. But before 1845 incorporeal hereditaments were said to lie in livery, incorporeal in grant. But by the Real Property Act 1845 all incorporeal hereditaments are, as regards the conveyance of the same, treated as incorporeal, whether incorporeal or corporeal. They are found both in the tenure and in the conveyance of land. The only customs of which judicial notice is taken are gavelkind (q.v.) and borough-English (q.v.). Any other local or personal tenures, must be proved by evidence. The tenure of frankalmoign and grand servitude were specially preserved by 12 Car. II. c. 24.

This is the name given to the mode of acquisition of rights over real estate. Title may arise either by alienation, voluntary or involuntary, or by succession. Voluntary alienation is either inter vivos or by will. The former is practically limited to individuals with capacity to contract, yet a title may be acquired either by gift, exchange, mortgage, or otherwise. As a general rule alienation of real estate inter vivos must be by deed since 8 & 9 Vict. c. 106. Since that act a deed of grant has superseded the old forms of foemint and escheat. Further simplification of the law has taken place. The shortness and simplicity have been made in the law of transfer of real estate by the Conveyancing Acts 1881 and 1882 and the Land Transfer Acts 1872 and 1897. The word "grant" is no longer necessary for a conveyance, nor are the old words of limitation "heirs" and "heirs of the body." It is sufficient to use the words "in fee-simple," "in tail," "in tail male," "in tail female." Many provisions usually inserted in deeds, such as covenants for title by a beneficial owner and powers of appointment or new trustees, obtain statutory sanction. Forms of mortgage, conveyance and settlement are appended to the deed. The Solicitors' Remuneration Act 1871 was as a non-Conveyancing Act by the Conveyancing Act, and the remuneration of solicitors now stands upon a different and more satisfactory basis. For acquisition by will and succession, see Will; Inheritance. Involuntary alienation comes from bankruptcy, or by operation of law, when the rights of creditors over land, such as distress or execution. It may also arise by the exercise by the state of its right of eminent domain for public purposes, as under the Lands Clauses and other Acts.

1 In spite of this objection the division is adopted by the legislature; see, for instance, the Intestate Estates Act 1884.

2 In the category of corporeal hereditaments are also included certain incorporeal hereditaments proper, such as growing crops, fixatures, title-deeds, &c.

3 It should be noticed that an easement in gross cannot exist.
Restrains on Alienation.—The alienation of real estate may be subject to almost any conditions, provided that such conditions do not contravene the law. As a general rule there can be no restrictions upon the alienation of an estate in fee-simple; the two ideas are inseparable. In this case, the property can be sold or conveyed as desired, restraint on anticipation is allowed within certain limits (see RESTRAINT). In another direction the imposition of a course of devotion upon property is forbidden by the law against perpetuity, but there are exceptions, and when the property is intended to be used for the propagation of a religious sect it is forbidden with a few exceptions. Certain persons are by the general policy of the law disabled from exercising full proprietary rights, such as convicts, infants and lunatics.

The right attaching to real estate are protected by peculiar remedies. At an early period it became more convenient to try the right to the possession of, rather than the right to the real estate itself, in the same manner as certain other rights connected with property, are now determined by equitable remedies, from their great simplicity and elasticity. The general mode of trying the right to both property and possession was from the time of Henry II. the real action, the form called "real action of replevin" (the proper legal term for a conveyance or contract of sale being used to determine the property, that called "assesse of novel disseisin" being the general means by which the possession was tried. About the reign of Elizabeth the action of ejectment became the ordinary form of possessory remedy. Real actions existed until the Real Property Limitation Act 1833, by which they were finally abolished, with the exception of writ of right of dower, writ of dower, and nihil habeat, quae impediunt et ejectment. Of these the latter appears to be the only one in use. The assesse of novel disseisin becomes, the action of ejectment in both its original and its reformed forms, and finally the action for the recovery of possession becomes the only general action connected with the proceeds of property subject to any lien or charge, the specific performance of contracts between vendors and purchasers of real estate, including contracts for land. The possession of any real estate by infants, convicts, and the care of infants' estates. In the case of rent a summary mode of remedy by act of the creditor still exists (see DISTRESS, RENT).

Ireland.—The law of real estate in Ireland is the English law with the modifications of the statute in James I's reign, as modified by subsequent legislation. The main difference is in the law of landlord and tenant, modified by the various local acts (see IRELAND) and the operation of the Irish Land Commission.

United States.—The law of real estate in the United States is the law of England modified to suit a different state of circumstances. The main point of difference is that in the United States the occupiers of land are generally wholly or in part owners, not tenants, and that there is a general defect of specific remedies. Instead of the assesse of novel disseisin, the remedy is based on homestead laws (see HOMESTEAD AND EXEMPTION LAWS). The traces of the feudal origin of the law are, as might be expected, considerably less prominent than in England. Thus estates tail are practically obsolete, and the tenants in common are treated as if they were tenants in fee. The law of descent is the same in real and personal estate. Mortgages do not exist, except in the state of New York, where they are created by the crown in chief duty (H. Brac. 1st Law Dict., "Mansion"). Registration of deeds is general. In some states forms of deed are prescribed by statute. Conveyancing is for the most part simpler than in England. The holding of real estate by religious or charitable corporations is generally forbidden by the act creating them rather than by anything like the English law of mortmain. Perpetuities are forbidden in most states. The right of eminent domain is at once acknowledged and limited by the Constitution. The right of taking private property is not to be taken for public use without just compensation. A similar provision is found in many of the state constitutions. By an Act of Congress of 9th April 1866, c. 31, all citizens of the United States have the same right in every state of the United States and Territory as is enjoyed by white citizens thereof to inherit, purchase, lease, sell, hold and convey real and personal property. In most states the conveyance of real estate is void if not recorded, so without becoming naturalized or at least filing in the specified manner a declaration of intention to become naturalized.

International Law.—The law of the place where real estate is situated (lex loci rei sitae) governs its tenure and transfer. The laws of the United States are strict in regard to the validity of real estate transactions, more so than the laws of most other countries. They require that the formalities of the lex loci rei sitae must be observed, even if not necessary to the title. In the place where the contract was made, the lex loci rei sitae determines what real estate is. A foreign court cannot as a general rule pass title to land situated in another country. The English and United States courts of equity have to a certain extent avoided the inconvenience which this inability to deal with land out of the jurisdiction sometimes causes by the use of the theory that equity acts upon the conscience of the party and not upon the title to the foreign land. Thus in the leading case of Penn v. Lord Baltimore in 1750 (1 Vesey, 444) the court of chancery on this ground and speedily performed 30 articles of agreements settling the boundaries of the provinces of Pennsylvania and Maryland. The difficulty always arises that, although the court professes to act upon the conscience, it must indirectly act upon the title and cannot determine its decision into execution without the aid of the local tribunals.

REAP (either through Du. riein, or O.Fr. rayme, reyme, mod. rame, Med. Lat. rismo, from Arabic risma, bale, bale or bundle), a certain quantity of paper, viz. 20 quires containing 24 sheets each or 480 sheets; a "printer's reap" contains 213 quires or 516 sheets. The word owes its introduction into Europe to the Moors, who were the originators of the paper manufactured in Spain. Its original meaning was simply bundle, applied either to paper or clothes.

REAPING (from O.E. ripan, rypan, probably allied to "ripe," mature, i.e. "fit for reaping"; the cognate forms are found in other languages), the action of cutting ripe grain crops. Till the invention of the reaping machine, which came into practical use only about the middle of the 19th century, sickles and scythes were the sole reaping implements. Of the two the sickle is the more ancient, and indeed there is some reason to conclude that its use is coeval with the cultivation of grain crops. Among the remains of the later Stone period in Great Britain and on the European continent curved flint knives have occasionally been found, the form of which has led to the suggestion that they were used as sickles. Sickles of bronze occur quite commonly among remains of the early inhabitants of Europe. Some of these are deeply curved hooks, flat on the upper side, and with a strengthening ridge or back on the upper surface, while others are curved, grooved knives, in form like the ordinary hedge-cut. Among the ancient Egyptians toothed or serrated sickles of both bronze and iron were used. Ancient Roman drawings show that both the scythe and the sickle were known to that people, and Pliny makes the distinction plain.3 Although both implements have lost much of their importance since the general introduction of mowing and reaping machinery, they are still used very extensively, especially in those countries like France where small agricultural holdings prevail. The principal modern forms are the toothed hook, the scythe hook, the Hainault scythe and the common scythe.

The toothed hook, which was in general use till towards the middle of the 10th century, consisted of a narrow-bladed curved hook, having the curved edge bent over at the base of the handle, with its edge inclined towards the heel or handle. The curve is that known to mathematicians as the "cissoid," where tangents at any point form equal angles with lines drawn to the middle point, i.e. the point of contact; it is a curve in common use because experience has shown that it tires out the arm of the worker less than any other curve. Sickles were formerly made of iron edged with steel; but in recent times they came to be made of cast steel entire. Towards the middle of the 19th century the toothed hook was gradually supplanted by the scythe hook or smooth-edged sicle, a somewhat heavier and broader-bladed implement, having an ordinary knife edge. Both these implements were intended for "shearing" handles, the crook being held in the left hand and cut with the whole held in the right. A heavy smooth-edged sickle is used for "bagging" or "clouting," the implement consists of a short sickle hook to the hook of the sickle, its lower end being fixed to the reaping hook and the left hand being used to gather and carry along the cut swath. The Hainault scythe is an implement intermediate between the scythe and the sickle, being worked with one hand, and the motion is entirely a swinging or bagging one. The implement consists of a short scythe blade mounted on a vertical handle, and in using it the reaper collects the grain with a crook, which holds the straw together and prevents the stroke of the instrument. The common hay scythe is extensively used in Belgium. The common hay scythe consists of a slightly curved broad blade varying in length from 28 to 46 in., mounted on a bent, or sometimes straight, wooden snad or snath, to which two handles are attached at such distances.

Of the sickle there are two varieties, the Italian, which is the shortest, and can be used only in walking or standing, and the Gallic sickle, which makes quicker work of it when employed on their [the Gauls'] extensive domains; for there they cut their grass only in the middle, and pass over the shorter blades. The Italian mowers cut with the right hand only.4 (H. N. xviii. 67).
as enable the workman, with an easy stoop, to swing the scythe blade along the ground, the cutting edge being slightly elevated to keep it clear of the inequalities of the surface. The grain-reaping scythe is similar, but provided with a cradle or short gathering rake attached to the heel and following the direction of the blade for about 12 in. The object of this attachment is to gather the stalks as they are cut and lay them in regular swathes against the line of still-standing corn. The reaping scythe, instead of a long sned, has frequently two halves, the right hand branching from the left or main helve and the two handles placed about 2 ft. apart. The best scythe blades are made from rolled sheets of steel, riveted to a back frame of iron, which gives strength and rigidity to the blade. On the continent of Europe it is still common to mould and hammer the whole blade out of a single piece of steel, but this method keeps up, in certain countries, a demand for scythes in Russia, chiefly supplied from the German empire and Austria. The principal manufacturing centre of scythes and sickles in the United Kingdom is Sheffield.

It was not until the beginning of the 19th century that any attempt was made to invent a reaping machine on anything like the lines that have been adopted since. In 1826 the Rev. Patrick Bell of Carmylie in Fifeshire brought out the first successful machine. He had worked at the making of it when a young man on his father's farm, and the principle he adopted, that of a series of scissors fastened on the "knife-board," was followed for a long time. There had been many trials during the thirty or forty years before his time both in this country and in America, but his invention was the first practical success.

After many modifications, however, the present or recent form of the common reaper was evolved by C. H. McCormick in America in 1831. A truck or carriage is carried on two travelling wheels some 30 to 36 in. high, with spuds or teeth on the circumference to make them "bite" the ground and thus give motion to the machinery without skidding; two horses are yoked in front with a pole between, with martingale and surcingle belts as part of their harness, to ease the backing of the machine by the horses; the knife-board is fixed out at right angles to the side of the carriage and in front, while the knives consist of a series of triangular "sections" on a bar which travels backwards and forwards in slots in the "fingers," as the dividing teeth are called. The motion was given to the knives by a connecting rod and crank driven by suitable gearing from the truck wheels. The cutting was thus done by a straight shearing action and not by clipping like scissors as in Bell's machine.

There were many modifications tried before the favourite form was ultimately adopted; thus the horses were yoked behind the truck or carriage of the machine so that they pushed it before them; a revolving web of cloth was placed behind the knives so as to deliver the cut corn in a continuous swath at the side; revolving "sails" or "rakes" pushed the standing grain against the knives as the machine advanced—some of which arrangements have been revived in our modern string-binders—and so on.

In the early days—from about 1860 to 1870—machines were fitted with a tilting board behind the cutting bar which caught the corn as it fell, and it was held there until enough for a sheaf was gathered, when it was cut off by a bone and fork carried by a man who sat and worked the tilting board simultaneously with his foot and dropped the corn, to be lifted and tied into a sheaf by hand afterwards. The same machine was generally used for mowing (grass) by an interchange of parts, and the "combined" reaper and mower was in common use in the seventies and eighties. Later, various devices were adopted to do the tilting or sheaving mechanically, and the self end-delivery and self side-delivery have long been in use whereby through the adoption of revolving rakes on frames the sheaf-lots are delivered in sizes ready for tying up by hand. The subsequent tying or binding was done variously in different parts of the country. In the south of England it was customary for five men to make bands, lift the sheaf-lot, place in the band and tie, and leave the sheaf lying on the ground to be set up afterwards, the gang of five being expected to keep up on a reaper cutting round the four sides of a field. In the north and in Scotland the cutting was only done on one side at a time, the machine riding back empty, and three boys made the bands ("straps"), three women lifted the lots and laid them on the bands, and three men bound the sheaves and set up in stooks. Thus three gangs of three each were required to keep a machine going, and only about five acres per day could be reaped in this way.

The development of the modern binder to reduce all this labour has been a very gradual process. There was no great difficulty in cutting the corn and delivering the stuff, but the tying of it into sheaves was the problem to be solved. As early as 1838 Marsh in America designed and carried out an arrangement whereby the cut grain crop was caught on revolving webs of canvas and carried up to a table, where two men stood who made bands of its own material and bound it into sheaves as it fell in front of them, dropping the sheaves off on to the ground as made, while the machine travelled along. The invention of a tying apparatus was the next advance, and in the seventies the American firm of Walter A. Wood & Co. brought out an arrangement for tying the sheaves up with wire. So slow and expensive had been the process of evolution, however, that it was reported at the time that the above firm had spent £20,000 in invention and experiment before they had even a wire-binder fit to put on the market.

Binding with string, however, was the aim of all, and it was reserved for J. F. Appleby, an English inventor, to hit on the arrangement now in use, or which was the prototype of all the knotters now to be met with in different varieties of the string-binder throughout the world.

While the string-binder is now in universal use in Great Britain, the British Colonies, America and all countries where farming and farm work are advanced, and hand labour is only followed where peasant-farming or small farming obtains, it must be noted that in certain regions the system of reaping or harvesting of corn crops has developed a good deal beyond this. In Australia and some of the hotter districts in the west of the United States the "stripper" is in use, an implement which carries long grooved teeth which are passed through the standing grain crop and strike off the heads, leaving the straw standing. The heads are passed backwards to a thrashing (rubbing) arrangement, which separates the corn from the chaff, chaff, &c., and the grain is sacked up straight away. The sacks are dropped off the machine as the work proceeds and are picked up by wagon for transport afterwards. It is a significant fact that strippers worked by hand, though pushed through the crop by oxen, were in use on the plains of Gaul in the first
REAR—REASON

The century of our era, though this system seems to have been lost sight of till re-invented by the Australians.

Again, in the Western states of America, where the climate is not hot and dry enough for stripping purposes, the method followed is to cut the straw as short as possible—just below the heads—and these fall on to a travelling canvas and are carried up into a thrasher and the grain separated and sacked as the work proceeds. An immense combined implement is used for this reaping and threshing purpose, taking a width of up to 40 ft. of crop at a time, and being propelled by a 50-horse-power traction engine running on broad-roller wheels, though smaller machines pulled by, say, 20 horses are also common. Sometimes the "heading" only is carried out, and the cut heads carried on a canvas up into a wagon travelled alongside, and then carted away for subsequent threshing, the "header" thus being the form of reaper adopted also in the Western states of America. In these regions, as in many other places on the prairies in general, the straw is of no value, and therefore the whole is set fire to and burned off, thus returning a certain amount of fertility to the soil in the ashes.

In the normal and ordinary system of reaping with the string-binder in Great Britain the rule is to "open up" a field by cutting "roads" round it: that is, a headland or roadway is mowed by the scythe and tied up by hand. Then the string-binder is started to cut around and continued till a finish is made at the centre of the field. Sometimes the crop is partly lodged and can only be cut on three sides of the field, and the binder is "slipped" past the fourth side. It is customary in some parts to yoke three horses to the machine and keep these at work all day with an interval for the midday meal only, but a better plan is to allow two men and four horses to each, and put one couple on and one couple off for meals and resting alternately. By this means the binder is kept going continuously without any stoppage for perhaps 14 hours daily in fine harvest weather. With a six-feet cutting width an acre per hour is fair work, but some have exceeded that, especially with wider cutting widths. A ball of twine weighing 3 to 4 lb is the usual requisite per acre for binding the sheaves, and it ought to be of Manila hemp: "sizal" fibre (derived from the American agaves and named after the port on the coast of Yucatan) is not so strong and good, though cheaper. Good twine is desirable, as otherwise frequent breakages leave many sheaves in a loose state.

The sheaves are dropped off on to the ground as tied, but some farmers use the "sheaf-carrier," which catches these as they are shot out from the binding apparatus, and dumps them in lots of six or so—sufficient to make a stock or shock. The stooling—that is, the setting up of the sheaves on end to dry—is a separate operation, and from two to three men can set up an ordinary good crop as fast as the binder can cut it. In this work the sheaves are set with their butts wide apart and the heads leaning against one another like the two legs of the letter A: a full-sized stock or "threave" is 24 sheaves—a relic of the days when the crop was all hand-reaped by piecework at so much per threave—but in practice now seldom more than 6 sheaves (3 each side) are put to each stock. When sufficiently dried or "fielded" the sheaves are then carried by cart or wagon to the stackyard, where they are built up sheaf by sheaf into round or oblong stacks: that is, they are stored until required for threshing or foddering purposes. The drying may be a tedious affair, and wet weather in harvest time is a national disaster from the spoiling of the corn, both grain and straw.

The tremendous development in labour-saving in the matter of reaping the corn crops is well exemplified in a comparison of harvesting with the hand hook or sickle as compared with the string-binder. With hand-reaping six men (or women) cut the corn and laid it on the bands in sheaf lots: one man came behind and tied the sheaves and set them up in stooks. Thus a gang of seven worked together and harvested about two acres per day. With the binder three or four men handle say twelve or fourteen acres daily: in other words, there is only one-tenth of the manual labour required now in reaping that was necessary only a generation ago, for the string-binder has revolutionized farming as a whole, and given the nations cheap bread.

REAR, the back or hind portion of anything, particularly a military or naval term for that part of a force which is placed last in order, in opposition to "van." As the last word, shortened from "van-guard," is an aphetic form of Fr. avant, in front, Lat. *ante*, so "rear" is an aphetic form of "arrear," O. Fr. *arere*, mod. *arrière*, Med. Lat. *ad retro*, to the back, backward. From this word must be distinguished the verb "to rear," used in two main senses: of a horse, to stand up on its hind legs, and to raise up or lift, of the construction of a building or of the breeding and bringing to maturity of domestic or other animals, often used also of young children. The O.E. *raran*, of which it is the modern representative, is a double of the Scandinavian *reisa*, which has given English "raise," both being causative verb forms of "rise."

REAR VAULT (Fr. *arrière voussure*), the term in architecture employed for the vault of the internal hood of a doorway or window to which a spayl has been given on the reveal; sometimes the vaulting surface is terminated by a small rib known as the scoinson rib (q.v.), and a further development is given by angle shafts carrying this rib, known as scoinson shafts.

REASON (Lat. *ratio*, through French *raison*), in philosophy, the faculty or process of drawing logical inferences. Thus we speak of man as essentially a rational animal, it being implied that man differs from all other animals in that he can consciously draw inferences from premises. It is, however, exceedingly difficult in this respect to draw an absolute distinction between men and animals, observation of which undoubtedly suggests that the latter have a certain power of making inferences. Between the higher animals and the lower types of mankind the distinction is so hard to draw that many psychologists argue that the difference is one of degree rather than of kind (see also INSTINCT). There can be little doubt, however, that inference by man differs from that of the brute creation in respect of self-consciousness, and, though there can be no doubt that some animals dream, it is difficult to find evidence for the presence of ideal images in the minds of

---

**Fig. 3.—American Header and Thrasher.**
any but the highest animals. In the nature of the case satisfactory conclusions as to the rationality which may be predicated of animals are impossible.

The term "reason" is also used in several narrower senses. Thus reason is opposed to sensation, perception, feeling, desire, as the faculty (the existence of which is denied by empiricists) by which fundamental truths are intuitively apprehended. These fundamental truths are the causes or "reasons" (αἰτια) of all derivative facts. With Kant, reason (Vernunft) is the power of synthesizing into unity, by means of comprehensive principles, the concepts provided by the intellect (Vorstand). The reason which gives a priori principles Kant calls "Pure Reason" (cf. the Kritik der reinen Vernunft), as distinguished from the "Practical Reason" (praktische Vernunft) which is specially concerned with the performance of particular actions. In formal logic the drawing of inferences (frequently called "ratiocination," from Lat. ratioecinari, to use the reasoning faculty) is classified from Aristotle downwards as deductive (from generals to particulars) and inductive (from particulars to generals); see Logic, Induction, Syllogism. In theology, reason, as distinguished from faith, is the human intelligence exercised upon religious truth whether by way of discovery or by way of explanation. The limits within which the reason may be used have been laid down differently in different churches and periods of thought: on the whole, modern Christianity, especially in the Protestant churches, tends to allow to a reason a wide field. Preserving, however, as the sphere of faith the ultimate (supernatural) truths of theology.

The Greek words for reason are νόει and λόγος, both vaguely used. In Aristotle the λόγος of a thing is its definition, including its formal cause, while the ultimate principles of a science are ψηφαί, the "reasons" (in a common modern sense) which explain all its particular facts. νοει in Plato and Aristotle is used both widely for all the meanings which "reason" can have, and strictly for the faculty which apprehends intuitively. Thus, in the Republic, νοει is the faculty which apprehends necessary truths, while διάφα (opinion) is concerned with phenomena.

For the Stoic and Neoplatonic uses of λόγος, as also for those of Philo Judaeus and the Fathers, see Logos.

RÉAUMUR, RENÉ ANTOINE FERCHAUD DE (1683-1757), French man of science, was born on the 28th of February 1683 at La Rochelle and received his early education there. He was taught philosophy in the Jesuits' college at Poitiers, and in 1699 went to Bourges to study civil law and mathematics under the charge of an uncle, canon of La Sainte-Chapelle. In 1703 he came to Paris, where he continued the study of mathematics and physics, and in 1708, at the early age of twenty-four, was elected a member of the Académie des Sciences. From this time onwards for nearly half a century hardly a year passed in which the Mémoires de l'Académie did not contain at least one paper by Réaumur. At first his attention was occupied by mathematical studies, especially in geometry. In 1710 he was appointed to the charge of a great government work—the official description of the useful arts and manufactures—which led him to many practical researches that resulted in the establishment of manufactures new to France and the revival of neglected industries. For discoveries regarding iron and steel he was awarded a pension of 12,000 livres; but, being content with his ample private income, he requested that the money should be secured to the Académie des Sciences for the furtherance of experiments on improved industrial processes.

In 1731 he became interested in meteorology, and invented the thermometer scale which bears his name. In 1735 family arrangements obliged him to accept the post of chamberlain and intendant of the royal and military order of Saint-Louis; he discharged his duties with scrupulous attention, but declined the emoluments. He took great delight in the systematic study of natural history. His friends often called him the Pliny of the 18th century. He loved retirement and lived much at his country residences, at one of which, La Bernardière (Maine), he met with a fall from horseback, the effects of which produced a fatal stroke on the 17th of October 1757. He bequeathed his manuscripts, which filled 158 portfolios, and his natural history collections to the Académie des Sciences.

Réaumur's scientific papers deal with nearly all branches of science; his first, in 1708, was on a general problem in geometry; his last, in 1756, on the forms of birds' nests. He proved experimentally the fact that the strength of a rope is less than the sum of the strengths of its separate strands. He examined and reported on the auriferous rivers, the turquoise mines, the forests and the fossil beds of France. He devised the method of tinning iron that is still employed, and investigated the differences between iron and steel, correctly showing that the amount of carbon (sulphur in the language of that day) is greatest in cast iron, less in steel, and least in wrought iron. His book on this subject (1722) was translated into English and German. The thermometer by which he is now best remembered was constructed on the principle of taking the freezing-point of water as 0°, and graduating the tube into degrees each of which was one-thousandth of the volume contained by the bulb and tube up to the zero mark. It was an accident dependent on the dilatability of the particular quality of alcohol employed which made the boiling-point of water 80°; and mercurial thermometers the stems of which reflected equal parts of the scale from the freezing- and boiling-points of water to Réaumur's thermometer in anything but name.

Réaumur wrote much on natural history. Early in life he described the locomotor system of the Echindermata, and showed that the supposed vulgar error of Crustaceans replacing their lost limbs was an actual fact. In 1710 he wrote a paper on the possibility of spiders being used to produce silk, which was so celebrated at the time that the Chinese emperor Kang-hê caused a translation of it to be made. He treated also of botanical and zoological subjects, and differently preserved, preserving birds and eggs. He elaborated a system of artificial insemination and made important observations on the digestion of carnivorous and granivorous birds. His greatest work is the Mémoires pour servir à l'histoire des insectes, 6 vols., with 267 plates (Amsterdam 1734-42). It describes the appearance, habits and locality of all the known insects except the beetles, and is a marvel of patient and accurate observation. Among other important facts stated in this work are the experiments which enabled Réaumur to prove the correctness of Peyssonel's hypothesis, that corals are animals and not plants.

REBAB, or RABAB (Persian rebáb; Arabic rebáb, rebába; Sp. rebé, rebé, rebal, arrabal, arrabáil; Fr. rebéba; It. rebeba), an ancient stringed instrument, having a body either pear-shaped or boat-shaped and the characteristics of vaulted back and the absence of neck; also a generic modern Arabic term applied by the Mahomedans of northern Africa to various stringed instruments played with a bow.

As the rebab exercised a very considerable influence on the history of stringed instruments in Europe, and was undoubtedly the means through which the bow was introduced to the West, it is necessary to examine its construction before deciding whether it may be accepted as the ancestor of the violin in deference to the claim made for it by certain modern writers.6

1 The Schoolmen's distinction of ratio cognoscendi (a reason for acknowledging a fact) and ratio essendi (a reason for the existence of this fact).

2 For Rückert, Grammatik, Poetik und Rhetorik der Perser, nach dem 2. Bande des Ilias (1814), p. 80. This translation of the introduction to the Seven Seas contains a reference to musical instruments; the one translated Laute (lute) is rendered in Persian rebáb, a point ascertained through the courteous assistance of Mr A. G. Ellis, of the Oriental Department, British Museum.

6 See F. J. Féret, Antoine Stadthart... Précédé de recherches historiques et critiques sur l'origine et les transformations des instru-
The two principal forms of rebab with which we are concerned as prototypes of European instruments of the middle ages are:

1. the long and narrow boat-shaped rebab, which may be traced back to Persia in the 6th century B.C., and is still in use in that country; and
2. the later barrel-shaped rebab, with rudimentary neck, consisting of the gradual narrowing of the body, which has the outline of a longitudinal section of a pear. This variety became very popular in Mediterranean countries of rebab, lute, and lyra; the archetype has been traced back to 1000 B.C.

The most characteristic feature in the construction of the rebab, and of all instruments derived from it, was the body, composed of two flat pieces of wood, originally scooped out of a solid piece of wood, to which was glued without the intermediary of ribs (an important structural feature of the violin) a flat sound-board of parchment or thin wood.

The “rebab-esh-sha’er,” or “poet’s rebab,” had a body consisting of an almost rectangular box covered with parchment and supported on an iron foot; the instrument was held like the modern violincello. No evidence has yet been brought forward that the rebab-esh-sha’er, as a prototype of the violin, reached its apex before the second place was beyond the pale of art.

According to Al-Farabi, the rebab had either one string, two strings or four, obtained by doubling these; they were tuned similarly to the rebab, and in minor thirds, or in the Arabian Ash-Shakandi, who flourished in Spain about A.D. 1200, states that the rebab had been known for centuries in Spain, but was not mentioned on account of its want of artistic merit. Juan Ruiz, archipreoste de Hita, in his enumeration of the musical instruments in use in his day (14th century), mentions two rebabs, and speaks of the real gildar con su alta nota and rii berce; the first rebab rebab was called rebab, and the second rebab was thus quoted somewhat contemptuously already in the 14th century.

The history of the origin of the rebab had until now not gone back beyond the 7th century A.D., and has been a matter of conjecture among its various prototypal descendants, which is now observed. No evidence had been given, or on the statement that the Arabs themselves declare that they obtained the instrument from the Persians. Recent archaeological discoveries, however, provide abundant evidence of archetypes of both pear-shaped and boat-shaped rebabs in high antiquity. We have at present no clue to the name of the archetype, but it is clear that the e-Old or lute of the Arabs and the wide pear-shaped rebab, really only one of the same instrument, is connected with the advent of the bow, which had probably also been made known to the Arabs through the Persians, since their word for the bow, kamān, is borrowed from the Persian, but at what date is unknown. Al-Farabi speaks of its construction, and his term, rebab-esh-sha’er, is thus deduced. The rebab does not deal with the construction of the instrument so much as with the production of sound and the divisions of the scale.

As far as is known at present, the archetype of the rebab and lute family is the instrument shown in fig. 1. The terra-cotta figure of the musician discovered in Egypt (1905-6) by Professor Flinders Petrie during the course of excavations in the cemetery of Goshen is Greek work of the post-Mycenaean age; it was found in surroundings assigned to the XXth Dynasty (c. 1060 B.C.) and shows the earliest pear-shaped instrument yet discovered. This statuette clearly establishes the origin of the instruments named by some lyra, by others (including the present writer) rebab or rebec, common all over western Europe from the 11th century, whose main characteristic is an almost entire absence of neck. Two terra-cotta statuettes of musicians playing upon ancient Persian rebabs (see fig. 2) have been excavated from the

---

Tell at Suza amongst objects offered to the reign of Shutruk-Nakhouna, who was king of Elam c. 789 B.C. The pear-shaped instrument, wide at the base and elongated to form a neck, with the head bent back at right angles and the strings plucked by the fingers—the lute of the 6th century A.D.—is seen first on a frieze from Afghanistan, forming one of the risers of steps to the tomb of Jamal-Garhi. These sculptures, preserved at the British Museum, are assigned to the 2nd or 3rd century, and are said to show traces of classical influence. The same instrument is found engraved on a Sassanian silver dish in the British Museum,3 of workmanship assigned to a period not later than the 7th century A.D., but probably earlier, as well as on other dishes of similar origin; one in the Hermitage, St Petersburg, was found at Irib in 1880, on which Eros is depicted playing the lute and riding on a horse.4 A third, found at Perm, forms part of Count Stroganov's collection.5

Excavations carried out in ancient Khotan6 or Ichki (Turkestan, on the caravan route to Kashgar) have brought to light further evidence of the ubiquity of the rebab type in Asia. In addition to the two principal types of rebab (fig. 3) mentioned above there is also to be found the spoon-shaped instrument with no neck and large head, the instrument sometimes seen in European medieval sculptures and MSS. of the 11th and 12th centuries.7

The pear-shaped rebab or lute appears also among the celebrated paintings in the Buddhist cave temples of Ajanta,8 assigned to the 6th century A.D. A later example at the Museum of a fragment of a dish found at Rhaiges or Ray9 in northern Persia,10

---

REBATE—REBEC

REBEC, or REBEC (Med. Fr. rubèbe, rebele, rebec, girou; Ger. Rubeba, Rebekh, Geige, Lyra; Ital. ribeba, ribeca, lyra; Sp. rabet, rebeca, rañe, rebè;), a medieval stringed instrument played with a bow, derived from the Oriental rebab. Like the rebab (q.v.), the rebec assumed at first one of two forms—the pear-shaped body with a wide base, stringed with three strings, or the long, narrow pear- or boat-shaped body with two strings and, in addition, the other Oriental characteristics of the rebab, i.e. the vaulted back, the absence of ribs and pegs set in the back of the head. Except for the addition of a fingerboard, what is now recognised as the rebec underwent no structural development and never entered the domain of art. When the guitar-fiddle and the oval vielle with five strings made their appearance in Europe, apparently during the 11th century, a number of hybrids combining characteristics of both types of construction spread rapidly over western Europe. A spoon-shaped instrument, in most cases without neck, the head being joined directly to the wide shoulders of the body, must not be confounded with these hybrids; the compass and capabilities of the instrument, which sometimes had but one single string, must have been extremely limited. What the name of the instrument was in the various ages is not known, but it may be classed with the rebab and rebec, from which it only differs in the outline of the body. The present writer discovered an Oriental archetype on a small terra-cotta figure in the style of the Gandhara school, unearthed at Yotkan on the south-west frontier of China. The round head is fastened directly to the shoulders, the three strings are issued from a vent in a deep indentation, the bridge tail-piece has three notches. The instrument (assigned to some period between the 5th and 8th centuries A.D.) may be compared with the European medieval type, such, for instance, as the bowed spoon-shaped rebec on the capital of the left pillar in the miniature of King David and his musicians, belonging to the 10th-century psalter of Labeo Notker at St Gallen; also with the musicians' lyra on the western doorway of the church at Moissans; and with the British Museum Add. MS. 17533, in which several of these spoon-shaped, neckless instruments are to be found.

The pear-shaped rebec with wide base was in all probability introduced into Europe through the Byzantine Empire, and the narrow boat-shaped by the Moors by way of Spain. The first of these types is represented on one of the sides of an ivory casket of 5th-century Byzantine workmanship preserved among the Carrand Collection in the Palazzo del Podesta in Florence. It belongs to the same group as a similar casket in the British Museum, Add. MS. 17533, all of which are assigned to the 9th century at the latest.

The pear-shaped rebec on the ivory casket, although like all rebecs it had no separate neck, was elongated to form one, and terminated in a long neck at the upper end. The back broadened and structural details on the soundboard being cut to the same outline and glued to the back. There were four strings to these rebecs, of which there are many examples in English MSS. from the 11th century. One of the best known, sometimes described as the Anglo-Saxon fylkebe, is the one played by Jeduthun in the usual illustration of King David and his musicians prefixed to the Psalms in an Anglo-Saxon psalter (Cambridge, Bib. C. VI., Brit. Mus.). Other examples are to be found in a Latin psalter illuminated by an English artist at the beginning of the 12th century (Landsd., 383, Brit. Mus.), in which the rebec has but one string and resembles the lyra teutonica mentioned above.

Medieval documentary evidence points to the fact that the long boat-shaped rebec had survived in Spain and spread by way of France over western Europe. The much-quoted 14th-century

2 See Laurent Grillet, Les ancêtres du violon (Paris, 1901), vol. i. p. 29. The author calls these instruments *lyra*, which is a synonym of *rebec*.

3 See Kathleen Schlesinger, The Instruments of the Orchestra, part ii. "Precursors of the Violin Family" (London, 1910), pl. iv. p. 154. The spoon-shaped instrument with a long neck on a 13th-century manuscript was referred to the pandoura family.

4 The casket has been reproduced by A. Venturi in his Galleria Naz. Ital., vol. iii., 1897, p. 263; and L'Arte, vol. i. 1896, p. 24.

5 See also English psalters of the 13th century in the British Museum, Lansd. Ms. 420, and Arundel, 157, fol. 71v.
poem by Juan Rius, archипreste de Hita,¹ containing an enumeration of the musical instruments of his day, includes el rabe grisiador con su alta nota (the shrill rebec with its high note) and el rabé morisco. By a process of deduction we have no difficulty in identifying the rabe grisiador with the tall-shaped rebec as described by Baudosa. Although since the instrument has survived almost unchanged among the Arabs of the present day from the 13th century, and probably from the early centuries of our era. The shrill rebec (a rabe grisiador) in Fig. 789, an engraving instead of a drawing, is one of the magnifics, MS. known as the Cantigas de Santa Maria, assigned to the 13th century,² there are three of those boat-shaped rebecs played with a bow and one twanged by the fingers; the rebec itself is held like the viola-da-gamba. Rebels of this type, but without bows, were in use in ancient Persia, c. 789 B.C., as is demonstrated by some little terra-cotta figures of musicians undated in a Persian vase. All the instruments, held, however, like the violin, are unmistakably the archetypes of this rebec.

The rebec did not escape the general tendency so noticeable in Europe from the 12th to the 15th century towards the ornamentation of music. The cittern, the harp, and the chanson de bandeau of the bagpipe, the heads of the cittern and gittern, the mandoline and the rebec, were all alike decorated with grotesque human or animal heads, which in England became proverbial as cittern-a- heads, and in Germany, boew and in Austria, the names in their French and German (Tasschenengeige) indicates, was small enough to be carried in the pocket; it measured from 15 to 18 in. and was played with a correspondingly small bow. The term pochette, as applied to the boat-shaped rebec, was called in Germany (figur in France), is figured by Sebastian Virdung;³ there were three strings tuned to G, D, A, and it had a finger-board cut in one piece with the sound-board in a square, and forming a step. Some writers consider that the addition of the finger-board constituted the difference between the geige and the rebec. Facts hardly support this theory, since the lyra teutonica of the 9th or 11th century already had a finger-board, and Farabu, the Arabi scholar of the 10th century, who was equally familiar with the Greek, Persian and Arabic musical systems, distinctly states that the rebec was also known as the lyra. The modern German lyra, as we know it today, is a most modern example of which is the zither. With the rise of the viol and later of the violin, which represent the most perfect type of construction for stringed instruments, the rebec tribe, inferior in every respect and without artistic merit, was gradually relegated beyond the pale,⁴ and by the 18th century had fallen into disuse except in certain rural districts, where for outdoor music, their shrill, penetrating tone continues to endear them to itinerant and village musicians. (K.S.)

⁵There is a portrait in the Galpin Collection, c. 1700; for an illustration see Kathleen Schlesinger, The Instruments of the Orchestra, part ii., "Precursors of the Violin Family," p. 201, fig. 158.

⁶Musica gadgeto und ausgenossen, Basel, 1511, reprinted in Publikationshefte der Musikgeschichte, 1883, No. 9.

⁷Antoine Vital in La Lutherie et les luthiers, to show the contempt with which the rebec was viewed in France in the 15th century, quotes from the charges of King Charles VIII., 1483, where the following occurs: "On demande au flet des musiciens qui veut pousser les flutes, qu'il le fasse tout seul." The lieutenant of Paris, in March 27, 1628, issued the following order: "Faisant défence à tous musiciens de jouer les cagots et maulaus vieux des ducs, basses ou autres parties de musique, acoustiques ou de musique nouvelle." A well-known passage in Chaucer testifies to a similar contempt in 14th-century England: "Brother, quod he, here wozeth an old rebelle," &c. (Royles Tale, 7150).

REBECCA RIOTS—REBUS

REBECCA RIOTS, the name given to some disturbances which occurred in 1843 in the counties of Pembroke, Carmarthen, Glamorgan, Cardigan and Radnor, after a slight outbreak of the same nature four years previously. During a period of exceptional distress the rioting was caused mainly by the heavy charges at the toll-gates on the public roads in South Wales, and the rioters took as their motto the words in Genesis xxiv. 60, "And they blessed Rebekah, and said unto her, Thou art our sister, be thou the mother of thousands of millions, and let thy seed possess the gate of those which hate them." Many of the rioters were disguised as women and were on horseback; each band was led by a captain called "Rebecca," his followers being known as "her daughters." They destroyed not only the gates but the toll-houses and toll-houses in a fierce and noisy manner. The government despatched a large number of soldiers and a strong body of London police to South Wales, and the disorder was soon at an end. In October a commission was sent down to inquire into the causes of the riots. It was found that the grievances had a genuine basis; measures of relief were introduced, and South Wales was relieved from the burden of toll-gates, while the few rioters who were captured were only lightly punished.

REBELLION, the act or continuance in act of a rebel or rebells (Lat. rebellio, rebellis, a compound of re-, against, and bellum, war). A rebel is one who engages in armed resistance to the government to which he owes allegiance. One who engages between Civil War and Rebellion, see Wars, Laws 98. Where individuals as distinguished from groups of men are concerned the character of rebel is easier to determine. That the alleged act of war was done by order of another cannot be in principle an excuse for a subject or citizen of any state taking arms against it. Under the rules of war adopted at the Hague in 1907, moreover, any excuse for doing so is removed by the provision that a belligerent is forbidden to compel nationals of the hostile party to take part in operations of war against their own country, "even if they were in the belligerent's service before the commencement of the war" (art. 123). In the case of R. v. Lawson, known as the "Calvinia Flogging case" (Supreme Court of the Cape Colony, Feb. 18, 1904), the question of the validity of the excuse of acting under orders contrary to allegiance was discussed in an uncertain spirit, and in a previous case, the Moritz case, tried before the Treason Court at Mafeking (Nov. 7, 1901), the court held that insurgent nationals "who had joined the burghers must be placed on the same footing as burghers fighting against us." There may be special circumstances operating to qualify the application of a principle, but the above stated principle, as such, must be regarded as the only legal basis of argument on the subject. (T.B.)

REBELLIO (Lat. rebellio, rebellis "by things"), a sort of ridicule consisting of the representation of some sentence or thing by means of pictures or words, or a combination of both. Reubes first became popular in France, where they were at first called rebus de Picardie, that province, according to G. Ménage (1612-1672), having been the scene of their origin, which he found in the satires written by the students and young clerks on the foibles of the day under the title "De rebus quae geruntur." Camden mentions an instance of this kind of wit in a gallant who expressed his love to a woman named Rose Hill by painting in the border of his gown a rose, a hill, an eye, a loaf and a well; this, in the style of the rebes, reads "Rosae, Hill, Pictura, Omni." This kind of wit was happily ridiculed by Ben Jonson in the humorous description of Abel Dragger's device in the Alchemist and by
the Spectator in the device of Jack of Newberry. The name is also applied to arrangements of words in which the position of the several vocables is to be taken into account in divining the meaning. Thus "I understand you undertake to overthrow my undertaking" makes the rebus

**stand** take to taking
I you throw my;
or in French
pir vent venir
un vient d'un

may be read "un soupir vient souvent d'un souvenir." A still simpler French rebus is expressed by the two letters G a, which may be read, J'ai grand appetit (G grand, a petit).

"Rebus" (or "allusive arms"), in heraldry, is a coat of arms which bears an allusion to the name of the person,—as three castles for Castleton, three cups for Butler, three cones for Coningsby.

**RÉCAMIER, JEANNE FRANÇOISE JULIE ADÉLAÏDE (1777-1849),** a famous Frenchwoman in the literary and political circles of the early 19th century, was born on the 4th of December 1777 at Lyons. Her maiden name was Bernard. She was married at fifteen to the banker Jacques Récamier (d. 1830), who was more than old enough to be her father. Beautiful, accomplished, with a real love for literature, she possessed at the same time a temperament which protected her from scandal, and from the early days of the consulate to almost the end of the July monarchy her salon in Paris was one of the chief resorts of literary and political society that pretended to fashion. The _habitudes_ of her house included many former royalists, with others, such as Bernadotte and General Moreau, more or less dissatisfied to the government. This circumstance, together with her refusal to act as lady-in-waiting to the Empress Josephine and her friendship for Madame de Staël, brought her under suspicion. It was through Madame de Staël that Madame Récamier became acquainted with Benjamin Constant, whose singular political tergiversations during the last days of the empire and the first of the restoration have been attributed to her persuasions. Madame Récamier was eventually exiled from Paris by Napoleon's orders. After a short stay at Lyons she proceeded to Rome, and finally to Naples, where she was on exceedingly good terms with Murat and his wife, who were then intriguing with the Bourbons. She persuaded Constant to plead the claims of Murat in a memorandum addressed to the congress of Vienna, and also induced him to take up a decided attitude in opposition to Napoleon during the Hundred Days. Her husband had sustained heavy losses in 1805, and she visited Madame de Staël at Coppet in Switzerland. There was a project for her divorce, in order that she might marry Prince Augustus of Prussia, but though her husband was willing it was not arranged. In her later days she lost most of the rest of her fortune; but she continued to receive visitors at the Abbaye-aux-Bois, the old Paris convent to which she retired in 1814. Here Chateaubriand was a constant visitor, and in a manner master of the house; but even in old age, ill-health and reduced circumstances Madame Récamier never lost her attraction. She was incapable of any serious attachment, and although she numbered among her admirers Mathieu Montmorency, Lucien Bonaparte, Prince Augustus of Prussia, Ballanche, J. J. Ampère and Constant, none of them obtained over her so great an influence as did Chateaubriand, though she suffered much from his impetuous temper. If she had any genuine affection, it seems to have been for Prosper de Barante, whom she met at Coppet. She died in Paris on the 11th of May 1849.

There are well-known portraits of her by Louis David in the galleries of the Louvre, and by François Gérard in the possession of the prefecture of the Seine. In 1839 _Souvenirs et correspondances tirés des papiers de Madame Récamier_ was edited by Mme Lenormant. See Mme Lenormant's _Madame Récamier, les amis de sa jeunesse et sa correspondance intime_ (1872); Mme Mohl, _Madame Récamier_, with a sketch of the history of society in France (1829 and 1862); also Guizot in _Revue des deux mondes_ for December 1859 and February 1873; H. Noel Williams, _Madame Récamier and her Friends_ (London, 1901); E. Herriot (Engl. trans., by Alyx Hallard), _Madame Récamier et ses amis_ (1904) (elaborate and exhaustive).

**RECANATI,** a city of the Marches, Italy, in the province of Macerata, 8 m. direct N.E. of the city of that name. Pop. (1901) 14,590 (town), 16,389 (commune). It has a station on the railway 17½ m. S. of Ancona, and distant 43 m. from the town, which is built on a hill, 331 ft. above the sea, and retains portions of its 15th-century walls and gateways. It was the birthplace of the poet Leopardi (1798-1837), whose monument adorns the principal piazza and whose family has collected in the town a very interesting museum of Leopardians; it also contains fine old mansions of the Leopardi, Mazzagalli, Massucci and Carradori in the main street, and a Gothic cathedral, built towards the close of the 14th century and dedicated to S Flavianus, patriarch of Constantinople. The churches of S Maria sopra Mercanti and S Domenico contain characteristic examples of the work of Lorenzo Lotto, as also does the new municipal palace, with a fine old battlemented tower, while the palace of Cardinal Venier has a fine Renaissance loggia by Giuliano da Maiano, who was probably responsible for the designs for the portals of S Agostino and S Domenico. The older buildings of the town are noteworthy for the curious terra-cotta work which adorns the majority of them.

Recanati appears as a strong castle in the 10th century or earlier. Round this gathered a community whose petty wars with Osimo (Austium) called for the interference of Innocent III. in 1198. From Frederick II. it obtained the right of having a port on the Adriatic; and by Gregory IX. it was made a city and the seat of the bishopric transferred from Osimo. This oscillation between Guelf and Ghibelline continued characteristic of Recanati. Urban IV. abolished the "city" and bishopric; Nicholas IV. restored them. John XXII. again, in 1320, removed the bishopric and placed the city under interdict. The interdict was withdrawn in 1328 on payment of a heavy fine, but the bishopric remained in abeyance till 1357. Gregory XII., who on his deposition by the council of Constance was made papal legate of the sees of Macerata and Recanati, died in this city in 1417. The assistance rendered by Recanati to the popes in their struggles with the Sforza seems to have exhausted its resources, and it began to decline. Considerable damage was done by the earthquake of 1741; and the French, who were twice in possession of the town, in 1797, pillaged it in 1799.

**RECEIPT (M.E. recoele, derived through L. of recepit, participle of recipere, to receive),** in law, an acknowledgment in writing that a sum of money or other valuable considered has been received by the person signing the acknowledgment in discharge of a debt or other obligation. Such a receipt is prima facie evidence only of payment, and it may be shown, for example, that it was signed by mistake, or obtained by fraud or misrepresentation. By the Stamp Act of 1861, which repealed and re-enacted other acts, a duty of ½d. is imposed on every receipt or form of writing discharging a debt of £2 or upwards; the payment of the duty is denoted by affixing a penny stamp to the document, and the onus of proving the same by the person giving the receipt. By § 103 if a person gives a receipt, liable to duty, duly stamped or, refuses to give a receipt, the duty, duly stamped or, on payment to the amount of £2 or upward, gives a receipt for a less sum than £2 or divides the amount paid with intent to evade the duty, he is liable to a fine of £10. A receipt not duly stamped may be stamped at the Inland Revenue Office within fourteen days on payment of a fine of £5 or within one month on payment of £10.

**RECEIVER, in English law, an official or manager appointed by a court to administer property for its protection, to receive rents or other income and to pay authorized outgoings. Receivers may be either appointed _ad ministrandum_, i.e. by way of equitable execution, _ex_ for the purpose of enabling the judgment creditor to obtain payment of his debt, when the position of the real estate is such that ordinary execution will not reach it. Formerly receivers were appointed only by the court of chancery, but by the Judicature Act 1873 it is now within the power of all
RECEPT—RECHBERG-ROTHENLÖWEN

DIVISIONS OF THE HIGH COURT TO APPOINT RECEIVERS. Their powers and duties are exhaustively set forth by Kerr, *On Receivers* (5th ed., 1905), who classifies the cases in which they may be appointed under the following heads: (a) infants; (b) executors and trustees; (c) pending litigation as to probate; (d) mortgagee and mortgagee; (e) debenture-holder and creditor; (f) public companies; (g) vendor and purchaser; (h) covenantor and covenantee; (i) tenant for life and remainderman; (j) partners; (k) lunacy; (l) tenants in common; (m) possession under legal title, and (n) other cases. The appointment of receivers is entirely within the discretion of the courts, and the power may be exercised “in all cases in which it shall appear just and convenient.” Application for a receiver is usually made by motion, and the court will appoint the fittest person, without regard to who may propose him, the appointment of a receiver being for the benefit of all parties. Under the Conveyancing Act 1881, when a mortgagee has become entitled to exercise his powers of sale, he may, by writing under his hand, appoint such person as he think fit to be receiver. In bankruptcy practice a receiver, termed official receiver, is an officer of the court who in this capacity takes possession on the making of a receiving order, of all a debtor’s assets. He is also an officer of the Board of Trade with the duty of taking cognisance of the conduct of the debtor and administering his estates (see Bankruptcy).

Receiver-general is the title given to a chief receiver, more especially as applied to the collection of public revenue. The title survived in the Inland Revenue up to 1891, but it is now only used as the designation of an officer of the dutchy court of Lancaster, who receives the revenues, &c., of the duchy.

RECEIPT (from Lat. *recipere*, to take back), a philosophical term, used by Romans (Mental Evolution of Man, i., 36, 37), on the analogy of “concept and percept,” for mental images assumed to be produced by the simple repetition of perceptions. The process is supposed to be the gradual elimination of elements in which the percepts disagree, and the emphasizing of those in which they agree. Thus the final residuum is a unity in difference. Recepts are, in fact, “spontaneous associations, formed unintentionally as what may be termed unperceived abstractions,” i.e., what are generally known as “generic images.”

RECESS (Lat. *recessus*, a going back, withdrawal, from *recedere*, to withdraw), a term particularly used of a cessation of work or relief from duty, e.g. of the periods during the life of a parliament when it is not sitting. The word is also applied to an indentation in a line, especially of a small alcove sunk in the wall of a room. A particular use is the historical one for the acts and decrees of the Imperial Diet, the *recessus Imperii*, and also for those of the Hanseatic League. According to Du Cange (s.v. *Recessus*) the reason for the use of this word was that these decrees, &c. (*codex deliberationum*), were written out *ante quem a conventibus recedant procesus congregiali*.

RECHABITES, or SONS OF RECHAB, a sort of religious order among the Israelites in some respects analogous to the Nazarites (q.v.), with whom they shared the rule of abstinence from wine. They also eschewed the luxuries and pursuits of settled life, and lived in tents, refusing to sow grain as well as to plant vineyards. They represent a protest against the contemporary Canaanite civilization and a reaction towards the simplicity of life which was felt more strongly in Judah or to the east of the Jordan than in the northern kingdom of Israel. Their “father,” or founder, was that Jehonadab or Jonadab, son of Rechab, who encouraged Jehu to abolish the Tyrian Baal-worship (2 Kings x.). The original Rechabite (Josh. xxvi. 1) has since become a sort of hereditary clan, and as such the “house of Rechab” appears in Judah after the fall of the northern kingdom and continued to observe the ordinances of Jehonadab till the approach of Nebuchadrezzar drove them for protection into Jerusalem (Jer. xxxv.). Jeremiah promised them as a reward of their obedience that they should never lack a man to represent them (as a priest) before Yahweh, whence perhaps the later Jewish tradition that the Rechabites intermarried with the Levites and so entered the temple service.

Later references to them are quite probable (Ezra. vii. 2; 2 Esdr. ii. 33), the particular form of asceticism (q.v.) being less essential. One may compare the modern society of total abstainers known as the “Rechabites.” In 1 Chron. ii. 53 the “house of Rechab” is associated with the Keverans (q.v.) as a family of scribes. Their origin is ascribed to Hamath (conceivably the Naphtalite city, Josh. xiv. 35), but in 1 Chron. iv. 12 Rechab (so the LXX) is of Calebite descent.

RECHBERG-ROTHENLÖWEN, JOHANN BERNHARD, COUNT (1806-1890), Austrian statesman, was the second son of the Bavarian statesman Count Aloys von Rechberg-Rothenlöwen (1766-1849). Johann Bernhard was destined for the Bavarian public service, his elder brother being a hereditary member of the Upper House in the parliament of Württemberg. He was educated at the universities of Strassburg and Munich, but he incurred the displeasure of King Louis I. by the part he played as second in a duel, and in 1828 he transferred himself to the Austrian diplomatic service. After being attached to the embassies in Berlin, London and Brussels, he was appointed envoy at Stockholm (1841) and at Rio de Janeiro (1843). Returning to Europe in 1847, on the outbreak of the revolution of 1848 in Vienna he was of great service to Prince Metternich, whom he accompanied and assisted in his flight to England. In July 1848 he was appointed Austrian plenipotentiary in the German federal diet at Frankfort, in 1851 became Austrian *intercornuus* at Constantinople, and in 1853 Radetzky’s civilian colleague in the government of Lombardo-Venetia. In 1855 he returned to Frankfort as Austrian representative and president of the federal diet. As a pupil of Metternich he would have wished to preserve the (good understanding with Prussia) which seemed the necessary foundation for a conservative policy; he was, however, made the instrument for the anti-Prussian policy of Buol; this brought about constant disputes with Bismarck, at that time Prussian envoy at the diet, which were sharpened by Rechberg’s choleric temper, and on one occasion nearly led to a duel. Bismarck, however, always expressed a high appreciation of his character and abilities. In May 1859, on the eve of the war with Italy, he was appointed Austrian minister of foreign affairs and minister president, surrendering the latter post to the archduke Rainer in the following year.

The five years during which Rechberg held the portfolio of foreign affairs covered the war with Italy and France, the insurrection in Poland, the attempted reform of the German Confederation through the Frankfort *Fürstentag*, and the Austro-Prussian war with Denmark. After the defeat of Magenta Rechberg accompanied the emperor to Italy, and he had to meet the crisis caused by a war for which he was not responsible. He began the concessions to Hungary and in the Polish question, and was responsible for the adhesion of Austria to the alliance of the Western Powers. In the German question Rechberg’s policy was one of compromise. To the project of the *Fürstentag* he was altogether opposed. The project had been suggested to the emperor Francis Joseph by his son-in-law, the hereditary prince of Torn and Taxis, and by a pamphlet of Julius Frobel, and the preliminary arrangements were made without Rechberg being informed. When at last he was told, he tendered his resignation, which was not accepted, and he accompanied the emperor to the abortive meeting at Frankfort (August 1863). The attempt made by Rechberg at the subsequent ministerial conference at Nuremberg to establish a German league without Prussia was equally unsuccessful, and he now returned to the policy, which in opposition to Schmerling he had throughout advocated, of a peaceful arrangement between Prussia and Austria as the indispensable preliminary to a reform of the Confederation.

At this juncture the death of King Frederick VII. of Denmark (19th of November 1863) opened up the whole Schleswig-Holstein question (q.v.). In the diplomatic duel that followed Rechberg was no match for Bismarck. It suited Austrian policy to act in concert with Prussia against Denmark; but Rechberg well knew that Bismarck was aiming at the annexation of the duchies. He attempted to guard against this by laying
down as a condition of the alliance that the duchies should only be separated from Denmark by common consent of the two German powers. Bismarck, however, insisted that the question of the ultimate destination of the duchies should be left open; and, when he backed his argument with the threat that unless Austria accepted his proposal Prussia would act alone, Rechberg gave way. His action was made the object of violent attacks in the Austrian Lower House (28-30 January 1864), and when the war was victoriously concluded and Prussia's designs on the duchies had become evident, public opinion turned more and more against him, demanding that Austria should support the duke of Augustenbourg even at the risk of war. Rechberg yielded so far as to ensure the duke's representative in Vienna that Austria was determined to place him in possession of the duchies, but only on condition that he did not sign away any of his sovereign rights to Prussia. The outcome of this was that the duke refused the terms offered by King William and Bismarck.

On the 22nd of August there was a meeting of the emperor Francis Joseph and King William at Schönbrunn, both Rechberg and Bismarck being present. Rechberg himself was in favour of allowing Prussia to annex the duchies, on condition that Prussia should guarantee Austria's possession of Venice and the Adriatic coast. On this point no agreement was reached; but the principles of an Austro-Prussian alliance in the event of a French invasion of Italy were agreed upon. This latter proposal was, however, received with violent opposition in the ministry, where Rechberg's influence had long been overshadowed by that of Schmerling; public opinion, utterly distrustful of Prussian promises, was also greatly excited; and on the 27th of October Rechberg handed in his resignation, receiving at the same time the order of the Golden Fleece from the emperor as a sign of special favour. He had been made an hereditary member of the Upper House of the Reichsrat in 1861, and as late as 1879 continued occasionally to take part in debates. He died at his chateau of Kettenthal near N., on the 26th of February 1890. He had married, in 1834, Barbara Jones, eldest daughter of the 6th Viscount Ranelagh, by whom he had one son, Count Louis (b. 1835).

See the biography by Franz Ilwo in Allgemeine Deutsche Biographie, B. 53. Nachräge (Leipzig, 1907).

RECIDIVISM (from Fr. récidive, to relapse and fall again into the same fault, or repeat the same offence as one committed before), a modern expression for "habitual crime." The recidivist is now universally known to exist in all civilized countries as one who has adopted wrong-doing and law-breaking as a profession. His persistence is ceaseless and inextinguishable by the ordinary methods of combating crime. Penal justice as generally exercised is unavailing, and is little better than an automatic machine which draws in a vast number within its wheels and casts them out again practically unchanged in character to qualify again for the ineffective treatment. This dangerous contingent is for ever on the move, into prison and out of it and in again; a large proportion of it, the criminal residuum, the very essence of the criminality of a country, resists all processes devised for its regeneration and cure. Nothing will mend it; neither severity nor kindness, neither the most remorseful reproofs nor the philanthropic methods of moral and educational persuasion. This failure has encouraged some ardent reformers to recommend the system of indefinite imprisonment or the indeterminate sentence, by which the enemy once caught is kept perpetually or for a lengthy period, and thus rendered innocuous. Habitual offenders, it is argued, should be detained as hostages until they are willing to lay down their arms and consent to make no further attempt to attack or injure society. The theory is sound and has been adopted in part in several countries, especially in the United States.

It was not until 1890 that the system of preventive detention was put into operation in the United Kingdom, when, by the Prevention of Crime Act 1908, power was given to the courts to pass on habitual criminals a sentence of preventive detention in addition to one of penal servitude. This further period may range within limits of from five to ten years, according to the discretion of the court. The English system is hardly more than tentative at present; the machinery is admittedly capable of improvement. The charge of being a habitual criminal has to be inserted in the indictment on which the offender is to be tried, and this cannot be done without the consent of the director of public prosecutions and after certain notice has been given to the officer of the court trying the prisoner and to the offender himself. The decision to charge a prisoner with being a habitual criminal has hitherto rested on the local police authorities, and it has been held that a mere accumulation of the facts of a drastic method of treatment would result if the decision were transferred to one authority, and some such reform was foreshadowed by the Home Secretary in a speech in the House of Commons on prison reform on the 20th of July 1910.

RECIFE, or PERNAMBUCO, a city and seaport of Brazil, capital of the state of Pernambuco, in 8° 3' S. and 34° 55' W., near the extreme eastern point of South America. Pop. (1904 estimate) 186,000. Recife is frequently called the "Venice of America"; it is at the mouths of the rivers Beberibe and Capibaribe which unite to form a small lagoon or bay inside the river. In the angle between the two rivers is the delta island of Antonio Vaz. The city is built on the southern extremity of the sandy sea beach, on the island of Antonio Vaz, and on the mainland to the westward, the river channels being crossed by numerous bridges. With the exception of the hills on which Olinda is built about 5 m. northward, the surrounding country is low and flat, the general elevation averaging 10 ft. As the tide rises about 6 ft., the general level of the city and neighbouring coast, which is wet and swampy to the southward, is too low to be generally healthy, and Pernambuco has a high death-rate (524 per 1000 in 1904), with malaria as one of the principal causes of death. The climate is hot, although agreeably tempered by the S.E. trade winds; the temperature ranges from an absolute minimum of 61° to an absolute maximum of 90° (1904). The rainfall (1904) is 75.3 in. The three principal parishes of the city are known as São José do Recife, occupying the sandy peninsula or beach north of the outlet of the united rivers; Santo Antonio, on the island of Antonio Vaz, which was called Mauritia or Mauritizstad during the Dutch occupation; and Boa Vista, on the mainland to the westward, which is the most modern and the most rapidly growing part. The first is the oldest and most crowded section, and is now devoted chiefly to the commercial and financial interests of the port; here are the custom house, merchants' exchange (Praca do Comércio), state and departmental offices, and the most ancient of the principal churches, the old Sant' Antonio dates from the Dutch occupation. Prince Maurice of Nassau, when governor-general, built here his private residence (Fribourg House) and made it his capital. Its business edifices and residences are largely of Dutch architecture, with many stores and steep roofs. The older part of Boa Vista dates from the 17th century. Recife has few public squares or gardens, and its streets are not usually well cared for. The older buildings are of the Portuguese type, usually plain, low and heavy, constructed of broken stone and mortar, and plastered and coloured on the outside. The city has gas and electric illumination, street and suburban railways, drainage and a public water supply drawn from a small tributary of the Beberibe about 7 m. to the N.W., in the direction of Caçaxá. Among its notable public buildings and institutions are the old government palace in Santo Antonio built upon the foundations of the official residence of Prince Maurice of Nassau, with a pretty garden attached; a theatre facing upon the Praça da Republica, dating from the second empire; the palace of the Provincial Assembly in Boa Vista, built in 1860-65, surrounded by a high dome; the municipal palace, or prefecture, on Rua do Imperador, with the public library (Biblioteca Publica) occupying its third floor and containing about 30,000 volumes; the Gymnasion, a large plain building of two floors standing near the legislative palace; the Pedro II. Hospital
RECIPE—RECLAMATION OF LAND

built between 1847 and 1861; a large penitentiary, insane asylum, orphans' asylum, and beggars' asylum; a law school, artisans' school (Lyceu de Artes e Officios), and archaeological institute; a normal school and school of engineering; and war and naval arsenals. One of the most attractive churches is that of Nossa Senhora da Penha, surmounted by two slender spires and a dome.

The port of Recife is one of the most important of Brazil, on account of its proximity to Europe and its convenience for vessels passing around the east shoulder of the continent. It is the landing-place for two transatlantic and one coastwise cable lines. Its harbour consists of an outer and inner anchorage, the former an open roadstead, which are separated by a remarkable stone reef running parallel with the shore-line, leaving an inside passage 400 to 500 ft. wide. The entrance to the inner anchorage, which has a depth of about 20 ft., is opposite Fort Brum in the northern part of the city, and is marked by a small Dutch fort (Pícão) and a lighthouse at the northern extremity of the reef. This remarkable natural breakwater, which is about 50 ft. wide on top and has been repaired with masonry in some places, covers a considerable part of the coast-line in this part of Brazil. It is not a coral reef, as is sometimes stated, but is a consolidated ancient beach, now as hard and firm as stone.1 In 1910 contractors were at work on improvements to the port to cost about £1,666,000, under a decree of the 3rd of December 1908. The exports include sugar, rum, cotton, hides, skins, rubber, wax, fibres, dyewoods, cazu, mandioc flour, pineapples and other fruits. Pernambuco is the principal sugar-producing state of Brazil, and Recife is therefore an important centre for this product. Its railway communications with the interior are good, and include the Linha da Região Nordeste and the Linha de São Paulo along the coast, and the Recife to Limoeiro lines, the first three now being under the management of the Great Western of Brazil Co. There are also suburban lines to Olinda and Caxangá, the latter providing communication with some of the prettiest suburbs about the city.

Recife was settled about 1535, when Duarte Coelho Pereira landed there to take possession of the captaincy granted him by the Portuguese crown. The site of Coelho's capital was Olinda, but Recife remained its port and did not become an independent ville (town) until 1710. Down to the close of the 18th century, when Rio de Janeiro became important, Recife was the second city of Brazil, and for a time its most important port. It was captured and plundered in 1555 by the English privateer James Lancaster. It was also captured by the Dutch in 1630 and remained in their possession till 1654, during which time the island of Antonio Vaz was occupied and the town greatly improved. At the end of the Dutch War the capital was removed from Olinda to Recife, where it has since remained.

RECIPE, a statement of the materials and ingredients used in the making and preparation of a dish for cooking, a receipt. This is the principal current use, which was first applied to medieval prescriptions from the custom of placing the word, meaning “take this” (imperative of Lat. recipere, to receive), often abbreviated R or B, at the head of the formula.

RECIPROCY (Lat. reciprocus, returning back the same way, alternating, probably from re back and pro forward), the condition or state of being reciprocal, i.e. where there is give and take, mutual influence or correspondence between two parties, persons or things. In a more particular sense, reciprocity is a special arrangement between two nations under which the citizens of each obtain advantages or privileges in the trading relations with the other. This meaning of reciprocity, however, bears a different interpretation in European and in American usage. In the former, reciprocity between two nations usually means little more than the extension by one to the other of most favoured nation treatment, i.e. such advantages as it extends to any third country (see COMMERCIAL TREATIES).

But in the United States reciprocity is the term applied to the concessions or arrangements made between that country and another without reference to any third country. Thus in the United States there are a maximum and minimum tariff, the rates of the maximum tariff being enforced on the goods of those countries which have no reciprocity treaty with the United States, and the rates of the minimum on certain products of those countries which have by a reciprocity treaty given special advantages or concessions to certain products of the United States.

RECIITAL (from Lat. recitare, to read out, particularly of a public document), an account or repetition of the details of some act, proceeding, fact, &c., particularly, in law, that part of a legal document, such as a lease, which contains a statement of certain facts, e.g. the purport for which the deed is made. In music, the word is used of an instrumental performance given by a single person, and also of a performance of the works of a single composer.

RECKLINGHAUSEN, a town in Germany, in the Prussian province of Westphalia, 22 m. by rail N.W. of Dortmund on the railway to Münster. Pop. (1890) 44,396. In the neighbourhood are extensive coal-mines and brick-works, and the industries embrace the manufacture of linen, beer, spirits and tobacco.

The county of Recklinghausen belonged to the archbishopric of Cologne until 1803, when it passed to the duke of Arenberg. It was known as the Recklinghausen. In 1810 it was divided by Napoleon between the grand duchy of Berg and France, but was, in 1815, restored to the duchy of Arenberg as a fief under Prussian sovereignty.

See Ritz, Die ältere Geschichte des Veste und der Stadt Reckling- hauser (Erzen, 1904).

RECLAMATION OF LAND. The boundaries between sea and land are perennally changing. In many sheltered bays and estuaries the sea is receding, while along other portions of the sea-coast it is continuously encroaching. The same causes operate to produce both results: the rivers carry down with them detritus and sediment from the higher ground; the sea, aided by wind and tide, is always eroding exposed portions of the seaboard; and even such lesser influences as rain and frost assist in disintegrating cliffs composed of softer strata.

The main object of reclaiming land from the sea is to increase the area of ground available for cultivation. Land which has been reclaimed by accretion nearly to high-water level can be cut off from the sea by works of a simple and inexpensive nature, and the fresh alluvial soil thus obtained is generally very fertile. Accretion in estuaries takes place very slowly under ordinary conditions. Although at any one time the sheltered areas may be large and the deposit of silt fairly rapid, not much permanent accretion will take place owing to the frequent shifting of the channels. Directly, however, a fixed channel is secured by longitudinal embankments or training walls, accretion progresses rapidly and uninterruptedly by the deposit of sediment in the slack-water behind the embankments and at the sides of the estuary; and this is especially the case if the training works are raised to the level of high water, for this has the effect of restricting the greater part of the scour of tide and fresh-water discharge to the one fixed channel. The rate of accretion varies with the shelter of the site and the amount of sediment carried by the water; but by degrees the foreshores, in the upper portion and at the sides of the embanked estuary, are raised sufficiently for sampire to make its appearance, and, later on, a coarse grass. Ultimately the time arrives when the water may be altogether excluded by the construction of enclosing embankments; these must be raised above the level of the highest tide, and should have a flat slope on the exposed side, protected, in proportion to exposure and depth of water, against the face with clay, sods, fiascines or stone pitching.

In the intermediate stages of the process outlined above much may be done to promote the growth of accretion, or warping as it is termed, and to ensure the fertility of the reclaimed land. The deposit of warp is accelerated by anything which tends to reduce the flow and consequent scour of the ebb-tide over the
foreshore; thus considerable advantage will accrue from placing rows of faggots or sods across the lines of flow; and banks, enclosing the higher portions of the foreshore, may often be constructed so as materially to increase the period of detention of the near high tide, of the silt-bearing water upon the lower adjacent foreshore. The light, fertilizing alluvium only deposits in shallow water at high tide, and where there are no tidal currents. The final enclosure, therefore, should not be effected until this deposit has taken place. The enclosing works, also, should be so carried out that increasing shelter may favour the deposits of this alluvium during construction. A final and rapid deposit can sometimes be effected by making sluices in the banks: the turbid water is admitted near high tide, and retained until the whole of its silt has been deposited, the clear water being allowed to escape slowly towards low tide. Premature enclosure must be guarded against; it is more difficult, the cost greater, the reclaimed land is less fertile and, being lower, less easy to drain.

The practice of reclaiming land in British estuaries is a very ancient one. The Romans effected reclaims in the Fen districts; the enclosing of Sunk Island in the Humber was begun in the 17th century, and now produces an annual revenue of something like £10,000; large reclaims in the Dee estuary took place in the 18th century; and, in recent times, works have been carried out in the estuaries of the Seine, the Ribble and the Dee.

In the reclamation of land adjoining the sea-coast, sites where accretion is taking place are obviously the most suitable. Marsh lands adjoining the sea, and more or less subject to inundation at high tides, can be permanently reclaimed by embankments; but these, unless there is protection from sand dunes or a shingle beach, require to be stronger, higher, with a less steeply inclined and better protected slope than is required in estuaries. The width of the bank will generally prevent percolation of water at the base; but if there is any danger of infiltration, owing to unsuitability of material, a central core of pudding clay, or a row of sheet-piling should be employed. Waves over-topping the bank will quickly cause a breach, and produce disastrous results; the height of the bank must, therefore, be calculated to meet the case of the severest on-shore gale coinciding with the highest spring tide. Undermining, caused by the recoil of waves on the beach, is liable to occur in exposed sites; this may be prevented by a line of sheet-piling along the outer toe of the bank.

Sea-coast embankments should not generally be constructed farther down the foreshore than half-tide level, as the cost of construction and maintenance would increase out of all proportion to the additional area obtained. It is, as a rule, more economical to reclaim a large area at one time, instead of enclosing it gradually in sections, as the cost varies with the length of embankment; it is, however, more difficult to effect the final closing of a bank, where a large area is thus reclaimed, on account of the greater volume of tidal-water flowing in and out of the contracted opening. The final closing of a reclamation embankment is best accomplished by leaving a fairly wide aperture, and by gradually raising a level bank across its entire length. The enclosed area may be left full of water to the height of the unfinished bank, or the tide-water may be allowed to escape and enter again by sluices in the finished sections. The embankments in Holland are closed by sinking long fascine mattresses across the opening; these are weighted with clay and stone, and effectually withstand the scour through the gap; the two terminal slopes of the finished sections are similarly protected.

There are many examples of sea-coast reclamation: Romney marsh was enclosed long ago by the Dymchurch wall (see fig. 1), and a large portion of Holland has been reclaimed from the sea by embankments (see fig. 2); the reclamation bank for the Hodbarrow iron mines (see fig. 3) illustrates the use of puddled clay to prevent infiltration.

The repair of a breach effected in a completed reclamation embankment is a more difficult task than that of closing the final gap during construction; this is owing to the channel or gully scoured out upon the opening of the breach. When a breach occurs which cannot be closed in a single tide, the formation of an over-deep gully may to some extent be prevented by enlarging the opening. Breaches in embankments have been closed by sinking barges across the gap, by piling and planking up, by lowering sliding panels between frames erected to receive them, and by making an inset wall or bank round the breach. By the last-mentioned method the new connecting bank can be formed on solid ground, and the necessary width of opening obtained to obviate excessive scour during the influx and efflux of the tide over the bank while it is being raised.

The gradual drying of reclaimed land lowers the surface some two or three feet; the land therefore becomes more liable to inundation after reclamation than before. Accordingly, it is most important to prevent breaching of the bank by promptly repairing any damage caused by storms; and if a breach should occur, it must be closed at the earliest possible opportunity.

The protection of the coast-line from encroachment by the sea is a matter of considerable importance and great difficulty: the more rapid the erosion, the more exposed must be the site; and, consequently, the more costly will be the construction and maintenance of protective works. These are of two kinds: sea-walls or banks, and groynes.

Upright sea-walls with some batter on the face have been constructed along the frontage of many sea-side towns, with the double purpose of making a promenade or drive, and of affording protection to the town. A very sloping and also a curved batter breaks the stroke of the wave by facilitating its rising up the face of the wall, but the force of the recoil is correspondingly augmented. A wall with a vertical face offers more direct opposition to a wave, minimizes the tendency to rise, and consequently the recoil; while a stepped face tends to break up both the ascending and recoiling wave in proportion to the recession of the steps, but there is a corresponding liability to displacement of the blocks composing the wall. The concrete sea-walls erected in front of Hove, Margate, and the north cliff at Scarborough (see figs. 4, 5, 6) exhibit straight, stepped, and curved forms of batter. The curvature of the last-named wall, though diverting the coil at its base, did not prevent erosion of the shale bed on which it was founded, and a protective apron in front of the toe had to be added subsequently.

The Beaconsfield sea-wall at Bridlington (see fig. 7) is stepped and slightly curved; it has a stone face with concrete backing,
strengthened at intervals by counterforts. The thickness of the wall varies from 11 ft. 6 in. at the base to 3 ft. at the top, and is

FIG. 4.—Sea-wall at Hove.  FIG. 5.—Sea-wall at Margate.  FIG. 6.—Sea-wall at Scarborough. surmounted by a dressed cornice and coping; the length is 340 yards. The work was constructed, in 1888, at a cost of £10,000, or £39, 8s. per lineal yard.

Walls with almost vertical faces, or slightly stopped, appear to be the best. Unless, however, the foreshore consists of hard rock, or a raised beach maintained by groynes, a wall of this kind should be protected by an apron, in order to prevent the destructive undermining to which such forms of wall are necessarily liable.

Where the coast is fringed by sand dunes, and the beach protected from erosion by a regular series of groynes, as at Ostend (Belgium), the sand dunes, or an embankment for a promenade in front of them, may be sufficiently protected by a simple slope, paved with brickwork or masonry, and having a maximum inclination of two to one. The paving requires to be laid on a bed of clay, rubble or concrete. Parts of the sea bank at Ostend had to be protected from undermining at the toe with piles and planks, and an apron of concrete or pitching, laid on fascines, extending down the foreshore. For the parts above high-water mark a short paved slope, with moderate protection at the toe, has been found sufficient. The top face of these slopes is reflexed so as to protect the esplanade from surf during storms.

Sea-walls are very costly and, while temporarily resisting, do not diminish, but actually increase, the erosive action of the sea. In short, sea-walls are a most unsatisfactory type of protective work.

The protection afforded to the coast by groynes is based on a totally different principle, which may be summarized as that of promoting natural accretion by the construction of artificial shelter. Along most coasts there is a littoral drift of sand or shingle; by means of groynes, projecting from the coast-line down the beach, this drift may be intercepted so as to produce accretion to the foreshore, where previously there has been constant erosion. The problem, however, of coast protection by this method presents difficulties. Littoral drift is the product of erosion, and the fate of a large portion of this drift is to be deposited in deep water. Any scheme, therefore, of stopping erosion altogether by means of groynes would be purely chimerical; in the same way, partial failure of groynes, from lack of drift and inability to stop wastage, must be expected in many localities. Another difficulty may be illustrated by the action of such natural projections as Dungeness: this point, by completely arresting the easterly drift of shingle, causes a rapid accretion to the beach on the one side, but a corresponding denudation on the other. The old type of high groyne, erected at Cromer and Hastings, has produced the same undesirable result; moreover, the general effect of groyning certain portions of the foreshore is to render the adjacent unprotected portions more liable to erosion. Nevertheless, the benefit which may be derived locally from suitable groyning is very great. The timber groynes erected between Lancin and Shoreham raised the shingle beach sufficiently to cause high-water mark to recede 85 ft. seawards in the course of a few years.

The eroding action of the river Scheldt in front of Blankenberge has been arrested by carrying out groynes at right angles to the coast-line, and down to below low water (see figs. 9, 10). These, on the average, are about 820 ft. long and 680 ft. apart: they are made wide, with a curved top raised only slightly above the beach, so as to minimize the scour from currents and wave action, and facilitate the ever
distribution of drift over the protected area. They are constructed with a foundation of focienes and concrete, faced with brickwork or stone pitching. The result has been the formation of a gently sloping beach which reduces wave action; such loss, too, as is still occasioned by storms is speedily made good by natural accretion in moderate weather. The Blankenberghe groynes are too expensive a type for ordinary use.

The beach at Bridlington, which rests on boulder clay, was rapidly disappearing owing to the increased scour due to the sea-walls. Accordingly, groynes (see figs. 11, 12) made of 14 ft. × 9 in. × 9 in. pitch-pine piles, and 11 in. × 4 in. planking, were erected along the foreshore. The piles originally projected about 6 ft.; but, to prevent heaping up of sand to windward with denudation to leeward, the planking was never raised more than two strakes above sand-level, fresh planks being added as the sand rose. The south-easterly gales are said to be the most erosive here, and prevalent during the winter months; on this account the groynes were given an inclination of 10° south of east, that is 10° from the perpendicular. It may be doubted whether this was the best angle, but the result has been very satisfactory. The cost of construction was from 12s. 3d. to 18s. per lineal foot.

The sand-banks at the entrance to Poole Harbour have been protected by groynes (see fig. 13) inclined at slightly varying angles, some yielding better results than others. This is a good example of the important work which may be accomplished by groyning. Unprotected, a break would soon have been effected in these sand-banks; with a double entrance to the bay the present deep channel would have silted up, and Poole Harbour would have been practically destroyed.

It is evident that the efficacy of groynes in collecting drift is proportionate to the distance which they can be carried out seawards, and that they should always be extended to low-water mark; whilst, by raising them only slightly above the beach, the accumulation of drift to leeward is promoted, the passage of drift over the obstruction being facilitated and the scour of the waves diminished. By this means, and by gradually raising and extending the groynes as the drift accumulates, the general elevation of the beach can be secured. Drift generally travels in both directions along a coast, veering with the wind; thus the prevailing wind determines the preponderating travel of the drift. Groynes are usually constructed at right angles to the shore, but it is believed that increased benefit may be obtained by slightly inclining them to leeward of the prevailing wind. Some engineers have advocated the extension of groynes below low-water mark; and as wood when permanently submerged is specially liable, even when creosoted, to be attacked by the terebro and limnoria, the use of reinforced or ferro-concrete has been suggested as the most suitable material for submarine groyning. These suggestions, however, and many other current theories on groyning, require to be demonstrated by repeated experiments.

For a useful bibliography of the subject see British Parliamentary Reports, Coast Erosion and the Reclamation of Tidal Lands, Cd. 3664, Appendix No. X, pp. 146-158.

RECLUS, JEAN JACQUES ELSÉÉ (1839-1905), French geographer, was born at Sainte-Foy la Grande (Gironde), on the 15th of March 1839. He was the second son of a Protestant pastor, who had a family of twelve children, several of whom acquired some celebrity either as men of letters, politicians or members of the learned professions. His education, begun in Rhenish Prussia, was continued in the Protestant college of Montauban, and completed at the university of Berlin, where he followed a long course of geography under Karl Ritter. Withdrawing from France in consequence of the events of December 1852, he spent the next six years (1852-57) visiting the British Isles, the United States, Central America, and Colombia. On his return to Paris he contributed to the Renne des deux mondes, the Tour du monde and other periodicals a large number of articles embodying the results of his geographical work. Among other works at this period was an excellent short book, Histoire d'un ruisseau, in which he traces the development of a great river from source to mouth. In 1867-68 he published La Terre; description des phénomènes de la vie du globe, in two volumes. During the siege of Paris, Reclus shared in the aerostatic operations conducted by M. Nadar, and also served with the National Guard, while as a member of the Association Nationale des Travaillleurs he published in the journal, La Revue de la réclamation, the history of the great work, L'Exécution et rénovation des terrains d'habitation,François, 13 vols. (1875-94). This is a stupendous compilation, profusely illustrated with maps, plans, and engravings, and was crowned with the gold medal of the Paris Geographical Society in 1892.

An English edition appeared simultaneously, also in 13 vols., the first four by E. G. Ravenstein, the rest by A. H. Keane. Extreme accuracy and brilliant exposition form the leading characteristics of all Reclus's writings, which thus possess permanent literary and scientific value. In 1882 Reclus initiated the "Anti-Marriage Movement," in accordance with which he allowed his two daughters to marry without any civil or religious sanction whatever. This step caused no little embarrassment to many of his well-wishers, and was followed by government prosecutions, instituted in the High Court of Lyons, against the anarchists, members of the International Association, of which Reclus and Prince Kropotkin were designated as the two chief organizers. The prince was arrested and condemned to five years' imprisonment, but Reclus, being resident in Switzerland, escaped. After 1882 he filled the chair of comparative geography in the university of Brussels, and contributed several important memoirs to French, German and English scientific journals. Among these may be mentioned "The Progress of Mankind" (Contemp. Rev., 1860); "Attila de Gerando" (Rev. Geograph., 1868); "A Great Globe" (Geograph. Journ., 1868); "L'Extrême-Orient" (Bull. Antwerp Geo. Soc.,
RECOGNIZANCE—RECORD

(1898), a truthful study of the political geography of the Far East and its possible changes; "La Perse" (Bull. Soc. Neuchateleise, 1899); "La Phénicie et les Phéniciens" (ibid., 1900); La Chine et la diplomatie européenne ("L'Humanité nouvelle" series, 1900); L'Enseignement de la géographie (Instit. Géograph. de Bruxelles, No. 5, 1901). Shortly before his death Reclus had completed L'Homme et la terre, in which he set the crown on his previous greater works by considering man in his development relative to geographical environment. Reclus died at Thourout, near Bruges, on the 4th of July 1905.

RECOGNIZANCES (from Lat. recognoscere to acknowledge), a term of English law usually employed to describe an obligation of record, entered into before some court or magistrate duly authorized, whereby the party bound acknowledges (recognizes) that he owes a personal debt to the Crown, with a defasance, i.e., subject to a condition that the obligation to pay shall be avoided if he shall do some particular act—as if he shall appear at the assizes, keep the peace, or the like. The system of taking recognizances in favour of the Crown at an early date superseded the common law practice as to pledges and main-prize (see re Nottingham Corporation, 1857, 2 Q.B. 503, 514).

Blackstone's definition extends the term to any recognizance to bind to the peace of persons. But at present it is rarely if ever used in this sense. Recognizances are now used almost solely with reference to criminal proceedings. In the Court of Chancery it was the practice to require recognizances from the guardian of a ward of court that the ward should not marry or leave the country with the property of the guardian and without the leave of the court. The security given by a receiver appointed by the High Court is still in the form of a recognizance acknowledging a debt to named officers of the court, and securing it on the real and personal estate of the receiver.

By an act of 1360 (3 Edw. III. c. 1), extended by Ireland by Poyning's Act, and by the terms of the commission of the peace, justices of the peace have jurisdiction to cause to come before them or any one of them "all those who to any one or more of our people concerning their bodies or the firing of their houses have used threats to find sufficient security for the peace or their good behaviour towards us and our people; and if they shall refuse to find such security, then there in our prisons until they shall find such security to cause to be safely kept." The security taken is by recognizance of the party and his sureties, which can be forfeited on conviction of any offence which is a breach of the conditions of the recognizance.

The procedure under the act of 1360 and the commission is usually described as exhibiting articles of the peace or swearing the peace. The High Court (King's Bench Division) has the same power, and by an order of court sessions is now the usual mode of procedure in such cases. The practice was superseded in England, so far as concerns courts of summary jurisdiction, by an equivalent but more modern procedure (42 & 43 Vict. c. 49, s. 25). Recognizances ordered under these enactments cannot be forfeited or as it is termed estreated without an order of court made upon proof of breach of the conditions, or of a conviction involving such breach. The procedure for estreats is governed by the Levy of Fines Acts 1822 and 1833, and by 16 & 17 Vict. c. 30, s. 2.

There is also a general jurisdiction on conviction of misdemeanour to put the offender under recognizances to keep the peace and (or) be of good behaviour, and to add to the recognizance a substitute for punishment. This power is specifically applied by the Criminal Law Consolidation Acts of 1861 to all indictable misdemeanours punishable under these acts, and power is given to the court to add a substitute for the act under a recognizance to keep the peace. On refusal to enter into recognizances as above, the court may order imprisonment for the period of sentences of 1861, twelve months, and in cases within the act of 1879 to six months.

The recognizances above described may be described as a form of punishment or a judicial security for good conduct. Recognizances are served with a process of convicts before conviction and judgment. In preliminary inquiries into indictable offences the inquiring justices take recognizances to ensure the attendance of the accused if libelated during any adjournment, and the accused, having taken the recognizance, cannot be accused (if allowed bail) to attend the court of trial and take his trial, and of the prosecutor and the witnesses for the prosecution or defence to attend and prosecute or give evidence. As to witnesses this power was first given in 1554 (1 Ph. & M. c. 13). The procedure is regulated by the Indictable Offences Act 1848 (11 & 12 Vict. c. 42) as amended in 1867 (30 & 31 Vict. c. 35) and the forms of recognizance are scheduled to the act of 1848. In the case of indictment for murder or manslaughter taken before a coroner a similar procedure is followed (Coroners Act 1887, 50 & 51 Vict. c. 71, s. 5). The recognizances taken are returnable under penalty to the court of trial, which orders their estreat in the event of breach of condition.

Similar powers as to the recognizances of persons prosecuted summarily are given by the Summary Jurisdiction Acts 1848 and 1849 to the courts of summary jurisdiction. In the case of breach of the High Court from courts of summary jurisdiction, recognizances or security are required from the appall (42 & 43 Vict. c. 49, ss. 31, 33). On the transfer of indictments from the Inferior Courts to the Crown, a recognizance of good behaviour is required (Crown Office Rules, 1896). In certain cases the police have authority to give bail to accused persons on their entering into a recognizance; and governors of prisons are allowed to release prisoners on bail on compliance with the terms on which it is allowed by the committing justices.

By the Land Charges Act 1900 (63 & 64 Vict. c. 26, s. 2) a recognizance, whether obtained or entered into on behalf of the Crown or otherwise, does not operate as a charge on land or on any interest on land or on the unpaid purchase money for any land, unless a writ or order for the purpose of enforcing it is returned under s. of the Land Charges, 8 &c. Act 1888 (51 & 52 Vict. c. 51) in the office of the Land Registry. This enactment is clearly applicable to receivers' recognizances, supra; and on purchases of land search is made for registered recognizances and other instruments of title and in the absence of a certificate that such instruments exist the existence of a registered entry (Conveying Act 1882, s. 2). By s. 30 of the Bankruptcy Act 1883, a discharge in bankruptcy does not release the debtor from debts on a recognizance unless the certificate of bankruptcy is produced.

By ss. 32, 34 of the Forgery Act 1861, it is made felony to forge recognizances, and to acknowledge them in the name of another without lawful authority is also felony (24 & 25 Vict. c. 98).

In Scotland the place of recognizances is filled by cautions: a caution in "law-burrows" corresponds very nearly to a recognizance to keep the peace.

In the United States recognizances are used for much the same purposes as in England. (W. F. C.)

RECONNAISSANCE (from Fr. reconnaître, to recognize, Lat. recognoscere), a military term denoting the reconnoitring or examination of an enemy's position or movements, or of a tract of ground. Reconnaissances naturally vary indefinitely according to the purposes for which they are undertaken. A topographical reconnaissance is practically a survey of a tract of country or route, comprising both a map and a report as to its advantages and disadvantages. All reconnoitring work of this character is done by officers with small patrols, escorts or assistants. Strategical reconnaissance is performed by combat squadrons, which send forward officers and patrols to find the enemy, to act on information falls to the hands of such officers, whether in contact with the enemy or for self-protection. A reconnaissance by a large force of all arms with the idea of provoking an enemy into showing his hand, if necessary by fighting, is called reconnaissance in force.

RECORD (Lat. recordari, to recall to mind, from cor, heart or mind), a verb or noun used in various senses, all derived from the original one of preserving something permanently in memory. In this article, however, we are only concerned with documentary records, or archives. In its accurate sense a record is a document regularly drawn up for a legal or administrative purpose, preserved as an exhibit of the transaction described in it; for the most part it forms a link in a complicated process, and unless the connection between it and the other documents making up the process has been preserved, a portion of its meaning will have perished. The first care, therefore, of the custodian of records should be to preserve this connexion, where it exists. In the majority of countries a previous task awaits him; it has been his duty to collect and arrange his documents. There are few countries in which records have not passed through a period of neglect; each office of state has kept or rather neglected its own papers; each court of justice has preserved a tradition, and the custodian of the document has been by a multitude of repositories among which he vainly sought the documents he required. To this stage two systems have succeeded; the system of centralization both of records and of

958
staff; and the system under which the records are kept in local repositories and the staff is centralized. There are of course countries which cannot be brought under either of these formulae. But for the most part it will be found that the record system has prevailed; there are a central office for records of state, provincial offices for legal records and those of local administration, town offices for municipal records, and a staff of archivists depending more or less strictly upon the central office. In England the first system has been preferred; almost all the records that can be collected have been gathered into the central office. In the future, indeed, it is inevitable that collections of administrative records should grow up for each county; but there is at present no means of ensuring their arrangement and preservation. Many towns possess old and valuable collections of municipal archives, and over these the central office has no control. It would be absurd to affirm that such control is needed for the preservation of the documents; but it is a curious fact that the English government, which has centralized records more freely than any other, should have refrained from establishing any system of administration for records in general.

The following article is intended to give a full account of the administration and nature of the records of Great Britain, and brief notices of those of other countries concerning which information is obtainable. It may be noticed that the directory of the leading record officers of the United Kingdom is not open to the public.

Until the establishment of this office, the records of the various courts of law and administration were kept in separate places, mostly of an unsuitable nature, whose contents were inaccessible and unknown. The Tower of London contained the records of the Chancery, which were kept in fair order; the records of the Exchequer were scattered in many places, chiefly unsuitable; and other collections were almost as unfortunately bestowed; the only attempt to provide a special place of custody was made in the 17th century, when the State Paper Office was set up as a place of deposit for the papers of the secretaries of state. From time to time efforts were made, chiefly by means of committees of the House of Lords, to procure reforms in the custody of documents whose value was well understood. In the reign of Queen Anne, an act was passed by which the Treasury was authorized to publish such documents as could be found bearing upon foreign politics; and this drew fresh attention to the question of custody. In 1730 Dr. Hoadly, librarian of the Royal Library, produced a committee of the House of Commons and another report, but it was not until 1800 that any serious steps were taken. In that year a committee of the House of Commons presented a valuable report, which was approved by the government and acted upon. This committee was renewed from year to year and did not expire until 1837. It fell partly because of internal dissensions, but principally owing to gross extravagance and almost complete neglect of its duty, so far as the arrangement and custody of the records went. The committee was, indeed, badly designed and badly executed; but their most prominent characteristic was their expense. To this commission succeeded the Royal Commission of 1800, which was very different from its predecessor. It consisted of 14 members, who were appointed by the King, and a central repository was begun; and with the completion of each portion of it further groups of records were brought in. At first only those collections specified in the act of parliament were dealt with. The work was continued by the Public Record Society, and the first examples were published by the Alcuin Club (see M6y et Bibliog., Bibliographie générale des inventaires imprimes, vol. i. p. 245). 

The -court of Exchequer on the King’s Remembrancer’s side is in cases connected directly with the revenue. These are enrolled upon the Memoranda Rolls, and for the period 35 Charles II. to William IV. there are Order Books.

King’s Remembrancer’s Memoranda Rolls. These are the records of the Deputy Keeper, and now deal merely with the administrative work of the office; up to 1889 they also contained in the form of appendices, inventories and detailed descriptions of various classes of records. In the present article these records are referred to by counties. The lists and indexes are the descriptions of special classes with more or less detail, or indexes to the contents of certain documents grouped for that purpose; they are here cited by their number. The calendars are volumes containing full abstracts, or extended indexes to certain classes of documents; they are unnecessary for critical purposes; they are equipped with full indexes. The contents of the Record Office are classified for the most part under the collections in which they were found. For personal account records, they are referred to in the record book to the Public Records (3rd ed. 1908).

We may now turn to the documents themselves, under the following heads—

[1] General Records. The records of the administrative and judicial sides of the Exchequer (q.v.) are here described under its several divisions. (1) Upper Exchequer, or Exchequer of Audit. (a) Lord Treasurer’s Remembrancer’s Office, or Office of final audit.

The result of the final audit is recorded in duplicate on the Pipe and Chanceller’s Rolls. These consist of a solitary (Pipe) roll for 31 Henry I., and a duplicate series extending from 2 Henry II. to 2 William IV. These records contain a Committee of the King’s Remembrancer’s Rolls, 31 Henry I., 2-4 Henry II., 1 Richard I.; Chancellors’ Rolls, 3 John. The Pipe Roll Society has printed the Pipe Rolls for 5-24 Henry II.

Originalia Rolls or Rolls of Accounts. These contain the records of the preliminary audit of accounts other than county accounts of the sheriffs; they run from 42 Edward III. to modern times; closely connected with them are the Enrolled Accounts, which deal with the more important items, and show that the final audit is not recorded upon either Foreign Rolls or Enrolled Accounts, but must be sought on the Pipe Roll, unless the accountant is found to be quit or to have a balance due to him. The Record Office has published a classified list (No. XL) of the Foreign and Enrolled Accounts taken from all the foregoing rolls of audit, but omitting the accounts of Customs and Subsidies.

Lord Treasurer’s Memoranda Rolls. These are the records of the administrative and judicial sides of the Exchequer. The records begin in the 16th century, and from the 17th century is fairly complete.

Originalia Rolls (20 Henry III. to 1837), or extracts from the Chancery Rolls communicated to the Exchequer for its information and guidance. Latin abstracts of the rolls from Henry III. to Edward III. were printed by the Record Commission as Abbbreviatio Exchequeria originalium. (2) King’s Remembrancer’s Office, or office of preliminary audit. The most important financial records of this branch of the Exchequer are the class known as “Exchequer K. R. accounts,” which comprise vouchers and audited accounts of expenditure. Of similar accounts relating to receipts, the Exchequer’s accounts have been listed in the 19th Report; but the inquisitions there described as filed with the accounts as vouchers are now classed separately, and are less certain than those in the calendars. Accounts and vouchers relating to Subsidies and Customs are at present only described in manuscript (see below under SPECIAL CORRESPONDENTS).

In the reign of Edward VI., returns were made into the Exchequer by commissioners appointed to take inventories of Church Goods, which the author of these pages were publishing being being published by the Alcuin Club (see M6y et Bibliog., Bibliographie générale des inventaires imprimes, vol. i. p. 245).

Judicial. The only judicial proceedings on the Lord Treasurer’s Remembrancer’s side are in cases connected directly with the revenue. These are enrolled upon the Memoranda Rolls; and for the period 35 Charles II. to William IV. there are Order Books.
the rolls for the period 1-16 Henry VIII. From this point over 30 volumes of a Calendar have been published, and the transcribing gaps in the series are being closed. For these gaps the Record Commission’s Calendarium Rotulorum Patrimonii is still useful, although the subject matter is printed in such a form that the rolls for the reign of Henry VIII. will demand a complete revision of the matter on the rolls. The Close Rolls of Henry VIII. have been published in 62 volumes, all containing a transcription of the rolls for the period 6 John to 11 Henry III. The Record Office has also published several volumes of the Calendaria Rotulorum Beneficiarum, of which the reign of Edward I. eighteen volumes of a calendar have appeared. The Fine Rolls (1 John to 23 Charles I.) contain the record of judicial proceedings, and are published under the great seal with a note of the fine or fee paid, and also of letters patents; from the latter the administration of the feudal incidents is drawn. The Record Commission published a transcript of the rolls for the reign of John (3 Richard to 2 John), and for the reign of Henry III. they also published two volumes of Exchequer Rolls consisting of the entries relating to the feudal incidents. There were also other rolls containing letters issued under the great seal which were not included in the earlier volumes. The rolls here mentioned deal with some rolls now placed in other classes.

Other rolls contain letters under the great seal relating to Ireland, Scotland and Wales. Of these the Record Commission printed the Scottish letter rolls (5 Henry IV. to 960), which are made up of various letters, and include in them numerous letters of protection contained in them. For the Welsh and Irish Rolls there is only a partial calendar in Ayloffe’s Calendar of Ancient Charters. The Roman and Almain Rolls have been used in Fodera, and many entries from the Roman rolls will be found there. The Liberale Rolls (2 John to 14 Henry VI.) contain the enrolments of writs for the issue of money out of the Exchequer. The rolls 4-7 to 4-7 have been printed in full by the Record Commission.

Documents forming Part of the Process of Issuing Letters under the Great Seal.—These are known as Chancery warrants, and consist of Privy Seals, Signed Bills and other documents forming steps in the course of the process of issuing letters. The first of these is the commission of the reign of Richard III., and Series II. to the end of the reign of Henry VIII.; Series III. ends with the view of Anne, and Series IV. with the reign of William IV., while Series V. is still in progress. Series IV. (4-67 to 4-67) containing entries of the latter being also classified); the remainder are in monthly bundles. The warrants for the reign of Henry VIII. are calendared in the Letters and Papers of Henry VIII.; those for the first seven years of Charles I. are calendared in the 43rd Report. The books here mentioned deal with some rolls now placed in other classes.

Documents drawn up for the Information of the Chancery.—The most important of these are the inquiries held under writs issued from the chancery. The first series of these (Henry III. to Richard II.) published with the reports of the Record Commission entitled Calendarium Rotulorum Chariarium. The Record Office has published three volumes of a calendar of Inquisitions Post Mortem including analogous documents relating to the feudal tenure of land, Criminal Inquisitions and Miscellaneous Inquisitions. The Record Office has published three volumes of a calendar of Inquisitions Post Mortem. The Record Commission calendars refer to the old arrangements of these inquiries into two series, known as Inquisitions Post Mortem &c., and Inquisitions ad quod damnum &c., a distinction of title which concealed the identity of the documents. These calendars correct many inaccuracies and omit much useful information. To supply some of these defects for the period Henry III. to Edward I., the Record Office published the Calendarium Genealogicum, but this work is not attested, and the original documents have been published in another series of inquiries. In the second series of these inquiries the three classes of inquiries are all placed together. One volume of a calendar of Inquisitions Post Mortem for the reign of John to 11 Henry III. has appeared. Certificates of Gilds are returned made under the statute of 12 Richard II. Those in English have been printed by J. and L. Toulmin Smith for the Early English Text Society. Chartable Uses: a list (No. X.) of all inquisitions and decrees of commissioners
apportioned under two statutes of Elizabeth to examine and rectify abuses of charitable bequests has been published by the Record Office. *Forests (Chancery)* contain perambulations and proceedings and proceedings before the justices in eyre of the forest. The perambulations for certain forests in Scotland are reprinted by G. J. Turner in *Select Pleas of the Forest* (Selden Society).

*Scottish Documents.*—Five rolls relating to the policy of Edward I. towards Scotland. The first two contain the proceedings touching the erection of the Scottish nobility to Edward I., and were printed by the Bannatyne Club in 1814. They contain duplicate submissions of the Scottish nobility to Edward I., and were reprinted in *Ragman Rolls* as *Select Pleas of the Chancery* (Selden Society), by W. P. Baldwin. For the reign of Elizabeth the proceedings are reprinted in *Select Pleas of the Chancery.* The records of the period 1739 to 1760 are described in J. Bain's *Calendar of Documents relating to Scotland.*

Most of these together with the earlier Forest proceedings are contained in the manuscripts held in the British Record Office. The rolls contain a number of other documents and rolls. Many of these relating to foreign affairs are printed in the *Foederer.*

(2) *Chancery Judicial.*—These may be divided into *Proceedings,* or Bills and Answers, &c., filed by the parties; *Decrees and Orders* of the court; and *Affidavits* and other documents connected with the course of the action. The series known as *Early Chancery Proceedings* (Richard II. to Philip and Mary), comprising documents of all three classes, is arranged roughly in chronological order. The Record Office has published three volumes of a descriptive list (Nos. XII., XVI. and XX.) of the whole of this series; and the first two have been included in the *Record Office Calendar of Proceedings in Chancery, Elizabeth,* published by W. P. Baldwin. For the reign of Elizabeth the proceedings are reprinted in the *Select Pleas of the Chancery.* Series I. is calendared in the Record Commission volume already mentioned for Series II.; the Record Office has published a descriptive list (Nos.VII. and VIII.) covering the years 1558-1621. To this series the reigns of Edward VI., Queen Mary, Elizabeth, and James I. have been added. Messrs. Topham's and Fry have published in the *Index Library* of the British Record Office an index taken from Topham's manuscript index in the Record Office. The same society has reproduced in an alphabetical form an index to the proceedings in the council's division for the years 1694-1714. These last indexes contain only the surnames of the parties, without reference to the nature of the suit. *Decrees* and *Orders* are included in the index to the records of the orders of the court; with them may be classed the *Reports and Certificates* of the masters and chief clerks. The *Affidavits,* &c., date from 1617.

A procedure formerly had a common law jurisdiction relating to certain matters touching feudal incidents and tenures, to receipt of letters patent, and to actions upon recognizances acknowledged in chancery or concerning officers of the court. No printed mecenat has been published.

**Court of King's Bench.**—The principal records of this court are the rolls recording its proceedings and judgments, of which clasical writers have made use in the *Rolls* (No. IV.), under the following heads. *Curia Regis Rolls* (5 Richard I. to 56 Henry III.) include all the rolls of the king's court with the exception of a few *Eyre Rolls.* Of these the Record Commission printed volumes of *Eyre Rolls* (vol. I., 1276-1497) and *Eyre Rolls* (vol. II., 1497-1660), published in the *Abbreviatio Placitorum* certain abstracts from a portion of the pleas on these rolls made in the 17th century. For specimens see Selden Society volumes, *Select Civil Pleas,* edited by W. Maitland, prefixed to the *Rolls.* *Pipe Rolls* (vol. I., 1166-1279), and *Pipe Rolls* (vol. II., 1279-1307), by W. Maitland, who has also edited for the Pipe Roll Society four rolls, of the reign of Richard II. From the end of the reign of Henry III. the rolls of the king's bench and those of the common pleas (see below) have been separated. The former, named *Coram Regis Rolls* (1 Edward I. to 13 William III.), divide from 1 Anne into two portions, *Judgment Rolls,* containing pleas between private persons, and *Crom Rolls,* containing crown business. References to some pleas on the *Coram Regis Rolls* will be found in the *Abbreviatio Placitorum;* the complete roll for 25 Edward I. has been printed by the British Record Society.

A great number of these heads are groups containing the proceedings before justices in eyre, as assize, of oyer and terminer, of gaol delivery (a few) and before justices sent on special commission. References to some of these will be found in the *Rolls* (No. IV.) under the heads *Curia Regis.* 5 Henry III. has been published by W. Maitland. The pleas of oyer and terminer of Queen Anne were printed during the period Edward I. to Edward III., and published by E. G. D. Topham. For specimens see *Coroners Rolls* (Henry III. to Henry VI.), see the Selden Society's volume edited by G. Gross, *Brevia de Coronis.* The proceedings for treason or felony held before the court of king's bench of special commissioners. An inventory and calendar will be found in the 3rd, 4th and 5th reports.

**Court of Common Pleas.**—The Pleas of this court, known as *De Banco Rolls,* run from 1 Edward I., before which dates pleas before justices of the common bench form part of the *Curia Regis*
in character from the State Papers Domestic. The Domestic Papers relating exclusively to Ireland have been calendared under the title of State Papers, Ireland, for the years 1590-1601 and 1603-1659, with a special volume dealing with the papers concerning Advertisements of the Irish Parliament. From 1670 these papers are calendared in the Domestic volumes.

Scotland.—Originally there were in the State Paper Office two sets of papers relating to Scotland, State Papers Domestic, Border Papers (for the period 1547-1559) and Border Papers (for the period 1560-1603), and of many of the Border Papers which were removed from their places without any record of the removal. Next came the Calendar of State Papers, Scotland, 1560-1603, containing brief notices of the events at this time in Scotland, and of many of the Border Papers which were not removed from their places without any record of the removal. Out of the original 75 volumes of Border Papers only 36 remained. At a later date the papers drawn for the Foreign Calendar were restored and now form the first 19 volumes of the series, while the 36 volumes originally remaining have now become the final 23. At the same time the State Papers Foreign, Scotland, were annexed, and became State Papers Domestic, Scotland. In their present arrangement the Border Papers have been calendared in the following volumes: vols. 1-19 in the State Papers Foreign 1547-1550; vols. 20-42 in the Scottish General Register Office Calendar of Border Papers 1560-1603. The State Papers Foreign, Scotland, are being fully calendared in the Scottish General Register Office Calendar of Scottish Papers with other material. Those from 1509 to 1547 are dealt with in the Letters and Papers of Henry VIII (1509-1547; 8 vols.; London, 1872-1883). A list of these three has been published (No. III).

Foreign.—Calendars of the State Papers Foreign have been published for the years 1567-1571, 1583-1587, and 1589-1594, and also calendared in the first volume of the State Papers Spanish (see below under Spain). The Record Office has published a list of the State Papers Foreign (No. XIX).

Colonial.—These papers are calendared in two sets, an "East Indies" (1513-1634, which has been continued to 1659 by the India Office in Miss E. B. Sainsbury’s Court Minutes of the East India Company) and an "America and West Indies" (1574-1693), respectively.

DEPARTMENTAL RECORDS.—From time to time all the government departments, with the exception of the India Office, deposit such papers as they wish to preserve in the Public Record Office; these are calendared in the Public Record Office General, Admiralty, War Office, Local Government Board and Board of Trade have all placed important papers in the care of the Master of the Rolls. A calendar of the earlier Treasury Papers, which extends from 1660 to 1668 and 1720 to 1745 has been published; also a list of the Admiralty Records (No. XVII). For each department a limiting date is fixed from time to time; documents before that time are open to students; later ones are only accessible under special circumstances.

SUBORDINATE AND INDEPENDENT JURISDICTIONS.—Palatinate of Durham.—For the earlier records see G. T. Lapsey’s County Palatine of Durham (Harvard Historical Series, vol. viii.), pp. 327-337. The Court Rolls are the basis of the Palatine Records, in the Public Record Office. There are also many other records of the Palatinate preserved in the Record Office and are calendared in the Calendar of Inquisitions Post Mortem (Nos. 164-180), calendared in the 44th Report; and a volume (No. 2) contains transcripts of some of the documents, calendared in the 45th Report. The records of the Exchequer of Durham, though deposited in the Public Record Office, are treated as the private records of the Ecclesiastical Commission, and are only accessible with a special permit. To the judicial records the following nos. mean reference is the list of Judgment Rolls (20 Henry VII. 7-8 Victoria) in the Record Office list of Plea Rolls (No. IV).

Palatinate of Chester.—The letters sent out from the chancery are enrolled upon the Chester Recognizance Rolls (1 Edward II. to 14 Charles II. with a few rolls down to 1 William IV.) calendared in Reports 36-37 and 39. The financial records of the Exchequer of Chester are listed in the Ministers’ Accounts (List No. V) of the Cely Roll. (The draft of a good damnor (Edward III. to Charles I.) are indexed in the 25th Report. The judicial records consist of pleas in the Exchequer, a court of equity, its records are Bills and Answers (Henry VII. to Edward IV.); sealed by the Master and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (44 Henry III. to 1 William IV.) with a separate series for Flint (from 12 Edward I.) are listed among the Plea Rolls (List No. IV) of the Cely Roll. A register keeps a record of all the Writs of Dower upon these rolls for the period Henry III. to Henry VIII. are calendared in the 26th-30th Reports without an index. The Assize Rolls for the counties of Chester and Flint and for the honour of Macclesfield are listed among the other assize rolls (List No. IV.)

Wales.—The following are the principal records of the principality of Wales: Ministers’ Accounts and Court Rolls, including those of the former privy council of the Principality of Wales, Lords Marchers, listed in Lists Nos. V. and VI. Of the judicial records of the Great Sessions of Wales, set up by the act 34 & 35 Henry VIII., c. 26, the Plea Rolls are listed in the list of Plea Rolls (No. IV) of the Cely Roll. The Records of the Palatinate, transferred to the Public Record Office from Lancaster castle, related to the county and are either enrolments of writs or of a judicial nature. The records of the duchy, transferred from the lower courts of the Duchy to the High Court of Justice, the Judges of Chester and the Justices of Chester, are dealing with the manorial and financial records of all the estates within and without the county. For the Duchy Records see the detailed list (Nos. XIV.); store the means of reference this collection are fully described. Of the Palatinate Records the enrolments of writs are classified as Patent and Close Rolls. The former, a broken series from 5 John of Gaunt to 21 Henry VII., are calendared in the 40th Report; the latter (in 3 rolls, a broken series, 11 Henry IV. to 9 Edward IV.) in the 37th Report; but certain enrolments of the palatinate are among the duchy records. The judicial records of the chambery are not calendared; but the proceedings before the Chamber of Lancashire are calendared in the 28th and 29th Reports. The Chamber at Westminster are dealt with in the duchy list. Proceedings under common law include Plea Rolls (2 Henry IV. to 11 Victoria) listed in the list of Plea Rolls (No. IV); and for criminal proceedings there are the Rolls of the Assize of the Duchy of Lancaster, of which there is a list in the same place. But certain rolls which were among the Duchy Records will be found apart under Wales.

Bishopric of Ely.—The act & 2 Victoria, c. 94, places the records of this palatinate under the charge of the Master of the Rolls. They have never been removed to the Record Office, but remain with the episcopal records, where they can be inspected. A valuable descriptive list has been published by Alfred Gibbons for private circulation.

SPECIAL COLLECTIONS.—For the classification of the records within the above-described paragraphs, the known purpose for which the purpose has been used. There exist, however, masses of records where this path is now inaccessible; these have been formed by putting together records of a similar nature either in ignorance of their history or without regarding it; the justification of this course of action must be found in the special circumstances of each case. These collections are as follows:—

Ministers’ Accounts are the accounts of bailiffs, receivers, and other officers managing estates, including, first, those of the duchy of Lancaster; second, accounts of crown lands filed as vouchers in the King’s Remembrancer’s Office; third, accounts of monastic and other lands seised by the crown, or acquired by it by purchase; fourthly, the lists of officers, or memos, which were published by the Record Office (Nos. V. and VIII) covering the period down to 1485. For the accounts of the duchy of Lancaster a list will be found in the 45th Report, extending to the reign of Queen Elizabeth.

Court Rolls are records of the proceedings and profits of manorial and other private courts coming from the same sources as the Ministers’ Accounts. These are arranged in a strictly chronological order, and are calendared in a list of Rolls (List No. VII). An ancient and indeterminate list of Select Pleas in Manorial Courts, edited for the Selden Society by W. Maitland. Leaf and Description.—In this collection are placed all documents which appear to have formed part of a title to land, some original royal charters and other analogous records. There are five series, A, B, C, D, and E, distinguished by their former place of custody. Documents in the former B series are too large to be calendared in detail; double letters, e.g. A.A., and to those bearing fine seals the letter S is added, e.g. AS or SAS. There are thus in all fifteen classes. The A classes are derived from the Treasury of Receipts, or Chapter House at Westminster, and are largely monastic; the B classes are from the court of Augmentations; the C classes are chancery deeds, probably deposited as exhibits in suits or for enrolments; the D classes are from the Court of Common Pleas; and the E classes are from the Land Revenue office. In 1909 five volumes of a descriptive catalogue had been published by the Record Office. Ancient Correspondence consists of documents which in form are rather of the nature of public than private records, but which are found detached in the chancery records, but similar documents from other sources have been added. The introduction to the Record Office List (No. XV.) contains some account of the formation of this class, and introduces other printed collections based upon these documents. Vol. 53 contains letters of the Cely Family and is published (Camen Society, 3rd series, vol. i.). Ancient Petitions.—The history of the formation of this class
is obscure; an account of it is in the Record Office Index to the class (No. 1); but see also the Introduction to F. W. Maitland’s Memoranda de Parlamento (Rolls Series, vol. 98), in which volume a number of these petitions are printed in full.

Diplomatic Documents in the Record Office. In the Record House at Westminster was a collection of treaties and other documents connected with foreign affairs, and to these have been added other similar documents found there. Of these there is a descriptive list in the 45th, 1867, part of the Reports. A collection of so-called Diplomatic Documents from the chancery forms part of the Chancery Miscellanea.

Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII. — This great collection of materials for the reign of Henry VIII. (Calendar of 20 volumes in 30) at present extends to the year 1547, and is intended to contain abstracts of all documents bearing upon that reign in the Record Office, the British Museum and other Catalogues. Considerable space in this Calendar has sometimes been left in their original place of custody and sometimes transferred to a series of bound volumes known as Letters and Papers, Henry VIII. References will be found in the Calendar to a previous series of State Papers of the Reign of Henry VIII., printed by a Royal Commission for printing State Papers.

Miscellaneous Books. — The many books and registers preserved in the Record Office will be found described in the Handbook. The following have been printed:

**Exchequer King’s Remembrancer**

Vol. 3. Book of Aids. (See feudal aids, published by Record Office.)

Vol. 4. Book of Knight’s Fees. (See feudal aids.)

Vols. 5 & 6. Testa de Nevell: printed by the Record Commission.

Vol. 17. A 16th-century transcript of an abstract of Kirkby’s *Quest* for certain counties; used in feudal aids.

Vol. 28. Chartulary of Ramsey Abbey (Rolls Series, No. 79).

Vol. 32. The Book of Common Prayer deposited under the Act of Uniformity. (Vols. 15 & 16 relate to the results of the voyages of Martin Frobisher (Hakluyt’s Voyages).)

**Exchequer Treasury of Receipt**

Domesday Book. — Indexes and supplementary matter were printed by the Record Commission. Since then facsimiles of the text for each county have been issued.

Miscellaneous Books. Vols. 6-55. Certificates of Masters. (See Letters and Papers of the Reign of Henry VIII.)

Vol. 69. Extents of Knights’ Fees in the Honour of Richmond; printed in Gale’s Registrum Honorum de Richmendo.

**Exchequer Augmentation Office**

Vols. 495-515. Inventories of Church Goods. For details of these printed, see Mély et Bishop, *Bibliographie Générale des Inventaires Imprimés*.

The following accounts of other collections of records are necessarily less detailed:

**Privy Council Office.** — The registers of the Privy Council are still preserved in that office, with the exception of a few volumes which have strayed into other places. J. R. Dassen has edited for the Master of the Rolls a series of volumes containing *The Acts of the Privy Council*, from 1342 to 1604. The Proceedings and Ordinances of the Privy Council, 1429-1503, Henry VI., edited for the Record Commission by Sir N. Harris Nicolas, are from documents in the Cotton MSS. and from transcripts made by Rymer from documents then at the disposal of the office.

**India Office.** — The records of the India Office are preserved there. Complete printed lists exist for the whole collection, and the following documents have been published: The *First Letter Book of the India Office* (1579-1602), edited by F. C. Foster; Letters received by the East India Company from its Servants in the East, edited by F. C. Danvers and W. Foster (6 vols.). The records in India may be mentioned here. Each presidency and other collection has a special jurisdiction; and this in the case of some of the smaller subdivisions. No printed lists appear to exist for any of the collections.

The following volumes have been published: Letters, Despatches and other Papers of the Foreign Department of the Government of India, 1772-1857, edited by G. W. Forrest (3 vols., Calcutta); Bengal 1756-1757, edited by S. C. Hill (3 vols., 1903); and Old Fort William, edited by C. R. Wilson (3 vols., 1906-7).

**Ireland.** — The Public Record Office of Ireland was established in 1867 by the Act 30 & 31 Vict. c. 70, where the records of the various courts of law, all wills proved in Ireland, and certain financial records, were collected into one building. The State Paper Office Ireland, the State Paper Office England, and the records of the Foreign Department of the Government of Ireland, in the Record Office tower of the Dublin Castle, whence the papers are only transferred to the Record Office by special order. The Deputy Keeper of the Irish Record Office publishes yearly reports with appendices. The most important collection of material here is that of Plantations, warrants for the issue of letters under the Great Seal, Henry VIII., to Elizabeth, contained in Reports 7–9, 11–13, 15–18, with indices, for each reign. Other reports cover another calendar, that is in the 20th, 23rd, 24th and 27th Reports. The Wills of the diocese of Dublin, down to the year 1800, are indexed under the names of the testators in the 26th and 30th Reports. The series of Proclamations by the lord lieutenant and council, and by the crown, which is among the records in the Record Tower of Dublin Castle, is catalogued in the 23rd and 24th Reports. Of the financial records very little has been published. In the 33rd Report there is a good account of the Books of the 17th, 18th and 19th centuries, and the 20th, 21st, 22nd, 25th and 26th reports. Scattered entries from the Pipe Rolls (13 Henry III. to Edward I.) are printed in the 33rd and 35th-38th Reports. Before the establishment of the Record Office the Irish Record Commission published a Latin calendar of the *Patent* and *Close* Rolls from Henry II. to Henry VII., and an incomplete calendar in English for the years 5–35 Henry VIII. (1509–47). The master of the rolls published for the period Henry VII. to Elizabeth, upon which some severe comments will be found in J. T. Gilbert’s *The History . . . of the Public Records of Ireland*.

A 6th-century calendar, with the reign of James I., was published by the Record Commission; and a calendar for the years 1–8 Charles I., under the authority of the Master of the Rolls. Two large folio volumes entitled *Liber Hiberniae* should here be mentioned. The history and contents of this astounding collection are gathered from its introduction, and from an index to it in the 9th Report. Inquisitions post mortem and on attainder, for the provinces of Leinster and Ulster only, are dealt with in the Record Commission’s *Inquisitiones Post Mortem et atas*.

Parliamentary. — The Record Commission of Great Britain printed the Acts of the Great Seal; and the *Acts of the Privy Council* (Rolls, 1288–1503) and the *Acts of the Lords of Council* (1478–1495) have been published. The Acts of the Lords of Council (1478–1495) being proceedings of a similar body.

**Privy Council.** — The register of the Privy Council of Scotland from 1545 is in course of publication at the General Register House. Exchequer. — The Exchequer Rolls, corresponding to the Great Roll of the English Exchequer, are being printed in full from 1264 at the General Register House; and the accounts of the Treasurer of Scotland from 1473 are being published at the same office.

Chancery. — The enrolments of letters issued under the Great Seal of Scotland are contained in twelve rolls and a series of volumes. The Record Commission printed these registers in full for the period 1306–1424; and the General Register House is continuing the publication in an abridged form.

**Court of Chancery.** — Only the enrolments of letters under the Great Seal are transferred to the General Register House; the remainder are transferred to the Chancery in the year 1673. The most substantial of these are the *Returns to Chancery*. To these the only printed means of reference is the *Inquisitionum ad capellam Domini Regis* (1515–16), *Inquisition de abreviario* (16th and 17th centuries), published by the Record Commission.

Local Records. — To deal with the municipal and local records of Great Britain in any detail is quite impossible in this article. Fortunately the admirable work of C. Gross, entitled *The Bibliography of Municipal Records* (2 vols., 1890, 1892) affords a complete view of the questions dealt with by it.
RECORD

Private Collections.—The publications of the Historical Manuscripts Commission are in most cases only printed in the form of reference to private muniments. The 17th Report of the Commission contains an index to all the collections of papers so far published, with the title

Wills.—Up to the date of the Probate Act (20 & 21 Vict. c. 77) the proving of wills was under ecclesiastical jurisdiction, and the wills themselves were scattered among peculiar courts—court of consistory, and the preceptive court of Canterbury. By the passing of the act a general National Wills Registry was set up at Somerset House, to which were transferred all the wills of the preceptive court of Canterbury and of many of the other registries. But even at the present day there remains much confusion and uncertainty as to the place of deposit of the wills of any particular court; and for accurate information on this point the inquirer must refer to the Handbook to the Ancient Courts of Probate and Depositories of Wills, by G. W. Marshall.

British Colonies.—For the British colonies the most important records, historically speaking, are the records of the Foreign Office, London; and those colonies which have published the records relating to their history have usually gone to that source. In New South Wales, however, there is in the Colonial Secretary’s office at Sydney a collection of records dating from 1759, which are included in the volumes published by that State. Cape Colony possesses records dating from 1652; G. McCaill Theal, historian of the colony, has also published important sections of it. For Canada, see the publications of the Colonial and Indian Office and other European sources. Canada has recently centralized its records, of which a large part so far consists of transcripts made in Europe. For an account see E. C. Burnett’s List of Manuscripts relating to Canada, and description of the archives and other repositories of Historical Manuscripts (American Historical Manuscripts Commission Report, 1897). The Dominion Archivist submits yearly to the Minister for Agriculture a report, in which (in Appendices) are given many lists and accounts of records.

European Countries.—In dealing with Great Britain it has seemed desirable to give some account of the public and private records which have been formed in the various government offices deposited in the Public Record Office, London; and those colonies which have published the records relating to their history have usually gone to that source. In New South Wales, however, there is in the Colonial Secretary’s office at Sydney a collection of records dating from 1759, which are included in the volumes published by that State. Cape Colony possesses records dating from 1652; G. McCaill Theal, historian of the colony, has also published important sections of it. For Canada, see the publications of the Colonial and Indian Office and other European sources. Canada has recently centralized its records, of which a large part so far consists of transcripts made in Europe. For an account see E. C. Burnett’s List of Manuscripts relating to Canada, and description of the archives and other repositories of Historical Manuscripts (American Historical Manuscripts Commission Report, 1897). The Dominion Archivist submits yearly to the Minister for Agriculture a report, in which (in Appendices) are given many lists and accounts of records.

RECORD

RECORD

RECORD

RECORD

RECORD
Hertogenbosch, Groningen, Haarlem, Maastricht, Middelburg and Utrecht.

Town archives are for the most part well preserved. Printed materials are generally exist, and in some cases, e.g. at Doeburg, the archives contain a large number of documents written in the various languages of the kingdom, and since 1788 these Verzamelingen omstreeks Rijks oude Archieven have been printed.

The English Public Record Office has four volumes of transcripts from the Norske Statens Historiske Arkiver.

ITALY.—The administration of the public records of the kingdom is attached to the Ministry of the Interior, for which office Signor Vazio published (1883) his Relazione sugli archivi di stato italiani. The archives are located in Rome, in the Palazzo della Consulta, and in the Palazzo della Consulta, and in the Palazzo della Consulta, and in the Palazzo della Consulta.

The most important are the following:

Florence, containing records of the foreign correspondence of the dukes of Tuscany and the Florentine republic.

Genoa, records of the family of Este.

Naples, in particular the Cancelleria Angioina, records of the Angevin kings of Naples, containing documents relative to their extensive dominions in Provence, Anjou and elsewhere, for a long time a local account of which see Les Archives angéiques de Naples: études sur les registres du Roy Charles Ier, by Paul Durrieu. Naples also possesses the important Archivio Farnesiano, mainly records of the duke of Parma, brought there by Charles I. of Bourbon in 1637, the archives of the Duchy of Parma in 1735.

Palermo, the records of the island of Sicily.

Milan, records of the duchy, in particular the registers called L’Archivio Panagorale.

Modena, records of the family of Este.

The Vatican.—For the history of the papal archives the work of H. Brossiau, Handbuch der Urkundenfhrung für Deutschland und Italien (Leipzig, 1889), may be consulted. The best English account is contained in an article in the American Historical Review (October 1896), by C. H. Haskins. But certain of the prefaces to the Record Office Calendar mentioned below may be consulted; and the publications issued from the Library of Congress. The Vatican archives have been open to students only since the year 1881. The chief portion of the collection is that called the Archivio Segreto, which may be divided into two heads, the original Archivio Segreto and the Archivio Segreto Postumo, a portion of the archives of the old papal palace kept in the castle of St Angelo and from special offices such as the Consistory, Dataria Apostolica, Rota, Secretaria Prensin, Signature Gratiae, Privy Seal, and Secretaries of the Holy Office. The records of the congregations of the Index, the Holy Office and the Propaganda are not usually accessible to students.

Since 1881 the importance of the archives has attracted many hands of students; most European governments have arranged for the publication of records dealing with their own countries. The classes of documents that have received most attention are the Regestir, or rolls of bulls and briefs, issued by the papal chancery; the Sigillata, or petitions; and the Notitiae, or despatches received from the nuncios and instructions sent to them. An account of the numerous publications the works already listed. Here it is only possible to mention the English publications. The Record Office in London has published one volume of Petitions, 1342-1427, and a Calendar from the Regestra, which covers the period 1108-1431. There are also the Archivio Segreto Postumo, and the Regestir up to the end of the 13th century. There are in the English Public Record Office one hundred and sixty-two volumes of transcripts from the Vatican archives arranged in two series.

The records of the Archivio Segreto are preserved at Christiania, and include a collection of papers of Christian II., King of Denmark. For the contents of the collection, see Diplomatarium Norwegicum, by Lange and Unger (1894-1891); and Norse Registrarsregister under the charge of the head of the division of Manuscripts at the Library of Congress, which office is acquiring important collections of the papers of former presidents, and may also have transferred to other permanent institutions national documents which are the concern of the historical section of the Carnegie Institution and of the Archives Commission of the Historical Association.

The American Historical Society, in association with the American Historical Association, has inaugurated the project of private collections through its Historical Manuscripts Commission and the Fulbright-Hays American state records. Some states, however, have themselves published American and European documents relating to their history; and mention must be made of the large series of American Archives and State Papers published from 1832 onwards by Congress.
RECORDE—RECORDE

The best guide for Federal records is the work of Leonard and Valentine; for a general bibliographical work of reference see E. C. Bateman, List of Printed Guides . . . (Historical MSS. Commission Report, 1897).

EXTRAVAGANIA

In various ways records are apt to wander from their proper custody and to lose their legal character. But in spite of this loss the record often continues to surface in the course of legal business or in the hands of private collectors or on to the shelves of some museum. No attempt can be made to discuss private collections or the manuscripts of foreign libraries. Even in the English record, records as it were, to mention the British Museum as the principal destination of wandering records. Of the collections in that library the most important to the student of records are the Cottonian, the Harleian and the Lansdowne, all catalogued by the Record Commission; the Additional, catalogued from time to time as new matter accrues; the Egeron, catalogued with the Additional; the Sloane, both catalogued. No distinction is made between documents that have been technically "records" and others that are not.

The whole collection is divided technically into Manuscripts, by which are meant volumes, and Charts and Rolls, meaning detached documents. To the latter class an Index Iuriscom, compiled by the Revd. F. Ellis and F. B. Bickley, has been added. (C. C. H. B.)

RECORDE, ROBERT (c. 1510–1558). Welsh physician and mathematician, was descended from a respectable family of Tenby in Wales. He entered the university of Oxford about 1525, and was elected fellow of All Souls' College in 1531. Having adopted medicine as a profession, he went to Cambridge, where he took the degree of M.D. in 1545. He afterwards returned to Oxford, where he publicly taught mathematics, as he had done prior to his going to Cambridge. It appears that he afterwards went to London, and acted as physician to Edward VI. and to Queen Mary, to whom some of his books are dedicated. He died in the King's Bench prison, Southwark, where he was confined for debt, in 1558.

Recorde published several works upon mathematical subjects, and in a form of dialogue between master and scholar. The Grounde of Artes, teaching the Workes and Practise of Arithmetike, both in whole numbers and fractions (1650); The Pathway to Knowledge, containing the First Principles of Geometry . . . , both with Diagrammes and Astronomicall Tables and also for Projection of Plates (London, 1551); The Castle of Knowledge, containing the Explicacion of the Spheres both Celestiall and Materiall, &c. (London, 1556); The Whetstone of Witte, which is the Book of Arithmetike, containing the Reduction of Roodes, the Cosseke Practice, with the Rules of Equation, and the Worooke of Surde Numbers (London, 1557). This was the first English book on algebra. He wrote also a medical work, The Urinall of Physicke (1548), frequently reprinted. Sherburne states that Recorde published Cosmographie图为a sago, and that he wrote a book De Arte factendi Horlogium and another De Uso Globorum et de Speculae Mathematica (1548). Recorde's chief contributions to the progress of algebra were in the way of systemizing its notation (see Algebra, History).

RECORDE, in its original sense, one who sets down or records. Hence applied to a person with a legal knowledge who was appointed by the mayor and aldermen to record or keep in mind the proceedings of their court, as well as the customs of the city. The word is now chiefly used of the principal legal officer of a city or borough having a separate court of quarter sessions. He must be a barrister of five years' standing, appointed by the crown and holding office during good behaviour, and receiving "such yearly salary, not exceeding that stated in the petition on which the grant of a separate court of quarter sessions was made," as the sovereign directs (Municipal Corporations Act 1885, s. 163). The record holder, once in every quarter of a year, or oftener, if he thinks fit, a court of quarter sessions in and for the borough. He is sole judge of the court, "having cognizance of all crimes, offences, and matters cognizable by courts of quarter sessions for counties in England," except that he may not allow or levy any borough rate, or grant licences (c. 165). He is not eligible to serve in parliament for the borough, or to be an alderman or councillor, or stipendary magistrate for the borough, though he may be revising barrister and is eligible to serve in Parliament except for the borough. He may be appointed record for two or more boroughs conjointly. He may, in case of sickness or unavoidable absence, appoint in writing a barrister of five years' standing to act as deputy recorder for him. A recorder is ex officio a justice for the borough.

The recorder of London is judge of the lord mayor's court, and one of the commissioners of the central criminal court. His salary is £4000 a year. He is appointed by the lord mayor and aldermen, but by the Local Government Act 1888, s. 42, sub-s. 14, after the vacancy next after the beginning of the act, no recorder may exercise any judicial function unless he is appointed by the sovereign to exercise such function. See Quarter Sessions, Court of.

RECORDE, Fipple Flute or English Flute (Fr. flûte à bec, flûte douce, flûte anglaise or flûte à neuf trous; Ger. Block- or Plockflöte, Schnabelflöte, Langflöte; Ital. flauto dolce, flauto diritto), a medieval flute, blown by means of a whistle mouthpiece and held vertically in front of the performer like a clarinet. The recorder only survives in the now almost obsolete flagelolet and in the so-called penny-whistle. The recorder consisted of a wooden tube, which was at first cylindrical or nearly so, but became, as the instrument developed and improved, an inverted cone. The whistle mouthpiece has been traced in almost prehistoric times in Egypt and other Oriental countries. The principle of the whistle mouthpiece is based on that of the simplest flutes without embouchure, like the Egyptian nay, with this modification, that, in order to facilitate the production of sound, the air current, instead of being directed through ambient air to the sharp edge of the tube (or the lateral embouchure in the modern flute), is blown through a chin directly into a narrow channel. This channel is so constructed within the mouthpiece that the stream of air impinges with force against the sharp edge of a lip or fipple cut into the pipe below the channel. This throws the air current into the state of a vortex. This vortex, in order to generate sound-waves in the main column of air within the tube, at least, may have the effect of softening the tone of the recorder still further, earning for it the name of fipple flute. Being so easy to play, the recorder always enjoyed great popularity in all countries until the greater possibilities of the transverse flute turned the tide against it. The want of character which distinguishes the timbre of the whistle-flute is due to the paucity of harmonic overtones in the clang. The recorder had seven holes in front and one at the back for the thumb. As long as the tube was made in one piece the lowest hole stopped by the little finger was generally made in duplicate to serve equally right- and left-handed players, the unused hole being stopped with wax. Being an open pipe, the recorder could overflow the octave and even the two following harmonics (i.e. the twelfth and second octave). The holes produced the diatonic scale, and by means of harmonics and cross-fingered the second and part of a third octave were obtained.

The recorder is described and figured by Sebastian Virdung, Martin Agricola and Ottmar Luscinus in the 16th century, and by Michael Praetorius and Marin Mersenne in the 17th century. Praetorius mentions eight different sizes ranging from the small flute two octaves above the cornetto to the great bass. The lowest notes of the large flutes were produced with inverted conical perforated wooden or brass cases, which served to protect the mechanism, as yet somewhat primitive; the keys usually had double touch pieces to suit right- and left-handed players. To the left at least, one set of records is extant: one is preserved in the Germanisches Museum at Nuremberg, consisting of eight flutes in a case and dating from the 17th century; the other is the Chester set of four 18th-century instruments, which are fully described and illustrated in a paper by Joseph C. Bridge. 1

The recorder has been immortalized by Shakespeare in the famous scene in Hamlet (II. 3), which has been treated from the ethical and spiritual point of view by C. W. F. Lindley, while a philosophical and psychological view has been presented by Christopher Welch, the author of an equally valuable paper, "The Literature of the Recorder." 2

The small whistle-pipe used to accompany the tabor (Fr. galoubel; Ger. Dautenpfeife or Schweppe) has but three holes, belongs to the same family as the recorder, but from its association with the tabor it acquired distinctive characteristics (see Pipe and Tabor).

2 Hamlet and the Recorder," ibid., 1902 and 1898.
RECTOR (Lat. for "ruler," "guide," &c., from regere, "rule"), a title given to the bearers of certain ecclesiastical and academical offices. In the Roman empire, after Constantine, the title rector was borne by governors of provinces subordinate to the prefects or exarchs. In the middle ages it was given to certain secular officials, e.g. the podestas of some Italian towns, but more especially to the heads of the universities, the representatives and rulers of the universitas magistrorum et scholarum, elected usually for a very short time. After the humanistic movement of the Renaissance the style rector was also given to the chief masters of schools containing several classes, and in some parts of Germany (e.g. Saxony, Württemberg) it is still thus used instead of the more modern title of Director. Rector is also still the title of the heads of the Scottish universities (Lord Rector), who are elected for three years, and of the German universities (Rector Magnificus), in which the office is held for a year by a representative of each faculty in turn. In those German universities where the rectorship is held by the sovereign (Rector Magnificentissimus), the acting head is known as Prorector. "Rector" is also the title of the heads of Exeter and Lincoln Colleges, Oxford. The rector of a parish is the spiritual head of the parishes.

As an ecclesiastical title rector was once loosely used for rulers of the Church generally, whether bishops, abbots or parish priests (see Du Cange, Rectores ecclesiarii). The Rectores Apostolici Patrimonii were clerics of the Roman Curia charged with the duty of looking after the interests of the patrimony of St. Peter. The ecclesiastical title rector, however, became ultimately confined in certain parts of Europe (Poland, Spain and notably England) to the office of a priest having a cure of souls. In its English use it is thus synonymous with "curate" in the sense used in the Prayer Book. In the middle ages a large number of rectories were held by religious houses, which drew the bulk of the tithes and appointed vicars to do the work. Hence the modern distinction in England between rectors and vicars. A rector is incumbent of a benefice never held under a monastery, and he receives all the tithes; a vicar (i.e. of an ancient benefice) draws only such tithes as were left to the benefice by the religious house which held it. On the suppression of the monasteries the "great tithes" were often bestowed by the crown on laymen, who, as owning the rectorial tithes, were and are known as "lay rectors." It follows that, rectors being usually richer than vicarages, the style of "rector" is in England slightly more dignified than that of "vicar." In the American Protestant Episcopal Church the incumbents of churches are called rectors.

RECUASANT (from Lat. recusare, to refuse), the name, in English history, given in the 16th and 17th centuries to those persons who persisted in refusing to attend the services of the English Church, and particularly to those of the Roman Catholic faith (see Roman Catholic Church, § English Law).

REDLAN, in fortification, a work of V-shape presenting a salient angle towards the expected attack. The gorge (rear) of a Redlan is open. When unsupported by other works, it has the disadvantage that its fire is divergent and but few guns can be brought to bear directly towards the front. Further, both its faces are usually open to enfilade. Redlans were therefore almost always used in conjunction with other works, one of the most common forms being the "lines of Redlan" used as field works. These consisted of lengths of plain trenches facing the front, with redans at intervals along the line. In the present day the term redan is loosely applied to works merely possessing salieney, as in the case of the celebrated bastions Nos. 3 and 2 at Sebastopol in 1854-55, usually called the "Redan" and "Little Redan" respectively (see Crimean War). The "Redan" was a large work of irregular outline, generally resembling a redan, but having the salient angle bluntly rounded off and the side faces broken into several minor fronts so as to obtain a field of fire in many directions. (See Fortification and Siegecraft.)

RED BANK, a borough of Monmouth county, New Jersey, U.S.A., on an estuary known as Navesink river, at the head of navigation, about 6 m. W. of the Atlantic Ocean, and about 25 m. S. of New York City. Pop. (1905) 6563; (1910) 7308. Red Bank is served by the Central of New Jersey and the Pennsylvania railways, and by steamboats to New York, and is connected with the neighbouring towns by electric lines. It is a residential suburb of New York City and a summer resort. In the winter ice-boating is a popular amusement, and Red Bank has fish and oyster industries of some importance.

The name Red Bank was applied to this locality as early as 1734, and in 1781 there were several buildings within the limits of the present borough. Red Bank was incorporated as a town in 1870 and became a borough in 1908. Near Red Bank was established in 1843 the North American phalanx, a Fourierite community, with a capital of about $8000 and 112 members, on about 673 acres; it was financially the most successful and the longest lived of the Fourierist phalansteries in America, but broke up in 1855 because of internal dissensions, following a fire which destroyed the mills.

REDBREAST, or Roun, perhaps the favourite among English birds because of its pleasing colour, its sagacity and fearlessness of man, and its cheerful song, even in winter. Besides red breasts which are not found in the same number in the United States as are the bluebirds in America, there are red-breasted species of birds in Europe. In England they are the most numerous, and are not in families, but as a single bird, which is called by the name of Redbreast. Besides the British Islands, the redbreast (Motacilla rubecula of Linnaeus and the Erithacus rubecula of modern authors) is generally dispersed over the continent of Europe, and is in winter found in the oases of the Sahara. Its eastern limits are not well determined. In northern Persia it is replaced by a nearly allied form, Erithacus cyanus, distinguishable by its songs.

The borough of Red Bank should be distinguished from a place of the same name in Gloucester county, New Jersey, about 6 m. E. of Philadelphia, on the north fork of the Schuylkill river, which was the site of Fort Mercer in the American War of Independence. Fort Mercer, with Fort Mifflin (nearly opposite it on an island in the Delaware), prevented the crossing of the Delaware river, which had occupied Philadelphia in September. On the 22nd of October Fort Mercer, held by 600 men under Col. Christopher Greene (1737-1781), was unsuccessfully attacked by a force of about 2500 men, mostly Hessians, under Col. Carl Emil Kurt von Donop, the Hessians losing about 400 men, including Donop, who was mortally wounded. The British naval force was prevented by the "Pennsylvania Line" (John Paul Jones against the British ships) from landing his forces, in the attack; two British ships were destroyed; and the fire from the American vessels added to the discomfiture of the Hessians. On the 15th of November Fort Mifflin was destroyed after a five days' bombardment from batteries on the Pennsylvania shore and from British vessels in the bay; and on the 20th Fort Mercer was abandoned before Cornwallis' approach and was destroyed by the British. Philadelphia was then put in touch with Admiral Howe's fleet and with the New York City Bank. A monument to Christopher Greene was erected in 1829.

English colonists in distant lands have applied the common name of "red breast" to the redbreast, which are not immediately allied to it. The ordinary "robins" of North America and Europe, which are not to be confused with the Turdus migratorius (see Fieldfare), and one of the bluebirds of the same continent, Stellula sialis, is in ordinary speech the bluebird; the Australian and Pacific turdus, Petroecus, are of doubtful affinity and have not all even the red breast; the Cape "robins" is Cosopsophia cafra, the Indian "robins" Tannobris and the New Zealand "robins" Miro.
more ruddy hues, while in northern China and Japan another species, *E. abakihg*, is found of which the sexes differ somewhat in plumage—the cock having a blackish band below his red breast and greyish-black flanks, while the hen closely resembles the familiar British species—but both cock and hen have the tail of chestnut-red. The genus *Erithacus*, as well as that containing the other birds to which the name “robin” has been applied, with the doubtful exception of *Petroeca*, belong to the sub-family Turdinae, of the thrushes (q.v.).

**REDCAR**, a watering-place in the Cleveland parliamentary division of the North Riding of Yorkshire, England, 8 m. N.E. of Middlesbrough, on a branch of the North-Eastern railway. Pop. of urban district (including the township of Coatham, 1901) 7605. Its long range of firm sands from Tees mouth to Saltburn, a distance of 10 m., has made it a popular summer resort. Race meetings are held here on Whit Monday and T. W. T. Wednesdays. The centre of a branch of the Cleveland iron-working district of which the centre is Middlesbrough, and is in great favour with the large industrial population of that district.

**REDDITCH**, a town in the eastern parliamentary division of Worcestershire, England, situated on an eminence near the Warwickshire border, 15 m. S. of Birmingham by the Midland railway. Pop. of urban district (1901) 13,403. It is the centre of a district producing needles and fish-hooks. There are also motor-engineering works. The town possesses a literary and scientific institute (1850). In the modern church of St. Stephen (1854) are preserved tiles from the famous Cistercian abbey of Bordesley, founded in 1138, of which the site may be traced at Bordesley Park, 2 m. N.

**REDSTONE, JOHN FREEMAN-MITFORD, BARON (1748-1839), English lawyer and politician, younger son of John Mitford (d. 1761) and brother of the historian William Mitford, was born in London on the 18th of August 1748. Having become a barrister of the Inner Temple in 1777, he wrote *A Treatise on the Pleasings in Suits in the Court of Chancery by English Bill*, a work of great value, which has been reprinted several times in England and America. In 1788 Mitford became member of parliament for the borough of Beveralston in Devon, and in 1791 he introduced the important bill for the relief of Roman Catholics, which was passed into law. In 1793 he succeeded Sir John Scott, afterwards Lord Eldon, as solicitor-general for England, becoming attorney-general six years later, when he was returned to parliament as member for East Loce, in Cornwall. In February 1801 Sir John Mitford (as he was now) was chosen speaker of the House of Commons. Exactly a year later, he was appointed lord chancellor of Ireland and was created a peer of the United Kingdom as Baron Redesdale. Being an outspoken opponent of Roman Catholic emancipation, Redesdale was unpopular in Ireland. In February 1806 he was dismissed on the formation of the ministry of Fox and Lord Grenville. Although Redesdale declined to return to official life, he was an active member of the House of Lords both on its political and its judicial sides. In 1813 he secured the passing of acts for the relief of insolvent debtors, and later he was an opponent of the repeal of the Test and Corporation Acts and of other popular measures of reform. Redesdale, who was a fellow of the Royal Society and a member of three commissions on the public records, died on the 16th of January 1830. In 1833 he married Frances (d. 1817), daughter of John, 2nd earl of Egmont. He took the additional name of Freeman in 1809 on succeeding to the estates of Thomas Edwards Freeman.

His only son, John Thomas Freeman Mitford (1805-1886), succeeded to the title. In 1831 he was chosen chairman of committees in the House of Lords, a position which he retained until his death, and in 1877 he was created earl of Redesdale. His chief interest was reserved for ecclesiastical questions, and he won some repute as a Protestant controversialist. He assisted to revive Convocation in 1853; was an active opponent of the disestablishment of the Irish Church; and engaged in controversy with Cardinal Manning on the subject of communion in both kinds. On his death, on the 2nd of May 1886, his titles became extinct. He wrote *Thoughts on English Prose and Translations from Horace*, and *Further Thoughts on English Prose* (Oxford, 1859), in addition to various pamphlets on ecclesiastical topics.

The earl bequeathed his estates to his kinsman, Algernon Bertram Freeman-Mitford (b. 1837), a great-grandson of Sir John Mitford. He had been in the diplomatic service from 1858 to 1873, and had been secretary to the Office of Works from 1874 to 1886. From 1892 to 1895 he was member of parliament for the Stratford-on-Avon division of Warwickshire, and he was created Baron Redesdale in 1902. He was well known for his writings on Japan, *Tales of Old Japan* (1871), *The Attack at Peking* (1900), &c.

**REDFERN**, a municipality of Cumberland county, New South Wales, Australia, adjoining the city of Sydney on the S.S.W. Pop. (1901) 24,282. It is a busy manufacturing centre, having numerous ironworks, coach factories, boot factories, printing works, iron and brass foundries, soap factories and extensive railway works.

**REDGRAVE, R. E. S. L. (1864-1888), English artist, was born at Pimlico on the 30th of April 1844, and worked at first as a designer. He became a student in the Royal Academy Schools in 1856, and was elected an Associate in 1840 and an Academician in 1851 (retired, 1882). His "Gulliver on the Farmer’s Table" (1837) made his reputation as a painter. He began in 1847 a connexion with the Government Art Schools which lasted for a long term of years, and among other posts he held those of inspector-general of art in the Science and Art Department, and art director of the South Kensington Museum. He was greatly instrumental in the establishment of this institution, and he claimed the credit of having secured the Sheppocks and Ellison gifts for the nation. He was also a surveyor of the royal pictures. He was offered, but declined, a knighthood in 1869. Redgrave was an assiduous painter of landscape and genre; his best pictures being “Country Cousins” (1848) and “The Return of Olivia” (1848), both in the national collection, “The Semipristress” (1844), “Well Spring in the Forest” (1865). He died on the 14th of December 1888.

See the *Memoir* by F. M. Redgrave, 1891.

**REDLANS**, a city of San Bernardino county, in southern California, U.S.A., 67 m. (by rail) E. of Los Angeles. Pop. (1900) 4979; (1910) 10,449. It is served by the Southern Pacific and the Atchison, Topeka & Santa Fe railways and by interurban and street lines. The city lies at an altitude of 1350-1600 ft. at the eastern end of the San Bernardino Valley, surrounded on three sides by mountains. To the east Grayback (11,725 ft.) and San Bernardino (11,600 ft.), to the south-east San Jacinto (10,805 ft.), and to the north-west Cajon Pass (4110 ft.) and San Antonio, of Old Baldy (10,142 ft.), are conspicuous landmarks. The city is a well-known tourist and health resort, with beautiful drives. Canyon Crest Park (Smiley Heights) contains about 300 acres, and Prospect Park 50 acres. The city has the A. K. Smiley Public Library, the gift of A. K. Smiley, and is the seat of the University of Redlands (Baptist; co-educational), incorporated in 1907 and opened in 1909. Redlands is one of the most famous orange-growing and shipping centres of California; it also ships other citrus fruits, olive oil, barley, wheat and stone. Olive oil and jam, marmalade and preserved fruits are manufactured. There are electric power plants in the mountains (three in Mill Creek Canyon and two in Santa Ana Canyon). A settlement called Lugonia was established within the limits of the present city in 1874, but Redlands dates from 1887, when it was settled by people from New England, and was chartered as a city.

**REDMOND, JOHN EDWARD (1851- ), Irish politician, son of W. A. Redmond, M.P., was born at Waterford in 1851.**
He was educated at Trinity College, Dublin, and was called to the bar at Gray's Inn in 1886, and subsequently to the Irish bar, though he never practised. He was a clerk in the vote office of the House of Commons before he entered parliament in 1881 as member for New Ross. From 1885 to 1891 he represented North Wexford. As party whip he rendered great service to the Irish members by his thorough grasp of the procedure of the House. At the time of the rupture of the Irish party consequent on the Parnell scandals, Redmond was the most eloquent member of the minority who continued to recognize his leadership, and in 1891 he became the accredited leader of the Parnellites. In 1890 the two Nationalist parties were amalgamated under his leadership. He contested Cork unsuccessfully in 1891, but was elected for Waterford, where he was re-elected in 1896. (For the political events under his leadership of the Irish parliamentary party up to 1910, see IRELAND: History; English History and allied articles.)

REDON, a town of western France, capital of an arrondissement in the department of Ille-et-Vilaine, 45 m. S.S.W. of Rennes by rail. Pop. (1906) 5170. Redon is situated on the right bank of the Vilaine, above the confluence of the Oust and on the canal from Nantes to Brest. The Church of St Sauveur, formerly belonging to an abbey, has a Romanesque central tower, square in form but with rounded angles. A fine tower of the 14th century with a stone spire stands isolated from the church, from which it was separated owing to the destruction of part of the nave by fire in 1752. The choir, with ambulatory and radiating chapels, forms one of the most remarkable examples of 13th-century architecture in Brittany. The abbey has been converted into an ecclesiastical college. Some 16th-century timbered houses have interesting carvings. The industries include the manufacture of emery and polish, agricultural implements and boat-building, tanning, brewing and flour-milling. The port is accessible at high tides for vessels of 600 to 700 tons. Redon grew up round a monastery founded in the first half of the 9th century. In the 14th century Jean de Tréal, one of the abbots, surrounded the town with walls, of which a remnant is still to be seen.

REDONDA, an island in the British West Indies. It is a dependency of Antigua, and lies 25 m. S.W. of it, in 25° 6' N. and 61° 35' W. Pop. (1901) 120. It is a rocky mountain, rising abruptly from the sea to a height of 1000 ft., and has an area of ¾ sq. m. It is valuable for its phosphates of alumina (discovered in 1865), of which 7000 tons are exported every year to the United States.

REDRUM, a town of north western Spain, in the province of Pontevedra; 7 m. N.E. of Vigo, in a bend of the Vigo estuary, and at the junction of the Tuy-Vigo and Vigo-Pontevedra railways. Pop. (1900) 10,833. The river is only accessible for small coasting vessels; it is the headquarters of a prosperous fishing industry. In the neighbourhood are ruins of several medieval castles, and the fine hall of the Marquess Vega de Armijo.

REDOUTE (Fr. redoulee, from Med. Lat. redactus, a place of retreat, refuge, redoulee, lead back, retire; the intrusive b is due to the O. Fr. redoublier, to fear, Lat. dubilare, to doubt), a term in fortification for a small, closely-packed work of plain trace, generally used in conjunction with lines of infantry trenches (see FORTIFICATION and SEIGECRAFT). The term “reduit” (Fr. réduit), often confused with “redoubt,” is only used for a keep or interior refuge for the garrison of a larger work, corresponding, on a small scale, to the citadel of a fortress.

RED RIVER, the name of two American rivers, one emptying into the Mississippi near its mouth, and the other emptying into Lake Winnipeg.

1. The Red river, sometimes called the Red River of Louisiana, is the southernmost of the large tributaries of the Mississippi. It rises in northern Texas, in the northern part of the Staked Plains, or Llano Estacado, flows E. by S. through Texas between Texas and Oklahoma, and to Fulto, in south-western Arkansas, there turns S.E. and continues in a general south-easterly direction through Louisiana to the bank of the Mississippi, where it discharges partly into the Mississippi and partly into the Atchafalaya. Its length is estimated at 1200 m. or more; its drainage basin has an area of at least 30,000 sq. m.; and its discharge ranges from 3500 cub. ft. to 180,000 cub. ft. per second. It is somewhat saline in its upper course, and in its middle and lower course is laden with a reddish silt from which it takes its name. From an elevation on the Staked Plains of about 2450 ft., the river plunges into a canyon which is about 500 m. long and has nearly perpendicular walls of sandstone and gypsum formation 500 to 800 ft. high. Immediately below the canyon the river spreads out over a broad and sandy bed and flows for about 500 m. through a semi-arid plain. It narrows on entering the alluvial bottom lands, through which it pursues a sluggish and meandering course for the last 600 m. At high stages, from December to June, it is continually shifting its channel in this part of its course, by eroding one bank and making deposits on the other, and as the upper portion is densely wooded the falling trees, unless removed, become an obstruction to navigation. In 1828 the trees which the river had felled formed the great “Red River raft” extending from Loggy Bayou, 65 m. below Shreveport, Louisiana, to Hurricane Bluffs, 27 m. above Shreveport. Congress began in that year to make appropriations for the removal of the raft, and by 1841 Henry M. Shreve had built a channel. The river was neglected from 1857 to 1872 and another raft, 32 m. in length, formed above Shreveport. A channel was opened through this in 1872-73, and the complete removal of the obstruction a few years later so improved the drainage that a large tract of waste land was reclaimed. In its course through Louisiana the river has built up a flood-plain with silt deposits more rapidly than its tributaries, with the result that numerous lakes and bayous have been formed on either side, and Cypress Bayou was so flooded that boats piled between Shreveport, Louisiana and Jefferson, Texas, 45 m. apart; but with the improvement of the river these lakes have become shallow or dry. For the improvement of navigation here not only must the course of the river be straightened, but there must be dredging, closure of outlets, building of levees to narrow and deepen the channel, and revetment works to protect the banks. The cost of these works has been great (up to July 1909 more than $2,360,000 below Fulton, Arkansas, and more than $215,000 above Fulton), but they have rendered the river navigable, except at very low stages, by vessels drawing 3 ft. of water from its mouth to Fulton, Arkansas, a distance of 508-6 m. and at the highest stages,1 in March and April, it is navigable to Denison, Texas, 292 m. farther up. The Ouachita and Black (one river), which is the principal tributary of the Red, near its mouth and is navigable at high stages to Arkadelphia, Arkansas; and in 1910 a system of nine locks with movable dams was under construction by the Federal government for the purpose of securing a channel 63 ft. deep at all stages to a point 10 m. above Camden, Arkansas, a distance of 360 m.

During the Civil War, in March and April 1864, Major-General Nathaniel P. Banks conducted a combined military and naval expedition up the Red river in an attempt to open a Federal highway to Texas, but on the 8th of April the vanguard of his army was repulsed with heavy loss at Sabine Cross-Roads by the Confederates under Lieutenant-General Richard Taylor and the expedition was abandoned; the gunboats commanded by D. D. Porter were held above Alexandria by the lowness of the river, but it was flooded by a hurriedly built dam, and they escaped.

See R. B. Marcy and G. B. McClellan, Exploration of the Red River of Louisiana (Washington, 1853), and the annual Reports of the Chief of Engineers of the U.S. Army.

2. The Red river, commonly called the Red River of the North, rises in the lake region of western Minnesota, not far from the headwaters of the Mississippi, flows north between Minnesota and North Dakota, continues northward through the Canadian prairies, and discharges into Lake Winnipeg. It has a course 20-50 ft. deep through clay deposits through

1 The range between low water and high water at Fulton is 35-65 ft.
out the greater part of its course; it drains a region that is familiar for the production of wheat; and much water power has been developed on its tributaries. The United States government has improved its channel from the international boundary to Breckenridge, Minnesota, a distance of 395.5 m., and occasionally the water reaches a height which permits small steamboats to ascend its S.W. branch to Lake Traverse and from there to descend the Minnesota river to the Mississippi.

RED RIVER SETTLEMENT, a Scottish colony founded in 1811 near the present city of Winnipeg by a philanthropic Scottish nobleman, Lord Selkirk, who at that time controlled the Hudson's Bay Company. Quarrars soon arose with the French and half-breed employees of the North-West Fur Company, and were fostered by its officials. On June 10, 1816, in a fight between the rivals, Governor Selkirk of the Hudson's Bay Company and twenty of his twenty-seven attendants were killed, an affair known as the Battle of Seven Oaks. New settlers were sent by Selkirk, and founded the village of Kildonan, now part of Winnipeg. In 1821 the rival companies united, and in 1836 repurchased from Selkirk's heirs all rights to the territory. In 1821 and in 1835 two forts, known as Lower and Upper Fort Garry, were built to command the junction of the Red and Assiniboine rivers, and are now the most important points in the Red River settlement.

See CANADA (History); also George Bryce, Remarkable History of the Hudson's Bay Company (1900).

RERDUTH, a market town in the Camborne parliamentary division of Cornwall, England, 17 m. E.N.E. of Penzance, on the Great Western railway. Pop. of urban district (1901) 10,451. It lies high, on the northward slope of the central elevation of the county, with bare rocky moors to the south. It is the chief mining town in Cornwall, and the bulk of the population is engaged in the numerous tin-smelting works. The parish church of St. Uny, of which only the tower is ancient (Perpendicular), stands outside the town to the west, at the foot of a rugged hill named Carn Brea. On the summit of this hill, besides a monument (1836) to Lord de Dunstanville and a small ancient castle, various prehistoric remains are traceable. A museum attached to the science and art schools and a miners' hospital are notable institutions in Redruth. A large quantity of the tin is sold by public auction at the mining exchange, the sales being known as tin-ticketings. There are manufactures of safety fuses, breweries, iron foundries and railway works.

TRAMWAYS. There are several tramways, one serving miners and the small part of Porthreath on the north coast.

RED SEA, a narrow strip of water extending S.S.E. from Suez to the Strait of Bab el-Mandeb in a nearly straight line, and separating the coasts of Arabia from those of Egypt, Nubia and Abyssinia. Its total length is about 2,000 m., and its breadth varies from about 250 m. in the southern half to 130 m. in 27° 45' N., where it divides into two parts, the Gulf of Suez and the Gulf of Akaba, separated from each other by the peninsula of Sinai.

The Gulf of Suez is shallow, and slopes regularly down to the northern extremity of the Red Sea basin, which has a maximum depth of 1,000 fathoms, and then over a shoal of 60 fathoms goes down to 1,200 fathoms in 28° 2' N. The Gulf of Akaba is separated from the Red Sea by a submarine bank only 70 fathoms from the surface, and in 28° 30' N. and 34° 43' E. it attains the depth of 700 fathoms. South of the 1,000-fathom depression a ridge rises to 500 fathoms in the latitude of Jidda, and south of this again a similar depression goes down to 1,100 fathoms. Throughout this northern part, i.e., to the banks of Suakin and Farsan in 20° N., the 100-fathom line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 500 m. long and 700 m. across, extends farther and farther seaward, until in the latitude of Hodeida the deep channel (marked by the 100-fathom line) is only 20 m. broad, the rest of the area being dangerous to navigation, even for small vessels. In the middle of the gradually narrowing channel three depressions are known to exist; soundings in two of these are: 1,110 fathoms in 29° N. and 850 fathoms in 16° N., a little to the north of Massawa. To the north-west of the volcanic island of Zebayir the depth is less than 500 fathoms; the bottom of the channel rises to the 100-fathom line at Hanish Island (also volcanic), then shoals to 45 fathoms, and sinks again in about the latitude of Mokha in a narrow channel which curves westward round the island of Perim (depth 170 fathoms), to lose itself in the Indian Ocean. The eastern branch of the canal is 5 m. wide in the Strait of Bab el-Mandeb, the eastern channel of the strait is 2 m. broad and 16 fathoms deep.

Murray estimates the total area at 158,750 sq. m., and its volume at 67,700 cub. m., giving a mean depth of 375 fathoms. Karstens gives the area at 44,800 sq. kilometres (130,424 sq. geographical m.) and the volume at 206,901 cub. kilometres (32,413 cub. geographical m.), which gives a mean depth of 252 fathoms.

Both these computations, however, were made before the date of the Austrian exploring expeditions (1896-98). Bludau's determinations give the total area draining into the Gulf at about 255,560 sq. kilometres; Krümml's more recent calculations (see OCEAN) give values somewhat higher than those of Karstens.

The Red Sea is formed by a line of fracture, probably dating from Pliocene times, crossing the centre of a dome of Archean rocks, on both flanks of which, in Egypt and Arabia, rest sedimentary and the granite rocks, forming the core of the dome appear at the surface on the Red Sea coast, at the western end of the transverse line of heights crossing Nejd. Along the line of fracture traces of volcanic activity is traceable, and the occurrence of a group of basaltic islands occurs in 14° N., and on Jebel Teir, farther north, a volcano has only recently become extinct. The margin of the Red Sea itself consists of the Arabian side, of a strip of low plain backed by range of mountains; the formation is here and there by mountains of considerable height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Akaba are steep, with numerous coral reefs on both sides. On the African side there are in the north wide stretches of desert plain, which towards the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red Sea are little indented; good harbours are almost wanting in the desert regions of the north, while in the south the chief inlets are at Massawa, and at Kamaran, almost directly opposite. Coral formations are abundant; immense piles of coral, generally backed by barrier reefs, extend over wide channels between the reef and the land. The reefs on the eastern side are the more extensive; they occur in places as much as 25 m. from the land. It has only recently been established that Red Sea coral is unworn, unlike the coral of the Pacific Ocean, and much has been done in recent years in investigating the levels of raised beaches found in different localities.

In the northern part, down to almost 19° N., the prevailing winds are north and north-west. The middle region, to 14°-16° N., has variable winds in an area of low barometric pressure, while in the southern Red Sea south-east and cast winds prevail. From June to August the north-west wind blows over the entire area; in September it retreats again as far as 16° N., south of which the winds are for a time variable. In the Gulf of Suez the westerly, or "Egyptian," wind blows more regularly from west to west, and is influenced by fog and clouds of dust. Strong north-north-east winds prevail in the Gulf of Akaba during the greater part of the year. There are occasional Alboran or Azores winds, and sometimes giving place at that season to southerly breezes. The high temperature and great relative humidity make the summer climate of the Red Sea one of the most disagreeable in the world. From the small part of the Red Sea which serve for navigation the nearest annual temperature is 77° F.; it rises to 80° in about 22° N., to 84° in 16° N., and drops again to 82° at the Strait of Bab el-Mandeb. Daily variations of temperature are observable to a greater extent than in any other sea. Temperature of the surface, however, is over 50° in summer, and seldom falls below 24°. Near the head of the Gulf of Suez temperature is relatively low, falling rapidly from south to north. The waters of the Gulf of Akaba are warmer, sometimes giving place at that season to southerly breezes. A uniform temperature of 70°-72° is observed at all depths below 270 fathoms.
The salinity of the waters is relatively great, the highest recorded being 42-7 per mille (Gulf of Suez), and the lowest 36-2 (Perim harbour). The distribution is, speaking generally, northwards, but more particularly with the tidals of the Gulf of Suez. From the observations of salinity it is inferred that a surface current flows inwards to the Red Sea in the eastern channel of the Strait of Bab el-Mandeb, while a current of very salt water flows outwards to the Indian Ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulf of Suez and Akaba, almost the only part of the Red Sea in which tidal phenomena are well developed, a sharply defined tidal circulation is found. Elsewhere the surface movement is almost everywhere by the prevailing winds, which give rise in places to complex "transverse" currents, and near the coast are modified by the channels enclosed by the coral reefs. During the prevalence of the north-east winds the windward side of the northern part of the Red Sea is depressed by as much as 2 ft. The great evaporation going on from the surface probably causes a slow vertical circulation in the water, but otherswriters agree that the winds ultimately escaping to the Indian Ocean. Extensive collections of the deposits forming the bed were made by the expeditions of the Austrian ship "Poln" (1896 and 1898). These were analysed by Dr. N. K. Korshina, who concluded that the deposits have been produced by a number of other investigators. The zoological collections of the "Poln" expeditions show that certain well-defined districts are extremely rich in plankton, while others are correspondingly poor; and it appears that the latter occur in districts surrounded by currents of relatively low temperature, while the richer parts are where the movements of water are blocked by irregularities in the coast-line.

REDSTART, the usual name of a bird—the Scolopax caprice of Linneaus and Tantonus salticus of modern authors—so-called in English from the colour of the bare part of its legs, which, being also long, are conspicuous as it flies or runs. In suitable localities it is abundant throughout the greater part of Europe and Asia, from Iceland to China, mostly retiring to the southward for the winter, though a considerable number remain during that season along the coasts and estuaries of some of the more northern countries. Before the great changes effected by drainage in England it was a common species in many districts, but at the present day there are very few to which it can resort for the purpose of reproduction. The body of the redstart is as big as a sparrow’s, but its longer neck, wings and legs make it appear a much larger bird. Above, the general colour is greyish-drab, flecked black, except the lower part of the back and a conspicuous band on each wing, which are white, while the flight-quills are black, thus producing a very harmonious effect. In the breeding season the back and breast are mottled with brown, but in winter the latter is white. The nest is generally concealed in a tuft of rushes or grass, a little removed from the wettest parts of the swamp whence the bird gets its sustenance, and contains four eggs, usually of a rather warm tinted brown, with blackish spots with blotches; but no brief description can be given that would point out differences from the eggs of other birds, more or less akin, among which, those of the lapwing (q.v.), especially, they are taken and find a ready sale.

The name Redstart, prefixed by some epiteth as Black, Dusky or Spotted, has been also applied to a larger but allied species—

the Tantonus fuscor of ornithologists. This is a much less common bird, and in Great Britain as well as the greater part of Europe it only occurs on its passage to or from its breeding-grounds, which are usually found south of the Arctic Circle, and differ much from those of its congeners—the spot chosen for the nest being nearly always in the thickets of woods and, though not in the thickest part of them, often with trees on all sides, generally where a fire has cleared the undergrowth and leaves a large patch of open ground, free from water. This peculiar habit was first ascertained by Wellesley in Lapland in 1853 and the following year. The breeding-dress this bird assumes is also very remarkable (as is suggested) to have some correlation with the burnt and blackened surface interspersed with white stones or tufts of lichen on which its nest is made—for the head, neck, shoulders and lower parts are of a deep black, contrasting vividly with the white of the back and rump; and the legs become of an intense crimson. At other times of the year the plumage is very similar to that of the common redstart, and the legs are of the same light orange-red.

REDSTART, a bird well known in Great Britain, in many parts of which it is called firetail—a name of almost the same meaning, since "start" is from the Anglo-Saxon stem, a tail. This beautiful bird, Rutilica phoenicurus, returns to England about the middle or towards the end of April, and at once takes up its abode in gardens, orchards and about old buildings, when its curious habit of flitting at nearly every change of wind, and strikingly brightening its back and breast, and, in the forehead, the black throat, and bright bay breast of the cock, renders him conspicuous, even if attention be not drawn by his lively though intermittent song. The hen is much more plainly attired; but the characteristic colouring and action of the tail pertain to her equally as to her mate. The nest is almost always placed in a hole in a tree or building, and contains from five to seven eggs of a delicate greenish blue, occasionally sprinkled with faint red spots. The young on assuming their feathers present a great resemblance to those of the redbreast (q.v.), at the same age; but the red tail, though of duller hue than in the adult, forms even at this early age an easy means of distinguishing them. The Redstart breeds regularly in all the counties of England and Wales. It also reaches the extreme north of Scotland; but in Ireland it is very rare. It appears throughout the whole of Europe in summer, and is known to winter in the interior of Africa. Several very nearly allied forms occur in Asia; and one, R. auroa, in Japan.

A congener species which has received the name of redstart, Rutilica ilia, is very common throughout the greater part of the continent of Europe, where, from its partiality for gardens in towns and villages, it is often better known than the preceding species. It yearly occurs in certain parts of England, chiefly at the Newton of London, or near by, during the autumn and winter, since it is in central Europe only a summer visitor, and it has by no means the high northern range of R. phoenicurus. The males of the black redstart seem to be more than one year in acquiring their full plumage (a rare thing in Passerine birds), and since they have been known to breed in the intermediate stage this fact has led to such birds being accounted a distinct species under the name of R. castri, thereby perplexing ornithologists for a long while, though now almost all authorities agree that these birds are, in one sense, intermediate forms.

More than a dozen species of the genus Rutilica have been described, and the greater number of them seem to belong to the Himalayan sub-region or its confines. One very pretty and interesting form is the R. moussieri of Barbary, which allies the redstart to the stone-chats (see Wheatear), and of late some authors have included it in that genus. In an opposite direction two blue-throats, apparently nearer to the redstart than to any other type, are placed in the genus Cyanecula, containing two or three distinguishable forms: (1) C. suecica, with a bright blue spot in the middle of its clear blue throat, breeding in Scandinavia; (2) C. australis, of Northern Russia and Siberia, and wintering in Abyssinia and India, though rarely appearing in the intermediate, while countries, to the wonder of all who have studied the migration

1. The orthography of the specific term would seem to be inus (Ann. Nat. Hist., ser. 4, x. p. 227), a word possibly cognate with the first syllable of titlark and titmouse.
of birds; (2) C. leucocorysana, with a white instead of a red
gular spot, a more Western form, ranging from Barbary to
Germany and Holland; (3) C. wolfe, with its throat wholly
blue—a form of comparatively rare occurrence. The first of
these is a not infrequent, though very irregular, visitant to
England, while the second has appeared there but seldom, and
the third never, so far as is known. The redstarts with their
allies mentioned in this article belong to the subfamily Turdinae
of the thrushes (q.v.).

In America the name redstart has been bestowed upon a bird
which has some curious outward resemblance, both in looks and
manners, to that of the Old Country, though the two are in the
opinion of some systematists nearly as widely separated from each
other as truly Passerine birds well can be. The American redstart
is sometimes confused with one belonging to the species
Minioptila nana, but differs from it, however, in the shape of
the bill, and in the colour of the feathers which makes up the
head and neck. It is also different from the species
Swainsoniana, which is rather scaly. But on the whole it
is a very curious and interesting bird, and deserves
remarking that its needle-like bill is perfectly well
adapted to the habits of the bird.

The redwing, a bird of the family Turdidae, is
often met with in Europe from the Baltic and
the Eastern parts of Russia; it is found in
England, Ireland, and Scotland, and is also
seen in the north of France. Its plumage,
particularly when seen from a distance, is
peculiarly beautiful, the feathers being
primarily black, with a red rump which
is reflected in the eye of the bird, giving
it a reddish appearance, and the bill,
which is of a blue cast, is also black
towards the base, with a white
band along the side from the base.

It breeds in forests and thick woods,
the nests being placed in forks of
trees, and being in a hole or
a hollow
in a branch. The eggs are yellow,
with a red spot on the large end;
and the young are gray.

The redwing is a songbird, and its
song is very melodious, being
composed of short notes, and an
upper part and a lower part of
the same notes. It is a very
brilliant fall bird, and is often
seen flying about in flocks of
several hundred individuals.

It is a bird of prey, and is often
seen flying about in flocks of
several hundred individuals.

educated at Trinity College, Cambridge, and became Congregational minister at Warminster (1871) and a secretary of the British and Foreign Bible Society. He was killed by a fall in Switzerland. Sir Charles Reed’s third son, Talbot Baines Reed (1852-1893), educated at the City of London School, became managing director of his father’s firm, and was one of the founders and secretary of the Bibliographical Society. He is best known as the author of popular boys’ books.

REED, ISAAC (1742-1807), English Shakespearian editor, son of a baker, was born on New Year’s Day, 1742, in London. He was articled to a solicitor, and eventually set up as a conveyancer at Staple Inn, where he had a considerable practice. His first important work was the *Biographia Dramatica* (2 vols., 1782), consisting of biographies of the dramatists and a descriptive dictionary of their plays. This book, which was an enlargement of David Erskine Baker’s *Companion to the Playhouse* (2 vols., 1764), was re-edited (3 vols.) by Stephen Jones in 1811, and is a valuable authority. The original work by Baker had been based on Gerard Langbaine’s *Account of the English Dramatich Poets* (1601), Giles Jacob’s *Postical Register* (1719), Thomas Whicnop’s “List of all the Dramatic Authors (printed with his tragedy of *Scanderbeg*, 1747) and the MSS. of Thomas Croker (1689-1749), an industrious antiquary who had collected much useful material. Reed’s *Notitia Dramatica* (Addit. MSS. 25390-2, British Museum), supplementary to the *Biographia*, was never published. He revised Dodson’s *Collection of Old Plays* (12 vols., 1780). He also re-edited Johnson and Steevens’s edition (1773) of Shakespeare. Reed’s edition was published in 10 vols. (1785), and he gave great assistance to Steevens in his edition (1793). He was Steevens’s literary executor, and in 1803 published another edition (21 vols.) based on Steevens’s later collections. This, which is known as the *first coriorum,* was re-issued ten years later. He died on the 5th of January 1807. His valuable library of theatrical literature was catalogued for sale as *Bibliotheca Reediana* (1807).

See John Nichol’s *Lit. A nec.* of the 18th Century (vol. ii., 1812); and Edward Dowden, *Essays, Modern and Elizabethan.*

REED, JOSEPH (1741-1785), American politician, was born in Trenton, New Jersey, on the 27th of August 1741. He graduated at Princeton in 1757, studied law under Richard Stockton and, in 1763-65, at the Middle Temple, London, and practised in Trenton from 1765 until his removal to Philadelphia in 1770. He was president of the Second Provincial Congress of Pennsylvania in 1775, was aide-de-camp and military secretary to General Washington in 1775-76, and was adjutant-general with the rank of colonel in 1776-77. He resigned his commission in the autumn of 1777, and in 1777-78 was a delegate to the Continental Congress. From December 1778 to October 1781 he was president of the state Executive Council. During his administration the proprietary rights of the Penn family were abrogated (1779), and provision was made for the gradual abolition of slavery (1780). During this time Reed led the attack on Benedict Arnold (q.v.) for the latter’s administration of Philadelphia. Reed was elected to Congress in 1784, but died in Philadelphia on the 5th of May 1785. (See *The Life and Correspondence of Joseph Reed* (2 vols., Philadelphia, 1874), by his grandson, William B. Reed, is based upon the family papers. It pictures Reed as an heroic patriot and statesman; George Bancroft, on the other hand, in the ninth volume (p. 229) of his *History* (1866) and in *Joseph Reed: an Historical Essay* (1867), pictures him as a trimmer of the most pronounced type. Bancroft’s principal charge against Reed was based on a passage in Count Dopeck’s diary referring to a Colonel Reed detected by the British in 1776. In 1876, however, Mr. W. S. Strong discovered that the reference in the diary was really to Col. Charles Reed (1715- c. 1780). Bancroft withdrew this definite charge in the 1876 edition of his *History,* in which, however, his tone towards Joseph Reed was unchanged.

Joseph Reed’s son, JOSEPH REED (1772-1846), published the *Laws of Pennsylvania* (5 vols., 1822-24), continuing the work of Charles Smith, published in 1810-13, which began with the laws of 1700. His grandson, WILLIAM BRADFORD REED (1866-1876), graduated at the university of Pennsylvania in 1822, was a representative in the Pennsylvania legislature in 1814-15, attorney-general of the state in 1838, and a state senator in 1841. He was professor of American history in the university of Pennsylvania in 1850-56, United States minister to China in 1857-58, and in 1858 negotiated a treaty with China, proclaimed in 1860. Besides the biography of his grandfather mentioned above, he published one of Joseph Reed’s wife, *Life of Esther De Berli, afterwards Esther Reed* (1833).

W. B. Reed’s brother, HENRY [HOPE] REED (1809-1854), graduated at the university of Pennsylvania in 1825, practised law in Philadelphia, and was assistant-professor of moral philosophy in the university of Pennsylvania in 1831-34 and professor of English literature and rhetoric there in 1835-54. He assisted Wordsworth in the preparation of an American edition of his poems in 1837, edited in America Christopher Wordsworth’s *Memoirs of William Wordsworth* (1851) and published *Lectures on English Literature from Chaucer to Tennyson* (1853).

REED, THOMAS BRACKETT (1839-1902), American statesman, was born in Portland, Maine, on the 18th of October 1839. He graduated at Bowdoin College in 1860; was acting adjutant of the U.S. navy from April to November 1865; and in 1866 was admitted to the bar. He was a member of the Maine House of Representatives in 1868-69 and of the state Senate in 1870, was attorney-general of the state in 1870-72, and was city solicitor of Portland in 1874-77. He was a Republican member of the National House of Representatives from 1877 until 1899; was a member of the Potter Committee to investigate the disputed presidential election of 1876, and conducted the examination of Samuel J. Tilden; and he was Speaker of the House in 1885-94, and in 1895-99. He was a “strong” speaker in his control of the proceedings, and he developed an organized committee system, making the majority of the Rules Committee on Rules consist of the speaker and chairman of the committees on ways and means and on appropriations. The “Reed Rules,” drawn up by him, William McKinley and J. G. Cannon, were adopted on the 14th of February 1890; they provided that every member must vote, unless peculiarly interested in a measure, that members present and not voting be counted for a quorum, and that no dilatory motion be entertained by the speaker. His parliamentary methods were bitterly attacked by his political enemies, who called him “Tar Reed.” He greatly hastened the passage of the McKinley Bill in 1890, and of the Dingley Bill in 1897. His rules and methods of control of legislation were adopted by his successors in the speakership, and the power of the Rules Committee was greatly increased under Charles F. Crisp (1845-1896), Democratic speaker in 1891-1895. After the war with Spain Reed broke with the administration on the issue of imperialism. He resigned his seat in 1899 and practised law in New York City. He died in Washington on the 7th of December 1902. Reed was a remarkable personality, of whom many good stories were told, and opinions varied as to his conduct in the chair; but he was essentially a man of rugged honesty and power, whose death was a loss to America. In public service he was a man of integrity.

Reed’s Rules were published as a parliamentary manual. He edited with others a *Library of Modern Eloquence* (10 vols., 1901). See the chapter on Reed in H. B. Fuller’s *Speakers of the House* (Boston, 1909).

REED, a term applied to several distinct species of large, water-loving grasses. The common or water-reed, *Phragmites communis* (also known as *Arundo paragmites*), occurs along the margins of lakes, swamps, marshes and plained streams, not only throughout Britain, but widely distributed in arctic and temperate regions. Another very important species in *Ammophila arenaria* (also known as *A. maritima* or *Phragmites arenaria*), the sea-reed or marsh-grass, a native of the sandy shores of Europe and N. Africa. Both species have been of notable geological importance, the former binding the soil and so impeding denudation, and actually converting swamp into dry land, largely by the
REEDBUCK—REED INSTRUMENTS

of its tail (5 to 10 ft.) close set stems. The latter species, of which the branching rootstocks may be traced 30 or even 40 ft., is of still greater importance in holding sand-dunes against the sea, and for this purpose has not only been long protected by law, but has been extensively planted on the coasts of Norfolk, Holland, Gascony, &c.

Other reeds are Calamagrostis (various species), Glycerium argenteum (pampas grass), Deyeuxia, &c., also Arundo Donax, the largest European grass (6 to 12 ft. high), which is abundant in Europe. Reeds have been used from the earliest times in thatching and in other branches of construction, and also for arrows, the pipes of musical instruments, &c. Reed pens are still used in the Eastern Plain belonging to other orders occurring here, especially the bur-reed (Sparganium) and the reed-mace (Typha), both belonging to the natural order Typhaceae. The bulrushes (Scirpus), belonging to the natural order Cyperaceae, are also to be distinguished.

REEDBUCK (Dutch rietbok), the popular name of a foxy red South African antelope (Cervicapra arundineum) of medium size, with a moderately long bushy tail, a bare gland-patch behind the ear, and in the male rather short horns which bend forwards in a regular curve. There are several other species of allied African antelopes included in the genus Cervicapra to which the name of reedbuck is also applied, one of these ranging as far N. as Abyssinia, and another inhabiting W. Africa.

REED INSTRUMENTS (Fr. instruments à anche; Ger. Blas-instrumente mit Zungen; It. Strumenti a bocca), a class of wind instruments in the tubes of which sound-waves are generated by the vibrations of a reed mouthpiece. Reed instruments fall into two great classes: (1) those blown directly by the breath of the performer, who is thus able in all but a few obsolete instruments to express his emotional feelings in music; (2) those in which the wind supply is obtained by mechanical devices, such as the bell of bagpipe instruments or the bellows of such keyboard instruments as the regal, harmonium and kindred instruments.

Directly-blown reed instruments comprise the section of modern wind instruments known as the "wood wind," with the exception of flute and piccolo; they are classified according to the kind of reed vibrator of which the mouthpiece is composed. There are three kinds of reed mouthpieces: (1) the single or beating reed; (2) the double reed; (3) the free reed, all of which perform the function of sound-producer (see MOUTHPIECE and FREE REED VIBRATOR). The reed used consists of a thin tongue or strip of reed, cane or some elastic material, thinned gradually to a delicate edge. It is adapted to a resonating tube in such a manner that when it is at rest the opening at the mouthpiece end of the tube consists only of a very slight aperture or chink, which is periodically opened and closed by the pulsations of the reed when acted upon by the compressed breath of the player. This principle is common to all reed mouthpieces, and the difference in timbre is in a measure due to the manner in which the pulsations are brought about and the degree of elasticity secured.

The double reed consists of two blades of reed or laminae of elastic material tightly bound together by many turns of waxed silk, so that above the construction the tube has an oval section; below, where it communicates with the main bore of the instrument, the tube is strictly cylindrical. The chink here formed is by two thin walls of reed of equal elasticity (see OBOE, BASSOON).

The double reed is common to the members of the oboe family, consisting, besides the oboe, of the cor anglais or tenor, of the bassoon and the contra bassoon, and of the contra bassoon and double bassoon.

The double mouthpiece is used besides on the sarrusophone family, instruments of brass but classed with the wood wind on account of the mouthpiece and fingering.

The single or beating reed consists of a single blade bevelled at the edge and placed over a table or frame communicating with the main bore of the instrument, against which it beats, causing a series of pulsations. The single reed is common to all the members of the clarinet family, consisting, besides the clarinet, of the basset-horn or tenor, and of the bass and pedal clarinets; of the bassophone, an early bass clarinet, and of the saxophone, a metal oboe with a beating reed instead of a double reed. The ancient Greek aulos was undoubtedly used with a beating reed during some period of its history.

The free reed is not represented among members of the modern wood wind, and, as adapted to a directly-blown instrument, only finds application in the Chinese cheng, the prototype of the harmonium, and in the mouth organ or harmonica.

The reed in wind instruments produces a peculiar tone quality to which it has given its name; it varies in the three different kinds of mouthpieces without losing the fundamental reedy timbre. In the single reed the reed acts against the hard wood or vulcanite of the table against which it beats produces a sound harsh and strident in inverse proportion to the degree of elasticity possessed by the vibrating tongue. In the clarinet the reed is carefully and delicately made of cane with due regard to the interdependence of reed and clarinet tube. The strong wooden or metallic beating reeds of the early organ reed pipes must have had an unpleasantly harsh timbre, which won for them in Germany the epithet Schnarrewerk.

In the double reed the two delicately shaped pieces of reed vibrate against each other, producing the somewhat nasal, reedy tone of the oboe family. In the free reed compressed air is the only buffer which the vibrators encounter while swinging through the aperture, alternately closing and reopening it; hence the soft and mellow timbre which it is possible to produce by proper treatment of the free reed. Experience has shown that the best results for the double reed are obtained when it is used in conjunction with a tube of conical bore, whereas the beating reed is heard to greater advantage in instruments with cylindrical bore, one notable exception in practice being, as already mentioned, the saxophone family. The double reed adapted to a conical tube confers upon the latter the acoustic properties of the open pipe, whose wave-length is equal to that of the tube and which is capable of overblowing the octave and successive harmonics (theoretically). Either a single or a double reed adapted to a cylindrical pipe converts it for all acoustic purposes into a closed pipe, in which the whole wave-length is twice the length of the tube, a node forming at the mouthpiece end. The fundamental note of such a tube will therefore be an octave lower than that of an open pipe of the same length, and it can only overblow the uneven numbers of the harmonic series, such as the third harmonic (or twelfth above the fundamental).

It is easier to overblow on instruments with reed mouthpieces, greater pressure of breath must be exerted, and the vibrating length of the reed must be decreased by the action of the lips upon it. This is what occurs in instruments of the oboe and clarinet type, which are blown directly from the mouth. There are, however, cases in which the reed is concealed within the instrument out of reach of the lips, either in a capsule, as in the old instruments hautbois de Poitou and cromorne, or else in a socket, as in the chalumeau and chalumeau and bagpipe or, again, as in the mouthpieces of organ reed pipes. In the last (each of which gives but one fixed note) the vibrating length of the reed to which the air is supplied is fixed, as is also the pressure of the compressed air supplied to them. The result in all these cases is similar: no harmonics can be obtained, and therefore the scale of the instrument depends solely on the number of holes and keys provided, whereas, where the lips control the reed, fewer holes are necessary to produce any given compass. The chalumeau of bagpipes have double reeds, but the drones are as a rule provided with beating reeds and are of cylindrical bore, a combination which, for the reason explained above, gives them a note an octave deeper in pitch, the length of pipe being equal, than would be the case if the bore were conical. In the musette, in the cornemuse used in concert with the hautbois de Poitou, and in the Neapolitan surdulina (see BAGPIPE), both chalumeau and drones had double reeds.

The aulos of the ancient Greeks and tibia of the Romans consisted in the older instruments of a cylindrical tube of very narrow
and became chairman of the Congregational Union of England and Wales, but died just before his term of office was to begin. His History of Protestant Nonconformity in Wales (1861; 2nd ed. 1885) is a sound and judicious piece of work.

REEVE, CLARA (1720–1807), English novelist, daughter of William Reeve, a Suffolk clergyman, was born at Ipswich in 1720. She was an industrious writer, and produced many works in prose and verse, including a history of the Progress of Romance (1785); but her only eminent success was the novel of The Old English Baron (1777), originally published under the title of The Champion of Virtue. In the history of the English novel she stands midway between Walpole and Mrs. Radcliffe. She died at Ipswich on the 3rd of December 1807.

REEVE, HENRY (1813–1895), English publicist, younger son of Henry Reeve, a well-known Whig physician and writer of Norwich, and nephew of Mrs. Sarah Austin, was born at Norwich on the 5th of September 1813. He was educated at the Norwich grammar school under Edward Valpy. During his holidays he saw a good deal of the young John Stuart Mill. In 1829 he studied at Geneva and mixed in Genevese society, then very brilliant, and including the Sismonds, Huber, Bonstetten, De Candole, Rossil, Krasinski (his most intimate friend), and Mickiewicz, whose Paris he translated. During a visit to London in 1831 he was introduced to Thackeray and Carlyle, and at Ipswich on the 3rd of December 1837.

REEVE, Sir (1842–1887), English writer, was the son of Sir Henry Reeve, a remembered Whig physician and writer of Norwich, and was educated at the Norwich grammar school under Edward Valpy. During his holidays he saw a good deal of the young John Stuart Mill. In 1829 he studied at Geneva and mixed in Genevese society, then very brilliant, and including the Sismonds, Huber, Bonstetten, De Candole, Rossil, Krasinski (his most intimate friend), and Mickiewicz, whose Paris he translated. During a visit to London in 1831 he was introduced to Thackeray and Carlyle, and at Ipswich on the 3rd of December 1837.

REEVE, REEVE (1777–1864), Welsh Nonconformist divine, was born at Gelligron, Glamorgan, and educated at the Presbyterian College, Carmarthen. He entered the Unitarian ministry in 1807 at Newtown Green Chapel, London, removing to Southwark 181 and to Stamford Street, Blackfriars, in 1823. He had the degree of L.L.D. of Glasgow (1818). He had a great knowledge of the history of ancient Christianity, especially during the 16th century. His scattered papers, chiefly in the Monthly Repository (1818–22), on such subjects as “Faustus Socinus and Francis David,” “The Italian Reformations,” “Memoirs of the Socinians,” are important. Financial troubles drove him to Spain in 1853, and he died in obscurity at Brighton on the 1st of August 1864.

Another Thomas Rees (1818–1883), a native of Pen Pontbren, Carmarthenshire, held pastorates at Aberdare (1840), Llanelly (1842), Cendul, Mon. (1849) and Swansea (1862).

The addition dates from the very end of the 18th or the beginning of the 19th century, and is connected with the beginning of the harmonium (q.v.).
and is the ancestor of the sheriff, the shire-reeve. In addition to the sheriff there were several kinds of reeves, and we are told in the body of laws known as the laws of Edward the Confessor that it is “multiplex nomen; greve enim dictur de scira, de wapentagis, de hundredis, de burgis, de villis.” Thus we hear of port-reeves, burg-reeves, and tun-reeves, while the Anglo-Saxon Chronicle mentions high reeves. It was the tun-reeve or reve of the township who with four other men represented the township in the courts of the hundred and the shire. In free townships he was probably chosen by the inhabitants; in dependent townships by the lord. A little later there were manor reeves, these being elected by the villains; according to Fleta, their duties were to attend to the cultivation of the land, and to see that each villain performed his proper share of service. The reve of Chaucer’s Canterbury Tales was doubtless a steward or bailiff, something equivalent to the grieve in Scotland to-day.

In early English the word reeve was sometimes used as a translation for the prefect or governor of Roman and Jewish times. Some authorities have thought that there is some connexion between the Anglo-Saxon gerefa and the German Graf, but Max Müller (Lectures on the Science of Language, 1885) is inclined to doubt this. J. M. Kemble (Saxons in England, 1876), who goes at length into the history of the reeve, connects the word with rofan or refan, to call aloud, this making him the original of the banniler, or proclaimer of the court. At the present time the word reeve is sometimes used to describe a foreman or overseer in a coal mine. It is also used in Canada for the president of a village or town council.

REEVES, JOHN SIMS (1818-1900), English vocalist, was born at Woolwich on the 26th of September 1818, and received his musical education from his father, a musician in the Royal Artillery. At the age of fourteen he had progressed so far as to be appointed organist of North Cray church, and could play the oboe, bassoon, violin, and violoncello. He seems to have studied medicine for a year, but changed his mind when he gained his adult voice: it was at first a baritone, and he made his earliest appearance at Newcastle in 1839 in various baritone parts. He studied with Hobbs and T. Cooke, and, his voice having become a tenor, he appeared under Macready’s management at Drury Lane (1841-43) in subordinate tenor parts in Purcell’s King Arthur, Der Freischütz, and Acis and Galatea, when Handel’s pastoral was mounted on the stage with Stanfield’s scenery. Four years were spent in study on the Continent, under Bordogni in Paris and Mazzucato in Milan, and his début in Italian opera was made at the Scala as Edgardo in Lucia. He reappeared in London in May 1847 at a benefit concert for Vincent Wallace, and at one of the Ancient Concerts in the following month, his career on the English operatic stage beginning at Drury Lane in December 1847 in Lucia, under the conductorship of Hector Berlioz. In Balfe’s Maid of Honour he created the part of Lynam in the same season. In 1849 he went to Her Majesty’s Theatre, singing in Lindo di Chamonix; and in the autumn of that year, at the Norwich Festival, made a great sensation in “The enemy said,” from Israel in Egypt, a song in which the finest qualities of his ringing voice could be appreciated. From his first appearance at the Sacred Harmonic Society in the following November he was recognized as the leading English tenor; and in Costa’s Eli and Naaman the tenor parts were written for him. His first Handel Festival was that of 1857, and the effect of his wonderful declamation in the Crystal Palace was a main attraction of this and of many subsequent festivals. His retirement from public life, at first announced as to take place in 1882, did not actually occur till 1891, when a farewell concert for his benefit was given at the Albert Hall. His savings were invested in an unfortunate speculation, and he was compelled to reappear in public for a number of years. He died at Worthing on the 25th of October 1900.
