REFECTORY (med. Lat. refectorium, from refecere, to refresh), the hall of a monastery, convent, &c., where the religious took their chief meals together. There frequently was a sort of ambo, approached by steps, from which to read the *legenda sanctorum*, &c., during meals. The refectory was generally situated by the side of the S. cloister, so as to be removed from the church but contiguous to the kitchen; sometimes it was divided down the centre into two aisles, as at Fountains Abbey in England, Mont St Michel in France and at Villers in Belgium, and into three aisles as in St Mary's, York, and the Bernardines, Paris. The refectory of St Martin-des-Champs in Paris is in two aisles, and is now utilized as the library of the École des Arts et Métiers. Its wall pulpit, with an arcaded staircase in the thickness of the wall, is still in perfect preservation.

REFEREE, a person to whom anything is referred; an arbitrator. The court of referees in England was a court to which the House of Commons committed the decision of all questions as to the right of petitioners to be heard in opposition to private bills. As originally constituted the referees consisted of the chairman of ways and means, and other members, the Speaker's counsel and several official referees not members of the House of Commons. In 1903 the appointment of official referees was discontinued. The court now consists of the chairman of ways and means, the deputy chairman and not less than seven other members of the House appointed by the Speaker, and its duty, as defined by a standing order, is to decide upon all petitions against private bills, or against provisional orders or provisional certificates, as to the rights of the petitioners to be heard upon such petitions. In the high court of justice, under the Judicature Act 1873, cases may be submitted to three official referees, for trial, inquiry and report, or assessment of damages. Inquiry and report may be directed in any case, trial only by consent of the parties, or in any matter requiring any prolonged examination of documents or accounts, or any scientific or local investigation which cannot be tried in the ordinary way.

REFERENDUM and INITIATIVE, two methods by which the wishes of the general body of electors in a constitutional state may be expressed with regard to proposed legislation. They are developed to the highest extent in Switzerland, and are best exemplified in the Swiss federal and cantonal constitutions. By these two methods the sovereign people in Switzerland (whether in the confederation or in one of its cantons) approve or reject the bills and resolutions agreed upon by the legislative authority (Referendum), or compel that authority to introduce bills on certain specified subjects (Initiative)—in other words, exercise the rights of the people as regards their elected representatives at times other than general elections. The *Referendum* means “that which is referred” to the sovereign people, and prevailed (up to 1848) in the federal diet, the members of which were bound by instructions, all matters outside which being taken “ad referendum.” A similar system obtained previously in the formerly independent confederations of the Grisons and of the Valais, in the former case not merely as between the Three Leagues, and even the bailiwicks of each within its respective league, but also (so far as regards the upper Engadine) the communes making up a bailiwick, though in the Valais the plan prevailed only as between the seven Zehnten or bailiwicks. The *Initiative*, on the other hand, is the means by which the sovereign people can compel its elected representatives to take into consideration either some specified object or a draft bill relating thereto, the final result of the deliberations of the legislature being subject by a referendum vote to the approval or rejection of the people. These two institutions therefore enable the sovereign people to control the decisions of the legislature, without having recourse to a dissolution, or waiting for the expiration of its natural term of office.

As might have been expected, both had been adopted by different cantons before they found their way into the federal constitution, which naturally has to take account of the sovereign rights of the cantons of which it is composed. Further, they (at any rate the referendum) were employed in the case of constitutional matters relating to cantonal constitutions before being applied to all or certain specified laws and resolutions. Finally, the action of both has been distinctly conservative in the case of the confederation, though to a less marked degree in the case of the cantons.
Two forms of the Referendum should be carefully distinguished: the facultative or optional (brought into play only on the demand of a fixed number of citizens), and the obligatory or compulsory (which obtains in all cases that lie within its sphere as defined in the constitutions). The Initiative exists only in the facultative form, being exercised when a certain number of citizens demand it. Both came into common use during the Liberal reaction in Switzerland after the Paris revolution of July 1830. In 1831 St Gall first adopted the facultative referendum (then and for some time after called the "Veto") and its example was followed by several cantons before 1848. The "obligatory referendum" appears first in 1852 and 1854 respectively in the Valais and the Grisons, when the older system was reformed, but in its modern form it was first adopted in 1863 by the canton of rural Basel. The Initiative was first adopted in 1845 by Vaud. Of course the cantons with Landsgemeinde, Uri, Unterwalden, Appenzell and Glarus (where the citizens appear in person) possessed both from time immemorial. Excluding these there were at the end of 1907 99 cantons, which had the "obligatory referendum" (Aargau, rural Basel, Bern, the Grisons, Schaffhausen, Schwyz, Soleure, Thurgau, the Valais and Zürich), while 72 cantons possess only the "facultative referendum" (Basel town, Geneva, Lucerne, Neuchâtel, St Gall, Ticino, Vaud and Zug). Fribourg alone had neither, save an obligatory referendum (like all the rest of the cantons, except the cantons of the cantonal constitution. As regards the Initiative, all the cantons have it as to the revision of the cantonal constitution; while all but Fribourg have it also as to bills or legislative projects. In the case both of the facultative referendum and of the Initiative each canton fixes the number of citizens who have a right to exercise this power. The constitution of the Swiss confederation lags behind those of the cantons. It is true that both in 1848 (art. 113) and in 1874 (art. 120) it is provided that a vote on the question whether the constitution shall be revised must take place if either house of the federal legislature or 50,000 qualified voters demand it; but of course a popular vote (obligatory referendum) must take place on the finally elaborated project of revision. But as regards bills the case is quite different. The facultative referendum was not introduced till 1874 (art. 89) and then only as regards all bills and resolutions not being of a pressing nature, 8 cantons or 30,000 qualified voters being entitled to ask for such a popular vote. But the Initiative did not appear in the federal constitution till it was inserted in 1891 (art. 121), and then merely in the case of a partial (not a total) revision of the constitution, if 50,000 qualified voters demand it; and of course a subject a subject in general or a draft bill,—of course the federal legislature had an Initiative in this matter in 1848 already. The results of the working of these two institutions in federal matters up to the end of 1908 are as follows. Excluding the votes by which the two federal constitutions of 1815 and 1874 were adopted, there have been 30 (10 of them between 1848 and 1874) votes (obligatory referendum) as to amendments of the federal constitution; in 15 cases only (of which only one was before 1874) did the people accept the amendment proposed. In the case of bills there have been 30 votes (very many bills have not been attacked at all), all of course since the facultative referendum was introduced in 1874; in 13 cases only have the people voted in the affirmative. Finally, with regard to the Initiative, there have been 7 votes, of which two only were in the affirmative. Thus, between 1874 and 1907, of 57 votes 27 only were in the affirmative, while if we include the 10 votes between 1848 and 1874 the figures are respectively 67 and 28, one only having been favourable during that period.

The result is to show that the people, voting after mature reflection, are far less radically disposed than has sometimes been imagined.

The method of referendum by itself is also in use in some of the states of the American Union (see United States) and in Australia, and under the name of plebiscite has been employed in France; but it is best studied in the Swiss constitution. The method of the referendum is used in the following states for the purpose of requiring the consent of both houses of Congress, or of both houses of the lower house. The United States of America has a system of referenda that is so different from that of Switzerland that it is only justifiable to speak of it as a unique case in the world. The American system of referenda is a method of submitting questions to the people for their determination, with the result that the people have, in fact, the power of making or altering the constitution, and the power of altering any law that is put before them. The American system of referenda is a method of submitting questions to the people for their determination, with the result that the people have, in fact, the power of making or altering the constitution, and the power of altering any law that is put before them.

**REFLECTION OF LIGHT.** When a ray of light in a homogeneous medium falls upon the bounding surface of another medium, part of it is usually turned back or reflected and part is scattered, the remainder traversing or being absorbed by the second medium. The scattered rays (also termed the irregularly or diffusely reflected rays) play an important part in rendering objects visible—in fact, without diffuse reflection non-luminous objects would be invisible; they are occasioned by irregularities in the surface, but are governed by the same law as holds for regular reflection. This law is: the incident and reflected rays make equal angles with the normal to the reflecting surface at the point of incidence, and are coplanar with the normal. This is equivalent to saying that the path of the ray is a minimum. In fig. 1, MN represents the section of a plane mirror; OR is the incident ray, RP the reflected ray, and TR the normal at R. Then the law states that the angle of incidence ORT equals the angle of reflection PRT, and that OR, RT, and RP are in the same plane.

This natural law is capable of ready experimental proof (a simple one is to take the altitude of a star with a meridian circle, its depression in a horizontal reflecting surface of mercury and the direction of the nadir), and the most delicate instruments have failed to detect any divergence from it. Its explanation by the Newtonian corpuscular theory is very simple, for we have only to assume that at the point of impact the perpendicular velocity of a corpuscle is reversed, whilst the horizontal velocity is unchanged (the mirror being assumed horizontal). The wave-theory explanation is more complicated, and in the simple form given by Huygens incomplete. The theory as developed by Fresnel shows that regular reflection is due to a small zone in the neighbourhood of the point R (above), there being destructive interference at all other points on the mirror; this theory also accounts for the polarization of the reflected light when incident at a certain angle (see Polarization of Light). The smoothness or polish of the surface largely controls the reflecting power, for, obviously, crests and furrows, if of sufficient magnitude, disturb the phase relations. The permissible deviation from smoothness depends on the wave-length in the medium employed; it appears that surfaces smooth to within 1/10 of a wave-length reflect regularly; hence long waves may be regularly reflected by a surface which diffuses short waves. Also the obliquity of the incidence would diminish the effect of any irregularities; this is experimentally confirmed by observing the images produced by matt surfaces or by smoked glass at grazing incidence.

We now give some elementary constructions of reflected rays, or, what comes to the same thing, of images formed by mirrors.

1. If O be a luminous point and OR a ray incident at R on the plane mirror MN (fig. 1) to determine the reflected ray and the image of O. If RP be the reflected ray and KT perpendicular

---

1 This principle of the minimum path, however, only holds for plane and convex surfaces; with concave surfaces it may be a maximum in certain cases.
to MN, then, by the law of reflection, angle ORT = TRP or ORM = PRN. Hence draw OQ perpendicular to MN, and produce it to S, making OQ = OQ', join SR and produce it to \( P \). It is easily seen that PR and OR are equally inclined to RT (or MN). A point-eye at \( P \) would see a point object \( O \) at \( S \), i.e., at a distance below the mirror equal to its height above. If the object be a solid, then the images of its corners are formed by taking points at the same distances below as the corners are above the mirror, and joining them. The eye, however, sees the image perverted, i.e., in the same relation as the left hand to the right. Fig. 2 shows how an extended object is viewed in a mirror by a natural eye.

2. If \( A, B \) be two parallel plane mirrors and \( O \) a luminous point between them (fig. 3) to determine the images of \( O \) all the images must lie on the line (produced) \( PO \) passing through \( O \) and perpendicular to \( AB \) or the mirrors. Let \( OP = \beta \), \( OQ = \gamma \). Then if \( O' \) be the image of \( O \) in \( A \), \( O'Q' = 2\gamma \); now \( O' \) has an image \( O' \) in \( B \), such that \( O'O'' = OQ' + \gamma + \gamma' = 2\gamma + 2\gamma \); similarly \( O'' \) has an image \( O'' \) in \( A \), such that \( O''O''' = O'Q' + \gamma + \gamma' = 2\gamma + 2\gamma \). In the same way we can show that the image first formed in \( B \) gives foci of the general distances: \( O''B'' = 2\gamma \), \( O''B''' = 2\gamma + 2\gamma \). The number of images is limited, for when any one falls on the arc \( ab \) between the mirrors produced, it lies behind both mirrors, and hence no further image is possible. Suppose \( \theta \) to be the first image to fall on this arc, then \( O'a \) is perpendicular to \( CA \), and \( O''a \) is 0a. Also \( \theta = CO \) and it is easily seen that all the images lie on a circle with centre \( C \) and radius \( CO \). The image \( a' \) forms an image \( a'' \) in \( B \) such that \( O'\theta = OB + O'B'' = \theta + OB + O'a = 2\theta + 2\theta \). Also \( a'' \) forms an image \( a''' \) in \( A \) such that \( O''a''' = O'A + O'a = 2\theta + 2\theta \). In the same way we can show that the image first formed in \( B \) gives foci of the general distances: \( O''B'' = 2\theta \), \( O''B''' = 2\theta + 2\theta \). The number of images is limited, for when any one falls on the arc \( ab \) between the mirrors produced, it lies behind both mirrors, and hence no further image is possible. Suppose \( \theta \) to be the first image to fall on this arc, then \( O'a \) is perpendicular to \( CA \), and \( O''a \) is 0a. Also \( \theta = CO \) and it is easily seen that all the images lie on a circle with centre \( C \) and radius \( CO \). The image \( a' \) forms an image \( a'' \) in \( B \) such that \( O'\theta = OB + O'B'' = \theta + OB + O'a = 2\theta + 2\theta \). Also \( a'' \) forms an image \( a''' \) in \( A \) such that \( O''a''' = O'A + O'a = 2\theta + 2\theta \). In the same way we can show that the image first formed in \( B \) gives foci of the general distances: \( O''B'' = 2\theta \), \( O''B''' = 2\theta + 2\theta \). The number of images is limited, for when any one falls on the arc \( ab \) between the mirrors produced, it lies behind both mirrors, and hence no further image is possible. Suppose \( \theta \) to be the first image to fall on this arc, then \( O'a \) is perpendicular to \( CA \), and \( O''a \) is 0a. Also \( \theta = CO \) and it is easily seen that all the images lie on a circle with centre \( C \) and radius \( CO \). The image \( a' \) forms an image \( a'' \) in \( B \) such that \( O'\theta = OB + O'B'' = \theta + OB + O'a = 2\theta + 2\theta \). Also \( a'' \) forms an image \( a''' \) in \( A \) such that \( O''a''' = O'A + O'a = 2\theta + 2\theta \).

This formula connects the distances of the object and image formed by a spherical concave mirror with the radius of the mirror. Points satisfying this relation are called "conjugate foci," for obviously they are reciprocal, i.e., if \( u \) and \( v \) can be interchanged in the formula.

If \( u \) be infinite, as, for example, if the luminous source be a star, then \( v = 1 \), i.e., \( v = \frac{1}{u} \). This value is called the focal length of the mirror, and the corresponding point, usually denoted by \( F \), is called the "principal focus." This formula requires modification for a convex mirror. If \( u \) be always considered as positive (\( v \) may be either positive or negative), \( r \) must be regarded as positive with concave mirrors and negative with convex. Similarly the focal length, having the same sign as \( r \), has different signs in the two cases.

In this formula all distances are measured from the mirror; but it is sometimes more convenient to measure from the principal focus. If the distances of the object and image from the principal focus be \( x \) and \( y \), then \( x = \frac{1}{u} + f \) and \( y = \frac{1}{v} + f \) (remembering that \( f \) is positive for concave and negative for convex mirrors). Substituting these values in \( u^2 + v^2 = f^2 \) and reducing we obtain \( z^2 = f^2 \). Since \( f \) is always positive, \( x \) and \( y \) must have the same sign, i.e., the object and image must lie on the same side of the principal focus.

We now consider the production of the image of a small object placed symmetrically and perpendicularly to the axis of a concave (fig. 7) and a convex mirror (fig. 8). Let \( PQ \) be the object and \( A \) the vertex of the mirror. Consider the point \( P \). Now a ray through \( P \) and parallel to the axis after meeting the mirror at \( M \) is reflected through the focus \( F \). The line \( MF \) must therefore contain the image of \( P \). Also a ray through \( P \) and also through the centre of curvature \( C \) of the mirror is reflected along the same path; this also contains the image of \( P \). Hence the image is at \( P \), the intersection of the lines \( MF \) and \( PC \). Similarly the image of any other point can be found, and the final image deduced. We notice that in fig. 6 the image is inverted and real, and in fig. 7 erect and virtual. The "magnification" or ratio of the size of the image to the object can be deduced from the figures by elementary geometry; it equals the ratio of the distances of the image and object from the mirror or from the centre of curvature of the mirror.

The positions and characters of the images for objects at varying

The above discussion of spherical mirrors assumes that the mirror has such a small aperture that the reflected rays from any point unite in a point. This, however, no longer holds when the mirror has a wide aperture, and in general the reflected rays envelop a caustic (q.v., see also ABBREVIATION). The only mirror which can sharply reproduce an object-point as an image-point has for its section an ellipse, which is so placed that the object and image are at its foci. This follows from a property of the curve, viz., the sum of the focal distances is constant, and that the focal axes are equally inclined to the normal at the point. More important than the elliptical mirror, however, is the parabolic, which has the property of converting rays parallel to the axis into a pencil through its focus; or, conversely, rays from a source placed at the focus are converted into a parallel beam; hence the use of this mirror in searchlights and similar devices.

**REFORMATION, THE.** The Reformation, as commonly understood, means the religious and political revolution of the 16th century, of which the immediate result was the partial disruption of the Western Catholic Church and the establishment of various national and territorial churches. These agree in repudiating certain of the doctrines, rites and practices of the medieval Church, especially the sacrifice of the Mass and the headship of the bishop of Rome, and, whatever their official designations, came generally to be known as "Protestant." In some cases they introduced new systems of ecclesiastical organization, and in all they sought to justify their innovations by an appeal from the Church's tradition to the Scriptures. The conflicts between Catholics and Protestants speedily merged into the chronic political rivalries, domestic and foreign, which distracted the European states; and the religious considerations played a very important part in diplomacy and war for at least a century and a half, from the diet of Augsburg in 1530 to the English revolution and the league of Augsburg, 1588-89. The terms "Reformation" and "Protestantism" are inherited by the modern historian; they are not of his devising, and come to him laden with reminiscences of all the exalted enthusiasms and bitter antipathies engendered by a period of fervid religious dissension. The unmeasured invective of Luther and Alexander has not ceased to re-echo, and the old issues are by no means dead.

The heat of controversy is, however, abating, and during the past thirty or forty years both Catholic and Protestant investigators have been vying with one another in adding to our knowledge and in rectifying old mistakes; while an ever-increasing number of writers pledged to neither party are aiding in developing an idea of the scope and nature of the Reformation which differs radically from the traditional one. We now appreciate too thoroughly the intricacy of the medieval Church; its vast range of activity, secular as well as religious; the inextricable intertwining of the civil and ecclesiastical governments; the slow and painful process of their divorce as the old ideas of the proper functions of the two institutions have changed in both Protestant and Catholic lands: we perceive all too clearly the limitations of the reformers, their distrust of reason and criticism—in short, we know too much about medieval institutions and the process of their disintegration longer to see in the Reformation an abrupt break in the general history of Europe. No one will, of course, question the importance of the schism which created the distinction between Protestants and Catholics, but it must always be remembered that the religious questions at issue comprised a relatively small part of the whole compass of human aspirations and conduct, even to those to whom religion was especially vital, while a large majority of the leaders in literature, art, science and public affairs went their way seemingly almost wholly unaffected by theological problems.

That the religious elements in the Reformation have been greatly overestimated from a modern point of view can hardly be controverted, and one of the most distinguished students of Church history has ventured the assertion that "The motives, both remote and proximate, which led to the Lutheran revolt were largely secular rather than spiritual." "We may," continues Mr H. C. Lea, "dismiss the religious changes incident to the Reformation with the remark that they were not the object sought, but the means for attaining the object. The existing ecclesiastical system was the practical evolution of dogma, and the overthrow of dogma was the only way to obtain permanent relief from the intolerable abuses of that system" (Cambridge Modern History, i. 653). It would perhaps be nearer the truth to say that the secular and spiritual interests intermingled and so permeated one another that it is almost impossible to distinguish them clearly even in thought, while in practice they were so bewilderingly confused that they were never separated, and were constantly mistaken for one another.

The first step in clarifying the situation is to come to a full realization that the medieval Church was essentially an international state, and that the character of the Protestant secession from it was largely determined by this fact.

As Maitland suggests: "We could frame no acceptable definition of a State which would not comprehend the Church. What has it not that a State should have? It has laws, law givers, law courts, lawyers. It uses physical force to compel men to obey the laws. It keeps prisons. In the 15th century, though, with squeamish phrases, it pronounced sentence of death. It is the voluntary society; if people are not born into it they are baptized into it when they cannot help themselves. If they attempt to leave they are guilty of crimen laesae majestatis, and are likely to be burned. It is supported by involuntary contributions, by tithe and tax" (Cannon Law in the Church of England, p. 110). The Church was not only organized like a modern bureaucracy, but performed many of the functions of a modern State. It dominated the intellectual and profoundly affected the social interests of western Europe. Its economic influence was multiform and in calculable, owing to its vast property, its system of taxation and its encouragement of monasticism. When Luther made his first great appeal to the German people in his Address to the German Nobility, he scarcely adverts to religious matters at all. He deals, on the contrary, almost exclusively with the social, financial, educational, industrial and general moral problems of the day. If Luther, who above all others had the religious issue ever before him, attacks the Church as a source of disorder, it is not surprising that his contemporary Ulrich von Hutten should take a purely secular view of the issues involved. Moreover, in the fascinating collection of popular satires and ephemeral pamphlets made by Schade, one is constantly impressed with the absence of religious fervour, and the highly secular nature of the matters discussed. The same may be said of the various Gravamina, or lists of grievances against the papacy drafted from time to time by German diets.

But not only is the character of the Reformation differently conceived from what it once was; our notions of the process of change are being greatly altered. Formerly, historians accounted for the Lutheran movement by some magnifying the horrors of the pre-existing regime that it appeared intolerable, and its abolition consequently inevitable. Protestant writers once contented themselves with a brief caricature of the Church,
Reformation, the

A superficial account of the traffic in indulgences, and a rough and ready assumption, which even Köstlin makes, that the darkness was greatest just before the dawn. Unfortunately this crude solution of the problem proved too much; for conditions were no worse immediately before the revolt than they had been for centuries, and German complaints of papal tyranny go back to Hildegard of Bingen and Walther von der Vogelweide, who anticipated Luther by more than three centuries. So a new theory is logically demanded to explain why these conditions, which were chronic, failed to produce a change long before it actually occurred. Singularly enough it is the modern Catholic scholars, Johannes Janssen above all, who, in their efforts further to discredit the Protestant revolt by defending the institutions which the reformers attacked, have done most to explain the success of the Reformation. A humble, patient Bohemian priest, Hask, set to work toward half a century ago to bring together the devotional works published during the seventy years immediately succeeding the invention of printing. Everything one knows that one at least of these older books, The German Theology, was a great favorite of Luther's; but there are many more in Hask's collection which breathe the same spirit of pietas and spiritual contemplation. Building upon the foundations thus laid and other Catholic writers who have been too much neglected by Protestant historians, Janssen produced a monumental work in defence of the German Church before Luther's defection. He exhibits the great achievements of the latter part of the 15th and the early portion of the 16th centuries; the art and literature, the material prosperity of the towns and the fostering of the spiritual life of the people. It may well be that his picture is too bright, and that in his obvious anxiety to prove the uselessness of an ecclesiastical revolution he has gone to the opposite extreme from the Protestants. Yet this rehabilitation of pre-Reformation Germany cannot but make a strong appeal to the unbiased historical student who looks to a conscientious study of the antecedents of the revolt as furnishing the true key to the movement.

Outwardly the Reformation would seem to have begun when, on the 19th of December 1520, a professor in the university of Wittenberg invited all the friends of evangelical truth among his students to assemble outside the wall at the ninth hour to witness a pious spectacle—the burning of the "godless book of the papal decrees." He committed to the flames the whole body of the canon law, together with an edict of the head of the Church which had recently been promulgated under his regime. In this manner he hoped to convey to his students a sense of the validity of the papal monarchies, the nature of its claims, the relations it established with the civil powers, the abuses which developed in it and the attempts to rectify them, the sources of friction between the Church and the government, and finally the process by which certain of the European states threw off their allegiance to the Christian commonwealth, of which they had so long formed a part.

It is surprising to observe how early the Christian Church assumed the form of a state, and how speedily upon entering into its momentous alliance with the Roman imperial court to strengthen the claim to the universal rights and privileges and prerogatives it was so long to retain. In the twelfth book of the Theodosian Code we see already the foundations of the medieval Church already laid; for it was the 4th, not the 13th century that established the principle that deposition from the Church was a crime in the eyes of the State, and raised the clergy to a privileged class, exempted from the ordinary taxes, permitted under restrictions to try its own members and to administer the wealth which flowed into its coffers from the gifts of the faithful. The bishop of Rome, who had from the first probably enjoyed a leading position in the Church as "the successor of the two most glorious of the apostles," elaborated his claims to the divinely appointed head of the ecclesiastical organization. Sirelius (384-389), Leo the Great (440-461), and Gelasius I. (492-496) left little for their successors to add to the arguments in favour of the papal supremacy. In short, if we recall the characteristics of the Church in the West from the times of Constantine to that of Theodoric—it relies upon the civil power for favours and protection, combined with its assumption of a natural superiority over the civil power and its innate tendency to monarchical unity—it becomes clear that Gregory VII, in his effort in the latter half of the 11th century to establish the popacy as the great central power of Western Europe was in the main only reaffirming and developing old claims in a new world. His brief statement of the papal powers as he
conceived them is found in his *Dictatus*. The bishop of Rome, who enjoys a unique title, that of “pope,” may annul the decrees of all other powers, since he judges all but is judged by none. He may depose emperors and absolve the subjects of the unjust from their allegiance. Gregory the Great knew that it was expedient at a time when it was conceded by practically all that spiritual concerns were incalculably more momentous than secular, that the Church was rightly one and indivisible, with one divinely revealed faith and a system of sacraments absolutely essential to salvation. No one called in question the claim of the clergy to control completely all “spiritual” matters. Moreover, the mightiest secular ruler was but a poor sinner dependent for his eternal welfare on the Church and its head, the pope, who in this way necessarily exercised an indirect control over the civil government, which even the emperor Henry IV. and William the Conqueror would not have been disposed to deny. They would also have conceded the pope the right to play the rôle of a secular ruler in his own lands, as did the German bishops, and to dispose of suchiefs as reverted to him. This class of prerogatives, as well as the right which the pope claimed to ratify the election of the emperor, need not detain us, although they doubtless served in the long run to weaken the papal power. But the pope laid claim to a direct power over the civil governments. Nicholas II. (1058–1061) declared that Jesus had conferred on Peter the control (jura) of an earthly as well as of a heavenly empire; and this phrase was the source of the canon law of Innocent III., a century and a half later, that taught that James the brother of the Lord left to Peter not only the government of the whole Church, but that of the whole world (toto societate gubernandum). So the power of the pope no longer rested upon his headship of the Church or his authority as a secular prince, but on a far more comprehensive claim to universal dominion. There was no reason why the bishop of Rome should justify such acts as Innocent himself performed in deposing King John of England and later in annulling Magna Carta; or Gregory IV. when he struck out fourteen articles from the Sachsenpflegel; or Nicholas V. when he invested Portugal with the right to subjugate all peoples on the Atlantic coast; or Julius II. when he threatened to transfer the kingdom of France to England; or the conduct of those later pontiffs who condemned the treaties of Westphalia, the Austrian constitution of 1867 and the establishment of the kingdom of Italy. The theory and practice of papal absolutism was successfully promulgated by Gratian in his *Decretum*, completed at Bologna about 1142. This was supplemented by later collections composed mainly of papal decretals. (See Canon Law and Decretals, False.) As every fully equipped university had its faculty of canon law in which the Canon juris canonici was studied, Rashdall is hardly guilty of exaggeration when he says: “By means of the happy thought of the Bolognese monk the popes were enabled to convert the new-born universities—the offspring of that intellectual new birth of Europe which might have been so formidable an enemy to the papal pretensions—to so many engines for the propagation of Ultramontane ideas.” Thomas Aquinas was the first theologian to describe the Church as a divinely organized absolute monarchy, whose head concentrated in his person the entire authority of the Church, and was the source of all the ecclesiastical law (conditor juris), issuing the decrees of general councils in his own name, and claiming the right to revoke or modify the decrees of former councils—indeed, to make exceptions or to set aside altogether anything which did not rest upon the dictates of divine or natural law. In practice the whole of western Europe was subject to the jurisdiction of one tribunal of last resort, the Roman Curia. The pope claimed the right to tax church property throughout Christendom. He was able to exact an oath of fidelity from the archbishops, named many of the bishops, and asserted the right to transfer and dispose them. The organs of this worldly monarchy were the papal Curia, which first appears distinctly in the 11th century (see *Curia Romana*), and the legates, who visited the courts of Europe as haughty representatives of the central government of Christendom.

It should always be remembered that the law of the Church was regarded by all lawyers in the later middle ages as the law of the Carolingian empire provided that one excommunicated by the Church who did not make his peace within a year and a day should be outlawed, and this general principle was not lost sight of. It was a capital offence in the eyes of the State to disagree with the teachings of the Church, and these, it must be remembered, included a recognition of the papal supremacy. The civil authorities burnt an obstinate heretic, condemned by the Church, without a thought of a new trial. The emperor Frederick II.’s edicts and the so-called Ablésiments of St. Louis provide that the civil officers should search out suspected heretics and deliver them to the ecclesiastical judges. The civil government recognized monastic vows by regarding a professed monk as civilly dead and by pursuing him and returning him to his monastery if he violated his pledges of obedience and ran away. The State recognized the ecclesiastical tribunals and accorded them a wide jurisdiction that we should now deem essentially secular in its nature. The State also admitted that large classes of its citizens—the clergy, students, crusaders, widows and the miserable and helpless in general—were justiciable only by Church tribunals. By the middle of the 13th century many lawyers took an empire of both (J.U.D.), civil and canon, and practised both. As is well known, the feudal rulers constantly selected clergymen as their most trusted advisers. The existence of this theocratic international state was of course conditioned by the weakness of the civil government. So long as feudal monarchy continued, the Church supplied to some extent the deficiencies of the turbulent and ignoble princes by endeavouring to maintain order, administer justice, protect the weak and encourage learning. So soon as the modern national state began to gain strength, the issue between secular rulers and the bishops of Rome took a new form. The clergy naturally stoutly defended the privileges and rights they had long enjoyed and believed to be rightly theirs. On the other hand, the State, which could count upon the support of an ever-increasing number of prosperous and loyal subjects, sought to protect its own interests and showed itself less and less inclined to tolerate the extreme claims of the pope. Moreover, owing to the spread of education, the king was no longer obliged to rely mainly upon the assistance of the clergy in conducting his government.

The chief sources of friction between Church and State were four in number. First, the growth of the practice of “reservation” and “provision,” by which the popes assumed the right to appoint their own nominees to vacant sees and other benefices, in defiance of the claims of the crown, the chapters and private patrons. In the case of wealthy bishops or abbacies this involved a serious menace to the secular authority. Both pope and king were naturally anxious to place their own friends and supporters in these influential positions. The pope, moreover, had come to depend to a considerable extent for his revenue upon the payments made by his nominees, which represented a corresponding drain on the resources of the secular states. Secondly, there was the great question, how far the lands and other property of the clergy should be subject to taxation. Was this vast amount of property to increase indefinitely without contribution to the maintenance of the secular government? A decretal of Innocent III. permitted the clergy to make voluntary contributions to the king when there was urgent necessity, and the resources of the laity had proved inadequate. But the pope maintained that, except in the most critical cases, his consent must be obtained for such grants. Thirdly, there was the inevitable jealousy between the secular and ecclesiastical courts and the serious problem of the exact extent of the original and appellate jurisdiction of the Roman Curia. Fourthly, and lastly, there was the most fundamental difficulty of all, the extent to which the pope, as the universally acknowledged head

See further, Innocent III.
of the Church, was justified in interfering in the internal affairs of particular states. Unfortunately, most matters could be viewed from both a secular and religious standpoint; and even in purely secular affairs the claims of the pope to at least indirect control were practically unlimited. The specific nature of the abuses which flourished in the papal monarchy, the unsuccessful attempts to remedy them, and the measures taken by the chief European states to protect themselves will become apparent as we hastily review the principal events of the 14th and 15th centuries.

As one traces the vicissitudes of the papacy during the two centuries from Boniface VIII to Leo X, one cannot fail to be impressed with the almost incredible strength of the ecclesiastical state which had been organized and fortified by Gregory VII, Alexander III, Innocent III, and Gregory IX. In spite of the perpetuation of all the old abuses and the continual appearance of new devices for increasing the papal revenue; in spite of the jealousy of kings and princes, the attacks of legists and the preaching of the heretics; in spite of seventy years of exile from the holy city, forty years of distracting schism and discord, and thirty years of conflict with stately ecumenical councils deliberating in the name of the Holy Spirit and intent upon permanently firming and strengthening her prerogatives; in spite of the unworthy conduct of some of those who ascended the papal throne, their flagrant political ambitions, and their greed; in spite of the spread of knowledge, old and new, the development of historical criticism, and philosophical speculation; in spite, in short, of every danger which could threaten the papal monarchy, it was still intact when Leo X died in 1521. Nevertheless, permanent partial dissolution was at hand, for no one of the perils which the popes had seemingly so successfully overcome had failed to weaken the constitution of their empire; and it is impossible to comprehend its complete dissolution without recognizing its weakness, even if the varied hostile forces which were accumulating and combining strength during the 14th and 15th centuries. The first serious conflict that arose between the developing modern state and the papacy centred about the pope’s claim that the property of the clergy was normally exempt from royal taxation. Boniface VIII was forced to permit Edward I and Philip the Fair to continue to demand and receive subsidies granted by the clergy of their realms. Shortly after the bitter humiliation of Boniface by the French government and his death in 1303, the bishop of Bordeaux was elected pope as Clement V. (1305). He preferred to remain in France, and as the Italian cardinals died they were replaced by Frenchmen. The papacy was therefore, primarily established at Avignon, on the confines of France, where it remained until 1377. While the successors of Clement V were not so completely under the control of the French kings as has often been alleged, the very proximity of the curia to France served inevitably to intensify national jealousies. The claims of John XXII. (1316-1334) to control the election of the emperor called forth the first fundamental and critical attack on the papal monarchy, by Marsiglio of Padua, who declared in his 

"The papacy in the 14th century." England and the papacy in the 14th century.

The Great Schism (1378-1417).

of the Schism, which was to endure for forty years. There had been many anti-popes in the past, but never before had there been such prolonged and genuine doubt as to which of two lines of popes was legitimate, since in this case each was supported by a college of cardinals, the one at Rome, the other at Avignon. Italy, except Naples, took the side of the Italian pope; France, of the Avignon pope; England, in its hostility to France,
REFORMATION, THE

sided with Urban VI. in Rome, Scotland with Clement VII., his rival; Flanders followed England; Urban secured Germany, Hungary and the northern kingdoms; while Spain, after remaining neutral for a time, went over to Clement. Western Christendom had now two papal courts to support. The schism extended down to the bishoprics, and even to the monasteries and parishes, where partisans of the rival popes struggled to obtain possession of sees and benefices. The urgent necessity for healing the schism, the difficulty of uniting the colleges of cardinals, and the prolonged and futile negotiations carried on between the rival popes inevitably raised the whole question of the papal supremacy, and led to the search for a still higher ecclesiastical authority, which, when the normal system of choosing the head of the Church broke down, might re-establish that ecclesiastical unity by which all Europe as yet clung. The idea of the supreme power on earth of a general council of Christendom, deliberating in the name of the Holy Spirit, convoked, if necessary, independently of the popes, was defended by many, and advocated by the university of Paris. The futile council of Pisa in 1409, however, only served to increase to three the number of rival representatives of God on earth. The considerable pamphlet literature of the time substantiates the conclusion of an eminent modern Catholic historian, Ludwig Pastor, who declares that the crisis through which the church passed in this terrible period of the schism was the most serious in all its history. It was at just this period, when the popes were scattered in a large number of annexes, that heretical movements appeared in England, France, Italy, Germany, and especially in Bohemia, which threatened the whole ecclesiastical order.

The council of Constance assembled in 1414 under auspices hopeful not only for the extinction of the schism but for the general reform of the Church. Its members showed no patience with doctrinal innovations, even such moderate ones as John Huss represented. They turned him over to the secular arm for execution, although they did not thereby succeed in checking the power of heresy in Bohemia (see Huss). The healing of the schism proved no very difficult matter; but the council hoped not only to restore unity and suppress heresy, but to re-establish general councils as a regular element in the legislation of the Church. The decree Sancrosancta (April 1415) proclaimed that a general council assembled in the Holy Spirit and representing the Catholic Church militant had its power immediately from Christ, and was supreme over every one in the Church, not excluding the pope, in all matters pertaining to the faith and reformation of the Church of God in head and members. The decree Frecuents (October 1417) provided for the regular convocation of councils in the future. As to ecclesiastical abuses the council could do very little, and finally satisfied itself with making out a list of those which the new pope was required to remedy in co-operation with the deputies chosen by the council. The list serves as an excellent summary of the evils of the papal monarchy as recognized by the unimpeachably orthodox. It included: the number, character and nationality of the cardinals, the abuse of the "reservations" made by the apostolic see, the annates, the collation to benefices, expectative favours, cases to be brought before the papal Curia (including appeals), functions of the papal chancery and penitentiary, benefits in commendams, confirmation of elections, income during vacancies, indulgences, tenents, for what reasons and how a pope to be corrected or deposed. The pope and the representatives of the council made no serious effort to remedy the abuses suggested under these several captions; but the idea of the superiority of a council over the pope, and the right of those who felt aggrieved by papal decisions to appeal to a future council, remained a serious menace to the theory of papal absolutism. The decree Frequents was not wholly neglected; though the next council, at Siena, came to naught, the council at Basel, whose chief business was to put an end to the terrible religious war that had been raging between the Bohemians and Germans, was destined to cause Eugenius IV. much anxiety. It reaffirmed the decree Sancrosancta, and refused to recognize the validity of a bull Eugenius issued in December 1431 dissolving it. Two years later political reverses forced the pope to sanction the existence of the council, which not only concluded a treaty with the Bohemian heretics but abolished the papal fees for appointments, confirmation and consecration—above all, the annates—and greatly reduced papal reservations; it issued indulgences, imposed tenths, and established rules for the government of the papal states. France, however, withdrew its support from the council, and in 1438, under purely national auspices, by the famous Pragmatic Sanction of Bourges, adjusted the relations of the Gallican Church to the papacy; and Eugenius soon found himself in a position to repudiate the council and auto-condemn it. Remonstrances in 1438 at Ferrara under his control to take up the important question of the pending union with the Greek Church. The higher clergy deserted the council of Basel, and left matters in the hands of the lower clergy, who chose an anti-pope; but the rump council gradually lost credit and its lingering members were finally dispersed. The various nations were left to make terms with a reviving papacy. England had already taken measures to check the papal claims. France in the Pragmatic Sanction reformulated the claim of the councils to be superior to the pope, as well as the decision of the council of Basel in regard to the annates, which, in the name of the Church, declared that the decrees of the highest ecclesiastical instance to the placet or approval of the civil authorities. But there was no strong power as in England and France, to attend to the execution of the provisions.

In 1448 Eugenius's successor, Nicholas V., concluded a concordat with the emperor Frederick III. as representative of the German nation. This confined itself to papal appointments and the annates. In practice it restored the former range of papal reservations, and extended the papal right of appointment to all benefices (except those of the higher offices in cathedrals and collegiate churches) which fell vacant during the odd months. It also accorded him the right to confirm all newly elected prelates and to receive the annates. Nothing was said in the concordat of a great expedition. This gave the princes an excuse for the theory that the decrees of Constance and Basel were still in force, limiting the papal prerogatives in all respects not noticed in the concordat. It was Germany which gave the restored papacy the greatest amount of anxiety during the generation following the dissolution of the council of Basel. In the "recesses" or formal statements issued at the conclusion of the sessions of the diet one can follow the trend of opinion among the German princes, secular and ecclesiastical. The pope is constantly accused of violating the concordat, and constant demands are made for a general council, or at least a national one, which should undertake to remedy the abuses. The capture of Constantinople by the Turks afforded a new excuse for papal taxation. In 1453 a crusading bull was issued imposing a tenth on all benefices of the earth to equip an expedition against the infidel. The diet held at Frankfort in 1456 recalled the fact that the council of Constance had forbidden the pope to impose tenths without the consent of the clergy in the region affected, and that it was clear that he proposed to "pull the German sheep's fleece over its ears." A German correspondent of Aeneas Sylvius assures him in 1457 that "thousands of tricks are devised by the Roman see which enables it to extract the money from our pockets very
neatly, as if we were mere barbarians. Our nation, once so
famous, is a slave now, who must pay tribute, and has lain in
the dust these many years bemoaning her fate." Aeneas Silius
issued, immediately after his accession to the papacy as Pius II.
The bull *Exercitabilis* forbidding all appeals to a future council.
This seemed to Germany to cut off its last hope. It found a
spokesman in the vigorous Gregory of Heimburg, who accused
the pope of issuing the bull so that he and his cardinals might
conveniently pillage Germany unhampered by the threat of
a council. "By forbidding appeals to a council the pope
treats us like slaves, and wishes to take for his own pleasures
all that we and our ancestors have accumulated by honest
labour. He calls me a chatterer, although he himself is more
talkative than a magpie." Heimburg's denunciations of
the pope were widely circulated, and in spite of the major excom-
uncation he was taken into the service of the archbishop of
Mainz and was his representative at the diet of Nuremberg in
1462. It is thus clear that motives which might ultimately
lead to the withdrawal of a certain number of German
princes from the papal ecclesiastical state were accumulat-
ing and intensifying during the latter half of the 15th
century.

It is impossible to review here the complicated political
history of the opening years of the 16th century. The
names of Charles VIII. and Louis XII. of France, of
Ferdinand and Isabella of Spain, of Henry VII. and
Henry VIII. of England, of Maximilian the German
king, of Popes Alexander VI., Julius II. and Leo X.,
stand for better organized civil governments, with
-growing powerful despotic heads; for a perfectly
worldly papacy absorbed in the interests of an Italian
princely, engaged in constant political negotiations with
the European powers which are beginning to regard Italy as their
chief field of rivalry, and are using its little states as convenient
counters in their game of diplomacy and war. It was in Ger-
many, however, seemingly the weakest and least aggressive of the
European states, that the first permanent and successful revolts
against the papal monarchy occurred. Nothing came of the lists
of German *gravamina*, or of the demands for a council, so long
as the incompetent Frederick III. continued to reign. His
successor, Maximilian, who was elected emperor in 1493, was
mainly preoccupied with his wars and attempts to reform the
constitution of the empire; but the diet gave some attention
to ecclesiastical reform. For instance, in 1501 it took measures
to prevent money raised by the granting of a papal indulgence
from leaving the country. After the disruption of the league of
Cambray, Maximilian, like Louis XII., was thrown into a violent
anti-curial reaction, and in 1510 he sent to the well-known humanist,
Joseph Wimpeling, a copy of the French Pragmatic Sanction,
asking his advice and stating that he had determined to
free Germany from the yoke of the Curia and prevent the
great sums of money from going to Rome. Wimpeling in his
reply rehearsed the old grievances and complained that the
contributions made to the pope by the archbishops on receiving
the pallium was a great burden on the people. He stated that
that of the archbishop of Mainz had been raised from ten to
twenty-five thousand guldens, and that there had been seven
vacancies within a generation, and consequently the subjects
of the elector had been forced to pay that amount seven times.
But Wimpeling had only some timid suggestions to make, and,
since Maximilian was once more on happy terms with the pope,
political considerations served to cool completely his momentary
ardour for ecclesiastical reform. In 1514 the archbishopric of
Mainz was offered to Cardinal Albrecht von Brandenburg, and
Maximilian, finding that the archbishop of Magdeburg and administrator of Halberstadt,
longing to add it to his possessions, was elected. After some
scandalous negotiations with Leo X., it was arranged that
Albert should pay 14,000 ducats for the papal confirmation and
10,000 as a "composition" for permission to continue to hold,
against the rules of the Church, his two former archbishoprics.
Moreover, in order to permit him to pay the sums, he was to
have half the proceeds in his provinces from an indulgence
granted to forward the rebuilding of St Peter's. A Dominican
monk, Johann Tetzel, was selected to proclaim the indulgence
(together with certain supplementary graces) in the three
provinces of the elector. This suggestion came from the curia,
not the elector, whose representatives could not suppress the
fear that the plan would arouse opposition and perhaps worse.
Tetzel's preaching and the exaggerated claims that he was re-
ported to be making for the indulgences attracted the attention
of an Augustinian friar, Martin Luther, who had for some
years been lecturing on theology at the university of Wittenberg.
He found it impossible to reconcile Tetzel's views of indulgences
with his own fundamental theory of salvation. He accordingly
hastily drafted ninety-five propositions relating to indulgences,
and posted an invitation to those who wished to attend a
disputation in Wittenberg on the matter, under his presidency.
He points out the equivocal character of the word *poenitentia*,
which meant both "penance" and "penitence"; he declared that
"true contrition seeks punishment, while the amleness of pardons relaxes it and causes men to hate it." Christians
ought to be taught that he who gives to a poor man or lends to
the needy does better than if he bought pardons. He concludes
with certain "keen questionings of the laity," as, Why does not
the pope empty purgatory forthwith for charity's sake,
instead of cautiously for money? Why does he not, since he
is rich as Croesus, build St Peter's with his own money instead
of taking that of poor believers? It was probably these close
reactions which led to the translation of the theses from Latin
into German, and their surprising circulation. It must not be
assumed that Luther's ninety-five theses produced any con-
siderable direct results. They awakened the author himself
to a consciousness that his doctrines were after all incompatible
with some of the Church's teachings, and led him to consider
the nature of the papal power which issued the indulgence.
Two or three years elapsed before Luther began to be
generally known and to exercise a perceptible influence upon
affairs.

In July 1518 a diet assembled in Augsburg to consider the
new danger from the Turks, who were making rapid conquests
under Sultan Selim I. The pope's representative, Cardinal Cajetan, made it clear that the only safety lay in the collection of a tenth from the clergy, monks,
and a twentieth from laymen; but the diet appointed a
committee to consider the matter and explain why they pro-
posed to refuse the pope's demands. Protests urging the diet
not to weaken came in from all sides. There was an espe-
cially bitter denunciation of the Curia by some unknown writer. He
claims that "the pope bids his collectors go into the whole
world, saying, 'He that believeth, and payeth the tenths, shall be
saved.' But it is not necessary to stand in such fear of the
thunder of Christ's vicar, but rather to fear Christ Himself,
for it is the Florentine's business, not Christ's, that is at issue."
The report of the committee of the diet was completed on the
27th of August 1518. It reviews all the abuses, declares that
the German people are the victims of war, devastation and
dearth, and that the common man is beginning to comment
on the vast amount of wealth that is collected for expedi-
tions against the Turk through indulgences or otherwise,
and yet no expedition takes place. This is the first recognition
in the official *gravamina* of the importance of the people.
Shortly after the committee submitted its report the clergy of Liège
presented a memorial which, as the ambassador from Frankfort
observed, set forth in the best Latin an account of which the pope
(i.e. curiales, officials of the curia) were guilty. From this time on three new streams begin
in an attempt to reinforce the rather feeble current of official efforts for reform.
The common man, to whom the diet of Augsburg alluded, had
long been raising his voice against the "parsons" (*Pfaffen*);
the men of letters, Brand, Erasmus, Reuchlin, and above all
Ulrich von Hutten, contributed, each in their way, to discredit
the Roman Curia; and lastly, a new type of theology, repre-
sented chiefly by Martin Luther, threatened to sweep away
the very foundations of the papal monarchy.

REFORMATION, THE
The growing discontent of the poor people, whether in country or town, is clearly traceable in Germany during the 15th century, and revolutionary agitation was chronic in southern Germany at least during the first two decades of the 16th. The clergy were satirized and denounced in popular pamphlets and songs. The title was an oppressive form of taxation, and were the various fees of the performance of the sacraments. The so-called "Reformation of Sigismund," drawn up in 1438, had demanded that the celibacy of the clergy should be abandoned and their excessive wealth reduced. "It is a shame which cries to heaven, this oppression by tithes, dues, penalties, excommunication, and tolls of the peasant, on whose labour all men depend for their existence." In 1476 a poor young shepherd drew thousands to Nicklashausen to hear him denounce the emperor as a rascal and the pope as a worthless fellow, and urge the division of the Church's property among the members of the community. The "parsons" must be killed, and the lords reduced to earn their bread by daily labour. An apocalyptic pamphlet of 1508 shows on its cover the Church upside down, with the peasant performing the services, while the priest guides the plough outside and a monk drives the horses. Doubtless the free peasants of Switzerland contributed to stimulate disorder and discontent, especially in southern Germany. The conspiracies were repeatedly betrayed and the guilty parties terribly punished. That discovered in 1517 made a deep impression on the authorities by reason of its vast extent, and doubtless led the diet of Augsburg to allude to the danger which lay in the renunciation of the common man to pay the ecclesiastical taxes. "It was into this mass of seething discontent that the spark of religious protest fell—the one thing needed to fire the train and kindle the social conflagration. This was the society to which Luther spoke, and its discontent was the sounding board which made his words reverberate." 1

On turning from the attitude of the peasants and poorer townpeople to that of the scholars, we find in their writings a good deal of harsh criticism of the scholastic theology, satirical allusions to the friars, and, in Germany, sharp denunciations of the practices of the Curia. But there are many reasons for believing that the elder estimate of the influence of the so-called Renaissance, or "new learning," in promoting the Protestant revolt was an exaggerated one. The class of humanists which had grown up in Italy during the 15th century, and whose influence had been spreading into Germany, France and England during the generation immediately preceding the opening of the Protestant revolt, represented every phase of religious feeling from mystic piety to cynical indifference, but there were very few anti-clericals among them. The revival of Greek from the time of Chrysoloras onward, instead of begetting a Hellenistic spirit, transported the more serious-minded to the nebulous shores of Neo-Platonism, while the less devout became absorbed in scholarly or literary ambitions, translations, elegantly phrased letters, clever epigrams or indiscriminate invective. It is true that Lorenzo Valla (d. 1457) showed the Donation of Constantine to be a forgery, denied that Dionysius the Areopagite wrote the works ascribed to him, and refuted the commonly accepted notion that each of the apostles had contributed a sentence to the Apostles' Creed. But such attacks were rare and isolated and were not intended to effect a breach in the solid ramparts of the medieval Church, but rather to exhibit the ingenuity of the critic. In the libraries containing the manuscripts which were the sources of the writings both Latin and Greek, and the scholastic doctors are conspicuous. Then most of the humanists were clerics, and in Italy they enjoyed the patronage of the popes. They not unnaturally showed a tolerant spirit of the whole toward existing institutions, including the ecclesiastical abuses, and, in general, cared little how long the vulgar herd was left in the superstitious darkness which befitted their estate, so long as the superior man was permitted to hold discreetly any views he pleased. Of this attitude Mutian (1471-1526), the German humanist who perhaps approached most nearly the Italian type, furnishes a good illustration. He believed that Christianity had existed from all eternity, and that the Greeks and Romans, sharing in God's truth, would share also in the celestial joys. Forms and ceremonies should only be judged as they promoted the great object of life, a clean heart and a right spirit, love to God and one's neighbour. He defined faith as commonly understood to mean "not the conformity of what we say with fact, but an opinion upon divine things founded upon credulity which seeks after profit." "With the cross," he declares, "we put our feet to flight, we extort money, we consecrate God, we shake hell, we work miracles."

These reflections were, however, for his intimate friends, and like him, his much greater contemporary, Erasmus, abhorred anything suggesting open revolt or revolution. The extraordinary popularity of Erasmus is a sufficient indication that his attitude of mind was viewed with sympathy by the learned, whether in France, England, Germany, Spain or Italy. He was a firm believer in the efficacy of culture. He maintained that old prejudices would disappear with the progress of knowledge, and that superstition and mechanical devices of salvation would be insensibly abandoned. The laity should read their New Testament, and would in this way come to feel the true significance of Christ's life and teachings, which, rather than the Church, formed the centre of Erasmus's religion. The dissidence of dissent, however, filled him with uneasiness, and he abhorred Luther's denial of free will and his exaggerated notion of man's utter depravity; in short, he did nothing whatever to promote the Protestant revolt, except so far as his frank denunciation and his witty arraignment and clerical and monastic weaknesses and soulless ceremonial, especially in his Praise of Folly and Colloquies, contributed to bring the faults of the Church into strong relief, and in so far as his edition of the New Testament furnished a simple escape from innumerable theological complications.

A peculiar literary feud in Germany served, about 1515, to throw into sharp contrast the humanistic party, which had been gradually developing during the previous fifty years, and the conservative, monkish, scholastic group, who found their leader among the Dominicans of the university of Cologne. Johann Reuchlin, a well-known scholar, who had been charged by the Dominicans with heresy, not only received the support of the newer type of scholars, who wrote him encouraging letters which he published under the title Epistolae clari comarum virorum, but this collection suggested to Crotus Rubianus and Ulrich von Hutten one of the most successful satires of the ages, the Epistolae obscuarum virorum. As Creighton well said, the chief importance of the "Letters of Obscure Men" lay in its success in popularizing the conception of a stupid party which was opposed to the party of progress. At the same time that the Neo-Platonists, like Ficino and Pico de la Mirandola, and the pantheists, whose God was little as viewed with the conception of the universe at large, and the purely worldly humanists, like Celtes and Bebel, were widely diverging each by his own particular path from the ecclesiastical Wittenauung of the middle ages, Ulrich von Hutten was busy attacking the Curia in his witty Dialogues, in the name of German patriotism. He, at least, among the well-known scholars eagerly espoused Luther's cause, as he understood it. A few of the humanists became Protestants—Melanchthon, Bucer, Oecolampadius and others—but the great majority of them, even if attracted for the moment by Luther's denunciation of scholasticism, speedily repudiated it (see below) we have perhaps the only instance of humanistic antecedents leading to the formation of a religious sect.

A new type of theology made its appearance at the opening of the 16th century, in sharp contrast with the Aristotelian scholasticism of the Thomists and Scotists. This was due to the renewed enthusiasm for, and appreciation of, St Paul with which Erasmus sympathized, and which found an able exponent in England in John Colet and in France in Lefèvre d'Étaples (Faber Stapulensis). Luther was reaching somewhat similar views at the same time,
although in a strikingly different manner and with far more momentous results for the western world. Martin Luther was beyond doubt the most important single figure in the Protestant revolt. His influence was indeed by no means decisive and so pervasive as has commonly been supposed, and his attacks on the evils in the Church were no bolder or more comprehensive than those of Marsiglio and Wycliffe, or of several among his contemporaries who owed nothing to his example. Had the German princes not found it to their interests to enforce his principles, he might never have been more than the leader of an obscure mystic sect. He was, moreover, no statesman. He was recklessly impetuous in his temperament, coarse and grossly superstitious according to modern standards. Yet in spite of all these allowances he remains one of the great heroes of all history. Few come in contact with his writings without feeling his deep spiritual nature and an absolute genuineness and marvellous individuality which seem never to sink into mere routine or affectation. In his more important works almost every sentence is alive with that authochthonous quality which makes it unmistakably his. His fundamental religious conception was his own hard-found answer to his own agonized question as to the nature and assurance of salvation. Even if others before him had reached the conviction that the Vulgate’s word justitiae in Romans i, 16-17 meant "righteousness" rather than "justice" in a juridical sense, Luther exhibited a supreme religious genius in his interpretation of "God’s righteousness" (Gerechtigkeit) as over against the "good works" of man, and in the overwhelming importance he attached to the promise that the just shall live by faith. It was his anxiety to remove everything that obscured this central idea which led him to revolt against the ancient Church, and this conception of faith served, when he became leader of the German Protestants, as a touchstone to test the expediency of every innovation. But only gradually did he come to realize that his source of spiritual consolation might undermine altogether the artfully constructed fabric of the Papacy. As late as 1516 he declared that the life of a monk was never a more enviable one than at that day. He had, however, already begun to look sourly upon Aristotle and the current scholastic theology, which he believed hid the simple truth of the gospel and the desperate state of mankind, who were taught a vain reliance upon outward works and ceremonies, when the only safety lay in throwing oneself on God’s mercy. He was suddenly forced to take up the consideration of some of the most fundamental points in the orthodox theology by the appearance of Tetzel in 1517. In his hastily drafted Ninety-five Theses he sought to limit the potency of indulgences, and so indirectly raised the question as to the power of the pope. He was astonished to observe the wide circulation of the theses both in the Latin and German versions. They soon reached Rome, and a Dominican monk, Prierus, wrote a reply in defence of the papal power, in an insolent tone which first served to rouse Luther’s suspicion of the theology of the papal Curia. He was summoned to Rome, but, out of consideration for his patron, the important elector of Saxony, he was permitted to appear before the papal legate during the diet of Augsburg in 1518. He boldly contradicted the legate’s theological statements, refused to revoke anything and appealed to a future council. On returning to Wittenberg he was tried to the canon law, and was shocked to find it so completely at variance with his notions of Christianity. He reached the conclusion that the papacy was but four hundred years old. Yet, although of human origin, it was established by common consent and with God’s sanction, so that no one might withdraw his obedience without offence.

It was not, however, until 1520 that Luther became in a sense the leader of the German people by issuing his three great pamphlets, all of which were published in German as well as in Latin—his Address to the Christian Nobility of the German Nation, his Babylonish Captivity of the Church as to his Freedom of the Christians. In the first he urged that, since the Church had failed to reform itself, the secular government should come to the rescue. "The Romanists have with great dexterity built themselves about with three walls, which have hitherto protected them against reform; and thereby is Christianity fearfully fallen. In the first place, when the temporal power has pressed them hard, they have affirmed and maintained that the temporal power has no jurisdiction over them—that, on the contrary, the spiritual is above the temporal. Secondly, when it was proposed to admonish them from the Holy Scriptures they said, 'It besemes no one but the pope to interpret the Scriptures,' and, thirdly, when they were threatened with a council, they invented the idea that no one but the pope can call a council. Thus they have secretly stolen our three rods that they may go unpunished, and have entrenched themselves safely behind these three walls in order to carry on all the rascality and wickedness that we now see." He declares that the distinction between the "spiritual estate," composed of pope, bishops, priests and monks, as over against the "temporal estate" composed of princes, lords, artisans and peasants, is a very fine hypocritical invention of which no one should be afraid. "A cobbler, a smith, a peasant, every man has his own calling and duty, just like the consecrated priests and bishops, and every one in his calling or office must help and serve the rest, so that all may work together for the common good." After overthrowing the other two walls, Luther invites the attention of the German rulers to the third, the "seditions and heresies of the Pope and Cardinals, for which the Germans must pay. "What the Romanists really mean to do, the 'drunken Germans' are not to see until they have lost everything... If we rightly hang thieves and beadle robbers, why do we leave the greed of Rome unpunished? For Rome is the greatest thief and robber that has ever appeared on earth, or ever will; and all in the holy names of the Church and St. Peter." After proving that the secular rulers were free and in duty bound to correct the evils of the Church, Luther sketches a plan for preventing money from going to Italy, for reducing the number of idle, begging monks, harmful pilgrimages and excessive luxury. Luxury and drinking were to be suppressed, the universities, especially the divinity schools, reorganized, &c.

Apart from fundamental rejection of the papal supremacy, there was little novel in Luther’s appeal. It had all been said before in the various protests of which we have spoken, and very recently by Ulrich von Hutten in his Dialogues, but no one had put the case so strongly, or so clearly, before. In addressing the German nobility Luther had refrained from taking up theological or religious doctrines; but in September 1520 he attacked the whole sacramental system of the Church. He wrote to his Babylonish Captivity of the Church. Many reformers, like Glapion, the Franciscan confessor of Charles V., who had read the Address with equanimity if not approval, were shocked by Luther’s audacity in rejecting the prevailing fundamental religious conceptions. Luther says: "I must begin by denying that there are seven sacraments, and must lay down for the time being that there are only three—baptism, penance and the bread, and that by the court of Rome all these have been brought into miserable bondage, and the Church despoiled of her liberty. It is, however, in the Freedom of the Christians that the essence of Luther’s religion is to be found. Man cannot save himself, but is saved and there is no other means, however, so soon as he believes God’s promises, and to doubt these is the supreme crime. So salvation was to him not a painful progress toward a goal to be reached by the sacraments and by right conduct, but a state in which man found himself so soon as he despairs absolutely of his own efforts, and threw himself on God’s assurances. Man’s utter incapacity to do anything to please God, and his utter personal dependence on God’s grace seemed to render the whole system of the Church well-nigh gratuitous even if it were purged of all the “sophistry” which to Luther seemed to bury out of sight all that was essential in Christianity. Luther’s gospel was crusade with a vengeance, not of fear and trembling, and came as an overwhelming revelation to those who understood and accepted it. The old question of Church reform inevitably reappeared
when the young emperor Charles V. opened his first imperial diet at Worms early in 1521, and a committee of German princes drafted a list of gravamina, longer and bitterer than any preceding one. While the resolve papal nuncio Alexander was indelicate in his efforts to induce the diet to condemn Luther's teachings, his curious and instructive despatch to the Roman Curia complain constantly of the ill-treatment and insults he encountered, of the readiness of the printers to issue innumerable copies of Luther's pamphlets and of their reluctance to print anything in the pope's favour. Charles apparently made up his mind immediately and once for all. He approved the gravamina, for he believed a thorough reform of the Church essential. This reform he thought should be carried out by a council, even against the pope's will; and he was destined to engage in many fruitless negotiations to this end before the council of Trent at last assembled a score of years later.

But he had no patience with a single monk who, led astray by his private judgment, set himself against the faith held by all Christians for a thousand years. "What my forefathers established at the council of Constance and other councils it is my privilege to maintain," he exclaims. Although, to Alexander's chagrin, the emperor consented to summon Luther to Worms, where he received a species of ovation, Charles readily approved the edict drafted by the papal nuncio, in which Luther is accused of having "brought together all previous heresies in one stinking mass," rejecting all law, teaching a life wholly brutish, and urging the lay people to bathe their hands in the blood of priests. He and his adherents were outlawed; no one was to print, sell or read any of his writings, "since they are foul, harmful, suspected, and come from a notorious and stiff-necked heretic." The edict of Worms was entirely in harmony with the laws of Western Christendom, and there were few among the governing classes in Germany at that time who really understood or approved Luther's fundamental ideas; nevertheless—if we except the elector of Brandenburg, George of Saxony, the dukes of Bavaria, and Charles V.'s brother Ferdinand—the princes, including the ecclesiastical rulers and the towns, commonly neglected to publish the edict, much less to enforce it. They were glad to leave Luther unmolested in order to spite the "Curtizaner," as the adherents of the papal Curia were called. The emperor was forced to leave Germany immediately after the diet had dissolved, and was prevented by a succession of wars from returning for nearly ten years. The governing council, which had been organized to represent him in Germany, fell rapidly into disrepute, and exercised no restraining influence on those princes who might desire to act on Luther's theory that the civil government was supreme in matters of Church reform.

The records of printing indicate that religious, social and economic betterment was the subject of an ever-increasing number of pamphlets. The range of opinion was wide. Men like Thomas Murner, for instance, heartily denounced "the great Lutheran fool," but at the same time bitterly attacked monks and priests, and popularized the conception of the simple man with the hoe (Karsthans). Hans Sachs, on the other hand, sang the praises of the "Wittenberg Nightingale," and a considerable number of prominent men of letters accepted Luther as their guide—Zell and Bucer, in Strassburg, Eberlin in Ulm, Oecolampadius in Augsburg, Osiander and others in Nuremberg, Pellicanus in Nördlingen. Moreover, there gradually developed a group of radicals who were convinced that Luther had not the courage of his faith; they proposed to abolish the "false superstitious fable" of the Mass and all other outward signs of what they deemed the old superstitions. Luther's colleague at Wittenberg, Carlstadt (q.v.), began denouncing the monastic life, the celibacy of the clergy, the veneration of images; and before the end of 1521 we find the first characteristic outward symptoms of Protestantism. Luther had meanwhile been concealed by his friends in the Warburg, near Eisenach, where he busied himself with a new German translation of the New Testament, to be followed in a few years by the Old Testament. The Bible had long been available in the language of the people, and there are indications that the numerous early editions of the Scriptures were widely read. Luther, however, possessed resources of style which served to render his version far superior to the older one, and to give it an important place in the development of German literature, as well as in the history of the Protestant churches. During his absence two priests from parishes near Wittenberg married; while several monks, throwing aside their cloaks, left their cloisters. Melancthon, who was for a moment carried away by the movement, partook, with several of his students, of the communion under both kinds, and on Christmas Eve a crowd invaded the church of All Saints, broke the lamps, threatened the priests and made sport of the venerable ritual. Next day, Carlstadt, who had laid aside his clerical robes, dispensed the Lord's Supper in the "evangelical fashion." At this time three prophets arrived from Zwickau, eager to hasten the movement of emancipation. They were weavers who had been associated with Thomas Münzer, and like him looked forward to a very radical reform of society. They rejected infant baptism, and were among the forerunners of the Anabaptists. In January 1522, Carlstadt induced the authorities of Wittenberg to publish the first evangelical church ordinance. The revenues from ecclesiastical foundations, as well as those from the industrial gilds, were to be placed in a common chest, to be in charge of the townspeople and the magistrates. The priests were to receive fixed salaries; begging, even by monks and poor students, was prohibited; the poor, including the monks, were to be supported from the common chest. The service of the Mass was modified, and the laity were to receive the elements in both kinds. Reminders of the old religious usages were to be done away with, and fast days were to be no longer observed. These measures, and the excitement which followed the arrival of the radicals from Zwickau, led Luther to return to Wittenberg in March 1522, where he preached a series of sermons attacking the impatience of the radical party, and setting forth clearly his own views of what the progress of the Reformation should be. The Word created heaven and earth and all things; the same Word will also create now, and not we poor sinners. Faith must be unconstrained and must be accepted without compulsion. To marry, to do away with images, to become monks and nuns, or for monks and nuns to leave their convent, to eat meat on Friday or not to eat it, and other like things—all these are open questions, and should not be forbidden by any man . . . . What we want is the heart, and to win that we must preach the gospel. Then the Word will drop into one heart to-day and to-morrow into another, and so will work that each will forsake the Mass." Luther succeeded in quieting the people both in Wittenberg and the neighbouring towns, and in preventing the excesses which had threatened to discredit the whole movement.

In January 1522, Leo X. had been succeeded by a new pope, Adrian VI, a devout Dominican theologian, bent on reforming the Church, in which, as he injudiciously confessed through his legate to the diet at Nuremberg, the Roman Curia had perhaps been the chief source of "that corruption which had spread from the head to the members." The Lutheran heresy he held to be God's terrible judgment on the sins of the clergy. The diet refused to accede to the pope's demand that the edict of Worms should be enforced, and recommended that the Christian council should meet in January, to include not only ecclesiastics but laymen, who should be permitted freely to express their opinions. While the diet approved the list of abuses drawn up at Worms, it ordered that Luther's books should no longer be published, and that Luther himself should hold his peace, while learned men were to admonish the erring preachers. The decisions of this diet are noteworthy, since they probably give a very fair idea of the prevailing opinion of the ruling classes in Germany. They refused to regard Luther as in any way their leader, or even to recognize him as a discreet
On the other hand, they did not wish to take the risk of radical measures against the new doctrines, and were glad of an excuse for refusing the demands of the pope. Adrian soon died, worn out by his futile attempts to correct the abuses at home, and was followed by Clement VII., a Medici, less gifted but not less worldly in his instincts than Leo X.

Clement sent one of his ablest Italian diplomats, Campeggio, to negotiate with the diet which met at Spire in 1524. He induced the diet to promise to execute the edict of Worms as far as that should be possible; but it was generally understood that it was impossible. The diet renewed the demand for a general council to meet in a German town to settle the affairs of the Church in Germany, and proposed the doctrine of a national council at Spire in November, to effect a temporary adjustment. In this precarious situation Campeggio, realizing the hopelessness of his attempt to induce all the members of the diet to co-operate with him in re-establishing the pope's control, called together at Regensburg a certain number of rulers whom he believed to be rather more favourably disposed toward the pope than their fellows. These included Ferdinand, duke of Austria, the two dukes of Bavaria, the archbishops of Salzburg and Trent, the bishops of Bamberg, Spire, Strassburg and others. He induced these to unite in opposing the Lutheran heresy on condition that the pope would issue a decree providing for some of the most needed reforms. There was to be no more financial oppression on the part of the clergy, and no unevenly payments for performing the church services. Abuses arising from the granting of indulgences were to be remedied, and the excessive number of church holidays, which seriously interfered with the industrial welfare of Germany, was to be reduced. The states in the Catholic League were permitted to retain for their own uses about one-fifth of the ecclesiastical revenue; the clergy was to be subjected to careful discipline and only authorized preachers were to be permitted to preach in the churches or on the works of the four Latin Church fathers. Thus the agreement of Regensburg is of great moment in the development of the Protestant revolt in Germany. For Austria, Bavaria and the great ecclesiastical states in the south definitely sided with the pope against Luther's heresies, and to this day they still remain Roman Catholic. In the north, on the other hand, it became more and more apparent that the princes were drifting away from the Roman Catholic Church. Moreover, it should be noted that Campeggio's diplomacy was really the beginning of an effective betterment of the old Church, such as had been discussed for two or three centuries. He met the long-standing and general demand for reform without a revolution in doctrines or institutions. A new edition of the German Bible was issued with the view of meeting the needs of Catholics, a new religious literature grew up designed to substantiate the beliefs sanctioned by the Roman Church and to carry out the movement begun long before toward spiritualizing its institutions and rites.

In 1525 the conservative party, which had from the first feared that Luther's teaching would result in sedition, received a new and terrible proof, as it seemed to them, of the peril so jealously felt by them. W. W. W. W., the papal movemenkt allduded to above, which had caused so much anxiety at the diet of Augsburg in 1518, culminated in the fearful Peasant Revolt in which the common man, both in country and town, rose in the name of "God's justice" to avenge long-standing wrongs and establish his rights. Luther was by no means directly responsible for the civil war which followed, but he had certainly contributed to stir up the ancient discontent. He had asserted that, owing to the habit of foreclosing small mortgages, "any one with a hundred guilden could gobble up a peasant a year." The German feudal lords he pronounced hangmen, who knew nothing of how to swindle the poor man—such fellows were formerly called scoundrels, but now we must call them 'Christians and revered princes.'" Yet in spite of this harsh talk about princes, Luther relied upon them to forward the reforms in which he was interested, and he justly claimed that he had greatly increased their powers by reducing the authority of the pope and subjecting the clergy in all things to the civil government.

The best known statement of the peasants' grievances is to be found in the famous "Twelve Articles" drawn up in 1524. They certainly showed the unmistakable influence of the evangelical teaching. The peasants demanded that the gospel should be taught them as a guide in life, and that each community should be permitted to choose its pastor and depose him if he conducted himself improperly. "The pastor thus chosen should teach us the gospel pure and simple, without any addition or subtraction; and if he should die, the church and state should have the right to choose another." "Whoever in charge of the parish church has not shown himself a helper to the poor and a persecutor of the peasantry shall be considered a thief and murderer and shall be punished accordingly. He who steals the things of a poor man shall continue to be paid, since that is established by the Old Testament. It will serve to support the pastor, and what is left over shall be given to the poor. Serfdom is against God's word, "since Christ has delivered and redeemed us all without exception, by the shedding of his precious blood, the lowly as well as the great." Protests follow against hunting and fishing rights, restrictions on wood-cutting, and excessive demands made on peasants. "In the twelfth place," the declaration characteristically concluded, "it is our conclusion and final resolution that if one or more of the articles herein set forth should not be in agreement with the word of God, as we think they are, such articles will we willingly retract if it be proved by a clear explanation of Scripture really to be against the word of God." More radical demands came from the working classes in the towns. The articles of Heilbronn demanded that the property of the Church should be conscripted and used for the community; clergy and nobility alike were to be deprived of all their privileges, so that they could no longer oppress the poor man. The more violent leaders, like Münzer, renewed the old cry that the parsons must be slain. Hundreds of castles and monasteries were destroyed by the irate peasantry, and some of the nobles were murdered with shocking cruelty. Luther, who believed that the peasants were trying to cloak their dreadful sins with excuses from the gospel, exhorted the government to put down the insurrection. "Have no pity on the poor folk; stab, smite, throttle, who can!" To him the peasants' attempt to abolish serfdom was wholly unchristian, since it was a divinely sanctioned institution, and if they succeeded they would "make God a liar." The German rulers took Luther's advice with terrible literalness, and avenged themselves upon the peasants, whose lot was apparently worse afterwards than before.

The terror inspired by the Peasant War led to a new alliance, the League of Dessau, formed by some of the leading rulers of central and northern Germany, to stamp out the "accursed Lutheran sect." This included Luther's old enemy, Duke George of Saxony, the electors of Brandenburg and Mainz, and two princes of Brunswick. The rumour that the emperor was planning to return to Germany in order to root out the growing heresy, led a few princes who had openly favoured Luther to unite also. Among these the chief were the new elector of Saxony, John (who, unlike his brother, Frederick the Wise, had openly espoused the new doctrines), and the energetic Philip, landgrave of Hesse. The emperor did not return, and since there was no one to settle the religious question in Germany, the diet of Spire (1526) determined that, pending the meeting of the proposed general council, each prince, and each knight and town owing immediate allegiance to the emperor, should decide individually what particular form of religion should prevail within the limits of their territories. Each prince was "so to live, reign and conduct himself as he would be willing to answer before God and His Imperial Majesty." While the evangelical party still hoped that some form of religion might be agreed upon which would prevent the disruption of the Church, the conservatives were confident that the heretics
would soon be suppressed, as they had so often been in the past. The situation tended to become more, rather than less, complicated, and there was every variety of reformer and every degree of conservatism, for there were no standards for those who had rejected the papal supremacy, and even those who continued to accept it differed widely. For example, George of Saxony viewed Alexander, the pope's nuncio, with almost as much suspicion as he did Luther himself.

The religious ideas in South Germany were affected by the development of a reform party in Switzerland, under the influence of Zwingli, who claimed that at Einsiedeln, near the lake of Zürich, he had begun to preach the gospel of Christ in the year 1516 before any one in my locality had so much as heard the name of Luther. Three years later he became preacher in the cathedral of Zürich. Here he began to denounce the abuses in the Church, as well as the traffic in mercenaries which had so long been a blot upon his country's honour. From the first he combined religious and political reform. In 1523 he prepared a complete statement of his beliefs, in the form of sixty-seven theses. He maintained that Christ was the only high priest and that the gospel did not gain its sanction from the authority of the Church. He denied the existence of purgatory, and rejected those practices of the Church which Luther had already set aside. Since no one presented himself to refute him, the town council ratified his conclusions, so that the city of Zürich practically withdrew from the Roman Catholic Church. Next year the Mass, processions and the images of saints were abolished. The shrines were opened and the relics burned. Some other towns, including Bern, followed Zürich's example, but the Forest cantons refused to accept the innovations. In 1525 a religious and political league was arranged between Zürich and Constance, which in the following year was joined by St. Gallen, Biel, Mühlhausen, Basel and Strassburg. Philip of Hesse was attracted by Zwingli's energy, and was eager that the northern reformers should be brought into closer relations with the south. But the league arranged by Zwingli was directed against the house of Habsburg, and Luther did not deem it right to oppose a prince by force of arms. Moreover, he did not believe that Zwingli, who conceived the eucharist to be merely symbolic in its character, "held the whole truth of God." Nevertheless, Philip of Hesse finally arranged a religious conference in the castle of Marburg (1529) where Zwingli and Luther met. They were able to agree on fourteen out of the fifteen of the Marburg Articles, which stated the chief points in the Christian faith as they were accepted by both. A fundamental difference as to the doctrine of the eucharist, however, stood in the way of the real union.

The diet of Spires (1529) had received a letter from the emperor directing it to look to the enforcement of the edict of Worms against the heretics. No one was to preach against the Mass, and no one was to be prevented from attending it freely. This meant that the evangelical princes would be forced to restore the most characteristic Catholic rite. As they formed only a minority in the diet, they could only draw up a protest, which was signed by John Frederick of Saxony, Philip of Hesse, and fourteen of the three towns, including Strassburg, Nuremberg and Ulm. In this they claimed that the majority had no right to abrogate the stipulations of the former diet of Spires, which permitted each prince to determine religious matters provisionally for himself, for all had unanimously pledged themselves to observe that agreement. They therefore appealed to the emperor and to a future council against the tyranny of the majority. Those who signed this appeal were called Protestants, a name which came to be generally applied to those who rejected the supremacy of the pope, the Roman Catholic conceptions of the clergy and of the Mass, and discarded sundry practices of the older Church, without, however, repudiating the Catholic creeds.

During the period which had elapsed since the diet of Worms, the emperor had resided in Spain, busy with a series of wars, waged mainly with the king of France. In 1530 the emperor found himself in a position to visit Germany once more, and summoned the diet to meet at Augsburg, with the hope of settling the religious differences and bringing about harmonious action against the Turk. The Protestants were requested to submit a statement of their opinions, and on June 26th the "Augsburg Confession" was read to the diet. This was signed by the elector of Saxony and his son and successor, John Frederick, by George, margrave of Brandenburg, two dukes of Lüneburg, Philip of Hesse and Wolfgang of Anhalt, and by the representatives of Nuremberg and Reutlingen. The confession was drafted by Melancthon, and the objections to it were minimized by the Lutherans from the old Church. In the first part of the confession the Protestants seek to prove that there is nothing in their doctrines at variance with those of the universal Church "or even of the Roman Church so far as that appears in the writings of the Fathers." They made it clear that they still held a great part of the beliefs of the medieval Church, especially as represented in Augustine's writings, and repudiated the radical notions of the Anabaptists and of Zwingli. In the second part, those practices of the Church are enumerated which the evangelical party rejected; the celibacy of the clergy, the Mass, the eucharist, the confessions, and the monastic vows, the objections to which are stated with much vigour. "Christian perfection is this: to fear God sincerely, to trust assuredly that we have, for Christ's sake, a gracious and merciful God; to ask and look with confidence for help from him in all our affairs, accordingly to our calling, and outwardly to do good works diligently, and to attend to our vocation. In these things doth true perfection and a true worship of God consist. It doth not consist in going about begging, or in wearing a black or a grey cowl." The Protestant princes declared that they had no intention of depriving the bishops of their jurisdiction, but this one thing only is requested of them, that they would suffer the gospel to be purely taught, and would relax a few observances in which we cannot adhere without sin.

The confession was turned over to a committee of conserva-tive theologians, including Eck, Faber and Coehlaeus. Their refutation of the Protestant positions seemed needlessly sharp to the emperor, and five drafts were made of it. Charles finally reluctantly accepted it, although he would gladly have had it milder, for it made reconciliation hopeless. The majority of the diet approved a recess, allowing the Protestants a brief period of immunity until the 15th of April 1531, after which they were to be put down by force. Meanwhile, they were made to make no further innovations, they were not to molest the conservatives, and were to aid the emperor in suppressing the doctrines of Zwingli and of the Anabaptists. The Lutheran princes protested, together with fourteen cities, and left the diet. The diet thereupon decided that the edict of Worms should at last be enforced. All Church property was to be restored, and, perhaps most important of all, the jurisdiction of the Imperial court (Reichskammergericht), which was naturally Catholic in its sympathies, was extended to appeals involving the seizure of ecclesiastical benefices, contempt of episcopal decisions and other matters deeply affecting the Protestants. In November the Protestants formed the Schmalkaldic League, which, after the death of Zwingli, in 1531, was joined by a number of the South German towns. The period of immunity assigned to the Protestants passed by; but they were left unmolested, for the emperor was involved in many difficulties, and the Turks were threatening Vienna. Consequently, at the diet of Nuremberg (1532) a recess was drafted indefinitely extending the religious truce and quashing such cases in the Reichskammergericht as involved Protestant...
innovations. The conservatives refused to ratify the recess, which was not published, but the Protestant states declared that they would accept the emperor’s word of honour, and furnished him with troops for repelling the Mahommedans. The fact that the conservative princes, especially the dukes of Bavaria, were opposed to any strengthening of the emperor’s power, and were in some cases hereditary enemies of the house of Habsburg, served to protect the Protestant princes. In 1534 the Schmalkaldic League succeeded in restoring the banished duke of Württemberg, who declared himself in favour of the Lutheran reformation, and thus added another to the list of German Protestant states. In 1539 George of Saxony died, and was succeeded by his brother Henry, who also accepted the new faith, and in the same year the new elector of Brandenburg became a Protestant. Indeed, there was reason to believe at this time that the archbishops of Mainz, Trier and Cologne, as well as some other bishops, were planning the secularization of their principalities.

To the north, Lutheran influence had spread into Denmark; and Sweden and Norway were also brought within its sphere. In 1530, Christian II. of Denmark, a nephew of the elector of Saxony, came to the throne in 1535, bent on bringing Sweden and Norway, over which he nominally ruled in accordance with the terms of the Union of Kalmar (1397), completely under his control. In order to do this it was necessary to reduce the power of the nobility and clergy, privileged classes exempt from taxation and rivals of the royal power. Denmark had suffered from all the abuses of papal provisions, and the nuncio of Leo X. had been forced in 1518 to flee from the king’s wrath. Christian II. set up a supreme court for ecclesiastical matters, and seemed about to adopt a policy similar to that later pursued by Henry VIII. of England, when his work was broken off by a revolt which compelled him to leave the country. Lutheranism continued to make rapid progress, and Christian’s successor permitted the clergy to marry, appropriated the annates and protected the Lutherans. Finally Christian III., an ardent Lutheran, ascended the throne in 1536; with the sanction of the diet he severed, in 1537, all connexion with the pope, introducing the Lutheran system of church government and accepting the Augsburg Confession. Norway was included in the changes, but Sweden had won its independence of Denmark, under Gustavus Vasa, and, in 1532, was proclaimed king. He used the Lutheran theories as an excuse for overthrowing the ecclesiastical aristocracy, which had been insolently powerful in Sweden. In 1527, supported by the diet, he carried his measures for secularizing such portions of the Church property as he thought fit, and for subjecting the Church to the royal power (Ordinances of Vesterås); but many of the old religious ceremonies and practices were permitted to continue, and it was not until 1592 that Lutheranism was officially sanctioned by the Swedish synod.  

Charles V., finding that his efforts to check the spread of the religious schism were unsuccessful, resorted once more to conferences between Roman Catholic and Lutheran theologians, but it became apparent that no permanent compromise was possible. The emperor then succeeded in disrupting the Schmalkaldic League by winning over, on purely political grounds, Philip of Hesse and young Maurice of Saxony, whose father, Henry, had died after a very brief reign. Charles V. had always exhibited the greatest confidence in the proposed general council, the summoning of which had hitherto been frustrated by the popes, and at last, in 1545, the council was summoned to meet at Trent, which lay conveniently upon the confines of Italy and Germany (see Trent, Council of). The Dominicans and, later, members of the newly born Order of Jesus, were conspicuous, among the theological deputies, while the Protestants, though invited, refused to attend. It was clear from the first that the decisions of the council would be uncompromising in character, and that the Protestants would certainly refuse to be bound by its decrees. And so it fell out. The very first anathemas of the council were directed against those innovations which the Protestants had most at heart. The emperor had now tried threats, conferences and a general council, and all had failed to unify the Church.

Maurice of Saxony, without surrendering his religious beliefs, had become the political friend of the emperor, who had promised him the bishopric of Saxony and the duchy of Brunswick; John Frederick, the elector, was defeated at Mühlberg, April 1547, and taken prisoner. Philip of Hesse also surrendered, and Charles tried once more to establish a basis of agreement. Three theologians, including a conservative Lutheran, were chosen to draft the so-called “ Augsburg Interim.” This reaffirmed the seven sacraments, transubstantiation and the invocation of saints, and declared the pope head of the Church, but adopted Luther’s doctrine of justification by faith in a conditional form, the marriage of priests, and considerably modified the theory and practice of the monasteries. In four years Charles, backed by the Spanish troops, made efforts to force the Protestant towns to observe the Interim, but with little success. He rapidly grew extremely unpopular, and in 1552 Maurice of Saxony turned upon him and attempted to capture him at Innsbruck. Charles escaped, but Maurice became for the moment leader of the German princes who gathered at Passau (August 1552) to discuss the situation. The settlement, however, was deferred for the meeting of the diet, which took place at Augsburg, 1555. There was a general anxiety to conclude a peace—“ besänderg, bekärslicher, unbedings, für uns und für ewig währender.” There was no other way but to legalize the new faith in Germany, but only those were to be tolerated who accepted the Augsburg Confession. This excluded, of course, not only the Zwinglians and Anabaptists, but the ever-increasing Calvinistic or “Reformed” Church. The principle cuius regio ejus religio was adopted, according to which each secular ruler might choose between the old faith and the Lutheran. His decision was to bind all his subjects, but a subject professing another religion from his prince was to be permitted to leave the country. The ecclesiastical rulers, however, were to lose their possessions if they abandoned the old faith. Freedom of conscience was thus established for princes alone, and their power became supreme in religious as well as secular matters. The Church and the civil government had been closely associated with one another for centuries, and the old system was perpetuated in the Protestant states. Scarcely any one dreamed that individual subjects could safely be left to believe what they would, and permitted, so long as they did not violate the law of the land, freely to select and practise such religious rites as afforded them help and comfort.

During the three or four years which followed the signing of the Augsburg Confession in 1530 and the formation of the Schmalkaldic League, England, while bitterly de-
dissolute and lazy monks. Scholars, like Colet, read the New Testament in Greek and lectured on justification by faith before they knew of Luther, and More included among the institutions of Utopia a rather more liberal and enlightened religion than that which he observed around him. Erasmus was read and approved, and his notion of reform by culture no doubt attracted many adherents among English scholars. Luther's works found their way into England, and were read and studied at both Oxford and Cambridge. In May 1521 Wolsey attended a pompous burning of Lutheran tracts in St Paul's churchyard, where Bishop Fisher preached ardently against the new German heresy. Henry VIII., himself stoutly maintained the headship of the pope, and, as is well known, after examining the argument half from the pulpit, he published his Defence of the Seven Sacraments in 1521, which won for him from the pope the glorious title of "Defender of the Faith." The government and the leading men of letters and prelates appear therefore to have harboured no notions of revolt before the matter of the king's divorce became prominent in 1527.

Henry's elder brother Arthur, a notoriously sickly youth of scarce fifteen, had been married to Catherine, daughter of Ferdinand and Isabella, but had died less than five months after the marriage (April 1502), leaving doubts as to whether his union had ever been physically consummated. Political reasons dictated an alliance between the young widow and her brother-in-law Henry, prince of Wales, nearly five years her junior; Julius II. was induced reluctantly to grant the dispensation necessary on account of the relationship, which, according to the canon law and the current interpretation of Leviticus xviii. 16, stood in the way of the union. The wedding took place one year later (1509), and several children were born, none of whom survived except the princess Mary. By 1527 the king had become hopeless of having a male heir by Catherine. He was tired of her, and in love with the black-eyed Anne Boleyn, who refused to be bridled as she imagined that he was beginning to have a horrible misgiving that his marriage with Catherine had been invalid, perhaps downright "incestuous." The negotiations with Clement VII. with the hope of obtaining a divorce from Catherine, the reluctance of the pope to impede the dispensation of his predecessor Julius II., and at the same time to alienate the English queen's nephew Charles V., the futile policy of Wolsey and his final ruin in 1530 are described elsewhere (see English History; Henry VIII.; Catherine of Aragon). The king's agents secured the opinion of a number of prominent universities that his marriage was void, and an assembly of notables, which he summoned in June next, and after which the pope of the dangers involved in leaving the royal succession in uncertainty, since the heir was not only a woman, but, as it seemed to many, of illegitimate birth.

Henry's next move was to bring a monstrous charge against the clergy, accusing them of having violated the ancient laws of England, by revolting against papal legates (although he himself had ratified the appointment of Wolsey as legate a latere). The clergy of the province of Canterbury were fined 500,000 and compelled to declare the king "their singular protector and only supreme over all as far as he allows," or else he would have the right to bring the pope of the dangers involved in leaving the royal succession in uncertainty, since the heir was not only a woman, but, as it seemed to many, of illegitimate birth.

The pope replied by ordering Henry under pain of excommunication to put away Anne and restore Catherine, his legal wife, within ten days. This sentence the emperor, all the Christian princes and the king's own subjects were summoned to carry out by force of arms if necessary.

As might have been anticipated, this caused no break in the policy of the English king and his parliament, and a series of famous acts passed in the year 1534 completed and confirmed the independence of the Church of England, which, except during five years under Queen Mary, was thereafter as completely severed from the papal dominion as the electorate of Saxony or the duchy of Hesse. The payment of annates and of Peter's pence

---

1 Cranmer himself had taken the oath of canonical obedience to the Holy See and duly received the pallium.
was absolutely forbidden, as well as the application to the bishop of Rome for dispensations. The bishops were thereafter to be elected by the deans and chapters upon receiving the king's congé d'êtir (p.p.). The Act of Succession provided that, should the king have no sons, Elizabeth, Anne's daughter, should succeed to the crown. The brief Act of Supremacy confirmed the king's claim to be reputed the "only supreme head in earth of the Church of England," he was to enjoy all the honours, dignities, jurisdictions and profits thereunto appertaining, and to have full power and authority to reform and amend all such errors, heresies and abuses, as by any manner of spiritual authority might lawfully be reformed, or amended, most to the pleasure of Almighty God, and the increase of virtue in Christ's religion, "foreign authority, prescription, or any other thing or things to the contrary hereof, notwithstanding." The Treasons Act, terrible in its operation, included among capital offences that of declining in words or writing the king to be "a heretic, schismatic, tyrant, infidel or usurper." The convocation were required to abjure the papal supremacy by declaring "that the bishop of Rome has not in Scripture any greater jurisdiction in the kingdom of England than any other foreign bishop." The king had now clarified the ancient laws of the realm to his satisfaction, and could proceed to abolish superstitious rites, remedy abuses, and seize such portions of the Church's possessions, especially pious and monastic foundations, as he deemed superfluous for the maintenance of religion.

In spite of the fact that the separation from Rome had been carried out during the sessions of a single parliament, and that there had been no opportunity for a general expression of opinion on the part of the nation, there is no reason to suppose that the majority of the people, thoughtful or thoughtless, were not ready to reconcile themselves to the abolition of the papal supremacy. It seems just as clear that there was no strong evangelical movement, and that Henry's pretty consistent adherence to the fundamental doctrines of the medieval Church was agreeable to the great mass of his subjects. The ten Articles devised by the Kyngs Majestie to stabylsh Christian quietnes (1536), together with the "Injunctions" of 1536 and 1538, are chiefly noteworthy for their affirmation of almost all the current doctrines of the Catholic Church, except those relating to the papal supremacy, purgatory, images, relics and pilgrimages, and the old rooted distrust of the Bible in the vernacular. The clergy were bidden to exhort their hearers to the "works of charity, mercy and faith, specially prescribed and commanded in Scripture, and not to repose their trust or affinity in any other works devised by men's phantasies beside Scripture; as in wandering to pilgrimages, offering of money, candles or tapers to images or relics, or kising or licking the same, saying over a number of beads, not understood or minded on, or in such-like superstition." To this end a copy of the whole English Bible was to be set up in each parish church where the people could read it. During the same years the monasteries, lesser and greater, were dissolved, and the chief shrines were despoiled, notably that of St. Thomas of Canterbury. Thus one of the most important of all medieval ecclesiastical institutions, monasticism, came to an end in England. Doubtless the king's sore financial needs had much to do with the dissolution of the abbeys and the plundering of the shrines, but it may be a reason to suppose that as a cure for the monasticism the monks had long outlived their usefulness and that the shrines were centres of abject superstition and ecclesiastical deceit. Henry, however, stoutly refused to go further in the direction of German Protestantism, even with the prospect of forwarding the proposed union between him and the princes of the Schmalkaldic League. An insurrection of the Yorkshire peasants, which is to be ascribed in part to the distress caused by the enclosure of the commons on which they had been wont to pasture their cattle, and in part to the destruction of popular shrines, may have caused the king to defend his orthodoxy by introducing into parliament in 1530 the six questions. These parliament enacted into the terrible statute of "The Six Articles," in which a felon's death was prescribed for those who obstinately denied transubstantiation, demanded the communion under both kinds, questioned the binding character of vows of chastity, or the lawfulness of privateMasses or the expediency of curricular confession. On the 30th of July 1540 three Lutheran clergymen were burned and three Roman Catholics beheaded, the latter for denying the king's spiritual supremacy. The king's ardent desire that diversities of minds and opinions should be done away with and unity be "charitably established" was further promoted by publishing in 1543 A Necessary Doctrine and Erudition for any Christian Man, set forth by the King's Majesty of England, in which the tenets of medieval theology, except for denial of the supremacy of the bishop of Rome and the unmistakable assertion of the supremacy of the king, were once more promulgated.

Henry VIII. died in January 1547, having chosen a council of regency for his nine-year-old son Edward, the members of which were favourable to further religious innovations. Somerset, the new Protector, strove to govern on the basis of civil liberty and religious tolerance.

The first parliament of the reign swept away almost all the species of treasons created during the previous two centuries, the heresy acts, including the Six Articles, all limitations on printing the Scriptures in English and reading and expounding the same, and all and every act or acts of parliament concerning doctrine or matters of religion." These measures gave a great impetus to religious discussion and local innovations. Representatives of all the new creeds hastened from the Continent to England, where they hoped to find a safe and fertile field for the particular seed they had to plant. It is impossible exactly to estimate the influence which these teachers exerted on the general trend of religious opinion in England; in any case, however, it was not unimportant, and the Articles of Religion and official homilies of the Church of England show unmistakably the influence of Calvin's doctrine. There was, however, no such sudden breach with the traditions of the past as characterized the Reformation in some continental countries. Under Edward VI. the changes were continued on the lines laid down by Henry VIII. The old hierarchy continued, but service books in English were substituted for those in Latin, and preaching was encouraged. A royal visitation, beginning in 1547, discovered, however, such a degree of ignorance and illiteracy among the parish clergy that it became clear that preaching could only be gradually given its due place in the services of the Church. Communion under both kinds and the marriage of the clergy were sanctioned, thus greatly modifying two of the fundamental institutions of the medieval Church. A conservative Book of Common Prayer and Administration of the Sacraments and other Rites and Ceremonies after the Use of the Church of England—commonly called the First Prayer Book of Edward VI.—was issued in 1549. This was based upon ancient "uses," and represented no revolutionary change in the traditions of the "old religion." It was followed, however, in 1552 by the second Prayer Book, which was destined to be, with some modifications, the permanent basis of the English service. This made it clear that the communion was no longer to be "given and taken," but as a sacrifice, the names "Holy Communion" and "Lord's Supper" being definitely substituted for "Mass" (q.v.), while the word "altar" was replaced by "table." In the Forty-two Articles we have the basis of Queen Elizabeth's Thirty-nine Articles. Thus during the reign of Edward we have not only the foundations of the Anglican Church laid, but there appears the beginning of those evangelical and puritanical sects which were to become the "dissenters" of the following centuries.
With the death of Edward there came a period of reaction lasting for five years. Queen Mary, unshaken in her attachment to the ancient faith and the papal monarchy, was able with the sanction of a subservient parliament to turn back the wheels of ecclesiastical legislation, to restore the old religion, and to reunit the English Church with the papal monarchy; the pope's legate, Cardinal Pole, was primate of all England. Then, the ancient heresy laws having been revived, came the burnings of Rogers, Hooker, Latimer, Ridley, Cranmer and many a less noteworthy champion of the new religion. It would seem as if this sharp, uncompromising reaction was what was needed to produce a popular realization of the contrast between the Ecclesia Anglicana of Henry VIII. and Edward VI., and the alternative of "perfect obedience to the See Apostolic."

Elizabeth, who succeeded her sister Mary in 1558, was suspected to be Protestant in her leanings, and her adviser, Cecil, had received his training as secretary of the Protector Somerset; but the general European situation as well as the young queen's own temperament precluded any abrupt or ostentatious change in religious matters. The new sovereign's first proclamation was directed against all such preaching as might lead to contention and the breaking of the common peace. In 1559 ten of Henry VIII.'s acts were revived. On Easter Sunday the queen ventured to display her personal preference for the Protestant conception of the eucharist by sacrificing the celebrant in her chapel to elevate the host. The royal supremacy was reasserted, the title being modified into "supreme governor"; and a new edition of Edward VI.'s second Prayer Book, with a few changes, was issued. The Marian bishops who refused to recognize these changes were deposed and imprisoned, but care was taken to preserve the "sacrament" by consecrating others in due form to take their places. For four years, like the Thirty-nine Articles imposed an official creed upon the English nation. This was Protestant in its general character: in its appeal to the Scriptures as the sole rule of faith (Art. VI.), its repudiation of the authority of Rome (Art. XXXVII.), its definition of the Church (Art. XIX.), its insistence on justification by faith only (Art. XI.) and repudiation of the sacrifice of the Mass (Arts. XXVIII. and XXXI.). As supreme governor of the Church of England the sovereign strictly controlled all ecclesiastical legislation and appointed royal deputies to hear appeals from the ecclesiastical courts, to be a "papist" or to "hear Mass" (which was construed as the same thing) was to risk incurring the terrible penalties of high treason. By the Act of Uniformity (1559) a uniform ritual, the Book of Common Prayer, was imposed upon clergy and laity alike, and no liberty of public worship was permitted. Every subject was bound under penalty of a fine to attend church on Sunday. While there was in a certain sense freedom of opinion, all printers had to seek a licence from the government for every manner of book or paper, and heresy was so closely affiliated with treason that the free expression of thought, whether reactionary or revolutionary, was beset with grave danger.

Attempts to estimate the width of the gulf separating the Church of England in Elizabeth's time from the corresponding institution as it existed in the early years of her father's reign are likely to be gravely affected by personal bias. There is a theory that no sweeping revolution in dogma took place, but that only a few medieval beliefs were modified or rejected owing to the practical abuses to which they had given rise. To Professor A. F. Pollard, for example, "The Reformation in England was mainly a domestic affair, a national protest against national grievances rather than part of a cosmopolitan movement toward doctrinal change." (Cumb. Mod. Hist. ii. 478-9). This estimate appeals to persons of widely different views and temperaments. It is as grateful to those who, like the writer, who have a "Anglo-Catholic" desire on religious grounds to establish the doctrinal continuity of the Anglican Church with that of the middle ages, as it is obvious to those who, like W. K. Clifford, perceive in the ecclesiastical organization and its influence nothing more than a perpetuation of demoralizing medieval superstition. The nonconformists have, moreover, never wearied of denouncing the "papistical" conservatism of the Anglican establishment. On the other hand, the impartial historical student cannot compare the Thirty-nine Articles with the contemporaneous canons and decrees of the council of Trent without being impressed by striking contrasts between the two sets of dogmas. Their spirit is very different. The unmistakable rejection on the part of the English Church of the conception of the eucharist as a sacrifice had alone the widest reaching implications. Even although the episcopal organization was retained, the conception of "tradition," of the conciliar powers, of the "characters" of the priest, of the celibate life, of purgatory, of "good works," &c.—all these serve clearly to differentiate the teaching of the English Church before and after the Reformation. From this standpoint it is obviously unhistorical to deny that England had a very important part in the cosmopolitan movement toward doctrinal change.

The little backward kingdom of Scotland definitely accepted the new faith two years after Elizabeth's accession, and after the French Protocols to which was a great blow to England. Scotland was then, and even destroyed the papal monarchy, was in a sense the foundation and beginning of Great Britain. Scottish Calvinism was destined to exercise little influence, not only on the history of England, but on the form that the Protestant faith was to take in lands beyond the seas, at the time scarcely known to the Europeans.

While France was deeply affected during the 16th century by the Protestant revolt, its government never undertook any thoroughgoing reform of the Church. During the reign of the latter part of the century its monarchs were engaged in a bloody struggle with a powerful religious-political party, the Huguenots, who finally won a free hand. It was in 1865 that the French Church of the middle ages lost its vast possessions and was subjected to a fundamental reconstruction by the Civil Constitution of the Clergy (1791). Yet no summary of the

In 1798 the National Convention gruffly declared that the Republic would no longer subsidize any form of worship or furnishing buildings for religious services. The law recognizes no higher number of religion, and no one is to appear in public with costumes or ornaments used in religious ceremonies." Bonaparte, in the Concordat which he forced upon the pope in 1801, did not provide for the return of any of the lands of the Church which had been sold, but agreed that the government should pay the salaries of bishops and priests, whose appointment it controlled. While the Roman Catholic religion was declared to be that accepted by the majority of Frenchmen, the state subsidized the Reformed Church, those adhering to the Augsburg Confession and the Jewish community. Over a
the Protestant revolt would be complete without some allusion to the contrast between the course of affairs in France and in the neighbouring countries. The French monarchy, as we have seen, had usually succeeded in holding its own against the centralizing tendencies of the pope. By the Pragmatic Sanction of Bourges (1438) it had secured the advantages of the conciliar movement. In 1516, after Francis I. had won his victory at Marignano, Leo X. concluded a new concordat with France, in which, in view of the repudiation of the officious Pragmatic Sanction, the patronage of the French Church was turned over, with scarce any restriction, to the French monarch, although in another agreement the annates were reserved to the pope. The envoys of the French Council, which had gone to Rome in 1515 for the purpose of reclaiming the French territories of the papal state, for the fair—of the king's lawyers on the ancient ecclesiastical jurisdiction, had reached a point where there was little cause for jealousy on the part of the State. The Placat had long prevailed, so that the king had few of the reasons, so important in Germany and England, for quarrelling with the existing system, unless it were on religious grounds. France had been conspicuous in the conciliar movement. It had also furnished its due quota of heretics, although no one so conspicuous as Wycliffe or Huss. Marsiglio of Padua had had Frenchmen among his sympathizers and helpers. Among the prominent French scholars to "preach Christ from the sources" was Jacques Lefèvre of Etaples, who in 1512 published a new Latin translation of the epistles of St. Paul. Later he revised an existing French translation of both the New Testament (which appeared in 1523, almost contemporaneously with Luther's German version) and, two years later, the Old Testament. He agreed with Luther in rejecting transubstantiation, and in believing that works without the grace of God could not make for salvation. The centre of Lefèvre's followers was Meaux, and they found an ardent adherent in Margaret of Angoulême, the king's sister, but had no energetic leader—was willing to face the Inquisition, successfully. Luther's works found a good many readers in France, but were condemned (1521) by both the Sorbonne and the parlement of Paris. The parlement appointed a commission to discover and punish heretics; the preachers of Meaux fled to Strasbourg, and Lefèvre's translation of the Bible was publicly burned. A council held at Sens, 1528–29, approved all those doctrines of the old Church which the Protestants were attacking, and satisfied itself with enumerating a list of necessary conservative reforms.

After a fierce attack on Protestants caused by the mutilation of a statue of the Virgin, in 1528, the king, anxious to conciliate both the German Protestants and anti-papists, invited some of the reformers of Meaux to preach in the Louvre. An address written by a young man of twenty-four, Jean Calvin (to become immortal under his Latin name of Calvus) was read by the rector of the university. It was a defence of the new evangelical views, and so aroused the Sorbonne that Calvin was forced to flee to Paris. In October 1534, the posting of placards in Paris and other towns, containing brutal attacks on the Mass and denouncing the pope and the vermin of bishops, priests and monks, blasphemers and liars, produced an outbreak of persecution, in which thirty-five Lutherans were burned, while many fled the country. The events called forth from Calvin, who was in Basel, the famous letter to Francis which forms the preface to his Institutes of the Christian Religion. In this address he sought to vindicate the high aims of the Protestants, and to put the king on his guard against those mad men who were disturbing his kingdom with their measures of persecution. The Institutes, the first great textbook of Protestant theology, was published in Latin in 1536, and soon (1541) in a French version. The original work is much shorter than in its later editions, for, as Calvin says, he wrote learning and learned century elapsed before the Concordat was abrogated by the Separation Law of 1905 which suppressed all government appropriations for religious purposes and vested the control of Church property in "associations for public worship" (associations cultuelles), to be composed of from seven to twenty-five members according to the size of the commune.
the councils, and it had no power to inflict civil punishment on offenders. Thus "we ought," as Lindsay says, "to see in the disciplinary powers and punishments of the Consistory of Geneva not an exclusion of the working of the Church organized on the principles of Calvin, but the ordinary procedure of the town council of a medieval city. Their petty punishments and their minute interferences with private life are only special instances of what was common to all municipal rule in the 16th century." This is true of the supreme crime of heresy, which in the notorious case of Servetus was only an expression of rules laid down over a thousand years earlier in the Theodosian Code. Geneva, however, with its most distinguished of Protestant theologians, became a school of Protestantism, which sent its trained men into the Nether land, England and Scotland, especially across the border into France. It served too as a place of refuge for thousands of the persecuted adherents of its beliefs. Calvin's book furnished the Protestants not only with a compact and admirably written handbook of theology, vigorous and clear, but with a system of Church government and a code of morals.

After the death of Francis I, his successor, Henry II., set himself even more strenuously to extirpate heresy; a special branch of the parlement of Paris—the so-called Chambre ardente (q.e.)—for the trial of heresy cases was established, and the fierce edict of Chateaubriand (1552) explicitly adopted many of the expedients of the papal inquisition. While hundreds were imprisoned or burned, Protestants seemed steadily to increase in numbers, and finally only the expostulations of the parlement of Paris prevented the king from introducing the Inquisition in France in accordance with the wishes of the pope and the cardinal of Lorraine. The civil tribunals, however, practically assumed the functions of regular inquisitorial courts, in spite of the objections urged by the ecclesiastical courts. Notwithstanding these measures for their extermination, the French Protestants were proceeding to organize a church in accordance with the conceptions of the early Christian communities as Calvin described them in his Institutes. Beginning with Paris, some fifteen communities with their consistories were established in French towns between 1555 and 1560. In spite of continued persecution a national synod was assembled in Paris in 1559, representing at least twelve Protestant churches in Normandy and central France, which drew up a confession of faith and a book of church discipline. It appears to have been from France rather than from Geneva that the Presbyterian churches of Holland, Scotland and the United States derived their form of government. A reaction against the extreme severity of the king's courts became apparent at this date. Bourges and others ventured warmly to defend the Protestants in the parlement of Paris in the very presence of the king and of the cardinal of Lorraine. The higher aristocracy began now to be attracted by the new doctrines, or at least repelled by the flagrant power enjoyed by the Guises during the brief reign of Francis II. (1559-1560). Protestantism was clearly becoming inextricably associated with politics of a very intimate sort. The leading members of the Bourbon branch of the royal family, and Gaspard de Coligny, admiral of France, were conspicuous among the converts to Calvinism. Persecution was revived by the Guises; Du Bourg, the bishop of Noyon, and others ventured as heretics; yet Calvin could in the closing years of his life form a cheerful estimate that some three thousand hundred of his countrymen had been won over to his views. The death of Francis II. enabled Catherine de' Medici, the queen mother, to assert herself against the Guises, and become the regent of her ten-year-old son Charles IX. A meeting of the States General had already been summoned to consider the state of the realm. Michel de l'Hôpital, the chancellor, who opened the assembly, was an advocate of toleration; he deprecated the abusive use of the terms "Lutherans," "Papists" and "Huguenots," and advocated dealing with them like "co-religionists," and called the deputies of the clergy were naturally conservative, but advocated certain reforms, an abolition of the Concordat, and a re-establishment of the older Pragmatic Sanction. The noblesse were divided on the matter of toleration, but the cabiers (lists of grievances and suggestions for reform) submitted by the Third Estate demanded, besides regular meetings of the estates every five years, complete toleration and a reform of the Church. This grew a little later into the recommendation that the revenues and possessions of the French Church should be appropriated by the government, which, after properly subsidizing the clergy, might hope, it was estimated, that a surplus of twenty-two millions of livres would accrue to the State. Two hundred and thirty years later this plan was realized in the Civil Constitution of the Clergy. The deliberations of 1561 resulted in the various reforms, the suspension of persecution and the liberation of Huguenot prisoners. These were not obtained for the freedom of worship, but naturally took advantage of the situation to carry on their services more publicly than ever before. An unsuccessful effort was made at the conference of Poissy to bring the two religious parties together; Beza had an opportunity to defend the Calvinistic cause, and Lainez, the general of the Order of Jesus, that of the bishop of Rome. The government remained tolerant toward the movement, and in January 1562 the Huguenots were given permission to hold public services outside the walls of fortified towns and were not forbidden to meet in private houses within the walls. Catherine, who had promoted these measures, cared nothing for the Protestants, but desired the support of the Bourbon princes. The country was Catholic, and disturbances inevitably occurred, culminating in the attack of the duke of Guise and his troops on the Protestants at Vassy, less than two months after the issuing of the edict.

It is impossible to review here the Wars of Religion which distracted France, from the "massacre of Vassy" to the publication of the edict of Nantes, thirty-six years later. Religious issues became more and more dominating by purely political and dynastic ambitions, and the whole situation was constantly affected by the policy of Philip II. and the struggle going on in the Netherlands. Henry IV. was admirably fitted to reunite France once more, and, after a superficial conversion to the Catholic faith, to meet the needs of his former co-religionists, the Huguenots. The edict of Nantes recapitulated and codified the provisions of a series of earlier edicts of toleration, which had come with each truce during the previous generation. Liberty of conscience in religious matters was secured and the right of private worship to those of the "so-called Reformed religion." Public worship was permitted everywhere where it had existed in 1566-1577, in two places with a more stringent control, a breach of the peace being a criminal offense, and in the chateaux of the Protestant nobility, with slight restrictions in the case of lower nobility. Protestants were placed upon a political equality and made eligible to all public offices. To ensure these rights, they were left in military control of two hundred towns, including La Rochelle, Montauban and Montpellier. Jealous of their "sharing the State with the king," Richelieu twenty-five years later reduced the exceptional privileges of the Huguenots, and with the advent of Louis XIV. they began to suffer renewed persecution, which the king at last flattered himself had so far reduced their number that in 1685 he revoked the edict of Nantes and reduced the Protestant to the status of outlaws. It was not until 1786 that they were restored to their civil rights, and by the Declaration of the Rights of Man, in 1789, to their religious freedom.

Contemporaneously with the Wars of Religion in France a long and terrible struggle between the king of Spain and his Dutch and Belgian provinces had resulted in the formation of a Protestant state—the United Netherlands, which was destined to play an important role in the history of the Reformed religion. Open both to German and French influences, the Netherlands had been the scene of the first executions of Lutherans; they had been a centre of Anabaptist agitation; but Calvinism finally triumphed in the Confession of Dordrecht, 1572, since Calvin's system of church government did not, like
Luther's imply the sympathy of the civil authorities. Charles V. had valiantly opposed the development of heresy in the Netherlands, and nowhere else had there been such numbers of martyrs, for some thirty thousand are supposed to have been put to death during his reign. Under Philip II. it soon became almost impossible to distinguish clearly between the religious issues and the resistance to the manifold tyranny of Philip and his representatives. William of Orange, who had passed through several phases of religious conviction, stood first and foremost for toleration. Indeed, Holland became the home of modern religious liberty, the haven of innumerable free spirits, and the centre of activity of printers and publishers, who looked to no other imprimatur than the prospect of intelligent readers.

It is impossible to offer any exhaustive classification of those who, while they rejected the teachings of the old Church, refused at the same time to conform to the particular types of Protestantism which had found favour in the eyes of the princes and been imposed by them on their subjects. This large class of "dissenters" found themselves as little at home under a Protestant as under a Catholic regime, and have until recently been treated with scant sympathy, both with reference to their social position. The Protestant revolt, simple, obscure people, under the influence of leaders whose names have been forgotten, lost confidence in the official clergy and their sacraments and formed secret organizations of which vague accounts are found in the reports of the 13th-century inquisitors, Rainerus Sacchoni, Bernard Gui, and the rest. Their anti-sacerdotalism appears to have been their chief offence, for the inquisitors admit that they were puritanically careful in word and conduct, and shunned all levity. Similar groups are mentioned in the town chronicles of the early 16th century, and there is reason to assume that informal evangelical movements were no new things when Luther first began to preach. His appeal to the Scriptures against the traditions of the Church encouraged a more active propaganda on the part of Balthasar Hubmaier, Carlstadt, Münzer, Johann Denk (d. 1527) and others, some of whom were well-trained scholars capable of maintaining with vigour and effect their ideas of an apostolic life as the high road to salvation. Münzer dreamed of an approaching millennium on earth to be heralded by violence and suffering, but Hubmaier and Denk were peaceful evangelists who believed that man's will was free and that each had within him an inner light which would, if he but followed it, guide him to God. To them persecution was an outrage upon Jesus's teachings. Luther and his sympathizers were blind to the reasonableness of the fundamental teachings of these "brethren." The idea of adult baptism, which had after 1525 become generally accepted among them, roused a bitterness which it is rather hard to understand nowadays. But it is easy to see that informal preaching to the people at large, especially after the Peasant Revolt, with which Münzer had been identified, should have led to a general condemnation, under the name "Anabaptist," or "Catahaptist," of the heterogeneous dissenters who agreed in rejecting the State religion and associated a condemnation of infant baptism with schemes of social betterment. The terrible events in Münster, which was controlled for a short time (1533-34) by a group of Anabaptists under the leadership of John of Leiden, the introduction of polygamy (which appears to have been a peculiar accident rather than a general principle), the speedy capture of the town by an alliance of Catholic and Protestant princes, and the ruthless retribution inflicted by the victors, have been cherished by ecclesiastical writers as a choice and convincing instance of the natural fruits of a rejection of infant baptism. Much truer than the common estimate of the character of the Anabaptists is that given in Sebastian Franck's Chronicle: "They taught nothing but love, faith and the crucifixion of the flesh, manifesting patience and humility under many sufferings, breaking bread with one another in sign of unity and love, helping one another with true helpfulness, lending, borrowing, giving, learning to have all things in common, calling each other 'brother.'" Menno Simons (b. circum 1500) succeeded in bringing the scattered Anabaptist communities into a species of association; he discouraged the earlier apocalyptic hopes, inculcated non-resistance, denounced the evils of State control over religious matters, and emphasized personal conversion, and adult baptism as its appropriate seal. The English Independents and the modern Baptists, as well as the Mennonites, may be regarded as the historical continuation of lines of development going back to the Waldensians and the Bohemian Brethren, and passing down through the German, Dutch and Swiss Anabaptists.

The modern scholar as he reviews the period of the Protestant revolt, will find certain, I trust not unnatural, but generally in vain, for those rationalistic tendencies which become so clear in the latter part of the 17th century. Luther found no intellectual difficulties in his acceptance and interpretation of the Scriptures as God's word, and in maintaining against the Anabaptists the legitimacy of every old custom that was not obviously contrary to the Scriptures. Indeed, he gloried in the inherent and divine unreasonableness of Christianity, and brutally denounced reason as a cunning fool, "a pretty harlot." The number of questions which Calvin indeed so ask or eluded by absolutely irrational expedients frees him from many tales which the modern rationalist, whose execution he approved, we find an isolated, feeble revolt against assumptions which both Catholics and Protestants of all shades accepted without question. It is very clear that the common accounts of the Renaissance and of the revival of learning grossly exaggerate the influence of the writers of Greece and Rome, for they produced no obvious rationalistic movement, as would have been the case had Plato and Cicero, Lucretius and Lucian, been taken really seriously. Neo-Platonism, which is in some respects nearer the Christian patricism than the Hellenic spirit, was as far as the radical religious thinkers of the Italian Renaissance were concerned, the only religious movement that can be regarded as even rather vaguely the outcome of humanism is the Socinian. Faustus Sozzini, a native of Sienna (1539-1603), much influenced by his uncle Leio Sozzini, after a wandering, questioning life, found his way to Poland, where he succeeded in uniting the various Anabaptist sects into a species of church, the doctrines of which are set forth in the Confession of Rakow (near Minsk), published in Polish in 1605 and speedily in German and Latin. The Latin edition declares that although this new statement of the elements of the Christian faith differs from the articles of other Christian creeds it is not to be mistaken for a challenge. It does not aim at binding the opinions of men or at condemning to the tortures of hell-fire those who refuse to accept it. Abstis a nobis ea mens, immo amentia. "We have, it is true, ventured to prepare a catechism, but we force it on no one; we express our opinions, but we coerce no one. It is free to every one to form his own conclusions in religious matters; and so we do no more than set forth the meaning of divine things as they appear to our minds without, however, attacking or insulting those who differ from us. This is the golden freedom of preaching which the holy words of the New Testa-

ment are strictly enjoined upon us... Who art thou, miserable man, who would sterno and extinguish in others the fire of God's Spirit which it has pleased him to kindle in them?" The Socinian creed sprang from intellectual rather than religious motives. Sufficient reasons could be assigned for accepting the New Testament as God's word and Christ as the Christian's guide. He was not God, but a divine prophet born of a virgin and raised on the third day as the first-fruits of them that slept. From the standpoint of the history of enlightenment, as Harnack has observed, "Socinianism with its systematic criticism (tentative and imperfect as it may now seem) and its rejection of all the assumptions based upon mere ecclesiastical tradition, can scarcely be rated too highly. That modern Unitarianism is all to be traced back to Sozzini and the Rakow Confession need not be assumed. The anti-Trinitarian path was one which opened invitingly before a considerable class of critical minds, seeming as it did to lead out into
a sunny open, remote from the unfathomable depths of mystery and clouds of religious emotion which beset the way of the sincere Catholic and Protestant alike.

The effects of the Protestant secession on the doctrines, organization and practices of the Roman Catholic Church are difficult to estimate, still more so to substantiate. It is clear that the doctrinal conclusions of the council of Trent were largely determined by the necessity of condemning Protestant tenets, and that the result of the council was to give the Roman Catholic faith a more precise form than it would otherwise have had. It is much less certain that the disciplinary reforms which the council, following the example of its predecessors in these things, proposed to be carried out to Reformation, unless indeed the council would have shown itself less intolerant in respect to such innovations as the use of the vernacular in the services had this not smacked of evangelicalism. In the matter of the pope’s supremacy, the council followed the canon law and Thomas Aquinas, not the decrees of the council of Constance. It prepared the way for the dogmatic formulation of the plenitude of the papal power three centuries later by the council of the Vatican. The Protestants have sometimes taken credit to themselves for the indubitable reforms in the Roman Catholic Church, which by the end of the 16th century had done away with many of the cryings abuses against which councils and diets had so long been protesting. But this conservative reformation had begun before Luther’s preaching, and might conceivably have followed much the same course had his doctrine never found popular favour or even been ratified by the princes.

In conclusion, a word may be said of the place of the Reformation in the history of progress and enlightenment. A “philosopher,” as Gibbon long ago pointed out, who asks from what articles of faith above and against reason the early Reformers enfranchised their followers will be surprised at the difficulty rather than the generalization by their freedom. They remained severely orthodox in the doctrines of the Fathers—the Trinity, the Incarnation, the plenary inspiration of the Bible—and they condemned those who rejected their teachings to a hell whose fires they were not tempted to extenuate. Although they surrendered transubstantiation, the loss of one mystery was amply compensated by the stupendous doctrines of original sin, redemption, faith, grace and predestination upon which they founded their theory of salvation. They ceased to appeal to the Virgin and saints, and to venerate images and relics, procure indulgences and go on pilgrimages, they forecasted the lives, and did not surrender faith by the daily repetition of miracles, but in the witch persecutions their demonology cost the lives of thousands of innocent women. They broke the chain of authority, without, however, recognizing the propriety of toleration. In any attempt to determine the relative importance of Protestant and Catholic countries in promoting modern progress it must not be forgotten that religion is naturally conservative, and that its avowed business has never been to forward scientific research or political reform. Luther and his contemporaries had not in any degree the modern ideas of progress, which first becomes conspicuous with Bacon and Descartes, but believed, on the contrary, that the strangling of reason was the most precious of offerings to God. “Free-thinker” and “rationalist” have been terms of opprobrium whether used by Protestants or Catholics. The pursuit of salvation does not dominate by any means the whole life and ambition of even ardent believers; statesmen, philosophers, men of letters, scientific inventors and inventors have commonly gone their way regardless of the particular form of Christianity which prevailed in the land in which they lived. The Reformation was, fundamentally, then, but one phase, if the most conspicuous, in the gradual decline of the majestic medieval ecclesiastical State, for this decline has gone on in France, Austria, Spain and Italy, countries in which the Protestant revolt against the ancient Church ended in failure.

BIBLIOGRAPHY.—Reference is made here mainly to works dealing with the Reformation as a whole. Only recent books are mentioned, since the older works have been largely superseded owing to modern critical investigations: Thomas A. Lindsay, A History of the Reformation, 2 vols. (1906, 1907, 1907); The Cambridge Modern History, vol. i. (1902), chaps. xviii. and xix., vol. ii. (1904), “The Reformation,” and vol. iii. (1905), “The Wars of Religion.” Other standard works are: M. Creighton, History of the Papacy during the Reformation, 6 vols. (new ed. 1899-1901). From a Catholic standpoint: L. Pastor, Geschichte der Päpste seit dem Ausgang des Mittelalters (1891 sqq.), especially vol. iv. in its second part (1899-1906). The most recent and comprehensive are: E. Troeltsch, Protestantisches Christentum und Kirche der Neuzeit, in the series “Kultur der Gegenwart,” Teil i. Abt. 4, i. Hülte, 1905; Charles Beard, The Reformation of the Sixteenth Century in its Relation to Thought and Civilization (1895); N. Cumont, Recherches sur la réforme byzantine (1901), and by the same, Martin Luther, vol. i. (no more published; 1899); A. Harnack, History of Dogma (trans. from the 3rd German edition, 1900); E. Maurenbrecher, Kirchenreform, 1907; J. F. Waleck, The Protestant Reformation (2nd ed., 1908); Thudichum, Papsttum und Reformation (1903): “Janus, The Pope and the Council (1869), by Döllinger and others, a suggestive if not wholly accurate sketch of the papal claims; J. Boehm, Luther im Lichte der Verh. der Vorzüge (1901); M. Creighton, First Principles of the Reformation, the Three Primary Works of Dr. Martin Luther, edited by Wace and Buchheim,—an English translation of the famous pamphlets of 1520. (J. H. R.)

REFORMATORY SCHOOL, an institution for the industrial training of juvenile offenders, in which they are lodged, clothed and fed, as well as taught. They are to be distinguished from “industrial schools,” which are institutions for delinquent and not actual delinquents. To reformatory schools in England are sent juveniles up to the age of sixteen who have been convicted of an offence punishable with penal servitude or imprisonment. This method is made by the court before which they are tried; the limit of detention is the age of nineteen. Reformatory schools are regulated by the Children Act 1908, which repealed the Reformatory Schools Act 1866, as amended by acts of 1872, 1874, 1891, 1893, 1899 and 1901. See further Juvenile Offenders.

REFORMED CHURCHES, the name assumed by those Protestant bodies who adopted the tenets of Zwingli (and later of Calvin), as distinguished from those of the Lutheran or Evangelical divines. They are accordingly often spoken of as the Calvinistic Churches, Protestant being sometimes used as a synonym for Lutheran. The great difference is in the attitude towards the Lord’s Supper, the Reformed or Calvinistic Churches repudiating not only transubstantiation but also the Lutheran consubstantiation. They also reject the use of crucifixes and other symbols and ceremonies retained by the Lutherans. Full details of these divergences are given in M. Schneckenburger, Protes- tante Kirchen in Deutschland und der Schweiz (Stuttgart, 1855); G. B. Winer, Comparative Darstellung (Berlin, 1866; Eng. tr., Edinburgh, 1873). See also Reformation; Presbyterianism; Cameronians.

REFORMED CHURCH IN AMERICA, until 1867 called officially “The Reformed Protestant Dutch Church in North America,” and still popularly called the Dutch Reformed Church, an American Calvinist church, originating with the settlement of the Dutch in Holland by the Rev. Henry Kuyper in 1621. It is one of the principal branches of the Reformed Church under the title of the Reformed Church in America, which was formed by the union of the Dutch Reformed Church in America and the Associate Reformed Church in America in 1825. The two churches were the first permanent settlers of the Reformed faith in the New World. Their earliest settlements were at Manhattan, Wallabout and Fort Orange (now Albany), where the West India Company formally established the Reformed Church of America.
Their first minister was Jonas Michaelius, pastor in New Amsterdam of the "church in the fort" (now the Collegiate Church of New York City). The second domine, Everardus Bogardus (d. 1647), migrated to New York in 1633 with Governor Wouter van Twiller, with whom he quarrelled continually; in the same year a wooden church "in the fort" was built; and in 1642 it was succeeded by a stone building. A minister, John van Mekelenburg (Johannes Megapolensis) migrated to Rensselaerwyck in 1644, preached to the Indians—probably before any other Protestant minister—and after 1649 was settled in New Amsterdam. With the access of English and French settlers, Samuel Drisius, who preached in Dutch, German, English and French, was engaged, and he was succeeded in 1656 by another Dutch from New York (whom the people of New Castle appealed) a classis was constituted for the ordination of a pastor for the church in New Castle, Delaware. The strong opposition the Church of England, and contributed largely toward the adoption (in October 1663) of the Charter of Liberties which confirmed in their privileges all churches then "in practice" in the city of New York and elsewhere in the province, but which was repealed by James II. In 1668, when he established the Church of England in New York but allowed religious liberty to the Dutch and others. The first step was prompted by Governor Leisler's rebellion. Under William III, Governors Slaught and Fletcher worked for a law (passed in 1693 and approved in 1697) for the settling of a ministry in New York, Richmond, Westchester and Queen's counties; but the Assembly foiled Fletcher's purpose of establishing a Church of England clergy, although he attempted to construed the act as applying only to the English Church. In 1696 the first church charter in New York was granted to the Reformed Protestant Dutch Church (now the Collegiate Church) of New York City; at this time there were Dutch ministers at Albany and Kingston, on Long Island and in New Jersey; and for years the Dutch and English (Episcopalians) churches alone received charters in New York and New Jersey—the Dutch church being treated practically as an establishment—and the church of the fort and Trinity (Episcopalians; chartered 1697) were fraternal harmoniously. In 1700 there were twenty-nine Reformed Dutch churches out of a total of fifty in New York. During the administration of Governor Edward Hyde, Lord Cornbury, many members joined the Episcopal Church and others removed to New Jersey. The Great Awakening crowned the efforts of Theodore Frelinghuysen, who had come over as a Dutch pastor in 1720 and had opposed formalism and preached a revival. The Church in America in 1738 asked in Classis of Amsterdam of whose care it had been transferred from the West India Company for the privilege of forming a Coetus or Association with power to ordain in America; the Classis, after trying to join the Dutch with the English Presbyterian churches, granted (1747) a Coetus first to the German and then to the Dutch churches, which therefore in September 1754 organized themselves into a classis. This action was opposed by the church of New York City, and partly through this difference and partly because of quarrels over the denominational control of King's College (now Columbia), five members of the Coetus seceded, and as the president of the Coetus was one of them they took the records with them; they were called the Conferee; they organized independently in 1764 and carried on a bitter warfare with the Coetus (now more properly called the American Classis), which in 1766 (and again in 1770) obtained a charter for Queen's (now Rutgers) College at New Brunswick. Theodore_van_Equator (1746-1825), who had become pastor of the New York City church in 1770, on the basis of a plan drafted by the Classis of Amsterdam Coetus and Conferentie were reunited with a substantial independence of Amsterdam, which was made complete in 1792 when the Synod (the nomenclature of synod and classis had been adopted upon the declaration of American Independence) adopted a translation of the eighty-four Articles of Dort on Church Order with seventy-three "explanatory articles."1 In 1800 there were about forty ministers and one hundred churches. In 1819 the Church was incorporated as the Reformed Protestant Dutch Church, and in 1867 the name was changed to the Reformed Church in America. Preaching in Dutch had nearly ceased in 1820, but about 1846 a new Dutch immigration began, especially in Michigan, and fifty years later Dutch preaching was common in nearly one-third of the churches of the country, only to disappear almost entirely in the next decade. Union with other Reformed churches was planned in 1743, in 1754, in 1816-20, 1873-75 and 1886, but unsuccessfully; however, ministers go from one to another charge in the Dutch and German Reformed, Presbyterian, and to a lesser degree Congregational church. One conservative sects ("on account of Hopkinson errors" organized in 1812 of six ministers (five then under suspension) organized a General Synod and the classes of Hackensack and Union (central New York) in 1824; it united with the Christian Reformed Church, established by immigrants from Holland after 1835, to which there was added a fresh American secession in 1882 due to opposition (on the part of the seceders) to secret societies.

The organization of the Church is: a General Synod (1794); the (particular) synods of New York (1800), Albany (1800), Chicago (1865), and New Brunswick (1860); classes, corresponding to the presbyteries of other Calvinistic bodies, and the churches, numbering, in 1906, 659. The agencies of the Church are: the Board of Education, privately organized in 1826 and adopted by the General Synod in 1821; a Widows' Fund (1837) and a Disabled Ministers' Fund; a Board of Publication (1855); a Board of Domestic Missions (1831; reorganized 1849) with a Church Building Fund and a Woman's Executive Committee; a Board of Foreign Missions (1832), succeeded the United Missionary Society (1816), which included Presbyterian, Dutch Reformed and Associate Reformed Churches, and which was merged (1826) in the American Board of Commissioners for Foreign Missions, from which the Church did not separate until 1857; and a Woman's Board of Foreign Missions (1875). The principal missions are in India at Arcot (1854; transferred in 1902 to the Synod of New England); at Amoy (1869); at Korea (1877). The Church in Japan was very successful, especially under Guido Frödin Verbeck2 (1830-1898), and 1877 native churches built up by Presbyterian and Dutch Reformed missionaries were organized as the United Church of our Lord Jesus Christ in Japan. There is also an Arabian mission, begun privately in 1888 and transferred to the Board in 1894. The colleges and institutions of learning connected with the Church are: Rutgers, already mentioned; Union College (1795), the outgrowth of Scheneectady Academy, founded in 1785 by Dirck Remyen, a Dutch minister; Hope College (1866; coeducational) at Holland, Michigan; 1875; an academy for the last-mentioned; the Western Theological Seminary at 1869 Holland, Michigan.

In 1838 (according to Bulletin 103 (1900) of the Bureau of the U.S. Census) there were 650 organizations with 773 church edifices reported and the total membership was 124,938. More than one-half of this total membership (63,350) was in New York state, the majority of whom were members of the United Missionary Society (1816). The founder of the Phelps Academy, one-quarter (32,290) was in New Jersey; and the other states were: Michigan (11,260), Illinois (4962), Iowa (4835), Wisconsin (2312), and Pennsylvania (1970). The Church was also represented in nine states: Dakota, Nebraska, Indiana, Ohio, Kansas, N. Dakota, S. Carolina, Washington and Maryland—the order being that of rank in number of communicants.

In 1838 (according to "Christian Reformed Church in America") 228 organizations, 181 churches and a membership of 26,669.

1 In 1832 the articles of Church government were rearranged and in 1772 they were replaced by a new constitution.

2 See W. E. Griffis, Verbeck of Japan (New York, 1900).
of which more than one-half (14,770) was in Michigan, where many of the immigrants who came after 1835 belonged to the secession church in Holland. There were 2990 in Iowa, 2392 in New Jersey, 2332 in Illinois, and smaller numbers in Wisconsin, Indiana, Minnesota, S. Dakota, and Washington. In Kansas, Massachusetts, Montana, N. Dakota, New Mexico, Nebraska, and Colorado.

REFORMED CHURCH IN THE UNITED STATES, a German Calvinistic church in America, commonly called the German Reformed Church. It traces its origin to the great German immigration of the 17th century, especially to Pennsylvania, where, although the German Lutherans afterwards outnumbered them, the Reformed element was estimated in 1730 to be more than half the whole number of Germans in the colony. In 1709 more than 2000 Palatines emigrated to New York with their pastor, Johann Friedrich Hager (d. c. 1723), who laboured in the Mohawk Valley. A church in Germantown, Virginia, was founded about 1714. Johann Philip Boehm (d. 1749), a school teacher from Worms, although not the first, preached in 1720 to congregations at Falkner's Swamp, Skippack, and White Marsh, Pennsylvania, and in 1729 he was ordained as a Dutch Reformed minister in New York. Georg Michael Weiss (c. 1700-c. 1762), a graduate of Heidelberg, ordained and sent to America by the Upper Consistory of the Palatinate in 1727, organized a church in Philadelphia; preached at Skippack; worked in Dutchess and Schoharie counties, New York, in 1731-46; and then returned to his old field in Pennsylvania. Johann Heinrich Goetschius was pastor (c. 1731-38) of ten churches in Pennsylvania, and was ordained by the Presbyterian Synod of Philadelphia in 1737. A part of his work was undertaken by Johann Conrad Wirtz, who was ordained by the New Brunswick (New Jersey) Presbytery in 1750, and in 1761-63 was pastor at York, Pennsylvania. A church was built in 1736 at Lancaster, Pennsylvania, where Johann Bartholomaeus Rieger (1707-1760), who came from Germany with Weiss on his return in 1731, had preached for several years. Michael Schlatter (1716-1790), a Swiss of St. Gall, sent to America in 1746 by the Synods (Dutch Reformed) of Holland, immediately convened Boehm, Weiss and Rieger in Philadelphia, and with them planned a Coetus, which first met in September 1747 at New York. The first meeting of the Coetus in Germany and Holland, where he gathered funds; in 1752 came back to America with six ministers, one of whom, William Stoy (1726-1801), was an active opponent of the Coetus and of clericalism after 1772. Thereafter Schlatter's work was in the charity schools of the Coetus in Pennsylvania, which the people thought were tending with Episcopalianism. Many churches and pastors were independent of the Coetus, notably John Joachim Zubly (1724-1781), of St. Gall, who migrated to S. Carolina in 1746, and was a delegate to the Continental Congress from Georgia, but opposed independence and was hanged in South Carolina in 1777. Within the Coetus there were two parties. Of the Pietists the second class one of the leaders was Philip William Otterbein (1726-1813), born in Dillenburg, Nassau, whose system of class-meetings was the basis of a secession from which grew the United Brethren in Christ, commonly called the "New Reformed Church," organized in 1800. During the War of Independence the Pennsylvania members of the Church were mostly attached to the American cause, and Nicholas Herkimer and Baron von Steuben were both Reformed; but in New York and in the South there were many German Loyalists.

Franklin College was founded by Lutherans and Reformed, with much outside help, notably that of Benjamin Franklin, at Lancaster, Pennsylvania, in 1787. The Coetus had actually assumed the power of ordination in 1772 and formally assumed it in 1791; in 1792 a synodical constitution was prepared; and in 1793 the first independent synod met in Lancaster and adopted the constitution, thus becoming independent of Holland. Its churches numbered 178, and there were about 15,000 communicants. The strongest churches were those of Philadelphia, Lancaster and Germantown in Pennsylvania, and Frederick in Maryland. The German Reformed churches in Lunenburg county, Nova Scotia, became Presbyterian in 1837; a German church in Waldoboro, Maine, after a century, became Congregational in 1850. The New York churches became Dutch Reformed. The New Jersey churches rapidly fell away, becoming Presbyterian, Dutch Reformed, or Lutheran. In Virginia many churches became Episcopalian and others United Brethren. By 1825, 13 Reformed ministers were settled W. of the Alleghanies. The Synod in 1819 divided itself into eight Classes. In 1824 the Classis of Northampton, Pennsylvania (13 ministers and 80 congregations), became the Synod of Ohio, the parent Synod having refused to allow the Classis to ordain. In 1825 there were 87 ministers, and in the old Synod about 23,300 communicants.

A schism over the establishment of a theological seminary resulted in the organization of a new synod of the "Free German Reformed Congregations of Pennsylvania," which returned to the parent synod in 1837. W. Christensen (1743), pastor in Harrisburg, Pennsylvania, left the Church in 1828, and in 1830 organized the "Church of God"; his main doctrinal difference with the Reformed Church was on infant baptism.

In 1825 the Church opened a theological seminary at Carlisle, Pennsylvania, affiliated with Dickinson College. James Ross Reilly (1788-1844) travelled in Holland and Germany, collecting money and books for the seminary. It was removed in 1829 to York, where an academy was connected with it; in 1835 the academy (which in 1836 became Marshall College) and in 1837 the seminary removed to Mercersburg, where, in 1840, John Nevin (1818-1877) became its president, and with Philip Schaff (p. 96) founded the Mercersburg theology, which lost to the Church many who objected to Nevin's (and Schaff's) Romanizing tendencies. The seminary was removed in 1871 from Mercersburg to Lancaster, whither the college had gone in 1853 to form, with Franklin College, Franklin and Marshall College.

In 1842 the Western Synod (i.e. the Synod of Ohio) adopted the constitution of the Eastern, and divided into classes. It founded in 1850 a theological school and Heidelberg University at Tiffin, Ohio. The Synods organized a general Synod in 1861; the New German Synod of the West (1857), organized at Fort Wayne, Ind.; that of the East (1857), organized at Philadelphia; and the Central Synod (1881), organized at Galion, Ohio. New English Synods were: that of Pittsburg (1870); that of the Potomac (1873); and that of the Interior (1887), organized at Kansas City, Missouri. In 1894 there were eight district synods.

After a long controversy over a liturgy (connected in part with the Mercersburg controversy) a Directory of Worship was adopted in 1887.

The principal organizations of the Church are: the Board of Publication (1842); the Society for the Relief of Ministers and their Widows (founded in 1755 by the Pennsylvania Coetus; incorporated in 1816; transferred to the Synod in 1833); a Board of Domestic Missions (1826); a Board of Foreign Missions (1838; reorganized in 1873), which planted a mission in Japan (1879), now a part of the Union Church of Japan, and one in China (1900). The Church has publishing houses in Philadelphia (replacing that of Chambersburg, Pa., founded in 1840 and destroyed in July 1864 by the Confederate army) and in Cleveland, Ohio. Churches are connected with the Church, besides the seminary at Lancaster, Franklin and Marshall College and Heidelberg University, are: Catawba College (1857) at Newton, North Carolina; and Ursinus College (1869), founded by the Low Church wing, at Collegeville, Pennsylvania, which had, until 1908, a theological seminary, then removed to Dayton, Ohio, where it united with Heidelberg Theological Seminary (until 1908 at Tiffin) to form the Central Theological Seminary.

In 1906, according to Bulletin 102 (1909) of the Bureau of the United States Census, the Church had 1736 organizations in the
REFORMED EPISCOPAL CHURCH—REFRACTION

United States, 1740 churches and 292,654 communicants, of whom 177,270 were in Pennsylvania, and about one-sixth (50,732) were in Ohio. Other states in which the Church had communicants were: Maryland, Wisconsin (8290), New York (5700), North Carolina (4718), Iowa (3692), Illinois (2652), Virginia (2288), Kentucky (2101), Michigan (1666), Nebraska (1616), and (less than 1500 in each of the following arranged in rank) S. Dakota, Missouri, New Jersey, and Tennessee, California, Colorado, Arkansas and Oklahoma.

See: History of the Reformed Church in the United States, 1725–1792 (Reading, Pa. 1899) and Historical Handbook (Philadelphia, 1902); and the sketch by Joseph Henry Dubbs in vol. viii. (New York, 1895) of the American Church History Series.

REFORMED EPISCOPAL CHURCH, a Protestant community in the United States of America, dating from December 1873. The influence of the Tractarian movement began to be felt at an early date in the Episcopal Church of the United States, and the ordination of Arthur Carey in New York, July 1843, a clergyman who denied that there was any difference in points of faith between the Anglican and the Roman Churches and considered the Reformation an unjustifiable act, brought into relief the antagonism between Low Church and High Church, a struggle which went on for a generation with increasing bitterness. The High Church party lost no opportunity of arraying any Low Churchman who conducted services in non-episcopal churches, and as the Triennial Conference gave no heed to remonstrances on the part of these ecclesiastics, offenders they came to the conclusion that they must either crush their consciences or seek relief in separation. The climax was reached when George D. Cummings (1822–1876), assistant bishop of Kentucky, was angrily attacked for officiating at the united communion service held at the meeting of the Sixth General Conference of the Evangelical Alliance in New York, October 1873. This prelate resigned his charge in the Episcopal Church on November 11th, and a month later, with seven other clergy men and a score of laymen, constituted the Reformed Episcopal Church. Cummings was chosen as presiding officer of the new body, and consecrated Bishop in (1870). (B. 1856), rector of Christ Church, Chicago, to be bishop. The following Declaration of Principles (here abridged) was promulgated:

I. An expression of belief in the Bible as the Word of God, and the sole rule of faith and practice, in the Apostles’ Creed, in the divine institution of the two sacraments and in the doctrines of grace substantially as set out in the 39 Articles.

II. The recognition of Episcopacy as of divine right but as a very ancient and desirable form of church polity.

III. An acceptance of the Prayer Book as revised by the General Convention of the Protestant Episcopal Church in 1859, with liberty to reject it as may seem most conducive to the edification of the people.

IV. A condemnation of certain positions, viz.:
(a) That the Church of God exists only in one form of ecclesiastical polity.
(b) That Christian ministers as distinct from all believers have any special priesthood.
(c) That the Lord’s Table is an altar on which the body and blood of Christ are offered anew to the Father.
(d) That the presence of Christ is a material one.
(e) That Regeneration is inseparably connected with Baptism

The Church recognizes no orders of ministry, presbyters and deacons; the Episcopalate is an office, not an order, the bishop being the chief presbyter, primus inter pares. There are some 7 bishops, 85 clergy and about 9500 communicants. £1600 annually is raised for foreign missionary work in India. The Church was introduced into England in 1877, and has in that country a presiding bishop and about 20 organized congregations. The Church has a theological seminary in Philadelphia.

REFRACTION (Lat. refringere, to break open or apart), in physics, the change in the direction of a wave of light, heat or sound which occurs when such a wave passes from one medium into another of different density.

I. REFRAC TION OF LIGHT

When a ray of light travelling a homogeneous medium falls on the bounding surface of another transparent homogeneous medium, it is found that the direction of the transmitted ray in the second medium is different from that of the incident ray; in other words, the ray is refracted or bent at the point of incidence. The laws governing refraction are:

(i) The refracted and incident rays are coplanar with the normal to the refracting surface at the point of incidence, and
(ii) the ratio of the sines of the angles between the normal and the incident and refracted rays is constant for the two media, but depends on the nature of the light employed, i.e., on its wave length. This constant is called the relative refractive index of the second medium, and may be denoted by $\mu_{b/a}$, the suffix $ab$ signifying that the light passes from medium $a$ to medium $b$; similarly $\mu_{a/b}$ denotes the relative refractive index of $a$ with regard to $b$. The absolute refractive index is the index when the first medium is a vacuum. Elementary phenomena in refraction, such as the apparent bending of a stick when partially immersed in water, were observed in very remote times, but the laws, as stated above, were first grasped in the 17th century by W. Snell and published by Descartes, the full importance of the dependence of the refractive index on the nature of the light employed being first thoroughly realized by Newton in his famous prismatic decomposition of white light into a coloured spectrum. Newton gave a theoretical interpretation of these laws on the basis of his corpuscular theory, as did also Huygens on the wave theory (see LIGHT, II. Theory of). In this article we only consider refractions at plane surfaces, refraction at spherical surfaces being treated under LENS. The geometrical theory will be followed, the wave theory being treated in LIGHT, DIFFRACTION and DISPERSION.

Refraction at a Plane Surface.—Let LM (fig. 1) be the surface dividing two homogeneous media $A$ and $B$; let IO be a ray in the first medium incident on LM at O, and let OR be the refracted ray. Draw the normal POQ. Then by Snell’s law we have

\[ \frac{\sin \theta_1}{\sin \theta_2} = \frac{\sin \phi_1}{\sin \phi_2} = \frac{\mu_{b/a}}{\mu_{a/b}}. \]

Hence if two of these quantities be given the third can be calculated. The commonest question is: Given the refractive index and the refractive index to construct the refracted ray. A simple construction is to take along the incident ray $OI$, unit distance OC, and a distance OD equal to the refractive index in the same units. Draw $CE$ perpendicular to LM, and draw an arc with centre O and radius OD, cutting CE in E. Then EO produced downwards is the refracted ray. The proof is left to the reader.

In the figure the given incident ray is assumed to be passing from a less dense to a denser medium, and it is seen by the construction or by examining the formula $\sin \beta = \alpha \sin \phi$ that for all values of $\alpha$ there is a corresponding value of $\beta$. Consider the case when the light passes from a denser to a less dense medium.

In the equation $\sin \beta = \alpha \sin \phi$ we have in this case $\mu_{a/b} < 1$. Now if $\sin \alpha = \mu_{a/b}$, we have $\sin \phi = \mu_{a/b} \sin \theta_1$ and hence $\beta$ is real. If $\sin \alpha = \mu_{b/a}$, then $\sin \beta = 1$, i.e., $\beta = 90^\circ$; in other words, the refracted ray in the second medium passes parallel to and grazes the bounding surface.

The angle of incidence, which is given by $\sin \theta_1 = \mu_{a/b}$, is termed the critical angle. For greater values it is obvious that $\sin \alpha > \mu_{a/b}$ and there is no refraction into the second medium, the rays being totally reflected back into the first medium; this is called total internal reflection.

Images produced by Refraction at Plane Surfaces.—If a luminous point be projected in a medium separated from one of less density by a plane surface, the image will be unrefracted, whilst the others will undergo refraction according to their angles of emergence. If the rays in the less dense medium are refracted into the denser medium, the image is said to be formed in the denser medium. The image is then called virtual. If the rays in the denser medium are refracted into the less dense medium, the image is said to be also formed in the denser medium. The image is then called real.
image of the luminous source. The position of this point can be easily determined. If \( l \) be the distance of the source below the surface, \( l' \) the distance of the image, and \( \mu \) the refractive index, then \( l' = l/\mu \).

This theory provides a convenient method for determining the refractive index of a plate. A micrometer microscope, with vertical motion, is focused on a scratch on the surface of its stage; the plate, which has a fine scratch on its upper surface, is now introduced, and the microscope is successively focused on the scratch on the stage as viewed through the plate, and on the scratch on the plate. The difference between the first and third readings gives the thickness of the plate, corresponding to \( l \), above, and between the second and third readings the depth of the image, corresponding to \( l' \).

Refraction by a Prism.—In optics a prism is a piece of transparent material bounded by two plane faces which meet at a definite angle, called the refracting angle of the prism. In a straight line called the edge of the prism; a section perpendicular to the edge is called a principal section. Parallel rays, refracted successively at the two faces, emerge from the prism as a system of parallel lines by an amount equal to the deviation. The deviation depends on the angles of incidence and emergence; but, since the course of a ray may always be reversed, there must be a stationary value, either a maximum or minimum, when the ray traverses the prism symmetrically, i.e., when the angles of incidence and emergence are equal. As a matter of fact, it is a minimum, and the position is called the angle of minimum deviation. The relation between the minimum deviation \( D \), the angle of the prism \( i \), and the refractive index \( \mu \) is found as follows. Let in fig. 2, PQRS be the course of the ray through the prism; the internal angles \( \phi', \psi' \) each equal \( \frac{1}{2}i \), and the angles of incidence and emergence \( \phi, \psi \) each equal and connected with \( \phi' \) by Snell's law, i.e., \( \sin \phi = \mu \sin \phi' \). Also the deviation \( D \) is \( 2(\psi - \phi') \). Hence \( \mu = \sin \phi/\sin \phi' = \sin \psi/\sin \psi' = \frac{D + i}{\sin i} \).

Refractometers.—Instruments for determining the refractive indices of media are termed refractometers.

The simplest are really spectrometers, consisting of a glass prism, usually hollow and fitted with accurately parallel glass sides, mounted on a table which carries fixed collimation tube and a movable observing tube, the motion of the latter being recorded on a graduated circle. The collimation tube has a narrow adjustable slit at its outer end and a lens at the nearer end, so that the light leaves the tube as a parallel beam. The refracting angle of the prism \( i \) in our previous notation, is determined by placing the prism with its refracting edge towards the collimator, and observing when the reflections of the slit in the two prism faces coincide with the cross-wires in the observing telescope; half the angle between these two positions gives \( i \). To determine the position of minimum deviation, or \( D \), the prism is removed, and the observing telescope is brought into line with the slit; in this position the graduation is read. The prism is replaced, and the telescope moved until it catches the refracted rays. The prism is now turned about a vertical axis until a position is found when the telescope has to be moved towards the collimator in order to catch the rays; this operation sets the prism at the angle of minimum deviation. The refractive index \( \mu \) is calculated from the formula given above.

More readily manipulated and of superior accuracy are refractometers depending on total reflection. The Abbe refractometer (fig. 3) essentially consists of a double Abbe prism AB to contain the substance to be experimented with; and a telescope F to observe the border line of the total reflection. The prisms, which are right-angled triangles of the same hard glass, are mounted in a hinged frame such that the lower prism, which is used for purposes of illumination, can be locked so that the hypotenuse faces are distant by about 0.15 mm., or rotated away from the upper prism. The double graduation in examining liquids, a line being placed between the prisms; the single prism is used when solids or plastic bodies are employed. The mount is capable of rotation about a horizontal axis by an alidade J. The telescope is provided with a reticle, which can be brought into exact coincidence with the observed border line, and is rigidly fastened to a sector 5 graduated directly in refractive indices. The reading is effected by a lens L. Beneath the prisms is a mirror for reflecting light into the apparatus. To use the apparatus, the liquid having been inserted between the prisms, or the solid attached by its own adhesiveness or by a drop of monobromnaphthalene to the upper prism, the prism case is rotated until the field of view consists of a light and dark portion, and the border line is now brought into coincidence with the reticle of the telescope. In using a lamp or daylight this border is coloured, and hence a compensator, consisting of two equal Amici prisms, is placed between the objective and the prisms. These Amici prisms can be rotated, in opposite directions, until they produce a dispersion opposite in sign to that originally seen, and hence the border line now appears perfectly sharp and colourless. When at zero the alidade corresponds to a refractive index of 1.3, and any other reading gives the corresponding index correct to about 0.001 units in the 4th decimal place. Since temperature markedly affects the refractive index, this apparatus is provided with a device for heating the prisms. Figs. 4 and 5 show the course of the rays when a solid and liquid are being experimented with. Dr R. Wollny's better refractometer, also made by Zeiss, is constructed similarly to Abbe's form, with the exception that the prism casing is rigidly attached to the telescope, and the observation made by noting the point where the border line intersects an appropriately graduated scale on the focal plane of the telescope objective, fractions being read by a micrometer screw attached to the objective. This apparatus is also provided with an arrangement for heating.

This method of reading is also employed in Zeiss's "dipping refractometer" (fig. 6). This instrument consists of a telescope K having at its lower end a prism P with a refracting angle of 63°, above which and below the objective is a movable compensator A for purposes of annulling the dispersion about the border line. In
the focal plane of the objective O there is a scale Sc, exact reading being made by a micrometer Z. If a large quantity of liquid be available it is sufficient to dip the refractometer perpendicularly into a beaker containing the liquid and to transmit light into the instrument by means of a mirror. If only a smaller quantity is available, it is enclosed in a metal beaker M, which forms an extension of the instrument, and the liquid is retained there by a plate D. The instrument is now placed in a trough B, containing water and having one side of ground glass G; light is reflected into the refractometer by means of a mirror S outside this trough. An accuracy of ± 3 units in the 3rd decimal place is obtainable. The Pulfrich refractometer is also largely used, especially for liquids. It consists essentially of a right-angled glass prism placed on a metal foundation with the faces at right angles horizontal and vertical, the hypotenuse face being on the support. The horizontal face is fitted with a small cylindrical vessel to hold the liquid. Light is led to the prism at grazing incidence by means of a collimator, and is refracted through the vertical face, the deviation being observed by a telescope rotating about a graduated circle. From this the refractive index is readily calculated if the refractive index of the prism for the light used be known; a fact supplied by the maker. The instrument is also available for determining the refractive index of isotropic solids. A little of the solid is placed in the vessel and a mixture of monobromnaphthalene and acetone in which the solid must be insoluble is added, and adjustment made by adding either one or other liquid until the border line appears sharp, i.e. until the liquid has the same index as the solid.

The Herbert Smith refractometer (fig. 7) is especially suitable for determining the refractive index of gems, a constant which is at a certain angle to the axis of the instrument. Light is admitted by a window on the under side, which is inclined at the same angle, but in the opposite sense, to the axis. The light on emerging from the hemisphere is received by a convex lens, in the focal plane of which is a scale graduated to read directly in refractive indices. The light then traverses a positive eye-piece. To use the instrument for a gem, a few drops of methylene iodide (the refractive index of which may be raised to 1-500 by dissolving in it) are placed on the plane surface of the hemisphere and a facet of the stone then brought into contact with the surface. If monochromatic light be used (i.e. the D line of the sodium flame) the field is sharply divided into a light and a dark portion, and the position of the line of demarcation on the scale immediately gives the refractive index. It is necessary for the liquid to have a higher refractive index than the crystal, and also that there is close contact between the facet and the lens. The range of the instrument is between 1-400 and 1-760, the results being correct to two units in the third decimal place if sodium light be used. (C. E. *)

II. Double Refraction

That a stream of light on entry into certain media can give rise to two refracted pencils was discovered in the case of Iceland spar by Erasmus Bartholinus, who found that one pencil had a direction given by the ordinary law of refraction, but that the other was bent in accordance with a new law that he was unable to determine. This law was discovered about eight years later by Christian Huygens. According to Huygens' fundamental principle, the law of refraction is determined by the form and orientation of the wave-surface in the crystal—the locus of points to which a disturbance emanating from a luminous point travels in unit time. In the case of a doubly refracting medium the wave-surface must have two sheets, one of which is spherical, if one of the pencils obey in all cases the ordinary law of refraction. Now Huygens observed that a natural crystal of spar behaves in precisely the same way whichever pair of faces the light passes through, and inferred from this fact that the second sheet of the wave-surface must be a surface of revolution round a line equally inclined to the faces of the rhomb, i.e. round the axis of the crystal. He accordingly assumed it to be a spheroid, and finding that refraction in the direction of the axis was the same for both streams, he concluded that the sphere and the spheroid touched one another in the axis. So far as his experimental means permitted, Huygens verified the law of refraction deduced from this hypothesis, but its correctness remained unrecognized until the measures of W. H. Wollaston in 1802 and of E. T. Malus in 1810. Moreover, its truth has been established with far more perfect optical appliances by R. T. Glazebrook, Ch. S. Hastings and others.

In the case of Iceland spar and several other crystals the extraordinarily refracted stream is refracted away from the axis, but Jean Baptiste Biot in 1814 discovered that in many cases the reverse occurs, and attributing the extraordinary refractions to forces that act as if they emanated from the axis, he called crystals of the latter kind "attractive," those of the former "repulsive." They are now termed "positive" and "negative" respectively; and Huygens' law applies to both classes, the spheroid being prolate in the case of positive, and oblate in the case of negative crystals. It was at first supposed that Huygens' law applied to all doubly refracting media. Sir David Brewster, however, in 1815, while examining the rings that are seen round the optic axis in polarized light, discovered a number of crystals that possess two optic axes. He showed, moreover, that such crystals belong to the rhombic, monoclinic and anorhnic (triclinic) systems, those of the tetragonal and hexagonal systems being uniaxial, and those of the cubic system being optically isotropic.

Huygens found in the course of his researches that the streams that had traversed a rhomb of Iceland spar had acquired new properties with respect to transmission through a second crystal. This phenomenon is called polarization (q.v.), and the waves are said to be polarized—the ordinary in its principal plane and the extraordinary in a plane perpendicular to its principal plane, the principal plane of a wave being the plane containing its normal and the axis of the crystal. From the facts of polarization Augustin Jean Fresnel deduced that the
vibrations in plane polarized light are rectilinear and in the plane of the wave, and arguing from the symmetry of uniaxial crystals that vibrations perpendicular to the axis are propagated with the same speed in all directions, he pointed out that this would explain the existence of an ordinary wave, and the relation between its speed and that of the extraordinary wave. From these ideas Fresnel was forced to the conclusion, that he at once verified experimentally, that in biaxial crystals there is no spherical wave, since there is no single direction round which such crystals are symmetrical; and, recognizing the difficulty of a direct determination of the wave-surface, he attempted to represent the laws of double refraction by the aid of a simpler surface.

The essential problem is the determination of the propagational speeds of plane waves as dependent upon the directions of their normals. These being known, the deduction of the wave-surface follows at once, since it is to be regarded as the envelope at any subsequent time of all the plane waves that at a given instant may be supposed to pass through a given point, the ray corresponding to any tangent plane or the direction of transport of energy being by Huygens' principle the radius-vector from the centre to the point of contact. Now Fresnel perceived that in uniaxial crystals the speeds of plane waves in any direction are by Huygens' law the reciprocals of the semi-axes of the central section, parallel to the wave-fronts, of a spheroid, whose polar and equatorial axes are the reciprocals of the equatorial and polar axes of the spheroidal sheet of Huygens' wave-surface, and that the plane of polarization of a wave is perpendicular to the axis that determines its speed. Hence it occurred to him that similar relations with respect to an ellipsoid with three unequal axes would give the speeds and polarizations of the waves in a biaxial crystal, and the results thus deduced he found to be in accordance with all known facts. This ellipsoid, he called the ellipsoid of polarization, the index ellipsoid and the indicatrix.

We may go a step further; for by considering the intersection of a wave-front with two waves, whose normals are indefinitely near that of the first and lie in planes perpendicular and parallel respectively to its plane of polarization, it is easy to show that the ray corresponding to the wave is parallel to the line in which the former of the two planes intersects the tangent plane to the ellipsoid at the end of the semi-diameter that determines the wave-velocity; and it follows by similar triangles that the ray-velocity is the reciprocal of the length of the perpendicular from the centre on this tangent plane. The laws of double refraction are thus contained in the following proposition: The propagational speed of a plane wave in any direction is given by the reciprocal of one of the semi-axes of the central section of the ellipsoid of polarization parallel to the wave; the plane of polarization of the wave is perpendicular to this axis; the corresponding ray is parallel to the line of intersection of the tangent plane at the end of the axis and the plane containing the axis and the wave-normal; the ray-velocity is the reciprocal of the length of the perpencular from the centre on the tangent plane. By reciprocating with respect to a sphere of unit radius concentric with the ellipsoid, we obtain a similar proposition in which the ray takes the place of the wave-normal, the ray-velocity that of the wave-slowness (the reciprocal of the velocity) and vice versa. The wave-surface is thus the apsidal surface of the reciprocal ellipsoid; this gives the simplest means of obtaining its equation, and it is readily seen that its section by each plane of optical symmetry consists of an ellipse and a circle, and that in the plane of greatest and least wave-velocity these curves intersect in four points. The radii-vectors to these points are called the ray-axes.

When the wave-front is parallel to either system of circular sections of the ellipsoid of polarization, the problem of finding the axes of the parallel central section becomes indeterminate, and all waves in this direction are propagated with the same speed, whatever may be their polarization. The normals to the circular sections are thus the optic axes. To determine the rays corresponding to an optic axis, we may note that the ray and the 'perpendiculars to it to through the centre, in planes perpendicular and parallel to that of the ray and the optic axis, are three lines intersecting at right angles of which the two latter are confined to given planes, viz. the central circular section of the ellipsoid and the normal section of the cylinder touching the ellipsoid along this section: whence by a known proposition the ray describes a cone whose sections parallel to the given planes are circles. Thus a plane perpendicular to the optic axis touches the wave-surface along a circle. Similarly the normals to the circular sections of the reciprocal ellipsoid, or the axes of the tangent cylinders to the polarization-ellipsoid, form circular normal sections, and directions of single-ray velocity or ray-axes, and it may be shown as above that corresponding to a ray-axis there is a cone of wave normals with circular sections parallel to the normal section of the corresponding tangent cylinder, and its plane of contact with the ellipsoid. Hence the extremities of the ray-axes are conical points on the wave-surface. These peculiarities of the wave-surface are the cause of the celebrated conical refractions discovered by Sir William Rowan Hamilton and H. Lloyd, which afford a decisive proof of the general correctness of Fresnel's law, though they cannot, as Sir G. Gabriel Stokes (Math. and Phys. Papers, iv. 183) has pointed out, be employed to decide between theories that lead to this surface as a near approximation.

In general, both the direction and the magnitude of the axes of the polarization-ellipsoid depend upon the frequency of the light and upon the temperature, but in many cases the possible variations are limited by considerations of symmetry. Thus the optic axis of a uniaxial crystal is invariably, being determined by the principal axis of the system to which it belongs; most crystals are of the same sign for all colours, the refractive indices and their difference both increasing with the frequency, and a few crystals are of opposite sign for the extraordinary and ordinary polarizations, becoming isotropic for some intermediate wave-length. In crystals of the rhombic system the axes of the ellipsoid coincide in all cases with the crystallographic axes, but in a few cases their order of magnitude changes so that the plane of the optic axes for red light is at right angles to that for blue light, the crystal being uniaxial for an intermediate colour. In the case of the monoclinic system one axis is in the direction of the axis of the system, and this is generally, though there are notable exceptions, either the greatest, the least, or the intermediate axis of the ellipsoid for all colours and temperatures. In the latter case the optic axes are in the plane of symmetry, and a variation of their acute bisectrix occasions the phenomenon known as "inclined dispersion": in the two former cases the plane of the optic axes is perpendicular to the plane of symmetry, and if it vary with the colour of the light, the crystals exhibit "crossed" or "horizontal dispersion" according as it is the acute or the obtuse bisectrix that is in the fixed direction.

The optical constants of a crystal may be determined either with a prism or by observations of total reflection. In the latter case the phenomenon is characterized by two angles—the critical angle and the angle between the plane of incidence and the plane limiting the region of total reflection in the field of view. With any crystalline surface there are four cases in which this latter angle is 90°, and the principal refractive indices of the crystal are obtained from those calculated from the corresponding critical angles, by excluding that one of the mean values for which the plane of polarization of the limiting rays is perpendicular to the plane of incidence. A difficulty, however, may arise when the crystalline surface is very nearly the plane of the optic axes, as the plane of polarization in the second mean case is then also very nearly perpendicular to the plane of incidence; but since the two mean refractive indices will be very different, the ambiguity can be removed by making as may easily be done, an approximate measure of the angle between the optic axes and comparing it with the values calculated by using in turn each of these indices (C. M. Viola, Zeit. für Kryst., 1902, 36, p. 245).

A substance originally isotropic can acquire the optical
properties of a crystal under the influence of homogeneous strain, the principal axes of the wave-surface being parallel to those of the strain, and the medium being uniaxial, if the strain be symmetrical. John Kerr also found that a dielectric under electric stress behaves as an uniaxial crystal with its optic axis parallel to the electric force, glass acting as a negative and bisulphide of carbon as a positive crystal (Phil. Mag., 1875 (4), L. 337).

Not content with determining the laws of double refraction, Fresnel also attempted to give their mechanical explanation. He supposed that the aether consists of a system of distinct material points symmetrically arranged and acting on one another by forces that depend for a given pair only on their distance. If in such a system a single molecule be displaced, the projection of the force of restitution on the direction of displacement is proportional to the inverse square of the parallel radius-vector of an ellipsoid; and of all displacements that can occur in a given plane, only those in the direction of the axes of the parallel central section of the quadric develop forces whose projection on the plane is along the displacement. In undulations, however, the system is conceived as vibrated, the plastic forces due to relative displacements, and, accordingly, Fresnel assumed that the forces called into play during the propagation of a system of plane waves (of rectilinear transverse vibrations) differ from those developed by the parallel displacement of a single molecule only by a constant factor, independent of the plane of the wave. Next, regarding the aether as incompressible, he assumed that the components of the elastic forces parallel to the wave-front are alone operative, and finally, on the analogy of a stretched string, that the propagational speed of a plane wave of permanent type is proportional to the square root of the effective force developed by the vibrations. With these hypotheses we immediately obtain the laws of double refraction, as given by the ellipsoid of polarization, with the result that the vibrations are perpendicular to the plane of polarization.

In its dynamical foundations Fresnel's theory, though of considerable historical interest, is clearly defective in rigour, and a strict treatment of the aether as a crystalline elastic solid does not lead naturally to Fresnel's laws of double refraction. On the other hand, Lord Kelvin's rotational aether (Math. and Phys. Papers, iii. 442)—a medium that has no true rigidity but possesses a quasi-rigidity due to elastic resistance to absolute rotation—gives the result that the aether furnishes the necessary mechanism, regarding it as gyrostatically isotropic, attribute to it aerotropic inertia. The equations then obtained are the same as those deduced in the electro-magnetic theory from the circuitual laws of A. M. Ampère and Michael Faraday, when the specific inductive capacity is supposed aerotropic. In order to account for dispersion, it is necessary to take into account the interaction with the radiation of the intra-molecular vibrations of the crystalline substance: thus the total current on the electro-magnetic theory must be regarded as made up of the current of displacement and that due to the oscillations of the electrons within the molecules of the crystal.

BIBLIOGRAPHY.—An interesting and instructive account of Fresnel's work on double refraction has been given by Émile Verdet in his introduction to Fresnel's works: Oeuvres d'Augustin Fresnel, l. 75 (Paris, 1866); Oeuvres d'É. Verdet, i. 360 (Paris, 1873). The most complete account of theories of double refraction see the reports of H. Lloyd, Sir G. G. Stokes and R. T. Glazebrook in the Brit. Ass. Reports for 1834, 1862 and 1885, and Lord Kelvin's Baltimore Lectures (1904). An exposition of the rotational theory of the aether has been given by H. C. Hart, Théorie gyrostatique de la lumière (Paris, 1904); and P. Drude's Lehrbuch der Optik, 2nd Aufl. (1906), the first German edition of which was translated by C. Riborg Mann and A. R. Meyer (1912), treats from the standpoint of the electro-magnetic theory. The methods of determining the optical constants of crystals will be found in Th. Liebisch's Physikalische Kristallographie (1891); F. Pockel's Lehrbuch der Kristallographie (1906), and G. Walker's Theory of Light (1904). A detailed list of papers on the geometry of the wave-surface has been published by E. Wölfing, Bild. Math., 1902 (3), iii. 361; and a general account of the subject will be found in the following treatises: L. Fletcher, The Optical Indicatrix (1892); Th. Preston, The Theory of Light, 3rd ed. by C. J. Joly (1901); A. Schuster, An Introduction to the Theory of Optics (1904); R. W. Wood, Physical Optics (1905); E. Mascart, Traité d'optique (1886); A. Winkelmann, Handbuch der Physik. (J. Wal.)

III. Astronomical Refraction

The refraction of a ray of light by the atmosphere as it passes from a heavenly body to an observer on the earth's surface, is called "astronomical." A knowledge of its amount is a necessary datum in the exact determination of the direction of the body. In its investigation the fundamental hypothesis is that the strata of the air are in equilibrium, which implies that the surfaces of equal density are horizontal. But this condition is being continually disturbed by aerial currents, which produce continual slight fluctuations in the actual refraction, and commonly give to the image of a star a tremulous motion. Except for this slight motion the refraction is always in the vertical direction; that is, the actual zenith distance of the star is always greater than its apparent distance. The refracting power of the air is nearly proportional to its density. Consequently the amount of the refraction varies with the temperature and baromeric pressure, being greater the higher the barometer and the lower the temperature.

At low zenith distances, the amount of the refraction varies nearly as the tangent of the zenith distance. Under ordinary conditions of pressure and temperature it is, near the zenith, about 1° for each degree of zenith distance. As the tangent increases at a greater rate than the angle, the increase of the refraction soon exceeds 1° for each degree. At 45° from the zenith the tangent is 1 and the mean refraction is about 58°. As the horizon is approached the tangent increases more and more rapidly, becoming infinite at the horizon; but the refraction now increases at a less rate, and, when the observed ray is horizontal, or when the object appears on the horizon, the refraction is, for a little greater than the diameter of the sun or moon. It follows that when either of these objects is seen on the horizon their actual direction is entirely below it. One result is that the length of the day is increased by refraction to the extent of about five minutes in low latitudes, and still more in higher latitudes. At 60° the increase is about nine minutes.

The atmosphere, like every other transparent substance, refracts the blue rays of the spectrum more than the red; consequently, when the image of a star near the horizon is observed with a telescope, it presents somewhat the appearance of a spectrum. The edge which is really highest, but because closest in the telescope, is blue, and the opposite one red. When the atmosphere is steady this atmospheric spectrum is very marked and renders an exact observation of the star difficult.

BIBLIOGRAPHY.—Refraction has been a favourite subject of research. See Dr. C. Bruhns, Die astronomische Strahlenbrechung (Leipzig, 1861), gives a résumé of the various formulæ of refraction which had been developed by the leading investigators up to the date 1861. Since then developments of the theory are found in: W. Chauvenet, Spherical and Practical Astronomy; F. Brünn, Sphärische Astronomie; R. Radau, "Recherches sur la théorie des réfractions astronomiques" (Annales de l'observatoire de Paris, xvi., 1882); "Essai sur les réfractions astronomiques" (ibid., xix., 1886). Among the tables of refraction which have been most used are Bessel's, derived from the observations of Bradley in Bessel's Fundamentum Astronomiae; and Bessel's revised tables in his Tabulae Regiomontanae, in which, however, the constant is too large, but which in an expanded form were mostly used at the observatories until 1870. The constant used of the Poulkova tables, Tabulae refractionum, which is reduced to nearly its true value, has gradually replaced that of Bradley. Later tables are those of de Poulain, published at Leipzig in 1906.

REFRESHER, in English legal phraseology, a further or additional fee paid to counsel where a case is adjourned from one term or sitting to another, or where it extends over more than one day and occupies, either on the first day or partly on the first and partly on a subsequent day or days, more than five hours without being concluded. The refresher allowed for every clear day subsequent to that on which the five hours have expired is five to ten guineas for a leading counsel and from three to seven guineas for other counsel, but the taxing
master is at liberty to allow larger fees in special circumstances. See Rules of the Supreme Court, O. 65, r. 48.

**REFRIGERATING and ICE-MAKING.** "Refrigeration" (from Lat. frigus, frost) is the cooling of a body by the transfer of a portion of its heat to another and therefore a cooler body. For ordinary temperatures it is performed directly with water as the cooling agent, especially when well water, which usually has a temperature of from 52° to 55° F., can be obtained. There are, however, an increasingly large number of cases in which temperature below that of any available natural cooling agent is required, and in these it is necessary to resort to machines which are capable of supplying the required cooling effect by taking in heat at low temperatures and rejecting it at temperatures somewhat above that of the natural cooling agent, which for obvious reasons is generally water. The function of a refrigerating machine, therefore, is to take in heat at a low temperature and reject it at a higher one.

This involves the expenditure of a quantity of work $W$, the amount in any particular case being found by the equation $W = Q_1 - Q_0$, where $W$ is the work, expressed by its equivalent in British thermal units, the quantity of heat, also in B.T.U., given out at the higher temperature $T_1$; and $Q_0$ the heat taken in at the lower temperature $T_0$. It is evident that the discharged heat $Q_1$ is equal to the abstracted heat $Q_0$, plus the work expended, seeing that the work $W$, which causes the rise in temperature from $T_0$ to $T_1$, is the thermal equivalent of the energy actually expended in raising the temperature to the level at which it is rejected. The relation then between the work expended and the actual cooling work performed denotes the efficiency of the process, and this is expressed by $Q_1/(Q_1 - Q_0)$; but as in a perfect refrigerating machine it is understood that the whole of the heat $Q_0$ is taken in at the absolute temperature $T_0$, and the whole of the heat $Q_1$ is rejected at the absolute temperature $T_1$, the heat quantities are proportional to the temperatures, and the expression $T_1/(T_1 - T_0)$ gives the ideal coefficient of performance for any stated temperature range, whatever working substance is used. These coefficients for a number of cases met with in practice are given in the following table. They are strictly very much above the temperature to be maintained in the room, because the cooling effect is produced by transferring heat from the room or its contents to the air, which is thereby heated. The rise in temperature of the air is, in fact, the measure of the cooling effect produced. If such a machine could be constructed with reasonable mechanical efficiency it could not compress the air to a temperature but slightly above that of the cooling water, and to expand the air to a temperature but slightly below that required to be maintained in the room, we should of course get a result approximating in efficiency somewhat nearly to the figures given in Table I. Unfortunately, however, such results cannot be obtained in practice, because the extreme lightness of the air and its very small heat capacity (which at constant pressure is -2370°) would necessitate the employment of a great volume, with extremely large and mechanically inefficient cylinders and apparatus. A pound of air, representing about 1200 lb. ft., if raised 10° F. will only take up about 2:4 B.T.U. Consequently, to make such a machine practicably successful a comparatively small weight of air must be used, and the temperature difference increased; in other words, the air must be discharged at a temperature much below that to be maintained in the room.

This theory of working is founded on the Carnot cycle for a perfect heat motor, a perfect refrigerating machine being simply a reversed heat motor. Another theory involves the use of the Stirling regenerator, which was proposed in connexion with the Stirling engine (see the Air Engines). The practical application of this was first attempted by Dr. A. Kirk in 1862, and described by him in a paper on the "Mechanical Production of Cold" (Proc. Inst. C.E., xxvii., 1874, 244), is simply a reversed Stirling air engine, the air working in a closed cycle instead of being actually discharged into the room to be cooled, as is the usual practice with ordinary compressed-air machines. Kirk's machine was used commercially with success on a fairly large scale, chiefly for ice-making; and it is recorded that it produced about 4 lb of ice for 1 lb of coal. In 1868 J. Davy Postle read a paper before the Royal Society of Victoria, suggesting the conveyance of meat on board ship in a frozen state by means of refrigerated air, and in 1869 he showed by experiment how it could be done; but his apparatus was not commercially developed. In 1877 a compressed-air machine was designed by J. J. Coleman of Glasgow, and in the early part of 1879 one of his machines was fitted to a board ship named "Glenlee," of 10,000 tons. It successfully brought a cargo of chilled beef from America—the first imported by the aid of refrigerating machinery, ice having been previously used. The first successful cargo of frozen mutton from Australia was also brought by a Bell-Coleman machine in 1879. In the Bell-Coleman machine the air was cooled during compression by means of an injection of water, and further by being brought into contact with a shower of water. Another, perhaps the principal, feature was the interchanger, an apparatus whereby the compressed air was further cooled before expansion by means of the comparatively cold air from the room in its passage to the compressor, the same air being used over and over again. The object of this interchanger was not only to cool the compressed air before expansion, but to condense part of the moisture in it, so reducing the quantity of ice or snow produced during expansion. A full description of the machine may be found in a paper on "Air Refrigerating Machinery" by J. J. Coleman (Proc. Inst. C.E. lviii., 1882). At the present time the Bell-Coleman machine has practically ceased to exist. In such compressed-air machines,

show that in all cases the heat abstracted exceeds by many times the heat expended. As an instance, when heat is taken in at 0° and rejected at 70°, a perfect refrigerating machine would abstract 6-6 times as much heat as the equivalent of the energy to be applied. If, however, the heat is to be rejected at 100°, then the coefficient is reduced to 4-6.

By examining Table I, it will be seen how important it is to reduce the temperature range as much as possible, in order to obtain the most economical results. No actual refrigerating machine does, in fact, take in heat at the exact temperature of the body to be cooled, and reject it at the exact temperature of the cooling water, but, for economy in working, it is of great importance that the differences should be as small as possible.

There are two distinct classes of machines used for refrigerating and ice-making. In the first refrigeration is produced by the expansion of atmospheric air, and in the second by the evaporation of a more or less volatile fluid.

**Compressed-air Machines.**—A compressed-air refrigerating machine consists in its simplest form of three essential parts—a compressor, a compressed-air cooler, and an expansion cylinder. It is shown diagrammatically in fig. 1 in connexion with a chamber which is keeping cool. The compressor draws in air from the room and compresses it, the work expended in compression being almost entirely converted into heat. The compressed air, leaving the compressor at the temperature $T_0$, passes through the cooler, where it is cooled by means of water, and is then admitted to the expansion cylinder, where it is expanded to atmospheric pressure, performing work on the piston. The heat equivalent of the mechanical work performed on the piston is abstracted from the air, which is discharged at the temperature $T_1$. This temperature $T_1$ is necessarily

31

as are now made there is no injection of water during compression, and the compressed air is cooled in a surface cooler, not by actual mixture with a shower of cold water. Further, though the air-changer is still used by some makers, it has been found by experience that, with properly constructed valves and passages in the expansion cylinder, there is no trouble from the formation of snow, when, as is the general practice, the same air is used over and over again in the compressor taking its supply from the insulated room. So far as the air discharged from the expansion cylinder is concerned, its heat is removed by the atmosphere. Its temperature rising to about 350° F. The compressed air then passes through coolers in which it is cooled to within about 5° of the initial temperature of the cooling water, and is deprived of a portion of its moisture, after which it is admitted into the expansion cylinder and expanded nearly to atmospheric pressure. The thermal equivalent of the power exerted on the piston is taken from the air, which, with cooling water at 60° F. and after allowing for friction and other losses, is discharged at a temperature of 60° to 80° below zero F. according to the size of the machine. The mumps of the compression and expansion cylinders are connected to the same crankshaft, and the difference between the power expended in compression and that restored in expansion, plus the friction of the machine, is supplied by means of a steam engine coupled to the crankshaft, or by any other source of power. For marine purposes two complete machines are frequently mounted on one bed-plate and worked either together or separately.

In some machines used in the United States the cold air is not discharged into the rooms but is worked in a closed cycle, the rooms being cooled by means of overhead pipes through which the cold expanded air passes on its way back to the compressor.

Liquid Machines.—Machines of the second class may conveniently be divided into three types: (a) Those in which there is no recovery of the refrigerating agent, water being the agent employed; they will be dealt with as "Vacuum machines." (b) Those in which the agent is recovered by means of mechanical compression; they are termed "Compression machines." (c) Those in which the agent is recovered by means of absorption by a liquid; they are known as "Absorption machines."

In the first class, since the refrigerating liquid is itself rejected, the only agent cheap enough to be employed is water. The Vacuum machines, one atmosphere or 14.7 lb per square inch it is 212° F., whereas at a pressure of 0.085 lb per square inch it is 32°, and at lower pressures there is a still further fall in temperature. This property is made use of in vacuum machines. Water at ordinary temperature, say 60°, is placed in an air-tight glass or insulated vessel, and when the pressure is reduced by means of a vacuum pump it begins to boil, the heat necessary for evaporation being taken from the water itself. The pressure being still further reduced, the temperature is gradually lowered until the freezing-point is reached and ice formed, when about one-sixth of the original volume has been evaporated.

The earliest machines of this kind appear to have been made in 1755 by Dr. William Cullen, who produced the vacuum by means of a pump alone. In 1810 Sir John Leslie combined with the air pump a vessel containing strong sulphuric acid for absorbing the vapour from the air, and it is said to have succeeded in producing 1 to 1½ lb of ice in a single operation. E. C. Carré later adopted the same principle. In 1878, F. Windhausen patented a vacuum machine for producing ice in large quantities, and in 1881 one of these machines, said to be capable of making about 12 tons of ice per day, was put to work in London. The installation was fully described by Carl Pieper (Trans. of Engineers, 1882, p. 145) and by Dr. John Hopkinson (Journal of Soc. of Arts, 1882, vol. xxxi. 240). The largest, however, being too expensive, the commercial point of view, was abandoned. At the present time vacuum machines are only employed for domestic purposes. The hand apparatus invented by H. A. Fleuss consists of a vacuum pump capable of reducing the air pressure to a fraction of a millimetre, the suction pipe of which is connected first with a vessel containing sulphuric acid, and second with the vessel containing the water to be frozen. Both these vessels are mounted on a rocking base, so that the acid can be thoroughly agitated while the machine is being worked. As soon as the pump has sufficiently exhausted the air from the vessel containing the water, vapour is rapidly given off and is absorbed by the acid until sufficient heat has been abstracted to bring about the desired reduction in temperature, the acid becoming heated by the absorption of water vapour, while the water freezes. The small Fleuss machine will produce about 1½ lb of ice in one operation of 20 minutes. Iced water in a carafe for drinking purposes can be produced in about three minutes. The acid vessel holds 9 lb of acid, and nearly 3 lb of ice can be made for each 1 lb of acid before the acid has become too weak to do further duty. Another machine, which can be easily worked by a boy, will produce 20 to 30 lb of ice in one hour, and is perhaps the largest size practicable with this method. The temperature attainable depends on the strength and condition of the sulphuric acid; ordinarily it can be reduced to zero F., and temperatures 20° lower have frequently been obtained.

Though prior to 1834 several suggestions had been made with regard to the production of ice and the cooling of liquids by the evaporation of a more volatile liquid than water, the Compression machine actually constructed and put to work was made by John Hague in that year from the designs of Jacob Perkins (Journal of Soc. of Arts, 1884, vol. xxxi. p. 77). This machine, though never used commercially, is the patent of all modern compression machines. Perkins in his patent specification states that the volatile fluid is by preference ether. In 1856 and 1857 James Harrison of Geelong, Victoria, patented a machine embodying the same principle as that of Perkins, but worked out in a much more complete and practical manner. It is stated that these machines were first made in New South Wales in 1859, but the first Harrison machine adopted successfully for industrial purposes in England was applied in the year 1861 for cooling oil in order to extract the paraffin. In Harrison's machine the agent used was ether (C,H)O. Improvements were made by Siebe & Company of London, and a considerable number of ether machines both for ice-making and refrigerating purposes were supplied by that firm and others up to the year 1880. In 1870 the subject of refrigeration was investigated by Professor Carl Linde of Munich, who was the first to consider the question from a thermodynamic point of view. He dealt with the coefficient of performance as a common basis of comparison for all machines, and showed that the compression vapour machine more nearly reached the theoretical maximum than any other (Bayerisches Industr. und Gewerkhblatt, 1870 and 1871). Linde also examined the physical properties of various fluids, and, after making trials with methyllic ether in 1872, built his first ammonia compression machine in 1873. Since then the ammonia compression machine has been most widely adopted, though the carbonic acid machine, also compression, which was first made in 1850 from Linde's designs, is now used to a considerable extent, especially on board ship.

A diagram of a vapour compression machine is shown in fig. 2. There are three principal parts, a refrigeration or evaporator, a compression pump, and a condenser. The refrigeration, which

![Fig. 2.—Vapour Compression Machine.](attachment://vapour_compression_machine.png)
REFRIGERATING

consists of a coil or series of coils, is connected to the suction side of the pump, and the delivery side of the pump is connected to the condenser, which is generally of somewhat similar construction to the refrigerator. The condenser is cooled by air or water. The refrigerating liquid (ether, sulphur dioxide, anhydrous ammonia, or carbonic acid) passes from the bottom of the condenser through the regulating valve into the coil or series of coils, and the pressure is reduced by the condenser being reduced by the pump and maintained at such a degree as to give the required boiling-point, which is of course always lower than the temperature outside the coils. The heat passes from the substance outside, through the liquid medium and is taken up by the heating liquid, which is converted into vapour at the temperature $T_1$. The vapours thus generated are introduced into the pump, compressed, and discharged into the condenser at the temperature $T_2$, which is somewhat above that of the condenser. Heat is transferred to the condenser, compressed vapour to the cooling water and the water is converted into a liquid, which collects at the bottom and returns by the regulating valve into the refrigerator. As heat is both taken in and discharged at constant temperature during the change in physical state of the agent, a vapour compression machine must approach the ideal much nearer than a compressed-air machine, in which there is no such change.

This will be seen by taking as an example a case in which the cold room is to be kept at $10^\circ$ F., the cooling water being at $60^\circ$ F. Under these conditions, the actual evaporating temperature $T_1$ is not 70°F. as the 70°F. is the coefficient of about 5-7, or nearly six times that of an ideal compressor-air machine of usual construction performing the same useful cooling work.

A vapour compression machine does not, however, work precisely in the reversed Carnot cycle, inasmuch as the fall in temperature between the condenser and the refrigerator is not produced, nor is it attempted to be produced, by the adiabatic expansion of the agent, but results from the evaporation of a portion of the liquid itself. In other words, the liquid-refrigerating agent enters the refrigerator at the condenser temperature and introduces heat which has to be taken up by the evaporating liquid before any cooling effect can be performed. The temperature of the liquid is determined by the relation between the liquid heat and the latent heat of vaporization at the refrigerator temperature. If $r$ represents the latent heat of the liquid, and $q$ the change of state of heat discharged in the liquid at the respective temperatures of $T_1$ and $T_2$, then the loss from the heat carried out of the condenser into the refrigerator is represented by $(q-qr)/r$, and the useful refrigeration effect produced in the refrigerator is $r(r-q)/r$. Assuming the previous example that $T_1$ is 75°F. and that $T_2$ is 5°F. below zero, the results for various refrigerating agents are as follows:

The results show that the loss is least in the case of anhydrous ammonia and greatest in the case of carbonic acid. At higher condenser temperatures the results are even more much more favourable to anhydrous ammonia than for the critical temperature (88.4°F.). If the carbonic acid is approached, the value of $r$ becomes less and less and the refrigerating effect is much reduced. When the critical point is reached the value of $r$ disappears altogether, and a carbonic-acid machine is then dependent for its refrigerating effect on the reduction in temperature produced by the internal work performed in expanding the gaseous carbonic acid from the condenser pressure to that in the refrigerator. The absorption of heat does not then take place at any fixed temperature. The temperature of the refrigerating liquid in the refrigerator at a temperature below that of the substance to be cooled, and whatever cooling effect is produced is brought about by the superheating of the vapour, the result being that above the critical temperature of $190^\circ$ F., absorption of heat from the substance outside the refrigerator as shown by the line BC. The vapour is then compressed along the line CD to the temperature $T_3$, when, by the action of the cooling water in the condenser, heat is removed at constant temperature and the vapour condensed along the line DA.

In a compression machine the refrigerator is a series of iron or steel coils surrounded by the air, brine or other substance it
is desired to cool. One end (generally the bottom) of the coils is connected to the liquid pipe from the condenser and the other end to the suction line. Liquid from the condenser is admitted to the coils through an adjustable regulating valve, and by taking heat directly to the outer surface, the substance is evaporated. The vapour being continually drawn off by the compressor, the temperature at the evaporator increases. This pressure is admitted to the condenser. The condenser is constructed of coils like the water being contained in a tank; frequently, however, a series of open coils are employed, the cooling water falling on the coils into a collecting tray below, and this form is perhaps the most convenient for ordinary use as it affords great facilities for inspection and cleaning. The compressor may be driven by a steam engine or in any other convenient manner. The pressure in the condenser varies according to the temperature of the cooling water, and that in the refrigerator is dependent upon the temperature to which the outside substance is cooled. In an ammonia machine copper and copper alloys must be avoided, but for carbonic acid they are not objectionable.

The compression of ammonia is sometimes carried out on what is known as the Linde or "wet" system, and sometimes on the "dry" system. When wet compression is used the regulating valve is opened to such an extent that a little more liquid is passed than can be evaporated in the refrigerator. This liquid enters the condenser with the vapour which is condensed and is evaporated there, the heat taken up preventing the rise in temperature during compression which would otherwise take place. The compressed vapour is discharged at a temperature but little above that of the cooling water. With dry compression, vapour and liquid are drawn into the condenser and the temperature rises to as much as 180 or 200 degrees. Wet compression theoretically is not quite so efficient as dry compression, but it possesses practical advantages in keeping the working parts of the compressor cool, and it also greatly facilitates the regulation of the liquid, and ensures the full duty of the machine being continuously performed. Very exact comparative trials have been made by Professor M. Schroeter and others with compression machines using sulphur dioxide and ammonia. The results are published in Vergleichende Versuche an Kältemaschinen, by Schroeter, Munich, 1890, and in Nos. 32 and 51 of Bayerisches Industrie und Gewerbeblatt, 1894. The results obtained in 1892 on ordinary brine cooling machine on the Linde ammonia system are given in Table VI.:

The principle of the absorption process is chemical or physical rather than mechanical; it depends on the fact that many vapours of low boiling-point are readily absorbable in water, and can be separated again by the application of Absorption machines. of heat. In its simplest form an absorption machine consists of two iron vessels connected together by a heat pipe. One of these contains a mixture of ammonia and water, which on the application of heat gives off a mixed vapour containing a large proportion of ammonia, a liquid containing but little ammonia being left behind. In the second vessel, which is placed in cold water, the vapour rich in ammonia is condensed under pressure. To produce refrigeration the operation is reversed. On allowing the weak liquor to cool to normal temperature, it becomes greedy of ammonia (at 60° F. at atmospheric pressure water will absorb about 760 times its own volume of ammonia vapour), and this produces an evaporation from the liquid in the vessel previously used as a condenser. This liquid, containing a large proportion of ammonia, gives off vapour at a low temperature, and therefore becomes a refrigerant abstracting heat from water or any surrounding body. When the ammonia is evaporated the operation as described must be again commenced. Such an apparatus is not much used now. Larger and more elaborate machines were made by F. P. E. Carré in France; but no very high degree of perfection was arrived at, owing to the impossibility of getting an anhydrous product of distillation. In 1867 Rees Reece, taking advantage of the fact that two vapours of different boiling-points, when mixed, can be separated by means of fractional condensation, brought out an absorption machine in which the distillate was very nearly anhydrous. By means of vessels termed the absorber and the rectifier, the bulk of the water was condensed and then evaporated, and the vapours of the vapour at a relatively high temperature and run back to the generator, while the ammonia passed into a condenser, and there assumed the liquid form under the pressure produced by the heat in the generator and the cooling action of water circulating outside the condenser tubes.

FIG. 4. is a diagram of an absorption apparatus. The ammonia vapour given off in the refrigerator is absorbed by a cold weak solution of ammonia and water in the absorber, and the strong liquor is pumped back into the generator through an interchanger supplied with water, which also washes the hot liquor from the generator passes on its way to the absorber. In this way the temperature is heated before it enters the generator, and the weak liquor is cooled before it enters the absorber. The generator being heated by means of a steam coil, ammonia vapour is driven off, and pressure and vacuum adjustments cause its condensation in the absorber. From the condenser it passes into the refrigerator through a regulating valve in the usual manner. The process continues to be repeated with the ammonia of the compression machine, with the exception of the return from the temperature T1 to the temperature T2, which is brought about by the direct application of heat instead of by means of mechanical devices. With the ordinary brine cooling machine the same amount of heat has to be acquired in both cases, though from the nature of the process the actual amount of heat demanded from the absorber is much greater in the absorption system than in the compression. This is chiefly due to the fact that in the former of vaporization acquired in the refrigerator is rejected in the absorber, so that the whole heat of vaporization has to be supplied again by the steam in the generator. In the latter the vapour passes direct from the refrigerator to the pump, and power has to be expended merely in raising the temperature to a sufficient degree to enable condensation to occur at the temperature of the condenser. On the other hand, a great advantage is gained in the absorption machine by using the direct heat of the steam, without first converting it into mechanical work, for in this way the latent heat of vaporization can be utilized by condensing the steam in the coils and letting it escape in the form of water. One pound of steam can thus be made to give up some 950 units of heat; while in a good steam engine only about 200 units are utilized in the expansion machinery. In the absorption engine per unit of heat has to be made for mechanical inefficiency. In the absorption machine the cooling water has to take up about twice as much heat as in the compression system, owing to the ammonia being twice liquefied—namely, once in the absorber and once in the condenser. It is usual to pass the cooling water first through the condenser and then through the absorber.

The absorption machine is not so economical as the compressor, but an actual comparison between the two systems is difficult to make. Information on this head is given in papers read by Dr. Linde and by Professor J. A. Ewing before the Society of Arts in 1890, and in the Society of Arts and the Science of 1894, p. 322, and Howard and James in January, February and March 1897.

An absorption apparatus as applied to the cooling of liquids consists of a generator containing coils to which steam is supplied a regenerator, which is a coil containing water inside its coils, an absorber, and a condenser. The liquid in the absorber is evaporated, an absorption machine is made by heating the generator, and a pump for forcing the strong liquor produced in the absorber back through an economizer into the absorber where, meeting with steam from the generator, the ammonia is given off, the process is repeated with the absorption machine. Sometimes an additional vessel is employed for heating liquor by means of the exhaust steam from the engine driving the ammonia in the absorption machine is also made without a pump for returning the strong liquor to the generator. In these cases they work intermittently. In some machines the same vessel is used alternately as a generator and absorber, while in others, in order
to minimize the loss of time, two vessels are provided which can be used alternately as generators and absorbers.

Applications.—Apart from the economical working of the machine itself, whatever system may be adopted, it is of importance that cold once produced should not be wasted, and it is therefore necessary to use some form of insulation to protect the vessels in which liquids are being cooled, or the rooms of ships' holds in which the freezing or storage processes are being carried on. This insulation generally consists of materials such as charcoal, silicate cotton, granulated cork, small pumice, hair-felt, sawdust, &c., held between layers of wood or brick, and forming a more or less heat-tight box. There is no recognized standard of insulation. For a cold store to be erected inside a brick or stone building, and to be maintained at an internal temperature of from 12° to 20° F., a usual plan is shown in fig. 5. The same insulation is used for the floors and ceilings, except that the wearing surface of the floor is generally made thicker than the inside lining of the sides. Should the walls or floor be damp, waterproof paper is added. Granulated cork has practically the same insulating properties as silicate cotton, and the same thicknesses may be used. About 10 in. of flake charcoal and vegetable silica, or 11 of small pumice, are required to give the same protection as 7 in. of good silicate cotton. Cork bricks made of compressed granulated cork are frequently used, a thickness of about 5 in. giving the same protection as 7 in. of silicate cotton. The walls and ceilings are finished off with a smooth coating of hard cement and the floors are protected by cement or asphalt, according to the nature of the traffic on them. For lager-beer cellars and fermenting rooms, for bacon-curing cellars, and for similar purposes, brick walls with single or double air spaces are used, and sometimes a space filled with silicate cotton or other insulating material. In Australia and New Zealand pumice, which is found in enormous quantities in the latter country, takes the place of charcoal and silicate cotton. In Canada air spaces are largely used either alone or in combination with silicate cotton or in place of air spaces, two or three in number, are formed between two layers of tongued and grooved wood, and the total thickness of the insulation is about the same as when silicate cotton alone is used. On board ship charcoal has been almost entirely employed, but silicate cotton and granulated cork are sometimes used. The material is either placed directly upon the skin of the vessel, and kept in place by a double lining of wood inside, in which case a thickness of about 10 in. is used depending upon the depth of the frames, or it is placed between two layers of wood, with an air space next the skin, in which case about 6 in. of flake charcoal is generally sufficient for the insulation of the holds, though for deck-houses and other parts exposed to the sun the thickness must be greater.

A layer of sheet zinc or tin has frequently to be used as protection from rats. Given a certain allowable heat transmission, the principal points to be considered in connexion with insulation are, first cost, durability, weight and space occupied, the two last named being specially important factors on board ship. No exact rules can be laid down, as the conditions vary so greatly; and though experiments have been made to determine the actual heat conduction of various materials per unit of surface, thickness and temperature difference, the experience of actual practice is at present the only accepted guide.

With compressed-air machines which discharge the cold air directly into the insulated room or hold, a snow box is provided close to the outlet of the expansion cylinder to catch the snow and congealed oil. The air is distributed by means of wood air trunks with openings controlled by slides, and similar trunks are provided in connexion with the suction of the compressor to conduct the air back to the machine. With liquid machines of the compression and absorption system, the rooms are either cooled by means of cold pipes or surfaces placed in them, or by a circulation of air cooled in an apparatus separately from the rooms. The cold pipes may be direct-expansion pipes in which the liquid evaporates, or they may be pipes or walls through which circulates an uncongeable brine previously cooled to the desired temperature. The pipes are placed on the ceilings or sides according to circumstances, but they must be arranged so as to induce a circulation of air throughout the compartment and ensure every part being cooled. With what is termed the air circulation system the air is generally circulated by means of a fan, being drawn from the rooms through ducts, passed over a cooler, and returned again to the rooms by other ducts. In some coolers the cooling surfaces consist of direct-expansion pipes placed in clusters of convenient form; in others brine pipes are used; and, in others, there is a shower of cold brine, and in some cases pipes must be made and brine showers. Whether pipes in the rooms or air circulation give the best results is to some extent a matter of opinion, but at the present time the tendency is decidedly in favour of air circulation, at any rate for general cold storage purposes. Whatever system be adopted, it is important for economical reasons that ample cooling surface be allowed, and that all surfaces be kept clean and active, to make the difference between the temperature of the evaporating liquid and the rooms as small as possible. Small surfaces reduce first cost, but involve higher working expenses by decreasing the value of $\frac{1}{T_1} - \frac{1}{T_2}$, and thus demanding more energy, and consequently more fuel, to effect the given result than if larger surfaces were employed.

The general arrangement of an ice factory for producing can ice is shown in fig. 6. The water to be frozen is contained in galvanized or tinned steel moulds suspended in a tank containing warm water, and on being tipped the blocks of ice fall out. Ordinary water contains air, and ice made from it is generally opaque, due to the formation of numerous small air bubbles. To purify the water must be agitated during the freezing process, or previously boiled to get rid of the air. Distilled water is frequently used, as well as the water produced by the condensation of the steam from the engine, which of course must be thoroughly purified and filtered. It should be noted, however, that with an ice-making plant of moderate size and a steam-engine of good construction the weight of steam used will not nearly equal the weight of ice produced, so that the difference must be made up either by distillation, which is a costly process, or by ordinary water. Can ice is usually made in blocks weighing 56, 112 or 224 lb, and from 4 to 8 in. thick. For cell ice ordinary water is used, agitated
during freezing. The cells are flat and constructed of galvanized iron, so as to form a hollow space of about 2 in. in width, through which cold brine is circulated by a pump. They are placed vertically in a tank, the distance between them being from 8 to 14 in., according to the thickness of the ice to be produced. The tank is filled with water, which is kept in agitation by means of a reciprocating paddle or piston; in this way the air escapes, and with proper care a block of great transparency is produced. To thaw it off, warm brine is circulated through the cells. A usual size for cell ice is 4 ft. by 3 ft. by 1 ft. mean thickness, the weight being about 6 cwt. If perfectly transparent ice is required, the two sides of the block are not allowed to join up, and it is then called plate ice, which is often made in very large blocks, afterwards divided by saws or steam cutters. In such cases the evaporation of the ammonia or other refrigerating liquid frequently takes place in the cells themselves, brine being dispensed with. With a well-constructed can ice-plant of say 25 tons capacity per day, from 15 to 16 tons of ice should be made in Great Britain to a ton of best steam. As temperature between the River and the plate ice the production is considerably below this, and the first cost of the plant is much greater than that for can ice.

Fig. 7 shows an arrangement of cold storage on land, refrigerated on the air circulation system. The insulated rooms, on two floors,

![Fig. 7.-Cold Stores.](image)

are approached by corridors, so as to exclude external air, which if allowed to enter would deposit moisture upon the cold goods. The air cooler is placed at the end, and the air is distributed by means of large bronze fans furnished with slats for regulating the temperature of the rooms, which are insulated according to the method shown in fig. 5. In some cases, instead of the entrance being at the sides or ends, it is at the top, all goods being raised to the top floor in lifts and lowered by lifts into the rooms. With good machinery the cost of raising is not great, and is probably equalled by the saving in refrigeration, since the rooms hold the heavy cold air as a glass holds water.

Large passenger vessels and yachts are now generally fitted with refrigerating machinery, for preserving provisions, cooling water and wine, and making ice. Usually two insulated compartments are provided, one for frozen meat at about 20° F., and one for vegetables, etc., at about 40°. They have a capacity of from 1500 to 3000 cub. ft. or more, according to the number of passengers carried, and they are generally cooled by means of brine pipes, though sometimes to a greater extent.

A passenger vessel requires from 2 to 4 cwt. of ice per day. On battleships and cruisers the British Admiralty use small compressed-air machines for ice-making, and larger machines, generally on the carbolic-acid system, for cooling the magazines. A modern frozen-meat-carrying vessel will accommodate as much as 120,000 carcases, partly sheep and partly lambs, requiring a hold capacity of about 300,000 cub. ft. In some vessels both fore and aft holds and tween decks are insulated. Lloyd's Committee now issue certificates for refrigerating installations, if constructed according to their rules, and most modern cargo-carrying vessels have their refrigerating machinery classed at L.lib. In the meat trade between the United States, Canada, and Great Britain, ammonia or carbolic acid machines are now exclusively used, but for the Australian and New Zealand frozen-meat trade compressed-air machines are still employed to a small extent. The holds of meat-carrying vessels are refrigerated either by cold air circulation or by brine pipes.

Though the adoption of refrigerating and ice-making machinery for industrial purposes practically dates from the year 1880, the manufacture of these machines has already assumed very great proportions, and in the branch of machinery, with the exception of electrical machinery, there has been so remarkable a development in recent years. The sphere of application is extended every year by the growing and drying of the air blast furnaces. Though this matter had been discussed for some years, it was only in 1901 that the first plant was put to work at Pitsburg.

(REGAL) a small late-medieval portable organ, furnished with beating-reeds and having two bellows like a positive organ; also, any name that the medieval reeds (a) of a large organ, and more especially the "vox humana" stop. The name was not at first applied to the small table instrument, but to certain small brass pipes in the organ, sounded by means of beating-reeds, the longest of the 8-ft. tone being but 5½ in. long. Praetorius (1618) mentions a larger regal used in the court orchestras of some of the German princes, more like a positive, containing 4-ft., 8-ft. and even sometimes 16-ft. tone reeds, and having behind the case two bellows. These regals were not used not only at banquets but often to replace positives in small and large churches. The very small regal, sometimes called a "miniature regal", because it was as big as a book, is also mentioned by the same writer, who states that these little instruments, first made in Nuremberg and Augsburg, have an unpleasantly harsh tone, due to their tiny pipes, not quite an inch long. The pipes in this case were not intended to reinforce the vibrations of the beating-reed or of its overtones as in the reed pipes of the organ, but merely to form an attachment for keeping the reed in its place without interfering with its functions. The beating-reed itself in the older organs of the early middle ages, many of which undoubtedly were reed organs, was made of wood; those of the regal were generally of brass (hence their "brass voices"). The length of the vibrating portion of the beating-reed governed the pitch of the pipe and was regulated by means of a wire passing through the socket, the other end pressing on the reed at the proper distance. Drawings of the reeds of regals and other reed-pipes, as well as of the instrument itself, are given by Praetorius (pl. iv., xxxviii).

There is evidence to show that in England, and France also, the word "regal" was applied to reed-stops on the organ; Mersenne (1636) states that "now the word is applied to the vox humana stop in the organs." In England, as late as the reign of George III., there was the appointment of "tuner of the regals" to the Chapel Royal.

The reed-stops required constant tuning, according to Praetorius, who lays special emphasis on the fact that the pitch of the reed-pipes alone falls in summer and rises in winter.

During the 16th and 17th centuries the regal was a very great favourite, and although, owing to the civil wars and the ravages
REGALIA—REGENERATION OF LOST PARTS

REGALIA (Lat. regalis, royal, from regis, king), the emblems of royalty. The crown (see Crown and Coronets) and sceptre (see Sceptre) are dealt with separately. Other ancient symbols of royal authority are bracelets, the sword, a robe or mantle, and, in Christian times, a ring. Bracelets, as royal emblems, are mentioned in the Bible in connection with Saul (1 Sam. 9, 18), and they have been commonly used by Eastern monarchs. In Europe their later use seems to have been chiefly confined to England, although they were a very ancient ornament for kings among the Teutonic races. Two coronation bracelets are mentioned among the articles of the regalia ordered to be destroyed at the time of the Commonwealth, and two new ones were made at the Restoration. These are of gold, 1½ in. in width, and ornamented with the rose, thistle, harp and fleur-de-lis in enamel round them. They have not been used for modern coronations.

The sword is one of the usual regalia of most countries, and is given to the sovereign during the coronation. In England the sword has been developed into five. The Sword of State is borne before the sovereign on certain state occasions, and at the coronation is exchanged for a smaller sword, with which the king is ceremonially girded. The three other swords of the regalia are the "Curtana," the Sword of Justice to the Spirituality, and the Sword of Justice to the Temporality. The Curtana has a blade cut off short and square, indicating thereby the quality of mercy.

The mantle, as a symbol of royalty, is almost universal, but in the middle ages other quasi-royal robes were added to it. The mantle of the great coat was formerly made of silk; latterly cloth of gold has been used. The ring, by which the sovereign is wedded to his kingdom, is not of so wide a range of usage. That of the English kings held a large ruby with a cross engraved on it. Recently a sapphire has been substituted for the ruby. Golden spurs, though included among the regalia, are merely used to touch the king's feet, and are not worn.

The orb and cross was not apparently placed in the king's hands during the coronation ceremony, but was carried by him in the left hand on leaving the church. It is emblematical of monarchical rule, and is only worn by a reigning sovereign. The orb is undoubtedly derived from the globe with the figure of Victory with which the Roman emperors are depicted. The larger orb of the English regalia is a magnificent ball of gold, 6 in. in diameter, with a band round the centre edged with gems and pearls. A similar band arches the globe, on the top of which is a remarkably fine amethyst 1½ in. in height, upon which rests the cross of gold outlined with diamonds. There is a smaller orb made for Mary II., who reigned jointly with King William III.

The English regalia, with one or two exceptions, were made for the coronation of Charles II. by Sir Robert Vyner. The Scottish regalia preserved at Edinburgh comprise the crown, dating, in part, from Robert the Bruce, the sword of state given to James IV. by Pope Julius II., and two sceptres.

Besides regalia proper, certain other articles are sometimes included under the name, such as the ampulla for the holy oil, and the thurible (see Benedictine). It is the burial place of the dog's head and embryo are steps toward regenerating the missing organs, the blood corpuscles, the ends of the nails, and many other portions of tissues are continuously being destroyed and replaced. The hair of many mammals, the feathers of birds, the epidermis of reptiles, and the antlers of stag are shed and replaced periodically. In these normal cases the regeneration depends on the existence of special formative layers or groups of cells, and must be regarded in each case as a special adaptation, with individual limitations and peculiarities, rather than as a mere exhibition of the fundamental power of growth and reproduction displayed by living substance. Many tissues, even in the highest animals, are capable of replacing an abnormal loss of substance. Thus in mammals, portions of muscular tissue, of epithelium, of bone, and of nerve, after accidental destruction or removal, may be renewed. The characteristic feature of such cases appears to be, in the higher animals at any rate, that lost cells are replaced only from cells of the same morphological order—epithelial cells from the epiblast, mesoblastic from the mesoblast, and so forth. It is also becoming clear that, at least in the higher animals, regeneration is in intimate relation with the central nervous system. The process is in direct relation to the general power of growth and differentiation possessed by pathologists as the consequence of "removal of resistances to growth." It is much less common in the tissues of higher plants, in which the adult cells have usually lost the power of reproduction, and in which the regeneration of lost parts is replaced by a very extended capacity for budding. Still, more complicated reproductions of lost parts occur in many cases, and are more difficult to understand.

In Amphibia the entire epidermis, together with the slime-glands and sub-epidermal tissue, is lost in many hermaphrodites, and the cells of the body are at times regenerative in form. The regenerative power is not limited to the epidermis in vertebrates. In the lower vertebrates, and especially in the fish, there are processes of regeneration which appear to indicate an almost perfect power of the organism to replace lost parts. In higher vertebrates, the only instance of complete regeneration is that of the tongue in the newt. But many organs and parts are capable of regenerating a certain portion of their lost parts, and in this the higher animals are far superior to the lower. The regenerative powers of the adult animal are not nearly so extensive as those of the young animal, and are limited to a very few organs. The regeneration of certain parts is often very difficult or impossible in the adult animal. The regenerative powers of the adult animal are often subject to a great variety of influences, as environmental and pathological. The power of regeneration in the adult animal is often much less than that of the young animal, and is usually limited to certain organs or parts, and is subject to a great variety of influences, as environmental and pathological. The power of regeneration in the adult animal is often much less than that of the young animal, and is usually limited to certain organs or parts, and is subject to a great variety of influences, as environmental and pathological.
REGALIA

1. ST. EDWARD'S CROWN. The ancient crown was destroyed at the Commonwealth, and a model made for Charles II's coronation.

2. THE IMPERIAL STATE CROWN, as worn by Queen Victoria. The Black Prince's ruby is in the centre. Modifications in the cap were made for the coronation of King Edward VII, and the smaller "Cullinan" diamond substituted for the sapphire below the ruby.

3. QUEEN ALEXANDRA'S CORONATION CROWN, with the Koh-i-Noor in centre.

4. THE CORONET OF THE PRINCE OF WALES.

5. THE LARGER OR KING'S ORB.

6. THE LESSER OR QUEEN'S ORB.

The illustrations on these plates are, except where otherwise stated, reproduced by permission from the unique collection of photographs in the possession of Sir Benjamin Stone, formerly M.P. for East Birmingham.
2. THE CORONATION SPOON.

4. THE GOLD SALT-CELLAR presented to the Crown by the City of Exeter.
so as to give rise to structures which in normal development they would not have formed.

It is clear that there are at least three kinds of factors involved in regeneration. There are: (1) Regenerations due to the presence of undifferentiated, or little differentiated, cells, which have retained the normal capacity of multiplication when conditions are favourable. (2) Regenerations due to the presence of special complicated rudiments, the stimuli to the development of which is the removal of the fully formed structure. (3) Regeneration involving the general capacity of protoplasm to respond to changes in the surroundings by changes of growth. The most general view is to regard regenerations as special adaptations; and A. Weismann, following in this matter Arnold Lang, has developed the idea at considerable length, and has found a place for regeneration in his system of the germ-plasm (see HEREDITY) by the conception of the existence of "accessory determinants." Hertwig, on the other hand, attaches great importance to the facts of regeneration as evidence for his view that every cell of a body contains a similar essential plasm.

In E. Schwalbe's Morphologie der Ausbildungen (1904), part i. chap. I, an attempt is made to associate the facts of regeneration with those of embryology and morphology. Our knowledge of the facts, however, is not yet systematic enough to allow of important general conclusions. The power of regeneration appears to be a necessary condition for the completion of the embryonic development, but we are left with an expression of the general power of protoplasm to grow and to reproduce its kind. It has been suggested that regenerated parts always represent ancestral stages, but there is no conclusive evidence for this view.

(REGENSBURG) a city and archdiocesan see of Germany, in the kingdom of Bavaria, and the ancient of the government district of the Upper Palatinate. Pop. (1905) 48,472. It is situated on the right bank of the Danube, opposite the influx of the Regen, 86 m. by rail N.E. from Munich, and 60 m. S.E. of Nuremberg. On the other side of the river is the suburb Stadt-am-Hof, connected with Regensburg by a long stone bridge of the 12th century, above and below which are the islands of Oberer and Unterer Wörth. In appearance the town is quaint and romantic, presenting almost as faithful a picture of a town of the early middle ages as Nuremberg does of the later. One of the most characteristic features in its architecture is the number of strong loopholed towers attached to the ancient buildings. The interesting "street of the envoys" (Gesandtenstrasse) is so called because it contained the residences of most of the envoys to the German diet, whose coats-of-arms may still be seen on many of the houses.

The cathedral, though small, is a very interesting example of pure German Gothic. It was founded in 1275, and completed in 1654, with the exception of the towers, which were finished in 1899. The interior contains numerous interesting monuments, including one of Peter Vischer's masterpieces. Adjoining the chasels are two chapels of earlier date than the cathedral itself, one of which, known as the "old cathedral," goes back perhaps to the 8th century. The church of St James—also called Schottenkirche—a plain Romanesque basilica of the 12th century, derives its name from the monastery of Irish Benedictines ("Scoti") to which it was attached; the principal doorway is covered with very singular grotesque carvings. The old parish church of St Ulrich is a good example of the Transition style of the 13th century, and contains a valuable antiquarian collection. Examples of the Romanesque basilica style are the church of Obermünster, dating from 1010, and the abbey church of St Emmeran, built in the 13th century, and remarkable as one of the few German churches with a detached bellfry. The beautiful cloisters of the and of St Emmeran are the only one of the oldest in Germany, are still in fair preservation. In 1809 the conventual buildings were converted into a palace for the prince of Thurn and Taxis, hereditary postmaster-general of the Holy Roman Empire. The town hall, dating in part from the 14th century, contains the rooms occupied by the imperial diet from 1603 to 1806. An historical interest also attaches to the Gasthof zum Goldenen Kreuz (Golden Cross Inn), where Charles V. made the acquaintance of Barbara Blomberg, the mother of Don John of Austria (b. 1547). The house is also shown where Kepler died in 1630. Perhaps the most pleasing modern building in the city is the Gothic villa of the king of Bavaria on the bank of the Danube. At Kumpfmühl, in the immediate neighbourhood of the city, was discovered, in 1855, the remains of a Roman camp with an arched gateway; the latter, known as "Donnerburger Tor," resembles the so-called Porta Praetoria in Rome. The public institutions of the city should be mentioned the public library, picture gallery, botanical garden, and the institute for the making of stained glass. The educational establishments include two gymnasium, an episcopal clerical seminary, a seminary for boys and a school of church music. Among the chief manufactures are iron and steel wares, pottery, parquet flooring, tobacco, and lead pencils. Boat-building is also prosecuted, and a brisk transit trade is carried on in salt, grain and timber.

Near Regensburg are two very handsome classical buildings, regular places of residence, the German Diet. The first was erected by the Elector Palatinate, as the centre of their power on the upper Danube. It is mentioned as a trade centre as early as the 2nd century. It afterwards became the seat of the dukes of Bavaria, and one of the main bulwarks of the East Frankish monarchy, and was also the focus from which Christianity spread over southern Germany. St Emmeran founded an abbey here in the middle of the 7th century, and St Boniface established the bishopric about a hundred years later. Regensburg was a great centre of learning, and was a centre of culture of a high order, and its influence is felt far and near. It became the chief seat of the trade with India and the Levant, and the boatmen of Regensburg are frequently heard of as expediting the journeys of the Crusaders. The city was loyally Gläubelline in its sympathies, and was a favourite residence of the emperors. Numerous diets were held here from time to time, and after 1653 it became the regular place of meeting of the diet. Regensburg found only temporary acceptance at Regensburg, and was met by a counter-reformation inspired by the Jesuits. Before this period the city had almost wholly lost its commercial importance and had been the victim of many changes in its form and name. It had its due share in the Thirty Years' and other wars, and is said to have suffered in no fewer than seventeen sieges. In 1807 the French occupation of the territory was re-established by the province of Dalmberg, and in 1810 they were ceded to Bavaria. After a siege of Eggmühl in 1809 the Austrians retired upon Regensburg, and the pursuing French defeated them again beneath its walls and reduced a great part of the city to ashes.

(REGENSBURG—REGENT) from Lat. regere, to rule), one who rules or governs, especially one who acts temporarily as an administrator of the realm during the minority or incapacity of the king. This latter function, however, is one unknown to the English common law. "In judgment of law the king, as king, cannot be said to be a minor, for when the royal body politic of the king doth meet with the natural capacity in one person the whole body shall have the quality of the royal politis, which is the greatest and more worthy and wherein is no minority. For omne majus continent se minus " (Coke upon Littleton, 434a). But for reasons of necessity a regency, however anomalous it may be in strict law, has frequently been appointed in both England and Scotland. The earliest instance in English history is the appointment of the earl of Pembroke with the assent of the loyal barons on the accession of Henry III.

Whether or not the sanction of parliament is necessary for the appointment is a question which has been much discussed. Lord Coke recommends that the office should depend on the will of
Reggio Calabria—Regicide

Parliament (Inst., vol. iv, p. 58), and in modern times provision for a regency has always been made by act of parliament. Under the Commonwealth, the regency was always by the assent of a council or parliament. Thus in 1315 the earl of Moray was appointed regent by Robert I. in a council. At a later period appointment was made by the council alone. The earl of Arran was declared regent during the minority of Mary. By an act of 1567 the appointment by Mary of the earl of Moray as regent was confirmed. As late as 1704 provision was made for a regency after the death of Anne. By an act of 1715, when the other regency resuming an express statute that was created by 28 Hen. VIII. c. 7, under which the king appointed his executors to exercise the authority of the crown till the successor to the crown should be crowned, they delegated their rights to the protector Somerset, with the assent of the lords spiritual and temporal. No other example of a statutory provision for a regency after the death of Anne exists. By an act of 1740, Geo. II. c. 24 constituted the princess-dowager of Wales regent of the kingdom, in case the crown should descend to any of her children before such child attained the age of eighteen. A council, called the council of regency, was appointed to assist the princess. A regent was to be taken by the regent and members of the council. Their consent was necessary for the marriage of a successor to the crown during minority. It was declared to be unlawful for the regent to make war or peace, or ratify any treaty with any foreign power, or prorogue, adjourn or dissolve any parliament without the consent of the majority of the council of regency, or give her assent to any bill for making or amending the Act of Setlement, or the Act of the Scottish parliament for securing the Protestant religion and Presbyterian church government in Scotland (1707, c. 6). The last is an invariable provision, and occurs in all subsequent acts made by the council of regency.

Act of 5 Geo. III. c. 27 vested in the king, during minority, the right to appoint a regent under the sign manual, such regent to be one of certain named members of the royal family. The remaining provisions closely followed those of the act of George II. In 1788 the immunity of the regent was limited to the act of Regency bill. In the course of the debate in the House of Lords the duke of York disclaimed on behalf of the prince of Wales any right to assume the regency without the consent of parliament. Owing to the king's regency the bill ultimately dropped. On a re-promotion of it in 1810 the act of 51 Geo. III. c. 1 was passed, appointing the prince of Wales regent during the king's incapacity. The royal assent was given by commission authorized by resolution of both Houses. By the act no council of regency was appointed.

Regicide (Lat. rex, a king; and caedere, to kill), the name given to any one who kills a sovereign. Regicides is the name given in English history at the Restoration of 1660 to those persons who were responsible for the execution of Charles I. On the 4th of April 1660 Charles II. in the Declaration of Breda promised a free pardon to all subjects "excepting only such persons as shall hereafter be executed by parliament," and on the 14th of May the House of Commons ordered the immediate arrest of "all those persons who sat in judgment upon the late king's majesty when sentence was pronounced." The number of regicides was estimated at 84, this number being composed of the 67 present at the last sitting of the court of justice, 11 others who had attended earlier sittings, 4 officers of the court and the 2 executioners. Many of them were arrested or surrendered themselves, and the House of Commons in considering the proposed bill of indemnity suggested that only twelve of the regicides, who were named, should forfeit their lives; but the House of Lords urged that all the king's judges, with three exceptions, and some others, should be tried in this way.

Eventually a compromise was agreed upon, and the bill as passed on the 29th of August 1666 divided the regicides into six classes for punishment: (1) Four of them, although dead—Cromwell, Ireton, Bradshaw and Pride—were to be attainted for high treason. (2) The estates of twenty others, also dead, were to be subjected to fine or forfeiture. (3) Thirty living regicides were excepted from all indemnity. (4) Nineteen living regicides were also excepted, but with a saving clause that their execution was to be suspended until a new parliament was summoned. (5) Six others were to be punished, but not capitally. (6) Two, Colonels Hutchinson and Thomas Lister, were simply declared incapable of holding any office. Two regicides—Inglodgley, who declared he was not a regicide, and Lord George Thurlow, who was put into the pillory and afterwards rescued by Sir George Smith—were wholly excepted.

Reggio nell'Emilia, a city and episcopal see of Emilia, Italy, the capital of the province of Reggio nell'Emilia (till 1859 part of the duchy of Modena), 36 m. by rail N.W. of Bologna. Pop. (1906) 19,681 (town); 64,548 (commune). The cathedral, originally erected on the site of the Roman forum, was restored in 1290; in the 15th and 16th; the façade shows traces of both periods, the Renaissance work being complete only in the lower portion. S. Prospero, close by, has a façade of 1504, in which are incorporated six marble lions belonging to the original Romanesque edifice. The Madonna della Ghiaia, built in 1597 in the form of a Greek cross, and restored in 1900, is beautifully proportioned and finely decorated in stucco and with frescoes of the Bolognese school of the early 17th century. There are several good palaces of the early Renaissance, a fine theatre (1857) and a museum containing important palazzo-ethnological collections, ancient and medieval sculptures, and the natural history collection of Spallanzani. Lodovico Ariosto, the poet (1474-1533), was born in Reggio, and his father's house is still preserved. The industries embrace the making of cheese, objects in cement, matches, and brushes, the production of silkworms, and printing; and the town is the centre of a rich agricultural district. It lies on the main line between Bologna and Milan, and is connected by branch lines with Guastalla and Sassuolo (hence a line to Modena).

Regium Lepidi or Regium Lepidum was probably founded by M. Lepidus, the son of Sempronius Lepidus the larger. It consisted of Aemilia (187 B.C.). It lay upon this road, half-way between Mutina and Parma. It was during the Roman period a flourishing municipium, but perhaps never became a colony; and it is associated with not a few of the annals of Narnia, and in particular with the father of Caesar's friend and foe. The bishopric dates perhaps from the 4th century A.D. Under the Lombards the town was the seat of dukes and counts; in the 12th and 13th centuries it formed a flourishing republic, buried in surrounding itself with walls (1229), controlling the Crostolo and constructing navigable canals to the Po, coining money of its own, and establishing prosperous schools. About 1590 it first passed into the hands of Olibio d'Este, and the authority of the Este family was after many vicissitudes more formally recognized in 1499. In the contest for liberty which began in 1796 and closed with annexation to Piedmont in 1859, Reggio took vigorous part.
REGILLUS, an ancient lake of Latium, Italy, famous in the legendary history of Rome as the lake in the neighbourhood of which occurred (496 B.C.) the battle which finally decided the hegemony of Rome in Latium. During the battle, so runs the story, the dictator Postumius was unable to escape from Pollux, who were specially venerated in Tusculum, the chief city of the Latins (it being a Roman usage to invoke the aid of the gods of the enemy), who appeared during the battle, and brought the news of the victory to Rome, watering their horses at the spring of Juturna, close to which their temple in the Forum was erected. There can be little doubt that the lake actually existed. Of the various identifications proposed, the best is that of Nibby, who finds it in a now dry crater lake (Pantano Secco), drained by an emissarium, the date of which is uncertain, some 2 m. N. of Frascati. Along the south bank of the lake, at some 30 or 40 ft. above the near bottom, ran the aqueducts of the Aqua Claudia and Anio Novus. Most of the other sites proposed are not, as Regillus should be, within the limits of the territory of Tusculum.

See T. Ashby in Rendiconti dei Lincei (1898), 103 seq., and Classical Review, 1898. (T. As.)

REGIMENT (from Late Latin regimentum, rule, regere, to rule, govern, direct), originally government, command or authority exercised over others, or the office of a ruler or sovereign; in this sense the word was common in the 16th century. The most familiar instance is the title of the tract of John Knox, The First Blast of the Trumpet against the Monstrous Regiment of Women. The term as applied to a large body of troops dates from the French army of the 16th century. In the first instance it implied "command," as nowadays we speak of "General A's command," meaning the whole number of troops under his command. The early regiments had no similarity in strength or organization, except that each was under one commander. With the regularization of armies the commands of all such superior officers were gradually reduced to uniformity, and a regiment came to be definitely a colonel's command. In the British army the term has no tactical significance, as the number of battalions in a regiment is variable, and one at least is theoretically abroad at all times, while the reserve or territorial battalions serve under a different code to that governing the regular battalions. The whole corps of Royal Artillery is called "the Royal Regiment of Artillery." In the cavalry a regiment is tactically as well as administratively a unit of four squadrons. On the continent of Europe the regiment of infantry is always together under the command of its colonel, and consists of three or four battalions under majors or lieutenant-colonels.

REGINA, the capital city of the province of Saskatchewan, Canada, situated at 104° 36' W. and 50° 27' N., and 357 m. W. of Winnipeg. Pop. (1907) 5804. After the Canadian Pacific Railway was completed in 1885, the necessity for a place of government on the railway line pressed itself upon the Dominion government. The North-West Territories were but little settled then, but a central position on the prairies was necessary, where the mounted police might be stationed and where the numerous Indian bands might be easily reached. The minister of the interior at Ottawa, afterwards Governor Dewdney, chose this spot, and for a number of years Regina was the seat of the Territorial government. The governor took his abode on the adjoining plain, and the North-West Council met each year, with a show of constitutional government about it. On the formation of the province of Saskatchewan in 1895 the choice of capital was left to the first legislature of the province. Prince Albert, Moss Jaw and Saskatoon all advanced claims, but Regina was decided on as the capital. It probably doubled in population between 1905 and 1907. Its public buildings, churches and residences are worthy of a place of greater pretensions. It is the centre for a rich agricultural district, and has a good college, legislation, education, law and other public benefits. It remains the headquarters of the mounted police for the Western provinces, and near it is an Indian Industrial school of some note.

REGINON, or REGINO OF PRÚM, medieval chronicler, was born at Altripp near Spires, and was educated in the monastery of Prúm. Here he became a monk, and in 892, just after the monastery had been sacked by the Danes, he was chosen abbot. In 899, however, he was deprived of this position and he went to Trier, where he was appointed abbot of St Martin's, a house which he reformed. He died in 915, and was buried in the abbey of St Maximin at Trier, his tomb being discovered there in 1581. Reginon wrote a Chronicle (under his name, See also D. Masson, Life of Milton, vol. vi. (1880), and M. Noble, Lives of the English Preachers (1798). (A. W. H. P.)

REGIMONTANUS (1436-1476), German astronomer, was born at Königsberg in Franconia on the 6th of June 1436. The son of a miller, his name originally was Johann Müller, but he called himself, from his birthplace, Joh. de Montefregio, an appellation which became gradually modified into Regiomontanus. At Vienna, from 1452, he was the pupil and associate of George Purbach (1423-1461), and they jointly undertook a reform of the mathematical astronomy necessary, by the errors they detected in the Alphonsine Tables. In this they were much hindered by the lack of correct translations of Ptolemy's works; and in 1456 Regiomontanus accompanied Cardinal Bessarion to Italy in search of authentic manuscripts. He rapidly mastered Greek at Rome and Ferrara, lectured on Alfraganus at Padua, and completed at Venice in 1463 Purbach's Epitome in Cl. Ptolemaei magnum compositionem (printed at Venice in 1496), and his own De Triangulis (Nuremberg, 1533), the earliest work treating of trigonometry as a substantive science. A quarry with George of Trebizond, the blunders in whose translation of the 42nd of 1458, he had pointed out, obliged him to quit Rome precipitately in 1468. He repaired to Vienna, and was thence summoned to Buda by Matthias Corvinus, king of Hungary, for the purpose of collating Greek manuscripts at a handsome salary. He also finished his Tabulae Directionum (Nuremberg, 1475), essentially an astrological work, but containing a valuable table of tangents. An outbreak of war, meanwhile, diverted
the king’s attention from learning, and in 1471 Regiomontanus settled at Nuremberg. Bernhard Walther, a rich patrician, became his pupil and patron; and they together equipped the first European observatory, for which Regiomontanus himself constructed instruments of an improved type (described in his posthumous Scripta, Nuremberg, 1544). His observations of the great comet of January 1672 supplied the basis of modern cometary astronomy. At a printing-press established in Walther’s house by Regiomontanus, Purbach’s Theoriae planetarum nova was published in 1472 or 1473; a series of popular calendars issued from it, and in 1474 a volume of Ephemerides calculated by Regiomontanus for thirty-two years (1474–1506), in which the method of “lunar distances,” for determining the longitude at sea, was recommended and explained. In 1472 Regiomontanus was summoned to Rome by Pope Sixtus IV. to aid in the reform of the calendar; and there he died, most likely of the plague, on the 6th of July 1476.

REGISTER, a record of facts, proceedings, acts, events, names, &c., entered regularly for reference in a volume kept for that purpose, also the volume in which the entries are made. The Fr. registre is taken from the Med. Lat. registrum for registram, Late Lat. regesta, things recorded, hence list, catalogue, from regere, to carry or bear back, to transcribe, enter on a roll. For the keeping of public registers dealing with various subjects see Registration and the articles there referred to, and for the records of marriages, births, and deaths made by a parish clergyman, see section Parish Registers below. The idea of a register was, until the beginning of the 19th century, usually known as a “register,” but that title has in Great Britain now been superseded by “registrar”; it still survives in the Lord Clerk Register, an officer of state in Scotland, nominally the official keeper of the national records, whose duties are performed by the Deputy Clerk Register. In the United States the title is still “register.” The term “register” has also been applied to mechanical contrivances for the automatic registration or recording of figures, &c. (see Cash Register), to a stop in an organ, to the compass of a voice or musical instrument, and also to an apparatus for regulating the inflow and outflow of air, heat, steam, smoke or the like. Some of these instances of the application of the term are apparently due to confusion in etymology, with Lat. regere, to rule, regulate.

Parish Registers were instituted in England by an order of Thomas Cromwell, as vicegerent to Henry VIII., “supreme hevd undre Christ of the Church of Engelande,” in September 1538. The idea appears to have been of Spanish origin, Cardinal Ximenes having instituted, as archbishop of Toledo, registers of baptisms in 1497. They included, under the above order, baptisms, marriages and burials, which were to be recorded weekly. In 1597 it was ordered by the Convocation of Canterbury that parchment books should be provided for the registers and that transcripts should be made on parchment of existing registers on paper, and this order was repeated in the 70th canon of 1603. The transcripts then made now usually represent the earliest registers. It was further provided at both these dates that an annual transcript of the register should be sent to the bishop for preservation in the diocesan registry, which was the origin of the “bishop’s transcripts.” The “Directory for the publice worship of God,” passed by parliament in 1645, provided for the date of birth being also registered, and in August 1653, an Act of “Barebones’ Parliament” made a greater change, substituting civil “parish registers” (sic) for the clergy, and ordering them to record births, banns, marriages and burials. The “register” was also to publish the banns and a justice to perform the marriage. The register books were well kept under this civil system, but at the Restoration the old system was resumed.

A tax upon births, marriages and burials imposed in 1664 led to the clergy being ordered to register all births, apart from baptisms, but the act soon expired and births were not again registered till 1836. Lord Hardwicke’s Marriage Act (1754), by its rigid provisions, increased the registration of marriages by the parochial clergy and prescribed a form of entry. In 1812 parish registers became the subject of parliamentary enactment, owing to the discovery of their deficiencies. Register Act provided for their safer custody, for efficient bishops, transcripts, and for uniformity of system. This act continued to regulate the registers till their supercession for practical purposes, in 1837, by civil registration under the act of 1836.

In age, completeness and condition they vary much. A blue book on the subject was published in 1833, but the returns it contains are often inaccurate. A few begin even earlier than Cromwell’s order, the oldest being that of Tipton, Staffs. (1513). Between 800 and 900, apparently, begin in 1538 or 1539. The entries were originally made in Latin, but this usage died out early in the 17th century: decay and the cramped handwriting of the time render the earlier registers extremely difficult to read. There is general agreement as to the shocking neglect of these valuable records in the past, and the loss of volumes appears to have continued even through the 19th century. Their custody is legally vested in the parochial clergy and their wardens, but several proposals have been made for their removal to central depositories. The fees for searching them are determined by the act of 1836, which prescribes half a crown for each certified extract, and sixpence a year for searching, with a shilling for the first year.

The condition of the bishops’ transcripts was, throughout, much worse than that of the parish registers, there being no funds provided for their custody. The report on Public Records in 1800 drew attention to their neglect, but, in spite of the provisions in Rose’s Act (1812), little or nothing was done, and, in spite of their importance as checking, and even sometimes supplementing deficient parish registers, they remained “unarranged, unindexed and uncontrollable.” Of recent years, however, some improvement has been made. It has also been discovered that transcripts from “peculiars” exist in other than episcopal registers.

Outside the parochial registers, which alone were official in character, there were, till 1734, irregular marriage registers, of which those of the Fleet prison are the most famous, and also registers of private chapels in London. Those of the Fleet and of Mayfair chapel were deposited with the registrar-general, but not authenticated. The registers of dissenting chapels remained unofficial till an act of 1840 validated a number which had been authenticated, and was extended to many others in 1858. Useful information on these registers, now mostly deposited with the registrar-general, will be found in Sims’ Manual, which also deals with those of private chapels, of English settlements abroad preserved in London, and with English Roman Catholic registers. These last, however, begin only under George II. and are restricted to certain London chapels.

The printing of parish registers has of late made much progress, but the field is so vast that the rate is relatively slow. There is a Parish Register Society, and a section of the Harleian Society engaged on the same work, as well as some county societies and also one for Dublin. But
so many have been issued privately or by individuals that reference should be made to the lists in Marshall's _Genealogist's Guide_ (1893) and Dr Cox's _Parish Registers_ (1910), and even this last is not perfect. The Huguenot Society has printed several registers of the Protestant Refugees, and Mr Moens that of the London Dutch church. There are also several registers of marriages alone now in print, such as that of St Dunstan's, Stepney, in 3 vols. Colonel Chester's extensive MS. collection of extracts from parish registers is now in the College of Arms, London, and the parishes are indexed in Dr Marshall's book. MS. extracts in the British Museum are dealt with in Sims' _Manual_.

In Scotland registers of baptisms and marriages were instituted by the clergy in 1537, and burials were added by order of the Privy Council in 1616; but these were very imperfectly kept, especially in rural parishes. Yet it was not till 1854 that civil registration was introduced, by act of parliament, in their stead. Some 900 parish registers, beginning about 1563, have been deposited in the Register House, Edinburgh, under acts of parliament which apply to all those prior to 1819. Mr Hallen has printed the register of baptisms of Muthill Episcopal Church.

In Ireland, parish registers were confined to the now disestablished church, which was that of a small minority, and were, as in Scotland, badly kept. Although great inconvenience was caused by this system, civil registration of marriages, when introduced in 1844, was only extended to Protestants, nor was it till 1864 that universal civil registration was introduced, great difficulty under the Old Age Pensions Act being now the result. No provision was made, as in Scotland, for central custody of the registers, which, both Anglican and Nonconformist, remain in their former repositories. Roman Catholic registers in Ireland only began, apparently, to be kept in the 19th century.

Not all registers; only of baptism, were first instituted in 1539. The Council of Trent, however, made registers both of baptisms and of marriages a law of the Catholic Church in 1563, and Louis XIV. imposed a tax on registered baptisms and marriages in 1707.

**REGISTRATION.** In all systems of law the registration of certain legal facts has been regarded as necessary, chiefly for the purpose of ensuring publicity and simplifying evidence. Registers, when made in performance of a public duty, are as a general rule admissible in evidence merely on the production of the proper custody of the registers themselves or (in most cases) of examined or certified copies. The extent to which registration is carried varies very much in different countries. For obvious reasons, judicial decisions are registered in all countries alike. In other matters no general rule can be laid down, except perhaps that on the whole registration is not as fully enforced in the United Kingdom and the United States as in continental states. The most important uses of registration occur in the case of judicial proceedings, land, ships, bills of sale, births, marriages and deaths, companies, friendly and other societies, newspapers, copyrights, patents, designs, trade marks and professions and occupations. In England registers are attached to the privy council, the Supreme Court and the county courts. In the king's bench division (except in its bankruptcy jurisdiction) the duty of registrars is performed by the masters. Besides exercising limited judicial authority, registrars are responsible for the drawing up and recording of various stages of the proceedings from the petition, writ or plaint to the final decision. With them are filed affidavits, depositions, pleadings, &c., when such filing is necessary. The difference between filing and registration is that the documents filed are filed without alteration, while only an epitome is usually registered. The Judicature Act 1873 created district registries in the chief towns, the district registrar having an authority similar to that of a registrar of the Supreme Court. In the admiralty division cases of account are usually referred to the registrar and merchants. The registration in the central office of the supreme court of judgments affecting lands, wills of execution, recognizances and _iles pendentes_ in England, and the registration in Scotland of abbreviates of adjudications and of inhibitions, are governed by special legislation. All these are among the incumbrances for which search is made on investigating a title. Decisions of criminal courts are said to be recorded, not registered, except in the case of courts of summary jurisdiction, in which, by the Summary Jurisdiction Act 1879, a register of convictions is kept. Probates of wills and letters of administration, which are really judicial decisions, are registered in the principal or district registries of the probate division. In Scotland registration is used for giving a summary remedy on obligations without action by means of the fiction of a judicial decision having been given establishing the obligation.

**Registration of Voters.**—Prior to 1832 the right of parliamentary electors in England was determined at the moment of the tender of the vote at the election, or, in the event of a petition against the return, by a scrutiny, a committee of the House of Commons striking off those whose qualification was held to be insufficient, and, on the other hand, adding those who, having tendered their votes at the poll, with a good title to vote. The Reform Act of 1832 was the introduction of a new mode of ascertaining the rights of electors by means of an entirely new system of published lists, subject to claims and objections, and after due inquiry and revision forming a register of voters. Registration was not altogether unknown in Great Britain in connexion with the parliamentary franchise before the Reform Acts of 1832. Thus in the Scottish counties the right to vote depended on the voter's name being upon the roll of freeholders established by an act of Charles II.; a similar register existed in Ireland of freeholders whose freeholds were under £20 annual value; and in the universities of Oxford and Cambridge the rolls of members of Convocation and of the Senate were, as they still are, the registers of parliamentary voters. But except in such cases as the above, the right of a voter had to be determined by the returning officer upon the evidence produced before him when the vote was tendered at a poll. This necessarily took time, and the result was that a contested election in a large constituency might last for weeks. The celebrated Westminster election of 1784, in which the poll began on the 1st of April and ended on the 17th of May, may be mentioned as an illustration. Moreover, the decision of the returning officer was not conclusive; the title of every one who claimed to vote was liable to be reconsidered on an election petition, or, in the case of a rejected vote, in an action for damages by the voter against the returning officer.

The inconvenience of such a state of things would have been greatly aggravated had the old practice continued after the enlargement of the franchise in 1832. The establishment of a general system of registration was therefore a necessary and important part of the reform then effected. It has enabled an election in the most populous constituency to be completed in a single day. It has also been instrumental in the extinction

1 The antiquity of registration of this kind is proved by the age of the _Registrum Breivium_, or register of writs, called by Lord Coke "a most ancient book of the Common Law" (Coke upon _Juxta l. p._, 1593).
of the "occasional voter," who formerly gave so much trouble to returning officers and election committees—the person, namely, who acquired a qualifying tenement with the view of using it for a particular election and then disposing of it. The period of qualification now required in all cases, being fixed with reference to the formation of the register, is necessarily so long anterior to any election which it could affect that the purpose or intention of the voter in acquiring the qualifying tenement has ceased to be material, and is not investigated.

England.—The reform of parliamentary representation in 1832 was followed in 1835 by that of the constitution of municipal corporations. The Act of 1835 was a confirmation of a tradition of municipal taxation (now known as the old borough qualification) for the municipal franchise. In 1888 the municipal franchise was enlarged, and was at the same time extended to the whole country for the formation of constituencies to elect county councils; and in 1894 parochial electors were called into existence for the election of parish councils and for other purposes. Inasmuch as provision was made for the registering of persons entitled to votes for the above purposes, there are now three registers of voters, namely, the parliamentary register, the local government register (i.e. in boroughs under the Municipal Corporations Acts, in towns with local government, and elsewhere in the county registers) and the register of parochial electors. Under the Municipal Corporations Act 1835 the registration of boroughs, though on similar lines to that of parliamentary voters, was entirely separate from it. Since, however, the qualification for the municipal franchise covered to a great extent the same ground as that for the parliamentary franchise, in boroughs which sent members to parliament, a considerable number of voters in such boroughs were entitled in respect of the same tenement to be upon both parliamentary register and borough roll. The waste of labour involved in settling this question over a twenty year period (1858-78) led to the system of parliamentary registration being extended to the boroughs in question for municipal purposes, and the lists were directed to be made out in such a shape that the portion common to the two registers could be detached and combined with the portion peculiar to each, so as to form the parliamentary register and the borough roll respectively. This system of registration was extended to the non-parliamentary boroughs and to the whole country in 1888; the separate municipal registration being completely abolished.

The procedure of parliamentary registration is to be found in its main lines in the Parliamentary Registration Act 1843, which superseded that provided by the Reform Act of 1832; new provisions have been contained in Acts passed between 1835 and 1888, and the Local Government Act 1894. Registration is carried out by local machinery, the common-law parish being taken as the registration unit; and the work of preparing and publishing the lists, which when revised are to form the register, is committed to the overseers. The selection of these officers was no doubt due to their position as the rating authority, and to their consequent opportunities for knowing the ownership and occupation of tenements; but it is only fair to say that, judged by their own standards, other persons being empowered to act for them in many parishes by general or local acts of parliament; but in all or almost all cases they are entitled to act personally if they think fit, they sign the lists, and the proceedings are conducted in their name.

In order to render intelligible the following summary of the procedure, the necessary facts are conveniently classified according to the nature of their qualification, since the practice differs in regard to each class. The classes are as follows: (1) Owners, including the old forty-shilling freeholders, and proprietors, long leaseholders and others entitled under the Reform Act of 1832 to vote at parliamentary elections for counties; (2) occupiers, including those entitled to (a) the 10 occupation qualification, (b) the household qualification and (c) the old borough qualification (i.e. those on the previous register for the same lodgings, and (d) new; (4) those entitled to reserved rights, i.e. in addition to those (if any still remain), who were entitled to votes before the Reform Act of 1832. In respect of qualifications abolished by that act, (2) freeholders and burgage tenants in Bristol, Exeter, Norwich, and Nottingham, and (b) freemen of the City of London and of certain old cities and boroughs, whose right to the parliamentary franchise was permanently abolished by the 1835 Act, are here excluded. To these classes it may be said that the general scheme is that owners must make a claim in the first instance before they can get their names upon the register, but that, once entered on the register, the names will be retained unless counteracted by the revising barrister; that the lists of occupiers and of freehold and burgage tenants are made out aforesaid every year by the overseers from their own information and inquiries, without any act being required on the part of the persons entitled: and that in cases in which their names are omitted; that lodgers must make claims every year; and that freeholders and freemen are in the same position; (3) tenementers, occupiers, and others entitled to be registered as owners, or to the registration of ownership electors, and to every parish within a parliamentary or municipal borough a precept with regard to the registration of occupation electors (which expression for this purpose includes lodgers and occupiers, in or near the borough, of every borough, municipal or parliamentary, is to send to the overseers of every parish in his borough a precept with regard to the registration of occupation electors. These precepts are set out in the Register; the Register and the occupied lodging books differ according as the borough is parliamentary only, or municipal only, or both parliamentary and municipal; in the cases of Bristol, Exeter, Norwich and Nottingham they contain directions as to the mechanics of burgage tenants. The duties of the overseers in regard to registration are set out in detail in the precepts. Along with the precepts are forwarded forms of the various lists and notices to be made out with the precept, and the certain number of copies of that portion of the parliamentary register of the county at the time in force which contains the ownership voters for the parish, the register being so printed that the portion relating to each parish can be detached. It is the duty of the overseers to publish on the 20th of June, in manner hereinafter described, the portion of the register so received, together with a notice to owners not already registered to send in claims by the 20th of July. Meanwhile the overseers are making the inquiries necessary for the preparation of the occupier list. For this purpose they may require returns to be furnished by owners of houses let out in separate tenements, who have to be determined as the service franchise. The registrars of births, deaths and marriages are required to furnish the overseers with returns of deaths, as must the assessed tax collectors with returns of defaulters; the relieving officers are required to give such information as may be of special use in the administration of public relief. On or before the 31st of July the overseers are to make out and sign the lists of voters. These are the following: the list of ownership electors, consisting of the portion of the register precept as before described; the list of occupiers, who must be entitled to votes by the 20th of June, the 20th of July, or the 25th of July. If any of the electors have been required to send in claims by the 20th of July, the occupier list; and the old lodge list, the last being formed from claims sent in by the 25th of July. The overseers do not decide the names in the first list and last of these lists; they take them as supplied in the register and claims. It is, however, their duty to write in "dead" or "objected" in the margin against the names of persons whom they have reason to believe to be dead or not entitled to vote in respect of the qualification described. The ownership and old lodge lists will be divided into two parts, if the register contains names of owners entitled to a parliamentary vote only, or if claims by owners or old lodgers have been received from them; they will contain the names of persons whom the overseers believe to be qualified, and no others, and therefore will be free from marginal objections. Except in the administrative county of London, it is made out in three parts—division 1 containing the names of property qualifying for both parliamentary and local government votes, divisions 2 and 3 those of occupiers of property qualifying only for local government, and division 4 those of persons not of property. It happens so frequently that a tenement, not of sufficient value to qualify for the £10 occupation franchise (parliamentary and local government), qualifies both for the household franchise (parliamentary and local government), that division 1 would in most cases be the whole list, but for two circumstances. The service franchise is a special modification of the household franchise only; and the service occupant, being chosen by the overseers, is entitled to the service of the parish of division 2; while peers and women, being excluded from the parliamentary vote, are consequently relegated to division 3. In the administrative county of London the local government register, being coextensive with the register of parochial electors, includes
the whole of the parliamentary register. The occupier lists are consequently made out in two divisions only, the names which would elsewhere appear in division 2 being placed in division 1. The lists of freeholders and burgage tenants in the boroughs of London and Nottingham are to be made out and signed by the same date. The overseers have also to make out and sign a list of persons qualified as occupiers to the elected aldermen or councillors, but as non-resident proprietors are to be excluded from every borough, the names of these are to be inserted in the register by the local commissioners of the rate. At the same date also the clerks of the livery companies are to make out, sign and deliver to the second councilor for the purpose of a record in the register, the names of all freemen who have made a declaration to vote as such at the parliamentary or town council elections, and the town clerks are to make out and sign the lists of freemen so entitled in towns where this franchise exists.

On the 1st of August all the above lists are to be published, the liverymen by the overseers, the second councilors by the freeholders and burgage tenants, and the rest by the overseers. In addition the overseers may have to publish a list of persons disqualified by having been found guilty of corrupt or illegal practices; this list they will receive, when it exists, from the clerk of the county council or town clerk with the precept. Publication of lists and notices by overseers is made by affixing copies on the doors of the church and other places of worship of the parish (or, if there be none, in some public or conspicuous situation in the parish) within the 25th day of August, and the list of freemen is to be sent to the county council or town clerk, and the rest by the overseers.

The exception is that lists and notices relating to ownership electors need not be published at the offices mentioned when the parish is within a parliamentary borough. Publication by the secondary councilors is made by the second councilors and delivered to the mayor or other officers in the town or borough to be sent to the secondary and town clerk, and in other cases to the overseers; and notices of objection must also in all cases be sent to the person objected to. All notices must be in the 25th day of August, and on or before the 25th of August the overseers, secondary and town clerks are to make out, sign and publish lists of the claimants and persons objected to. It remains to be added that any person on a list of voters or on the list of freemen, or on the list of occupiers for the purpose of making up the parliamentary, local government and parochial registers respectively. The alphabetical order is followed, except in London and some other large towns, where street order is adopted for all except the ownership lists and lists of liverymen and freemen. The parliamentary register for a county will consist of the ownership lists for all parishes in the county, and of the occupier lists for parishes within the county and not within a parliamentary borough. The local government register for parliamentary boroughs will consist of the list of voters, the list of freemen, and the list of occupiers for parishes within the county, and also of the list of occupiers (if any) of liverymen or freemen. The local government register for an administrative county will consist of divisions 1 and 3 of the occupier lists for all parishes in the county, and of the list of occupiers for parishes within the county, and not within a parliamentary borough. The return of the parliamentary register for a parliamentary borough will consist of the list of voters, the list of freemen, and the list of occupiers for parishes within the borough, and also of the list of occupiers (if any) of liverymen or freemen. The list of electors for a parliamentary borough will consist of the list of voters, the list of freemen, and the list of occupiers for all parishes in the borough. It will be seen, therefore, that, except in county boroughs, the local government register is a part of the parliamentary register. It is subject to the same rules as the parliamentary register, and is also subject to the same scrutiny as the parliamentary register. The registration of a parliamentary register is a matter of the utmost importance, and is subject to the same scrutiny as the parliamentary register. The registration of a parliamentary register is a matter of the utmost importance, and is subject to the same scrutiny as the parliamentary register.
the ordinary way. The universities are also exempt from the general law of registration. At Oxford and Cambridge the members of Convocation and the Senate respectively have always formed the regent and the corporators, and it has been customary among the registrars in those universities, the registers of those members were before 1832, and still are now to the presidential register of that body.

Scotland.—In Scotland the qualifications for local government and parish electors are the same as those for parliamentary electors. The is done by the register and the parish council. The incapacity for the parliamentary franchise, incapacity for the other franchises by reason of non-payment of rates, and duplicates. The principal act regulating registration in burghs is 19 & 20 Vict. c. 44, § 20. County registration, formerly regulated by 24 & 25 Vict. c. 83, has been assimilated to burgh registration by 48 & 49 Vict. c. 3, § 8 (d). The procedure consists, as in England, of the making and publication of lists of voters, the making of claims and objections and the holding of revision courts; but there are important differences of detail. Though the parish is the registration unit, personal property is not used for the formation of the register. The parish registers for a county are made up yearly by one or more of the assessors of the county, and those for a burgh by one or more of the assessors for the burgh, or by the clerk of the council, as provided in the act. Claims and objections must be in and claims and objections must be sent in by the 21st and are published on the 25th of the same month. Publication is made in burghs by posting on or near the town hall, or in some other conspicuous place in the burgh. Counties by public notices in the parish church, and in both cases giving notice by newspaper advertisement of a place where the lists may be procured. The revision is conducted by the sheriff, the time within which objections may be filed being the 1st of each month. The clerk of the parish church, in the parish of the 16th of October, both days inclusive. An appeal lies to three judges of the Court of Session, one taken from each division of the province, by the local authorities of the county. The revised lists are delivered in counties to the sheriff clerk, in burghs to the town clerk, or person to whom the registration duties of town clerk are assigned. The register comes into force for all purposes by the 1st of the month following the date of the register. In the case of an irregularity in the date of the register, the register is invalid.

The municipal register of a royal burgh which is coextensive, or of that part of a royal burgh which is coextensive with a parliamentary burgh, consists of the parliamentary register with a supplementary list of persons from outside the burgh. The county rate is a disqualification for the county electors’ franchise, the names of persons so disqualified are to be marked with a distinctive mark in the register, and the office of the clerk of the peace and the sheriff of the county to whom the register is to be submitted. As aforesaid in this district, and in the case of the clerk of the county council, all objections are to be published by the clerk of the peace and town clerk by the 24th of the same month. Publication of the lists and notices by a clerk of the peace is made by posting copies of the lists to the residents and the occupiers, and the occupiers of the property adjacent to the registration unit outside every court-house, petty sessions court, and other public offices in the unit; publication by a town clerk is made by posting copies outside the town hall, or, if there be none, in some public and conspicuous place in the borough.

Revising barristers are specially appointed for the county and city of Dublin by the lord lieutenant; elsewhere by the county and city of London, or by the county and city of York. The list is submitted to the court of session for revision, and the list is returned to the clerk of the peace. The register is conclusive to the same extent as in England, except that the vote of a parish elector who is one year in arrear in payment of a parish rate is not to be registered as a parish elector. The register of the parish is to be available for the parishioners at all times during the session. In cases of disputed claims or the existence of a corporation, the register is to be available for the petitioners at all times during the session. The register is conclusive to the same extent as in England, except that the vote of a parish elector who is one year in arrear in payment of a parish rate is not to be registered as a parish elector. A colony, mainly of Chalcidians, partly of Messenians from the Peloponnesus, settled at Regium in the 8th century B.C. About 494 B.C. Anaxilas, a member of the Messenian party, made himself master of Regium (apparently—from numismatic evidence, for the coins assignable to this period are modelled on Samian types—with the help of the Samians: see Messina) and about 488 joined them in occupying Zancle (Messina). Here they remained. (See C. H. Dodd in Journal of Hellenic Studies, xxviii. (1908) 56 seq.) This coinage was resumed after the establishment of the democracy about 461 B.C., when Anaxilas' sons were driven out. In 433 Regium made a treaty with Athens, and in 427 joined the Athenians against Syracuse, but in 415 it remained neutral. An attack which it made on Dionysius I. of Syracuse in 399 was the beginning of a great struggle which in 387 resulted in its complete destruction and the dispersion of its inhabitants as slaves. Restored by the younger Dionysius under the name of Phoebias, the colony soon recovered its prosperity and resumed its original designation. In 280, when Pyrrhus invaded Italy, the Regians admitted within their walls a Roman garrison of Campanian troops; these mercenaries revolving through the city in 270 they were besieged and put to death by the Roman consul Genuclus. The city remained faithful to Rome throughout the Punic wars, and Hannibal never succeeded in taking it. Up till the Social War it struck coins of its own, with Greek legends. Though one of the cities promised by the triumvirs to the veterans, Regium escaped through the favour of Octavius (hence it took the name Regium Julium). It continued, however, to be a Greek city even under the Empire, and never became a colony. Towards the end of the Empire it was made the chief city of the Bruttii.

Of ancient buildings hardly anything remains at Regium, and nothing of the ancient period is except perhaps the remains of a temple of Artemis Phaeactis, which have not yet been explored, though various inscriptions relative to it have been found. The museum, however, contains a number of terra-cottas, vases, inscriptions, &c., and a number of Byzantine lead seals. Several baths of the Greek period, modified by the Romans, have been found, and the remains of one of these may still be seen. A large mosaic of the 3rd or 4th century A.D. with representations of wild animals and the figure of a warrior in the centre was found in 1904 and covered up again. The aqueduct and various cisterns connected with it have been traced, and some tombs of the 5th or 4th century B.C. (or later) were found in 1907.

See Notizi degli studi, passim; P. Larizza, Rhegium Chalcdense (Rome, 1905).

REGIUM DONUM. OF ROYAL GIFT, an annual grant formerly made from the public funds to Presbyterians and other Non-conformist ministers in Great Britain and Ireland. It dates from the reign of Charles II., who, according to Bishop Burnet, after the declaration of indulgence of 1672 ordered sums of money to be paid to Presbyterian ministers. These gifts or pensions were soon discontinued, but in 1690 William III. made a grant of £1,200 a year to the Presbyterian ministers in Ireland as a reward for their services during his struggle with James II. Owing to the opposition of the Irish House of Lords the money was not paid in 1711 and some subsequent years, but it was revived in 1715 by George I., who increased the amount to £2,000 a year. Further additions were made in 1724 and in 1792, and in 1868 the sum granted to the Irish Presbyterian ministers was £45,000. The Regium Donum was withdrawn by the act of 1869 which disestablished the Irish church. Provision was made, however, for existing interests therein, and many Presbyterian ministers commuted these on the same terms as the clergy of the church of Ireland.

In England the Regium Donum proper dates from 1731, when Dr Burnet, on behalf of the nonconformists, applied to the king for a grant. This application met with the approval of the committee of ministers for "the use and behalf of the poor widows of dissenting ministers." Afterwards this sum was increased to £1,000 and was made an annual payment "for the assisting either ministers or their widows," and later it amounted to £1,605 per annum. It was given to distributors who represented the three denominations, Presbyterians, Baptists and Independents, enjoying the grant. Among the Nonconformists themselves, however, or at least among the Baptists and the Independents, there was some objection to this form of state aid, and in 1851 the chancellor of the exchequer announced that it would be withdrawn. This was done six years later.

See J. Stoughton, History of Religion in England (1901); J. S. Reid, History of the Presbyterian Church in Ireland (Belfast, 1867); and E. Calamy, Historical Account of my own Life, edited by J. T. Rutt (1816).

REGLA, formerly an important suburb of Havana, Cuba, opposite that city, on the bay; now a part of Havana. Pop. (1890) 11,361. It was formerly the scene of the Havana bull-fights. The church is one of the best in Cuba; the building dates substantially from 1805, but the church settlement goes back to a hermitage established in 1600. Regla is the shipping-point of the Havana sugar trade. It has enormous sugar and tobacco warehouses, fine wharves, a dry dock, foundries and an electric railway plant. It is the western terminus of the eastern line of the United Railways of Havana, and is connected with the main city of Havana by ferry. A fishing village was established here about 1733. At the end of the 18th century Regla was a principal centre of the smuggling trade, and about 1820 was notorious as a resort of pirates. It first secured an ayuntamiento (city council) in 1872, and after 1899 was annexed to Havana.

REGNAUD, JEAN FRANCOIS (1655-1706), French comic dramatist, was born in Paris on the 7th of February 1655. His father, a rich shopkeeper, died when Regnard was about twenty; leaving him master of a considerable fortune. He set off at once for Italy, and, after a series of romantic adventures, he journeyed through Holland, Sweden and Lapland, and thence by Poland, Turkey, Hungary and Germany back to France. He returned to Paris at the end of 1683, and bought the place of treasurer of France in the Paris district; he had a house at Paris in the Rue Richelieu; and he acquired the small estate of Grillon near Dourdan in the department of Seine-et-Oise, where he hunted, feasted and wrote comedies. This latter amusement he began in 1688 with a piece called Le Divorce, which was performed at the Théâtre Italien. In four slight pieces of the same nature he collaborated with Charles Rivière Dufresny. He gained access to the Théâtre Français on the 11th of May 1694 with a piece called Attendez-moi sous l'orne, and two years later, on the 10th of December 1696, he produced there the masterly comedy of Le Joueur. The idea of the play was evolved in collaboration with Dufresny, but the authors disagreed in carrying it out. Finally they each produced a comedy on the subject, Dufresny in prose, and Regnard in verse. Each accused the other of plagiarism. The plot of Regnard's piece turns on the love of two sisters for Valère, the gambler, who loves one and pretends to love the other, really deceiving them both, because there is no room for any other passion in his character except the love of play. Other of his plays were La Sérénade (1694), Le Bourgeois de Poitou (1669), Le Distrait (1697), Déméter (1700), Le Retour imprévu (1700), Les Folies amoureuses (1704), Les Mémoires (1705), a clever following of Plautus, and his masterpiece, Le Légataire universel (1708).

Regnard's death on the 4th of September 1709 renews the doubtful and romantic circumstances of his earlier life. Some hint at poison, but the truth seems to be that his death was hastened by the rate at which he lived.

Besides the plays noticed above and others, Regnard wrote several epigrams, the famous *Eulogy on Death* and several short accounts in prose of his travels, published posthumously under the title of Voyages. Regnard had written a reply to the tenth satire of Boileau, Contre les femmes, and Boileau had retorted by publishing Regnard among the poets depreciated in his epistle Sur mes vers. After the appearance of Le Joueur the poet altered his opinion and cut out the allusion. The saying attributed to Boileau when some one, thinking to carry favour, remarked that Regnard was only a mediocre poet: "Il n'est que médiocre tant que je suis", is both true and very appropriate. His French style, especially in his purely prose works, is not considered faultless. He is often unoriginal in his plots, and, whether Dufresny was or was not justified in his complaint about Le Joueur, it seems likely that Regnard owed not a little to him and to others; but he had a thorough grasp of
REGNAULT, H.—REGNAULT DE SAINT JEAN D’ANGÉLY

comic situation and incident, and a most amusing faculty of dialogue.

The first edition of Regnault’s works was published in 1831 (5 vols., Rouen and Paris). There is a good selection of most everything important in the Collection Didot (4 vols., 1819), but there is no absolutely complete edition. The best is that published by Crapelet (6 vols., Paris, 1822). A selection by L. Moland appeared in 1893. See also a Catalogue biographique des œuvres de J. F. Regnault (Paris, Rouquette, 1878); Le Poète J. F. Regnard en son chasteau de Grillon, by J. Guyot (Paris, 1907).

REGNAULT, HENRI (1843–1871), French painter, born at Paris on the 31st October 1843, was the son of Henri Victor Regnault (q.c.). On leaving school he successively entered the studios of Montfort, Lamotte and Cabanel, was beaten for the Grand Prix (1863) by Layraud and Montchalbon, and in 1864 exhibited two portraits in no wise remarkable at the Salon. In 1866, however, he carried off the Grand Prix with a work of unusual force and distinctiveness—“The Thetis bringing the Arms forged by Vulcan to Achilles” (School of the Fine Arts). The past in Italy did not touch him, but his illustrations to Wey’s Rome show how observant he was of actual life and manners; even his “Automedon” (School of Fine Arts), executed in obedience to Academical regulations, was but a lively recollection of a carnival horse-race. At Rome, moreover, Regnault came into contact with the modern Hispano-Italian school, a school highly materialistic and inclined to regard even the human subject only as one amongst many sources whence to obtain amusement for the eye; if many of his successors were in opposition to Regnault with ever-increasing force during the few remaining years of his life. In 1868 he had sent to the Salon a life-size portrait of a lady in which he had made one of the first attempts to render the actual character of fashionable modern life. While making a tour in Spain, he saw Prim pass at the head of his troops, and received that lively image of a military demagogue which he afterwards put on canvas, somewhat to the displeasure of his subject. But this work made an appeal to the imagination of the public, whilst all the later productions of Regnault were addressed exclusively to the eye. After a further flight to Africa, abridged by the necessities of his position as a pensioner of the school of Rome, he painted “Judith,” then (1870) “Salome,” and, as a work due from the Roman school, despatched from Tangier the large canvas, “Execution without Hearing under the Moorish Kings,” in which the painter had played with the blood of the victim as if he were a jeweller toying with rubies. The war arose, and found Regnault foremost in the devoted ranks of Buzenval, where he fell on the 19th of January 1871.

See Correspondance de H. Regnault; Duparc, H. Regnault, sa vie et ses œuvres; Thanh, H. Regnault, 1843–1971; Bailliére, Les Artistes de mon temps; C. Blanc, H. Regnault; F. Manta, Gazette des Beaux Arts (1872).

REGNAULT, HENRI VICTOR (1810–1878), French chemist and physicist, was born on the 21st of July 1810 at Aix-la-Chapelle. His early life was a struggle with poverty. When a boy he went to Paris and obtained a situation in a large drapery establishment, where he remained, occupying every spare hour in study, until he was in his twentieth year. Then he entered the École Polytechnique, and passed in 1833 to the École des Mines, where he developed an aptitude for experimental chemistry. A few years later he was appointed to a professorship of chemistry at Lyons. His most important contribution to organic chemistry was a series of discoveries, begun in 1835, on the haloid and other derivatives of unsaturated hydrocarbons. He also studied the alkaloids and organic acids, introduced a classification of the metals according to the facility with which they or their sulphides are oxidized by steam at high temperatures, and effected a comparison of the chemical composition of atmospheric air from all parts of the world. In 1840 he was recalled to Paris by his appointment to the chair of chemistry in the École Polytechnique; at the same time he was elected a member of the Académie des Sciences, in the chemical section, in room of P. J. Robiquet (1780–1849); and in the following year he became professor of physics in the Collège de France, there succeeding P. L. Dulong, his old master, and in many respects his model. From this time Regnault devoted almost all his attention to practical physics; but in 1847 he published a four-volume treatise on Chemistry which has been translated into many languages.

Regnault executed a careful redetermination of the specific heats of all the elements obtainable, and of many compounds—solids, liquids and gases. He investigated the expansibility of gases by heat, determining the coefficient for air as c=0065, and showed that, contrary to previous opinion, no two gases had precisely the same rate of expansion. By numerous delicate experiments he proved that Boyle’s law is only approximately true, and that those gases which diverge most widely from obedience to it. He studied the whole subject of thermometry critically; he introduced the use of an accurate air-thermometer, and compared its indications with those of a mercurial thermometer, determining the absolute dilatation of mercury by heat as a step in the process. He also paid attention to hygrometry and devised a hygrometer in which a cooled metal surface is used for the deposition of moisture.

In 1854 he was appointed to succeed J. J. Ebelmen (1814–1852) as director of the porcelain manufactory at Sèvres. He carried on his great research on the expansion of gases in the laboratory at Sèvres, but all the results of his latest work were destroyed during the Franco-German War, in which also his son Henri (noticed above) was killed. Regnault never recovered from the double blow, and, although he lived until the 15th of January 1878, his scientific labours ended in 1872. He wrote more than eighty papers on scientific subjects, and he made important researches in conjunction with other workers. His greatest work, bearing on the practical treatment of steam-engines, forms vol. xx. of the Mémoires de l’Académie des Sciences.

REGNAULT, JEAN BAPTISTE (1754–1819), French painter, was born at Paris on 9th October 1754, and died in the same city on the 12th of November 1829. He began life at sea in a merchant vessel, but at the age of fifteen his talent attracted attention, and he was sent to Italy by M. de Monval under the care of Bardin. After his return to Paris, Regnault, in 1776, obtained the Grand Prix, and in 1783 he was elected Academician. His diploma picture, the “Education of Achilles by Chiron,” is now in the Louvre, as also the “Christ taken down from the Cross,” originally executed for the royal chapel at Fontainebleau, and two minor works—the “Origin of Painting” and “Pygmalion praying Venus to give Life to his Statue.” Besides various small pictures and allegorical subjects, Regnault was also the author of many large historical paintings; and his school, which reckoned amongst its chief attendants Guérin, Crepin, Lafitte, Blondel, Robert Lefèvre and Menjaud, was for a long while the rival in influence of that of David.

REGNAULT DE SAINT JEAN D’ANGÉLY, MICHEL LOUIS ÉTIENNE, COMTE (1761–1816), French politician, was born at Saint Fargeau (Yonne) on the 3rd of December 1761. Before the Revolution he was an avocat in Paris and lieutenant of the maritime provostship of Rochefort. In 1795 he was elected deputy to the States General by the Third Estate of the état d’armes of Saint Jean d’Angély. His eloquence made him a prominent figure in the Constituent Assembly, where he boldly attacked Mirabeau, and settled the dispute about the ashes of Voltaire by decreeing that they belonged to the nation. But the moderation shown by the measures he proposed at the time of the flight of the king to Varennes, by his refusal to accede to the demands for the king’s execution, and by the articles he published in the Journal de Paris and the Ami des patriotes, marked him out for the hostility of the advanced parties. He was arrested after the revolution of the 10th of August 1792, but succeeded in escaping, and during the reaction which followed the fall of Robespierre was appointed administrator of the military hospitals in Paris. His powers of organization brought him to Bonaparte’s notice, and he took part in the coup d’état of 18 Brumaire, year VIII. (9th of November 1799). Under the Empire he enjoyed the confidence of Bonaparte, and was made councillor of state, president of section in the Council of State,
RÉGNIER, H.—REGULA

member of the French Academy, procureur général of the high court, and a count of the Empire. He was dismissed on the first restoration of the Bourbons, but resumed his posts during the Hundred Days, and after Waterloo persuaded the emperor to abdicate. He was exiled by the government of the second Restoration, but subsequently obtained leave to return to France. He died on the day of his return to Paris (14th of March 1819). Les Souvenirs du Comte Regnault de St Jean d'Angély (Paris, 1817) are spurious. His son, Auguste Michel Étienne Regnault de Saint Jean d'Angély (1794–1870), an army officer, was dismissed from the army by the Restoration government, fought for the Greeks in the Greek War of Independence, and rejoined the French army in 1830. In 1848 he was elected deputy and sat on the right. Under the Second Empire he went through the Crimean and Italian campaigns, and was made senator and marshal for bravery at the battle of Magenta.

RÉGNIER, HENRI FRANÇOIS JOSEPH DE (1864– ). French poet, was born at Honfleur (Calvados) on the 28th of December 1864, and was educated in Paris for the law. In 1885 he began to contribute to the Parisian reviews, and his verses found their way into most of the French and Belgian periodicals favourable to the symbolist writers. Having begun, however, to write under the leadership of the Parnassians, he retained the classical tradition, though he adopted some of the innovations of Moréas and Gustave Kahn. His gorgeous and vaguely suggestive style shows the influence of Stéphane Mallarmé, of whom he was an assiduous disciple. His first volume of poems, Lesdestaunis, appeared in 1885, and among numerous later volumes are Poésies anciennes et romanesques (1890), Les Jeux rustiques et divins (1890), Les Médailles d'argent (1900), La Cité des eaux (1903). He is also the author of a series of realistic novels and tales, among which are La Conne de jaspe (2nd ed., 1897), La Double Maîtresse (3rd ed., 1900), Les Vacances d'un jeune homme sage (1904), and Les Amants singuliers (1905). M. de Régnier married Mlle. Marie de Hédéria, daughter of the poet, and herself a novelist and poet under the name of Gérard d'Houville.

See E. Gousse, French Profils (1905), and Poètes d'aujourd'hui (6th ed., 1909), by van Bever and Léautaud.

RÉGNIER, MATHURIN (1573–1613), French satirist, was born at Chartres on the 21st of December 1573. His father, Jacques Régnier, was a bourgeois of good means and position; his mother, Simone Desportes, was the sister of the poet Desportes. Desportes, who was richly benefited and in great favour at court, seems to have been regarded as Mathurin Régnier's natural protector and patron; and the boy himself, with a view to his following in his uncle's steps, was tonsured at eight years old. Little is known of his youth, and it is chiefly conjecture which fixes the date of his visit to Italy in a humble position in the suite of the cardinal, François de Joyeuse, in 1587. The cardinal was accredited to the papal court in that year as "protector" of the royal interests. Régnier found his duties irksome, and when, after many years of constant travel in the cardinal's service, he returned definitely to France about 1605, he took advantage of the hospitality of Desportes. He early began the practice of satirical writing, and the enmity which existed between his uncle and the poet Malherbe gave him occasion to attack the latter. In 1606 Desportes died, leaving nothing to Régnier, who, though disappointed of the succession to Desportes's abbeys, obtained a pension of 2000 livres, chargeable upon one of them. It was also made the occasion of 200 letters through his friendship with the lax bishop, Philippe Hurault, at whose abbey of Royaumont he spent much time in the later years of his life. But the death of Henry IV. deprived him of his last hope of great preferments. His later life had been one of dissipation, and he died at Rouen at his hotel, the Écu d'Orléans, on the 22nd of October 1613.

About the time of his death numerous collections of licentious and satirical poems were published, while others remained in manuscript. Gathered from these there has been a floating mass of licentious epigrams, &c., attributed to Régnier, little of which is certainly authentic, so that it is very rare to find two editions of Régnier which exactly agree in contents. His undeniable work falls into three classes: regular satires in alexandrine couplets, serious poems in various metres, and satirical or jocular epigrams and light pieces, which often, if not always, exhibit colloquial, or liberum of language. The national greatness of Régnier consists in the variety and poetical value of his satires, contrasted and heightened as that vigour is with the exquisite feeling and melancholy music of some of his minor poems. In these Régnier is a disciple of Ronsard (whom he defended brilliantly against Malherbe), without the occasional pedantry, the affectation or the undue fluency of the Ælade; but in the satires he seems to have had no master except the ancients, for some of them were written before the publication of the satires of Vauquelin de la Fresnaye, and the Tragiques D'Aubigné did not appear until 1616. He has sometimes followed Horace closely, but always in an entirely original spirit. His vocabulary is varied and picturesque, and is not marred by the maladroit classicism of some of the Ronsardists. His verse is extraordinarily forcible and nervous, but his chief distinction as a satirist is the way in which he avoids the commonplaces of satire. His keen and accurate knowledge of human nature and even his purely literary qualities excuted the admiration of Boileau. Régnier displayed remarkable independence and acuteness in literary criticism, and the famous passage (Satire ix., À Monsieur RAPIN) in which he satirizes Malherbe contains the best denunciation of the merely "correct" theory of poetry that has ever been written. Lastly, Régnier had a most unusual descriptive faculty, and the vividness of what he called his narrative satires was not approached in France for at least two centuries after his death. All his merits are displayed in the masterpiece entitled Macette ou l'Hypocrisie déconcertée, which does not suffer even on comparison with Taurin; but hardly any one of the sixteen satires which he has left falls below a very high standard.

Les Premières Œuvres ou satyres de Régnier (Paris, 1608) included the Discours au roi and ten satires. There was another in 1609, and others in 1612 and 1613. The author had also contributed to two collections—Les Muses guerillards in 1609 and Le Temple d'Apollon in 1611. In 1616 appeared Les Satyres et autres œuvres folastres du sieur Régnier, with many additions and some poems by other hands. Among the famous editions of Régnier are those of Etienne Delécluse (1616) and of H. de Poitiers (1617), which were highly praised. The chief editions of the 18th century are that of Claude Brossette (printed by Lyon & Woodman, London, 1729), which supplies the standard commentary on Régnier; and that of Prosper Poitevin (Paris, 1860), of Ed. de Barthélemy (Paris, 1862), and of E. Courbet (Paris, 1875), may be specially mentioned. The last, printed after the originals in italic type, and also called a "révisée," is perhaps the best. See also V. de Chaussay's M. du Père de Chaussay, M. C. Chaussay, M. de H. de Chaussay (1896); M. H. Cherrier, Bibliographie de Mathurin Régnier (1884).

RÉGNIITZ, a river of Germany, and a left-bank tributary of the Main, the most important river of the province of Lower Bavaria. It is formed by the confluence, near Fürth, of the Rednitz and Pegnitz. The united river flows north through an undulating vine-clad country, past Erlangen, Baiersdorf and Forchheim, from which point it is navigable, and falls into the Main at Bischberg, just below Bamberg, after a course of 126 m. Near Bamberg it is joined by the Ludwigskanal, which, running parallel to it from Fürth and separated by the railway, forms the water-connexion between the Main and the Danube. Its main tributaries from the right are the Gründach and the Wiesent, and from the left the Zenn, the Aurach and the Aschach.

REGRATING (O.Fr. regrater, to sell by retail), in English criminal law, was the offence of buying and selling again in the same market, or within four miles thereof. (See En-graSSING.)

REGULA, the Latin word for a rule, hence particularly applied to the rules of a religious order (see MONASTICISM). In architecture the term is applied to a rule or square, the short fillet or rectangular block, under the taenia (q. v.) on the architrave of the Doric entablature.
REGULAR, orderly, following or arranged according to a rule (Lat. regula, whence O.Fr. roule, whence English "rule"), steady, uniform, formally correct. The earliest and only use in English until the 16th century was in the Med. Lat. sense of regularis, one bound by and subject to the rule (regula) of a monastic or religious order, a member of the "regular" as opposed to the "secular" clergy, and so, as a substantive, a regular, i.e. a monk or friar. Another specific application is to that portion of the armed forces of a nation which are organized on a permanent system, the standing army, as opposed to "irregulars," levies raised on a voluntary basis and disbanded when the particular campaign or war for which they were raised is at an end. In the British army, the forces were divided into regulars, militia and volunteers, until 1906, when they were divided into regular and territorial forces.

REGULUS, MARCUS AURELIUS (256 B.C.-), was one of the commanders in the Punic naval expedition which shattered the Carthaginian fleet at Ecnomus, and landed an army on Carthaginian territory (see Punic Wars). The invaders were so successful that the other consul, L. Manlius Vulso, was recalled to Rome, Regulus being left behind to finish the war. After a severe defeat at Adys near Carthage, the Carthaginians were inclined for peace, but the terms proposed by Regulus were so harsh that they resolved to continue the war. In 255, Regulus was completely defeated at Adys and Carthage, and the Carthaginians were captured. There is no further trustworthy information about him. According to tradition, he remained in captivity until 250, when after the defeat of the Carthaginians at Panormus he was sent to Rome on parole to negotiate a peace or exchange of prisoners. On his arrival he strongly urged the senate to refuse both proposals, and returning to Carthage was tortured to death (Horace, Odes, iii. 3). This story made Regulus to the later Romans the type of heroic endurance; but most historians regard it as insufficiently attested, Polybius being silent. The tale was probably invented by the annalists to excite the cruel treatment of the Carthaginian prisoners by the Romans.

See Polybius i. 25-34; Florus ii. 43; Clever, De Officiis, iii. 26; Livy, Eplt. 18; Valerius Maximus ix. 2; Sil. Ital. vi. 299-550; Appian, Punica, 4; Zonaras viii. 15; see also O. Jüger, M. Aurelius Regulus (1878).

REHAN, ADA (1860- ), American actress, whose real name was Crehan, was born in Limerick, Ireland, on the 22nd of April 1860. Her parents removed to the United States when she was five years old, and it was in Newark, N.J., that in 1874 she made her first stage appearance in a small part in A New Constance. She was married to John Drew's stock company in Philadelphia, John W. Albangh's in Albany and Baltimore, and other companies for several seasons, playing every kind of minor part, until she became connected with Augustin Daly's theatrical management in 1879. Under his training she soon showed her talents for vivid, charming portrayal of character, first in modern and then in older comedies. She was the heroine in all the Daly adaptations from the German, and added to her triumphs the parts of Peggy in Wycherly's Country Girl, Julia in the Hunchback, and especially Katharina in The Taming of the Shrew, besides playing Rosalind and Viola regularly. Miss Rehan accompanied Daly's company to England (first in 1884), France and Germany (1885). Her life-size portrait as Katharina is in the picture-galley, but her bust, with Ellen Terry's, at the entrance to the theatre in the Shake-speare Memorial at Stratford-on-Avon.

REHEARSAL (from "rehearse," to say over again, repeat, recount, O.Fr. hercere, from re, again, and herce, to harrow, cf. "hearst," the original meaning being to rake or go over the same ground again as with a harrow), a recital of words or statements, particularly the trial performance in private of a play, musical composition, recitation, &c., for the purpose of practicing or criticism as to the performance in public. In the theatre a "full rehearsal" is one in which the whole performance is gone through with all the performers, a "dress rehearsal" one in which the performance is carried out with scenery, costumes, properties, &c., exactly as it is to be played in public.

REHOBOAM (Heb. raphōb'ām, probably "the clan is en-larged," see Ex. lxxvii. 23, although on the analogy of Rehobiah and Bab, ra-bi-îlu, 'Am may represent some god; Septuagint reads ραβσαυα, son of Solomon and first king of Judah. On the events which led to his accession and the partition of the Hebrew monarchy, see JEROBOAM, SOLOMON. Although his age is given as forty-one (1 Kings xiv. 21), the account of his treatment of the Israelite deputation (1 Kings xii.), as also 2 Chron. xii. 7, give an impression of youth. He was partly of Ammonite origin (1 Kings xiv. 21), and, like his father, continued the foreign worship which his connexions involved. The chief event of his reign was the incursion of Egypt under Sheshonk (Shishak) I., was called upon against Judah and despoiled the temple about 930 B.C. (see Egypt, History, § "Deltic Dynasties"). That this invasion is to be connected with the friendly relations which are said to have subsisted between the first of the Libyan dynasty and Rehoboam's rival is unlikely. Sheshonk has figured his campaign outside the great temple of Karnak with a list of some 150 places which he claims to have conquered, but it is possible that these were only tributary, and the names may be largely based upon older lists. Towns of both Judah and Israel are incorporated, and it is possible that Jerusalem once stood where now the site was mutilated as a temple. The book of Chronicles enumerates several Judean cities fortified by Rehoboam (not necessarily connected with Sheshonk's campaign), and characteristically regards the invasion as a punishment (2 Chron. x. 5 sqq., xii. 1-15; for the prophet Shemaiah see 1 Kings xii. 21-24). Of Rehoboam's successor Abijah (or Abijam) little is known except a victory over Jeroboam recorded in 2 Chron. xiii. See further Asa, Osmi, and Jews (History), §§ 7, 9.

REICHA, ANTON JOSEPH (1770-1836), French musical theorist and teacher of composition, was born at Prague on the 27th of February 1770, and educated chiefly by his uncle, Joseph Reiche (1746-1795), a clever violoncellist who first received him into his house at Wallerstein in Bohemia, and afterwards carried him to Bonn. Here, about 1789, he was made flutist in the orchestra of the elector. In 1794 he went to Hamburg and gave music lessons there, also producing the opera Godefroid de Montfort. He was in Paris in 1799 and in Vienna from 1802 to 1808, during which period he saw much of Beethoven and Haydn. In the latter year he returned to Paris, where he produced three operas without much success. In 1817 he succeeded Méhul as professor of counterpoint at the Conservatory, where he remained until 1833. In 1835 he was admitted as a member of the Institute in the place of Boieldieu. He died in Paris on the 28th of May 1836. He produced a vast quantity of church music, five operas, a number of symphonies, oratorios and many miscellaneous works. Though clever and ingenious, his compositions are more remarkable for their novelty than for the beauty of the ideas upon which they are based. His fame is, indeed, more securely based upon his didactic works. His Traité de méthode (Paris, 1814), Cours de composition musicale (Paris, 1818), Traité de musique (Paris, 1824-26), and Art du compositeur dramatique (Paris, 1833), are valuable and instructive essays for the student, though many of the theories they set forth are now condemned as erroneous.

REICHENAU, a picturesque island in the Untere or western arm of the lake of Constance, 3 m. long by 1 broad, and connected with the east shore by a causeway three-quarters of a mile long. It belongs to the grand duchy of Baden. The soil

1 The once popular view that "king of Judah" stands in no. 29 is untenable. See Petrie, Hist. of Egypt, ii. p. 235; L. B. Paton, Syria and Pal., p. 193 sqq.; W. M. Müller, Méthode Vorderasiatische, Genell, 1900. See also Breasted (Amer. Journ. of Sem. Lang., 1904, p. 30) has made the interesting observation that the list mentions "the field of Abram" (nos. 71 and 72); see further, id., Egypt. Hist. Records, iv. pp. 348-357.
is very fertile, and excellent wine is produced in sufficient quantity for exportation. The Benedictine abbey of Reichenschau, founded in 724, was long celebrated for its wealth and for the services rendered by its monks to the cause of learning. In 1540 the abbey, which had previously been independent, was annexed to the see of Constance, and in 1790 it was secularized. The abbey church, dating in part from the 9th century, contains the tomb of Charles the Fat (d. 888), who retired to this island in 887, after losing the empire of Charlemagne. It now serves as the parish church of Mittelzell, while the churches of Oberzell and Unterrzell are also interesting buildings of the Carolingian era.

Reichenbach, Georg von (1772-1826), German astronomical instrument maker, was born at Durlach in Baden on the 24th of August 1772. From 1796 he was occupied with the construction of a dividing engine; in 1804, with Joseph, Liebher and Joseph Utschneider, he founded an instrument-making business in Munich; and in 1808 he was established, with Joseph Fraunhofer and Utschneider, optical works at Benedictbeurn, which were moved to Munich in 1823. He withdrew from both enterprises in 1814, and founded with T. L. Ertel a new optical business, from which also he retired in 1821, on obtaining an engineering appointment under the Bavarian government. He died at Munich on the 21st of May 1856.

Reichenbach's principal merit was that he introduced into observatories the meridian or transit circle, combining the transit instrument and the mural circle into one instrument. This had already been done by O. Römer about 1794, but the idea had not been adopted by any one else, except in the transit circle constructed by Edward Troughton for Stephen Groomebridge in 1806. The transit circle in the form given it by Reichenbach had one finely divided circle attached to one end of the horizontal axis and read by four verniers on an "allidade circle," the unaltered position of which was tested by a spirit level. The instrument came almost at once into universal use on the continent of Europe (the first one was made for F. W. Bessel in 1816), but in England the mural circle and transit instrument were not superseded for many years.

Reichenbach, a town of Germany, in the Prussian province of Silesia, situated on the Peile, at the foot of the Elbeingebirge, a spur of the Riesengebirge, 30 m. S.W. of Breslau by rail. Pop. (1905) 15,884. Among its industries are weaving, spinning, dyeing, brewing and machine building, and there is a considerable trade in grain and cattle. Reichenbach is memorable for the victory gained here on the 16th of August 1762 by the Prussians over the Austrians. Here was held the congress which resulted in the convention of Reichenbach—signed on the 27th of July 1790 between Great Britain, Prussia, Austria, Poland and Holland—guaranteeing the integrity of Turkey. Here, too, in June 1815, was signed the treaty of alliance between Austria and the Allies for the prosecution of the war against France.

See the Kurze Geschichte der Stadt Reichenbach (Reichenbach, 1874).

Reichenbach, a town in the kingdom of Saxony, situated in a hilly district, known as the Vogtland, 11 m. S.W. of Zwitkaus, at the junction of the main lines of railway Dresden-Leipzig-Hof. Pop. (1905) 24,015. It contains a handsome town-hall rebuilt in 1833, and a natural history museum. The industries embrace the manufacture of cloth, machinery and carriages, also dyeing and bleaching. The earliest mention of the town occurs in a document of 1212, and it acquired municipal rights in 1367. The woollen manufacture was introduced in the 15th century, and took the place of the mining industry which had been established earlier.

Reichenburg (Czech, Liberec), a town of Bohemia, 87 m. N.E. of Prague by rail. Pop. (1900) 34,099, chiefly German. The most prominent buildings are the new town-hall (1893); the castle of Count Clam Gallas, built in the 17th century, with additions dating from 1774 and 1850; the Erzdekanatskirche, of the 16th century; the Protestant church, a handsome modern Romanesque edifice (1864-68) and the hall of the cloth-workers. Reichenberg is one of the most important centres of trade and industry in Bohemia, its staple industry being the cloth manufacture. Next in importance comes the spinning and weaving of wool, cotton, linen and carpet manufactures, and dyeing.

Reichenberg is first mentioned in a document of 1348, and from 1622 to 1634 was among the possessions of the great Wallenstein, since the death of his house it has belonged to the Gallias and Clam Gallias families, though their jurisdiction over the town has long ceased. The cloth-making industry was introduced in 1579.

Reichenhall, a town and watering-place in the kingdom of Bavaria, finely situated in an amphitheatre of lofty mountains, on the river Saalach, 1570 ft. above sea-level, 9 m. S.W. of Berchtesgaden. Pop. (1900) 4927, exclusive of the suburbs. Reichenhall possesses several natural springs, producing about 8,900 tons of salt per annum. The water of some of the springs, the sources of which are 50 ft. below the surface, is so strongly saturated with salt (up to 24%) that it is at once conducted to the boiling houses, while that of the others is first submitted to a process of evaporation. Reichenhall is the centre of the four chief Bavarian salt-works, which are connected with each other by brine conduits having an aggregate length of 60 m. The surplus brine of Berchtesgaden is conducted to Reichenhall, and thence, in increased volume, to Traunstein and Rosenthal, and of these latter supplies of timber for use as fuel in the process of boiling. Since 1846 Reichenhall has become one of the most fashionable spas and climatic health resorts in Germany, and it is now visited annually by about ten thousand patients, besides many thousand passing tourists. The saline springs are used both for drinking and bathing, and are said to be efficacious in scrofula and incipient tuberculosis.

The brine springs of Reichenhall are mentioned in a document of the 8th century and were perhaps known to the Romans; but almost all trace of antiquity of the town was destroyed by the conflagration in 1854. The brine conduit to Traunstein dates from 1618. The environs abound in numerous charming Alpine excursions.

See G. von Liebig, Reichenhall, sein Klima und seine Heilmittel (6th ed., Reichenhall, 1886); and Goldschmidt, Der Kurort Bad Reichenhall und seine Umgebung (Vienna, 1892).

Reichenberger, August (1806-1893), German politician, was born at Coblenz on the 22nd of March 1806, studied law and entered government service, becoming counsellor to the court of appeal (Appellationsgerichtsrat) at Cologne in 1849. He was a member of the German parliament at Frankfurt in 1848, when he attached himself to the Right, and of the Erfurt parliament in 1850, when he voted against the Prussian Union. From 1850 to 1863 he sat in the Prussian Lower House, from 1867 to 1884 in the Reichstag, and from 1879 onwards also in the Prussian Chamber of Deputies. Originally of Liberal tendencies, he developed from 1837 onwards ultramontane opinions, founded in 1852 the Catholic group which in 1861 took the name of the Centre party (Centrum) and became one of its most conspicuous orators. He died on the 16th of July 1893 at Cologne. He published a considerable number of works on art and architecture, including Die christlich-germanische Baukunst (Trier, 1852; 3rd ed., 1869; Fingerzeige auf dem Gebiete der christlichen Kunst (Leipzig, 1854); Augustus Pugin, der Neubegründer der christlichen Kunst in England (Freiburg, 1877).

His brother, Peter Reichenberger (1816-1892), counsellor to the appeal court at Cologne (1839) and until 1870 to the Obertribunal at Berlin, was elected to the Reichstag in 1867 as a member of the Liberal Opposition, but subsequently joined the Centre party. In the Kulturkampf he took an active part on the ultramontane side. He had been a member of the Prussian National Assembly in 1848, and in 1888 he published his Erlebnisse eines alten Parlamentariers im Revolutionsjahr 1848.

Reichstadt, Napoleon Francis Joseph Charles, Duke of (1811-1832), known by the Bonapartists as Napoleon II., was the son of the Emperor Napoleon I. and Marie Louise, archduchess of Austria. He was born on the 20th of
March 1811, in Paris at the Tuileries palace. He was at first named the king of Rome, after the analogy of the heirs of the emperors of the Holy Roman Empire. By his birth the Napoleonic dynasty seemed to be finally established; but in three years it crumbled in the dust. At the time of the downfall of the empire (April 1814) Marie Louise and the king of Rome were at Blois with Joseph and Jerome Bonaparte, who wished to keep them as hostages. This design, however, was frustrated. Napoleon abdicated in favour of his son; but events prevented the reign of Napoleon II. from being more than titular. While Napoleon repaired to Elba, his consort and child went to Vienna; and they remained in Austria during the Hundred Days (1815), despite efforts made by the Bonapartists to carry off the prince to his father at Paris.

Meanwhile the congress of Vienna had carried out the conditions of the treaty of Fontainebleau (March 1814) whereby the duchies of Parma and Guastalla were to go to the ex-Empress Marie Louise and her son, although much opposition was offered to this proposal by Louis XVIII and even (so it now appears) by Metternich. The secret treaty of the 31st of May 1815 between Austria, Russia and Prussia secured those possessions to her, her son bearing the title Prince of Parma, with hereditary rights for his descendants. But after the second abdication of Napoleon in favour of his son (22nd of June 1815)—a condition which was wholly nugatory—the powers opposed all participation of the prince in the affairs of Parma. He therefore remained in Austria, while Marie Louise proceeded to Parma. From this time onward he became, as it were, a pawn in the complex game of European politics, his claims being put forward sometimes by Metternich, sometimes by the unionists of Italy, while occasionally malcontents in France used his name to discredit the French Bourbons. The efforts of malcontents increased the resolve of the sovereigns never to allow a son of Napoleon to hear rule; and in November 1816 the court of Vienna informed Marie Louise that her son could not succeed to the duchies. This decision was confirmed by the treaty of Paris of the 20th of June 1817. Marie Louise demanded as a slight compensation that he should have a title derived from the lands of the "Jedermann" of Bohemia, and the title of "duke of Reichstadt" was therefore conferred on him on the 22nd of July 1818. Thus Napoleon L., who once averred that he would prefer that his son should be Stranger rather than brought up as an Austrian prince, lived to see his son reduced to a rank inferior to that of the Austrian archdukes.

His education was confided chiefly to Count Dietrichstein, who found him precocious, volatile, passionate and fond of military affairs. The same judgment was given by Marshal Marmon, duke of Ragusa, who recognized the warlike strain in his character. His nature was sensitive, as appeared on his receiving the news of the death of his father in 1821. This upheaval in France in 1830 and the disturbances which ensued led many Frenchmen to turn their thoughts to Napoleon II.; but though Metternich dallied for a time with the French Bonapartists, he had no intention of inaugurating a Napoleonic revival. By this time, too, the duke's health was on the decline; his impatience of all restraint and his indulgence in physical exercise far beyond his powers aggravated a natural weakness of the chest, and he died on the 22nd of July 1832.

(Paris, 1832); G. de l'Hérald, Histoire de Napoléon II. (Paris, 1833); Count Anton von Prokesch-Osten, Mein Verhältniss zum Herzog von Reichstadt (Vienna, 1878); J. H. Proksch-Osten, "Reichstadt," (Paris, 1879); E. de Wertheimer, The Duke of Reichstadt (Eng. ed., London, 1905); M. Rostand's play L'Aiglon is a dramatic setting of the career of the prince.

REID, SIR GEORGE (1841– ), Scottish artist, was born in Aberdeen on the 31st of October 1841. He developed an early passion for drawing, which led to his being apprenticed in 1854 for seven years to Messrs Keith & Gibb, Lithographers in Aberdeen. In 1861 Reid took lessons from an itinerant portrait-painter, William Niddrie, who had been a pupil of James Giles, R.S.A., and afterwards entered as a student in the school of the Board of Trustees in Edinburgh. He returned to Aberdeen to paint landscapes and portraits for any trifling sum which his work could command. His first portrait to attract attention, from its fine quality, was that of George Macdonald, the poet and novelist, now the property of the university of Aberdeen. His early landscapes were conscientiously painted in the open air and on the spot. But Reid soon came to see that such work was inherently false, painted as the picture was day after day under varying conditions of light and shade. Accordingly, in 1865 he proceeded to Utrecht to study under A. Mollinger, whose work he admired, from its unity and simplicity. This change in his method of viewing Nature was looked on as revolutionary by the Royal Scottish Academy, and for some years his work found little favour in that quarter; but other artists gradually adopted the system of tone-studies, which ultimately prevailed. Reid went to Paris in 1868 to study under the figure painter Yvon; and he worked in 1872 with Josef Isaaks at the Hague. From this time forward Reid's success was continuous and marked. He showed his versatility in landscape, as in his "Whins in Bloom," which combined great breadth with fine detail; in flower-pieces, such as his "Roses," which were brilliant in rapid suggestiveness and force; but most of all in his portraits, which are marked by great individuality; and by fine insight into character. His work in black-and-white, his admirable illustrations in brushwork of Edinburgh and its neighbourhood, and also his pen-drawings, about which it has been declared that "his work contains all the subtleties and refinements of a most delicate etching," must also be noted. Elected Associate of the Royal Scottish Academy in 1870, Reid attained full membership in 1877, and took up his residence in Edinburgh in 1882. In 1891 he was elected President—a post which he held until 1902—receiving also the honour of knighthood, and he was awarded a gold medal at the Paris Exhibition of 1900. His brother Samuel (b. 1854) was also a painter and a writer of tales and verse.

REID, ROBERT (1862– ), American artist, was born at Stockbridge, Mass., on the 29th of July 1862. He studied at the art schools of the Boston Museum of Fine Arts, the Art Students' League, New York, and under Boulanger and Lefebvre in Paris. His early pictures were figures of French peasants, painted at Étaples, but subsequently he became best known for mural decoration and designs for stained glass. He contributed with others to the frescoes of the dome of the Liberal Arts Building at the Columbian Exposition, Chicago, in 1893. Other work is in the Congressional Library, Washington, the Appellate Court House, New York, and the State House, Boston, where are his three large panels, "James Otis Delivering his Speech against the Writs of Assistance," "Paul Revere's Ride" and the "Boston Tea Party." He executed a panel for the American Pavilion at the Paris Exhibition, 1900, and in 1906 he completed a series of ten stained glass windows for a church at Fairhaven, Mass., for the Rogers Memorial. In 1906 he became a full member of the National Academy of Design.

REID, SIR ROBERT GILLESPIE (1849–1908), Canadian railway contractor, was born at Coupur-Angus, Scotland. When a young man he spent a few years in Australia gold-mining, and in 1871 he settled in America, where he began his career as a contractor. He built one section of the Canadian Pacific railway, and was responsible for the erection of the international bridge over the Niagara river, the international railway bridge over the Rio Grande river and the Lachine bridge over the St Lawrence. In 1893 Reid signed a contract with the government of Newfoundland by which he undertook to construct a railway from St John's to Port-aux-Basques and to work the line for ten years in return for a large grant of land. In 1898 he further contracted to work all the railways in Newfoundland for fifty years on condition that at the end
of this time they should become his property. This bargain, which included other matters such as steamers, docks and telegraphs, was extraordinarily favourable to Reid, who, by further enormous grants of land, became one of the largest landed proprietors in the world; public opinion was aroused against it, and at first the governor, Sir Herbert Murray, refused to ratify it. After the premier, Sir James Winter, had been replaced by Sir John Stuart (a later Reid's cousin, the terms of the contract were revised, being made more favourable to Newfoundland, and Reid's interests were transferred to a company, the Reid Newfoundland Company, of which he was the first president (see NEWFOUNDLAND, Roads and Railways). Reid was knighted in 1907, and he died on the 3rd of June 1908.

REID, THOMAS (1710-1790), Scottish philosopher, was born at Strachan in Kincardineshire, on the 26th of April 1710. His father was minister of the place for fifty years, and traced his descent from a long line of Presbyterian ministers on both sides. His mother belonged to the brilliant Gregory family (q.v.), which, in the 18th century, gave so many representatives to literature and science in Scotland. Reid graduated at Aberdeen in 1726, and remained there as librarian to the university for ten years, a period which he devoted largely to mathematical reading. In 1737 he was presented to the living of Newmacher near Aberdeen. The parishioners, violently excited at the time about the law of patronage, received him with open hostility; and tradition asserts that his uncle defended him on the pulpit stool with a drawn sword. Though not distinguished as a preacher, he was successful in winning the affections of his (afterwards Sir) Robert Bond, the terms of whose contract were revised, being made more favourable to Newfoundland, and Reid's interests were transferred to a company, the Reid Newfoundland Company, of which he was the first president (see NEWFOUNDLAND, Roads and Railways). Reid was knighted in 1907, and he died on the 3rd of June 1908.
in the structure of all languages, and therefore must be common to all men who speak with understanding." (Hamilton's Reid, p. 229, note 435.)

The principles which Reid insists upon as everywhere present in experience evidently correspond pretty closely to the Kantian notion of the Copula subjectum. Similarly, an assertion of the essential distinction between space or extension and feeling or any succession of feelings may be compared with Kant's doctrine in the Aesthetics. Space, he said, is incapable of quantity, nor so properly an object [Kant's "matter"] as a necessary concomitant of the objects both of sight and touch." Like Kant, too, Reid finds in space the source of a necessity which sense, as sense, cannot give (Hamilton's Reid, p. 232). In the main, therefore, their standpoint that the two philosophers have therefore much in common. But Reid lacked the art to give due impressiveness to the important advance which he has made by retaining at the same time the formal principles with a wonderful degree of breadth and insight, he mars the effect by looseness of statement, and by the incorporation of irrelevant psychological matter. And, if Kant was overcome by a love of symmetry, Reid's indifference to form and system is an even more dangerous defect. Further, Reid is inclined to state his principles dogmatically rather than as logical deductions. The transcendental deduction, or proof from the possibility of experience in general, which forms the vital centre of the Kantian system, is wanting in Reid; or, at all events, if the spirit of the proof is occasionally present, it is nowhere adequately developed. Nevertheless, Reid's insistence upon the unit of knowledge and his attempt to draw a sharp distinction between sensation and perception must still be recognized as of the highest importance.

The relativism or phenomenalism which Hamilton afterwards adopted from Reid, on the supposition of Reid's Scottish School is wholly absent from the original Scottish doctrine. One or two passages may certainly be quoted from Reid in which he asserts that we know only properties of things and are ignorant of their essence. But the exact meaning which he attaches to such expressions is not quite clear; and they occur, moreover, only incidentally and with the air of current phrases merely incidentally repeated. Dugald Stewart, however, deliberately emphasizes the merely qualitative nature of our knowledge of the foundation of philosophical argument, and thus paves the way for the thoroughgoing philosophy of nescience elaborated by Hamilton. But while he accepts the method of the Scottish School, he have repudiated his relativistic doctrine, and returned to the original tradition of the school. For Reid's ethical theory, see ETHICS.

The complete edition of the works by Sir William Hamilton, published in two volumes with notes and supplementary selections by the editor (6th ed. 1863), has superseded all others. For Reid's life see D. Stewart's Memoir prefixed to Hamilton's edition of Reid's works. See also McCosh, Scottish Philosophers (1875); Rack, Universities of Aberdeen, pp. 199-203, 258; A. C. schafer, Monograph (1898); A. Bain, Mental Science, p. 207, p. 422 (for his theory of free will), and Appendix, pp. 29, 63, 88, 89.

(A. S. P.-P. X.)

REID, THOMAS MAYNE (1818-1883), better known as MAYNE REID, British novelist, the son of a Presbyterian minister, was born at Ballylrony, Co. Down, Ireland, on the 4th of April 1818. His own early life was as adventurous as any boy reader of his novels could desire. He was educated for the church, but did not take orders, and when twenty years old went to America in search of excitement and fortune. He made trading excursions on the Red river, studying the ways of the red man and the white pioneer. He made acquaintance with the Missouri in the same manner, and roved through all the states of the Union. In Philadelphia, where he was engaged in journalism from 1834 to 1846, he made the acquaintance of Edgar Allan Poe. When the war with Mexico broke out in 1846 he obtained a captain's commission, was present at the siege and capture of Vera Cruz, and led a forlorn hope at Chapultepec, where he sustained such severe injuries that his life was despaired of. In one of his novels he says that he believed theoretically in the military value of untrained troops, and that he had the theory of untrained troops in actual warfare. An enthusiastic republican, he offered his services to the Hungarian insurgents in 1849, raised a body of volunteers, and sailed for Europe, but arrived too late. He then settled in England, and began his career of a novelist with the publication, in 1850, of the Rifle Rangers. This was followed next year by the Scalp Hunters. He never surpassed his first productions, except perhaps in The White Chief (1859) and The Quadroon (1856); but he continued to produce tales of self-reliant enterprise and exciting adventure with great fertility. Simplicity of plot and variety of exciting incident are among the merits that contribute to his popularity with boys. His reflections are not profound, but are frequently more sensible than might be presumed at first from his aggressive manner of expressing them. He died in London on the 22nd of October 1883.

REID, WHITELAW (1837-1905), American journalist and diplomatist, was born of Scotch parentage, near Xenia, Ohio, on the 27th of October 1837. He graduated at Miami University in 1856, and spoke frequently in behalf of John C. Frémont, the Republican candidate for the presidency in that year; was superintendent of schools of South Charleston, Ohio, in 1856-58, and in 1858-59 was editor of the Xenia Gazette. In 1860 he became legislative correspondent at Columbus for several Ohio newspapers, including the Cincinnati Gazette, of which he was made city editor in 1861. He was war correspondent for the Gazette in 1861-62, serving also as volunteer aide-de-camp (with the rank of captain) to General Thomas A. Morris (1811-1904) and General William S. Rosecrans in West Virginia. He was Washington correspondent of the Gazette in 1862-68, acting incidentally as clerk of the military committee of Congress (1862-63) and as librarian of the House of Representatives (1863-66). In 1868 he became a leading editorial writer for the New York Tribune, in the following year was made managing editor, and in 1872, upon the death of Horace Greeley, became the principal proprietor and editor-in-chief. In 1905 Reid relinquished his active editorship of the Tribune, but retained financial control. He declined an appointment as United States minister to Germany in 1877; and again in 1881, but served as minister to France in 1886-92, and in 1902 was the unsuccessful Republican candidate for vice-president on the ticket with Benjamin Harrison. In 1897 he was special ambassador of the United States on the occasion of Queen Victoria's jubilee; in 1898 was a member of the commission which arranged the terms of peace between the United States and Spain; in 1902 was special ambassador of the United States at the coronation of King Edward VII., and in 1905 became ambassador to Great Britain. He was elected a life member of the New York State Board of Regents in 1878; and in 1902 he became vice-chancellor and, in 1904, chancellor of the university of the state of New York. In 1881 he married a daughter of Darius Ogden Mills (1825-1910), a prominent financier.

His publications include After the War (1867), in which he gives his observations during a journey through the Southern States in 1866; Ohio in the War (2 vols., 1868); Some Consequences of the New Treaty of Paris; or, Problems of Expansion (1871); Aspects of Our New Duties (1893); Problems of Expansion (1900); The Greatest Fact in Modern History (1906), and How America faced its Educational Problem (1906).

REID, SIR WILLIAM (1791-1858), Scottish administrator and man of science, was born on the 25th of April 1791 at the manse of Kinglassie, Fifehire, and entered the Royal Engineers in 1809. He saw active service in the Peninsula under Wellington, and took part in the bombardment of Algiers in 1816. In 1835 and 1836 he again saw active service, in Spain against Don Carlos. In 1838 he published his Attempt to develop the Law of Storms, which obtained wide popularity. In 1839 he was appointed governor of the Bermudas, where he did much to develop the agricultural resources of the islands, and in 1846 he was transferred to Barbados. In 1850-51 he was chairman of the executive committee of the Great Exhibition; on the completion of the work he was made a K.C.B. and appointed governor of Malta. He died in London on the 31st of October 1858.

REIGATE, a market town and municipal borough in the Reigate parliamentary division of Surrey, England, 24 m. S. by W. of London by the South-Eastern & Chatham railway. Pop. (1901) 25,993. It is situated at the head of the long valley of Holmsdale Hollow, beneath the North Downs. A very fine prospect over a great part of Surrey and Sussex, and extending to Hampshire and Sussex, is obtained from the neighbouring Reigate Hill. Of the old castle, supposed to
have been built before the Conquest to command the pass through the valley, there only remains the entrance to a cave beneath, 150 ft. long and from 10 to 12 ft. high, excavated in the sandstone, which was used as a guardroom. The grounds are laid out as a public garden. Near the market house is the site of an ancient chapel dedicated to Thomas à Becket. Above the vestry there is a library containing choice manuscripts and rare books. The grammar school was founded in 1675. Among the other public buildings are the town hall, the public hall, the market, and the working men's institute. The borough includes the township of Redhill, adjacent on the east. The town has some agricultural trade, and in the neighbourhood are quarries for freestone, heathstone and white sand. The borough is under a mayor, 6 aldermen and 18 councillors. Area, 5994 acres.

Regigate (Cherchelle, Regeal, Roygaye) owed its first settlement to its situation at a cross-road on the Pilgrim's Way, at the foot of the North Downs; and its early importance to the castle which was the stronghold of the De Warennes in the 12th, 13th and 14th centuries. On the death of Edith, the widow of Edward the Confessor, to whom it had been sold by the Conquest with the whole of the manor, it was then called. It was granted by William Rufus to Earl Warenne, through whose family it passed in 1347 to the earls of Arundel. The manor of Redhill was granted to the town in 1350. When the manors were mentioned in deeds it was in a close roll of 1343, but no early charter is known. The town was incorporated in 1803. It returned two members to parliament from 1295 till 1831, and afterwards one member only until 1867, when it was disfranchised for corruption. In the reign of Edward I. Earl Warenne held a weekly market on Saturdays, and fairs on Tuesday in Whit-sun-week, the eve and day of St. Lawrence, and the eve and day of the Exaltation of the Cross, by prescriptive right.

Edward II. granted a market on Tuesdays, which is still held. The fair days are now Whit-Tuesday and the 9th of December.

REIMARUS, HERMANN SAMUEL (1694-1768), German philosopher and man of letters, was born at Hamburg; on the 22nd of December 1694. He was educated by his father and by the famous scholar J. A. Fabricius, whose son-in-law he subsequently became. He studied theology, ancient languages, and philosophy at Jena, became Privatdozent in the university of Wittenberg in 1716, and in 1720-21 visited Holland and England. In 1723 he became rector of the high school at Wismar in Mecklenburg, and in 1727 professor of Hebrew and Oriental languages in the university of Lubeck. He held this last position till his death, though offers of more lucrative positions were made to him. His duties were light, and he employed his leisure in the study of philology, mathematics, philosophy, history, political economy, natural science and natural history, for which he made large collections. His house was the centre of the highest culture of Hamburg, and a monument of his influence in that city still remains in the Haus der patriotischen Gesellschaft, where the learned and artistic societies partly founded by him still meet. He had seven children, only three of whom survived him—the distinguished physician Johann Albrecht Heinrich, and two daughters, one of them being Lessing's close friend and correspondent. He died on the 1st of March 1768.

Reimarus's reputation as a scholar rests on the valuable edition of Dio Cassius (1750-52) which he prepared from the materials collected by J. A. Fabricius. He published a work on logic (Vernunftlehre als Anweisung zum richtigen Gebrauche der Vernunft, 1756, 5th ed., 1790), and two popular books on the religious questions of the day. The first of these was a collection of essays on the principal truths of natural religion (Abhandlungen von den vornehmsten Wahrheiten der natürlichen Religion, 1755, 7th ed., 1758); the second (Betrachtungen über die Trieb der Thiere, 1760, 4th ed. 1768) dealt with one particular branch of the same subject. His philosophical position is essentially that of Christian Wolff. But he is best known by his Apologie oder Schriftschrift für die vernünftigen Verehrer Gottes (carefully kept back during his lifetime), from which, after his death, Lessing published certain chapters under the title of the Wolfenbüttel Fragments (see Lessing). The original MS. is in the Hamburg town library; a copy was made for the university library of Göttingen, 1814, and other copies are known to exist. In addition to the seven fragments published by Lessing, a second portion of the work was issued in 1787 by C. A. E. Schmidt (a pseudonym), under the title Uebrige noch ungedruckte Werke des Wolfenbüttelischen Fragmentsisten, and a further portion by D. W. Klose in Nieder's Zeitschrift für historische Theologie, 1830-32. Two of the five books of the first part and the whole of the second part, as well as appendices, of the canon, remain unprinted. But D. F. Strauss has given an exhaustive analysis of the whole work in his book on Reimarus.

The standpoint of the Apologie is that of pure naturalistic deism. Miracles and mysteries are denied, and natural religion is put forward as the absolute contradiction of revealed. The essential truths of the former are the existence of a wise and good Creator and the immortality of the soul. These truths are discoverable by reason, and are such as can constitute the basis of a universal religion. A revealed religion could never obtain universality, as it could never be intelligible and credible to all men. Even supposing its possibil-
REIMS

Royale, with a statue of Louis XV, and the place du Parvis, with an equestrian statue of Joan of Arc. The rue de Vesle, the chief street, continued under other names, traverses the town from S.W. to N.W., passing through the Place Royale.

The oldest monument in Reims is the Mars Gate (so-called from a temple of Mars built here by the Romans), 134 ft. in length by 43 ft. in height, consisting of three archways flanked by columns. It is popularly supposed to have been erected by the Remi in honour of Augustus when Agrippa made the great roads terraced here for his army. But perhaps the carvings go back to 15th century. In its vicinity a curious mosaic, measuring 36 ft. by 26, with thirty-five medallions representing animals and gladiators, was discovered in 1863 and is now placed in the Basiliques St. Remi, probably from the Roman catacombs. This is said to be that of the consul Jovinian (see below) and preserved in the archaeological museum in the cloister of the abbey of St Remi. The cathedral of Notre-Dame, where the kings of France were crowned, is the crown jewel of this old church, built in 1211 on the site of the basilica where Clovis was baptized by St Remigius. The cathedral, with the exception of the west front, was completed by the end of the 13th century. That portion was erected in the 12th century after 12th-century designs—the nave having in the meantime been lengthened to afford room for the crowds that attended the coronations. In 1481 fire destroyed the roof and the spires. In 1875 the National Assembly voted 300,000 for the rebuilding of the cathedral south transept and facade of the nave. The spire, 418 ft. high, is an example of the Gothic nave, the three portions of the building, and one of the most perfect masterpieces of the middle ages. The three portals are adorned with statues and statuary. The arch of St. Vital, in the north transept, is flanked by a rose-window framed in an arch itself decorated with statuary. The “gallery of the kings” above has the baptism of Clovis in the centre and statues of his successors. The towers, 267 ft. high, were originally 393 ft. high, but the eastern tower, the south and south-east great bells, one of which, named “Charlotte” by Cardinal de Lorraine in 1570, weighs more than 11 tons. The façades of the transepts are also decorated with sculptures—that on the north with the archbishops of Reims, a representation of the Last Judgment and a figure of Christ (le Beaus Dieu) while that on the south side has a beautiful rose-window with the prophets and apostles. Of the four towers which flanked the transepts nothing remains of the arch of the roof of the transepts, which, in 1483, the choir rises an elegant bell-tower in timber and lead, 50 ft. high, reconstructed in the 15th century. The interior of the cathedral is 455 ft. long, 162 ft. wide, and 108 ft. high, and comprises a nave with aisles, transepts with aisles, a choir, with double aisles, and an apse with deambulatory and radiating chapels. It has a profusion of statues similar to those of the outside, and stained glass of the 14th century. The rose-window over the main portal and the gallery beneath are of rare magnificence. The cathedral possesses fine tapestries. Of these similar to those of the east front is that represented by Robert de Lenoncourt, archbishop under Francois I. The life of the hero contains a fine organ in a Flamboyant Gothic case. The choir clock is ornamented with curious mechanical figures. Several paintings, by Tintoretto, Nicolas Poussin, and others, and the carved woodwork and stalls of the choir also deserve mention. The treasury contains the Sainte Ampoule, or holy flask, the ancient of the old broken at the Revolution (see below), a fragment of which it contains.

The archiepiscopal palace, built between 1498 and 1509, and in part rebuilt in 1675, was occupied by the kings on the occasion of their coronation. The saloon (salle du Tau), where the royal banquet was held, has an immense stone chimney of the 15th century, medallions of the archbishops of Reims, and portraits of fourteen kings crowned in the city. Among the other rooms of the royal suite, all of which are of great beauty and richness, is that now used for the meetings of the Reims Academy; the building also contains a library. The chapel of the archiepiscopal palace consists of two storeys, of which the upper still serves as a place of worship. Both the chapel and the salle du Tau are decorated with tapestries of the 17th century and the Perpussack tapestries, after the Flemish weaver who executed them.

After the cathedral, which it almost equals in size, the most celebrated church is St Remi, once attached to an important abbey, the buildings of which are used as a hospital. St Remi dates from the 11th, 12th, 13th and 15th centuries. The nave and transepts, Romanesque in style, date mainly from the earliest, the façade of the south transept, of the 13th century. The church has five chapels from the 12th and 13th centuries. The valuable monuments with which the church was at one time filled were pillaged during the Revolution, and even the tomb of the saint is a modern work. The fine 12th-century windows and large windows with medallions of the figures of the apostles and saints (within its walls), are of minor interest. Of the fine church of St Nicaise only insignificant remains are to be seen.

The town hall, erected in the 17th and enlarged in the 19th century, has a pediment with an equestrian statue of Louis XIII. and a tall and elegant campanile. It contains a picture gallery, representing local, archdiocesan, other ecclesiastical, and public library. There are many old houses, the House of the Musicians (13th century) being so called from the seated figures of musicians which decorate the front.

In 1874 the construction of a chain of detached forts was begun in the vicinity, Reims being selected as one of the chief defences of the northern approaches of Paris. The ridge of St Thierry is crowned with a fort of the same name, which with the neighbouring work of Chenay closes the west side of the place. To the north the hill of Brimont has three works guarding the Laroche railway and the Aisne canal. Further east, on the old Roman road, lies the fort de Fresnes. Due east the hills of Array are crowned with five large and important works which cover the approaches from the upper Aisne. Forts Pompelle and Monthiré close the south-east side, and the Falaise hills on the Paris side are open and unguarded. The perimeter of the defences is not quite 22 m., and the forts are a mean distance of 6 m. from the centre of the city.

Reims is the seat of an archbishop, a court of assize and a sub-prefect. It is an important centre for the combing, carding and spinning of wool and the weaving of flannel, merino, cloth and woollen goods of all kinds, these industries employing some 24,000 hands; dyeing and “dressing” are also carried on. It is the chief wool market in France, and has a “conditioning house” which determines the loss of weight resulting from the drying of the wool. The manufacture of and trade in champagne is also very important. The wine is stored in large cellars tunnelled in the chalk. Other manufactures are machinery, chemicals, safes, capsules, bottles, casks, candles, soap and paper. The town is well known for its cakes and biscuits.

History.—Before the Roman conquest Reims, as Durocortorum, was capital of the Remi, from whose name that of the town was subsequently derived. The Remi made voluntary submission to the Romans, and by their fidelity throughout the various Gallic insurrections secured the special favour of their conquerors. Christianity was established in the town by the middle of the 3rd century, at which period the bishopric was founded. The consuls Jovinus, an influential supporter of the new faith, repulsed the barbarians who invaded Champagne in 336; but the Vandals captured the town in 406, and slew St Nicasius, and Attila afterwards put it to fire and sword. Clovis, after his victory at Soissons (486), was baptized at Reims in 496 by St Remigius. Later kings desired to be consecrated at Reims with the oil of the sacred phial which was believed to have been brought from heaven by a dove for the baptism of Clovis and was preserved in the abbey of St Remi. Meetings of Pope Stephen III. with Pippin the Short, and of Leo III. with Charlemagne, took place at Reims; and here Louis the Debonnaire was crowned by Stephen IV. Louis IV. gave the town and cenship of Reims to the archbishop Artaldus in 940. Louis VII. gave the title of duke and peer to William of Champagne, archbishop from 1176 to 1202, and the archbishops of Reims took precedence of the other ecclesiastical peers of the realm. In the 10th century Reims had become a centre of intellectual culture, Archbishop Adalberon, seconded by the monk Gerbert (afterwards Pope Silvester II.), having founded schools where the “liberal arts” were taught. Adalberon was also one of the prime authors of the revolution which put the Capet house in the place of the Carolingians. The most important prerogative of the archbishops was the coronations of the kings of France—a privilege which was exercised, except in a few cases, from the time of Philip Augustus to that of Charles X. Louis VII. granted the town a communal charter in 1139. The treaty of Troyes (1420) ceded it to the English, who had made a futile attempt to take it by siege in 1560; but they were expelled on the appeal of Joan of Arc, who in 1429 caused Charles VII. to be consecrated in the cathedral. A revolt at Reims, caused by the salt tax in 1461, was cruelly repressed by Louis XI. The town sided with the League (1583), but submitted to Henry IV. after the battle of
Ivy. In the foreign invasions of 1814 it was captured and recaptured; in 1870–71 it was made by the Germans the seat of a governor-general and impoverished by heavy requisitions.

See G. Marlot, Histoire de la ville, cité et université de Reims, 4 vols. (Reims, 1843–46); J. Justinus (Baron L. Taylor), La Ville de Reims (Paris, 1854).

REIN, a guiding or controlling leather strap or thong, attached to the bit of a ridden or driven horse (see SADDLE). The word is taken from the O. Fr. renne, modern ren, and is usually traced to a supposed Late Latin substantive reitina formed from retinere, to hold back, restrain, cf. classical Latin retilinaculum, halter. The word, usually in the plural, has been often used figuratively, as a type of which guides, restrains or controls, e.g. in such phrases as the "reins of government," &c. The "reins," i.e. the kidneys (Lat. renes, cf. Gr. χορδή, the midriff), or the place where the kidneys are situated, hence the loins, also, figuratively, the seat of the emotions or affections, must be distinguished.

REINACH, JOSEPH (1850–1920), French author and politician, was born in Paris on the 30th of September 1850. After leaving the Lycée Condorcet at the age of fifteen he studied for the bar拉丁文 was added in 1887. He attracted the attention of Gambetta by articles on Balkan politics published in the Revue bleue, and joined the staff of the République française. In Gambetta's grand ministère M. Reinach was his secretary, and drew up a paper for the case a partial revision of the constitution and for the electoral method known as the scrutin de liste. In the République française he waged a steady war against General Boulanger which brought him three duels, one with Edmond Magnier and two with Paul Déroulède. Between 1889 and 1898 he sat for the Chamber of Deputies for Digne. As member of the Army Commission, reporter of the budgets of the ministries of the interior and of agriculture he brought forward bills for the better treatment of the insane, for the establishment of a colonial ministry, for the taxation of alcohol, and for the reparation of judicial errors. He advocated complete freedom of the theatre and the press, the abolition of public executions, and denounced political corruption of all kinds. He was indirectly implicated in the Panama scandals through his father-in-law, Baron de Reinach, though he made restitution as soon as he learned that he was benefiting by fraud. But he is best known as the champion of Captain Dreyfus. At the time of the original trial he attempted to secure a public hearing of the case, and in 1897 he allied himself with Scheurer-Kestener to demand its revision. He denounced in the Siècle the Henry forgery, and Esterhazy's complicity. His articles in the Siècle aroused the fury of the anti-Dreyfusard party, especially as he was himself a Jew and therefore open to the charge of having undertaken to defend the innocence of Dreyfus on racial grounds. He lost his seat in the Chamber of Deputies, and, having refused to fight Henri Rochefort, eventually brought an action for libel against him. Finally, the "affaire" being terminated and Dreyfus pardoned, he undertook to write the history of the case. The first four volumes of this work appeared in 1901. This was completed in 1909. In 1906 M. Reinach was re-elected for Digne. In that year he became member of the commission of the national archives, and next year of the council on prisons. Reinach was a voluminous writer on political subjects. On Gambetta he published three volumes in 1884, and he also edited his speeches. For the criticisms of the anti-Dreyfusard press see Henri Dutrait-Croyon, Joseph Reinach, historien (Paris, 1905), a violent criticism in detail of Reinach's history of the "affaire."

His brother, the well-known savant, SALOMON REINACH (1859–1936), born at St Germain-en-Laye on the 29th of August 1858, was educated at the Ecole normale supérieure, and joined the French school at Athens in 1879. He made valuable archaeological discoveries at Smyrna near Smyrna in 1882–83, at Cyme in 1881, at Thasos, Imbros and Lesbos (1882), at Carthage and Meninx (1883–84), at Odessa (1893) and elsewhere. He received honours from the chief learned societies of Europe, and in 1886 received an appointment at the National Museum of Antiquities at St Germain; in 1903 he became assistant keeper, and in 1909 keeper of the national museums. In 1903 he became joint editor of the Revue archéologique, and in the same year officer of the Legion of Honour. The lectures he delivered on art at the École du Louvre in 1902–3 were published by him under the title of Apollo. This book has been translated into most European languages, and is one of the most compact handbooks of the subject.

His first published work was a translation of Schopenhauer's Essay on Free Will (1877), which passed through many editions. It was followed by many works and articles in the learned reviews of which a large number are available in Bibliographie de S. R. (Angers, 1903). His Manuel de philologie classique (1880–84) was crowned by the French association for the study of Greek; his Grammaire latine (1886) received a prize from the Society of Secondary Education; La Nécropole de Myrina (1887), written with E. Portier, and Antiquités nationales were crowned by the Academy of Inscriptions. He compiled an important Répertoire de la statuette grecque et romaine (3 vols., 1897–98); also Répertoire de peintures du moyen âge et de la Renaissance 1280–1580 (1905, &c.); Répertoire des vases peints grecs et éttrusques (1900). In 1905 he began his Cütes, mythes et religions; and in 1909 he published the Répertoire of the history of religions under the title of Orphée. He also translated from the English H. C. Lea's History of the Inquisition.

A younger brother, THEODORE REINACH (1860–1935), also had a brilliant career as a scholar. He pleaded at the Parisian bar in 1881–86, but eventually gave himself up to the study of numismatics. He wrote important works on the ancient kingdoms of Asia Minor—Trois royaumes de l'Asie Mineure, Cappadoce, Bithynie, Pont (1888), Mithridate Eupator (1890); also a critical edition and translation with H. Wéll of Plutarch's Treatise on Music; and an Histoire des arêtes des naissance de leur indépendance nationale jusqu'à nos jours (2nd ed., 1901). From 1888 to 1897 he edited the Revue des études grecques.

REINAUD, JOSEPH TOUSSAINT (1795–1867), French orientalist, was born on the 4th of December 1795 at Lambesc, Bouches du Rhône. He came to Paris in 1815, and became a pupil of Silvestre de Sacy. In 1818–19 he was at Rome as an attaché to the French minister, and studied under the Maronites of the Propaganda, but gave special attention to Mahomedan coins. In 1834 he entered the department of oriental MSS. in the Royal Library at Paris, and in 1838, on the death of De Saule, he succeeded to his chair in the school of living oriental languages. In 1847 he became president of the Société Asiatique, and in 1858 conservator of oriental MSS., in the Imperial Library. His first important work was his classical description of the collections of the Duc de Blacas (1828). To history he contributed an essay on the Arab invasions of France, Savoy, Piedmont and Switzerland (1836), and various collections for the period of the crusades; he edited (1840) and in part translated (1848) the geography of Abulfeda; to him too is due a useful edition of the very curious records of early Arabic intercourse with China of Eustache Renanod had given but an imperfect translation (Re-

Reindeer, in its strict sense the title of a European deer distinguished from all other members of the family Cervidae (see Deer), save those of the same genus, by the presence of antlers in both sexes; but, in the wider sense, including Asiatic and North American deer of the same general type, the latter of which are locally designated caribou. Reindeer, or caribou, constitute the genus Rangifer, and are large clumsy built deer, inhabiting the sub-Arctic and Arctic regions of both hemispheres. As regards their distinctive features, the antlers are of a uniform type and situated close to the occipital ridge of the skull, and thus far away from the sockets of the eyes, with the brow-tines in adult males palmed, laterally compressed, deflected towards the middle of the face, and often unsymmetrically developed. Above the brow-tine is developed a second palmed tine,
which appears to represent the bez-tine of the red-deer; there is no trez-tine, but some distance above the bez the beam is suddenly bent forward to form an "elbow," on the posterior side of which is usually a short back-tine; above the back-tine the beam is continued for some distance to terminate in a large expansion or palmation. The antlers of females are simple and generally smaller. The muzzle is entirely hairy; the ears and tail are short; and the throat is maned. The coat is unsptotted at all ages, with a whitish area in the region of the tail. The male hoofs are small and rounded and the lateral hoofs very large. There is a tarsal, but no metatarsal gland and tuf. In the skull the gland-pit is shallow, and the vacuity of moderate size; the nasal bones are well developed, and much expanded at the upper end. Upper canines are wanting; the cheek-teeth are small and low-crowned, with the third lobe of the last molar in the lower jaw minute. The lateral metacarpal bones are represented only by their lower extremities; the importance of this feature being noticed in the article DEER.

In spite of the existence of a number of more or less well-marked geographical forms, reindeer from all parts of the northern hemisphere present such a marked similarity that it seems preferable to regard them as all belonging to a single widespread species, of which most of the characters will be the same as those of the genus. Among the exceptions might, however, generally regard these as specific species. The coat is remarkable for its density and compactness; the general color of the head and upper parts being clove-brown, with more or less white or whitch gray on the under parts and inner surfaces of the limbs. There is also some white bone on the hoofs and on the muzzle, and there may be whitish rings round the eyes; there is a white area in the region of the tail, which includes the sides but not the upper surface of the latter; and the tarsal tuft is generally white. The antlers are smooth, and brownish white in colour, but the hoofs jet black. Albino varieties occasionally occur in the wild state. A height of 4 ft. 10 in. at the shoulder has been recorded in the case of one reindeer.

The wild Scandinavian reindeer (Rangifer tarandus) may be regarded as the typical form of the species. It is a smaller animal than the American woodland race, with antlers approximating to those of the barren-ground race, but with the distinct back-tine in the male, the brow-tines moderately palmated and frequently nearly symmetrical, and the bez-tine not excessively expanded. Female antlers are generally much smaller than those of males, although occasionally as large, but with much fewer points. The antlers make their appearance at an unusually early age.

Mr. Madison Grant considers that American reindeer, or caribou, may be grouped under two types, one represented by the barren-ground caribou R. tarandus articus, which is a small animal with immense antlers characterized by the length of the beam, and the convergence of the palmation of the brow-tine; and the other by the woodland-caribou (R. t. caribou), which is a larger animal with shorter and more massive antlers, in which the great terminal expansions are in approximation to the brow-tine. The white is shorter and thicker at the stem. Up to seven other American races had been described, four of which are grouped by Grant with the first and three with the second type.

Some of these forms are, however, more or less intermediate between the two main types, as is a pair of antlers from Novalia Zemlia described by the present writer as R. t. pearsoni. The Scandinavian reindeer is identified by Mr. Grant with the barren-ground type.

Reindeer are dotedinated by the Lapps and other aboriginals of northern Europe and Asia, to whom these animals are all-important. Domesticated reindeer have also been introduced into Alaska.

REINECKE, CARL HEINRICH CARSTEN (1824-1910), German composer and pianist, was born at Altona on the 23rd of June 1824; his father, Peter Reinecke (who was also his teacher), being an accomplished musician. At the age of eleven he made his first appearance as a pianist, and when scarcely eighteen he went on a successful tour through Denmark and Sweden. After a stay of about a year in Sweden he returned to Berlin and went, under Schumann, Reinecke went on tour with Königstäd and Wasielowski, Schumann's biographer, in North Germany and Denmark. From 1846 to 1848 Reinecke was court pianist to Christian VIII. of Denmark. After resigning this post he went first to Paris, and next to Cologne, as professor in the Conservatorium. From 1854 to 1859 he was music director at Barmen, in the latter year filling this post at Breslaus University; in 1860 he became conductor of the famous Leipzig Gewandhaus, a post which (together with that of professor at the Conservatorium) he held with honour and distinction for thirty-five years. He finally retired into private life in 1902 and died in March 1910. During this time Reinecke continually made concert tours to England and elsewhere. His pianoforte playing belonged to a school now almost extinct. Grace and neatness were its characteristics, and at one time Reinecke was probably unrivalled as a Mozart player and an accompanist. His grand opera König Mauryed, and the comic opera Auf hohen Befohl, were at one time frequently played in Germany; and his cantata Haken Jari is melodiously beautiful, as are many of his songs; while his Friedensfeier overture was once quite hankered. By far his most valuable works are those written for educational purposes. His sonatas, his "Kindergarten" and much that he has ably edited will keep his name alive.

REINHART, CHARLES STANLEY (1844-1890), American painter and illustrator, was born at Pittsburg, Pennsylvania, and after having been employed in railway work and at a steel factory, went in 1874 to Paris at the Munich Academy under Straehuber and Otto. He afterwards settled in New York, but spent the years 1882-1886 in Paris. He was a regular exhibitor at the National Academy in New York, and contributed illustrations in black and white and in colour to the leading American periodicals. He died in 1896. Among his best-known pictures are: "Reconnoitring," "Caught Napping," "September Morning," "Mussel Fisherwoman," "At the Ferry," "Normandy Coast," "Gathering Wood," "The Old Life Boat," "Sunday," and "English Garden;" but it is as an illustrator that he is best known.

REINHART, JOACHIM CHRISTIAN (1761-1847), German painter and etcher, was born at Hof in Bavaria in 1761, and studied under Oeser at Leipzig and under Klingel at Dresden. In 1789 he went to Rome, where he became a follower of the classicist German painters Carstens and Koch. He devoted himself more particularly to landscape painting and to aquatint engraving. Examples of his landscapes are to be found at most of the important German galleries, notably at Frankfort, Munich, Leipzig and Gotha. In Rome he executed a series of landscape frescoes for the Villa Massimi. He died in Rome in 1847.

REINHOLD, KARL LEONHARD (1758-1823), German philosopher, was born at Vienna. At the age of fourteen he entered the Jesuit college of St Anna, on the dissolution of which (1774) he joined a similar college of the order of St Barnabas. Finding himself outside of sympathy with monastic life, he fled in 1783 to North Germany, and settled in Weimar, where he became Wieland's collaborateur on the German Mercurius, and eventually his son-in-law. In the German Mercurius he published, in the years 1786-87, his Briefe über die Kantische Philosophie, which were most important in making Kant known to a wider circle of readers. As a result of the Lettres, Reinhold received a call to the university of Jena, where he taught from 1787 to 1794. In 1790 he published his chief work, the Vorschlag einer neuen Theorie des menschlichen Vorstellungsvermögens, in which he attempted to simplify the Kantian theory and make it more of a unity. In 1794 he accepted a call to Kiel, where he taught till his death in 1823, but his independent activity was at an end. In later life he was powerfully influenced by Fichte, and subsequently, on grounds of religious feeling, by Jacobi and Bardili. His historical importance belongs entirely to his earlier activity. The development of the Kantian standpoint contained in the "New Theory of Human Understanding" (1780), and in the Fundament des philosophischen Wissens (1792), was called by its author Elemente-philosophie.

"Reinhold lays greater emphasis than Kant upon the unity and activity of consciousness. The principle of consciousness tells us that every idea is related both to an object and a subject, and is partly to be distinguished, partly united to both. Since form cannot produce matter nor subject object, we are forced to assume a thing-in-itself. But this is a notion which is self-contradictory if consciousness be essentially a relating activity. There is there-
fore something which must be thought and yet cannot be thought” (Höffding, History of Modern Philosophy, Eng. trans., vol. ii.).

REINKENS, JOSEPH HUBERT (1821-1896), German Old Catholic bishop, was born at Burtscheid, near Aix-la-Chapelle, on the 1st of March 1821, his father being a gardener. In 1836, on the death of his brother, he took to manual work in order to support his numerous brothers and sisters, but in 1849 he was able to go to the gymnasion at Aix, and he afterwards studied theology at the universities of Bonn and Munich. He was ordained priest in 1848, and in 1849 graduated as doctor in theology. He was soon appointed professor of ecclesiastical history at Breslau, and in 1865 he was made rector of the university. During this period he wrote, among other treatises, on Clement of Alexandria, Hilary of Poitiers and Martin of Tours. In consequence of an essay on art, especially in tragedy, after Aristotle, he was made doctor in philosophy in the university of Leipzig. When, in 1876, the question of papal infallibility was raised, Reinkens attached himself to the party opposed to the proclamation of the dogma. He wrote several pamphlets on church tradition relative to infallibility and on the procedure of the Council. When the dogma of infallibility was proclaimed, Reinkens joined the band of influential theologians, headed by Döllinger, who resolved to organize resistance to the decree. He was one of those who signed the Declaration of Nürnberg in 1877, and at the Bonn conferences with Orientals and Anglicans in 1874 and 1875 he was conspicuous. The Old Catholics having decided to separate themselves from the Church of Rome, Reinkens chose their bishop in Germany at an enthusiastic meeting at Cologne in 1873 (see OLD CATHOLICS). On the 11th of August of that year he was consecrated by Dr Heykamp, bishop of Cologne. Reinkens found this a sore task and took his office, and it was due to his efforts that the Old Catholic movement crystallized into an organized church, with a definite status in the various German states. He wrote a number of theological works after his consecration, but none of them so important as his treatise on Cyprian and the Unity of the Church (1873). The chief act of his episcopal career was his consecration in 1876 of Dr Edward Herzog to preside as bishop over the Old Catholic Church in Switzerland. In 1881 Reinkens visited England, and received Holy Communion more than once with bishops, clergy and laity of the Church of England, and in 1894 he defended the validity of Anglican orders in a speech given against the objections of his co-religionists, the Old Catholics of Holland. He died at Bonn on the 4th of January 1896.

See Joseph Hubeit Reinkens, by his nephew, J. M. Reinkens (Gotha, 1896).

REISKE, JOHANN JACOB (1716-1774), German scholar and physician, was born on the 25th of December 1716 at Zöbing in Electoral Saxony. From the Waisenhaus at Halle he passed in 1733 to the university of Leipzig, and there spent five years. He tried to find his own way in Greek literature, to which German schools then gave little attention; but, as he had not mastered the grammar, he soon found this a sore task and took up Arabic. He was very poor, having almost nothing beyond his allowance, which for the five years was only two hundred thalers. But everything of which he could cheat his appetite was spent on Arabic books, and when he had read all that was then printed he thirsted for manuscripts, and in March 1738 started on foot for Hamburg, joyous though totally unprovided, on his way to Leiden and the treasures of the Warnerianum. At Hamburg he got some money and letters of recommendation from the Hebrist Wolf, and took ship to Amsterdam. Here d'Orville, to whom he had an introduction, proposed to retain him as his amanuensis at a salary of six hundred guilders. Reiske refused, though he thought the offer very generous; he did not want money, he wanted manuscripts. When he reached Leiden (June 6, 1738) he found that the lectures were over for the term and that the MSS were not open to him. But d'Orville and A. Schultens helped him to private teaching and reading for the prize, by which he was able to live. He heard the lectures of A. Schultens, and practiced himself in Arabic with his son J. J. Schultens. Through Schultens too he got at Arabic MSS., and was even allowed sub rosa to take them home with him. Ultimately he seems to have got free access to the collection, which he re-catalogued—the work of almost a whole summer, for which the curators rewarded him with nine guilders.

Reiske's first years in Leiden were not unhappy, till he got into serious trouble by introducing emendations of his own into the second edition of Burmann's Petronius, which he had himself translated. His patrons now turned against him, and his chance of perhaps becoming professor was gone; d'Orville indeed soon came round, for he could not do without Reiske, who did work of which his patron, after dressing it up in his own style, took the credit. But A. Schultens was never the same as before to him; Reiske indeed was too independent, and hurt him by his open criticisms of his master's way of making Arabic mainly a handmaid of Hebrew. Reiske, however, himself admits that Schultens always behaved honourably to him. In 1742 by Schultens's advice Reiske took up medicine as a study by which he might hope to live; his health could not do so, however. In 1746 he was employed by the publisher, the firm of M. D., the famous Folckenberg, as a proof-reader; and he was remitted at Schultens's intercession. It was Schultens too who conquered the difficulties opposed to his graduation at the last moment by the faculty of theology on the ground that some of his theses had a materialistic 'ring.' On the 10th of June 1746 he left Holland and settled in Leipzig, where he hoped to get medical practice.

But his shy, proud nature was not fitted to gain patients, and the Leipzig doctors would not recommend one who was not a Leipzig graduate. In 1747 an Arabic dedication to the great prince of Saxony got him the post of professor in the university. He found neither the laboratory nor the great prince to be very willing to admit him among them, and he never delivered a course of lectures. He had still to go on doing literary task-work, but his labour was much worse paid in Leipzig than in Leiden. Still he could have lived and sent his old mother, as his custom was, a yearly present of a piece of leather to be sold in retail if he had been a better manager. But, careless for the morrow, he was always printing at his own cost great books which found no buyers. His academic colleagues were hostile; and Ernesti, under a show of friendship, secretly hindered his promotion. His untiring reviewing made bad blood with the pillars of the university.

At length in 1758 the magistrates of Leipzig rescued him from his misery by giving him the rectorate of St Nicolai, and, though he still made no way with the leading men of the university and suffered from the hostility of men like Ruiken and J. D. Michaelis, he was compensated for this by the esteem of Frederick the Great, of Lessing, Karsten Niebuhr, and many foreign scholars. The last decade of his life was made cheerful by his marriage with Ernestine Müller, who shared all his interests and learned Greek to help him with translations. In the course of the last summer he worked on the first volume of the Oroalesgraci. Reiske died on the 14th of August 1774, and his MS. remains passed, through Lessing's mediation, to the Danish minister Suhm, and are now in the Copenhagen library.

Reiske certainly surpassed all his predecessors in the range and quality of his knowledge of Arabic literature. It was the history, the realia of the literature, that always interested him; he did not care for Arabic poetry as such, and the then much praised Hariri seemed to him cold and lifeless. He had a notion of the grammatical correctness of the verses of their verse, than for such scholia as supplied historical notices. Thus for example the scholia on Jarir furnished him with a remarkable notice of the prevalence of Buddhist doctrine and asceticism in I'rrk under the Omayyads. In the Adnotationes historicae to his Abdul Felc (Abulfelx, Annales Moslemici, 5 vols., Copenhagen, 1789-91) he collected a veritable treasure of sound and original research; he knew the Byzantine writers as thoroughly as the Arabic authors, and was alike at home in modern works of travel in all languages and in ancient and medieval authorities. He was interested too in
numismatics, and his letters on Arabic coinage (in Eichhorn's 
Reperiorium, vols. ix.-xi.) form, according to De Saecy, the 
basis of that branch of study. To comprehensive knowledge and very 
wide reading he added a sound historical judgment. He 
like Sylburg, set the precedent of the Yemenite Kasidas. 1 Errors no doubt he made, as in the attempt to ascertain 
the date of the breach of the dam of Marib. 

The same late epimedium did not afford a starting-
point for methodical study of the sources, Reiske's edition with this 
version and notes certainly laid the foundation for research in Arabic 
history. The foundation of Arabic philology, however, was laid not by 
him, but by his contemporaries, especially Eichhorn's. His knowledge was great, 
but he used it only to understand his authors; he had no feeling for 
form, for language as language, or for metre.

In Leipzig Reiske worked mainly at Greek, though he continued to 
draw on his Arabic predecessors accumulated in Leiden. Yet his merit 
as an Arabist was sooner recognized than the value of his work 
reiske. The Greek scholar has been rightly valued only in 
recent years, and has been in the background that he was the first German 
since Sylburg who had a living knowledge of the Greek tongue. His 
reputation, does not rest on his numerous editions, often hasty or 
even made to bookmakers' orders, but in his remarks, especially his 
conjectures. He himself is opposed to his work, and it is now 
known that he was the first German 
since Sylburg who had a living knowledge of the Greek tongue. His 
reputation, does not rest on his numerous editions, often hasty or 
even made to bookmakers' orders, but in his remarks, especially his 

For a list of Reiske's writings see Meuser, x. 192 seq. His chief 
Arabic works (all posthumous) have been mentioned above. 
In Greek he has his chief works are Constantine Porphyrogeniti 
I. de ceremoniis aulae Byzant. (1756-60), vol. ii. (Leipzig, 1751-60), vol. iii. 
(Bonn, 1829); Animate de Graecos actuores (5 vols., Leipzig, 1751-60) 
the rest lies unprinted at Copenhagen); Oratorium Graec. quae 
supervivunt, sive Graec. Poetis ad De hominem (3 vols., ib., 1774-75); Maximus Tyr. (ib., 1774); Plutarchus (11 vols., 
ib., 1774-76); Dionysius Ial. (6 vols., ib., 1774-77); Libanius (4 vols., 
Altenburg, 1784-91). Various reviews in the Acta eruditorum and 
Sitzungsberichte. Compare also his contributions to MSS. And, though 
his merits as a Grecian lie mainly in his conjectures, his realism is 
still felt in this sphere also; his German translations especially show 
freedom and practical insight, more feeling for actual life, than is 
common with the scholars of that age.

RELAPSING FEVER (Feveris recurrens), the name given to a 
specific infectious disease occasionally appearing as an epidemic in 
communities suffering from scarcity or famine. It is char-
acterized mainly by its sudden invasion, with violent febrile 
symptoms, which continue for about a week and end in a 
crisis, but are followed, after another week, by a return of the 
fever. This disease has received many other names, the best known 
of which are famine fever, seven-day, bilious relapsing fever, 
and spirillum fever. As in the case of typhoid, relapsing fever was 
long believed to be simply a form of typhus. The distinction 
between the two appeared to be clearly established in 1826, 
in connexion with an epidemic in Ireland.

Relapsing fever is highly contagious. With respect to the nature 
of the contagion, certain important observations have been made 
(see also PARASITIC DISEASES). In 1873 Obermeier discovered 
in the blood of persons suffering from relapsing fever minute organisms 
in the form of spiral filaments of the genus Spirachrymea, measured 
in length $\frac{30}{1000}$ to $\frac{60}{1000}$ inch and in breadth $\frac{20}{1000}$ to $\frac{30}{1000}$ inch, 
and possessed of rotatory or twisting movements. This organism 
eventuated in the name of Fritz Schaumann has brought forward evidence that it is an animal parasite. The most 
commonly recognized factor in the origin and spread of relapsing 
fever is destitution; but this cannot be regarded as more than a 
precondition. Disease, since many cases of destitution and famines 
have prevailed without any outbreak of this fever. 

There have been recorded where epidemics were distinctly 
associated with overcrowding rather than with privation. Relapsing 
fever is the most commonly met with in the tropics. Though it 
does not appear to protect from others, but rather, according to some 
authorities, engenders liability.

The incubation of the disease is about one week. The symptoms 
of the fever then show themselves with great abruptness and violence 
by a rigor, accompanied with pains in the limbs and severe 
headache. The febrile phenomena are very marked, and the tempera-
ture quickly rises to a high point (105°-107° Fahr.), at which it 
continues with little variation, while the pulse is rapid (100-140), 
full and strong. There is intense thirst, a dry brown tongue, 
violent vomiting, tenderness over the liver and spleen, and occas-
ionally - palpable and peculiar. Sometimes the skin is involved, and 
the skin is noticed, but there is no characteristic rash as in typhus. 
There is much prostration of strength. After the termination 
of these symptoms for a period of from five to seven days, the tempera-
ture gradually falls to the normal point or below it, the pulse 
becomes correspondingly slow, and a profuse perspiration occurs, 
while the severe headache disappears and the appetite returns. 
Except for a name of spirillum, the patient feels well and may 
even return to work, but in some cases there remains a condition of 
great debility, accompanied with rheumatic pains in the limbs.

This state of freedom from fever continues for about a week, when 
thermometer again rises to a high point, and a relapse results. The fever 
may say persist with less and severity than in the first attack, and the whole symptoms 
are of the same character, but they do not act, as a rule, continue so 
long, and they terminate in a crisis in three or four days, after which 
the face becomes correspondingly slow, and a profuse perspiration occurs, 
while the severe headache disappears and the appetite returns.

the face becomes correspondingly slow, and a profuse perspiration occurs, 
while the severe headache disappears and the appetite returns. 
Except for a name of spirillum, the patient feels well and may 
even return to work, but in some cases there remains a condition of 
great debility, accompanied with rheumatic pains in the limbs.
the emphasis upon the object of knowledge, "I know this," we have the other sense of absoluteness of knowledge: it is an assertion that the knower knows the "this," whatever it may be, in its essence or as it truly is in itself. The phrase "relativity of knowledge" has therefore two meanings: (a) that no portion of knowledge is absolute, but is always affected by its relations to other portions of knowledge; (b) that what we know are not absolute things in themselves, but things conditioned in their quality by our channels of knowledge. Each of these two propositions must command assent as soon as uncritical ignorance gives place to philosophic reflection; but each may be exaggerated, indeed has recently been exaggerated, into falsity. The simplest example—a single note struck upon the piano—would not be what it is to us but for its relation by contrast or comparison with other experiences. This is true; but we may easily exaggerate it into a falsehood by saying that a piece of experience is entirely constituted by its relations to other experiences. Such an extreme relativity, as advocated by T. H. Green in the first chapter of his Prolegomena to Ethics, involves the absurdity that our whole experience is a tissue of relations with no points of attachment on which the relations depend. The only motive for advocating it is the prejudice of absolute idealism which would deny that sensation has any part whatever in the constitution of experience. As soon as we recognize the part of sensation, we have no reason to deny the common-sense position that each piece of experience has its own quality, which is modified indefinitely by the relations in which it stands.

The second sense of relativity, that which asserts the impossibility of knowing things except as conditioned by our personal faculties, is more important philosophically and has had a more interesting history. To apprehend it is really the first great step in philosophical education. The unphilosophical person assumes that a tree as he sees it is identical with the tree as it is in itself and as it is for other percepient minds. Reflection shows that our apprehension of the tree is conditioned by the sense-organs with which we have been endowed, and that the apprehension of a blind man, and still more the apprehension of a dog or horse, is quite different from ours. What the tree is in itself—that is, for a perfect intelligence—we cannot know, any more than a dog or horse can know what the tree is for a human mind. So far the relativity is in the immediate apprehension; but from this truth is developed the paradox that the tree has no objective existence at all and consists entirely of the conscious states of the perceiver. Observe the parallelism of the two paradoxical forms of relativity: one says that things are relations with nothing that is related; the other says that things are perceptive conditions with nothing objective to which the conditions apply. Both make the given nothing and the work of the mind everything.

To see the absurdity of the second paradox of relativity is easier than to refute it. If nothing exists but the conscious states of the perceiver, how does he come to think that there is an objective tree at all? Why does he regard his conscious states as produced by an object? And how does he come to imagine that there are other minds than his own? In short, this kind of relativity leads straight to what is generally known as "the abyss of solipsism." But, like all the great paradoxes of philosophy, it has its value in directing our attention to a vital, yet much neglected, element of experience. We cannot avoid solipsism (q.v.) so long as we neglect the element of force or power. If, as Hegel asserted, our experience is all knowledge, and if knowledge is indefinitely transformed by the conditions of its reception, whether temporal or, as the object is placed, the object itself, then the object is a delusion which philosophical reflection is destined to dispel. The remedy for the paradox is to recognize that the foundation for our belief in the existence of objects is the force which they exercise upon us and the resistance which they offer to our will. What the tree is in regard to its specific qualities depends on what faculties we have for perceiving it. But, whatever specific qualities it may have, it will still exist as an object, so long as it comes into dynamic relations with our minds.

In the history of thought the relativity of knowledge as just described begins with Descartes, the founder of modern philosophy: the characteristic of modern philosophy is that it lays more stress upon the subjective than upon the objective side of experience. It is a mistake to refer it back to the Greeks. The maxim of Protagoras, for example, "Man is the measure of all things," has a different purpose; it was meant to mean that man rather than nature is the primary object of human study: it is an expression of humanism rather than of relativity. To appreciate the relativistic doctrines we find in various thinkers we must take account of the fact that they were all in the same position. Descartes, who used as an instrument of scepticism, the beneficent scepticism of pulling down medieval philosophy to make room for modern science; by Berkeley it was used to combat the materialists; by Hume in the case of the absolutism once more against the intellectual dogmatists; by Kant to prepare a justification for a noumenal sphere to be apprehended by faith; by J. S. Mill and Herbert Spencer to support their derivation of all our experience from sensation. In H. H.前者的 "Examination of Sir William Hamilton's Philosophy" that the classical statement of the Relativity of Knowledge is to be found. The second chapter of that book sets forth the various forms of the "relativity of knowledge," and gives many references to other writers.

For the sake of clearness it seems desirable to keep for the future the term "relativity of knowledge" to the first meaning explained above, and the second meaning it has been superseded in contemporary philosophizing by the terms "subjectivism," "subjective idealism," and, for its extreme form, "solipsism" (q.v.). (H. S.)

RELEASE (O.Fr. relez, variant of relais, from relaizer, to release, let go, Lat. relaxare), freedom or deliverance from trouble, pain or sorrow, the freeing or discharge from some obligation or debt, the action of letting go or releasing something. In this sense, in the discharge of some obligation, by which it is extinguished (see DEBT), and to the conveyance of an estate or interest in real or personal property to one who has already some estate or interest therein. For the special form of conveyancing known as "lease and release," see CONVEYANCING.

RELICS (Lat. reliquiae, the equivalent of the English "remains" in the sense of a dead body), the name given in the Catholic Church to, (1) the bodies of the saints, or portions of them, (2) such objects as the saints made use of during their lives, or as were used at their martyrdom. These objects are held by the Church in religious veneration, and by their means it has been to obtain divine grace and miraculous benefits (Conc. Trid. sess. 24).

These ideas had taken shape, in all essentials, during the early days of the Church, underwent further development in the middle ages, and were maintained by the Catholic Church in the face of the opposition of the Reformers, while all the Protestant Churches rejected them.

The origins of the veneration of relics lie in the anxiety for the preservation of the bodies of the martyr. Nothing is more natural than that the pious solicitude felt by all men for the bodies of their loved ones should in the primitive Christian Churches have been turned most strongly towards the bodies of those who had met with death in confessing their faith. The account given by the church at Smyrna of the death of their bishop Polycarp (155) gives us an insight into these feelings. The church collected and buried the remains of the martyr, who had been burnt, in order duly to celebrate the anniversary of the martyrdom at the place of burial. The possession of the relics seemed to assure the continuation of the common life of the church with their bishop, of the living with the dead (Mart. Poly. c. 17).

The custom of which we have here for the first time an account has become universal by the 3rd century. In all parts the Christians assembled on the anniversary of the martyrs' death at their graves, to celebrate the Agape and the Eucharist at this spot. It was a favourite custom to bury the dead near the graves of the martyrs; and it was the highest wish of many to "rest with the saints." It was the body lying in the tomb which was venerated (see Euseb. Hist. eccl. vii. 11, 24; viii. 6, 7).

But these customs soon underwent a further development. About the end of the 3rd and the beginning of the 4th century
it became customary for the bodies of the martyrs not to be buried, but preserved for the purpose of veneration. Already individual Christians began to possess themselves of portions of the bodies of martyrs, and to carry them about with them. Both these practices met with criticism and opposition, especially from the leading men of the Church. According to the testimony of Athanasius of Alexandria, the hermit Anthony decided that it should be held to be unlawful and impious to leave the bodies of the martyrs unburied (Vita Aut. 90). In Carthage the archdeacon and later the bishop Caeceanus severely blamed a certain Lucullus for carrying about with her a relic which she used to kiss before receiving the Eucharist (Optatus, De schism. Donat, i. 16). The compiler of the Acta S. Francisci, a Spanish ecclesiastic, represents the martyred bishop as himself requesting the burial of his relics. But energetic as the opposition was, it was unsuccessful, and died out. For in the meantime opinion as to the efficacy of relics had undergone a transformation, parallel with the growth of the theory, which soon predominated in the Church, that material instruments are the vehicles of divine grace. When the Christians of Smyrna decided that the bones of the martyr were of more worth than gold or gems, and when Origen (Ech. ad mart. 56) spoke of the precious blood of the martyrs, they were thinking of the act of faith which the martyrs had accomplished by the sacrifice of their life. Now, on the other hand, the relic came to be looked upon as in itself a thing of value as the channel of miraculous divine powers. These ideas are set forth by Cyril of Jerusalem. He taught that a certain power dwelt in the body of the saint, even when the soul had departed from it; just as it was the instrument of the soul during life, so the power passed permanently into it (Cath. xviii. 16). This was coming very near to a belief that objects which the saints had used during their life had also a share in their miraculous powers. And this conclusion Cyril had already come to (loc. cit.).

We can see how early this estimate of relics became general from the fact that the former hesitation as to whether they should be venerated as sacred died out during the 4th century. The Fathers of the Greek Church especially were united in recommending the veneration of relics. All the great theologians of the 4th and 5th centuries may be quoted as evidence of this: Eusebius of Caesarea (Praep. Eccl. viii. 11.1), Gregory of Nazianzus (Orat. in Cyrp. 17), Gregory of Nyssa (Orat. de S. Thed. mart.), Basil of Caesarea (Ep. ii. 197), Chrysostom (Laud. Dossidii, theodoret of Cyrus (Inps. 67, 21), &c. John of Damascus, the great exponent of dogma in the 8th century, gave expression to the result of a uniform development which had been going on for centuries when he taught that Christ offers the relics to Christians as means of salvation. They must not be looked upon as something that is dead; for through them all good things come to those who pray with faith. Why should it seem impossible to believe in this power of the relics, when water could be made to gush from a rock in the desert? (De fide orthodox. iv. 15)

Such was the theory; and the practice was in harmony with it. Throughout the whole of the Eastern Church the veneration of relics prevailed. Nobody hesitated to divide up the bodies of the saints in order to afford as many portions of them as possible. They were shared among the inhabitants of cities and villages, Theodoret tells us, and cherished by everybody as healers and physicians for both body and soul (De sacr. Græc. aff. 8). The transition from the true relic to the hallowed object was especially common. Jerusalem, as early as the time of Eusebius, rejoiced in the possession of the episcopal chair of James the Just (Hist. eccl. vii. 15); and as late as the 4th century was discovered the most important of the relics of Christ, the cross which was alleged to have been His. Cyril of Jerusalem already remarks that the whole world was filled with portions of the wood of the cross (Cat. iv. 15).

The development which the veneration of relics underwent in the West did not differ essentially from that in the East. Here also the idea came to prevail that the body of the saint, or a portion of it, was possessed of healing and protective power (Paulinus of Nola, Poem. xix. 14 et seq., xxvii. 443). The objection raised by the Aquitanian presbyter Vigilantius (c. 400) to the belief that the souls of the martyrs to a certain extent clung to their ashes, and heard the prayers of those who approached them, appeared to his contemporaries to be frivolous; and he nowhere met with any support.

The only doubt which was felt was as to whether the bodies of the saints should be divided, and removed from their original resting-place. Both practices were forbidden by law under the emperor Theodosius I. (Cod. Theodos. ix. 17, 7); and the division of the bodies of martyrs into pieces was prohibited for centuries. Even Pope Gregory I., in a letter to the empress Constantia, disapproved it (Ep. iv. 36). Ambrose of Milan, by the discovery of the relics of Protasius and Gervasius (cf. Ep. 22 and Augustine, Confess. ix. 7), started in the West the long series of discoveries and translations of hitherto unknown relics. His example was followed, to name only the best known instances, by Bishop Theodore of Octodurum (now Martigny in the Vaud), who discovered the relics of the Théban legion which was alleged to have been destroyed by the emperor Maximian on account of its belief in the Christian faith (see Passio Acacii. Mart. 16), and by Clematius, a citizen of Cologne, to whom the virgin martyrs of this city revealed themselves (Kraus, Inschriften der Rheinlande, No. 294), afterwards to be known as St Ursula and her eleven thousand virgins.

The West was much poorer in relics than the East. Rome, it is true, possessed in the bodies of Peter and Paul a treasure the virtue of which outshone all the sacred treasures of the East. But many other places were entirely wanting in relics. By the discoveries which we have mentioned their number was notably increased. But the longing for these pledges of the divine assistance was insatiable. In order to satisfy it relics were made by placing pieces of cloth on the graves of the saints, which were afterwards taken to their homes and venerated by the pilgrims. The same purpose was served by oil taken from the lamps burning at the graves, flowers from the altars, water from some holy well, pieces of the garments of saints, earth from Jerusalem, and especially keys which had been laid on the grave of St Peter at Rome. All these things were not looked upon as mementoes, but the conviction prevailed that they were informed by a miraculous power, which had passed into them through contact with that which was originally sacred (cf. Greg. Tur. De glor. mart. i. 25; Greg. I. Ep. iv. 29, No. 36). A dishonest means of satisfying the craving for relics was that of forging them, and how common this became can be gathered from the many complaints about spurious relics (Sulp. Sev. Vita Mart. 8; Aug. De op. mot. 28; Greg. I. Ep. iv. 30, &c.).

But in the long run these substitutes for relics did not satisfy the Christians of the West, and, following the example of the Eastern Church, they took to dividing the bodies of the saints. Medieval relics in the West also were mostly portions of the bodies of saints or of things which they had used during their lives. The veneration of relics also received a strong impulse from the fact that the Church required that a relic should be deposited in every altar. Among the first of those whom we know to have attached importance to the placing of relics in churches is Ambrose of Milan (Ep. 22), and the 7th general council of Nicæa (787) forbade the consecration of churches in which relics were not present, under pain of excommunication. This has remained part of the law of the Roman Catholic Church.

The most famous relics discovered during the middle ages were the remains of the apostle James at Saintago de Compostella in Spain (see Pilgrimage), the bodies of the three kings, which were brought from Milan to Cologne in 1164 by the emperor Frederick I. (Chron. reg. Colon, for the year 1164), the so-called sudarium of St Veronica, which from the 12th century onwards was preserved in the Capella Santa Maria ad praesepe of St Peter's in Rome (see Dobschütz, Christusbilder, p. 218 seq.), and the seamless robe of Christ, the possession of which lent
The number of relics increased to a fabulous extent during the middle ages. There were churches which possessed hundreds, even thousands, of relics. In the cathedral of Eichstätt were to be found, as early as 1071, 683 relics (Gundech, *Lib. pont. Estit., Mon. Germ. Sar. vii. p. 246 seq.); the monastery of Hirschau had 222 in the year 1091 (De cons. mat. mon., Mon. Germ. Sar. xiv. p. 261); the monastery of Stedernburg 515 in the year 1166 (Ann. Sted. Sar. vi. p. 212 seq.). But these figures are trilling compared with those at the end of the middle ages. In the year 1520 could be counted 19,013 in the Schlosskirche at Wittenberg, and 21,483 in the Schlosskirche at Halle in 1521 (Kötlin, Friedrich der W., und die Schlosskirche zu Wittenberg, p. 38 seq.; Redlich, *Cardinal Albrecht und das Neue Stift zu Halle*, p. 260). There were also collections on the same scale belonging to individuals; a patrician of Nuremberg named Muffel was able to gain possession of 368 relics (*Chroniken der deutschen Städte*, xi. p. 745).

It is curious that while the popular craving for relics had passed all bounds, medieval theology was very cautious in its declarations on the subject of the veneration of relics. Thomas Aquinas based his justification of them on the idea of reverent commemoration; since we venerate the saints, we must also show reverence for their relics, for whoever loves another does honour to that which remains of him after death. On this account it is our duty, in memory of the saints, to pay due honour to their relics and especially to their bodies, which were the temples and dwellings of the Holy Ghost in which He dwelt and worked, and which in the resurrection are to be made like to the body of Christ; and in likewise because God honours them, in that He works through them in their presence (Summa theol. ii. 25, art. 6). The great scholastic philosopher abandoned the theory that the relics in themselves are vessels and instruments of the divine grace and miraculous power. But these ideas were revived, on the other hand, by the Catholicism of the counter-Reformation, which again taught and teaches that God grants many benefits to mankind through the sacred bodies of the martyrs (Conc. Trid. sess. xxv.). The doctrine has adapted itself to the popular belief. (A. H.)

**RELIEF** (through Fr. from Lat. relevare, to lift up), an act of raising or lifting off or up. Apart from the general sense of a mitigation, cessation or removal of pain, sorrow, discomfort, &c., and the artistic use (It. rilievo) of the projection of a figure, or design in sculpture from the ground on which it is formed, which is treated below, the term "relief" is used in the following senses; it was one of the feudal incidents between lord and vassal, and consisted of a payment to the lord in kind or money made by the heir on the death of the ancestor for the privilege of succession, for, iffs not being hereditary, the estate had lapsed to the lord; by this payment the heir caduca praedium relevabat (Du Cange, Gloss. s.v. Relevare). The word is also generally used, in law, for any exemption granted by a court from the strict legal consequences of an act, &c., e.g. to a parli- made body, from the penal consequences of a breach of the regulations of the Corrupt and Illegal Practices Acts. Relief is also the term used in English law for the assistance given to the indigent poor by the Poor Law authorities (see Poor Law).

**RELIEF**, a term in sculpture signifying ornament, a figure or figures raised from the ground of a flat surface of which the sculptured portion forms an inherent part of the body of the whole. The design may be in high relief—"alto-relievo" (q.v.) or low relief—"bas-relief" or "basso-relievo" (q.v.); and in the former case the design is almost wholly detached from the ground, the attachment, through "under-cutting," remaining only here and there; in the latter it is wholly attached and may scarcely rise above the surface (as in the modern medal), or it may exceed in projection to about a half the proportionate thickness of the figure or object represented. Formerly three terms were commonly employed to express the degree of relief—alto-relievo, basso-relievo and mezzo-relievo (or half-relief); but the two last-named have been merged by modern custom into "low-relief," to the disadvantage of accurate description. The term relief belongs to modern sculpture. To low relief as understood by us Pliny applied the word *anaglypta*, but it is to be observed that embossing and chasing came within the same category. It may be considered that less sculptural skill (independently of manipulative skill) is needed in high relief than in low relief, because in the former the true relative proportions in the life (whether figure or other object) have to be rendered, while in the latter, although the true height and, in a measure, breadth can be given, the thickness of the object is reduced by at least one-half, sometimes to almost nothing; and yet in spite of this departure from actuality, this abandon- ment of fact for a pure convention, a true effect must still be produced, not only in respect to perspective, but also of the actual shadows cast. And inasmuch as the compositions are often extremely complicated and have sometimes to suggest retreating planes, the true plane of the material affords little scope for reproducing the required effect. In the beginning the essential idea of the relief was always maintained: that is to say, the sense of the flatness of the slab from which it was cut was impressed throughout the design on the mind of the spectator. Thus the Egyptians merely sunk the outlines and scarcely more than suggested the modelling of the figures, which never projected beyond the face of the surrounding ground. The Persians, the Etruscans and the Greeks carried on the art to the highest perfection, alike in sculpture and architectural ornament, and they applied it to gem sculpture, as in the case of "cameo." Similarly, the inverse treatment of relief—that is, sunk below the surface, in order that when used for seals a true relief is obtained—was early brought to great completeness; this form of engraving is called "intaglio." The degree of every work in relief, broadly speaking, has varied greatly with the periods of art. Thus, in Byzantine and Romanesque art the relief was low. In Gothic it increased with the increased desire to render several planes one behind the other. With the advent of the Renaissance it became still more accentuated, the heads and figures projecting greatly; but such high relief is sometimes found in early work, especially in metal-work. Although we see a return to lower relief in the Henri II. period, it becomes stronger in the Louis XIII. style, very full in Louis XIV. and Louis XV., but in Louis XVI. is considerably reduced. (M. H. St.)

**RELIGION.** The origin of the Latin word *religio* or *religio* has been the subject of discussion since the time of Cicero. Two alternative derivations have been given, viz. from *religere*, to gather together, and *relegere*, to bind back, fasten. *Religere* meant to gather together, collect, hence to go over a subject again in thought, from *re* and *legere*, to collect, hence to read, collect at a glance. This view is that given by Cicero (*Nat. Deor*. ii. 28, 72). He says: "Qui omnia quae ad cultum deorum pertinent diligenter retractaret et tanquam rerum religare, sunt dicti religiosis ex relegendo," "men were called 'religious' from *relegere*, because they reconsidered carefully and, as it were, won it in relief; in this speaking, has varied greatly with the periods of art. He compares *elegantes* from *eliger* from *eliger*, because they reconsidered carefully and, as it were, won in relief, to much the same, with the former, in the worship of the gods." He compares *elegantes* from *eliger*, *diligentes* from *diligere*, and continues, "his enim in verbis omnibus inest vis legendi eadem quae religio in religioso." This view is supported by the form of the word in the verse quoted by Gallius (iv. 9), "religentem esse opertum, religiosum nefas," and by the use of the Greek *Δελειον*, to pay heed to, frequently with a negative, in the sense of the Latin *negligere* (neg-legere), *θεοι όνων οι Δελειον* (Homer, *H. xvi. 388), heeding not the visitation of the gods, or οὐ γὰρ Κόλωσες ἄλλοι έλειον (Od. ix. 275). The alternative derivation, from *relegere*, to fasten, bind, is that adopted by Lactantius (Inst. iv. 28)."Vinculo petatis obstruisti, Dei religati sumus unde ipsa religio nomen cepit," He quotes in support the line from Lucretius (i. 931), "religionum nodis animos exsovere." Servius (on Virgil, *Aen*. vii. 340) and St Augustine (*Retracit. i.* 13) also take *relegere* as the source of the word. It is one that has certainly coloured the meaning of the word, particularly in that use which restricts
it to the monastic life with its binding rules. It also has appealed to Christian thought. Liddon (Some Elements of Religion, Lecture I. 190) says: "Tactitius may be wrong in his etymology, but he has certainly seized the broad popular sense of the word when he connects it with the idea of an obligation by which man is bound to an invisible God." Archbishop Trench (Study of Words) supposed that when "religion" became the monastic life, and "religious" to a monk, the words lost their original meaning, but the Ancuren Riale, ante 1225, and the Cursor Mundi use the words both in the general and the more particular sense (see quotations in the New English Dictionary), and both meanings can be found in the Imitation Christi and in Erasmus's Colloquia.

The study of the forms of belief and worship belonging to different tribes, nations or religious communities has only recently acquired a scientific foundation. The Greek historians early directed their attention to the ideas and customs of the peoples with whom they were brought into contact; and Herodotus has been called the "first anthropologist of religion." Theopompos described the Persian dualism in the 4th century B.C., and when Megasthenes was ambassador to the court of Chandragupta, 302 B.C., he noted the religious usages of the middle Ganges valley. The early Christian Fathers recorded many a valuable observation of the Gentile faiths around them from varying points of view, sympathetic or hostile; and Eusebius and Epiphanius, in the 4th century A.D., attributed to the librarian of Ptolemy Philadephus the design of collecting the sacred books of the Ethiopians, Indians, Persians, Elamites, Babylonians, Assyrians, Romans, Phoenicians, Syrians and Greeks. The Mahomedan Biruni (b. A.D. 973) compared the doctrines of the Greeks, Christians, Jews, Manichaean and Sufis with the philosophies and religions of India. Abar (1542-1605) gathered Brahmins and Zoroastrians, Jews, Christians and Mahomedans at his court, and endeavoured to get translations of their scriptures. In the next century the Persian author of the Dakhtaran exhibited the doctrines of no less than twelve religions and their various sects. Meanwhile the scholars of the West had begun to work. Thomas Hyde (1656-1703) studied the religion of the ancient Persians; John Spencer (1680-1693) analysed the laws of the Hebrews; and Lord Herbert of Cherbury (De Religione Gentilium, 1645) endeavoured to trace all religions back to five "truly Catholic truths" of primitive faith, the first being the existence of God. The doctrine of a primeval revelation survived in various forms for two centuries, and appeared as late as the Juventus Mundi of W. E. Gladstone (1868, p. 207 ff.). David Hume, on the other hand, based his essay on The Natural History of Religion (1757) on the conception of the development of human society from rude beginnings, and all modern study is frankly founded on the general idea of Evolution.1

The materials at Hume's command, however, were destined to vast and speedy expansion. The Jesuit missionaries had already been at work in India and China, and a brilliant band of English students, led by Sir William Jones and H. T. Colebrooke, began to make known the treasures of Sanskrit literature, which the great scholars of Germany and France proceeded to develop. In Egypt the discovery of the Rosetta stone placed the key to the hieroglyphics within Western reach; and the decipherment of the cuneiform character enabled the patient scholars of Europe to recover the clues to the contents of the ancient libraries of Babylonia and Assyria. With the aid of inscriptions the cults of Greece and Rome have been largely reconstructed. Travellers and missionaries reported the beliefs and suppositions of those who spoke the modern tongues, and with the result that "ethnography knows no race devoid of religion, but only differences in the degree to which religious ideas have developed" (Ratzel, History of Mankind, i. 40). Meanwhile philosophy was at work on the problem of the religious consciousness. The great series of German thinkers, Lessing, Herder, Kant, Hegel, Fichte, Schleiermacher and their successors, sought to explain religion by means of the phenomena of mind, and to track it to its roots in the processes of thought and feeling. While ethnography was gathering up the facts from every part of the globe, psychology began to analyse the forms of belief, of action and emotion, to discover if possible the key to the multitudinous variety which history revealed. From the historical and linguistic side attention was first fixed upon the myth, and the publication of the ancient hymns of the Rig Veda led Max Müller to seek in the common elements of Aryan thought for the secrets of primitive religion (essay on Comparative Mythology, 1856). The phenomena of day and night, of sunshine and storm, and other aspects of nature, were invoked by different interpreters to explain the conceptions of the gods, their origins and their relations. Fresh materials were gathered at the same time out of European folk-lore; the work begun by the brothers Grimm was continued by J. W. E. Mannhardt, and a lower stratum of beliefs and rites began to emerge into view beneath the poetic forms of the more developed mythologies. By such preliminary labours the way was prepared for the new science of anthropology.

Since the appearance of Dr E. B. Tylor's classical treatise on Primitive Culture (1871), the study of the origins of religion has been pursued with the utmost zeal. Comte had already described the primitive form of the religious consciousness as that in which man conceives of all external bodies as animated by a life analogous to his own (Philos. Positive, tome v., 1841, p. 30). This has been since designated as polyzoism or pantheism or pantheism, and represents the obscure undifferentiated groundwork out of which Tylor's Animism arises. Many are the clues by which it has been sought to explain the secret of primitive religion. Hegel, before the anthropological stage, found it in magic. Max Müller, building on philosophy and mythology, affirmed that "Religion consists in the perception of the infinite under such manifestations as are able to influence the moral character of man" (Natural Religion, 1859, p. 188). Herbert Spencer derived all religion from the worship of the dead (Principles of Sociology, i.), like Grant Allen, and Lippert in Germany. Mr Andrew Lang, on the other hand, supposes that belief in a supreme being came first in order of evolution, but was afterwards thrust into the background by belief in ghosts and lesser divinities (Magic and Religion, 1901, p. 224). Dr Jevons finds the primitive form in totemism (Intro. to the History of Religion, 1866, chap. ix.). Mr J. G. Frazer regards religion (see his definition quoted below) as superposed on an antecedent stage of magic. In The Tree of Life (1905), Mr E. Crawley interprets it by the vital instinct, and connects its first manifestations with the processes of the organic life. The veteran Wilhelm Wundt (Mythus and Religion, ii. 1906, p. 177) recurs to the primitive conceptions of the soul as the source of all subsequent development. The origin of religion, however, can never be determined archaeologically or historically; it must be sought conjecturally through psychology. (J. E. C.)

A. PRIMITIVE RELIGION

There is a point at which the History of Religion becomes in its predominant aspect a History of Religions. The conditions that we describe by the comprehensive term "civilization" occasion a specification and corresponding differentiation of the life of societies; whence there result competing types of culture, each instinct with the spirit of propagandism and one, might almost say, of empire. It is an age of conscious selection as between ideal systems. Instead of necessitating a wasteful and precarious elimination of inadequate customs, the actual emergence of the human mind into a region of intellectual security provides the method of natural selection, which, like some Spanish Inquisition, abolishes the heresy by wiping out the heretics one and all—progress now becomes possible along the more direct and less

1 This does not, of course, preclude the possibility of degeneration in particular instances.2 Comte's own term "fetishism" was most unfortunately misleading (see Fetishism). MARETT proposed the term "Animatism," Folk Lore (1900), xi. p. 17.
painful path of conversion. The heretic, having developed powers of rational choice, perceives his heresy, to wit, his want of adaptation to the moral environment, and turning round embraces the new faith that is the passport to survival.

Far otherwise is it with man at the stage of savagery—the stage of petty groups pursuing a self-centred life of invertebrate custom, in an isolation almost as complete as if they were marooned on separate atolls of the ocean. Progress, or at all events change, does indeed take place, though very slowly, since the most primitive savage we know of has his portion of human intelligence, looks after and before, nay, in regard to the pressing needs of every day shows a quite remarkable shrewdness and resource. Speaking generally, however, we must pronounce him unprogressive, since, on the whole, unreflective in regard to his ends. It is the price that must be paid for social discreteness and incoherence. And the consequence of this atomism is not what a careless thinker might be led to assume, extreme diversity, but, on the contrary, extreme homogeneity of culture. It has been found unworkable, for instance, to classify the religions of really primitive peoples under a plurality of heads, as becomes necessary the moment that the presence of a distinctive basis of linked ideas testifies to the individuality of this or that type of higher creed. Primitive religions are like so many similar beads on a string; and the concern of the student of comparative religion is at this stage mainly with the nature of the string, to wit, the common conditions of soul and society that make, say, totemism, or taboo, very much the same thing all the savage world over, when we seek to penetrate to its essence.

This fundamental homogeneity of primitive culture, however, must not be made the excuse for a treatment at the hands of psychology and sociology that dispenses with the study of details and trusts to an a priori method. By all means let universal characterization be attempted—we are about to attempt one here, though well aware of the difficulty in the present state of our knowledge—but they must at least model themselves on the composite photograph rather than the impressionist sketch. An enormous mass of material, mostly quite in the raw, awaits reduction to order on the part of anthropological theorists, as yet a small and ill-supported body of enthusiasts. Under these circumstances it would be presumptuous to expect agreement as to definition. In the event of method, however, there is little difference of opinion. Thus, whereas the popular writer abounds in wide generalizations on the subject of primitive humanity, the expert has hitherto for the most part deliberately restricted himself to departmental investigations. Religion, for example, seems altogether too vast a theme for him to embark on, and he usually prefers to deal with some single element or aspect. Again, origins attract the littorateur; he revels in describing the transition from the pre-religious to the religious era. But the expert, confining his attention to the known savage, finds him already religious, nay, clothed with religious survivals of all kinds; for him, then, it suffices to describe things as they now are, or as they were in the comparatively recent fore-time.

Lastly, there are many who, being competent in some other branch of science, but having small acquaintance with the scientific study of human culture, are inclined to explain primitive ideas and institutions from without, namely by reference to various external conditions of the mental life of peoples, such as race, climate, food-supply and so on. The anthropological expert, on the other hand, insists on making the primitive point of view itself the be-all and end-all of his investigations. The inwardness of savage religion—the meaning it has for those who practise it—constitutes its essence and meaning likewise for him, who after all is a man and a brother, not one who stands really outside.

In what follows, then, we shall, indeed, venture to present a wholesale appreciation of the religious idea as it is for primitive man in general; but our account will respect the modern anthropological method that bids the student keep closely to the actualities of the religious experience of savages, as it can with reasonable accuracy be gathered from what they do and say. We have sought to render only the spirit of primitive religion, keeping clear both of technicalities and of departmental investigations. These are left to the separate articles bearing on the subject. There the reader will find the most solid results of recent anthropological research. Here is he merely offered a flimsy thread that, we hope, may guide him through the maze of facts, but alas! is only too likely to break off short in his hand.

Definition of Primitive Religion.—In dealing with a development of culture that has no immutability essence, but is intrinsically fluid and changing, definition must consist either in a definition of type, which indicates prevalence of relevant resemblance as between specimens more or less divergent, or in exterior definition, which delimits the field of inquiry by laying down within what extreme limits this divergence holds. Amongst the numberless definitions of religion that have been suggested, those that have been most frequently adopted for working purposes by anthropologists are Tylor's and Frazer's. Dr E. B. Tylor in Primitive Culture (1), i. 444, proposes as a "minimum definition" of religion "the belief in spiritual beings." Objections to this definition on the score of incompleteness are, firstly, that, besides belief, practice must be reckoned with (since, as Dr W. Robertson Smith has made clear in his Lectures on the Religion of the Semites, 18 sqq., ritual is in fact primary for primitive religion, whilst dogma and myth are secondary); secondly, that the outlook of such belief and practice is not exclusively towards the spiritual, unless this term be widened until it mean next to nothing, but is likewise towards the quasi-material, as will be shown presently. The merit of this definition, on the other hand, lies in its bilateral form, which calls attention to the need of characterizing both the religious attitude and the religious object to which the former has reference. The same form appears in Dr J. G. Frazer's definition in The Golden Bough (2nd ed.), i. 63. He understands by religion "a propitiation or conciliation of powers superior to man which are believed to direct and control the course of nature and of human life." He goes on to explain that by "powers" he means "conscious or personal agents." It is also to be noted that he is here definitely opposing religion to magic, which he holds to be based on the (implicit) assumption "that the course of nature is determined, not by the passions or caprice of personal beings, but by the operation of immutable laws acting mechanically." His definition improves on Tylor's in so far as it makes worship integral to the religious attitude. By regarding the object of religion as necessarily personal, however, he is led to exclude much that the primitive man undoubtedly treats with awe and respect as exerting a mystic effect on his life. Further, in maintaining that the powers recognized by religion are always superior to man, he leaves unclassed a host of practices that display a bargaining, or even a hectoring, spirit on the part of those addressing them (see PRAYER). Threatening or beating a fetish cannot be brought under the head of magic, even if we adopt Frazer's principle (op. cit. i. 64) that to constrain or coerce a personal being is to treat him as an inanimate agent; for such a principle is quite inapplicable to cases of mere terrorism, whilst it may be doubted if it even renders the sense of the savage magician's typical notion of his modus operandi, viz. as the bringing to bear of a greater mana or psychic influence (see below) on what has less, and must therefore do as it is bidden. Such definitions, then, are to be accepted; if at all, as definitions of type, selective designations of leading but not strictly universal features. An encyclopaedic account, however, should rest rather on an exterior definition which can serve as it were to pigeon-hole the whole mass of significant facts. Such definition would be that of the English phrase "the Tree of Life," in the Tree of Life, 209, where he points out that "neither the Greek nor the Latin language has any comprehensive term for religion, except in the one isk, and in the other sacra, words which are equivalent to 'sacred.' No other term covers the whole of religious phenomena, and a survey of the complex details of various worships results in showing that no other conception will comprise the whole body of religious facts." It may be added that we have here no generalization imported from a
RELIGION

Aspects of the Nature of the Sacred.—To exhibit the general character of the sacred as it exists for primitive religion is simplest to take stock of various aspects recognized by primitive thought as expressed in language. If some, and not the least essential, of these aspects are quasi-negative, it must be remembered that negations—witness the Unseen, the Unknown, the Infinite of a more advanced theology—are well adapted to supply that mystery on which the religious consciousness feeds with the slight basis of conceptual support it needs. (1) The sacred as the forbidden. The primitive notion that perhaps comes nearest to our "sacred," whilst it immediately underlies the meanings of the Latin sanctus, is that of a taboo, a Polynesian term for which equivalents can be quoted from most savage vocabularies. The root idea seems to be that something is marked off as to be shunned, with the added hint of a mystic sanction or penalty enforcing the avoidance. Two derivative senses of a more positive import call for special notice. On the one hand, that which is tabooed is held to punish the taboo-breaker by a sort of mystical infection, taboo comes to stand for uncleanness and sin. On the other hand, since the isolation of the sacred, as the accepted, is so far-reaching that even the profane, though not actually the sacred, may be interpreted as self-protection on the part of the sacred as against defining contact, taboo takes on the connotation of ascetic virtue, purity, devotion, dignity and blessedness. Primary and secondary senses of the term between them cover so much ground that it is not surprising to find taboo used in Polynesia as a name for the whole system of religion, founded as it largely is on prohibitions and abstentions. (2) The sacred as the mysterious. Another quasi-negative notion of more restricted distribution is that of the mysterious or strange, as we have it expressed, for example, in the Siouan wakan, though possibly this is a derivative meaning. Meanwhile, it is certain that what is strange, new, or potentent is regularly treated by all savages as sacred. (3) The sacred as the secret. The literal sense of the term churinga, applied by the Central Australians to their sacred objects, and likewise used more abstractly to denote mystical power, as when a man is said to be "full of churinga," is "secret," and is symptomatic of the esotericism that is a striking mark of Australian, and indeed of all primitive, religion, with its insistence on initiation, its exclusion of women, and its strictly enforced reticence concerning traditional lore and proceedings. (4) The sacred as the potent. Passing on to positive connotations of the sacred, perhaps the most fundamental is that which identifies the efficacy of sacredness with such mystical or magical power as is signified by the mana of the Pacific or orénda of the Hurons, terms for which analogies are forthcoming on all sides. Of mana Dr R. H. Codrington in The Melanesians, 119 n., writes: "It essentially belongs to personal beings to originate it, though it may act through the medium of water, or a stone, or a bone. All Melanesian religion consists... in getting this mana for oneself, or getting it used for one's benefit." E. Tregear's Maori-Polynesian Comparative Dictionary shows how the word and its derivatives are used to express thought, memory, emotion, desire, will—in short, psychic energy of all kinds. It also stands for the vehicle of the magician's energy—the spell; which would seem likely to be a meaning, perhaps the root-meaning, of orénda (cf. J. N. B. Hewitt, American Anthropologist, N.S., iv. 40). Whereas everything, perhaps, has some share of inducing potency, whatever is sacred manifests this potency in an extraordinary degree, as typically the wonder-working leader of society, whose mana consists in his cunning and luck together. Altogether, in mana we have what is par excellence the primitive religious idea in its positive aspect, taboo representing its negative side, since whatever has mana is taboo, and whatever is taboo has mana. (5) The sacred as the animistic. The term "animism," which embodies Tylor's classical theory of primitive religion, is unfortunately somewhat ambiguous. If we take it strictly to mean the belief in ghosts or spirits having "vampirism-like quality," it would include the objects of dream or hallucination, it is certain that the agency of such phantasmata is not the sole cause to which all mystic happenings are referred (though ghosts and spirits are everywhere believed in, and appear to be endowed with greater predominance as religious synthesis advances amongst primitive peoples). Thus there is good evidence to show that many of the early gods, notably those that are held to be especially well disposed to man, are conceived rather in the shape of magnified non-ordinary men dwelling somewhere apart, such as the Mangugur of the Kurnai of S.E. Australia (cf. A. Lang, The Mythology of the Natives of Australia, i), and such anthropomorphisms as are difficult to reduce to the Tylorian animism. The term, however, will have to be used still more vaguely, if it is to cover all attribution of personality, will or vitality. This can be more simply brought under the notion of mana. Meanwhile, since quasi-mechanical means are freely resorted to in dealing with the sacred, as when a Maori chief snuffs up the sanctity his fingers have acquired by touching his own sacred head that he may restore the virtue to the part whence it was taken (R. Taylor, Te Ika a Maui, 165), or when uncleanness is removed as if it were a physical secretion by washing, thus compelled to remain, such what are now called a "material" nature is not ascribed to the sacred, more especially when its transmissibility after the manner of contagion is the trait that holds the attention. It is possible, however, that the savage always distinguishes in a dim way between the material medium and the indwelling principle of vital energy, examples of a pure fetishism, in the sense of the cult of the purely material, recognized as such, being hard to find. (6) The sacred as the ancient. The prominence of the notion of the Acheringsia "dreamtime," or sacred past, in Central Australian religion illustrates the essential connection perceived by the savage to lie between the sacred and the traditional. Idealistic conservatism may be instanced as a practical outcome of this feeling. Another development is ancestor-worship, the organized cult of ancestors marking, however, a certain stage of advance beyond the very primitive, though the dead are always sacred and have mana which the living may exploit for their own advantage.

The Activity of the Sacred.—The foregoing views of the sacred, though starting from distinct conceptions, converge in a single complex notion, as may be seen from the many-sided sense borne by such a term as wakan, which may stand not only for "mystery," but also for magic, sacred, ancient, grandeur, animating of Religion," x. seqq. Such anthropomorphisms may be instanced as a practical outcome of this feeling. Another development is ancestor-worship, the organized cult of ancestors marking, however, a certain stage of advance beyond the very primitive, though the dead are always sacred and have mana which the living may exploit for their own advantage.

to the participants, being overlaid by its traditional character, which but guarantees a general efficacy. "Blessings come, evils go," may be said to be the magico-religious formula implicit in all socially approved dealings with the sacred, however specialized in semblance. 

(2) Ambiguity. Mystic potency, however, because of the very indefiniteness of its action, is a two-edged sword. The sacred is not to be approached lightly. It will heal or blast, according as it is handled with or without due circumspection. That which is taboo, for instance, the person of the king, or woman's blood, is poison or medicine according as it is manipulated, being inherently just a pot of gold or a pot of wonder-working in any direction. What primitive thought shows a tendency to mark off a certain kind of mystic power as wholly bad by a special name, e.g. the arungquilkina of Central Australia; and here, we may note, we come nearest to a conception of magic as something other than religion, the trafficker in arungquilkina being socially suspect, nay, liable to persecution, and even death (as amongst the Arunta tribe, see Spencer and Gillen, Native Tribes of C. Australia, 336), at the hands of his fellows. On the other hand, wholly beneficent powers seem hardly to be recognized, unless we find them in beings such as Mungan-ngaur ("father-our"), who derive an ethical character from their association with the initiation ceremonies and the moral instruction given thereon (cf. Lang, l.c.).

(3) Relativity. So far we have tended to represent the activity of the sacred as that of a universal force, somewhat in the style of our "electricity" or "mind." It remains to add that this activity manifests itself at numberless independent centres. These differ amongst themselves in the degree of their energy. One spell is stronger than another, one taboo more inviolable than another. Dr W. H. R. Rivers (The Todas, 448) gives an interesting analysis of the grades of sanctity apparent in Toda religion. The gods of the hill-tops come first. The sacred buffaloes, their milk, their bells, the dairies and their vessels are on a lower plane; whilst we may note that there are several grades amongst the dairies, increase of sanctity going with elaboration of dairy ritual (cf. ibid. 232). Still lower is the dairyman, who is in no way divine, yet has sanctity as one who maintains a condition of ceremonial purity. 

(4) Transmissibility. If, however, this activity originates at certain centres, it tends to spread therewith from all directions. Dr F. B. Jevons (in An Introduction to the History of Religion, vi.) distinguishes between "things taboo," which have the mystic contagion inherent in them, and "things tabooed," to which the taboo-infection has been transmitted. In the former class he places supernatural beings (including men with mana as well as ghosts and spirits), blood, new-born children with their mothers, and corpses; which list might be considerably extended, for instance, by the inclusion of natural portents, and animals and plants such as are strikingly odd, dangerous or useful. Any one of these can pass on its sacred quality to other persons and objects (as a corpse defiles the mourner and his clothes), nay to actions, places and times as well (as a corpse will likewise cause work to be tabooed, ground to be set apart, a holy season to be observed). Such transmissibility is commonly explained by the association of ideas, that becoming sacred which it were reminded one of the sacred; though it is important to add, firstly, that such association takes place under the influence of a selective interest generated by strong religious feeling, and, secondly, that this interest is primarily a collectible product, being governed by a social tradition which causes certain possibilities of ideal combination alone to be realized, whilst it is the chief guarantee of the objectivity of what they suggest.

The Explanation of the Sacred. A. Methods.—It is hard to find terms general enough to cover dealings with the sacred that range from the manipulation of an almost inanimate type of power to intercourse modelled on that between man and man. Primitiveness as a wonder-working power is not in itself any better evidence that the sacred is something sacred than that the sacred is something together. Not so indifferently as to prove that there is little or no awareness of an inconsistency of attitude. The radical contrast between mechanical and spiritual religion, though fundamental for modern theology, is alien to the primitive point of view, and is therefore inappropriate to the purposes of anthropological description. 

(1) Acquisition. Mystic power may be regarded as innate so far as skill, luck or querueness are signs and conditions of its presence. On the whole, however, savage society tends to regard it as something acquired, the product of acts and abstinence having a traditional character for imparting magico-religious virtue. An external symbol in the shape of a ceremony or cult-object is of great assistance to the dim eye of primitive faith. Again, the savage universe is no preserve of man, but is an open field wherein human and non-human activities of all sorts compete on more or less equal terms, yet so that a certain measure of predominance may be secured by a judicious combination of forces. The sacred society or individual practitioner piles ceremony, name of power on name of power, relic on relic, to consolidate the forces within reach and assume direction thereof. The transmissibility of the sacred ensures the fusion of powers drawn from all sources, however disparate. 

(3) Induction. It is necessary, however, as it were to bring this force to a head. This would appear to be the essential significance of sacrifice, where a number of sacred operations and instruments are made to discharge their efficacy into the victim as into a vat, so that a blessing-yielding, evil-neutralizing force of highest attainable potency is obtained (see H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice" in L'Année sociologique, ii.).

(4) Renovation. An important motif in magico-religious ritual, which may not have been without effect on the development of sacrifice, is, as Dr Frazer's main thesis in The Golden Bough asserts, the imparting of reproductive energy to animals, plants and man himself, its cessation being suggested by such phenomena as old age and the fall of the year. To concentrate, induce and renovate are, however, but aspects of one process of acquisition by the transfusion of a transmissible energy. 

(5) Demission. Hubert and Mauss show in their penetrating analysis of sacrifice that after the rite has been brought to its culminating point there follows as a pendant a ceremony of re-entry into ordinary life, the idea of which is preserved in the Christian formula Ite, missa est. 

(6) Insulation. Such deposition of sacredness is but an aspect of the wider method that causes a ring-fence to be erected round the sacred to ward off casual trespassers at once in their own interest and to prevent contamination. We see here a natural outcome of religious awe supported by the spirit of esotericism, and by a sense of the need for an expert handling of that which is so potent for good or ill. 

(7) Direction. This last consideration brings to notice the stimulating force of sacred lore; and the expert director of rites, who is likewise usually at this stage the leader of society, comes more and more to be needed as an intermediary between the lay portion of the community and the sacred powers.

B. Results.—Hitherto our account of primitive religion has had to move on somewhat abstract lines. His religion is, however, anything but an abstraction to the savage, and stands rather for the whole of his concrete life so far as it is penetrated by a spirit of earnest endeavour. The end and result of primitive religion is, in a word, the consecration of life, the stimulation of that life which is to be lived and to do this. This bracing of the vital feeling takes place by means of imaginative appeal to the great forces man perceives stirring within him and about him, such appeal proving effective doubtless by reason of the psychological law that to conceive strongly is
to imitate. Meanwhile, that there shall be no clashing of conceptions to inhibit the tendency of the idea of an acquired "grace" to realize itself in action, is secured by the complete unanimity of public opinion, dominated as it is by an inveterate custom. To appreciate the consecrating effect of religion on primitive life we have only to look at the churging-worship of the Central Australians (as described by Spencer and Gillen in *The Native Tribes of Central Australia and The Northern Tribes of Central Australia*). Contact with these repositories of mystic influence "makes them glad" (*Nat. Tr. 169*); it likewise makes them "good," so that they are no longer greedy or selfish (*North. Tr. 260*); it endows them with second sight (ibid.); it gives them confidence and success in war (*Nat. Tr. 130*); in fact, there is no end to its "strengthening" effects (ibid. n.). Or, again, we may note the earnestness and solemnity that characterize all their sacred ceremonies. The inwardness of primitive religion is, however, non-existent for those who observe it as uninitiated strangers; whilst, again, it evaporates as soon as native custom breaks down under pressure of civilization—when only remnants of meaningless superstition survive, wherefore do travesties of primitive religion abound.

It remains to consider shortly the consecration of life in relation to particular categories and departments. (1) Education. Almost every tribe has its initiation ceremonies, and in many tribes adult life may almost be described as a continuous initiation. The object of these rites is primarily to impart mystic virtue to the novice, such virtue, in the eyes of the primitive man, being always something more than social usefulness, amounting as it does to a share in the tribal luck by means of association with all it holds sacred. Incidentally the candidate is trained to perform his duties as a tribesman, but religion presides over the course, demanding earnest endeavour of an impressionable age. (2) Government. Where society is most primitive it is most democratic, as in Australia, and magico-religious powers are possessed by the whole body of fully initiated males, age, however, conferring increase of sacred lore and consequently of authority; whilst even at this stage the experts tend to form an inner circle of rulers. The man with *mana* is bound to come to the top, both because his gifts give him a start and because his success is taken as a sign that he has the gift. A decisive "moment" in the evolution of chieftship is the recognition of hereditary *mana*, bound up as this is with the handing on of ceremonies and cult-objects. Invested, as society grows more complex, with a sanctity increasingly superior to that of the layman, the priest-king becomes the representative of the community as repository of its luck, whilst, as controller of all sacred forces that bear therein, he is, as Dr Frazer puts it, "dynamical centre of the universe" (*The Golden Bough* (2nd ed.), i. 233). Only then the holy man's duty to preserve his holiness binds him hand and foot in a network of taboos does his temporal power tend to devolve on a deputy. (3) Food-supply. In accordance with the principle of Renovation (see above), the root-idea of the application of religion to economics is not the extorting of boons from an unwilling nature, but rather the stimulation of the sources of life, so that all beings alike may increase and multiply. (4) Food-taking. Meanwhile, the primitive meal is always more or less of a sacrament, and there are many food-taubs, the significance of which is, however, not so much that certain foods are unclean and poisonous as that they are of special virtue and must be partaken of solemnly and with circumspection. (5) Kinship. It is hard to say whether the unit of primitive society is the tribe or the group of kinsmen. Both are forms of union that are consolidated by means of religious usages. In the tribal group, the members are regarded as partly are with marriage, always an affair between the kin-groups, are tribal, whilst the totemic rites are the prime concern of the members of the totem clans. The significance of a common name and a common blood is immensely enhanced by its association with mystic rights and duties, and the pulse of brotherhood beats faster. (6) The Family. Side by side with the kin there is always found the domestic group, but the latter institution develops fully only as the former weakens, so that the one comes largely to inherit the functions of the other, whilst the tribe too in its turn hands over certain interests. Thus in process of time birth-rites, marriage-rites, funeral-rites, not to mention subordinate ceremonies such as those of name-giving and food-taking, become domestic sacraments. (7) Sex. Woman, for certain physiological reasons, is always for primitive peoples hedged round with sanctity, whilst man does all he can to inspire awe of his powers in woman by keeping religion largely in his own hands. The result, so far as woman is concerned, is that, in company with those males who are endowed with sacredness in a more than ordinary degree, she tends as a sex to lose in freedom as much as she gains in respect. (8) Personality. Every one has his modicum of innate *mana*, or at least may develop it in himself by communicating with powers that can be brought into answer relation by the proper means. Nagualism, or the acquisition of a mystic guardian, is a widely distributed custom, the essence of which probably consists in the procuring of a personal name having potency. The exceptional man is recognized as having *mana* in a special degree, and a belief thus held at once by others and by himself is bound to stimulate his individuality. The primitive community is not so custom-bound that personality has no chance to make itself felt, and the leader of men possessed of an inner fund of inspiration is the wonder-worker who encourages all forms of social advance.

**Psychology of the Primitive Attitude towards the Sacred.**—We are on firmer ground when simply describing the phenomena of primitive religion than when seeking to account for these in terms of natural law—in whatever sense the conception of natural law be applicable to the facts of the mental life of man. One thing is certain, namely, that savages stand on virtually one footing with the civilized as regards the type of explanation appropriate to their beliefs and practices. We have no right to refer to "instincts" in the case of primitive man, any more at any rate than we have in our own case. A child of civilized parents brought up from the first amongst savages is a savage, neither more nor less. Though race may count for something in the matter of mental endowment—and at least it would seem to involve differences in weight of brain—it clearly counts for much less than does milieu, to wit, that social environment of ideas and institutions which depends so largely for its effectiveness on mechanical means of tradition, such as the art of writing. The outstanding feature of the mental life of savages known to psychologists as "primitive credulity" is doubtless chiefly due to sheer want of diversity of suggestiveness in their intellectual surroundings. Their notions stick fast because there are no competing notions to dislodge them. Society suffers a sort of perpetual obsession, and remains self-hypnotized as it were within a magic circle of traditional views. A rigid orthodoxy is sustained by means of purblind imitation assisted by little persecution. Such changes as occur come about, not in consequence of a new direction taken by conscious policy, but rather in the way that fashions in dress alter amongst ourselves, by subconscious, hardly purposive drifting. The crowd rather than the individual is the thinking unit. A proof is the mysterious rapid extinction of savages the moment that their group-life is broken up; they are individually so many lost sheep, without self-reliance or initiative, And the thinking power of a crowd—that is, a mob, not a deliberative assembly—is of a very low order, emotion of a "panicky" type driving it hither and thither like a rudderless ship. However, as the students of mob-psychology have shown, every crowd tends to think and feel similarly. As a rule, its mob-leader, the "man of honor" or "man of the people" as it were, is the same as the mob-leader of the mob, and then, with the primitive society. Grossly ignorant of all that falls outside the "daily round", the "common task," they are full of panicky fears in regard to this unknown, and the primary attitude of society towards it is sheer avoidance, taboo. But the mysterious has another face. To the mob the mob-leader is mysterious in his power of bringing luck and salvation; to himself also he is a wonder, since he wills, and lo! things happen accordingly. He has
mana, power, and by means of this mana, man felt inwardly by himself, acknowledged by his fellows, he stems the social impulse to run away from a mystery. Not without nervous dread—witness the special taboo to which the leader of society is subject—and he draws near and strives to constrain, conciliate or coax the awful forces with which the life of the group is set about. He enters the Holy of Holies; the rest remain without, and are more than half afraid of their mediator. In short, from the standpoint of lay society, the manipulator of the sacred is himself sacred, and shares in all the associations of sacredness. An anthropomorphism which is specifically a "mago-morphism" renders the sacred powers increasingly one with the governing element in society, and religion assumes an ethnico-political character, whilst correspondingly authority and law are invested with a deeper meaning.

The Abuse of the Sacred.—Let us picture our primitive religion appear too brightly coloured, a word must be said on the perversions to which the exploitation of the sacred is liable, Envy, malice and uncharitableness are found in primitive society, as elsewhere, and in their behalf the mystic forces are not unfrequently unloosed by those who know how to do so. To use the sacred to the detriment of the community, as does, for instance, the expert who casts a spell, or utters a prayer, to his neighbour’s hurt, is what primitive society understands by magic (cf. arungquillaha, above), and anthropology has no hesitation in calling it idolatry, nor makes hesitation to interpret the primitive point of view. On the other hand, if those in authority perpetrate in the name of what their society holds sacred, and therefore with its full approval, acts that to the modern mind are cruel, silly or revolting, it is bad science and bad ethics to speak of vice and degradation, unless it can be shown that the community in which these things occur is thereby brought nearer to elimination in the struggle for existence. As a matter of fact, the earlier and more democratic types of primitive society, uncompounded by our civilization, do not present many features to which the common conscience can take exception, but display rather the edifying spectacle of religious brotherhoods encouraging themselves by mystical communion to common effort. With the evolution of rank, however, and the concentration of magico-religious power in the hands of certain orders, there is less solidarity and more individualism, or at all events more opportunity for sectional interests to be pursued at other than critical times; whereupon fraud and violence are apt to infect religion. Indeed, as the history of the higher religions shows, religion tends in the end to break away from secular government with its aristocratic traditions, and to revert to the more democratic spirit underlying primitive religion; and the consciousness of its importance, yet nevertheless clinging to the inerterate forms of human ritual as still adequate to symbolize the consecration of life—the quickening of the will to face life earnestly.

BIBLIOGRAPHY.—The number of works dealing with primitive religion is endless. The English reader who is more or less new to the subject is recommended to begin with E. B. Tylor, Primitive Culture (4th ed., London, 1900), and then to proceed to J. G. Frazer, The Golden Bough (2nd ed., London, 1900). The latter author’s Lectures on the Early History of the Kingship (London, 1903) may also be consulted. Only second in importance to the above are W. K. S. Jones, The Cyprus and the Semites (2nd ed., London, 1903); A. Lang, Myth, Ritual and Religion (2nd ed., London, 1899), and Magic and Religion (London, 1902); E. S. Hartland, The Legend of Perseus (Lond. 1884-1896); F. E. Devons, An Introduction to the History of Religion (2nd ed., 1902); E. Crawley, The Mystic Rose (London, 1902), and The Tree of Life (London, 1905). The two last-mentioned works perhaps most nearly represent the views taken in the present volume, as developed within the framework of Ananimistic Religion, "Folk-Lore" xi. (1900), "From Spell to Prayer, Folk-Lore, xv. (1904), and "Is Taboo a Negative Magic?" Anthropological Essays presented to E. B. Tylor (1907); L. R. Farnell, The Essential Legend (1908). The present work owes something to Goëetz d’Alviella, Histoire Lectures (1891), and more to H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice," L’Annee sociologique, i; and "Esquisse d’une théorie générale de la magie," ibid. vii. If the reader wishes to keep pace with the output of literature on this vast subject, he will find L’Annee sociologique (1896 onwards) a wonderfully complete bibliographical guide.

Side by side with works of general theory, first-hand authorities should be freely used. To make a selection from these is not easy, but the following at least are very important: R. H. Codrington, The Melanesians (Oxford, 1891); W. B. Spencer and E. J. Gillen, The Native Tribes of Central Australia (Lond., 1899); The Northern Tribes of Central Australia (Lond. 1904); A. W. Howitt, The Native Tribes of South-Eastern Australia (Lond. 1934); A. C. Haddon, Reports of the Cambridge Anthropological Expedition to Torres Straits (Lond., 1904, vols.); A. B. Ellis, The Yellow Beaks and the Peoples of the Gold Coast (Lond. 1897); The Ewe-speaking Peoples of the Slave Coast (Lond. 1890); The Yoruba-speaking Peoples of the Slave Coast (Lond. 1894); Miss M. H. Kingsley, Travels in West Africa (Lond., 1896); W. H. R. Rivers, The Toadas, 1896). An immense amount of valuable evidence is to be obtained in the Reports of the Bureau of Ethnology, Smithsonian Institution, Washington. See Nos. 2, 5, 6, 7, 8, 9, 11, 13, 14, 15, 16, 18, 19, 21, 22, 23, and specially J. O. Dorsey, A Study of Siouan Cults, in No. 11; A. C. Hollis, The Masai (1905); W. Crooke, The North-West Provinces of India (Lond. 1897); W. H. R. Rivers, The Todas (1906). An immense amount of valuable evidence is to be obtained in the Reports of the Bureau of Ethnology, Smithsonian Institution, Washington.

B. THE HIGHER RELIGIONS

Various phenomena associated with the religions of the lower culture will be found discussed in the articles on Animism; Fetishism; Magic; Mythology; Prayer; Ritual; Sacrifice; and Theosophy. In the following article relative to the higher religions from the point of view of morphology, and no attempt can be made in the allotted limits to connect them with the phases of ritual, sociological or ethical development. See the separate articles on each religious system, and the separate headings for different forms of ritual.

1. Developments of Animism.—Animism is not, indeed, itself a religion; it is rather a primitive kind of philosophy which provides the intellectual form for the interpretation alike of Man and of Nature. It implies that the first great step has been taken: to see in the objects of the world the force—whether the conscious body, or the rocks, trees and animals—and the powers that act in or through them. The Zuñi of New Mexico, U.S.A., supposed “the sun, moon and stars, the sky, earth and sea, in all their phenomena and elements, and all inanimate objects as well as plants, animals and men, to belong to one great system of all-conscious and interrelated life, in which the degrees of relationship seem to be determined largely, if not wholly, by the degrees of resemblance.” If the earliest conception is that of an obscure undifferentiated animation (panzélatism), the analysis of the human person into his physical and spiritual “souls” (e.g. the totem or “invisible rulers” of every object among the Eskimo) constitutes an important development. Matter is no longer animated or self-acting; it is subject to the will of an agent which can enter or quit it, perhaps at its own pleasure, perhaps at the compulsion of another. The transition has usually been effected ages before the higher religions come into view; but it has left innumerable traces in language and custom. Thus the Vedic hymns, which exhibit the deposits of so many stages of thought, are founded ultimately on the conceptation of the animate and the inanimate objects—the visible world are themselves mighty to hurt or help. The springs and rivers, the wind, the sun, fire, the Earth-Mother, the Sky-Father, are all active powers. The animals, domesticated or wild, like the horse or cow, the guardian dog, the bird of omen, naturally share the same life, and are approached with the same invocation. The sacred energy is also discerned in the ritual implements, in the stones for squeezing the soma-juice, and the sacrificial post to which animals were bound; nay, it was even recognized in fabricated products like the plough (the “tearer” or “divider”), the

war-car, the drum, quiver, bow and axe. The Earth-Mother and Sky-Father are to be found again and again in religions, at various stages of development, as co-ordinating conceptions which comprehend the universe. Sometimes one is more prominent, sometimes the other. In many cases the Sky has been already resolved into the visible firmament and its lord and owner, like the Yoruban Oluron or the Finnish Ukko. The consort of Ukko is *Maana-emaa*, "mother of the earth," or *Maana emantat*, "mistress of the earth." But the rare expression *maana-emaa*, "Mother-earth," still used in the ancient lays, points to the older type of belief in the animation of the productive soil. So the Peruvians designated the Earth as Pacha-mama, "mother of (all) that the relations were curiously reversed; the earth-god Keb was the husband of Nut, the sky, represented sometimes as a woman, overarching the earth and supported on hands and feet, sometimes as a gigantic cow, upheld on the outstretched hands of Shu, the atmosphere. When earth and sky were still unseparated, Shu thrust himself between them and raised Nut to the heights. So in the New Zealand myth, Rangi and Papa, Sky and Earth, who once clave together in the darkness, were rent asunder by the forest-god Tane-mahuta, who forced up the sky far above him. The most elaborate presentation of this mode of thought is to be seen in the organized animism of the ancient state religion of China, where the supreme power is lodged in the living sky (Tien). Tien was originally the actual firmament. In the *Shi-King* it is addressed in prayer as "great and wide," as "vast and distant"; it is even "blue" (Pt. II. v. 6, 5). So it is the ancestor of all things; and Heaven and Earth are the father and mother of the world. From the imperial point of view the sky bore the name of Ti, "ruler," or Shang Ti, "supreme ruler" (emperor); and later commentators readily took advantage of this to discriminate between the visible expanse and the indwelling spirit, production was kind of "verum." But the older conception still holds its own.

"Why" (says Edkins, *Religion in China*, 95), "they have often asked, should you speak of those things which are dead matter, fashioned from nothing by the hand of God, as living beings? Why not? they have replied. The Sky pours down rain and sunshine; the Earth produces corn and grass. We see them in perpetual movement, and we therefore say that they are living." *Tien Ti, Fu Mu*, "Heaven and Earth, Father and Mother," are conjoined in common speech, and are the supreme objects of imperial worship. The great altar to Heaven, round in shape like the circuit of the sky, and white as the symbol of the light principle (Yang), stands in the southern suburb of Peking in the direction of light and heat. The altar to the Earth is dark and square, on the north side of the city, the region of *yin*, the principle of cold and gloom. Associated with the Sky are tablets to the sun and moon, the seven stars of the Great Bear, the five planets, the twenty-eight constellations, and all the stars of heaven; tablets to clouds, rain, wind and thunder being placed next to that of the moon. With the Earth are grouped the tablets to the five lofty Mountains, the three Hills of perpetual peace and the four buds. The five celebrated Mountains and the four great Rivers are the ancient ritual (*Chou Li*) carefully graded the right of sacrifice from the viceroys of provinces down to the humblest district-superintendent who offered to the spirits of his district, the hills, lakes and grains. With these spirits ranged in feudal order in two vast groups beneath Heaven and Earth is associated a third class, those of human beings. They are designated by the same name, *shin*; and they are inextricably mingled with the operations of nature. So in the Vedic hymns the departed "Fathers" inhabit the three zones of earth, air and sky; they are invoked with the streams and mountains of this lower earth, as well as with the Dawns and the sky itself; even cosmic functions are ascribed to them; and they adorn the heaven with stars. The Chinese conception of the *Shin* under the name of *Shin-to* (Chinese *too*) or "spirits'-way" profoundly influenced Japanese thought from the 6th century A.D. onwards; and the great Shinto revival of the 18th century brought the doctrine again into prominence. The Japanese Kami are the "higher" powers, the *supeeri*, conceived as acting through nature on the one hand and government on the other. Just as the emperor is *kami*, and provincial officers of rank, so also mountains, rivers, the sea, thunder, winds, and even animals like the tiger, wolf or fox, are all *kami*. The spirits of the dead also become *kami*, of varying character and position; some reside in the temples built in their honour; some hover near their tombs; but they are constantly active, mingling in the vast multitude of agencies which makes every event in the universe, in the language of Motowori (1730-1801), the act of the Kami. They direct the changing seasons, the wind and the rain; and the good and bad fortunes of individuals, for all the diversity of phenomena. Everywhere, in the final resort to death the entire life of man is encompassed and guided by the Kami, which are sometimes reckoned at 8,000,000 in number.

2. Transition to Polytheism.—In such ways does the Polytheism of early faith survive in the modern practice of religion. The process of enrolling the spirits of the dead in the ranks of what may be more or less definitely called "gods" may be seen in the popular usages of India at the present day, or traced in the pages of the *Peking Gazette* under the direction of the Board of Rites, one of the most ancient branches of the government. In all the agricultural—"the struggle with fores and swarm, the clearings for settlement, the protection of the dwelling-place, the safety of flocks and herds, the production of corn,—the migration of peoples, the founding of colonies, the processes of conquest, fusion, and political union—have all reacted on the elaboration of the higher polytheisms, before bards and poets, priesthoods and theological speculations, began to systematize and regulate the relations of the gods. Certain phases of thought may be more or less clearly indicated; certain elements of race, of local condition, of foreign contact, may be distinguished with more or less historic probability; but no single race, in all the diversity of phenomena. Broadly speaking it may be said that a distinction may be drawn between "spirits" and "gods," but it is a distinction of degree rather than of kind, obvious enough at the upper end, yet shading off into manifold varieties of resemblance in the lower forms. Some writers only recognize friendly agencies as gods; but destructive powers like the volcano, or the lords of the underworld, cannot be regarded as the protectors of the life of man, yet they seem in many mythologies to attain the full personalised stature of gods with definite names. Early Greek religion recognized a class of gods of Aversion and Riddance, *apotropaios* and *apotelesmatos*. Neither the spirit nor the god, conceived as

1 The Japanese name is *Ame-tsuchi*, "heaven and earth," a translation of the Chinese *tenchi*, *Aston*, *Shinto* (1903), p. 35.

2 Edkins, *Finnische Mythologie*, p. 86.

3 Ermann, *Handbook of Egyptian Religion* (1907), pp. 8, 12.

5 The English "Heaven" has acquired a quasi-scientific meaning, and is usually employed as its equivalent, but, like the Jewish use (e.g. Luke xv. 18), tends to carry too definite religious associations with it.

7 So the epithet *'el* might be applied in Hebrew to men of might, to lofty cedars, or mountains of unusual height, as well as to the Supreme Being.

immaterial. They can take food, though the crudest form of this belief soon passes into the more refined notion that they consume the impalpable essence of the meals provided for them. The ancient Indian ritual for the sacrifice to the Fathers required the officiating priest to turn away with bated breath that he might not see the spirits engaged upon the rice-balls laid out for them. The elastic impalpable substance of the spirit-body is apparently capable of compression or expansion, just as Athena can transform herself into a bird. The spirits can pass swiftly through the air or water; they can enter the stone or the tree, the animal or the man. The spirit-land of the Ibo on the Lower Niger had its rivers, forests or hills, its towns and roads, as upon earth: the spirits of the Mordvinian mythology, created by Chkal, not only resembled men, they even possessed the faculty of reproduction by multiplication. The Finns ascribed a halituk or genius to each object, which could, however, guard other individuals of the same species. This is the beginning of the species-ghost, and implies a step of thought comparable to the production in language of general terms. These protecting spirits were free beings, having form and shape, but not individualized; while above them rose the higher deities like the forest-god Tapio and his maiden Hillervo, protectress of herds, or Ahto the water-god who gradually took the place of Vesi, the actual element originally conceived as itself divine, and ruled over the spirits of lakes and rivers, wells and springs. The Finns came to apply to the upper gods the term Yumala which originally denoted the living sky; the Samoyedes made the same use of Num, and the Mongols of Tengri. Above these innumerable wongs of the Gold Coast rose Nyongmo, the Sky-god, giver of the sunshine and the rain. The Yoruba-speaking peoples generalized the spirits of mountain and hill into Oke, god of heights; and the multitude of local sea-gods on the western half of the slave coast was fused into one god of the Ocean, Olokun. The Babylonian theology recognized a Zi or "spirit" in both men and gods, somewhat resembling the Egyptian "double" or ka; spirits are classed as spirits of heaven and spirits of earth; but the original identity of gods and spirits may be inferred from the fact that the same sign stands before the names of both. Out of the vast mass of undifferentiated powers certain functional deities appear; and the Kami of Japan-to-day who preside over the gilds and crafts of industry and agriculture, over the trees and grasses of the field, the operations of the household, and even the kitchen-range, the saucepan, the rice-pot, the well, the garden, the scarecrow and the privy, have their counterparts in the lists of ancient Rome, the indiglantia over whose contents Tertullian and Augustine made merry. The child was reared under the superintendence of Educa and Politia. Aedona and Adeona taught him to go out and in. Cuba guarded him when he was old enough to exchange a cradle for a bed. Osiyapa strengthened his bones; Leshia helped him to get up, and Salatina to stand. There were powers protecting the threshold, the door and the hinge: and the deities of household, of the farm, the mill, had each its appointed guardian. But such powers were hardly persons. The settler who went into the woods might know neither the name nor the sex of the indwellings numen: "si deus si dea," "sive mas sive femina," ran the old formulae. So the Baals of the Semitic peoples constituted a group of powers fertilizing the land with water-springs, the givers of corn and wine and oil, out of which under conditions of superior political development a high-god like the Tyrian Baal, the majestic City-King, might be evolved. The Celts who saw the world peopled with the spirits of trees and animals, rocks, mountains, springs and rivers, grouped them in classes like the Dervonnea (oak-spirits), the Niskal (water-spirits), the Prozima, the Matronae (earth-goddesses) and the like. Below the small band of Teutonic divinities were the elves of forest and field, the water-elues or nixes and spirits of house and home. The Vedic deities of the nobler sort, the shining devas, the asuras (the "breathers" or living, perhaps to be identified with the Scandinavian asir) rose above a vast multitude of demonic powers, many of them doubtless derived from the local customs and beliefs of the native races whom the immigrant Aryans subdued. In the earliest literary record of Greek religion Homer distinguishes between the Ídes and the dégous, the personalized god and the numen or divine power. In Homer the element of time is definitely recognized. The gods are the "Immortals." They are born, and their parentage is known, but they do not die. Zeus is not self-existent in the sense in which the Indian Brahmac is svayambhu, but certain questions have been by implication asked and answered, which the demonology of the savage has not yet raised. But behind Homer stretches the dim scene of pre-Hellenic religion, and the conflict of elements "Pelagic," oriental and Hellenic, out of which the Homeric religion emerged; and beneath the Homeric religion how many features of the religious of ghosts and nature-spirits survived in popular usage and the lower cults. When Herodotus (ii. 52) tried to trace the origin of the beliefs around him, he found his way back to an age before Hesiod or Homer, when the gods were nameless. To that age the traditions preserved at Dodona bore witness; and the designations of special groups like the thei mýgista, thei melíxos, thei πραξίδικα, or, possibly, the Venerable Goddesses (thei semen) of Athens, point to a mode of thought when the divine Powers were not definitely individualized. They are just at the point of transition from the ranks of spirits to the higher classes of the gods. As they had no names, they had no relations. Nor had any images yet been made of them. They were associated with hallowed trees and sacred stones and pillars, out of which came the square rough-hewn Hermacas which were anointed with oil like the sacred stone attributed by legend to Jacob at Bethel. By what processes the Hellenic immigration introduced new deities and the Greek pantheon was slowly formed, can only be conjecturally traced with the help of archaeology. But Herodotus and Aeschylus were well aware that the religion of Greece had not been uniformly the same; and the gods whom they knew had been developed out of intercourse with other peoples and the succession of races in the obscure and distant past.

3. Polytheism.—The lower and unprogressive religions practically remain in the polydaemonistic stage, though not without occasionally feeling the stimulus of contact with higher faiths, like some of the West African peoples in the presence of the Mahomedan advance. Among the more progressive races, on the other hand, continual processes of elevation and decline may be observed, and the activities of the greater gods are constantly being enriched with new functions. Personal or social experiences of the satisfaction of some desire or escape from some danger are referred to some particular deity. Elements of race-consciousness help to shape the outlook on nature or human life. Slight differences in the linguis language sometimes lead to the multiplication of diverse forms. Exacter observation of nature; closer attention to its contrasts of life and death, or light and darkness, or male and female, of the seasons, of the movements of the stars, of the lines of the landscape, of the types of human beings, and the rise of contrasts of the human nature itself in a more individual human life; the rise of the more specific descriptive terms sometimes lead to the multiplication of diverse forms. 6. Jastrow, Religion of Babylon and Assyria (1898), p. 181. The Zufis applied the term σάκες "All-Life" or "the Beings" to all supernatural beings, men, animals, plants, and many objects in nature regarded as having personal existences, as well as to the highest anthropomorphic powers known as "Finishers or Makers of the Paths of Life," Report of Bureau of Ethnol., (1883). p. 11. On the distinction between "bodily" and "spiritual," "Ed. Meyer, Gesch. des Alterthums, 2nd ed. Band i. erste Haeltte (1907), p. 57 ff.
female; the distinction between its permanent objects, and its occasional or recurring operations, the recognition of the behind sudden manifestations of its power, like the thunderstorm, are steady forces and continuous cosmic agencies at work—lead to the gradual rise of the higher deities. And from the social side the development of law, the influence of city life, the formation of priesthoods, the connexion of particular deities with the fortunes of dynasties or the vicissitudes of nations, the processes of migration, of conquest and political fusion, the deportations of vanquished peoples, even the sale of slaves to distant lands and the growth of trade and travel, all contribute to the processes which expand and modify different pantheons, and determine the importance of particular deities. In the midst of the bewildering variety, where all types co-exist together and act and react on each other, it is impossible to do more than point out some obvious groups receiving their special forms chiefly from the side (1) of nature, (2) of human life, and (3) from moral or theological speculation. Divine persons, objects or powers, connected with ritual, are not here considered, such as the Brahman priests who claimed to be manuskyayadéth (human-gods), or the sacred soma-juice which grew by strange analogies into a mysterious element, linking together heaven and earth.

On the side of Nature the lowest rank (1) seems to belong to what Usener has designated "monumentary" or "occasional" gods. They embody for the time being a vague consciousness of the divine, which is concentrated for some single act into an outward object, like a warrior's spear or the thunderbolt, or the last sheaf of corn into which the Corn-Mother has been driven. Above these, to use again Usener's nomenclature, are the "special" or "functional" gods, "departmental gods," as Mr Lang has called them. Such were some of the deities of the Indigímenta already compared with the Japanese Kami. Among them, for example, were twelve deities of ploughing and harvest operations, who were invoked with Tellus and Ceres. Another class may be seen in the species-deities previously named; the Samoan gods which could become incarnate as a heron or an owl, did not die with particular birds. A dead owl was not a dead god; he yet lived in all other owls.

(4) The worship of trees, plants and animals is a particular phase of the wider series of nature-cults, only named here because of its frequency and its obvious survivals in some of the higher polytheisms, where, as in Egypt, the Apis bulls were worshipped; or where, as in Mesopotamia, the great gods are partly symbolized by animal forms; or where, as in Israel, Yahweh might be represented as a bull; or where, as in Greece, such epithets as Dyonisos and Endéndros preserved traces of the association of Dionysus and Zeus with vegetation; while sacred animals like the serpents of Aesculapius were preserved in the temples.

(5) The higher elemental gods sometimes, like the sun, as the Indian Surya, the Egyptian Ré, the Babylonian Shamash (Samas), the Greek Helios, retain their distinct connexion with the visible object. It was naturally more easy for a relatively spiritual worship to gather round a god whose name did not immediately suggest a familiar body. No one ever thought of confessing sin, for instance, to a river. But the daily survey of the sun (occasionally also the function of the moon as measurer of time) with his importance for life, secured him a high moral rank; and Ré, united with the Théban Ammon, became (under the New Empire) the leading god of Egypt for a thousand years, "He who hath made all, the sole One with many hands." Other deities, like Zeus, rise to the head of a monarchical polytheism, in which their physical base is almost if not quite, forgotten in cosmic and moral grandeur. The gods are often arranged in groups, three, seven and twelve being frequent numbers. Egyptian summaries recognized gods in the sky, on earth and in the water; gods of the north and south, the east and west, gods of the field and the cities. Indian theologians classified them in three zones, earth, air and sky. Babylonian speculation embraced the world in a triad of divine powers, Anu the god of heaven, Bel of earth and Ea of the deep; and these became the symbols of the order of nature, the divine embodiments of physical law. Sometimes the number three is essential to the distribution of the universe into sky, earth and underworld, and the gods of death claim their place as the rulers of the world to come. Among these deities all kinds of analogies such as Samas, or the sun, is called in the Samoan language (Leiden, 1903).

said Motowori (18th century), “the Mikado is the child of the Sun-goddess.” (3) The dead hero (historical or mythic) signalizes his power by gracious saving acts; and Heracles, Asclepius, Amphairos, and others pass into the ranks of the gods, which are thus continually recruited from below.

III. A third great group rises out of the sentiments and affections of man, or the moral energies which he sees working in human life. (1) The Vedic Cradha, “faith,” the Greek Metemdetela, “repentance,” the Latin Spes, and a hand of other figures, represent the dispositions of the heart; Nemesis and Niké and Concordia and their kin belong to a somewhat different sphere, the divine powers avenging, conquering, harmonizing the counterparts of the “departmental” gods in the field of moral agencies. (2) Over these theological speculation erects a few lofty and impressive forms; sometimes below the highest, like Vohu Mano, “the Good Mind” of Ahura Mazda; or the Bodhisattva Avalokiteśvara, who vowed not to enter into final peace till every creature had received the saving truth; sometimes supreme, like Brahmā or Prabār ($l$ lord of creatures”) in the early Brahmanic theology; or Ādī Buddha, or the Zervan Akaran, a boundless time, of a kind of Persian genius. Let us call the goddess of grace whose worship appears among other syncretic cults of the Roman empire.

4. **The Order of Nature.—Polytheism is here on the way to monotheism, and this tendency receives significant support from the recognition of an order in nature which is the ground and framework of social ethics. Not only does a sky-god like Varuna, or a sun-god like the Babylonian Shamash, survey all human things, and take cognizance of the evil-doer, but the daily course of the world is itself the expression of an intellectual and moral power.** In the Chinese combination of Heaven and Earth as the parents and nourishers of all things, the energy and action lie with Heaven being docile and receptive. Then it is intelligible and all-observing, and its “sincerity” or steadfastness, displayed in the courses of the sun and moon and the succession of the seasons, becomes the basis of right human conduct, personal and social. The “way” of Heaven, the “course” of Heaven, the “lessons” of Heaven, the law or “decrees” (ming) of Heaven, are constantly cited as the pattern for the emperor and his subjects. This conception is even reflected in human nature: “Heaven in giving birth to the multitude of the people, to every faculty and relationship affixed its laws” (Shi King, III. iii. 6; cf. IV. iii. 2, tr. Legge), and the “Grand Unity” forms the source of all moral order (Li Ki, in Sacred Books of the East, xxviii. p. 387). Indian thought presented this Order in a semi-personal form. The great elemental gods imposed their laws (dhāman, dharman, trata) on the visible objects of nature, the flow of rivers, the march of the heavenly bodies across the sky. But the idea of Law was generalized in the figure of Rita (what is “fitted” or “fixed”; or the “course” or “path” which is traversed), whose Zend equivalent asha shows that the conception had been reached before the separation of the Eastern Aryans produced the migrations into India and Iran. In the Rig Veda the gods (even those of storms) are again and again described as “horned from the Rita,” or born in it, according to it, or of it. Even Heaven and Earth rejoice in the womb or lap of the Rita. In virtue of the mystic identity between the cosmic phenomena and sacrifice, Rita may be also viewed as the principle of the cultus; and from that sphere it passes into conduct and acquires the meaning of morality and is equated with what is “true.” The fundamental idea remains the same in the Zend Asha, its philological counterpart, but it is applied with a difference. Its form is more personal, for A sha is one of the six Holy Immortals round the throne of Ahura Mazda (Aramazda). In the primitive conflict between the powers of good and evil, the Bounteous Spirit chose A sha, the Righteous Order which knit the world together and maintained the stars. The immediacy of the relation between Ahura and A sha is implied in the statements that Ahura created A sha and that he dwells in the paths which proceed from A sha; and when he created the inspired word of Reason, A sha consented with him in his deed. In its ritual form A sha becomes the principle of sacrifice, and hence of holiness, first ritual and then moral. Like Rita, it rises into an object of worship, and in its most exalted aspect (A sha vaikīta, the “best” A sha, most excellent righteousness) it is identified with Ahura himself, being fourth among his sacred names (Ormuzd Yasht, § 7; S.B.E. xxii. p. 15). Egyptian speculation, in like manner, impersonated the concrete and intellectual aspects of physical and moral order as two sides of a fundamental unity in the goddess Māa. Derived from the verb mā “to stretch out,” her name denoted the ideas of right and rule, and covered the notions of order, law, justice and truth, which remained steadfast and unalterable. Mythologically she was the daughter (or the eye) of the sun-god Rē; but she became Lady of Heaven and Queen of Earth, and even Lady of the land of the West, the mysterious habitation of the dead. Each of the great gods was said to be lord or master of Māa; but from another point of view she knew no lord or master, and the peculiar quality which was expressed in the phrase by Māa “living by Māa,” which was applied to the gods of the physical world, the sun and moon, the days and hours, as well as to the divine king. She was solemnly offered by the sovereign to his god; and the deity replied by laying her within the heart of his worshipper “to manifest her eternally before the gods.” So in the famous scene of the weighing of the soul, which first appears pictorially under the New Empire, she introduces the deceased before the forty-two assessors of the heavenly judge, Osiris, and presides over the scale in which his actions and life are weighed. From the zenith to the realm of the departed she is the “queen of all gods and goddesses.”

The Hellenic polytheism of Homer and Hesiod is already at work upon similar ideas, and a whole group of mythic personifications slowly rises into view representing different phases of the same fundamental conception.Themis (root θεί Sanskr. dha, as in dhāman) appears in Homer as the embodiment of what is fit or right; she convenes or dismisses assemblies, she even keeps order at the banquet of the gods. Next, Hesiod supplies a significant biography. She is the daughter of Ouranos and Gaia; and after Metis she becomes the bride of Zeus; Findar describes her as born in a golden car from the primeval Oceanus, source of all things, to the sacred height of Olympus to be the consort of Zeus the saviour; and she bears the same august epithet, as the symbol of social justice and the refuge for the oppressed. Law was thus the spouse of the sovereign of the sky, but Aeschylus identified her with the Earth (worshipped at Athens as Gē-Themis), not only the kindly Mother, but the goddess who bound herself by fixed rules or laws of nature and life. For the cultus of the earth as the source of fertility was associated with the maintenance of the family, with the operations of agriculture and the social order of marriage. So Themis became the mother of the seasons, the regular sequence of blossom and fruit was her work; and Good Order, Justice and Peace were her offspring. By such conceptions the Hellenic polytheism was moralized; the physical character of the greater gods fell into the background, and the sculptor’s art came to the aid of the poet by completely ending them with personality.

1 Worshipped at Argos. Usener, Götternamen, p. 366.

6 Theog. 135, 901.

7 Or. viii. 29.

8 Farmel, however, supposed that Gē acquired the cult-appellative through her prophetic character (Cults of the Greek States, ii. p. 12). The union of Zeus and Themis is, then, a later equivalent of the marriage of Zeus and Earth (ibid., p. 14.).

5. Transition to Monothelm. — From the higher Polytheism an easy step leads to some form of Monothelm. The transition may be effected in various ways. Max Müller observed the Vedic poets addressing themselves to the several objects of their devotion, as if each occupied the field alone. Varuna or Indra was for the time being the only god within the worshipper’s view; and to this mode of thought he gave the name Heno-

thelism.4 It reappears elsewhere, as it is the natural attitude of prayer, and may be seen in the pious homage of the pilgrims to the Virgin of Loreto or Einsiedeln. Pfeiderer employed the word to denote a relative monothelism like that of the early religion of Israel, whose teachers demanded that the nation should worship but one god, Yahweh, but did not deny the existence of other gods for other peoples. Yet once again the term has been applied to characterize a whole group of religions, like the Indo-Germanic, which are ultimately founded on the unity of the divine nature in a plurality of divine persons. A designation of such doubtful meaning it seems better (with Chantepie de la Sausaye) to abandon. But the unifying process may advance along different lines. The deities of different local centres may be identified; many such combinations took place in Egypt, and Isis in late days served to her votaries as the unitary principle which appeared in one figure after another of whole pantheons. Again, the gods may be viewed as a collective totality, like the “All-gods” of the Vedic poets, or as at Olympia where there was a “common altar for all the gods” (cf. the frequent Roman dedication in later days; “Jovi optimo maximo caeterisque divs immortalibus”). Or the relation between the inferior deities and the most exalted may be conceived politically and explained by Tertullian’s formulæ, “Imperium penes unum, officia penes multos.” One particular god may be eminent enough, like Zeus, to rise above all others, and supply cultivated thought with a name for the supreme power; and this may be strengthened by the national motive as in the case of Israel. Or philosophic theology may penetrate to an abstract conception of deity, like the Babylonian ‘iluh, or the Vedic devata and asurtas; and some seer may have the courage and insight to formulate the principle that “the great asurtas of the deos is one” (R.V. iii. 55. 1).5 The One with many names was recognized alike in India and in Greece; “συνόν του του παντός,” says Aeschylus, almost in the words of the Vedic poet.6 Historians have usually recognized only three monothestic religions, Judaism, Christi-
nity and Islam. The Christian apologists of the 2nd century, however, found plenty of testimony to their doctrine of the unity of God in the writings of Greek poets and philoso-

phers; it was a commonplace in the revival under the Empire; and among the group of religions embraced under the name Buddhism more than one form must be ranked as mono-

thetic. The idealist philosophy of the Prajña Pāramitā in the system of the “Great Vehicle” declared that “every pheno-
momenon is the manifestation of mind” (Beal, Catena, p. 503). In the “Lotus of the Good Law” (S.B.E. xxi) the Buddha is the “Father of the World,” “Self-born” or Uncreate (like the eternal Brahma of the Hindu theology), the protector of all creatures, the Healer (Saviour) of the sickness of their sins. These types have reappeared in Japan. Nichiren taught a philosophical monism in the 13th century which is the basis of a vigorous sect at the present day; and the “True Sect of the Pure Land,”7 founded by his older contemporary Shinran, and now the most numerous, wealthy and powerful of the Buddhist denominations, demands the highest homage from all outward evidence. It is not a matter of sight, and permits worship to Amida alone, the sublime figure of “Boundless Light,” whose saving power is appro-

priated by faith. Here is a monothelism of a definite and clear-

cut type, arising apparently by spontaneous development apart from any external impulse.8 On the other hand, the mono-

3 Or Kathenotheism, a term which did not succeed in gaining permanent support, Hibbert Lect., p. 27.

10 Evolution of Religion (1893), lect. vii.
drawn up by Tiele (Ency. Brit., 9th ed., vol. xx. p. 360) will show what diversified products are blended together. Why should philosophical Brahmanism, or the Buddhism which reacted against it, be associated with so undeveloped a form as the religion of the ancient Latin settlers in mid-Italy? And why, on the other hand, should the religions of the lower culture, which are practically of a common type, be separated genealogically into numerous independent families? (2) Whitney found the most important distinction to lie between religions which were the collective product of the wisdom of the community, race-religions as they might be called, and those which proceeded from individual founders. But, as Tiele pointed out, the "individual" element cannot be eliminated from the "race-religion," where each myth has been first uttered, each rite first performed, by some single person. And the founder who enters history with an impressive personality can only do his work through the response made to him by the insight and feeling of his time. (3) Kuenen disengaged another characteristic, the scope and aim of any given religion; was it limited to a particular people, or could it be thrown open to the world? On this foundation the higher religions were classed as national or universal, the latter group being formerly supposed to include Buddhism, Christianity and Mahomedanism. Here, once more, the student is confronted with many qualifications. A missionary religion like Mithraism, which established itself all the way from Western Asia to the borders of Scotland, was certainly not "national." Judaism and Brahmanism both passed beyond the confines of race. The Confucian morality could be adapted without difficulty in Japan. In other words, there was either a definite tendency to expansion, or there was no impediment in the religion itself when circumstances promoted its transplantation. Further, there are elements of Islam, like the usages of the hajj (or pilgrimage to the sacred places at Mecca), the dryness of its official doctrine and the limitations of its real character as indicated in the Wahhabi revival, which so impair its apparent universalism that Kuenen found himself obliged to withdraw it from the highest rank of religions. (4) Professor M. Jastrow, jun., starting from the relation of religion to life, distinguishes four groups, the religions of savages, the religions of primitive culture, the religions of advanced culture and the religions which emphasize as an ideal the coextensiveness of religion with life. It may, however, be doubted whether the fundamental assumption of such a scheme, viz., that in the life of the savage religion plays a comparatively small part, can be satisfactorily established. The evidence rather implies that, so far as the sanctions of religion affect the savage at all, they affect him with unusual force. In the absence of other competing interests his religious beliefs and duties occupy a much larger share of his attention than the votaries of many higher faiths bestow on theirs; and though his ethical range may be very limited, yet the total influence of his religion in determining for him what he may do and what he may not, brings the greater part of conduct under its control. The savage who finds himself encompassed by taboos which he dare not break, lives up to his religion with a faithfulness which many professing Christians fail to reach. (5) There remains a broad distinction between religions that are in the main founded on the relation to man of the powers of Nature, and those based on ethical ideas, which partly corresponds to the philosophical division already cited. This enabled Professor Tiele to arrange the chief religions in certain groups, starting from the primitive conception of the common life of the objects of the surrounding scene.

2 National Religions and Universal Religions (Hibbert Lectures, 1894).
4 For a long series of suggested bases of classification see Raoul de la Grasserie, Des Religions Comparees au Point de Vue Sociologique (1899), chap. xii.; cf. further E. von Hartmann, Religionsphilosophie.

I. Nature Religions—
1. Polyzoic Naturalism (hypothetical).
2. Polytheism (Monogenesis of Religion under the control of Animism (religions of savages).  
3. Purified or organized magical religions. Therianthropic Polytheism.
4. (a) Unorganized religions of the Japanese, Dravidians, Finns, Esths, the ancient Arabs, the ancient Persians, the Old-Italian peoples, the Etruscans (?), the Old-Slavs.
5. (b) Organized religious of the half-civilized peoples of America, ancient Chinese state-religion, religion of the Egyptians.
6. Worship of deities in human form, but of superhuman power and half-ethical nature. Anthropomorphic polytheism (religions of the Vedic Indians, the ancient Persians, the later Babylonians and Assyrians, the advanced Semites, the Persians, the Greeks, the Celts, the Gauls, the Germaniks).

II. Ethical Religions (spiritualistic ethical religions of Revelation)—
1. National Nomistic (nomothetic) Religious Communions (Taoism and Confucianism, Brahmanism, Jainism, Mazzette, Mosallism, and Judaism, the two last already passing into 2).
2. Universalistic Religious Communions (Buddhism, Christianity, Islam with its particularistic and nomistic elements only partially belongs to this group).

7. Revelation.—The second group in this division practically corresponds to the second stage recognized by Caïd; but it rests upon a somewhat different basis, the conception of revelation addressed to the conscience in the form of religious law. Neither Taoism nor Confucianism, indeed, makes this claim, The Tao-ih-kung, or book of aphorisms on "the Tao and virtue," ascribed to Lao Tze, is wholly unlike such a composition as Deuteronomy; and the disciples of Confucius carefully refrained from attributing to him any kind of supernatural inspiration in his conversations about social and personal morality. The sacred literatures of India and Israel, however, present many analogies, and emerge out of a wide range of phenomena which have their roots in the practices of the lower culture. The belief that the Powers controlling man's life are willing upon occasion to disclose something of their purpose, has led to widespread rites of divination, which Plato described as the "art of fellowship between gods and men," and the Stoics defended on grounds of a priori religious expectation as well as of universal experience. Through the dream the living was put into communication with the dead, which sometimes embodied itself in peculiar and pathetic literary forms, such as the Icelandic dream-verses imparted by the spirits of those who had been lost at sea or overwhelmed by the snow; and a whole series of steps leads up from necromancy to prophecy and oracles, as the higher gods become the teachers of men. The gods of revelation are naturally not the highest, since they appear as the interpreters of one superior to themselves. The revealing agency may be only a voice like Aias Locutius, to which the Romans raised a temple; or, like Hermes, he may be the messenger of the gods; or, like Marduk, pre-eminent the god of oracles in Babylonia, he may be the son of Ea, the mighty deep encompassing the earth, source of all wisdom and culture. To Marduk the prophet-god Nabu in his turn became son, and his consort Tashmii ("causing to hear") was the personification of Revelation. Egyptian thought ascribed this function to Thoth, who played somewhat different parts in different systems, but emerges as the representative of the immanent intelligence (1888); Siebeck, Lehrbuch der Religionsphilosophie (1893); Donner, Grundris der Religionsphilosophie (1903). Siebeck proposed to distribute religions in three grades: (1) Nature-Religions, i.e. those of the lower culture; (2) Monolithic Religions in various grades and stages, e.g. Mexicans and Peruvians, Dravidians, Chinese, Egyptians, Hindus, Persians, Germans, Romans, with the Greek religion in the highest rank; (3) Religions of Redemption (Judaism forming the transition from the second to the third grade). The last of these is somewhat negative, and, positively, Christianity. Bousset, What is Religion? (1907) reckons Platonism along with Buddhism. For criticism of Siebeck's scheme see Tiele, Elements of the Science of Religion, vol. i. (1897), pp. 63, 65. Pfeiderer, Religion and Historic Faiths (1907), p. 88, recognizes more clearly the difficulty of carrying almost any division through the whole field, without frequent breach of historical connotations.
of the world, brother of Maat and the giver of laws and culture to man. Thoth the thrice-great 2 passed into Hermes Trismegistus whom Christian fathers could recognize,4 when the supremely beautiful figure of Greek theology, Apollo, had lost his dignity and ceased to be desired. Thoth was a voluminous author, and the collection of forty-two books which bore his name was a kind of primitive cyclopædia of theology, astronomy, geography and physiology. Apollo proclaims at his birth that he will declare the counsel of Father Zeus to men.5 But his utterances have been only casually preserved. A special literature of oracles did indeed arise; the divine words were collected and the circumstances which produced them were recorded, and Delphi became in fact the centre of Greece, as Plato conceived it, here might have been the nucleus of a scripture. Theories of inspiration lurk behind the rich vocabulary of Greek prophecy; the seer is ἐνθέος, θεόπρατος, τρίπνευστος, τριθνύστος, and Bakis and Museus give their names to sacred verses. The story of the Sibylline books in Rome, on the other hand, shows the growth of the idea of authority. They are deposited in a temple, in charge of a small sacred college; new deities and rites are introduced under their sanction; when they are accidentally destroyed, emblems are sent to the East and fresh collections are made; these are in their turn purged, the false are discarded and the true reverently preserved. By what method the books were consulted is not known; but they exhibit the idea of a sacred canon in process of formation. The theologians of India guarded their ancient hymns with the utmost care. A vast literary apparatus was devised for their protection. The famous Purusha-hymn (R.V. x. 90) already claimed a divine origin for the three Vedas, the Rik, the Saman and the Yajush. The "triple knowledge" 7 was sometimes derived from the "Lord of Creatures" Prajapati—one of the unifying forms of Brahmanical theology—through Yac or "speech." The Veda, that is to say, had existed in the divine mind ere it was made known to men, and as such it belonged to the realm of the deathless and the infinite. The tribal poets were supposed to have "seen" the heavenly originals; elaborate arguments were devised to explain how the names of particular objects like rivers and mountains could have existed in the Eternal; while the grounds of belief in the inassailability of the sacred verses were enforced with the double weight of philosophical and tradition. Buddhism repudiated the authority of the Veda, but found it needful to supply its place; and the word of the omniscient Teacher, faithfully reported by his disciples and guaranteed by concurrent traditions, became the rule of belief for the new Order. Nor were the authors of the scriptures whose fragments are preserved in the Zend Avesta less conscious of their divine value. The ancient Gathas, which were supposed to be the composition of Zarathustra himself, received the homage of later worshippers.4 Daena, the ideal personification of law and religion, is the object of praise and sacrifice. She dwells on high in the Heavenly Home, the radiant "Abode of song," but Zarathustra summons her thence, begs for her fellowship, and prays her for righteous- ness of thought, speech and deed.5 She is produced by Vohu Mano, the "Good Thought" of Ahura Mazda, one of the six Hahs of the six Hahs, the sphere of the heavens. She holds the key to the ideal creation before the earth and its inhabitants;6 but how the heavenly Daena was brought by Zarathustra into written form is nowhere stated. This conception of pre-existent spiritual counterparts was not without influence on the later theology of Israel. The sacred law (Torah) was the earthly reproduction of a heavenly Torah which had no origin in time, and constituted the sum of ideal wisdom into which God looked when he would create the world.7

7 Midrash Bereshith Rabba, tr. Wunsche, i. v. er. i.

Even Mahomedanism felt the spell of the same modes of thought. The idea of revelation was expressed by "sending down" (from nasala, to descend); that which passed from heaven to earth was a pre-existent word, eternal as God Himself. Allusions in particular passages of the Koran to the "mother of the scripture," the invisible originals of the prophet's speech, led to the doctrine of its uncreated being. The whole history of religion presents perhaps no more singular spectacle than the mosques of Bagdad in the middle of the 9th century filled with vast crowds of twenty and thirty thousand of the faithful, assembled to discuss the dogmas of the created and the uncreated Koran.

8. "Religions and Eschatology."—The second distinguishing mark in Tiele's higher group is implied in the term "Ethical." By this it is not intended to assert that moral ideas are wanting in the so-called "naturist" religions. Anthropologists have, it is true, taken widely different views of the relation of ethics and religion, and the stage at which an effective alliance between them might be recognized. Like all problems of origins, the question is necessarily extremely obscure, and cannot be definitely settled by historical evidence. Broadly speaking, however, it may be said that the attempt to show that certain savages are destitute of moral feeling cannot be sustained;8 and evidence has been already cited above (in the section on Polytheistic RELIGION) proving the varied and immediate effects of religion on the life of the lowest tribes. Continuous interaction marks the slow courses of advance. At a very early period in social development the rules of conduct are referred to some higher source. Thus among the tribes of south-eastern Australia described by Mr Howitt,9 the native rites and laws handed down from generation to generation were supposed to have been first imparted by some higher being such as Narrundere, who made all things on the earth; or Nurelli, who created the whole country, with the rivers, trees and animals; or Daramulan, who (like Narrundere) bestowed weapons on the men, and instituted the rites and ceremonies connected with life and death. As religion advances with improved social organization, a series of figures, partly human, partly divine, embodies the idea that the command of nature implied in the progress of the arts is due to some kind of instruction from above, and that the obligations of law are of more than human origin. The Algonquin Manibozo and Quetzalcoatl of Mexico stand for a whole group of typical personalities in North and Central America. The mysterious fish-man Oannes, who taught the primitive inhabitants of Babylonia, according to Alexander Polyhistor, has been identified with Ra, god of the deep, the source of wisdom, culture and social order. Zeus gave laws to Minos; Apollo revealed the Spartan constitution to Lycurgus; Zaleucus received the laws for the Locrians from Athena in a dream; Vishnu and Manu descendend to draw up law-books in India. The worship of ancestors has again and again gathered around it powerful and ethical influences, emphasizing the parental and filial relations, and strengthening the mutual obligations of communal life. Hirata answered by anticipation the modern reproach against Shinto, founded on the absence of any definite code, without a Book, without a God, without a world, and "Act so that you need not be ashamed before the Kami of the unseen."10 The mythological embodiments of the connexion of law in nature with the social and moral order have already been briefly noted: a few words may be said in conclusion on another product of the union of religion and ethics, viz. the doctrine of judgment after death. That this doctrine is not essential to a highly moralized religion is clear from the fact that it formed no part of the earlier Hebrew prophecy. Judgment, indeed, was an inevitable outcome of the sovereignty of Yahweh, but it would be passed upon the nation in the immediate scene of its misdoings; and even when the scope of the divine doom

was extended to include the nations of the world, it was still upon the living that it would alight. The seers of Israel were content to dismiss their dead to a land of silence and darkness, the vast hollow gloom of the subterranean Sheol. A far ruder outlook on life, however, which has again and again appealed to some form of the divine cognizance by means of the ordeal and the oath, frequently supplements the moral issues of this world by the judicial award of the next. Assuming the proper fulfillment of the ritual of death, ethics gradually extends its control over the future. At first the social distinctions of this life are simply continued hereafter: the chief remains a chief, the slave a slave; and the conditions of the future only prolong those of the present. In so far as tribal eminence depends on superior skill or courage or wisdom, the germs of ethical differentiation may be discovered even here. The process is carried further (1) in individual cases of retribution, when (as among the Kauputs) crime within the tribe was punished, and a murderer becomes in the next life his victim’s slave; or (2) when service to the community received special reward, and warriors who had fallen in battle, women who had died in childbirth and merchants who had perished on a journey were sent in Mexico to the house of the sun. As the social order acquires more definiteness and stability, the control of life by the gods tends to become more clearly moralized. This brings with it new standards independent of clan-customs or tribe-usage. Only the worst offences, however, at first draw down post-mortem punishment. The Homeric Erinyes chastise outrages on the poor, injuries to guests, failure to show the respect due to parents or to recognize the rights of age, in this life; only on perjury does the divine doom extend to the next. On the other hand, the Egyptian version of “the whole duty of man” in the famous 22nd chapter of the Book of the Dead embraces a singular complex of ritual, social and personal sins, in which the inwards state of lying, anger and ill-will are condemned along with murder, theft and adultery, beside violation of the tions of offerings to the gods, or interference with the food of the blessed dead. The great judgment of Osiris formulates with the utmost precision the alliance between morals and religion. The doctrine established itself in Greek theology under the influence of the Age of Orpheus. After the victories of Plato with mythic forms for his “criticism of life.” In India the union of morality and religion was effected in another manner. True, Yama, first of men to enter the world beyond, became the “King of Righteousness” before whose tribunal the dead must appear. But a new agency began to engage the speculations of thinkers, the moral values of action embodied in the Deed. “The deed does not perish,” ran an early formula. “A man is born into the world that he has made,” said another; and what was laid down first as a ritual principle survived as an ethical. Buddhism conceived men as constantly making their own world for good and ill; it took over from Brahmanism a whole series of heavens and hells to provide an exact adjustment in the future for the virtue or vice of the present; and its eschatological confidence was one of the potent instruments of its success in countries which, like China and Japan, had developed no theories of retribution or reward beyond the grave. Along a different line of thought the Iranian teachers, beholding the world divided between hostile powers, demanded, as the fundamental postulate of religion, the victory of the good. The conflict must end with the triumph of light, truth and right. The details of this remarkable scheme must be studied elsewhere (see Zoroaster). The award of the angel-judges at the Bridge of Assembly, such as death, dispatched the individual to his appropriate lot in the homes of Good or Evil Thought; Word and Deed. But at length the long struggle would draw to an end. The great “divine event,” the frasho-kereti, the renovation, would set in. A new heaven and a new earth would be created: a general resurrection should take place; the powers of evil should be overthrown and extinguished; and hell should be brought back for the enlargement of the world. Eschatology has again and again expressed the alliance between ethics and religion. It remains for the future to show how long that alliance may be requisite.

BIBLIOGRAPHY.—(For primitive religion see preceding section.) Only a selection of the copious and ever-increasing literature can here be named. Monographs on the separate religions are named in the respective sections.

1. After Hume’s Natural Hist. of Religions (1752) earlier surveys will be found in Meiners, Allgem. Krit. Gesch. der Religionen (2 vols., 1806–7); Constant, De la religion (5 vols., 1824–31); Baur, Israel und die Myth. der alt-kulturel. Völker (2 vols., 1857); F. D. Maurice, The Religions of the World (1846); Hardwick, Christ and other Masters (4 vols., 1855–59); Döllinger, The Gentle and the Jew (2 vols., 1863). On Mythology and Religion English study was chiefly influenced by F. Max Müller, Essay on Comparative Mythology (1856); Chips from a German Workshop (1867 onwards); Lectures on the Science of Mythology (2 vols., 1872); Das Wesen der Religionen (2 vols., 1897); cf. A. Lang, Modern Mythology (1897). Earlier Anthropology, Bastian, Der Mensch in der Gesch. (3 vols., Leipzig, 1860); Waitz-Gerard, Anthropology (6 vols., Leipzig, 1877).

2. Monographs on religions from the time of the Sacred Books of the East (49 vols., 1879 and onwards); Annales du Musée Guimet (1880 and onwards).

3. Manuals, treatises and series in single or collective authorship.

4. "Die Orientalischen Religionen," by the Authors of The Anthropology of Religion, tr. Pfeiderer, Religion und Religionen (Berlin, 1906); Eng. trans., Religion and Historic Faiths (London, 1907); Haarlem, Die Vornahmste Godsdiensten, beginning with Islam, by Dozy (1863 onwards); Soc. de Littérature Christiane, Les Principes de la religion (Paris, 1892); Hibbert Lectures on The Origin and Growth of Religion (15 vols., 1875), beginning with F. Max Müller, 1875); Aschendorff’s series, Dargestellung aus dem Gesch. der Religionen, Religiongesch. (14 vols., Münster, 1895), beginning 1890); Handbuch der Religionen, ed. Jastrow, beginning with Hopkins on India (1895); American Lectures on the History of Religions, beginning with Rhy’s study of Buddhism in London (1880); Buddha, Buddhism, and Modern Religion (London, beginning 1895), brief and popular: J. J. E. C.)

REMAiGEn, a town of Germany, in the Prussian Rhine Province, on the left bank of the Rhine, 12 m. above Bonn, by the railway from Cologne to Coblenz, and at the junction of the Ahr valley railway to Adenau. Pop. (1900) 3534. The (Roman Catholic) parish church is remarkable for a gate (Römertor) with grotesque sculptures of animals, dating from the 12th century. It has been frequently interpreted as the original purpose, whether as church door, city gate or part of the wall. The industry of the place is almost wholly concerned with the preparation of wine, in which a large export trade is done. Just below the town, on a height overlooking the Rhine, stands the Apollinaris church, built 1839–93 on the site of a chapel formerly dedicated to St Martin, and containing the relics of St Apollinaris. It is a frequent place of pilgrimage from all parts of the lower Rhine. According to legend, the ship conveying the relics of the three kings and of Bishop Apollinaris from Milan to Cologne in 1164 could not be got to move away from the place, and bones of St Apollinaris had been interred in St Martin's chapel.

Remagen (the Rığomagus of the Romans) originally belonged to the duchy of Jülich. Many Roman antiquities have been discovered here. In 1857 a votive altar dedicated to Jupiter, Mars and Mercury was unearthed, and is now in the Provincial Museum at Bonn.

See Kinkel, Der Führer durch das Ahrthal nebst Beschreibung der Stadt Remagen (2nd ed., Bonn, 1854).

REMAiNDEr, REVERsiON. In the view of English law, a remainder or reversion is classed either as an incorporeal remainder or, with greater correctness, as an estate in expectancy. That is to say, it is a present interest in an existing estate in possession called the particular estate, which must determine before the estate in expectancy can become an estate in possession. A remainder or reversion is in strictness confined to real estate, whether legal or equitable, though a similar interest may exist in personality. The particular estate and the remainder or reversion together make up the whole estate over which the grantor has power of disposition.\(^1\) Accordingly a remainder or reversion limited on an estate in fee simple is void. The difference between a remainder and a reversion is stated as simply as possible, viz., that the remainder is that undisposed-of part of the estate which after the determination of the particular estate will fall into the possession of the original grantor or his representative. A reversion, in fact, is a special instance of a remainder, distinguishable from it in two important respects: (1) a reversion arises by operation of law on every grant of an estate where the whole interest is not positively vested; whereas a remainder is created by express words; (2) tenure exists between the reversioner and the tenant of the particular estate, but not between the latter and the remainderman. Accordingly rent service is said to be an incident of a reversion but not of a remainder, and a reversioner could distrain for it at common law. A reversion may be limited upon any number of remainders, each of them as it falls into possession becoming itself a particular estate. A remainder or reversion may be alienated either by deed or by will. A conveyance by the tenant of a particular estate to the remainderman or reversioner is called a surrender; a conveyance by the remainderman or reversioner to the tenant is a release.

Remainder.—Remainders are either vested or contingent. An estate is vested in interest when there is a present fixed right of enjoyment. A contingent remainder is one whose enjoyment is to accrue on an event which is dubious and uncertain. A contingent remainder is a remainder limited so as to depend on an event or condition which may never happen or be performed, or which will happen and be performed in the future, at the uncertain date of the preceding event or condition. (See EARNT Gre. CONTINGENT REMAINErs, 2, 3.) Contingent remainders are of two kinds, those limited to uncertain events and those limited on uncertain events. A grant by A to B for life, followed by a remainder to C of the remainder of the estate, is a remainder limited to uncertain events. Until the death of C he can have no right in the remainder. If C dies during the lifetime of B, the remainder is unvested for there is no unaltered remainderman. A settlement of the former remainder is at common law destroyed owing to the determination of the particular estate, for every remainder must have a particular estate to support it. In the case of a contingent remainder, it must become vested in the remainderman at the uncertain date of the transfer of the reversion. This rule of law no doubt arose from the disavowal shown by the law to contingent remainders on their first introduction. They were not firmly established even then. The uncertainty was regarded as a limitation. (See REAL PROPERTY.) The inconveniences resulting from this liability of contingent remainders to destruction were formerly overcome by the device of appointing trustees to hold that part of the estate which was a contingent remainder. It should be noticed, were indestructible, for they were supported by the legal estate. In modern times the matter has been dealt with by act of Parliament, e.g. the Real Property Act 1845, § 8, a contingent remainder is rendered capable of taking effect notwithstanding the determination by forfeiture, surrender or merger of any preceding estate of freehold in the same manner as if such determination had not taken place. The determination of a contingent remainder is met by the Contingent Remainders Act 1877. The act provides that a contingent remainder which would have been valid as a reversion or shifting of a reversionary devise or other limitation had it not had a sufficient estate to support it, is a remainder; that a remainder is, in the event of the particular estate determining before the contingent remainder vests, to be capable of taking effect as though the particular estate remained unaltered. A remainder vesting or shifting or use or executory devise or other executory limitation. It will accordingly be good if the springing use, &c. (for which see TRUST), would be good. If the springing use be void as a breach of the rule against perpetuities (see PERPETUITY), the remainder will likewise be void. Apart from this act, there is some uncertainty as to the application of the rule against perpetuities to remainders. The better opinion is that it applies to equitable remainders and to legal remainders expectant upon an estate for life limited to an unborn person. In the latter case the rule as applied to contingent remainders is somewhat different from that applied to fee remainders. A remainder is destroyed when allowing the tying up of property for a longer time than the executory interest. There is also the further difference that the rule does not affect a contingent remainder if it become vested before the expiration of the particular estate. But if the contingent remainder is void if it may transgress the rule, even though it does not actually so do. For the rule in Shelley's case, important in connexion with testamentary remainders, see TRUST.

The state laws of the United States affecting remainders will be found in Washburn, Real Property, ii, bk. ii. As a general rule contingent remainders have been rendered of little practical effect by a statute allowing the tying up of property for a longer time than the executory interest. There have been considerably modified by statute. It was formerly considered

\(^1\) Compare the life-ten and fee of Scots law.

\(^2\) A contingent remainder amounting to a freehold cannot be limited on a particular estate less than a freehold.
that on the grant of the reversion the tenant should have the opportunity of objecting to the substitution of a new landlord. It was not unimportant that the tenant should be a good purchaser. Without such attornment the grant was void, unless indeed attornment were compelled by levying a fine. The necessity of attornment was abolished by 4 & 5 Anne c. 16. Its only use at present is in the case of a mortgage. A mortgagor in possession sometimes attorns tenant to the mortgagee in order that the latter may treat him as his tenant and distrain for his interest in the lessee's collateral rights. If the reversion was intestate reversion led at common law to a destruction of the rent by destruction of the reversion. This would chiefly happen in the case of an under-tenant and his immediate reversioner, if the intermediaries between them were all intestate. But even in this difficulty it was provided by the Real Property Act 1845 § 9, that, on surrender or merger of a reversion expectant on a lease, the rights under it should subvert to the reversion conferment of the next right. The question as to what covenants must with the reversion is one of the most difficult in law. The rule of common law seems to have been that covenants ran with the land but not with a new tenant or to a new landlord. The effect of the act of 32 Hen. VII. c. 34, and of the Conveyancing Act 1881, has been to annex to the reversion as a general rule the benefit of the rent and the lessee's covenants and the burden of the lessee's covenant. Merely collateral covenants, however, do not run with the reversion, but are regarded as personal contracts between lessor and lessee. At common law the severability of a reversion a great part of every condition that takes place of re-entry, on the ground that the condition was entire and not severable. This doctrine was abolished by one of Lord St Leonards Act 1845 § 12, making the reversioner in wider terms than those of the act of 1859 that on severance of the reversion every condition capable of apportionment is to be apportioned. In order to guard against fraudulent concealment of the death of a cessant que vie, or person for whose life any lands are held by another, it was provided by 6 Anne c. 15 that on application to the court of chancery by the person entitled in remainder, reversion or expectancy, the cessant que vie should be produced at the court or its commissioners, or in default should be taken to be dead. In Scotland reversion is generally used in a sense approaching that of the equity of redemption of English law. A reversion is either legal, as in an adjudication, or conventional, as in a warded. Reversions are registered under the system established by the Act 1671 c. 16.

In the United States the act of 32 Hen. VIII. c. 34 "is held to be in force in Massachusetts, Pennsylvania, Illinois, and Connecticut, but was never in force in New York till re-enacted" (Washburn, Real Property, i).

REMAND (Lat. remanendae), a term of English law meaning the return of a prisoner by order of a court to the custody from which he came to the court. Thus where an application for release is unsuccessfully made by means of habeas corpus, the applicant is remanded to the custody which he has challenged as illegal. Where trials or indictments are not concluded at a single sitting the court of trial has power to remand the accused into proper custody during any necessary adjournment. Where a preliminary inquiry into an indictable offence is not completed at a single sitting, the prisoner, if not released on bail, may be remanded to prison or some other place of custody for a period not exceeding eight days, and so on by further remands till the inquiry is completed and the accused is discharged, or committed to prison to await his trial, or released on bail to take his trial. If the remand is for more than three days the order must be in writing (Indictable Offences Act 1848, 11 & 12 Vict. c. 42, s. 21). Similar powers of remand or commitment to prison during adjournments are given to justices in the exercise of their summary criminal jurisdiction, whether as to offences punishable only on summary conviction, or as to indictable offences with which it is proposed to deal summarily (Summary Jurisdiction Acts 1854, s. 16, and 1861, s. 4). The practice varies according to the character of the prisoner, whether the justices commit for trial or order a remand pending inquiry, or with a view to sending a child to an industrial school or a reformatory, they may remand to the workhouse or to some fit custody instead of remanding to prison (Youthful Offenders Act 1901, s. 4). For this purpose remand homes have been established.

REMBRANDT (1606-1669). Rembrandt Harmens van Rijn, Dutch painter, was born in Leiden in the 15th of July 1606. It is only within the past fifty years that we have come to know anything of his real history. A tissue of fables formerly represented him as ignorant, boorish and avaricious. These fictions, resting on the loose assertions of Houbraken (De Grote Schouburgh, 1718), have been cleared away by the untiring researches of Scheltema and other Dutchmen, notably by C. Vosmaer, whose elaborate work (Rembrandt, sa vie et sesœuvres; 1868, and ed., 1879) is the basis of our knowledge of the man and of the chronological development of the artist. Rembrandt's high position in European art rests on the originality of his mind, the power of his imagination, his profound sympathy with his subjects, the boldness of his system of light and shade, the thoroughness of his modelling, his subtle colour, and above all on his intense humanity. He was great in conception and in execution, a poet as well as a painter, an idealist and also a realist; and this rare union is the secret of his power. From his dramatic action and mastery of expression Rembrandt has been well called "the Shakespeare of Holland." In the beginning of the 17th century Holland had entered on her grand career of national enterprise. Science and literature flourished in her universities, poetry and the stage were favoured by her citizens, and art found a home not only in the capital but in the provincial towns. It was a time also of new ideas. Old conventional forms in religion, philosophy and art had fallen away, and liberty was inspiring new conceptions. There were no church influences at work to fetter the choice and treatment of his subject, no academies to prescribe rules. Left to himself, therefore, the artist painted the life of the people among whom he lived and the subjects which interested them. It was thus a living history that he painted, scenes from the everyday life and amusements of the people, as well as the civic rulers, the "regents" or governors of the hospitals and the heads of the guilds, and the civic guards who defended their towns. So also with religious pictures. The dogmas and legends of the Church of Rome were no longer of interest to such a nation; but the Bible was read and studied with avidity, and from its page the artist drew directly the scenes of the simple narrative. Perhaps the earliest trace of this new aspect of Bible story is to be found in the pictures painted in Rome about the beginning of the 17th century by Adam Elsheimer of Frankfurt, who had undoubtedly a great influence on the Dutch painters studying in Italy. These in their turn carried back to Holland the simplicity and the picturesque effect which they found in Elsheimer's work. Among these, the precursors of Rembrandt, may be mentioned Moeyaert, Raveesteyn, Lastman, Pinas, Honthorst and Bramer. Influenced doubtless by these painters, Rembrandt determined to work out his own ideas of art on Dutch soil, resisting apparently every inducement to visit Italy. Though an admirer of the great Italian masters, he yet maintained his own individuality. Rembrandt was born at No. 3 Weddesteg, on the rampart at Leiden overlooking the Rhine. He was the fourth son of Gerrit Harmens van Rijn, a well-to-do miller. As the older boys had been sent to trade, his parents resolved that he should enter a learned profession. With this view he was sent to the High School at Leiden; but the boy soon manifested his dislike of the prospect, and determined to be a painter. Accordingly he was placed for three years under Swanenburch, a painter of no great merit, who enjoyed some reputation from his having studied in Italy. His next master was Lastman of Amsterdam, a painter of very considerable power. In Lastman's works we can trace the germs of the colour and sentiment of his greater pupil, though his direct influence cannot have been great, as 1638 and by 1643 Rembrandt was the master of his own style.

"Vosmaer's first volume, on the precursors and apprenticeship of Rembrandt, was published in 1863. New light has since been thrown on important points by Dr Bose (Holländische Malerei, 1883), De Roveo, De Vries and others."

1 Vosmaer's first volume, on the precursors and apprenticeship of Rembrandt, was published in 1863. New light has since been thrown on important points by Dr Bose (Holländische Malerei, 1883), De Roveo, De Vries and others.
and above all light were the aims of these studies. His mother was a frequent model, and we can trace in her features the strong likeness to her son, especially in the portraits of himself at an advanced age. In the collection of Rembrandt’s works at Amsterdam in 1638 were shown three portraits of his father, who died about 1632; nine are catalogued altogether. The last portrait of his mother is that of the Vienna Museum, painted the year before her death in 1640. One of his sisters also frequently sat to him, and Bode suggests that she must have accompanied him to Amsterdam and kept house for him till he married. This conjecture rests on the number of portraits of the same young woman painted in the early years of his stay at Amsterdam and before he met his bride. Then, again, in the many portraits of himself painted in his early life we can see with what zeal he set himself to master every form of expression, now grave, now gay—how thoroughly he learned to model the human face not from the outside but from the inner man. Dr Bode gives fifty as the number of the portraits of himself (perhaps sixty is nearer the actual number), most of them painted in youth and in old age, the times when he had leisure for such work.

Rembrandt’s earliest pictures were painted at Leiden, from 1627 to 1631. Bode mentions about nine pictures as known to belong to these years, chiey paintings of single figures, as “St Paul in Prison” and “St Jerome”; but now and then compositions of several, as “Samson and Delilah” and “Presentation in the Temple.” The prevailing tone of all the portraits is a greycsh grey, the effect being somewhat cold and heavy. The gallery at Cassel gives us a typical example of his studies of the heads of old men, firm and hard in workmanship and full of detail, the effects of light and shade being carefully thought out. His work was now attracting the attention of lovers of art in the great city of Amsterdam, and, urged by their calls, he removed about 1631 to live and die there. At one bound he leaped into the position of the first portrait painter of the city, and received numerous commissions. During the early years there are at least fifty known portraits from his hand, firm and solid in manner and style in their own right. It has been remarked that the fantasy in which he indulged through life was reserved only for the portraits of himself and his immediate connexions. The excellent painter Thomas de Keyser was then in the height of his power, and his influence is to be traced in some of Rembrandt’s smaller portraits. Pupils also now flocked to his house in the Bloemgracht, among them Gerard Douw, who was nearly of his own age. The first important work executed by Rembrandt in Amsterdam is “Simeon in the Temple,” of the Hague Museum, a fine early example of his treatment of light and shade and of his subtle colour. The concentrated light of the picture, while the background is full of mystery. The surface is smooth and enamel-like, and all the details are carefully wrought out, while the action of light on the mantle of Simeon shows how soon he had felt the magical effect of the play of colour. In the life-sized “Lesson in Anatomy” of 1632 we have the first of the great portrait subjects—Tulp the anatomist, the early friend of Rembrandt, discounting to his seven associates, who are ranged with eager heads round the foreshortened body. The picture had been treated in former years by the Mierevelds, A. Petersen and others, for the Sons of the Surgeons. But it was reserved for Rembrandt to make it a great picture by the grouping of the expressive portraits and by the completeness of the conception. The colour is quiet and the handling of the brush timid and precise, while the light and shade are somewhat harsh and abrupt. But it is a marvellous picture for a young man of twenty-five, and it is generally accepted as marking a new departure in the career of the painter.

About 700 pictures are known to have come from Rembrandt’s own hand. It is impossible to notice more than the prominent works. Besides the Pellicom family portraits of 1632 now in the Wallace Collection, we have the calligraphist Coppenol of the Cassel Gallery, interesting in the first place as an early example of Rembrandt’s method of giving permanent interest to a portrait by likenesses of several, as Rembrandt’s last work, the portrait of a mother, the portraits etchings (1661) is the Coppenol of large size. The two small portraits of the family of the Louvre date from 1633, delicate in execution and full of mysterious effect.

The year 1634 is especially remarkable as that of Rembrandt’s marriage with Saskia van Uylenborch, a beautiful, fair-haired Frisian maiden of good connections. Till her death in 1642 she was the centre of his life and art, and lives for us in many a canvas as the girl whose beauty he carried on in his oil sketch of the young woman in a magnificient power, painting her as the Queen of Artemisia or Bathsheba, and as the wife of Samson—always proud of her long fair locks, and covering her with pearls and gold as precious in their play of colour as those of the Indies. A joyous pair we see them in the Dresden Gallery, Saskia sitting on his knee while he laughs gaily, or promenading together in a fine picture of 1636, or putting the last touches of ornament to her toilette, for thus Bode interprets the so-called “Burgomaster Pancras and his Wife.” These were his happy days when he painted himself in his portrait and his fantasy, and adorned himself, at least in his portraits, in scarfs and feathered chair. He brings to the marriage portion of forty thousand guilders, a large sum for those times, and she brought him also a large circle of good friends in Amsterdam. She bore him four children, Rumbartus and two girls, successively named Cornelia after his beloved mother, all of whom died in infancy, and Titus, named after Titia a sister of Saskia. We have several noble portraits of Saskia, a good type of the beauty of Holland, all painted with the utmost love and care, at Cassel (1633), at Dresden (1641), and a posthumous one (1643) at Berlin. But the greatest in size and most pathetic in expression seems to us, though it is December 1641, that of Antwerp (1641), in which it is impossible not to trace declining health and to find a melancholy presage of her death.

One of Rembrandt’s greatest portraits of 1634 is the superb full-length of Martin Daey, which, with that of Madame Daey, painted according to Vossmaer some years later, formed one of the ornaments of the Van Loon collection at Amsterdam. Both now belong to Baron Gustave de Rothschild. From the firm detailed execution of this portrait one turns with wonder to the broader handling of the magnificent “Portrait of Dr Bode” (Frederik van Wasserhoven), aged eighty-three, in the National Gallery, of the same year, which, remarkable for the effect of reflected light and still more for the sympathetic rendering of character.

The portraits of Samson supplied many subjects in these early days. The so-called “Count of Guelders threatening his Father-in-law” of the Berlin Gallery has been restored to its proper significance by M. Koloff, who finds it to be Samson. It is forced and violent in execution. The greatest of this series, and one of the most prominent pictures of Rembrandt’s work, is the “Marriage of Samson” of the Dresden Gallery, painted in 1638. Here Rembrandt gives the rein to his imagination and makes the scene live before us. Except the bride (Saskia), who sits calm and grand on a dais in the centre of the feast, with the full light again playing on her flowing locks and wealth of jewels, all is animad and full of bustle. Samson, evidently a Rembrandt of fantasy, leans over a chair groaning his riddle to the Philistine lords. In execution it is a great advance on former subject pictures; it is bolder in manner, and we have here signs of his approaching love of warmer tones of red. The picture is a beauty.

The story of Susannah also occupied him in these early years, and he returned to the subject in 1641 and 1643. The “Bather” of the National Gallery may be another interpretation of the same theme. All of these compositions show the difficulty of converting it into a picture. He invests it with a sense of life by a momentary expression as Coppenol raises his head towards the spectator while he is mending a quilt. The same motive is to be found in the “Shipbuilder” of 1633 (Buckingham Palace), which breaks up from his work with a sense of interruption at the approach of his wife. Coppenol was painted thrice and etched twice by the artist, the last of which portrait etchings (1661) is the Coppenol of large size. The two small portraits of the family of the Louvre date from 1633, delicate in execution and full of mysterious effect.
shop and the mother watching over the infant reverently and lovingly, with a fine union of realism and idealism. This young picture, in which the kindling of the fire in the hearth is portrayed, is the "Storm of the "Geldert," appearing to Mary, of 1638 (Buckingham Palace).

We have now arrived at the year 1640, the threshold of his second manner, which extended to 1654, the middle age of Rembrandt. During the latter part of the previous decade we find the shadows more transparent and the blending of light and shade more perfect. There is a growing power in every part of his art. The coldness of his first manner had disappeared, and the tones were gradually changing into golden-brown. He had passed through what Bode calls his "Sturm-und-Drang" period of exaggerated expression, as in the Berlin Samson, and had attained to a truer, calmer form of dramatic expression, of which the "Manoah" of Dresden is a good example (1641). The portraits painted "to order" became more rare about this time, and those which we have are chiefly friends of his circle, such as the "Mennonite Preacher" (C. C. Anloo) and the "Gilder," a fine example of his golden tone, formerly in the Morny collection and now in America. His own splendid portrait (1640) in the National Gallery illustrates the change in his manner. It marks the change of a turbulent and wild, impetuous, powerful house, firm and compressed lips and determined chin, with heavy eyebrows, separated by a deep vertical furrow, and with eyes of keen penetrating glance—altogether a self-reliant man that would carry out his own ideas, careless whether his popularity waxed or waned. The fantastic rendering of himself has disappeared; he seems more conscious of his dignity and position. He has now many friends and pupils, and numerous commissions, even from the stadhoudler; he has bought a large house in the Breedstraat, in which during the next sixteen years of his life he gathers his large collection of paintings, engravings, armour and costume which figure afterwards in his inventory. His taste was wide and his purchasing vast; for he was owner with picture-dealers of paintings by Giorgione and Palma Vecchio, while for a high-priced Marcantonio Raimondi print he gave in exchange a fine impression of his "Christ Healing the Sick," which has since been known as the "Hundred Guilder Print." The stadhoudler was not a prompt payer, and an interesting correspondence took place between Rembrandt and Constantijn Huygens, the poet and secretary of the prince. The Rembrandt letters which have come down to us are few, and these are of great importance. Rembrandt puts a high value on the picture, which he says had been painted "with much care and with the scene full of sentiment." The dominant colour is the citron yellow uniform of the lieutenant, wearing a blue sahit, while a Titian-like red dress of a musketeer, the black velvet dress of the captain, and the varied green of the girl and drummer, all produce a rich and harmonious effect. The background has become dark and heavy by accident or neglect, and the scutcheon on which the name is painted is scarcely to be seen. It is to be observed that, as proved by the copy of "The Night Watch," in the National Gallery, it represents not a "night watch," except in name, but a day watch. But this year of great achievement was also the year of his great loss, for Saskia died in 1642, leaving Rembrandt her sole trustee for all his property. She had willed him monies till he should marry again or till the marriage of Titus. The words of the will express her love for her husband and her confidence in him. With her death his life was changed, and his marriage, which is removed with the same simplicity of his pictures of the Holy Family—a favourite subject at this period of his life. All of these he treats with the naive simplicity of Reformed Holland, giving us the real carpenter's
REMBRANDT

to live with him, for we find her claiming a chest as her property at his sale in 1658. Doubtless she is the historical Srlf of Rostorf to whom Houbaken says Rembrandt was married. Sad as the story is, Hendrickje has an interest for us. Bode asserts that in his art there was always a woman in close relationship to Rembrandt and appearing in his work—his mother, his sister and then Saskia.

He also suggests that the beautiful portrait of the "Lady" in the Salon Carré of the Louvre and the "Venus and Cupid" of the same gallery may represent Hendrickje and her child. Both pictures belong to this date, and by their treatment are removed from the category of Rembrandt's usual portraits. But if this is conjecture, we get nearer to fact when we look at the picture executed for Mr. Robert Pearsall, the House of 1859, to which tradition has attached the name of "Rembrandt's Mistress," now in the Edinburgh National Gallery. At a glance one can see that it is not the mere head of a model, as she lies in bed raising herself to put aside a curtain as if she heard a well-known footstep. It is clearly a woman in whom Rembrandt had a personal interest. The date is clearly 165— the fourth figure being illegible; but the brilliant carnations and masterly touch connect it with the "Potiphar's Wife" of 1654 and the Jagers period. In 1656 Rembrandt's financial affairs became more involved, and the Orphan's Chamber transferred the house and ground to Titus, then Rembrandt's eldest son, at the charge of selling the estate. Nothing, however, could avert the ruin of the painter, who was declared bankrupt in July 1656, an inventory of all his property being ordered by the Insolvency Chamber. The first sale took place in 1657 in the Keizerskroon hotel; and the second in 1658, when the larger part of the etchings and drawings were disposed of—as collected by Rembrandt himself with much love and care," says the catalogue. The sum realized, under 5000 guil derners, was but a fraction of their value. The time was unfavourable over the whole of Europe for such sales, the renowned collection of Charles I. of England having brought but a pitiful sum. At a sale in 1669, when thirty had been stripped of everything he possessed, even to his table linen, Rembrandt took a modest lodging in the same Keizerskroon hostelry (the amounts of his bills are on record), apparently without friends and thrown entirely on himself.

But this dark year of 1665 stands out prominently as one in which some of his greatest works were produced, as, for example, "John the Baptist preaching in the Wilderness," of the Berlin Gallery, and "The Woman of Samaria at the Well," of the Capet towns. It is impossible not to respect the man who, amid the utter ruin of his affairs, could calmly conceive and carry out such noble work. Yet even in his art one can see that the tone of his mind was sombre. Imagination of the brilliancy of 1654 we have for two or three years a preference for dull yellows, reds and greens, with a certain uniformity of tone. The handling is broad and rapid, as if to give utterance to the ideas which crowded on his mind. There is less stressing of colour for its own sake, even less straining after vigorous effect of light and shade. Still the two pictures just named are among the greatest works of the master. To the same year belongs the "Lesson in Anatomy of Johann Deyman." The subject is similar to the great Tulp of 1632, but his manner and power of colour had advanced so much that Sir Joshua Reynolds, in his visit to Holland in 1781, was reminded by it of Michelangelo and Titian. In 1665 Rembrandt produced the great "Burghers of Amsterdam," which lastly, in 1669, when the "Portrait of Jan Six," the future burgomaster, consummate in its ease and character, as Six descends the steps of his house drawing on his glove. The connexion between Rembrandt and the great family of Six was long and close. In 1641, the mother of Six, Anna Wymer, had been painted with consummate skill by Rembrandt, who also executed in 1657 the beautiful etching of Six standing by a window reading his tragedy of Medea, afterwards illustrated by his friend.

Now he paints the portrait in the prime of manhood, and in the same year of gloom paints for him the masterly "John the Baptist." Six, if he could not take himself and Rembrandt, appears as a man whom the darkest hour, when certainly the creative energy of Rembrandt was in full play. The same period gives us the "Master of the Vineyard," and the "Adoration of the Magi" of Buckingham Palace.

After the sale of the house in the Breestraat, Rembrandt retired to the Keizerskroon, an obviously gloomy and of his own. We are now drawing to the splendid close of his career in his third manner, in which his touch became broader, his impasto more solid and his knowledge more complete. We may mention the "Old Grey Bed," the "Braamfontein," the "Three Princes of the Blood," the "Bluemingh, the Secretary of the Insolvents' Chamber," of the Cassel (1658), both leading up to the great portraits of the " Syndics of the Drapers' Company," of 1661. "Portrait of Hendrickje," "Lesson in Anatomy," years of long-continued observation and labour. The knowledge thus gathered, the problems solved, the mastery attained, are shown here in abundance. Rembrandt had now accumulated the most brilliant works of his life, bold and rapid in execution and marvellous in the subtle mixture and play of colours in which he seems to revel. The woman and children are painted with such love that the impression is conveyed that they represent a fancy family group of the painter in his old age. This idea received some confirmation from the supposed discovery that he left a widow Catherine Van Wyck and two children, but this theory falls to the ground, for de Roever has shown (Oud Holland, 1885) that Catherine was the widow of a marine painter and that the children died in the same time as Rembrandt. The mistake arose from a misconception of the year.

The subject of these pictures is thus more mysterious than ever. In 1668 Titus, the only son of Rembrandt, died, leaving one child, and on the 8th of October 1669 the great painter himself passed away, leaving two children, and was buried in the Wester Kerk. He had outlived his popularity, for his manner of painting, as we know from contemporaries, was no longer in favour with a people who preferred the smooth trivialities of Van der Werff and the younger Miers, the leaders of an expiring school.

We must give but a short notice of Rembrandt's achievements in etching. One will observe in him throughout the change of style arising by his unrivalled technical skill, his mastery of expression and the lofty conceptions of many of his great pieces, as in the "Death of the Virgin," "the Christ Preaching," "the Christ Healing the Sick" (the Hundred Guilders at different periods). The Rembrandt of his "Burghers," the "Woman of Samaria," the "Adoration of the Magi," the " Crucifixion" and others. So great is his skill simply as an etcher that one is apt to overlook the nobleness of the etcher's ideas and the depth of his nature, and this tendency has been doubtless confirmed by the enormous difference in money value between "states" of the same plate, rarity giving in many cases a fictitious worth in the eyes of collectors. A single impression of one of his greatest plates, such as the "Hundred Guinea Print," was sold at Holford sale in 1893, when "Ephraim Bonus, with black ring" fetched £1500, and the "Hundred Guilder Print," £1750. The points of difference between these states arise from the additions and changes made by Rembrandt on the plate; and the prints taken off by him have been subjected to the closest inspection by Bartsch, Gersaint, Wilson, Daubly, De Clausus, C. Blanc, Willshear, Seymour Haden, Middleton and others, who have described them at great length, and to whom the reader is referred. The classification of Rembrandt's etchings adopted till lately was according to the subject, as Biblical, portrait, landscape, and so on; until the present writer attempted a systematic classification by the "continuation of chronology. This method has been developed by Sir F. Seymour Haden and Middleton." But even in 1873 C. Blanc, in his fine work L'Œuvre complet de Rembrandt, still adheres to the older and less systematic classification, as does the more recent monumental work of his great pupil Eeftinck. The absence of dates on the etchings and more strangely still on the etching of the quality of the work. Sir Seymour Haden's reply is that the "more important etchings which may be taken as types are dated, and that the style of the etching differs all through Rembrandt's career being fully as marked as that of his paintings, no more
REMEMBRANCE—REMIREMONT

"difficulty attains the classification of one thing than of the other." In
deed Vosmaer points out in his Life of Rembrandt that there is a
marked parallelism between Rembrandt's painted and etched work,
his early work in both cases being timid and tentative, while he
gradually increases the strength and character both with the brush and
the graver's tools.

In his L'Œuvre complet de Rembrandt (Paris, 1889), Eugène Dutuit
rejects the classification of C. Blanc as dubious and unwarranted.
different thematic arrangements were adopted by Seymour Haden and
Middleton as open to discussion and lacking in possibility of proof, and
reverts to the order established by Gersaint, ranging the materials under
thirteen heads: Parnassus (real and supposed), Old Testament, New Testament,
subjects, histories, landscapes, &c. Sir Seymour Haden originated the
theory that many of the etchings ascribed to Rembrandt up to 1660
were, in fact, the works of pupils, and seem to make out his case, though
it may be carried too far. He argues in his monograph on The Etched Work
of Rembrandt, 1877 that Rembrandt's real work in etching began after Saskia's death, when he assumes that Rembrandt
brought himself to Elthbrock, the country house of his "powerful friend" Jan Six. But it must be remembered that the future
burgomaster was then but a student of twenty-four, a member of a
family greatly it is true, but unmarried and taking as yet no share in
public life. That Rembrandt was a frequent visitor at Elthbrock and
that the "Three Trees" and other etchings may have been produced
there, may be admitted without requiring us to believe that his
debut as an etcher of any importance. The great period of his etching lies between 1639 and 1661, after which the old painter
seems to have renounced the needle. In these twenty years were
produced his greatest works in portraiture, landscape and Bible
subjects by him, and the basis of the whole etchings of the man.

In addition to the names added, the reader is referred to W. Bürger,
(Ann. de plume de T. Thore, Musées de la Hollande (1895–60); E. Fromentin, Maîtres d'autrefois; H. Havard, L'Ecole Hollandaise de Rembrandt (1900)); G. H. F. Leflare, Rembrandt, son individualisme dans l'art (Paris, 1869); Dr Langbehn, Rembrandt als Ersterker (Leipzig, 1890); Emile Michel, Rembrandt, sa vie, son œuvre, et son temps (Paris, 1893); P. G. Hamerton, Rembrandt's Etchings (London, 1894); Malcolm Bell, Rembrandt van Rijn and his Work (London, 1896); Adolf Rosenberg, Rembrandt, des Meisters Gemälde (Stuttgart and Leipzig, 1900); W. H. Raffalovich, Rembrandt and Rembrandt's pictures, and its companion volume, Hans Wolfgang Singer, Rem-
brandt, des Meisters Radierungen (Stuttgart and Leipzig, 1906), reproducing 402 etchings. The chronological, geographical and classifying indexes in both books are of particular utility.

J. F. W.; P. G. K.)

REMEJOS, or SAN JUAN DE LOS REMEDIOS, town of Santa
Clara province, Cuba, in the municipality of San Juan de Los
Remedios. Pop. of the town (1907), 6988; of the municipi-
ality, 21,572. The town is served by a branch of the Cuban
Central railway, extending from Caibarién to Camajuani,
where it connects with the main line. The site is low and flat, and
unhealthily wet in the rainy season. The port of Remedios is
Caibarién (pop. in 1907, 5333), on the N. coast, about 5 m. E.
Both are in the sugar country, and sugar is the base of their
economic interests. The first settlement on the site of the
present town was made in 1515–16, and in 1545 Remedios was
created a villa with an ayuntamiento (council).

REMEMBRANCER, the name originally of certain subordinate
officers of the English Exchequer. The office itself is of great
antiquity, the holder having been termed remembrancer, memora-
tor, remembrator, registrar, keeper of the register, despatcher of business (Madox, History of the Exchequer). There
were at one time three clerks of the remembrance, styled king's remembrancer, lord treasurer's remembrancer and
remembrancer of first-fruits. The latter two offices have become
extinct, that of remembrancer of first-fruits by the diversion of
the fund (Queen Anne's Bounty Act 1838), and that of lord
treasurer's remembrancer on being merged in the office of king's
remembrancer (1833). By the Queen's Remembrancer Act
1839 the office ceased to exist separately, and the queen's
remembrancer was required to be a master of the court of
exchequer. The Judicature Act 1873, s. 77, attached the office
to the Supreme Court, and the Supreme Court of Judicature
(Officers) Act 1879 transferred it to the central office of the
Supreme Court. By s. 8 the king's remembrancer is a master of
the Supreme Court, and the office is usually filled by the
senior master. The king's remembrancer department of the
central office is now amalgamated with the judgments and
married women's acknowledgments department. The King's
remembrancer still assists at certain ceremonial functions—
relics of the former importance of the office—such as the nomina-
tion of sheriffs, the swearing-in of the lord mayor of London,
the trial of the peace and the acknowledgments of homage for
crown lands. Other duties are set out in the Second Report of
the Legal Departments Commission, 1874.

"Remembrancer" is also the title of an official of the cor-
poration of the city of London, whose principal duty is to
represent that body before parliamentary committees and at
council and treasury boards.

REMIGIUS, ST (c. 437–533), bishop of Reims and the friend of
Clovis, whom he converted to Christianity. According to
Gregory of Tours, 3000 Franks were baptized with Clovis by
Remigius on Christmas Day, 496, after the defeat of the Al-
amanics. With the growing power of the papacy a good many
fictions grew up around his name, e.g. that he converted
with oil from the sacred ampulla, and that Pope Hormisdas
had recognized him as primate of Rome. The Commentary
on the Pauline Epistles (ed. Villalpandus, 1609) is not his work, but that
of Remigius of Auxerre.

For authorities see H. Jadart, Bibliographie des ouvrages conc.
la vie et le culte de S. Remi. (Reims, 1891), which contains 126
references.

REMINGTON, FREDERICK (1861–1909), American artist,
was born at Canton, New York, on the 4th of October 1861.
He was a pupil of the Yale Art School, and of the Art Students'
League, New York, and became at the art of portrait, painter and
sculptor. Having spent much time in the West, whither he went for his health, and having been with the
United States troops in actual warfare, he made a specialty of
rendering the North American Indian and the United States
soldier as seen on the western plains. In the Spanish-American
War he was with the army under General Shafter as war corre-
pondent. He died on the 26th of December 1909, near Ridge-
field, Connecticut. His statuettes of soldiers, Indians, cowboys
and trappers are full of character, while his paintings have been
largely reproduced. He contributed several volumes of stories,
including Pony Tracks (1892), Crooked Trails (1898), Sundown
Leflare (1899), and John Ermine of the Yellowstone (1902).

REMINISCENCE (Lat. reminisci, to remember), the
recognized translation of the Greek ἀναμνῄσκειν, which is used
technically by Plato in his doctrine that the soul recovers
knowledge of which it had direct intuition in a former incorporeal
existence. The doctrine may be regarded as the poetical
precursor of modern a priori theories of knowledge and of
"race-memory" and the like. In common language "re-
imniscence" is synonymous with "recollection."

REMIREMONT, a town of eastern France, capital of an
arrondissement in the department of Vosges, 17 m. S.S.E. of
Épinal by rail, on the Moselle, a mile below the confluence with the
Moselotte. Pop. town, 8782; commune, 10,548. Remi-
remont is surrounded by forest-clad mountains, and commanded
by Fort Parmont, one of the Moselle line of defensive works.
The abbey church, consecrated in 1539, has a crypt of the 11th
century in which are the tombs of some of the abbesses, but as
a whole belongs to the late 13th century. The abbatial residence
(which now contains the mairie, the court-house and the public
library) has been twice rebuilt in modern times (in 1750 and
again after a fire in 1871), but the original plan and style have
been preserved in the imposing front, the vestibule and the
grand staircase. Some of the houses of the canonniers dating
from the 17th and 18th centuries also remain. Remiremont is
the seat of a sub-prefect and has a tribunal of first instance,
a communal college, a board of trade-arbitration and a chamber
of arts and manufactures. Its industries include cotton-spinning
and weaving, the manufacture of hosiery and embroidery, iron
and copper founding and the manufacture of boots and shoes
and brushes.

Remiremont (Remarci Mens) derives its name from St Romaric, one of the companions of St Columban of Luxem-
burg, who in the 7th century founded a monastery and a conven-
t on the hills above the present town. In 910 the nuns, menaced
by the invasion of the Hungarians, took refuge at Remiremont, which had grown up round a villa of the Frankish kings, and in the 11th century they permanently settled there. Enriched by dukes of Lorraine, kings of France and emperors of Germany, the ladies of Remiremont attained great power. The abbess was a princess of the empire, and received consecration at the hands of the pope. The fifty canons were selected from those who could give proof of noble descent. On Whitsunday the neighbouring parishes paid homage to the chapter in a ceremony called the "Kyrioles"; and on their accession the dukes of Lorraine, the immediate suzerains of the abbey, had to come to Remiremont to swear to continue their protection. The "War of the Scutcheons" (P'anonceaux) in 1566 between the duke and the abbess ended in favour of the duke; and the abbess never recovered her former position. In the 17th century the ladies of Remiremont fell away so much from the original monastic rule as to take the title of countesses, renounce their vows, and marry. The town was attacked by the French in 1638 and ruined by the earthquake of 1682. With the rest of Lorraine it was joined to France in 1766. The monastery on the hill and the nunnery in the town were both suppressed in the Revolution.

REMONSTRANTS, the name given to those Dutch Protestants who, after the death of Arminius (q.v.), maintained the views associated with his name, and in 1610 presented to the states of Holland and Friesland a "remonstrance" in five articles formulating their points of departure from stricter Calvinism. These were: (1) that the divine decree of predestination is conditional, not absolute; (2) that the Atonement is in intention universal; (3) that man cannot of himself exercise a saving faith; (4) that though the grace of God is a necessary condition of human effort it does not act irresistibly in man; (5) that believers are all saved, but are not beyond the possibility of falling from grace. Their adversaries (the Gomarists) met them with a "counter-remonstrance," and so were known as the Counter-Remonstrants. Although the states-general issued an edict tolerating both parties and forbidding further dispute, the conflict continued, and the Remonstrants were assailed both by personal enemies and by the political weapons of Maurice of Orange, who executed and imprisoned their leaders for holding republican views. In 1618-19 the synod of Dort (see Dort, Synod of), the thirteen Arminian pastors headed by Simon Episcopius (q.v.) being shut out, established the victory of the Calvinist school, drew up ninety-three canonical rules, and confirmed the authority of the Belgic Confession and the Heidelberg Catechism. The judgment of the synod was enforced by the deposition and in some cases the banishment of Remonstrant ministers; but the government soon became convinced that their party was not dangerous to the state, and in 1636 they were formally allowed liberty to reside in all parts of Holland and build churches and schools. In 1621 they had already received liberty to make a settlement in Schleswig, where they built the town of Friedrichstadt. This colony still exists. The doctrine of the Remonstrants was embodied in 1621 in a confessio written by Episcopius, their great theologian, while J. Uyttenboogaert gave them a catechism and regulated their churchly order. The Remonstrants adopted a simple synodical constitution; but their importance was henceforth more theological than ecclesiastical. Their seminary in Amsterdam has boasted of many distinguished names--Curellaeus, Limborch, Wetstein, Le Clerc; and their liberal school of theology, which naturally grew more liberal and even rationalistic, reacted powerfully on the state church and on other Christian denominations. The Remonstrants first received official recognition in 1795. As a church they now number 27 communities with about 12,500 members, in a flourishing condition and respected for their traditions of scholarship and liberal thought. Their chief congregation is in Rotterdam.

REMPHAN, the Authorized Version's rendering of the Greek word variously appearing in Acts vii. 48 as Ρεμφά, Ρεμφαρ, Ρεμφάν, Ραφάν, Ραφάν. It is part of a quotation from Amos v. 26, where the Septuagint Ραφάν or Ραφάν stands for the Hebrew נָחַ לַעֲשָׂע שֵׁם רְאָעָן. The Greek forms are probably simple mistakes for the Hebrew, k (ך) having been replaced by r (ר) and ph (פ) substituted for v (ו). Kewen is probably the old Babylonian Kar(y)awannu, the planet Saturn, another (the Akkadian) name for which is Sukbat, which appears as Sīcīth in the earlier part of the verse.

REMSCHEID, a town of Germany, in the Prussian Rhine Province, situated on an elevated plateau, 1100 ft. above sea-level, 6 m. by rail S. of Barmen and 20 m. N.E. of Cologne. Pop. (1905) 64,340. Remscheid is a centre of the hardware industry, and large quantities of tools, scythes, skates and other small articles in iron, steel and brass are made for export to all parts of Europe, the East, and North and South America. The name of Remscheid occurs in a document of 1152, and the town received the first impulse to its industrial importance through the immigration of Protestant refugees from France and Holland.

RÉMUSAT, CHARLES FRANÇOIS MARIE, COMTE DE (1797-1879), French politician and man of letters, was born in Paris on 20 March 1797. His father, M. de Remusat, was of the name of Remusat, a good family of Toulouse, but acquired in the restoration and became prefect first of Haute Garonne, and then of Nord. His mother's maiden name was Claire Elisabeth Jeanne Gravier de Vergennes, born in 1780. She married at sixteen, and was attached to Josephine as duchesse de la palais in 1802. Talleyrand was among her admirers, and she was generally recognized as a woman of great intellectual capacity and personal grace. After her death (1824) an Essai sur l'éducation des femmes was published and received an academic couronne. But it was not until her grandson Paul de Remusat published her Mémoires (3 vols., Paris, 1879-80), which have since been followed by some correspondence with her son (2 vols., 1881), that justice could be done to her literary talent. Much light was thrown on the Napolonic court by this book, and on the youth and education of her son Charles. He early developed political views more liberal than those of his parents, and, being bred to the bar, published in 1830 a pamphlet on trial by jury. He was an active journalist, showing in philosophy and literature the influence of Cousin, and is said to have furnished to no small extent the original of Balzac's brilliant egoist Henri de Marsay. He signed the journalists' protest against the Ordinances of July 1830, and in the following October was elected deputy for Haute Garonne. He then ranked himself with the doctrinaires, and supported most of those measures of restriction on popular liberty which made the July monarchy unpopular with French Radicals. In 1836 he became for a short time under-secretary of state for the interior. He then became an ally of Thiers, and in 1840 held the ministry of the interior for a brief period. In the same year he became an Academician. For the rest of Louis Philippe's reign he was in opposition till he joined Thiers in his attempt at a ministry in the spring of 1848. During this time Rémusat constantly spoke in the chamber of deputies, and in regard to more important and weightier subjects, the most remarkable of his works being his book on Abond (2 vols., 1845). In 1848 he was elected, and in 1849 re-elected, for Haute Garonne, and voted with the Conservative side. He had to leave France after the coup d'etat; nor did he re-enter political life during the Second Empire until 1869, when he founded a moderate opposition journal at Toulouse. In 1871 he refused the Vienna embassy offered him by Thiers, but in August he was appointed minister of foreign affairs in succession to M. Jules Favre. Although minister he was not a deputy, and on standing for Paris in September 1873 he was beaten by Désiré Barrodet. A month later he was elected (having already signed with Thiers) for Haute Garonne by a great majority. He died in Paris on the 6th of January 1875.

During his abstention from politics Rémusat continued to write on philosophical history, especially English. Saint Anselme de Cantorbery appeared in 1854; L'Angleterre au XVIIIe siècle in 1856 (2nd ed. enlarged, 1862); Bacon, sa vie,
son temps, etc., in 1828; Channong, sa vie et ses œuvres, in 1863; John Wesley in 1870; Lord Herbert de Cherbury in 1874; Histoire de la philosophie en Angleterre depuis Bacon jusqu’à Locke in 1875; besides other and minor works. He wrote well, was a forcible speaker and an acute critic; but his adoption of the indeterminate eclecticism of Cousin in philosophy and of the somewhat similarly indeterminate liberalism of Thiers in politics probably limited his powers, though both no doubt accorded with his critical and unenthusiastic turn of mind.

His son Paul de Rémusat (1831–1897) became a distinguished journalist and writer. He was for many years a regular contributor to the Revue des deux mondes. He stood for election in Haute-Garonne, in 1869, in opposition to the imperial policy, and failed, but was elected to the National Assembly in 1871 and later. In 1890 he entered the Académie des sciences morales et politiques.

RÉMUSAT, JEAN PIERRE ABEL (1788–1832). French Chinese scholar, was born in Paris on the 5th of September 1788. He was educated for the medical profession, but a Chinese herbal in the collection of the Abbé Tersan attracted his attention, and he taught himself to read it by great perseverance and with imperfect help. At the end of five years' study he produced in 1811 an Essai sur la langue et la littérature chinoises, and a paper on foreign languages among the Chinese, which procured him the patronage of Silvestre de Sacy. In 1814 a chair of Chinese was founded at the Collège de France, and Rémusat was placed in it. From this time he gave himself wholly to the study of the Far East, and published a series of useful works, among which his contributions from Chinese sources to the history of the Tatar nations claim special notice. Rémusat became an editor of the Journal de savants in 1818, and founder and first secretary of the Paris Asiatic Society in 1822; he also held various Government appointments. He died at Paris on the 4th of June 1832. A list of his works is given in Quérard’s France littéraire s.v. Rémusat.

RENAISSANCE, THE.—The “Renaissance” or “Renascence” is a term used to indicate a well-known but indefinite space of time and a certain phase in the development of Europe. On the one hand it denotes the transition from that period of history which we call the middle ages (q.v.) to that which we call modern. On the other hand it implies those changes in the intellectual and moral attitude of the Western nations by which the transition was characterized. If we insist upon the literal and etymological meaning of the word, the Renaissance was a re-birth; and it is needful to inquire of what it was the re-birth. The metaphor of Renaissance may signify the entrance of the European nations upon a fresh stage of vital energy in general, implying a fuller consciousness and a freer exercise of faculties than had belonged to the medieval period. Or it may mean the resuscitation of simply intellectual activities, stimulated by the revival of antique learning and its application to the arts and literatures of modern peoples. Upon our choice between these two interpretations of the word depend important differences in any treatment of the subject. The commoner has the disadvantage of making it difficult to separate the Renaissance from other historical phases of the Reformation, for example—with which it ought not to be confounded. The latter has the merit of assigning a specific name to a limited series of events and group of facts, which can be distinguished for the purpose of analysis from other events and facts with which they are intimately but not indissolubly connected. In other words, the one definition of Renaissance makes it denote the whole change which came over Europe at the close of the middle ages. The other confines it to what was known by our ancestors as the Revival of Learning. Yet, when we concentrate attention on the recovery of antique culture, we become aware that this was only one phenomenon or symptom of a far wider and more comprehensive alteration in the conditions of the European races. We find it needful to retain both terms, Renaissance and Revival of Learning, and to show the relations between the series of events and facts which they severally imply. The Revival of Learning must be regarded as a function of that vital energy, an organ of that mental evolution, which brought into existence the modern world, with its new conceptions of philosophy and religion, its reawakened arts and sciences, its firmer grasp on the realities of human nature and the world, its manifold inventions and discoveries, its altered political systems, its expansive and progressive forces. Important as the Revival of Learning undoubtedly was, there are essential factors in the complex called the Renaissance with which it can but remotely be connected. When we analyse the whole group of phenomena which have to be considered, we perceive that some of the most essential have nothing or little to do with the revival of learning. By speaking, the decay of those great fabrics, church and empire, which ruled the middle ages both as ideas and as realities; the development of nationalities and languages; the enfeoffment of the feudal system throughout Europe; the invention and application of paper, the mariner’s compass, gunpowder, and printing; the exploration of continents beyond the ocean; and the substitution of the Copernican for the Ptolemaic system of astronomy. Europe in fact had been prepared for a thorough-going metamorphosis before that new ideal of human life and culture which the Revival of Learning brought to light had been made manifest. It had recovered from the confusion consequent upon the dissolution of the ancient Roman empire. The Teutonic tribes had been Christianized, civilized and assimilated to the previously Latinized races over whom they exercised the authority of conquerors. Comparative tranquillity and material comfort had succeeded to discord and rough living. Modern nationalities, defined as separate factors in a common system, were ready to co-operate upon the basis of European federation. The ideas of universal monarchy and of indivisible Christendom, incorporated in the Holy Roman Empire and the Roman Church, had so far lost their hold that scope was offered for the introduction of new ideas, both of Western origin, which have seen visionary or impious to the medieval mind. It is therefore obvious that some term, wider than Revival of Learning, descriptive of the change which began to pass over Europe in the 14th and 15th centuries, has to be adopted. That of Renaissance, Rinascimento, or Renascence is sufficient for the purpose, though we have to guard against the tyranny of what is after all a metaphor. We must not suffer it to lead us into rhetoric about the deadness and the darkness of the middle ages, or hamper our inquiry with preconceived assumptions that the re-birth in question was in any true sense a return to the irrecoverable pagan past. Neither must we imagine that there was any abrupt break with the middle ages. On the contrary, the Renaissance was rather the last stage of the middle ages, emerging from ecclesiastical and feudal despotism, developing what was original in medieval ideas by the light of classic arts and letters, holding in itself the promise of the modern world. It was therefore a period and a process of transition, fusion, preparation, tentative endeavour. And just at this point the real importance of the Revival of Learning may be indicated. That rediscovery of the classic past restored the confidence in their own faculties to men striving after spiritual freedom; revealed the continuity of history and the identity of human nature in spite of diverse creeds and different customs; held up for emulation master-works of literature, philosophy and art; provoked inquiry; encouraged criticism; shattered the narrow mental barriers imposed by medieval orthodoxy. 1) Humanism, a word which will often recur in the ensuing paragraphs, denotes a specific bias which the forces liberated in the Renaissance took from contact with the ancient world,—the particular form assumed by human self-esteem at that epoch,—the ideal of life and civilization evolved by the modern nations. It indicates the endeavour of man to reconstitute himself as a free being, not as the thrall of theological despotism, and the peculiar assistance he derived in this effort from Greek and Roman literature, the literae humaniores, letters leaning rather to the side of man than of divinity.
In this article the Renaissance will be considered as implying a comprehensive movement of the European intellect and will toward self-emancipation, toward reassertion of the natural rights of the reason and the senses, toward the conquest of this planet as a place of human occupation, and toward the formation of regulative theories both for states and individuals differing from those of medieval times. The key words here must be emphasized, for they point to the dual conception of universal empire and universal church, divinely appointed, sacred and inviolable, began to control the order of European society. Charles the Great (Charles Magne) lent his forces to the destruction of the communal empires of the Crusaders, and his own power made him the arbiter of western Europe, when the popacy needed his alliance, and when the Eastern Empire had passed under the usurped regency of a female. He modelled an empire, Roman in name but essentially Teutonic, since it owed such substance to its fabric possessed to Frankish armies and the sinews of the German people. As a structure composed of divergent ill-connected parts it fell to pieces at its builder's death, leaving little but the incubus of a memory, the fascination of a mighty name, to dominate the mind of medieval Europe. As an idea, the empire grew in visionary power, and remained one of the chief obstacles in the way of both Italian and German national cohesion, for real force was not in it but rather in that counterpart to its unlimited pretensions, the church, which had evolved it from barbarian night, and which used her own more vital energies for undermining the rival of her creation. Charles the Great, hell-bent human, had his successors, who were perhaps less ambitious of imitating the Augustus also in the sphere of letters. He caused a scheme of humanistic education to be formulated, and gave employment to his court of philosophers, of which there was then no end. But very little was accomplished in the revival of learning which Charles is supposed to have encouraged; and the empire he restored was accepted by the medieval intellect as the new theology. But, as the march of the modern literature, of the Italian Renaissance, was the more advanced, the Frankish codes, kept alive the practice and revived the science of Latin jurisprudence at an early period.

Philosophy had attempted to free itself from the trammels of theologism, of orthodoxy; and the speculations of some schoolmen, notably of Scotus Eriugena and Abelard. These innovators found, however, small support, and were defeated by opponents who used the same logical weapons with authority to back them. Nor were the rationalistic opinions of the Averroists without their value, though the church condemned these deviators from her discipline as heretics. The true material of the movement had been the man, since it rested upon the substance of real imperfection. Imperfect acquaintance with authors whom they studied in Latin translations made by Jews from Arabic commentaries on Greek texts, together with almost total ignorance of the laws, codes, and institutions of other scholastics of their epoch, they fought with phantoms in a visionary realm. A similar judgment may be passed upon those philosophers who were the champions of the French school, the Catholic creed who opposed the phalanxes of orthodoxy with frail imaginative weapons, and alarmed established orders in the state by the audacity of their communal opinions. Physical science strove to find a defect in the fundamental idea of the creation. But these men were accounted magicians by the vulgar; and, while the one eventually assumed the tiaara, the other was incarcerated in a dungeon. The schools meanwhile resounded still to the interminable dispute upon abstractions. Are only universals real, or has each name a corresponding entity? From the midst of the Franciscans who had persecuted Roger Bacon because he presumed to attack the dogma of the Assumption, their successor, the abbot of Parma, adopting and popularizing the mystical prophecy of Joachim of Flora. The reign of the Father is past; the reign of the Son is passing; the reign of the Spirit is at hand. Such was the symbolic meaning of the Eternity and the Spirit, which is the present of the Renaissance, has attracted retrospective students by its felicity of adaptation to their historical method. Yet we must remember that this bold intuition of the abbot Joachim indicated a monastic interpretation of the history of the church, as an anti-image of the current of Catholic faith was threatened with various forms of prophetism and Oriental mysticism, symptomatic of a widespread desire to grasp at something simpler, purer and less rigid than Latin science. The spirit which this movement evoked was not one of profound love of the life, devoid of a firm hold on the realities of life, these heresies passed away without solid results and were forgotten.
We are too apt to take for granted that the men of the middle ages were immersed in meditations on the other world, and that their lives were filled with the contemplation of the sacred page. The universities, halls, hermitages of the friars, and the Latin scholars, who had the great books of the ancient world in their libraries, were the only ones who were not deprived of positive knowledge. Yet there are abundant signs that the native human instincts, the natural human appetites, remained unaltered and alive beneath the crust of orthodoxy. The men of the middle ages resembled those natural forces of the natural man assumed, if we may trust the depositions of ecclesiastics well acquainted with his life, a form of ruthless atheistic cynicism. In the person of an emperor, Frederick II., the Pope, and the most cultivated monks, their philosophy was Epicurean scepticism. Frederick dreamed of remodelling society upon a mundane type, which anticipated the large toleration and cosmopolitan enlightenment of the actual Renaissance. But his efforts were stilted and impracticable, but unsuccessful, and by the incapacity of his contemporaries to understand his aims. After being forced in his lifetime to submit to authority, he was consigned by Dante to hell. Frederick's ideal of civilization was derived in a large measure from Provence, where a beautiful culture had prematurely bloomed, filling southern Europe with the perfume of poetry and gentle living. Here, if anywhere, it seemed as though the ecclesiastical and feudal fevers of the middle ages might be broken, and humanity might enter on a new stage of joyous unimpeded evolution. This was, however, not to be. The church preached Simon de Montfort's crusade, and organized Dominie's Inquisition. We must not call the Renaissance an "Age of Reason," for "L'amour" was exalted by sword, fire, famine and pestilence. Meanwhile the Provençal poets had developed their modern language with obscurities and paradoxes. Their chivalrous perfections of the Middle Ages, their chivalrous wit, their chivalrous witticisms, their chivalrous chivalrous dances were the life of the Renaissance.

In the naturalism of which we have been speaking found free utterance now in the fabulae of John Gower, of the romances of Chrétien de Troyes, of the romances of Britain, of the romances of Arthur and his knights—compositions varied in type and tone, but in all of which sincere passion and real enjoyment of life pierce through the thin veil of chivalrous mysticism or of allegory with which they are sometimes completely draped. The tales of Lancelot and Tristram, the lives of the troubadours and the Wacchus, the wanderer of the minnesingers, sufficiently prove with what sensuous freedom a knight loved the lady whom custom and art made him professedly constraining and too beautiful to be touched. Beatrix's adorer had a wife and children, and that Laura's poet owned a son and daughter by a concubine, in order to perceive that the poetic passion which was fostered by the middle ages, the passion with commonplace marriage or vulgar illegitimate connexions. But perhaps the most convincing testimony to the presence of this ineradicable naturalism is afforded by the Latin songs of wandering students. Galaard, Polyphemos, Goliardi. In these compositions, remarkable for their facile handling of medieval Latin rhymes and rhythms, the poetizing mysticism which envelopes chivalrous poetry is discarded, and simply calls for the frank and unadulterated view. Bacchus and Venus go hand in hand, as in the ancient antecedent of the Christian age. The open-air enjoyment of the wood, the field, the day, the daydream, the adoration of love, and the health of the body.

No grave note, warning us that the pleasures of this earth are fleeting, that the visible world is but a symbol of the invisible, that human life is a probation for the life beyond, interrupts the timbre of this song. The measure that whistles, and the charm to these unique relics of the 13th century. Goliardic poetry is further curious as showing how the classics even at that early period were a fountain-head of pagan inspiration. In the taverns and low places of amusement haunted by those lettered sons of the road, and in the forests trodden by their vagrant feet, the deities of Greece and Rome were not in exile, but at home within the hearts of living men. Thus, while Christendom was still preserving the sacred pages, the church, with its naturalism and enthusiasm for antique modes of feeling, already brought their latent potency to light, preternaturally indeed, and presented a new form to the theme that was destined to be broken.

When due regard is paid to these miscellaneous evidences of intellectual and sensual freedom during the middle ages, it will be seen that there were by no means lacking elements of naturalism and vice ready to be seized. What the church was not vitality and licence, not aducity of speculation, not lawless instinct or rebellious impulse. It was rather the right touch on life, the right feeling for human independence, the right image of the soul as the sovereign of philosophy, scholarship and literature, that failed. The courage that is born of knowledge, the calm strength begotten by a positive attitude of mind, found no more adequate exponent than the shadowing of divinity, of theology, of law. We may fairly say that such a failure had more of the just intuition that was needed than learned folk trained in the schools. But these people were rendered licentious in regard to heathen and sanctimonious, that by ignominy, by uncease dread of the doom declared for heretics and rebels. The massive vengeance of the church hung over them, like a heavy sword suspended in the cloudy air. Superstition and stupidity hung in an oracular attitude above the heads of observers and was the only means of winning power over nature or insight into mysteries surrounding human life. The path from darkness to light was lost; the works of art and the combat of reason with prejudice was perverted into an incept system of grotesque and pious palming; the pursuit of truth had become a game of wordy dialectics. The other world, with its imagined heaven and hell, haunted the conscience of man. The mind of the middle ages seemed, however fair the flesh, both world and flesh were theoretically given over to the devil. It was not worth while to master and economize the resources of this earth, to utilize the good and ameliorate the evils of this life, while everyone agreed, in theory, at any rate, that the present was but a bad prelude to an infinitely worse or infinitely better future. To escape from these preoccupations and prejudices except upon the path of conscious and deliberate sin was impossible, but it was possible for them to find courage; and these were too often reduced to the recantation of their supposed errors no less by some secret clinging sense of guilt than by the church's iron hand. Man and the actual universe kept on reasserting their rights and claims, announcing their goodliness and delightfulness, in one way or another; but they were always being thrust back again into Cimmerian regions of abstractions, fictions, visions, spectral hopes and fears, in the midst of which the intellect somnambulist made an unknown way.

At this point the Revival of Learning intervened to determine the course of the Renaissance. Medieval students possessed a considerable portion of the Latins classics, though the Greek had become in the fullest sense of the phrase a dead language. But what they retained of ancient literature they could not comprehend in the right spirit. Between them and the text of poet or historian hung a veil of mysticism, a vapour of misapprehension. The odour of unsanctity clung around those relics of the pagan past. Men bred in the cloister and the lecture-room of the logicians, trained in scholastic disputations, versed in allegorical interpretations of the plainest words and most apparent facts, could not find those new lights which might dispel the mist of beauty. Petrarch first opened a new method in scholarship, and revealed what we denote as humanism. In his teaching lay the twofold discovery of man and of the world. For humanism, which was the vital element in the Revival of Learning, consists mainly of a just perception of the dignity of man as a rational, volitional and sentient being, born upon this earth with a right to use it and enjoy it. Humanism implied the rejection of those visions of a future and imagined state of souls as the only absolute reality, which had the imagination of the middle ages. It involved a vivid recognition of the value of the earth as the home and abode of the great monuments of human power recovered from the past. It stimulated the curiosity of latent sensibilities, provoked fresh inquisition into the groundwork of existence, and strengthened man's self-esteem by knowledge of what men had thought and felt and done in ages when Christianity was not. It roused a desire to reappropriate the whole abandoned provinces of mundane energy, and a hope to emulate antiquity in works of living loveliness and vigour. The Italians of the 14th century, more precocious than the other European races, were ripe for this emancipation of enslaved intelligence. In the classics found the fertile minds of the highest order as they were, and a variety of circumstances, among which must be reckoned the pride of a nation boasting of its descent from the Populus Romanus, rendered them apt to sling aside the obstacles that had impeded the free action of the mind through many centuries. Petrarch not only set his countrymen upon the right method of studying the Latin classics, but he also divinized the importance of recovering a knowledge of Greek literature. To this task Boccaccio addressed himself; and he was followed by numerous Italian enthusiasts, who visited Byzantium before its fall as the sacred city of a new revelation. The next step was to collect MSS. to hunt out, copy and preserve the precious relics of the past. In this work of accumulation Guarino and Filippo, Auriel and Poggi, took the chief part, aided by the wealth of Italian patricians, merchant-princes and despot, who were inspired by the sacred thirst for learning. Learning was then,
no mere pursuit of a special and reclusive class. It was fashionable and it was passionate, pervading all society with the fervour of romance. For a generation nurtured in decadent scholasticism and a stereotyped theological formula it was the fountain of renascent youth, beauty and freedom, the shape in which the Helen of art and poetry, appeared to the ravished eyes of medieval Faustus. It was the resurrection of the mightiest spirits of the past. “I go,” said Cynric of Ancona, the indefatigable though uncritical explorer of antiquities, “I go to awake the dead!” This was the enthusiasm, this the vitalizing faith, which made the work of scholarship in the 15th century so highly strung and ardent. The men who followed it knew that they were restoring humanity to its birthright after the expiation of ten centuries. They were instinctively aware that the effort was for liberty of action, thought and conscience in the future. This conviction made young men leave their loves and pleasures, grave men quit their counting-houses, churchmen desert their missals, to crowd the lecture-rooms of philologers and rhetoricians. When Greek had been acquired, MSS. accumulated, libraries and museums formed, came the age of printers and expositors. Aldus Manutius in Italy, Froben in Basel, the Étèennes in Paris, committed to the press what the investigators had recovered. Nor were there wanting men who dedicated their powers to Hebrew and Oriental erudition, laying, together with the Grecians, a basis for those Biblical studies which advanced the Reformation. Meanwhile the languages of Greece and Rome had been so thoroughly appropriated that a final race of scholars, headed by Politian, Pontano, Valla, handled once again in verse and prose both antique dialects, and thrilled the ears of Europe with new-made pagan melodies. The church itself at this epoch lent its influence to the prevalent enthusiasm. Nicholas V. and Leo X. not to mention intervening popes who showed themselves tolerant of Humanistic culture, were heroes of the classical revival. Scholarship became the surest path of advancement to ecclesiastical and political honours. Italy was one great school of the new learning at the moment when the German, French and Spanish nations were invited to her feast.

It will be well to describe briefly, but in detail, what this meeting of the modern with the ancient mind effected over the whole field of intellectual interests. In doing so, we must be careful to remember that the study of the classics did but give a special impulse to pent-up energies which were bound in one way or another to assert their independence. Without the Revival of Learning the direction of those forces would have been different; but that novel intuitions into the nature of the world and man which constitute what we describe as Humanism must have been destined to make their appearance. As the facts, however, stand before us, it is impossible to dissociate the rejection of the other world as the sole reality, the joyous acceptance of this world as a place to live and act in, the conviction that “the proper study of mankind is man,” from Humanism. Humanism, as it actually appeared in Italy, was positive in its conception of the problems to be solved, pagan in its contempt for medieval mysticism, invigorated for sensuous enjoyment by contact with antiquity, yet holding in itself the germ of new religious aspirations, profounder science and sterner probings of the mysteries of life than had been attempted even by the ancients. The operation of this humanistic spirit has now to be traced.

It is obvious that Italian literature owed little at the outset to the Revival of Learning. The Divine Comedy, the Canzoniere and the Decameron were works of monumental art, and already in the form which we now possess, than any of the classics, but applying the originality of Italian genius to matter drawn from previous medieval sources. Dante showed both in his epic poem and in his lyrics that he had not abandoned the sphere of contemporary thought. Allegory and theology, the vision and the symbol, still determine the form of masterpieces which for perfection of workmanship and for emancipated force of intellect rank among the highest products of the human mind. Yet they are not medieval in the same sense as the song of Roland or the Arthurian cycle. They proved that, though Italy came late into the realm of literature, her action was destined to be decisive and alternative by the introduction of a new spirit, a firmer and more positive grasp on life and art. These qualities she owed to her spiritual prosperity; to in a word, the leading idea of the Reformed, rationalized church, her commercial nobility, her political independence in a federation of small states. Petrarch and Boccaccio, though they both held the medieval doctrine that literature should teach some moral lesson and that the function of the poet was to bring up the sick, to purify, to improve, to describe, to persuade, to poise and to improve the vernacular abandoned both allegory and symbol. In their practice they ignored their theory. Petrarch’s lyrics continue the Provencal tradition as it had been followed by Tournel and Francesco Petrarca; his sonnets, with the intervening emotion, a purer and more chastened style, than his masters could boast. Boccaccio’s tales, in like manner, continue the tradition of the fabliaux, raising that literary species to the rank of finished literature, and slightly changing it by keen insight into all varieties of character. The Canzoniere and the Decameron distinguish themselves from medieval literature, above all, by the truth of the conviction, and the natural handling of human nature. So much had to be premised in order to make it clear in what relation Humanism stood to the Renaissance, since the Italian work of Dante, Petrarch and Boccaccio is sufficient to indicate the re-birth of the spirit after ages of apparent deadness. Had the Revival of Learning not intervened it is probable that the vigorous efforts of these writers alone would have inaugurated a new age of European culture. Yet, while noting the operation of Petrarch’s influence must also be noted that they felt themselves under some peculiar obligation to the classics. Dante, medieval as his temper seems to us, chose Virgil for his guide, and of his metrical work he would have been the first to admire. Petrarch and Boccaccio were, as we have seen, the pioneers of the new learning. They held their writings in the vernacular cheap, and initiated that contempt for the mother tongue which was a note of the earlier Renaissance; Giovanni Villani, the chronicler who used Italian for the compilation of a methodical history, tells us how he was impelled to write by musing on the ruins of Rome and thinking of the vanished greatness of the Latin race. We have therefore to recognize that the four greatest writers of the 14th century, while the Revival of Learning was yet in its cradle, each after his own fashion acknowledged the vivifying touch upon their spirit of the antique genius. They seem to have been conscious that they could not partake of the church, and art without contact with the classics; and, in spite of the splendour of their achievements in Italian, they found no immediate forerunners than the Latins.
practice of Italian poetry. Their work is the absolutely modern work,—modern in the sense of having absorbed the stores of classic learning and reproduced those treasures in forms of simple, natural, but melodious verse. Boiardo and Ariosto adopted a similar technique, the fusion of classic mythology with chivalrous romance in his Orlando Innamorato. But the victim's laurels were reserved for Ariosto, whose Orlando Furioso is the purest and most perfect example of the genre. The work, written in Italian a form which they had acquired and assimilated from the classics that these poets showed the transformation effected in the field of literature by humanism. The whole method and spirit of medieval art had been submerged in the flood of ideas coming from the Copernican revolution of the Renaissance, as if it were a preposterous notion. The men of the Renaissance conceived the deities, if deity there be, that rules in it, is beauty. Interest is confined to the actions, passions, sufferings and joys of human life, without a thought of its spiritual and immortal destinies. Of the idea of salvation, of the power and glory of God, they are supposed to care nothing. In the drama the pedantry of the Revival, which had not injured romantic literature, made itself entirely felt. The nobler elements of poetic feeling were supplanted by the more brutal elements of the stage. Seneca was chosen as the model of tragedy; Plautus and Terence supplied the groundwork of comedy. Thus in the plays of Rucellai, Tirschino, Sperone and other tragic poets the noble elements of humanism considered as a revelation of the world's spiritual truths, were lavished with full technique and originality. At about the same time Niccolò Fasano (d. 1728) studied the style of sculpture in fragments of Gracco-Roman marbles. His manner influenced Giott, who set painting on a firm footing for the first time by subordinating the other arts to the shortcomings of the human body, that it was but a fresh light on the antique workmanship of the 14th and 15th centuries. The classical stimulus came to painters, sculptors and architects chiefly through literature. There was a definite movement for imitation of ancient sculpture. This interest displayed itself in a passionate study of perspective, nature and the nude. Yet we find in the writings of Ghiberti and Alberti, we notice in the masterpieces of these men and their compatriots Brunelleschi, Pollaiuolo, Doni, the 15th century artists, who were fascinated by the world of classical grace and science. Gradually, as the race became penetrated with antique thought, the taste of modern artists was modified. Gothic architecture, which had always flourished fearfully on Italian soil, was supplanted by a hybrid Roman style. The study of Vitruvius gave strong support to that pseudo-classic manner, which, when it reached its final point in Palladio's work, overspread the whole of Europe and dominated taste during the 18th century. But the perfect plastic art of Italy, the pure art of the Cinque Cento, the painting of Raphael, Da Vinci, Titian and Michelangelo, the sculpture of Donatello, the architecture of Sansovino, the architecture of Brancante, Omodeo and the Venetian Lombardi, however much imbued with the spirit of the classical revival, takes rank beside the poetry of Ariosto as a free intelligent production of an enriched mind. It is characteristic of the outcome of studies in antiquity as an exhibition of emancipated modern genius fired and illuminated by the masterpieces of the past. The Renaissance art seemed remote from the middle ages, insomuch as it is permanently natural. It is terrible, not in each and all of its many-sided manifestations strictly human. Its touch on classical mythology is original, rarely imitative or pedantic. The art of the Renaissance was an apotheosis of the beauty of the world and man in unaffected spontaneity, without side thoughts for piety or erudition, inspired by pure delight in loveliness and harmony for their own sake. In the fields of science and philosophy humanism was cut with similar important changes. Petrarch began by weighing relentless war with the logicians and materialists of his own day. With the advance made in Greek studies scholastic methods were finally abandoned. The spirit of the Renaissance is characterized by the curiosity for nature encouraged men like Alberti, da Vinci, Toscacelli and Da Porta to make practical experiments, as to the workings of physical forces, and invent scientific instruments. Anatomy began to be studied, and the time was not far distant when Titian should lend his pencil to the epoch-making treatise of Vesalius. The middle ages had been satisfied with abstract conceptions and dogmas about the body of man, which was regarded with too much suspicion to be studied. Now the right method of interrogating nature with patience and loving admiration was instituted. At the same time the one-sided and rigid orthodoxy that led to the scientific so far-reaching in their results as those of Copernicus, Columbus and Galileo. In philosophy, properly so called, the ethical and philosophical ideas of the ancient thinkers were preserved and many a second-rate scholar wrote a clumsy and clutzy compilation. So the ethical traditions of the ancients were deficient in substance, while Ficino's attempt to revive Platonism betrays an unconcealed conception of his master's drily. It was something, however, to have shaken off the shackles of ecclesiastical authority; and, even if a new authority, that of humanism, was substituted, there was no room for the ponderous methods of classic humanism. This is noticeable in Pomponazzo's system of materialism, based on the interpretation of Aristotle, but revealing a virile spirit of disinterested and unprefunctioned research. The thinkers of southern Italy, Leonardo, Bruno and Campanella, at last opened the two chief lines on which modern speculation has since moved. Telesio and Campanella may be termed the predecessors of Bacon. Bruno was the precursor of Descartes. Campanella's materialist philosophy of the world had been evolved from the poets and their minds from classical as well as ecclesiastical authority, proving that the emanicipation of the will had been accomplished. It must be added that their writings, like every other product of the Renaissance, were remained chiefly in the hands of the scholars and the few who could find a reading public, although their ideas were gradually assumed by the public at large, and were seen in a new light, as religious and worldly, in the hands of the orators, taught Greek, and commented upon the systems of philosophers. The medieval curriculum offered no defined place for the study of classical literature. That place is the name. Chairs had to be founded under the title of rhetoric, from which men like Chrismarolos and Guarini, Filielo and Politz expounded orally to hundreds of eager students from every town and county and from the foreign students, who found in the universities an open door to the secrets of antiquity. One mass of Greek and Roman erudition, including history and metaphysics, law and science, civic institutions and the art of war, mythology and magicstracies, medical knowledge and religious rites, grammar and philology, biography and numismatics, formed the miscellaneous subject-matter of this so-styled rhetoric. Notes taken at the lecture-room, and a certain tradition of treating the antique authors for the display of general learning, as well as for the elucidation of their texts, came into vogue, which has...

Criticisms

Fine art.

The relation of the plastic arts to the revival of learning is similar to that which has been sketched in the case of poetry. Cimabue and Giotto were working in the direction of Gothic art, but little was brought to light of antique workmanship during the 14th and 15th centuries. The classical stimulus came to painters, sculptors and architects chiefly through literature. Therefore these three branches of art, like poetry, were more or less influenced by the spirit of the Renaissance, that displayed itself in a passionate study of perspective, nature and the nude. Yet we find in the writings of Ghiberti and Alberti, we notice in the masterpieces of these men and their compatriots Brunelleschi, Pollaiuolo, Doni, the 15th century artists, who were fascinated by the world of classical grace and science. Gradually, as the race became penetrated with antique thought, the taste of modern artists was modified. RENAISSANCE

determined the method of scholarship for the last three centuries in Europe. The lack of printed books in the first period of the Renaissance, and the comparative rarity of Greek erudition among students, combined with the intense enthusiasm for the monuments of the classics, gave special value to the personal teaching of these professors. They journeyed from city to city, attracted by promises of higher pay, and allure of ever-growing laurels of popularity. Even large and famous academies, universities, or universities, similar institutions under varying designations, for the exposition of the *litterae humaniores*. The humanists, or professors of that branch of knowledge, became known as *humanitatius* for their diligence in the study of Latin and Greek. The *humanitatius* undertook the charge of private education, opening schools which displaced the medieval system of instruction, and taking engagements as tutors in the families of dukes, noblemen and wealthy merchants. The academy established by Iturrieda de Feltrer at Mantua under the protection of Gian Francesco Gonzaga for the training of pupils of both sexes, might be chosen as the type of this Italian method. His scholars, who were lodged in appartment, met daily to hear the master read and lecture on the classics. They learned portions of the best authors by heart, exerted themselves in translation from one language to another, and practised composition in producing elegies, epistles, and *conversi,* or short cuts, written in imitation of the classics. As the *humanitatius* did not subscribe to the memory, and the classics, as they were unspoken, they were not in the least neglected. The judgment should be formed by critical analysis, attention to style, and comparison of the authors of a decadent age with those of a golden period. During the 15th century, a large numbers of recreative physical exercises, as fencing, riding and gymnastics, were conducted under qualified trainers. From this sketch it will be seen how closely the educational system which came into Europe at the beginning of the Renaissance, to which Italy was the most accessible and in which it prevails to the present time, was modelled upon the Italian type. European youths who spend their time at Eton between athletic sports and Latin verses, and who take an Ireland with a first of Greek, are pursuing the same course of physical and mental discipline as the princes of Gonzaga or Montefeltro in the 15th century.

The humanists effect a deeply penetrating change in social manners. Through their influence as tutors, professors, orators and courtiers, society was permeated by a fresh ideal of culture. To be a gentleman in Italy meant at this epoch to conform to the principles of that new fermentation. Not content with the traditional occupations of scholarship, refined in diction, capable of corresponding or of speaking in choice phrases, open to the beauty of the arts, intelligently interested in archaeology, taking for his models of conduct the great men of antiquity rather than the saints of the Christian religion, was expected to prove himself an adept in physical exercises and in the courteous observances which survived from chivalry. The type is set before us by Castiglione in that book which ranks with the court literature of the age.* The genre is further emphasized in a famous passage of the *Orlando Innamorato* where Boiardo compares the Italian ideal of an accomplished gentleman with that of the Greeks. "The men of the north, exalted by the thought of the enlightened awakening of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the race was still comparatively barbarous.

This picture has undoubtedly a darker side. Humanism, in its revout against the middle ages, was, as we have seen already, mundane, pagan, irreligious, positive. The Renaissance can, after all, be regarded only as a period of transition in which much of the good of the past was sacrificed while some of the evil was retained, and neither the bad nor the good of the future was brought clearly into fact. Beneath the surface of brilliant social culture lurked gross appetites and savage passions, unrestrained by medieval piety, untutored by modern experience. Italian society exhibited an almost unexampled licence and immorality. The men of the movement were crossed by lusts of lust, treasons, poisonings, assassinations, violence. A succession of worldly pontiffs brought the church into flagrant discord with the principles of Christianity. Steeped in paganism and immorality, their doctrines were accepted by men used to think and feel in harmony with Ovid and Theocritus, and at the same time rendered cynical by the corruption of papal Rome, the educated classes lost their grasp upon morality. Political movements, which in the Middle Ages were the expression of both good and evil, were in the Renaissance performances of both good and evil, were in the Renaissance the expression of political battles, of the interests of factions. When the insidious foreigner of their age, the bitter satirists of its vices, but themselves infected with its incapacity for moral goodness. Not only were the Italians vitiated; but they also had become impotent for action and resistance. At the height of the Renaissance the five great powers in the peninsula formed a confederation of independent but mutually attractive and rebellious states. Equilibrium was maintained by diplomacy, in which the humanists played a foremost part, casting a network of intrigue over the nation which helped in no small degree to contribute to the propagation of culture, but which accustomed statesmen to believe that everything could be achieved by wire-pulling. Wars were conducted on a showy system by means of mercenaries, who were trained and drilled by the common לר, in a way of bloodless campaigns. Meanwhile the people grew up unused to arms. When Italy between the years 1494 and 1530 became the battlefield of French, German and Spanish forces, it was seen to what a point of helplessness the political, moral and social conditions of the Renaissance had brought the nation.

It was needful to study at some length the main phenomena of the Renaissance in Italy, because of the history of that phase of evolution in the other Western races turns almost entirely upon points in which they either adhered to or diverged from the type established there. Speaking broadly, what France, Germany, Spain and England assimilated from Italy at this epoch was in the first place the new learning, as it was then called. This implied the new conception of human life, the new interest in the material universe, the new teaching for the new condition which we have seen to be inseparable from Italian humanism. Under these forms of intellectual enlightenment and polite culture the renascence of the human spirit had appeared in Italy, where it was more than elsewhere connected with the study of classical antiquity. But that audacious exploratory energy which formed the motive force of the Renaissance as distinguished from the Revival of Learning took, as we shall see, very different directions in the several nations who now were sending the flower of their youth to study at the feet of Italian rhetoricians.

The Renaissance ran its course in Italy with strange indifferences and consequences. The five great powers, held in equilibrium by Lorenzo de' Medici, dreamed that the peninsula could be maintained in status quo by diplomacy. The church saw no danger in encouraging a pseudo-pagan ideal of life, violating its own principle of existence by assuming the policy of an agrandizing secular state, and outraging Christendom openly by its acts and utterances. Society at large was hardly aware that an intellectual force of stupendous magnitude and in calculable explosive power had been created by the new learning. Why should not established institutions proceed upon the customary and convenient methods of routine, while the delights of the world were augmented by the new literature, and a golden age of epicurean ease made decent by a state religion which no one cared to break with because no one was left to regard it seriously? This was the attitude of the Italians when the Renaissance, which they had initiated as a thing of beauty, began to operate as a thing of power beyond the Alps.

Germany was already provided with universities, seven of which had been founded between 1348 and 1400. In these haunts of learning the new studies took root after the year 1440, chiefly through the influence of travelling professors, Peter Pirckheimer, and Samuel Karoch. German scholars made their way to Lombard and Tuscan lecture-rooms, bringing back the methods of the humanists. Greek, Latin and Hebrew erudition soon found itself at home on Teutonic soil. Like Italian men of letters, these pioneers of humanism gave a classic turn to their patronymics; unfamiliar names, Crotsus Rabanus and Plierus partus, continued to be used by the north. This opened the awakened intelligence of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the race was still comparatively barbarous.

The Revival of Learning in Germany.

In these haunts of learning the new studies took root after the year 1440, chiefly through the influence of travelling professors, Peter Pirckheimer, and Samuel Karoch. German scholars made their way to Lombard and Tuscan lecture-rooms, bringing back the methods of the humanists. Greek, Latin and Hebrew erudition soon found itself at home on Teutonic soil. Like Italian men of letters, these pioneers of humanism gave a classic turn to their patronymics; unfamiliar names, Crotsus Rabanus and Plierus partus, continued to be used by the north. This opened the awakened intelligence of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the race was still comparatively barbarous.

The Revival of Learning in Germany.

The German Reformation was incapable of propagating itself in Italy, chiefly for the reason that the intellectual forces which it had to contend with were the more developed, and that the public taste was more widely and accurately disseminated. It would have been sufficient for the Reformers to have converted only the fathers and sons of humanist families, and to have induced them to go to the universities of Italy and France to acquire the human learning which they so much desired. But the Italian humanists were not content with acquiring this learning. They attempted to make humanism the foundation of a new world, and to use it as a weapon against the superstitions of the age.

The Italian humanists were led to this conclusion by the fact that they were the first to perceive the full import of the discoveries of the ancients. They saw that the ancients had written in Latin, and that Latin was the language of the Church. They therefore concluded that the true way to the heart of the Church was through Latin. They therefore turned their attention to the study of Latin, and to the reproduction of the Latin classics.

The Italian humanists were also led to this conclusion by the fact that they were the first to perceive the full import of the discoveries of the ancients. They saw that the ancients had written in Latin, and that Latin was the language of the Church. They therefore concluded that the true way to the heart of the Church was through Latin. They therefore turned their attention to the study of Latin, and to the reproduction of the Latin classics.

displayed essential qualities of intellectual freedom, delight in life, exultation over rediscovered earth and man. The note of Renaissance work in the field of art was new. This we feel a penetrative earnestness of Dürrer, in the homeliness of Hans Sachs, in the grotesque humour of Eulenspiegel and the Narrenschiff, the sombre pregnancy of the Faust legend, the almost stolid mastery of Cranach. In the other arts, the more or less successful attempt to escape the preoccupations and the limitations of the middle ages, for this reason mainly that what we call medieval was to a very large extent Teutonic. But on the Spanish peninsula, in the masterpieces of the still colourless and cold years of Pizarro’s rise to power, the centre into an atmosphere of art, definitely national, distinctly modern, where solid natural forms stand before us realistically modelled, with light and shadow coming alike, and the siring of the whole a whole, the fancy take shape and weave a dance of rhythmical, light, incomparable intricacy. The Spanish Renaissance would in itself suffice, if other witnesses were wanting, to prove how inaccurate is the theory that limits this movement to one revival of learning. Touched by Italian influences, enriched and fortified by the new learning, Spanish genius walked firmly forward on its own path. It was only crushed by forces generated in the nation that produced it, by the Inquisition and by despotic Catholic absolutism.

In the history of the Renaissance, Spain and Portugal represent the exploration of the ocean and the colonization of the other Hemisphere. The voyages of Columbus and Vasco da Gama, the discovery of the sea route to India by Vasco da Gama, the occupation of the Gulf of Mexico by La Salle, and Pizarro’s campaign against the Inca, marked a new era for the human race and inaugurated the modern age more decisively than any other series of events has done. It has recently been maintained that modern European history begins as a result of the voyages of discovery, but the nations of the Mediterranean, the states for the possession of lands revealed by Columbus and Da Gama. Without challenging or adopting this speculation, it may be safely affirmed that nothing so pregnant of results has happened as this exploration of the new continents. The initiative of the civilizations of the East was dissolved, the centre of gravity in politics and commerce, substituting the ocean for the Mediterranean, dethroning Italy from her seat of central importance in traffic, depressing the eastern and elevating the western powers of Europe. The Renaissance in Spain received a powerful impulse from the discovery of the New World and the dislodging of humanist power from the center of intellectual life. It is true enough to vindicate the vast significance of these discoveries. The Renaissance, far from being the re- birth of antiquity with its civilization confined to the Mediterranean, with its Hercules’ Pillars beyond which lay Cimmerian darkness, was thus effectively the entrance upon a quite in calculably wider stage of life, on which mankind at large has since enacted one great drama.

While Spanish navies were exploring the ocean, and Spanish paladins were overturning empires, Charles V. headed the reaction of Catholicism against reform. Stronger as king of Spain than as Emperor, far more at home for the conquest of Italy, he lent the weight of his authority to that system of coercion and repression which enslaved Italy, desolated Germany with war, and drowned the Low Countries in blood. Philip II. was the most religious of the Catholic monarchs, pursuing a policy in an even stricter spirit. He was powerfully assisted by two institutions, in which the national character of Spain expressed itself, the Inquisition and the Society of Jesus. Of the former it is not needful to speak here. We have to observe that the last great phenomenon of the Spanish Renaissance was Ignatius Loyola, who organized the militia by means of which the church worked her Counter-Reformation. His motto, Per as ac cadre, expressed that recognition of absolutism which anarchy and monarchy demanded for their consolidation (see Jesuits and Loyola).

The logical order of an essay which attempts to show how Renaissance was correlated to Reformation and Counter-Reformation has necessitated the treatment of the subject in the reverse order. Germany and Spain in succession; for these three nations were the three main agents in the triple process to be analysed. It was due to their specific qualities that the repercussions of the new impulse, of the development, that the re-birth of Europe took this form of duplex action on the lines of intellectual and moral process, followed by reaction against mental freedom. We have now to speak of France, which earliest absorbed the influence of the Italian revival, and of England, which received it latest. The Renaissance may be said to have begun in France with Charles VIII.’s expedition to Naples, and to have continued until the extinction of the house of Valois. Louis XII. and Francis I. spent a considerable portion of their reigns in the attempt to secure possession of the Italian provinces they claimed. Henry II.’s queen was Catherine of the Medicin family; and her children, Charles IX. and Henry III., were Italianated Frenchmen. Thus the connexion between France and Italy during the period 1540-1559 was continuous. The French passed to and fro across the Alps on military and peaceful expeditions. Italians came to France as courtiers, ambassadors, men of business, captains and artists. French society assumed a marked foreign character. The manners of the upper classes were different from those of an Italian city, except that externally they remained ruder and less polished. The relation between the crown and its great feudatories, the military bias of the aristocracy, and the marked distinction between classes which survived from the middle ages, rendered in many vital points unlike Italy. Yet the annals of that age, and the anecdotes retailled by Brantôme, prove that the royalty and nobility of France had been largely Italianized.

This is shown by the fact that Louis XII. brought Fra Giocondo of Verona back with him to France, and founded a school of architects. But we need not recur to this legend for the explanation of such Italian influences as were already noticeable during the Empire. What was determining the French style, Italian intercourse helped to stimulate its formation and development. There are students of the 15th century in France who resent this intrusion of foreign elements. But, as we have already said, the inexorable laws of human evolution to obey the impulse which communicated itself to every form of art in Europe. In the school of Fontainebleau, under the patronage of Francis I., that Italian art made itself felt; yet the work of that art had been already formed, which, when it was subsequently applied at Paris, preserved a marked national quality. The characteristic features which were to give to French art a new form, and elevate it above the rest, were in the process of being formed: the spirit of the French nobility, the outlines and spirit of the French outline. We find, in the Louvre and elsewhere, a blending of capricious fancy and inventive richness of decoration with purity of outline that was typical of the French School. It was under Francis I. that the Louvre was planned, and the designs of the Louvre, with the other castles of Touraine, and passing onward to the Tuileries, we trace the passage from the medieval fortress to the modern pleasure-house, and note how architecture obeyed the special demands of that new phenomenon of Renaissance civiliza tion, the court. In the general distribution of parts these monumental buildings express the peculiar conditions which French court life assumed under the influence of Francis I. and Diane de Poitiers. In detail execution and harmonic combinations they illustrate the precision, logic, lucidity and cheerful spirit of the national genius. Here, as in Lombardy, a feeling for serene beauty that came from the study of architecture was at work, that formed a style indigenous to France and eminently characteristic of the French temperament.

During the reign of Francis I., several Italian painters of repute, including Domenico Beccafumi, Del Rosso, Francesco Salviati, and Domenico and Domenico Fetti, were in France, and the French court took a great interest in the Flemish, to embody the spirit of the classical revival. These three masters were the contemporaries of Correggio, and do not belong to the Renaissance period. Sculpture, on the contrary, in which art, as in architecture, the medieval French had been surpassed by no other people of Europe, was practised with originality and power in the reigns of Henry II. and Francis I. Pontezio and Cellini, who quitted Italy for France, found themselves outrivalled in their own sphere by Jean Goujon, Cousin and Pilon. The decorative sculpture of this epoch, whether combined with architecture or isolated in monumental statuary, ran through surface and gained a beauty which is at the same time is unmistakably inspired by a sense of beauty different from the Italian—more piquant and pointed, less languorous, more restrained perhaps, but less of the chaste and noble. All this while, the minor arts of enamelling, miniature, glass-painting, goldsmith’s work, jewellery, engraving, tapestry, wood-carving, pottery, &c., were cultivated with a spontaneity and freedom which profoundly impressed the French. Italy, in the 16th century, was able to use both influences without a sacrifice of native taste. It may indeed be said in general that what is true of France is likewise true of all countries which felt the artistic impulses of the Italian Renaissance. With regard to France, we are in our present position towards Italy. At the present day we find a national impress stamped upon the products of the plastic and the decorative arts, notwithstanding the prevalence of certain forms derived from the antique and Italy. It was only at a later period that the formalism of the pedantry reduced natural and national originality to a dead unanimity.
French literature was quick to respond to Renaissance influences. De Comines, the historian of Charles VIII's expedition to Naples, wrote of the world of perspicuity and analytical penetration of a Venetian ambassador. Villon, his contemporary, may rather be ranked, so far as artistic form and use of knowledge are concerned, with poets of the French School, and in particular with La Fontaine, for he is essentially modern in the vividness of his self-portraiture and in what we are wont to call realism. Both De Comines and Villon indicate the entrance of a new quality into literature. The Rhetoriqueurs, with their profane elegance, and their treatment by their use of allegory and complicated metrical systems, sought to improve the French language by introducing Latinism. Thus the Revival of the classical type, made popular by Garnier's genius, was elaborated, as in Italy, upon the model of Seneca and the canons of the three unities. The tradition thus formed was continued and developed by the French poets of the 16th century. Translation from Greek and Latin into French progressed rapidly at the commencement of this period. It was not till the 17th century that it was continued to approach on a scale. The spoils of Greece and Rome for the profit of the mother tongue. Amyot's Plutarch and his Daphnis and Chloe rank next to the most exquisite examples of beautiful French prose. Prose had now the charm of the refined skill of Du Bartas combined with the lucidity of the poet. The French poet is mentioned in the most entertaining of gossips. To speak of Montaigne is to speak of the best as well as the first of essayists. In all the literary work which has been mentioned, the originality and strength of the French style is not so much to be contrasted with its saturation with the new learning and with Italian studies. But the greatest name of the epoch, the name which is synonymous with the Renaissance in France, has yet to be uttered. That, of course, is Rabelais. His incomparable masterpieces of mingled humour, wisdom, satire, erudition, indigence, profusion, levity, imagination, reason, and eloquence are the whole skin and flesh of the Aristophanic farce. What Ariosto is for Italy, Cervantes for Spain, Erasmus for Holland, Luther for Germany, Shakespeare for England, that is Rabelais for France. The Renaissance cannot be described in France without reference to him, the Renaissance group of his time, with these seven representatives of its manifold and many-sided inspiration.

The French Renaissance, so rich on the side of arts and letters, was, however, less rich on the side of classical studies. The revival of learning has a noble nester roll of names in France—Turnebus, the patriarch of Hellenistic studies; the Eratines of Paris, equaling in numbers, industry, and learning their Venetian rivals; the two Scalliers; impassioned Dolet; eloquent Muret; learned Cujas; terrible Calvin; Ramus, the intrepid antagonist of Aristotle; De Thou and De Béze Aponderous Casaubon; brilliant young Saumaise. The distinguishing characteristics of French scholars are vivace intelligence, critical acuteness and polemical acumen, perspicuity of expression, learning directed in its application to a practical and intellectual end far rather than to aesthetic ends. Some of the names just mentioned remind us that in France, as in Germany and Holland, the Reformation was closely connected with the Renaissance. The latter has never been in France to the narrow sense of that term Protestant; still less has it been strictly Catholic. In Italy it fostered a temper of mind decidedly averse to, theological speculation and religious earnestness. In Holland and France it was the Reuchlin and Melanchthon, the developed types of character, urban religion, and religious poignancy, which, of course, left to themselves, would not have plunged the north of Europe into the whirlpool of belligerent reform. Yet none the less they both worked through the same spirit, which is nourished, its vindication of the private reason, its enthusiasm for republican antiquity, and its proud assertion of the rights of human independence, linked by a strong and subtle chain to that turbid revulsion from the fine complexity of human society, which was draped in fallacies and throned upon abuses. To this rebellion we give the name of Reformotion. But, while the necessities of antagonism to papal Rome made it assume at first the form of narrow and sectarian opposition, it marked in fact a vital struggle of the intellect towards truth and freedom, involving future results of scepticism and rationalistic audacity from which its earlier character was but a faint reflection.

The French Renaissance was far from being the relation of humanism in general to reform, French learning in particular displayed such innovating boldness as threw many of its most conspicuous professors into the camp at war with Rome. Calvin, the French student of Farel's origin, created the type of Protestantism to which the majority of French Huguenots adhered. This too was a moment at which philosophical seclusion was hardly possible, and the need for the last means by which the other had to be adopted. Those of the French humanists who did not proclaim Huguenot opinions found themselves obliged with Morets to lend their talents to the Counter-Reformation, or, to suffer persecution for heterodoxy, like Dolet. The church, then, could in turn say that the progress of reform, suspected learning on its own account. To be an eminent scholar was to be accused of immorality, heresy and atheism in a single indictment; and the defence of weaker minds lay in joining the Jesuits, or, as Heinæus was fain to do. France had already absorbed the earlier Renaissance in an Italianizing spirit before the Reformotion made itself felt as a new and sharp anathema.

The Italian bias of the Valois, serves to explain in some degree the reason why the Counter-Reformation entailed those fierce entangled civil wars, massacres of St Bartholomew, murders of the Italian, the French, the English, the German Protestants, and the Huguenots, and the adoption of the compromise of Henry IV. It is part of the present subject to analyse the political, religious and social interests of that struggle. The upshot was the triumph of the Counter-Reformation and, therefore, in the end, the final principle, absolutism, as the basis of French government. It was a French king who, when the nation had been reduced to an utterance the famous word of absolutism, "L'Etat, c'est moi."

The French Renaissance, as elsewhere, had its brilliant age of arts and letters. During the middle ages the wealthy few, developed from the merchant and the capitalist into the moneyed aristocracy, was dissimilar to those of the Italian republicans. They raised the edifices of architectural beauty, which were modified in the 16th and 17th centuries by characteristic elements of the type, following, of course, Van Eyck and Jan van Eyck, followed by Rembrandt and Poussin. The paintings of the French school produced a new path in the revival of painting and taught Europe the secret of oil-colouring. But it was reserved for the 17th century to witness the flower and fruit time of this powerful art in the work of Rubens, Rubens and Vandyck, in the Dutch schools of landscape and home-life, and in the unique masterpieces of Rembrandt and Hals, to complete the development of the Renaissance, because the distracted state of the Netherlands during the 16th century suspended, while it could not extinguish, their aesthetic development. The various schools of the 17th century each flamed with its triumph, and each flamed with its defects. The art of the Low Countries is less surely than the Florentine school of the 15th or the Venetian of the 16th. The animal vigour and carnal enjoyment of Rubens, the refined Italianizing beauty of Vandyck, the mystery of light and shadow of Rembrandt, the dignity of Frans Floris, of Van Dyck, of the more exquisite, of Cuyp and Van Hooghe, with their luminously misty skies, silvery daylight and broad expanse of landscape, the interest in common life displayed by Ter Borch, Van Steen, Douw, Ostade and Teniers, the instinct for the beauty of animals in Potter, the vast sea spaces of Vandervelde, the grasp on reality, the acute intuition into character in portraits, the scientific study of the world and man, the robust sympathy with natural appetites, which distinguish the whole art of the Low Countries, are a direct emanation from the Renaissance.

The veracissimus in the Netherlands profited at first but little by this intellectual stimulus which raised Italian, Spanish, French and English to the rank of classic languages. But humanism, first of all in its protagonist Erasmus, afterwards in the long list of successive scientific scholars, next of all by Grotius, Heim, and Grotius, in the print offices of Elzevir and Plantin, developed itself from the centre of the Leiden university with massy force, and proved that it was still a motive force of the intellectual life in the Low Countries. The students of the Low Countries broke new ground chiefly by methodological collection, classification and constructive criticism of previously accumulated stores. Their works were solid and substantial, their discipline, original. In addition to this they brought philosophy and scientific thoroughness to bear on studies which had been pursued in a more literary spirit. It would, however, be unrealistic to pursue the subject further at this point. The paintings of the Low Countries belong to a period when the Renaissance was overpast. For the same reason it is inadmissible to do more than mention the name of Spinoza here.
The Netherlands became the battlefield of Reformation and Counter-Reformation in even a stricter sense than France. Here the antagonistic principles were plainly posed in the course of struggle against foreign despotism. The Ancien Régime and the assumption of political absolutism as opposed to absolute dominion. Europe in large measure owes the modern ideal of political liberty to that spirit of stubborn resistance which broke the power of Spain. Recent history, and in particular the history of absolutism, is one in which the several stages whereby this principle was developed in England and America, and its outburst in the frenzy of the French Revolution. It is enough here to have alluded to the part played by the Low Countries in the genesis of a motive force which may be described as the last manifestation of the Renaissance striving after self-emancipation.

The insular position of England, combined with the nature of the English people, has allowed us to feel the vibration of European movements later and with less of shock than any of the continental nations. Before a wave of progress has reached our shores we have had the opportunity of watching it as spectators, and of considering how we shall receive it. Revolutions have passed from the tumultuous stages of their origin into some settled and recognizable state before we have been called upon to cope with them. It was thus that England tooled the influences of the Renaissance and Reformation simultaneously, and almost at the same time found herself engaged in that struggle with the Counter-Reformation which, crowned by the defeat of the Spanish Armada, stimulated the sense of nationality and developed the naval forces of the race. Both Renaissance and Reformation had been anticipated by at least a century in England. Chaucer's poetry, which owed so much to Italian examples, gave an early foretaste of the former. Wickliffe's teaching was a vital moment in the latter. But the French wars, the Wars of the Roses and the persecution of the Lollards deferred the coming of the new age; and the year 1536, when Henry VIII. pronounced the English divorcement, was not a Copperplate evolution through parliament, may be fixed as the date when England entered definitely upon a career of intellectual development abreast with the foremost nations of the continent. The circumstances just now insisted on explain the specific character of the English Renaissance. The Reformations had been adopted by consent of the king, lords and commons; and this change in the state religion, though it was not confirmed without reaction, agitation and bloodshed, cost the nation comparatively little disturbance. Humanism, before it affected the bulk of the English people, had already permeated Italy in the atmosphere of the fifteenth century. Classical erudition had been adapted to the needs of modern England. The hard work of collecting, printing, annotating and translating Greek and Latin authors had been accomplished. The masterpieces of antiquity had been interpreted and made intelligible. Much of the learning popularized by our poets and dramatists was derived at second hand from modern literature. This does not mean that England was deficient in ripe and sound scholars. More, Colet, Ascham, Cheke, Camden were men whose familiarity with the classics was as profound as it was impartial. Public schools and universities conformed to the modern methods of instruction which were not there wanting opportunities for youths of humble origin to obtain an education which placed them on a level with Italian scholars. The single case of Ben Jonson sufficiently proves this. Yet learning did not at this epoch become a marked specialty in England. There was no class corresponding to the humanists. It should also be remembered that the best works of Italian literature were introduced into Great Britain together with the classics. Phaer's Virgil, Chapman's Homer, Harrington's Orlando, Marlowe's Hero and Leander, Fairfax's Jerusalem Delivered, North's Plutarch, Hoby's Courtois—to mention only a few examples—placed English readers on the same intellectual plane as the most eminent and representative works of Greece, Rome and Italy. At the same time Spanish influences reached them through the imitators of Guevara and the dramatists; French influences in the versions of romances; German influences in popular translations of the Faust legend, Eulenspiegel and similar productions. The authorized version of the Bible had also been recently given to the people—so that almost at the same period of time England obtained in the vernacular an ample library of Latin authors. This was a privilege enjoyed in like measure by modern French literature and it sufficiently accounts for the richness and variety of Elizabethan literature, and for the enthusiasm with which the English language was cultivated.

Speaking strictly, England borrowed little in the region of the arts from other nations, and developed still less that was original. What is called Jacobean architecture marks an intermediate stage in the development of a style derived from Gothic. But, compared with Italian, French, Spanish, German and Flemish work of a like period, it is both timid and dry. Sculpture was represented in London for a brief space by Torrigiani; painting by Holbein and Antonio Moro; music by Italians and Frenchmen of the Chapel Royal. But no Englishmen rose to European eminence in these departments. With literature the case was very different. Wyatt and Surrey began by engraving the forms and graces of Italian poetry upon the native soil; they introduced the sonnet and blank verse. Sidney followed with the sestine and terza rima and with various experiments in classic metre. The first real attempts on English soil were Wotton's translation of Virgil, and his attempt to hard the octave stanza. Marlowe gave new vigour to the couplet. The first period of the English Renaissance was one of imitation and assimilation. Academies after the Italian type were opened to promote the study of language, history, and the new modes of the French dramas of the epoch, were produced. Attempts to Latinize ancestral rhythms, similar to those which had failed in Italy and Greece, were made. Studies in criticism and dissertations on the art of poetry abounded. It seemed as if England ran a risk of being throttled in its cradle by superfluity of foreign and pedantic nutriment. But the natural vigour of the English genius has produced two influences and created a capacity for digesting the varied diet offered to it. As there was nothing despotic in the temper of the ruling classes, nothing oppressive in English culture, the literature of that age evolved itself freely from the soil and climate of the time. It was under these conditions that the romantic epic to the world, a poem which derived its allegory from the middle ages, its decorative richness from the Italian Renaissance, its moral purity, harmony and imaginative splendour from the most poetic nation of the modern world. Under the same conditions the Elizabethan drama, which in its totality is the real exponent of the English Renaissance, came into existence. This drama very early drew itself from the pseudo-classic manner which imposed on taste in Italy and France. Depicting in the melodious and colours of an age at war with feudal institutions, breathing into antique histories the breath of actual life, embracing the romance of the Middle Ages, the spirit of the Reformation, the splendour and the fancy and the facts of daily life, humours of the moment and abstractions of philosophical speculation, in one homogeneous amalgam instinct with intense vitality, this extraordinary birth of time, with its peculiar conditions and its peculiar influences, the English Renaissance unvailed for pure creative power by any other product of that epoch. To complete the sketch, we must set Bacon, the naturalistic scientific method, beside Spenser and Shakespeare, as the third representative of those who were in England. Nor should Raleigh, Drake, Hawkins, the semi-buccaneer explorers of the ocean, be omitted. They, following the lead of Portuguese and Spaniards, combating the Counter-Reformation on the seas, opened for England her career of colonization and plantation. All this while the political policy of Tudors and Stewarts tended towards monarchical absolutism, while the Reformation in England, modified by contact with the Low Countries during their struggles, was narrowing into strict reactionary intolerance. Puritanism, with the tolerant spirit of the religious conscience of the nation against the narrow nationalism of the Reformation, fought against the encroachments of belligerent Catholicism, against the corrupt and Italianated court of James I, against the unconditional absolutism of James Charles. In its final manifestation during the Commonwealth, Puritanism won a transient victory over the mundane forces of both Reformation and Renaissance, as these had taken shape in England. It also secured the triumph of absolutism. But the new political systems were not yet mature. It had been generated by the English of matured Italian and German influences, give peculiar complexity to the phenomena of Reformation and Renaissance, culture. The period of our history between 1536 and 1642 shows it to be impossible to separate these two factors in the re-birth of Europe, both of which contributed so powerfully to the formation of modern English nationality.
It has been impossible to avoid an air of superciliousness, and the repetition of facts known to every schoolboy, in this sketch of so complicated a subject as the Renaissance,—embracing many nations, a great variety of topics and an indefinite period of time. Yet no other treatment was possible upon the lines laid down at the outset, where it was explained why the term Renaissance cannot be confined to the Revival of Learning and the effect of antique studies upon literary and artistic ideals. The purpose of this article has been to show that, while the Renaissance implied a new way of regarding the material world and man's nature, the introduction of new duties and new perceptions penetrating every sphere of thought and energy, it also involved new reciprocal relations between the members of the European group of nations. The Renaissance closed the middle ages and opened the modern era,—not merely because the mental and moral ideas which then sprang into activity and owed their force in large measure to the revival of classical learning were opposed to medieval modes of thinking and feeling, but also because the political and international relations specific to it as an age were in variance with fundamental theories of the past. The state of empire and church, the sun and moon of the medieval system, a federation of peoples, separate in type and divergent in interests, yet bound together by common tendencies, common culture and common efforts, came into existence. For obedience to central authority was substituted balance of power. Henceforth the hegemony of Europe attached to no crown, imperial or papal, but to the nation which was capable of winning it, in the spiritual region by mental ascendancy, and in the temporal by force.

That this is the right way of regarding the subject appears from the events of the last two decades of the 16th century, those years in which the humanistic revival attained its highest point in Italy. Luther published his theses in 1517, sixty-four years after the fall of Constantinople, twenty-three years after the expedition of Charles VIII to Naples, ten years before the sack of Rome, at a moment when France, Spain and England had only felt the influences of Italian culture but feebly. From that date forward two parties wrestled for supremacy in Europe, to which may be given the familiar names of Liberalism and Conservatism, the party of progress and the party of established institutions. The triumph of the former was most signal among the Teutonic peoples. The Latin races, championed by Spain and supported by the papacy, fought the battle of the latter, and succeeded for a time in rolling back the tide of revolutionary conquest. Meanwhile that liberal culture which had been created for Europe by the Italians before the contest of the Reformation began continued to spread, although it was stifled in Italy and Spain, retarded in France and the Low Countries, well-nigh extinguished by wars in Germany, and diverted from its course in England by the counter-movement of Puritanism. The auto da fé of Seville and Madrid, the flames to which Bruno, Doleet and Palerme were flung, the dungeon of Campanella and the seclusion of Galileo, the massacre of St Bartholomew and the faggots of Smithfield, the desolated plains of Germany and the cruelties of Alva in the Netherlands, disillusioned Europe of those golden dreams which had arisen in the earlier days of humanism, and which had been so pleasantly indulged by Rabelais. In truth the Renaissance was ruled by no Astraæa redux, but rather by a severe spirit which brought no peace but a sword, reminding men of sternest duties, testing what of moral force and tenacity was in them, compelling them to strike for the old order or the new, suffering no lukewarm halting between two opinions. That, in spite of retardation and retrogression, the new order of ideas should have yielded to the new all over Europe,—that science should have won firm standing-ground, and political liberty should have struggled through those birth-throes of its origin,—was in the nature of things. Had this not been, the Renaissance or re-birth of Europe would be a term without a meaning.

LITERATURE.—The special articles on the several arts and the literatures of modern Europe, and on the biographies of great men mentioned in this essay, will give details of necessity here omitted. Of what the Renaissance in general may be generally mentioned Jacob Burckhardt, Die Cultur der Renaissance in Italien (Eng. trans., 1879); G. Voigt, Wiederbelebung des Classischen Alterthums (2 vols. 3rd ed., by M. Lemerith, 1893); J. A. Symonds, Renaissance in Italy; Marc Monnier, Renaissance de Dante à Luther; Eugène Münzt, Précurseurs de la Renaissance (1882), Renaissance en Italie et en France (1885), and Hist. de l'art pendant la Renaissance (1889-93); Ludwig Geiger, Humanismus und Renaissance in Italien und Deutschland (1897); Cambridge Modern History, of St. A. J. Smeth, The Renaissance (Cambridge, 1903), where full bibliographies will be found.

RENAIX,—a town in Belgium in the province of East Flanders, 8 m. S. of Oudenarde. It has extensive dyeworks, bleaching grounds and manufactories for linen and woollen goods. Pop. (1902) 20,760.

RENNAN, ERNEST (1823-1894), French philosopher and Orientalist, was born on the 27th of February 1823 at Tréguier. His father's people were of the fisher-clan of Renans or Ronans; his grandfather, having made a small fortune by his fishing smack, bought a house at Tréguier and settled there, and his father, captain of a small cutter and an ardent Republican, married the daughter of Royalist trading-folk from the neighbouring town of Lannion. All his life Renan was divided between his father and his mother's political beliefs. He was only five years old when his father died, and his sister Henriette, twelve years older than Ernest, a girl of remarkable character, was henceforth morally the head of the household. Having in vain attempted to keep a school for girls at Tréguier, she left her native place and went to Paris as teacher in a young ladies' boarding-school. Ernest meanwhile was educated in the ecclesiastical seminary of his native place. His good-conduct notes for this period describe him as "docile, patient, diligent, painstaking, thorough." We do not hear that he was brilliant, but the priests cared little for such qualities. While the priests were grounding him in mathematics and Latin, his mother completed his education. She was only half a Breton. Her paternal ancestors came from Bordeaux, and Renan used to say that in his own nature the Gascon and the Breton were constantly at odds.

In the summer of 1838 Renan carried off all the prizes at the college of Tréguier. His sister in Paris told the doctor of the school in which she taught about the success of her brother, and he carried the news to F. A. P. Dupanloup, then engaged in organizing the ecclesiastical seminary at Issy. Dupanloup, a man of vast learning, had been brought up at the Collège des Bernardins, a school in which the young Catholic nobility and the most gifted pupils of the Catholic seminaries were to be educated together, with a view to cementing the bond between the aristocracy and the priesthood. Dupanloup sent for Renan at once. He was fifteen and a half. He had never been outside his Breton province. "I learned with stupor that knowledge was not a privilege of the church...I awoke to the meaning of the words talent, fame, celebrity." Above all, religion seemed to him wholly different in Tréguier and in Paris. The superfluous, brilliant, pseudo-scientific Catholicism of the capital did not satisfy Renan, who had accepted the austere faith of his Breton masters.

In 1840 Renan left St Nicholas to study philosophy at the seminary of Issy. He entered with a passion for Catholic scholasticism. The rhetoric of St Nicholas had wearied him, and his serious intelligence hoped to satisfy itself with the vast and solid material of Catholic theology. Reid and Malebranche first attracted him among the philosophers; and after these he turned to Hegel, Kant and Herder. Renan began to perceive the essential contradiction between the metaphysics which he studied and the faith that he professed, but an appetite for truths that can be verified restrained his scepticism. "Philosophy excites and only half satisfies the appetite for truth; I am eager for mathematics," he wrote to his sister Henriette. Henriette had accepted in the family of Count Zamoyski an engagement more lucrative than her former place. She exercised
the strongest influence over her brother, and her published letters reveal a mind almost equal, a moral nature superior, to his own.

It was not mathematics but philology which was to settle the gathering doubts of Ernest Renan. His course completed at Issy, he entered the college of St Sulpice in order to take his degree in philology prior to entering the church; and here he began the study of Hebrew. He saw that the second part of Isaiah differs from the first not only in style but in date; that the grammar and the history of the Pentateuch are posterior to the time of Moses; that the book of Daniel’s apocalyptic spirit. It followed that, if you omit one error in a revealed text, you incriminate the whole. Secretly, Renan felt, himself cut off from the communion of saints, and yet with his whole heart he desired to live the life of a Catholic priest. Hence a struggle between vocation and conviction; owing to Henriette, conviction gained the day. In October 1845 Renan left the seminary of St Sulpice for Stavistas, a lay college of the Oratorians. Finding himself even there too much under the domination of the church, a few weeks later he reluctantly broke the last tie which bound him to the religious life and entered M. Crouzet’s school for boys as an usher.

It was always dangerous to educate a really great mind in only one order of truth. Renan, brought up by priests in a world ruled by authority and curious only of feeling and opinion, was to accept the scientific ideal with an extraordinary expansion of all his faculties. He was henceforth ravished by the splendour of the cosmos. At the end of his life he wrote of Amiel, “The man who has time to keep a private diary has never understood the immensity of the universe.” The certitudes of physical and natural science were revealed to Renan in 1846 by the chemist Marcellin Berthelot, then a boy of eighteen, his pupil at M. Crouzet’s school. To the day of Renan’s death their friendship continued. Renan was occupied as usher only in the evenings. In the daytime he continued his researches in Semitic philology. In 1847 he obtained the Prix Volney—one of the principal distinctions awarded by the Academy of Inscriptions—for the manuscript of his “General History of Semitic Languages.” In 1847 he took his degree as Agrégé de Philosophie; that is to say, fellow of the university, and was offered a place as master in the lycée de Vendôme. In 1848 a small temporary appointment to the lycée of Versailles permitted him to return to the capital and resume his studies.

The revolution of 1848 aroused in Renan that side of him which loved the priesthood because “the priest lives for his fellows.” He for the first time confronted the problems of Democracy. The result was an immense volume, The Future of Science, which remained in manuscript until 1850. L’Avenir de la science is an attempt to conciliate the privileges of a necessary élite with the diffusion of the greatest good of the greatest number. The difficulty haunted Renan throughout his life. By the time he had finished his elaborate scheme for regenerating society by means of a devoted aristocracy of knowledge, and the diffusion of culture, the year 1848 was past, and with it his fever of Democracy. In 1849 the government sent him to Italy on a scientific mission. He remained eight months abroad, during which he forgot his anxiety about the toilers’ lot. Hitherto he had known nothing of art. In Italy the artist in him awoke and triumphed over the savant and the reformer. On his return to Paris Renan lived with his sister Henriette. A small post at the National Library, together with his sister’s savings, furnished him with the means of livelihood. In the evenings he wrote for the Revue des deux mondes and the Débats the exquisite essays which appeared in 1857 and 1859 under the titles Études d’histoire religieuse and Essais de morale et de critique. In 1852 his book on Averroës brought him not only his doctor’s degree, but his first reputation as a thinker. In his two volumes of essays Renan shows himself a Liberal, but no longer a Democrat. Nothing, according to his philosophy, is less important than prosperity. The greatest good of the greatest number is a theory as dangerous as it is illusory. Man is not born to be prosperous, but to realize, in a little vanguard of chosen spirits, an ideal superior to the ideal of yesterday. Only the few can attain a complete development. Yet there is a solidarity between the chosen few and the masses which produce them; each has a duty to the other. The acceptance of this duty is the only foundation for a moral and just society. The aristocratic idea has seldom been better stated.

The success of the Études d’histoire religieuse and the Essais de morale had made the name of Renan known to a cultivated public. While Mademoiselle Renan remained shut up at home copying her brother’s manuscripts or compiling material for his work, the young philosopher began to frequent more than one Parisian salon, and especially the studio of Ary Scheffer, at that time a noted social centre. In 1856 he proposed to marry Cornélie Scheffer, the niece and adopted daughter of the great Dutch painter. Not without a struggle Henriette consented not only to the marriage, but to make her home with the young couple, whose housekeeping depended on the sum that she could contribute. The history of this romance has been told by Renan in the memorial essay which he wrote some six years later, entitled Ma Sœur Henriette. His marriage brought much brightness into his life, a naturalness into his style and a greater attention to the picturesque. He did not forego his studies in Semitic philology, and in 1859 appeared his translation of the Book of Job with an introductory essay, followed in 1859 by the Song of Songs.

Renan was now a candidate for the chair of Hebrew and Chaldaic languages at the Collège de France, which he had desired since first he studied Hebrew at the seminary of St Sulpice. The death of the scholar Quatremère had left this post vacant in 1857. No one in France save Renan was capable of filling it. The Catholic party, upheld by the empress, would not appoint an unfrocked seminarist, a notorious heretic, to a chair of Biblical exegesis. Yet the emperor wished to conciliate Ernest Renan. He offered to send the young scholar on an archaeological mission to Phoenicia. Renan immediately accepted. Leaving his wife at home with their baby son, Renan left France, accompanied by his sister, in the summer of 1860. Madame Renan joined them in January 1861, returning to France in July. The mission proved fruitful in Phoenician inscriptions which Renan published in his Mission de Phénicie. They form the base of that Corpus Inscriptionum Semiticarum on which he used in later years to declare that he founded his claim to recognition. He wished, to complete his exploration of the upper range of Lebanon; he remained, therefore, with Henriette to avert the dangerous misas of a Syrian autumn. At Amshit, near Byblus, Henriette Renan died of intermittent fever on the 24th of September 1860. Her brother, himself at death’s door, was carried unconscious on board a ship waiting in harbour and bound for France. The sea air revived him, but he reached France broken apparently in heart and health. His sister in her last days had entreated him not to give up his candidature for the chair of Hebrew, and on the 11th of January 1862 the Minister of Public Instruction ratified Renan’s election to the post. But his opening lecture, in which, amid the applause of the students, Renan declared Jesus Christ “an incomparable Man,” alarmed the Catholic party. Renan’s lectures were pronounced a disturbance of the public peace, and he was suspended. On the 2nd of June 1864, on opening the newspaper, Renan saw that he had been transferred from the chair of Hebrew at the College of France to the post of sub-librarian at the National Library. He wrote to the Minister of Public Instruction: “Pecunia tua tecum sit!” He refused the new position, was deprived of his chair, and henceforth depended solely upon his pen.

Henriette had told him to write the life of Jesus. They had begun it together in Syria, she copying the pages as he wrote them, with a New Testament and a Josephus for all his library. The book bears the mark of its origin—it is filled with the atmosphere of the East. It is the work of a man familiar with the Bible and theology, and no less acquainted with the inscriptions, monuments, types and landscapes of Syria. But it is scarcely the work of a great scholar: Renan’s debt to the school
of Tübingen has been exaggerated, in so far as regards the Life of Jesus. The book appeared on the 23rd of June 1863; before November sixty thousand copies of it were in circulation. Renan still used his literary gifts to pursue a scientific ideal. In the days when he had composed his huge, immature treatise on the Future of Science, he had written: 'I envy the man who shall evolve from the past the origins of Christianity. Such a writer would compose the most important book of the century.' He set to work to realize this project, and produced the Apostles in 1866, and St Paul in 1869, after having visited Asia Minor with his wife, where he studied the scenes of the labours of St Paul as minutely as in 1861 he had observed the material surroundings of the life of Jesus.

Renan was not only a scholar. In St Paul, as in the Apostles, he shows his concern with the larger social life, his sense of fraternity, and a revival of the democratic sentiment which had inspired L'Avenir de la science. In 1869 he presented himself as the candidate of the liberal opposition at the parliamentary election for Menoux. While his temper had become less aristocratic, his Liberalism had grown more tolerant. On the eve of its dissolution Renan was half prepared to accept the Empire, and, had he been elected to the Chamber of Deputies, he would have joined the group of l'Empire liberal. But he was not elected. A year later war was declared with Germany, the Empire fell, and Napoleon III. went into exile. The Franco-German War was a turning-point in Renan's history. Germany had always been to him the asylum of thought and disinterested science. Now he saw the land of his ideal destroy and ruin the land of his birth; he beheld the German no longer as a priest, but as an invader. His heart turned to France. In La Réforme intellectuelle et morale (1871) he endeavoured at least to bind her wounds, to safeguard her future. Yet he was still under the influence of Germany. The ideal and the discipline which he proposed to his defeated country were those of her conqueror—a feudal society, a monarchical government, an élite, which the rest of the nation exists merely to support and nourish; an ideal of honour and duty imposed by a chosen few on the recalcitrant and subject multitude. The errors of the Commune confirmed Renan in this reaction. At the same time the irony always perceptible in his work grows more bitter. His Dialogues philosophiques, written in 1871, his Ecclesiastes (1882) and his Antichrist (1876) (the fourth volume of the Origins of Christianity, dealing with the reign of Nero) are incomparable in their literary genius, but they are examples of a disenchanted and sceptical temper. He had tried to adapt himself to watch her drift towards perdition. The progress of events showed him, on the contrary, a France which every day left a little stronger, and he aroused himself from his disbeliefing, disillusioned mood, and observed with genuine interest the struggle for justice and liberty of a democratic society. For his mind was the broadest of the age. The fifth and sixth volumes of the Origins of Christianity (No Christian Church and Marcus Aurelius) show him reconciled with democracy, confident in the gradual ascent of man, aware that the greatest catastrophes do not really interrupt the sure if imperceptible progress of the world—reconciled also in some measure, if not with the truths, at least with the moral beauties of Catholicism, and with the remembrance of his pious youth.

On the threshold of old age the philosopher cast a glance at the days of his childhood. He was nearly sixty when, in 1883, he published those Souvenirs d'enfance et de jeunesse which, after the Life of Jesus, are the work by which he is chiefly known. There is a personal interest in these memoirs, which the public prizes in a man already famous. They showed the blast modern reader that a world no less poetic, no less primitive than that of the Origins of Christianity exists, or still existed within living memory, on the north-western coast of France. They have the Celtic magic of ancient romance and the simplicity, the naturalness, the veracity which the 19th century prized so highly. But his Ecclesiastes, published a few months earlier, his Drames philosophiques, collected in 1888, give a more adequate image of his fastidious critical, disenchanted, yet not hopeless spirit. These books are often bitter and melancholy, yet not destitute of optimism. They show the attitude towards uncultured Socialism of a philosopher liberal by conviction, by temperament an aristocrat. We learn in them how Caliban (democracy), the mindless brute, educated to his own responsibility, makes after all an adequate ruler; how Prospero (the aristocratic principle, or, if we will, the mind) accepts his dethronement for the sake of greater liberty in the intellectual world, since Caliban proves an effective policeman, and leaves his superiors a free hand in the laboratory; how Ariel (the religious principle) acquires a firmer hold on life, and no longer gives up the ghost at the faintest hint of change. Indeed, Ariel flourishes in the service of Prospero under the external government of the many-headed brute. For the one thing needful is not destined to succumb. Religion and knowledge are as imperishable as the world they dignify. Thus out of the depths rises unvanquished the essential idealism of Ernest Renan.

Renan was a great worker. At sixty years of age, having finished the Origins of Christianity, he began his History of Israel, based on a lifelong study of the Old Testament and on the Corpus Inscriptionum Semiticarum, published by the Académie des Inscriptions under Renan's direction from the year 1881 till the end of his life. The first volume of the History of Israel appeared in 1887, the third and finest volume in 1891, the last two only after the historian's decease. As a history of facts and theories the book has many faults; as an essay on the evolution of the religious idea it is (despite some passages of triviality, irony, or incoherence) of extraordinary importance; as a reflection of the mind of Ernest Renan it is the most lifelike of images. In a volume of collected essays, Feuilles détachées, published also in 1891, we find the same mental attitude, an affirmation of the necessity of piety independent of dogma. On the 12th of October 1892 he died after a few days' illness. In his last years he received many marks of honour, being made an administrator of the Collège de France and grand officer of the Legion of Honour. Two volumes of the History of Israel, his correspondence with his sister Henriette, his Letters to M. Berthelot, and the History of the Religious Policy of Philippe-le-Bel, which he wrote in the years immediately before his marriage, all appeared during the last eight years of the 19th century.

RENARD, ALPHONSE FRANÇOIS (1842-1903), Belgian geologist and petrographer, was born at Renaix, in Eastern Flanders, on the 27th of September 1842. He was educated for the church of Ghent, and from 1866 to 1886 he was superintendent at the Collège de la Paix, Namur. In 1870 he entered the Jesuit Training College at the old abbey of Maria Laach in the Eifel, and there, while engaged in studying philosophy and science, he became interested in the geology of the district, and especially in the volcanic rocks. Thenceforth he worked at chemistry and mineralogy, and qualified himself for those petrographical researches for which he was distinguished. In 1874 he became professor of chemistry and geology in the college of the Belgian Jesuits at Louvain, a few years later he was appointed one of the curators of the Institute and became superintendent of the Museum and Library of Ghent University. In 1883 he relinquished his post at Louvain. In 1888 he was chosen professor of geology at the university of Ghent, and retained the post until the close of his life. Meanwhile he had been ordained priest in 1877, and had intended to enter the Society of Jesus. He was known as the Abbé Renard; but, as remarked by Sir A. Geikie, "As years passed, the longing for mental freedom grew ever stronger, until at last it overmastered all the traditions and associations of a lifetime, and he finally separated himself from the church of Rome." His first work,
written in conjunction with Charles de la Vallée-Poussin (1827–1904), was the *Mémoire sur les caractères mineralogiques et stratigraphiques des roches dites plutonniennes de la Belgique et de l'Ardennaise française* (1876). In later essays and papers he dealt with the structure and mineral composition of many igneous and sedimentary rocks, and with the phenomena of metamorphism in Belgium and other countries. In acknowledgment of his work the Bigsby Medal was in 1885 awarded to him by the Geological Society of London. Still more important were his later researches connected with the Challenger Expedition. The various rock specimens and oceanic deposits were submitted to him for examination in association with Sir John Murray, and their detailed observations were embodied in the *Report on the Scientific Results of the Voyage of H.M.S. "Challenger."* Deep Sea Deposits (1891) The more striking additions to our knowledge included "the detection and description of cosmic dust, which as fine rain slowly accumulates on the ocean floor; the development of zeolitic crystals on the sea-bottom at temperatures of 35° and under; and the distribution and mode of occurrence of manganiferous concretions and of phosphatic and glauconite deposits on the bed of the ocean" (Geikie).

Renard died at Brussels on the 9th of July 1903.

**Renaud de Montauban** (Rinaldo di Montalbano), one of the most famous figures of French and Italian romance. His story was attached to the *geste* of Doon of Mayence by the 13th-century trouvère who wrote the *chanson de geste* of *Renaus de Montauban*, better known perhaps as *Les quatre fils d'Aymon*. The four sons of Aymon give their name to inns and streets in nearly every town of France, and the numerous prose versions show what a hold the story gained on the popular imagination. Renaud's sword Floberge, and his horse Bayard passed with him into popular legend. The poem of *Renaus de Montauban* opens with the story of the dissensions between Charlemagne and the sons of Doon of Mayence, Beuves d'Aigremont, Doon de Nanteuil and Aymon de Dordone. The rebellious vassals are defeated by the imperial army near Troyes, and, peace established, Aymon rises in favour at court, and supports the emperor, even in his persecution of his four sons, Renaud, Alain, Guichard and Richard. A second feud arises from a quarrel between Renaud and Bertolai, Charlemagne's nephew, over a game of chess, in the course of which Renaud kills Bertolai with the chess-board. The hero then mounts his steed Bayard, and escapes with his brothers to the Ardennes, where they build the castle of Montessor over-looking the Meuse. At Château Renaud, near Sédan, there existed in the 18th century a ruined castle with a tower called the "tour Maugis" and the reputed stable of Bayard. The outlaws are eventually persuaded to seek their fortune outside Charlemagne's kingdom, and cross the Loire to take service with King Yon of Gascony against the Saracens, accompanied by their cousin, the enchanter Maugis. Yon, however, is compelled by Charlemagne to withdraw his protection, and the castle of Montauban, which the brothers have built on the Dordogne, is besieged by the emperor. They next seek refuge beyond the Rhine, and sustain a third siege at Trémoigne (Dortmund), after which the emperor is persuaded by the barons to make peace. Bayard is abandoned to Charlemagne, and thrown into the Meuse, only to rise again. He still gallops over the hills of the Ardennes on St John's Eve. Renaud, who throughout the story is a type of the Christian and chivalric virtues, makes a pilgrimage to the Holy Land, accompanied by several other lords of Gascony, and of Bouillon. On his return he gives himself up to religion, working as a mason on the church of St Peter at Cologne, where he receives martyrdom at the hands of his jealous fellow-labourers.

The story is closely connected with the legend of Girard de Roussillon. The *chanson de geste* of *Renaus de Montauban* falls into sections which had probably been originally the subject of separate recitals. These may have arisen at different dates, and were not necessarily told in the first instance of the same person, the account of Renaud on the crusade being obviously a late interpolation. The outlaw life of the brothers in the Ardennes bears the marks of trustworthy popular tradition, and it was even at one time suggested that the Gascon and Rhenish episodes were reduplications of the story of Montessor. The connexion of the four brothers with Montessor, Dortmund, Mayence and Cologne, and the abundant local tradition, mark the heroes as originating from the region between the Rhine and the Meuse. Nevertheless, their adventures in Gascony are corroborated by historical evidence, and this section of the poem is the oldest. The enemy of Renaud was Charles Martel, not Charlemagne; Yon was Odo of Gascony, known indifferently as duke, prince, or king; the victory over the Saracens at Toulouse, in which the brothers are alleged to have taken part, was won by him in 721, and in 719 he sheltered refugees from the dominions of Charles Martel, Chilperic II., king of Neustria, and his mayor of the palace, Reginfrid, whom he was compelled to abandon. In a local chronicle of Cologne it is stated that Saint Reinoldus died in 697, and in the Latin rhetorical *Vile* his martyrdom is said to have taken place under Bishop Agilolf (d. 717). Thus the romance was evidently composite before it took its place in the Carolingian cycle.

In Italy Renaud had his greatest vogue. His connexion with the treacherous family of Mayence was thrust into the background, and many episodes were added, as well as the personage of the hero's sister, Bradamante. Rinaldo di Montalbano had been the subject of many Italian poems before Il Rinaldo di Tasso.

**BIBLIOGRAPHY.**—The *chanson* of Maugis d'Aigremont and the prose romance of the *Conquête de Trebizonde* belong to the same cycle. The prose *Ystoire de Renauclus de Montaubon* (Lyons, c. 1480) had a great vogue. It was generally printed as *Les quatre fils Aymon*, and published in [*Foure Poèmes d'Ayme* (Paris, 1534)]; by John Wyclif, [257], and subsequently by Wynkyn de Worde and William Copland. See *Hist. litt. de la France*, xxii., analysis by Païva Paris; *Renaus de Montauban* (Stuttgart, 1862), edited by H. Michelant; F. Walli, *Recherches sur les sagas de Maugis d'Aigremont* (Lund, 1873); *Maugis saga*, ed. G. Cedersköld (Lund, 1876); *Renout de Montalban*, ed. J. C. Matthins (Groningen, 1873); A. Longnon, in *Revue des questions historiques* (1879); R. Zwick, *Über die Sprache des Renout von Montau Baton* (Halle, 1884); F. Pfaff, *Das deutsche Volkbuch von den Heymonskynen* (Freiburg in Breisgau, 1887), with a general introduction to the study of the saga; *The Four Sons of Aimon* (E. E. Text. Soc., ed. Octavía Richardson, 1884); a special bibliography of the printed editions of the prose romance in L. Gautier's *Bibl. des chansons de geste* (1897); rejuvenations of the story by Karl Simrock (Frankfurt, 1885); by Roy Richardson (London, 1897); *Storia di Rinaldino*, ed. C. Minutoli (Bologna, 1865). Stage versions are: *Renaud de Montauban*, a play translated from Lope de Vega was played at the Théâtre Italien, Paris, in 1717; *Les quatre fils Aymon*, opéra comique by MM. de Leuven and Brunswick, music by Balle, in 1884.

**Renaudot, Eusèbe** (1646–1720), French theologian and Orientalist, was born in Paris in 1646, and educated for the church. Notwithstanding his taste for theology and his title of abbe, much of his life was spent at the French court, where he attracted the notice of Colbert and was often employed in confidential affairs. The unusual learning in Eastern tongues which he acquired in his youth and maintained amid the distractions of court life did not bear fruit till he was sixty-two. His best-known books are *Historia Patriarcharum Alexandrinorum* (Paris, 1713) and *Liturgiarum orientalis collectio* (2 vols., 1715–16). The latter was designed to supply proofs of the "perpetuity of the faith" of the church on the subject of the sacraments, the topic on which most of his theological writings turned, in which he inveighed against the innovations of the controversies of his time, according to Arnauld's *Perpetuitas de la foi*, a burning one between French Catholics and Protestants. Renaudot was not a fair controversialist, but his learning and industry are unquestionable. He died in 1720.

**Renaudot, Théophraste** (1586–1653), French physician and philanthropist, was born at Loudun (Vienne), and studied surgery in Paris. He was only nineteen when he received, by favour apparently, the degree of doctor at Montpellier. After some time spent in travel he began to practise in his native town. In 1612 he was summoned to Paris by
RENDEZVOUS—RENÉ I.

Richelieu, partly because of his medical reputation, but more because of his philanthropy. He received the titles of physician and councillor to the king, and was desired to organize a scheme of public assistance. Many difficulties were put in his way, however, and he therefore retired on until 1624 to Paris, where Richelieu made him "commissionary general of the poor." It was six years before he was able to begin his work in Paris by opening an information bureau at the sign of the Grand Coq near the Pont Saint-Michel. This bureau d'adresse was labour bureau, intelligence department, exchange and charity organization in one; and the sick were directed to doctors prepared to give them free treatment. Presently he established a free dispensary in the teeth of the opposition of the faculty in Paris. The Paris faculty refused to accept the new medicaments proposed by the heretic from Montpellier, restricting themselves to the prescriptions of an old letting and purgation. In addition to his bureau d'adresse Renaud established a system of lectures and debates on scientific subjects, the reports of which from 1633 to 1642 were published in 1651 with the title Recueil des conférences publiques. Under the protection of Richelieu he started the first French newspaper, the Gazette (1631), which appeared weekly and contained political and foreign news. He also edited the Mercure français and published all manner of reports and pamphlets. In 1637 he opened in Paris the first Mont de Piété, an institution of which he had seen the advantages in Italy. In 1640 the medical faculty, headed by Guy Patin, started a campaign against the innovator of the Grand Coq. After the death of Richelieu and of Louis XIII. the victory of Renaudot's enemies was practically certain. The parliament of Paris ordered him to return the letters patent for the establishment of his bureau and his Mont de Piété, and refused to allow him to practise medicine in Paris. The Gazette remained, and in 1646 Renaudot was appointed by Mazarin historiographer to the king. During the first Fronde he had his printing presses at Saint-Germain. He died on the 25th of October 1653. His difficulties had been increased by his Protestant opinions. His sons Isaac (d. 1688) and Eusèbe (d. 1679) were students for ten years before they could obtain their doctorates from the faculty. They carried on their father's work, and defended the virtues of antimony, laudanum and quinine against the schools.

See E. Hatin, Théodore Renaudot (Poitiers, 1888), and La Maison du Coq (Paris, 1885); Michel Emery, Renaudot et l'introduction de la médication chimique (Paris, 1886); and G. Bonnefont, Un Oublié. Théophile Renaudot (Limoges, n.d.).

RENDEZVOUS, a place of meeting appointed for or arranged for the assembling of troops, or persons. The word was adopted in English at the end of the 16th century from the French substantival use of the imperative rendez vous, i.e. "rendezvous or betake yourselves."

Rendsburg, a town of Germany, in the Prussian province of Schleswig-Holstein, situated on the Eider and on the Kaiser Wilhelm canal, in a flat and sandy district, 20 m. W. of Kiel, on the Altona-Vandrup railway. Pop. (1902) 15,577. It consists of three parts—the crowed Altstadt, on an island in the Eider; the Neuwerk, on the south bank of the river; and the Kronwerk, on the north bank. Rendsburg is the chief place in the basin of the Eider, and when in the possession of Denmark was maintained as a fortress. Its present importance, however, rests on the commercial facilities afforded by its connexion with the North Sea and the Baltic through the Kaiser Wilhelm canal, by which transit trade is carried on in grain, timber, Swedish iron and coal. The principal industries are cotton-weaving, tanning and the manufacture of artificial manures.

Rendsburg came into existence under the shelter of a castle founded by the Danes about the year 1100 on an island of the Eider, and was an object of dispute between the Danish kings and the counts of Holstein. In 1252 it was adjudged to the latter. The town was surrounded with ramparts in 1530, but the fortifications of the Kronwerk were not constructed till the end of the 17th century. During the Thirty Years' War Rendsburg was taken both by the Imperialists and the Swedes, but in 1645 it successfully resisted a second siege by the latter.

The war of 1848–50 began with the capture of Rendsburg by the Holsteiners by a coup de main, and it formed the centre of the German operations. On the departure of the German troops in 1852 the Danes demolished the fortifications on the north side. Immediately after the death of King Frederick VII. (15th of November 1863) the town was occupied by the Saxon troops acting as the executive of the German Confederation, and it was the base of the operations of the Austrians and Prussians against Schleswig in the spring of the following year. On the termination of the Danish war in 1864 Rendsburg was jointly occupied by Austrian and Prussian military until 1866, when it fell to Prussia.

See Warmstedt, Rendsburg (Kiel, 1890).

RENÉ I. (1409–1480), duke of Anjou, and Lorraine and Bar, count of Provence and of Piedmont, king of Naples, Sicily and Jerusalem, was born at Angers on the 16th of January 1409, the second son of Louis II., king of Sicily, duke of Anjou, count of Provence, and of Yolande of Aragon. Louis II. died in 1417, and his sons, together with their brother-in-law, afterwards Charles VII. of France, were brought up under the guardianship of their mother. The elder, Louis III., succeeded to the crown of Sicily and to the duchy of Anjou, René being known as the count of Guise. By his marriage treaty (1419) with Isabel, elder daughter of Charles II., duke of Lorraine, he became heir to the duchy of Bar, which was claimed as the inheritance of his mother Yolande, and, in right of his wife, heir to the duchy of Lorraine. René, then only ten, was to be brought up in Lorraine under the guardianship of Charles II. and Louis, cardinal of Bar, both of whom were attached to the Burgundian party, but he retained the right to bear the arms of Anjou. He was far from sympathizing with the Burgundians, and, joining the French army at Reims in 1429, was present at the coronation of Charles VII. When Louis of Bar died in 1430 René came into sole possession of his duchy, and in the next year, on his father-in-law's death, he succeeded to the duchy of Lorraine. But the inheritance was claimed by the heir-male, Antoine de Vaudémont, who, with Burgundian help defeated René at Bulgnéville in July 1431. The Duchess Isabel effected a truce with Antoine de Vaudémont, but the duke remained a prisoner of the Burgundians until April 1432, when he recovered his liberty on parole on yielding up as hostages his two sons, Jean and Louis of Anjou. His title as duke of Lorraine was confirmed by his suzerain, the Emperor Sigismund, at Basel in 1434. This proceeding roused the anger of the Burgundian duke, Philip the Good, who required him early in the next year to return to his prison, from which he was released two years later on payment of a heavy ransom. He had succeeded to the kingdom of Naples through the deaths of his brother Louis III. and of Jeanne II. de Duras, queen of Naples, the last heir of the earlier dynasty. Louis had been adopted by her in 1431, and she now left her inheritance to René. The marriage of Marie de Bourbon, niece of Philip of Burgundy, with John, duke of Calabria, René's eldest son, cemented peace between the two princes. After appointing a regency in Bar and Lorraine, he visited his provinces of Anjou and Provence, and in 1438 set sail for Naples, which had been held for him by the Duchess Isabel. René's captivity, and the poverty of the Angevin resources due to his ransom, enabled Alphonso of Aragon, who had been first adopted and then repudiated by Jeanne II., to make some headway in the kingdom of Naples, especially as he was already in possession of the island of Sicily. In 1441 Alphonso laid siege to Naples, which he sacked after a six months' siege. René returned to France in the same year, and though he retained the title of king of Naples his effective rule was never recovered. Later efforts to recover his rights in Italy failed. His mother Yolande, who had governed Anjou in his absence, died in 1442. René took part in the negotiations with the English at Tours in 1444, and peace was consolidated by the marriage of his younger daughter, Margaret, with Henry VI. at Nancy. René now made over the government of Lorraine to John, duke of Calabria, who was, however, only formally installed as duke of Lorraine on the death of Queen Isabel in
RENÉE OF FRANCE—RENFREWSHIRE

1453. René had the confidence of Charles VII., and is said to have initiated the reduction of the men-at-arms set on foot by the king, with whose military operations against the English he was closely associated. He entered Rouen with him in November 1449, and was also with him at Formigny and Caen. After his second marriage with Jeanne de Laval, daughter of Guy XIV., count of Laval, and Isabel of Brittany, René took a less active part in public affairs, and devoted himself more to artistic and literary pursuits. The fortunes of his house declined in his old age. The duke of Calabria, after repeated misfortunes in Italy, was offered the crown of Aragon in 1467, but died apparently by poison, at Barcelona on the 16th of December 1470; the duke’s eldest son Nicholas perished in 1472, also under suspicion of poisoning; René’s daughter Margaret was a refugee from England, her son Prince Edward was murdered in 1471, and she herself became a prisoner, to be rescued by Louis XI. in 1476. His only surviving male descendant was then René II., duke of Lorraine, son of his daughter Yolande, comtesse de Vaudémont, who was gained over to the party of Louis XI., who suspected the king of Sicily of complicity with his enemies, the duke of Brittany and the Constable Saint-Pol. René retired to Provence, and in 1474 made a will by which he left Bar to his grandson René II., duke of Lorraine; Anjou and Provence to his nephew Charles, count of Le Maine. Louis seized Anjou and Bar, and two years later sought to compel the king of Sicily to exchange the two duchies for a pension. The offer was rejected, but further negotiations assured the lapse to the crown of the duchy of Anjou, and the annexation of Provence was only postponed until the death of the count of Le Maine. René died on the 10th of July 1480, his charities having earned for him the title of “the good.”

He founded an order of chivalry, the Ordre du Croissant, which was anterior to the royal foundation of St Michael, but did not survive René.

The king of Sicily’s fame as an amateur of painting has led to the attribution to him of many old paintings in Anjou and Provence, in many cases simply because they bear his arms. These works are generally in the Flemish style, and were probably executed under his patronage and direction, so that he may be said to have formed a school of the fine arts in sculpture, painting, gold work and tapestry. Two of the most famous works formerly attributed to René are the tapestry of the “Burning Bush,” in the cathedral of Aix, showing portraits of René and his second wife, Jeanne de Laval, and an illuminated Book of Hours in the Bibliothèque nationale, Paris. The “Burning Bush” was in fact the work of Nicolas Froment, a painter of Avignon. Among the men of letters attached to his court was Antoine de la Sale, whom he made tutor to his son, the duke of Calabria. He encouraged the performance of mystery plays; on the performance of a mystery of the Passion at Saumur in 1462 he remitted four years of taxes to the town, and the representations of the Passion at Angers were carried out under his auspices. He exchanged verses with his kinsman, the poet Charles of Orleans. The best of his poems is the idyl of Regnault and Jeannelet, representing his own courtship of Jeanne de Laval. Le Livre des tournois, a book of ceremonial, and the allegorical romance, Conquête qu’un chevalier nommé le Cuir d’amour espris feist d’une dame appelée Douce Mercy, with other works ascribed to him, were perhaps dictated to his secretaries, or at least composed under his direction. His Œuvres were published by the comte de Quatrebarbes (4 vols., Paris and Angers, 1845-46).

See A. Lecoy de la Marche, Le Roi René (2 vols., 1875); A. Valler de Virville, in the Nouvelle Biographie générale; and there is a succinct account of the MSS. of his works; and J. Renouvier, Les Peintres et entumineurs du roi René (Montpellier, 1857).

RENÉE OF FRANCE (1510–1572), second daughter of Louis XII. and Anne of Brittany, was born on Blois on the 20th of October 1510. After being betrothed successively to Gaston de Foix, Charles of Austria (the future emperor Charles V.), his brother Ferdinand, Henry VIII. of England, and the elector Joachim II. of Brandenburg, she married in 1528 Hercules of Este, son of the duke of Ferrara, who succeeded his father six years later. Renée’s court became a rendezvous of men of letters and a refuge for the persecuted French Calvinists. She received Clément Marot and Calvin at her court, and finally embraced the reformed religion. Her husband, however, who viewed these proceedings with disfavour, banished her friends, took her children from her, threw her into prison, and eventually made her abandon at any rate the outward forms of Calvinism. After his death in 1559, Renée returned to France and turned the duchy of Montargis into a centre of Protestant propaganda. During the wars of religion she was several times molested by the Catholic troops, and in 1562 her château was besieged by her son-in-law, the duke of Guise. She died at Montargis.

RENEVIER, EUGÈNE (1831— ), Swiss geologist, was born at Lausanne on the 26th of March 1831. In 1857 he became professor of geology and palaeontology in the university at Lausanne. He is distinguished for his researches on the geology and palaeontology of the Alps, on which subjects he published numerous papers in the proceedings of the scientific societies in Switzerland and France. With F. J. Picot he wrote a memoir on the Fossiles du terrain piéden de la Perte-du-Rhône (1854). In 1864 he was appointed president of the Swiss Geological Commission, and also of the International Geological Congress held that year at Zürich, in the previous meetings of which he had taken a prominent part. He published a noteworthy Tableau des terrains sédimentaires (1874); and a second more elaborate edition, accompanied by an explanatory article Chronographe géologique, was issued in 1887 as a supplement to the Report of the Zürich Congress. This new table was printed on coloured sheets, the colours for each geological system corresponding with those adopted on the International geological map of Europe.

RENFREW, a royal, municipal and police burgh and county town of Renfrewshire, Scotland, near the southern bank of the Clyde, 7 m. W. by N. of Glasgow, via Carbondal, by the Glasgow & South-Western and Caledonian railways (5 m. by road). Pop. (1891) 6777; (1901) 9206. Industries include ship-building (the construction of dredgers and floating docks is a speciality), engineering, dyeing, weaving, chemicals and candle-making. The Clyde trust has constructed a large dock here. Renfrew belongs to the Kilmarnock district group of parliametary burghs (with Kilmarnock, Dunbarton, Rutherglen and Port Glasgow). Robert III. gave a charter in 1396, but it was a burgh (Renfry) at least 250 years earlier. About 1160 Walter Fitzalan, the first high steward of Scotland, built a castle on an eminence by the side of the Clyde (still called Castle Hill), the original seat of the royal house of Stewart. Close to this town, on the site of Elderslie House, Somerled, lord of the Isles, was defeated and slain in 1164 by the forces of Malcolm IV., against whom he had rebelled. In 1404 Robert II. bestowed upon his son James (afterwards James I.) the title of Baron of Renfrew, still borne by the prince of Wales.

RENFREWSHIRE, a south-western county of Scotland, bounded N. by the river and firth of Clyde, E. by Lanarkshire, S. and S.W. by Ayrshire and W. by the firth of Clyde. A small detached portion of the parish of Renfrew, situated on the northern bank of the Clyde, is surrounded on the landward side by Dumbartonshire. The county has an area of 153,332 acres, or 395-6 sq. m. Expiring towards the Ayrshire border on the south-west, where the principal heights are Hills of Stakel (1717 ft.), East Crag Hill and South Crag Hill (1446 ft.), and the confines of Lanarkshire on the south-east, where a few points attain an altitude of 1200 ft.—the surface is undulating rather than rugged. Much of the higher land in the centre is well wooded. The Clyde forms part of the northern boundary of the shire. In the N.W. Loch Thom and Gryfe Reservoir provide Greenock with water, and Balgray Reservoir and Glen Reservoir reinforce the water-supply of a portion of the Glasgow area. The other lakes are situated in the S. and S.E. and
from Glasgow by Paisley to Greenock, Gourc and Wemys Bay; southwardto the other to Busby. The Glasgow & South-Western railway runs to Greenock by Paisley, Johnstone and Kilmalcolm; to Nithhill and other places south-westwards; by Lochwinnoch (for Dalry and Ardeer to Ayrshire); and to Renfrew jointly with the Caldeonian. The Clyde and the railway steamers call at Renfrew, Prince's Pier (Greenock), Gourc and Wemys Bay.

Population and Administration.—In 1801 the population numbered 350,812, and in 1901 it was 268,808, or 1123 to the sq. m. In 1901 there were 40 persons who spoke Gaelic only and 5385 Gaelic and English. Thus though the shire is but twenty-seven in point of size of the 33 Scottish counties, it is fifth in respect of population, and only Lanarkshire and Mid Lothian are more densely populated. The county is divided into the upper and lower sections, the former with Paisley as district centre, and the lower ward, consisting of the parishes of Inverkip, Greenock, Port-Glasgow and Kilmalcolm, with Greenock as district centre. The chief towns are Paisley (pop. 79,363), Greenock (68,142), Port-Glasgow (16,857), Pollokshaws (11,369), Johnstone (11,331), Barrhead (1865), Renfrew (9296), Gourc (5261), Cathcart (5685). The shire returns one member to parliament for the eastern, and another for the western division. Paisley and Greenock return each one member, and Renfrew and Port-Glasgow belong to the Kilmarnock district, group of parliamentary burghs. Renfrewshire has 1123 a sheriff-substitute and 1124 a sheriff-substitute at Paisley and one at Greenock. The county is under school-board jurisdiction. For secondary and special-ized education there are an academy at Greenock and a grammar school and technical school at Paisley, while some of the schools in the county earn grants for higher education. The county secondary committee also makes provision for the free education of Renfrewshire children in Glasgow High School and the Spier School at Beith. The Paisley Technical School and the Glasgow and West of Scotland Technical College are subsidized by the "residue" grant, part of which also defrays the travelling expenses of students and supports science and art and technological classes in the burghs and towns in the county.

History.—At the time of the Roman advance from the Solway the land was peopled by the British tribe of Dumnoll. To hold the natives the conquerors built in 84 the fort of Vanduara on high ground now covered by houses and streets in Paisley; but after the Romans retired (460) the territory was overrun by Cumbrian Britons and formed part of the kingdom of Strathclyde, the capital of which was situated at Alcyde, the modern Dumbarton. In the 7th and 8th centuries the region practically passed under the supremacy of the heathen Britons, but in the reign of Alfred of Wessex came to be incorporated with the rest of Scotland. During the first half of the 12th century, Walter Fitzalan, high steward of Scotland, ancestor of the royal house of Stuart, settled in Renfrewshire on an estate granted to him by David 1. Till their accession to the throne the Stuarts identified themselves with the district, which, however, was only disjoined from Lanarkshire in 1404. In that year Robert III. erected the barony of Renfrew and the Stuart estates into a separate county, which, along with the earldom of Carrick and the barony of King's Kyle (both in Ayrshire), was bestowed upon his son, afterwards James I. From their grant are derived the titles of earl of Carrick and earl of Renfrew, borne by the eldest son of the sovereign. Apart from such isolated incidents as the defeat of Somerled near Renfrew in 1164, the battle of Langside in 1568 and the capture of the 9th earl of Argyll at Inchinnan in 1685, the history of the shire is scarcely separable from that of Paisley or the neighbouring county of Lanark.

Millar, Castles and Mansions of Renfrew (Glasgow, 1889).
RENNELL, JAMES (1742–1830), British geographer, was born on the 3rd of December 1742, near Chudleigh in Devonshire. His father, an officer in the Artillery, was killed in action shortly after the birth of his son. He entered the navy as a midshipman in 1756, and was present at the attack on Cherbourg (1758), and the disastrous action of St Cast in the same year. At the end of the Seven Years' War, seeing no chance of promotion, he entered the service of the East India Company, and was appointed surveyor of the Company's dominions in Bengal (1764), with the rank of captain in the Bengal Engineers. To this work he devoted the next thirteen years. In 1766 he received a severe wound in an encounter with some Sannysis, or religious fanatics, from which he never thoroughly recovered; and in 1777 he returned to England. During the fifty-three years of his life were spent in London, and were devoted to geographical research chiefly among the materials in the East India House. His most important works include the Bengal Atlas (1790), the first approximately correct map of India (1783), the Geographical System of Herodotus (1800), the Comparative Geography of Western Asia (1831), and important studies on the geography of northern Africa—in introductions to the Travels of Mungo Park and Hornemann—and the currents of the Atlantic and Indian Oceans. He also contributed papers to Archaeologia on the site of Babylon, the island of St Paul's shipwreck, and the landing-place of Caesarea in Britain. He was elected F.R.S. in 1781; and he received the Copley medal of the Royal Society in 1791, and the gold medal of the Royal Society of Literature in 1825. While in India he had married (1772) Jane Thackeray, a great-aunt of the novelist. He died on the 29th of March 1830, and was buried in the nave of Westminster Abbey.

RENNES, a town of western France, formerly the capital of Brittany and now the chief town of the department of Ille-et-Vilaine. It is situated at the meeting of the Ille and the Vilaine and at the junction of several lines of railway connecting it with Paris (232 m. E.N.E.), St Malo (51 m. N.N.W.), Brest (155 m. W.N.W.). A few narrow winding streets with old houses are left in the vicinity of the cathedral, but the town was for the most part rebuilt on a regular plan after the seven days' fire of 1720. Dark granite was used as building material. The old town or Ville-Haute, where the chief buildings are situated, occupies a hill bounded on the south by the Vilaine, and on the west by the canalized Ille. The Vilaine flows in a deep hollow bordered with quays and crossed by six bridges leading to the new town of Ville-Basse on a peninsula 1000 a year. The cathedral of Rennes was rebuilt in a pseudo-Ionic style between 1787 and 1844 on the site of two churches dating originally from the 4th century. The west façade with its twin towers was finished in 1700 and is in the Renaissance style. The interior is richly decorated, a German altar-piece of the 15th century being conspicuous for its carving and gilding. The architect's palace occupies in part the site of the abbey dedicated to St Melaine, whose church is the sole specimen of 12th-century architecture among the numerous churches in the town. A colossal statue of the Virgin was placed above its dome in 1867.

The Morlaizé Gate, by which the dukes and bishops used to make their state entry into the town, is a curious example of 15th-century architecture, and preserves a Latin inscription of the 3rd century, a dedication by the Redones to the emperor Gordianus. The finest building in Rennes is the old parliament house (now the law-court), designed by Jacques Debrosse in the 17th century, and decorated with statues of legal celebrities, carving, and paintings by Jean Jovenet and other well-known artists. The town hall was erected in the first half of the 18th century. It contains the library and the municipal archives, which form of great importance for the history of Brittany. In the Palais Universitaire, a modern building occupied by the university, there are scientific collections and important galleries of painting and sculpture, the chief work being the "Perseus delivering Andromeda" of Paul Veronese. About 2 m. from the town is the castle (16th century) of La Prévayale, a hamlet famous for its butter.

Rennes is the seat of an archbishop and a prefect, headquarters of the X. army corps and centre of an académie (educational division). Its university has faculties of law, science and letters, and a preparatory school of medicine and pharmacy, and there are training colleges, a lycée and schools of agriculture, dairying, music, art, architecture and industry (École pratique). The town is also the seat of a court of appeal, of a court of assizes, of tribunals of first instance and commerce, and of a chamber of commerce, and has a branch of the Bank of France. Tanning, iron founding, timber-sawing and the production of paper are noted. The manufacture of eggs and the manufacture of tenting and other coarse fabrics, bleaching and various smaller industries are carried on. Trade is chiefly in butter made in the neighbourhood, and in grain, flour, leather, poultry, eggs and honey.

Rennes, the chief cty. of the Redones, was formerly (like some other places in Gaul) called Condite (hence Condait, Condé), probably from its position at the confluence of two streams. Under the Roman empire it was included in Lugudunensis Tertia, and became the centre of various Roman roads still recognizable in the vicinity. The name Urbis Rubra given to it on the oldest chronicles is explained by the bands of red brick in the foundations of its first circuit of walls. About the close of the 10th century Constan le Tort, count of Rennes, subdued the whole province, and his son and successor Geoffroy first took the title duke of Brittany. The dukes were crowned at Rennes, and before entering the city by the Morlaizé Gate they had to swear to preserve the privileges of the church, the nobles and the commons of Brittany. During the War of Succession the city more than once suffered siege, notably in 1356–57, when Bertrand du Guesclin saved it from capture by the English under Henry, first duke of Lancaster. The parlement of Rennes (1364), which consists of 17 counselors as at Rennes from 1561, they have been previously shared with Nantes. During the troubles of the League Philip Emmanuel, duke of Mercœur, attempted to make himself independent at Rennes (1589), but his scheme was defeated by the loyalty of the parliament. Henry IV. entered the city in state on the 9th of May 1598. In 1675 an insurrection at Rennes, caused by the taxes imposed by Louis XIV. in spite of the advice of the parlement, was cruelly suppressed by Charles, duke of Chaunons, governor of the province. The parlement was banished to Vannes till 1689, and the inhabitants crushed with forfeits and put to death in the streets. The castle of Rennes, built in 1790, which destroyed eight hundred houses, completed the ruin of the town. At the beginning of the Revolution Rennes was again the scene of bloodshed, caused by the discussion about doubling the third estate for the convention of the states-general. In January 1790, Jean Victor Moreau (afterwards general) led the law-students in their demonstrations on behalf of the parlement against the royal government. During the Reign of Terror Rennes suffered less than Nantes, partly through the courage and uprightness of the mayor, Jean Leperdit. It was soon afterwards the centre of the operations of the Republican army against the Vendéans. The bishopric, founded in the 5th century, in 1859 became an archbishopric, a rank to which it had previously been raised from 1790 to 1802. In 1890 the revision of the sentence of Captain Alfred Dreyfus was carried out at Rennes.

See Oeuvres Rennes et ses environs (Reims, 1904).

RENNEVILLE, RÉNÉ AUGUSTE CONSTANTIN DE (1650–1723), French writer, was born at Caen in 1650. In consequence of his Protestant principles, he left France for Holland in 1690, and on his return three years later he was denounced as a spy and imprisoned in the Bastille, where he remained until 1713. During his imprisonment he wrote on the margins of a copy of Auteur désigné (Paris, 1693), volumes, which he called Olio Brittannico. These were rediscovered by Mr James Tregaski in 1906. Rennerville was set at liberty through the intercession of Queen Anne, and made his way to England, where he published
his Histoire de la Bastille (7 vols., 1713–24), dedicated to George I. At the age of his death in 1725 he was a major artillery in the service of the elector of Hesse. His other important work is a Recueil des voyages qui ont servi à l'établissement de la Compagnie des Indes Orientales aux Provinces Unies (10 vols., new ed., Rouen, 1725).

Rennie, John (1761–1821), British engineer, was the youngest son of James Rennie, a farmer at Phantassie, Haddingtonshire, where he was born on the 7th of June 1761. On his way to the parish school at East Linton he used to pass the workshop of Andrew Meikle (1719–1800), the inventor of the thrashing machine, and its attractions were such that he spent there much of the time that was supposed to be spent at school. In his twelfth year he was placed under Meikle, but after two years he was sent to Dunbar High School, where he showed marked aptitude for mathematics. On his return to Phantassie he occasionally assisted Meikle, and soon began to erect corn mills on his own account. In 1780, while continuing his millwright's business, he began to attend the classes on physical science at Edinburgh University. Four years later he was commissioned by Boulton and Watt, to whom he was introduced by Professor John Robison (1739–1805), his teacher at Edinburgh, to superintend the construction of the machinery for the Albion flour mill, which they were building at the south end of Blackfriars Bridge, London, and a feature of his work there was the use of iron for many portions of the machines which had formerly been made of wood. The completion of these mills established his reputation as a mechanical engineer, and soon secured him a large business as a maker of millwork of all descriptions. But his fame chiefly rests on his achievements in civil engineering. As a canal engineer his services began to be in request about 1790, and the Avon and Kennet, the Rochdale and the Lancaster canals may be mentioned among his numerous works in England. His skill solved the problem of draining and reclaiming extensive tracts of marsh in the eastern counties and on the Solway Firth.

As a bridge maker he soon became one of the most celebrated in England and Scotland, among the most conspicuous being three over the Thames—Waterloo Bridge, Southwark Bridge and London Bridge—the last of which he did not live to see completed. A notable feature in many of his designs was the flat roadway. Among the harbours and docks in the construction of which he was concerned may be mentioned those at Wick, Torquay, Grimsby, Holyhead, Howth, Kingstown and Hull, together with the London dock and the East India dock on the Thames, and he was consulted by the government in respect of improvements at the docks of Portsmouth, Sheerness, Chatham and Plymouth, where the breakwater was built from his plans. He died in London on the 4th of October 1821, and was buried in St Paul's. In person he was of great stature and strength, and a bust of him by Chantrey (now in the National Gallery), when exhibited at Somerset House, obtained the name of Jupiter Tonans. Of his family, the eldest son George, who was born in London on the 3rd of September 1791 and died there on the 30th of March 1866, carried on his father's business in partnership with the second son John, who was born in London on the 30th of August 1794 and died near Hertford on the 3rd of September 1874. George devoted himself especially to the mechanical side of building and John completed the construction of London Bridge, and at its opening in 1831 was made a knight. He succeeded his father as engineer to the Admiralty, and finished the Plymouth breakwater, of which he published an account in 1848. He was also the author of a book on the Theory, Formation and Construction of British and Foreign Harbours (1821–54), and his Autobiography appeared in 1875. He was elected president of the Institution of Civil Engineers in 1845, and held the office for three years.

Reno, a city and the county-seat of Washoe county, Nevada, U.S.A., in the W. part of the state, on the Truckee river, and about 3,14 m. E. of San Francisco. Pop. (1850) 3563; (1900) 4500 (915 foreign-born); (1910 census) 10,807. It is served by the Southern Pacific, the Virginia & Truckee and the Nevada-California-Oregon railways. The city lies near the foot of the Sierra Nevada Mountains, 4,484 ft. above the sea, and is in the most humid district of a state which has little rainfall. Among the public institutions are the university of Nevada (see NEVADA), a United States Agricultural Experiment Station, a public library (1903), the Nevada Hospital for Mental Diseases (1882), the City and County Hospital and the People's Hospital. At Reno are railway shops (of the Nevada-California-Oregon railway) and reclamation works, and the manufactures include flour, foundry and machine-shop products, lumber, beer, plaster and packed meats. Farming and stock-raising are carried on extensively in the vicinity. On the site of the present city a road house was erected in 1859 for the accommodation of travellers and freight teams on the way to and from California. By 1865 this house had become known as Lake's Crossing, and five years later it was chosen as a site for a station by the Central (now the Southern) Pacific railway, then building through the Truckee Valley. The new station was then named Reno, in honour of Gen. Jesse Lee Reno (1823–1862), a Federal officer during the Civil War, who was commissioned brigadier-general of volunteers in November 1861 and major-general of volunteers in July 1862, and led the Ninth Corps at South Mountain, where he was killed. The city twice suffered from destructive fires, in 1873 and 1879. Reno was incorporated as a town in 1879 and chartered as a city in 1883. Its city charter was withdrawn in 1901, but it was rechartered in 1903.

Renoir, Firmin Auguste (1841– ), French painter, was born at Limoges in 1841. In his early work he followed, with pronounced modern modifications, certain traditions of the French 18th-century school, more particularly of Boucher; of whom we are reminded by the decorative tendency, the pink and ivory flesh tints and the facile technique of Renoir. In the 'seventies he threw himself into the impressionist movement and became one of its leaders. In some of his paintings he carried the new principle of the division of tones to its extreme; he used the best works of Turner. In some of his paintings of the nude, he retained much of the refined sensibility of beauty of the 18th century. Renoir has tried his skill almost in every genre—in portraiture, landscape, flower-painting, scenes of modern life and figure subject; and though he is perhaps the most unequal of the great impressionists, his finest works rank among the masterpieces of the modern French school. Among these are some of his nude "Bathers," the "Rovers' Luncheon," the "Ball at the Moulin de la Galette," the "Box," the "Terceret," the "La Pensée," and the portrait of "Jeanne Samary." He is represented in the Galerieboome in the Luxembourg, in the collection of M. Durand-Ruel, and in most of the collections of impressionists' paintings in France and in the United States.

Comparatively few of his works have come to England, but the full range of his capacity was seen at the exhibition of impressionist art held at the Grafton Galleries in London in 1905. At the Vía sale in Paris in 1907, a garden scene by Renoir, "La Tonnelle," realized 26,000 frs., and a little head, "Ingrita," 25,100 frs.

Renoir, Sir Peter Le Page (1822–1897), Egyptologist, was born in Guernsey, on the 23rd of August 1822. He was educated at Elizabeth College there, and proceeded to Oxford, which, upon his becoming a Roman Catholic, under the influence of Dr Newman, he quitted without taking a degree. Like many other Anglican converts, he proved a thorn in the side of the Ultramontane party in the Roman Church, though he did not, like some of them, return to the communion of the Church of England. He opposed the promulgation of the dogma of Papal Infallibility, and his treatise (1868) upon the condemnation of Pope Honorius for heresy by the council of Constantinople in A.D. 680 was placed upon the index of prohibited books. He had been from 1855 to 1864 professor of ancient history and Oriental languages in the Roman Catholic university which Newman mainly strove to establish in Dublin, and during part of this period edited the Irish Review and the Byzantine Review, which latter had to be discontinued on account of the hostility of the Roman Catholic hierarchy. In 1864 he was appointed a government inspector of schools, which position he
held until 1886, when his growing celebrity as an Egyptianist procured him the appointment of Keeper of Oriental Antiquities in the British Museum, in succession to Dr Samuel Birch. He was also elected in 1887 president of the Society of Biblical Archaeology, to whose Proceedings he was a constant contributor. The most important of his contributions to Egyptology are his Hibbert Lectures on "The Religion of the Egyptians," delivered in 1879; and the translation of The Book of the Dead, with an ample commentary, published in the Transactions of the society over which he presided. He retired from the Museum under the superannuation rule in 1891, and died in London on the 14th of October 1897. He had been knighted the year before his death. He married in 1857 Ludovica von Brentano, member of a well-known German literary family.

RENOUVIER, CHARLES BERNARD (1815-1903), French philosopher, was born at Montpellier on the 1st of January 1818, and educated in Paris at the École Polytechnique. In early life he took an interest in politics, and the approval extended by Hippolyte Carnot to his Manuel républicain de l'homme et du citoyen (1848) was the occasion of that minister's fall. He never held public employment, but spent his life writing, retired from the world. He died on the 1st of September 1903. Renouvier was the first Frenchman after Malebranche to formulate a complete idealistic system, and had a vast influence on the development of French thought. His system is based on Kant's, as his chosen term "Néo-criticisme" indicates; but it is a transformation rather than a continuation of Kantianism. The two leading ideas are a dislike to the Unknowable in all its forms, and a reliance on the validity of our personal experience. The former accounts for his acceptance of Kant's phenomenalism, combined with rejection of the thing in itself. It accounts, too, for his polemic on the one hand against a Substantial Soul, a Buddhist Absolute, an Infinite Spiritual Substance; on the other hand against the no less mysterious material or dynamic substratum by which naturalistic Monism explains the world. He holds that nothing exists except presentations, which are not merely sensational, and have an objective aspect no less than a subjective. To explain the formal organization of our experience he adopts a modified version of the Kantian categories. The insistence on the validity of personal experience leads Renouvier to a yet more important divergence from Kant in his treatment of volition. Liberty, he says, in a much wider sense than Kant, is man's fundamental characteristic. Human freedom acts in the phenomenal, not in an imaginary nouménal sphere. Liberty is not intellectual merely, but is determined by an act of will affirming what we hold to be morally good. In his religious views Renouvier makes a considerable approximation to Leibnitz. He holds that we are rationally justified in affrming human immortality and the existence of a finite God who is to be a constitutional ruler, but not a despot, over the souls of men. He would, however, regard atheism as preferable to a belief in an infinite Deity.

His chief works are: Essais de critique générale (1853-64), Science de la morale (1869), Uchronie (1876), Essai d'une classification systématique des doctrines philosophiques (1885-86), Philosophie analytique de l'histoire (1890-97), Histoire et solution des problèmes métaphysiques (1901); Victor Hugo; Le Poète (1893), Le Philosophoph (1902); Les Dilemmes de la métaphysique pure (1901); Le Personnalisme (1903); Critique of the doctrine of Kant (1906, pub. in English by L. Prat).

Darlu, La Morale de Renouvier (1900); J. Prat, La Revue de C. R. (1905); A. Arnal, La Philosophie religieuse de C. R. (1907).

RENSSLEAER, a city of Rensselaer county, New York, U.S.A., in the eastern part of the state, on the E. bank of the Hudson river, opposite Albany. Pop. (1900) 7466, of whom 1089 were foreign-born; (1910 census) 10,711. It is served by the New York Central and the Boston & Albany railways, which have shops here, and is connected with Albany by three bridges across the Hudson. Rensselaer, originally called Greenbush, was first settled in 1631, and the site formed part of the large tract bought from the Indians by the agents of Killian van Rensselaer and known as Rensselaerwyck. In 1810 a square mile of land within the present city limits was acquired by a land speculator, was divided into lots and offered for sale. Development followed, and five years later the village was incorporated. In 1897 Greenbush was chartered as a city, and its name was changed to Rensselaer. Its limits were extended in 1907 by the annexation of the village of Bath (pop. in 1900, 2504) and the western part of the township of East Greenbush. Rensselaer manufactures knit-goods, wool shoddy, felt, &c.

RENT. Various species of rent appear in Roman Law; rent (canon) under the long leasehold tenure of Emphyteusis; rent (reditus) of a farm; ground-rent (solarium); rent of state lands (vectigal); and the annual rent (prezzo) payable for the jus superficialum or right to the perpetual enjoyment of anything built on the surface of land. (See Roman Law.)

ENGLISH LAW. (As to the rent of apartments, &c., see LODGER AND LODGINGS.)—Rent is a certain and periodical payment or service made or rendered by the tenant of a corporeal hereditament and issuing out of (the property of) such hereditament. Its characteristics, therefore, are (1) certainty in amount; (2) periodicity in payment or rendering; (3) the fact that rent is yielded and is, therefore, said "to lie in render," as distinguished from profits à prendre in general, which are taken, and are, therefore, said to lie in prendre; (4) that it must issue out of (the profits of) a corporeal hereditament. A rent cannot be reserved out of incorporeal hereditaments such as advowsons (Co. Litt. 479, 1438). But rent may be reserved out of estates in reversion or remainder (see REAL PROPERTY) which are not purely incorporeal. It is not essential that rent should consist in a payment of money. Apart from the rendering of services, the delivery of hens, horses, wheat, &c., may constitute a rent. But, at the present day, rent is generally a sum of money paid for the occupation of land. It is important to notice that this conception of rent was attained at a comparatively late period in the history of the law. The earliest rent seems to have been a form of personal service, generally labour on land, and was fixed by custom. The exaction of a competition or rack rent beyond that limited by custom was, if one may judge from the old Breton law of Ireland, due to the presence upon the land of strangers in blood, probably at first outcasts from some other group.¹ The strict feudal theory of rent admitted labour on the lord's land as a lower form, and developed the military service due to the crown or a lord as a higher form. Rent service is the oldest and most dignified kind of existing rent. It is the only one to which the power of distress attaches at common law, giving the landlord a preferential right over other creditors exercisable without the intervention of judicial authority (see DISTRESS). The increasing importance of socage tenure, arising in part from the convenience of paying a certain amount, whether in money or kind, rather than comparatively uncertain services, led to the gradual evolution of the modern view of rent as a sum due by contract between two independent persons. At the same time the primitive feeling which regarded the position of landlord and tenant from a social rather than a commercial point of view is still of importance.

Rents, as they now exist in England, are divided into two great classes—rent service and rent charge.

Rent Service.—A rent service is so called because by it a tenure by means of service is created between the landlord and tenant. The tenant advances a certain sum of money to the landlord, who is to be held for life by the tenant, and is nothing more than nominal. Rent service is said to be incident to the reversion—that is, a grant of the reversion carries the rent with it (see REMAINDER). A power of distress is incident to

¹ "The three rents are: rack rent from a person of a strange tribe, a fair rent from one of the tribe, and the stipulated rent which is paid equally by the tribe and the strange tribe."—Senchus Mor, p. 159, cited by Maine, Village Communities, p. 187. See also Vinogradoff, Villainage in England (Oxford, 1892), pp. 181, 188, 215; The Growth of the Manor (by the same author) (London, 1905), pp. 230, 328; Pollock and Maitland, Hist. Eng. Law (Cambridge, 1895), ii. 128-134.
at common law to this form of rent. Copyhold rents and rents reserved on lease fall into this class.

Rent Charge.—A rent charge is the grant of an annual sum payable out of lands in which the grantor has an estate. It may be in fee, in tail, for life—the most common form—for years. It must be created by deed or will, and may be either at common law or under the Statute of Uses (1536). The grantor has no reversion, and the grantees have at common law no power of distress, though such power may be given him by the instrument creating the rent charge. The Statute of Uses (1536) gave a power of distress for a rent charge created under the statute. The Conveyancing Act 1881, § 44, has given a power of distress for a sum due on any rent charge which is twenty-one days in arrear. By § 45 a power of redemption of certain perpetual rents in the nature of rent charges is given to the owner of the land out of which the rent issues. Rent charges granted since April 26th, 1855, otherwise than by marriage settlement or will or for a life or lives or for any estate determinable on a life or lives must, in order to bind lands against purchasers, mortgagees or creditors, be registered in the Land Registry in Lincoln's Inn Fields (Judgments Act 1855 and Land Charges Act 1900) in certain other cases it is also necessary to register rent charges, for instance, under the Improvement of Land Act 1864 and the Land Transfer Acts 1875 and 1897. Rent charges are barred by non-payment or non-acknowledgment for a period of twelve years. The period of limitation for the arrears of such rent is six years.

Various Forms of Rent Charge.—Forms of rent charge of special interest are (i) the rent charge (see Tithes), and the rent charges formerly used for the purpose of creating "faggot" votes. The device was adopted of creating parliamentary voters by splitting up freehold interests into a number of rent-charges of the annual value of 40s., so as to satisfy the freeholders' franchise. But such rent charges are now rendered ineffective by the Representation of the People Act 1884, § 4, which enacts (subject to a saving for existing rights and an exception in favour of tenants of copyhold or leasehold) that a rent charge which a man shall not be entitled to be registered as a voter in respect of the ownership of any rent charge.

A rent charge reserved without power of distress is termed a rent-seck (reditus siccus) or "dry rent," from the absence of the power of distress. But, as power of distress for rent-seck was given by the Landlord and Tenant Act 1736, the legal effect of such rents has been since the act the same as that of a rent charge.

Other Varieties of Rent.—Rents of assise or Quit rents are a relic of the old customary rents. They are presumed to have been exacted in some styled a great rent (e.g. the rent of a fagot. All peppercorn, or nominal, rents seem to fall under this head. 1 The object of the peppercorn rent is to secure the acknowledgment by the tenant of the landlord's right. In modern building leases a peppercorn rent is sometimes reserved as the rent for the first few years. Services rendered in lieu of payment by tenants in grand and petit serjeancy may also be regarded as examples of rents in kind. Grand serjeancy is a form of tenure in chivalry under which the king's tenants (serrientes) in chief owed his rent before the day on which it is due: runs the risk of being called upon in certain circumstances to pay it over again. Such a payment is an advance to the landlord, subject to an agreement that, when the rent becomes due, the advance shall be treated as a fulfillment of the tenant's obligation to pay rent. The payment is, therefore, generally speaking, a defence to an action by the landlord or his heirs. But if the landlord mortgages his reversion, either before or after the advance, the assignee will, by giving notice to the tenant, before the proper rent-day, to pay rent to him, become entitled to the rent then falling due. Payment by cheque is conditional payment only, and if the cheque is dishonoured the original obligation revives. Where a cheque in payment of rent is lost in the course of transmission through the post, the loss falls on the tenant, unless the landlord has expressly or impliedly authorized it to be forwarded in that way: and the landlord's consent to take the risk of such transmission will not be inferred from the fact that payments were ordinarily made in this manner in the dealings between the parties. A tenant may deduct from his rent (i) the "landlord's property tax" (on the annual value of the premises for income tax purposes), which is paid by the tenant, if the statute imposing the tax authorizes the deduction (which should be made from the rent next due after the payment); (ii) taxes or rates which the landlord had undertaken to pay but had not paid, payment having theretofore been made by the tenant; (iii) payments made by the tenant which ought to have been made by the landlord, e.g. rent due to a superior landlord; (iv) compensation under the Agricultural Holdings Acts 1883-1900.

Remedies for Non-payment of Rent.—A landlord's main remedy for non-payment of rent is distress (Lat.\, *distingere*, to draw asunder, detain, occupy), i.e. the right to seize all goods found upon the demised premises, whether those of the tenant or of a stranger, except goods specially privileged, and to detain and, if need be, to sell them, in satisfaction of his claim. The requisites of a valid distress are these: (a) There must be "a certain and proper rent," i.e. rent due in respect of an actual tenancy of corporeal hereditaments; (b) the rent must be in arrear; (c) there must be a reversion in the person distraining; and (d) there must be goods on the premises liable to be distrained.

1 When peppercorn rents were instituted, in the middle ages, they were not, however, nominal, the cost of spices being then very great. A peppercorn rent, generally an obligation to pay 1 lb of pepper at the usual rent days, constituted a substantial impost even as late as the 18th century.
All personal chattels are distrainable with the following exceptions: (i) Goods evidently privileged (e. g., fixtures (q. e. d.) are sold to the tenant in the way of trade; (2) things which cannot be restored, e. g., meat and milk; growing corn and corn in sheaves formerly fell within this category, but the Distress for Rent Act 1737 reversed the decision in the case of the latter; and a statute of 1699 abolished it in that of the latter; (d) things in actual use, e. g., a horse while it is drawing a cart; (e) animals famine-proof and tamed down (or tamed in an animal way may be distrained); (f) things in the custody of the law, e. g., in the possession of a sheriff under an execution (q. e. d.); (g) straying cattle; (h) in the case of agricultural holdings under the Agricultural Holdings Act 1885, Acts 1883–1900 hired agricultural machinery and implements; (i) the wearing apparel and "bedding"—a term which includes "bedstead"—of tenant and his family, and the tools and implements of his trade to the value of £5 (Law of Distress Amendment Act 1888); (j) the goods or动ables in the premises (Diplomatic Privileges Act 1708). (ii) Goods conditionally privileged, i. e., privileged if there are sufficient goods of other kinds on the premises to satisfy the distress; (a) implements of trade not in actual use; (b) beasts of the plough and sheep; (c) agisted cattle; (d) growing crops sold under an execution (Landlord and Tenant Act 1851, s. 2); (e) loggers' goods. The Loggers' Goods Protection Act 1871 provides that where a logger's goods have been seized by the superior landlord the logger may serve him with a notice stating that the intermediate landlord had no interest in the property seized, but that it is the property, or in the lawful possession, of the logger, and set down in the register of the sheriff's court by the due by the logger to his immediate landlord. On payment or tender of such rent the landlord cannot proceed with the distress against the goods in question.

Landlords cannot distrain except upon the premises denounced, but he has a statutory right to follow things clandestinely or fraudulently removed from the premises within 30 days after their removal, unless they have been in the meantime sold bona fide without notice. A landlord may, by statute (Landlord and Tenant Act 1709, s. 6), distrain within six months after the determination of the lease provided that the tenant has remained in possession. A distress must be made in the daytime, i.e., between 6 a.m. and 9 p.m. after suit has been brought in the court, and only are recoverable by distress (Real Property Limitation Act 1853, s. 12): the Real Property Limitation Act 1874 (s. 1), which has been applied, with the exception of four years' rent-charges, and not to rent under a lease, and the six years' arrears may be recovered in spite of the lapse of time. In the case of agricultural tenancies falling within the Agricultural Holdings Act 1883–1900, the right of distress is confined to one year's arrears of rent. Where the tenant is bankrupt, a distress levied after the bankruptcy is limited to six months' rent accrued due prior to the date of adjudication; see Bankruptcy Act 1883 (s. 42) and 1890 (s. 28). Where a tenant is a bankrupt, the landlord's right to proceed with a distress is a fine or equitable prejudice to his civil liability (Law of Distress Amendment Act 1893, s. 2). The seizure must not be excessive (statute of Henry III., 1267): but enough must be taken to satisfy the claim, for the landlord cannot distrain twice for the same rent where he could have taken sufficient in the first instance. After being seized, the goods must be impounded (Distress for Rent Act 1707, s. 10; and see the statute of 1690, s. 3, on impounding of corn, straw, hay; the Distriess for Rent Act 1737, s. 8, on impounding of growing crops; and the statute of 1554 and the Cruelty to Animals Act 1849, s. 5, on impounding of cattle); and the landlord has a statutory power of impounding all other things. It will be proceeded with only if the tenant tenders the rent before the impounding; and a tenant, has, by statute (1690, s. 5), five clear days' grace, excluding the date of seizure, between impounding and sale. On the written request of the sheriff within ten days it will be returned (Statute of Westminster Distress Amendment Act 1888, s. 6). A tenant may, before sale, recover goods illegally distrained by an action of reprieve (L. Lat. repugurare, to redeem a thing taken by another). Where no rent was tendered before the tenancy the tenant may recover by distress the value of the goods sold (statute 1690, s. 5); and summary remedies for the recovery of the property have been created by modern enactments (Law of Distress Amendment Act 1893, s. 4, on impounding of growing crops; and the statute of 1690, s. 46). Where rent was due, but the distress was irregular, the tenant can only recover special damage (Distress for Rent Act 1737, s. 6).

Goods taken under an execution (q. e. d.) are not removables till a year's rent has been paid to the landlord (Landlord and Tenant Act 1790).

The landlord has, besides distress, his ordinary remedy by action. In addition, special statutory remedies are given in the case of tenants holding over after the expiration of their tenancy. By the Distress for Rent Act 1737 any tenant giving notice to quit, and holding over, is liable to pay double rent for such time as he continues in possession (see further under EJECTMENT).

Ireland.—The main differences between Irish and English law have been caused by legislation (see EJECTMENT; LANDLORD AND TENANT).

Scotland.—Rent is properly the payment made by tenant to landlord for the use of land held under lease (see LANDLORD AND TENANT). In agricultural tenancies the legal terms for the payment of rent are at Whitsunday after the crop has been shown, and at Martinmas after it has been reaped. But a landlord and tenant may substitute conventional terms of payment, either anticipating (fore, or forehand rent) or postponing (back, or backhand rent) the legal term. The rent paid by vassal to superior is called feu-duty (see FEU). Its nearest English equivalent is the see farm rent. The remedy of distress does not exist in Scots law. Rents are recovered (i) by summary diligence, proceeding on a clause, in the lease, of consent to registration for execution; (ii) by an ordinary petitory action; (iii) by an action of maills and duties" (the tenant in the grand, the tenant in the small was a coin at one time current in Scotland) in the Sheriff Court or the Court of Session; and (iv) in non-agricultural tenancies by procedure under the right of hypothec, where that still exists; the right of hypothec over land exceeding 2 acres in extent let for agriculture or pasture was abolished as from November 11, 1884 (see HYPOTHEC); (v) by action of removing (see EJECTMENT). Arrears of rent prescribe in five years from the time of the tenant's removal from the land.

Labour or service rents were at one time very frequent in Scotland. The events of 1715 and 1745 showed the vast influence over the tenantry that the great proprietors acquired by such means. Accordingly acts of 1716 and 1746 provided for the commutation of services into money rents. Such services may still be created amendatory to the act of 1751. The law thus works out for the sheriff by the Conveyancing Act 1874 (§§ 20, 21). In the more remote parts of Scotland it is understood that there still exist customary returns in produce of various kinds, which being regulated by the usage of the district or of the barony or estate cannot be comprehended under any general rule" (Hunter, Landlord and Tenant, ii. 298). Up to 1848 or 1850 there existed in Scotland "stealow" leases— analogous to the chêtdel de fer de French law—under which the landlord stocked the farm with corn, cattle, implements, &c., the tenant returning similar articles at the expiration of his tenancy and paying in addition to the ordinary rent a stealow rent of 5 % on the value of the stock. Act of 1848.

As to the rent of apartments, &c., see LODGER AND LODGINGS.

United States.—The law is in general accordance with that of England. The tendency of modern state legislation is unfavourable to the continuance of distress as a remedy. In the New England states, attachment on mesne process has, to a large extent, superseded it. In New York and Missouri it has been abolished by statute; in Mississippi the landlord has a claim for one year's rent on goods seized under an execution and a lien on the growing crop. In Ohio, Tennessee and Alabama it is not recognized, but in Ohio the landlord has a lien in the growing crop to the prejudice of the executory creditor. The legislatures of nearly all the states agree with the law of England as to the exemption from distress of household goods, wearing apparel, &c. (see Dillon's Laws and Jurisprudence of England and America, pp. 360, 367; also Homestead). As to the rent of apartments, &c., see LODGER AND LODGINGS.

Fee farm rents exist in some states, like Pennsylvania, which have not adopted the statute of Quia Emptores as a part of their common law (Washburn's Real Property, ii. 252).

Other Laws.—Under the French Code Civil (art. 2102) the landlord is a privileged creditor for his rent. If the lease is by authentic act, or under private signature, he has a right over the year's harvest and produce, the furniture of the house and everything employed to keep it up, and (if a farm) to work it, in addition to satisfy all rents due up to the expiry of the term. If the lease is not by authentic act nor for a specified term, the landlord's claim is limited to the current year and the year next following (see law of 12th Feb. 1872). The goods of a sub-lessee are protected: and goods bailed or deposited with the tenant are in general not
REPAIRS (from Lat. reparare, to make ready again), acts necessary to restore things to a sound state after damage; the question of repairs is important in the relations between landlord and tenant. (See the articles FLAT; LANDLORD AND TENANT.)

REPEAL (O.F. rapel, modern rappel, from raperel, ropperel, revoke, re and oppeler, appeal), the abrogation, revocation or annulling of a law (see ABROGATION and STATUTE). The word is particularly used in English history of the movement led by Daniel O'Connell (q.v.) for the repeal of the act of Union between Great Britain and Ireland in 1830 and 1841-46, which in its later development became known as the Nationalist or Home Rule movement (seee IRELAND, History).

REPIN, ILJA JEFIMOVICH (1844-1930), Russian painter, was born in 1844 at Tschuguev in the department of Charkov, the son of parents in straitened circumstances. He learned the rudiments of art under a painter of saints named Bunakov, for three years gaining his living at this humble craft. In 1863 he obtained a studentship at the Academy of Fine Arts of St. Petersburg, where he remained for six years, winning the gold medal and a travelling scholarship which enabled him to visit France and Italy. He returned to Russia after a short absence, and devoted himself exclusively to subjects having strong national characteristics. In 1884 he became professor of historical painting at the St. Petersburg Academy. Repin's paintings are powerfully drawn, with not a little imagination and with strong dramatic force and characterization. A brilliant colourist, and a portrait-painter of the first rank, he also became known as a sculptor and etcher of ability. His chief pictures are "Procession in the Government of Kiey," "Home-coming," "The Arrest," "Faran the Terrible's murder of his Son," and best known of all, "The Reply of the Cossacks to Sultan Mahmoud IV." The portraits of the Baroness V. I. Ulskii, of Anton Rubinstein and of Count Leo Tolstoy are among his best achievements in this class. The Tretiakov gallery at Moscow contains a very large collection of his work. See "Professor Repin," by Prince Bojdzar Karageorgevich, in the Magazine of Art, xxii. p. 783 (1899); "Russian Art," a paper by E. Brayley Hodgetts in the Proceedings of the Anglo-Russian Literary Society (5th of May 1896); "Ijia Jefimovich Repin," by Julius Norden, in Velhagen and Klasing's Monatshefte, xx. p. 1 (1905); also R. Muther, History of Modern Painting (ed. 1907), iv. 380.

REINGTON (or REPYNGDON), PHILIP (d. 1424), English bishop and cardinal, was educated at Oxford and became an Augustinian canon at Leicester before 1382. A man of some learning, he came to the front as a defender of the doctrines taught by John Wycliffe; for this he was suspected and afterwards excommunicated, but in a short time he was pardoned and restored by Archbishop William Courtenay, and he appears to have completely abandoned his unorthodox opinions. In 1394 he was made abbot of St Mary de Pré at Leicester, and after the accession of Henry IV. to the English throne in 1399 he became chaplain and confessor to this king, being described as "a clerico specialissimus domini regis Henrici." In 1404 he was chosen bishop of Lincoln, and in 1408 Pope Gregory XII. made him a cardinal. He resigned his bishopric in 1419. Some of Repington's sermons are in manuscript at Oxford and at Cambridge.

REPLEVIN, an Anglo-French law term (derived from replévin, to recover; see PLEDGE for further etymology) signifying the recovery by a person of goods unlawfully taken out of his possession by means of a special form of legal process; this falls into two divisions—(1) the "replevy," the steps which the owner takes to secure the physical possession of the goods, by entry, detinue, the actual taking of the goods if the case goes against him, and (2) the "action of replévin" itself. The jurisdiction in the first case is in the County Court; in the second case the Supreme Court has also jurisdiction in certain circumstances. The proceedings are now regulated by the County Courts Act 1888. At common law, the ordinary action for the recovery of goods wrongfully taken would be one of detinue; but no means of immediate recovery
was possible till the action was tried, and until the Common Law Procedure Act 1854 the defendant might exercise an option of paying damages instead of restoring the actual goods. The earliest regulations with regard to the action of replevin are to be found in the Statute of Marlborough (Marlebridge), 1367, cap. 21. For the early history, see Blackstone's Commentaries, iii. 145 seq. Only goods and cattle can be the subjects of an action for replevin. Although the action can be brought for the wrongful taking of goods as long as, so long as the taking was wrongful and it was from the possession of the owner; it is practically confined to goods taken by an illegal as opposed to an excessive distress (see Distress and Rent, § 31). REPNIN, the name of an old Russian princely family, the first of whom to gain distinction was

Prince Anikita Ivanovich Repin (1665–1726), Russian general, and one of the collaborators of Peter the Great, with whom he grew up. On the occasion of the Sophiaan insurrection of 1689, he carefully guarded Peter in the Troitsa monastery, and subsequently took part in the Azov expedition, during which he was raised to the grade of general. He took part in all the principal engagements of the Great Northern War. Defeated by Charles XII at Holowczyn, he was degraded to the rank of colonel, but was pardoned as a reward for his valor at Lysean and recovered all his lost dignities. At Potlava he commanded the centre. From the Ukraine he was transferred to the Baltic Provinces and was made the first governor-general of Riga after its capture in 1710. In 1724 he succeeded the temporarily disgraced favourite, Menshikov, as war minister. Catherine I. created him a field-marshall.

See A. Bauman, Russian Statesmen of the Old Time (Rus.), vol. i. (Petersburg, 1877).

His grandson, Prince Nikolai Vasilevich Repnin (1734–1801), Russian statesman and general, served under his father, Prince Vasili Anikitch, during the Rhenish campaign of 1745 and subsequently resided for some time abroad, where he acquired "a thoroughly sound German education." He also participated in the Seven Years' War in a subordinate capacity. Peter III. sent him as ambassador in 1763 to Berlin. The same year Catherine transferred him to Warsaw as minister plenipotentiary, with special instructions to form a Russian party in Poland from among the dissidents, who were to receive equal rights with the Catholics. Repnin convinced himself that the dissidents were too poor and insignificant to be of any real support to Russia, and that the whole agitation in their favour was factitious. At last, indeed, the dissenters themselves even petitioned the empress to leave them alone. It is clear from his correspondence that Repnin, a singularly proud and high-spirited man, much disliked the very dirty work he was called upon to do. Nevertheless he faithfully obeyed his instructions, and, by means more or less violent or inconceivable, forced the diet of 1768 to concede everything. The immediate result was the Confederation of Bar, which practically destroyed the ambassador's handiwork. Repnin resigned his post for the more congenial occupation of fighting the Turks. At the head of an independent command in Moldavia and Walachia, he gained a large victory over them at the battle of the Pruth (1770); distinguished himself at the actions of Larga and Kagaula; and captured Izmail and Kilia. In 1771 he received the supreme command in Walachia and routed the Turks at Bucharest. A quarrel with the commander-in-chief, Rumyantsev, then induced him to send in his resignation, but in 1774 he participated in the capture of Silistria and in the negotiations which led to the peace of Kuchuk-Kalnari. In 1775–76 he was ambassador at the Porte. On the outbreak of the war of the Bavarian Succession he led 30,000 men to Breslau, and at the subsequent congress of Teschen, where he was Russian plenipotentiary, compelled Austria to make peace with Prussia. During the second Turkish war (1787–92) Repnin was, after Suvarov, the most famous of the Russian commanders. He defeated the Turks at Salcha, captured the whole camp of the seraskier, Hassan Pasha, shut him up in Izmail, and was preparing to reduce the place when he was forbidden to do so by Potemkin (1789). On the retirement of Potemkin (q.v.) in 1791, Repnin succeeded him as commander-in-chief, and immediately routed the grand vizier at Machin, a victory which compelled the Turks to accept the truce of Galatz (31st of July 1791). In 1794 he was made governor-general of the newly acquired Lithuanian provinces.

The emperor Paul raised him to the rank of field-marshal (1796), and, in 1798, sent him on a diplomatic mission to Berlin and Vienna in order to detach Prussia from France and unite both Austria and Prussia against the Jacobins. On his return unsuccessful he was dismissed the service.

See A. Kraushar, Prince Repnin in Poland, 1704–8 (Pol.) (Warsaw, 1868). Correspondence with Frederick the Great and others (Rus. and Fr.), in Russky Arkiv (1868) 1869, 1874, &c. (Petersburg); M. Longinov, True Anecdotes of Prince Repnin (Rus.) (Petersburg, 1865).

(R. N. B.)

REPORTING, the art or business of reproducing in readable form, mainly for newspapers, but also for such publications as the Parliamentary or Law Reports, the words of speeches, or describing in narrative form the events, in contemporary history, by means of the notes made by persons known generally as reporters. The special business of reporting is a comparatively modern one, since it must not be confounded with the general practice of quoting, or of mere narrative, which is old and writing. There was no truly systematic reporting until the beginning of the 19th century, though there was parliamentary reporting of a kind almost from the time when parliaments began, just as law reporting (which goes back to 1292) began in the form of notes taken by lawyers of discussions in court. The first attempts at parliamentary reporting, in the sense of seeking to make known to the public what was done and said in parliament, began in a pamphlet published monthly in Queen Anne's time called The Political State. Its reports were mere indications of speeches. Later, the Gentleman's Magazine began to publish reports of parliamentary debates. Access to the Houses of Parliament was obtained by Edward Cave (q.v.), the publisher of this magazine, and some of his friends, and they took surrupitiously what notes they could. These were subsequently transcribed and brought into shape for publication by another hand. Dr Johnson for some years wrote the speeches, and he took care, as he admitted, not to let the "Whig dogs" get the best of it; the days of verbatim reporting were not yet come, and it was considered legitimate to make people say in print what substantially was supposed to represent their opinions. With the coming of a stronger sense of obligation on all public reporting, but the Gentleman's Magazine appeared, we have continued its reports for some time without attracting the attention or rousing the jealousy of the House of Commons. The publisher, encouraged by immunity from prosecution by parliament, grew bolder, and began in his reports to give the names of the speakers. Then he was called to account. A standing order was passed in 1728, which declared "that it is an Indignity to, and a breach of, the privilege of this House for any person, to presume to give, in written or printed newspapers, any account or minute of the debates or other proceedings, that upon discovery of the authors, printers or publishers of any such newspaper this House will proceed against the offenders with the utmost severity." Under this and other standing orders, Cave's reports were challenged, with the result that they appeared without the proper names of the speakers, and under the guise of "Debates in the Senate of Lilliput."
or some other like title. France was Blefuscu; London was Mildenlos; pounds were sprugs; the duke of Newcastle was the Nardey secretary of state; Lord Hardwicke was the Hurg Hickrad; and William Pulteney was Wungul Pumulb.

In the latter half of the century the newspapers began to report parliamentary debates more fully, with the result that, in 1771, several printers, including those of the Morning Chronicle and the London Evening Post, were ordered into custody for publishing debates of the House of Commons. A long and bitter struggle between the House and the public ensued. John Wilkes took part in it. The lord mayor of London and an alderman were sent to the Tower for refusing to recognize the Speaker's warrant for the arrest of certain printers of parliamentary reports. But the House of Commons was beaten. In 1772 the newspapers published the reports as usual; and their right to do so has never since been really questioned. Both Houses of Parliament, indeed, now show as much anxiety to have their debates fully reported as aforesaid they showed resentment at the intrusion of the reporter. Elaborate provision is made in the House of Lords and in the House of Commons for reporters. They have a Press Gallery in which they may take notes, writing rooms in which those notes may be extended, and a special dining-room. Reporting is nowhere carried to such an extent as in the United Kingdom, since in most other countries the newspapers do not find it sufficiently interesting "copy" for their readers to justify the amount of space required. Consequently the verbatim reports, though now no longer hindered by law, and made possible by shorthand (which was first employed in the service of parliament in 1802) and by all the arts of communication and reproduction, are considerably restricted.

But parliamentary work is only a small part of newspaper reporting. The newspapers in the beginning of the 19th century rarely contained more than the barest outline of any speech or public address delivered in or in the neighbourhood of the towns where they were published. After the peace of 1815 a period of much political fermentation set in, and the newspapers began to report the speeches of public men at greater length. It was not, however, until well into what may be called the railway era that any frequent effort was made by English newspapers to go out of their own district for the work of reporting. The London newspapers had before this led the way. Early in the 19th century, Richard Rainey, then editor of the Morning Chronicle, and the manager of the Morning Chronicle established a staff of reporters. Each reporter took his "turn"—that is, he took notes of the proceedings for a certain time, and then gave place to a colleague. The reporter who was relieved at once extended his notes, and thus prompt publication of the debates was made possible. The practice grew until there was a good deal of competition among the papers as to which should first issue a report of any speech of note in the country. Reporters had frequently to ride long distances in post-chaises, doing their best as they jolted along the roads to transcribe their notes, so that they might be ready for the printer on arrival at their destination. Charles Dickens, whose efforts in the way of reporting were celebrated, used to tell several stories of his adventures of this kind while he held an engagement on the Morning Chronicle. One result was that the provincial newspapers were stimulated to greater efforts, and as daily newspapers sprang up in all directions, and the electric telegraph provided greater facilities for reporting, the old supremacy of the London journals in this department of newspaper work gradually disappeared. No public man made a speech but it was faithfully reproduced in print. Local governing bodies, charitable institutions, political associations, public companies—all these came in a short time to furnish work for the reporter, and had full attention paid to them. By the second half of the 19th century, parliamentary reporting was a leading feature of the London newspapers. They had a monopoly of it. All the reporting arrangements in the House of Lords and in the House of Commons were made with sole regard to their requirements. There had indeed been a long battle between The Times and some of the other London newspapers as to which should have the best parliamentary report, and The Times had established its supremacy, which has never been shaken. The provincial newspapers were in the main obliged to copy the London reports, and rarely made any attempt to get reports of their own. When the electric telegraph came into use for commercial purposes a change began. The company which first carried wires from London to the principal towns in the country started a reporting service for the country newspapers. In addition, it procured admission to the parliamentary galleries for reporters in its employment, and began to send short accounts of the debates to the newspapers in the country. These newspapers were thus enabled to publish in the morning some account of the parliamentary proceedings of the previous night, instead of having to take like reports a day later from the London journals. The telegraph companies (not yet taken over by the state) for a long time could or would do no more than they had begun by doing; and they offered no inducements to the provincial newspapers to telegraph speeches. The public meanwhile wanted to know more fully what their representatives were saying in parliament, and gradually the leading provincial newspapers adopted the practice of employing reporters in the service of the London journals to report debates on subjects of special interest in localities; and these reports, forwarded by train or by post, were printed in full, but of course a day late. The London papers paid little attention to debates of local interest, and thus the provincial papers had parliamentary reporting which was not to be found elsewhere. Bit by bit this feature was developed. It was greatly accelerated by a movement which the Scotsman was the first to bring about. About 1865, a new company having come into existence, it was agreed that wires from London should be put at the disposal of such newspapers as desired them. Each newspaper was to have the use of a wire—of course on payment of a large subscription—from six o'clock at night till three o'clock in the morning. This was the beginning of the "special wire" which now plays so important a part in the production of almost all newspapers. The arrangement was first made by the Scotsman and by other newspapers in Scotland. The special wires were used to their utmost capacity to convey reports of the speeches of leading statesmen and politicians; and, instead of bare summaries of what had been done, the newspapers contained pretty full reports.

When the telegraphs were taken over by the state in 1870 the facilities for reporting were increased in every direction. The London papers, with the exception of The Times, had given less and less attention to parliamentary debates, while on the other hand several of the provincial newspapers were giving more space than ever to the debates. These newspapers had to get their reports as best they could. The demand for such reporting had led, on the passing of the telegraphs into the hands of the state, to the formation of news agencies, which undertook to supply the provincial papers. These agencies were admitted to the reporters' galleries in the Houses of Parliament, but the reports which any agency supplied were identical; that is to say, all the newspapers taking a particular class of report had exactly the same material supplied to them—the reporter producing the number of copies required, by means of manifold copying paper. Accordingly attempts were made to get separate reports by engaging the services of some of the reporters employed by the London papers. The "gallery" was shut to all save the London papers and the news agencies. The Scotsman sought in vain to break through this exclusiveness. The line, it was said, must be drawn somewhere, and the proper place to draw it was at the London Press. One of that line was departed from every newspaper in the kingdom must have admission. But in 1880 a select committee of the House of Commons was appointed to consider the question. It took evidence, and it reported in favour of the extension of the gallery and of the admission of provincial papers. The result was that three or four papers which would be satisfied with the same report joined in providing the necessary reporting
REPOUSSE—REPRESENTATION

staff. In other cases individual newspapers put themselves on the same footing as the London newspapers by engaging separate staffs of reporters.

The effect of telegraphic improvements may be partially gauged by the fact that in 1871 the number of words handed in for transmission through the British Post Office for Press purposes (special rates being allowed) was 22,000,000, and that in 1900 it had risen to 835,000,000. Meanwhile the evolution of the modern newspaper had brought many other kinds of reporting, besides parliamentary, into play.

When it is said "descriptive reporting" has in some cases nearly shouldered the reporting of speeches out of newspapers, the special correspondent or the war correspondent is a "descriptive reporter." The interviewee came in great prominence during the "eighties" and "nineties," and the influence of American journalistic methods, which made smart reporting the most valuable commercial asset of the popular newspaper, and the reporter correspondingly important, spread to other countries. No daily newspaper now confines its reporting to the affairs of the part of the country in which it is published. The electric telegraph has made the work of the reporter more arduous and his responsibility greater. The variety of work open to reporting causes considerable difference, of course, in the professional status of the journalists who do such work. This subject generally is discussed in the article NEWSPAPERS, but one instance of the recognition of the modern reporter as a world-wide special mention. In the year 1900, in the English case of Walter v. Lane (see COPYRIGHT), it was decided, on the final appeal to the House of Lords, that the reporter of a speech, printed verbatim in a newspaper, was under the Copyright Act as the "author" of the "word" and "not to be used at all without the leave of the author." To call the reporter the author of another man's speech, the decision gave effect to the fact that it is his labour and skill which bring into existence the "copy" to which alone can result. Strictly speaking, he is the author of the report of the speech; but for literary purposes the report is the speech. It must, however, be borne in mind that there may be more than one verbant report, and therefore more than one "author."

See also NEWSPAPERS; SHORTHAND; PRESS LAWS; TELEGRAPH.

REPOUSSE (Fr., "driven back"), the art of raising designs upon metal by hammering from the back, while the "ground" is left relatively untouched (see METAL WORK AND PLATE). The term is often loosely used, being applied indiscriminately to "embossing." Embossing is also called "repoussé sur coquille" and "estampage," but the latter consists of embossing by mechanical means and is therefore not to be considered as an art process. Moreover, it reverses the method of repoussé, the work being done from the front, and by driving down the ground leaving the raised relief. Gold and silver, being easily malleable metals, are specially suitable to repoussé, which at the present day, in its finer forms, is mainly employed for silver-plate and jewelry. The silver-plate in repoussé of Gilbert Marks (d. 1905) in England, and the portrait-plates from life by Stephan Schwartz (b. in Hungary, 1851) in Austria, are noteworthy modern examples of the art.

Repoussé—a term of relatively recent adoption, employed to differentiate the process from embossing—has been known from remote antiquity. Nothing has ever excelled, and little has ever approached, the perfection of the bronzes of Siris (4th century B.C., in the British Museum), of which the armament—especially the shoulder-pieces—presents heroic figure-groups beaten up from behind with punches from the flat plate until the heads and other portions are wholly detached—that is to say, in high relief from the ground of which they form a part. Yet the metal, almost as thin as paper, is practically of constant thickness, and nowhere is there any sign of puncture. The "Bernar treasure," in the Bibliothèque Nationale, Paris, discovered in 1830, belongs to the 2nd century B.C., and includes silver vases of Roman execution decorated with groups in mezzo-relief, being up in sections. They were united together by means of which the finest is that known from its subject as "La nymphe de la fontaine Pérée et Pégase," belong to the noblest period of Roman art. The Hildesheim treasure (discovered 1868) comprises a patera on the ground of which is a superb emblème representing Minerva in high relief. These repoussé emblèmes were usually of another metal and applied to the vase which they decorated; indeed repoussé was of leading importance in coëtalcia, or the metallic art (statuary) excepted of classic times. Thus the patera of Hildesheim, the patera of Rennes, and the earlier shoulder-plate of the Sirius bronze may be accepted as illustrative of the highest development of repoussé.

The art was not only Greek and Graeco-Roman in its early practice; it was pursued also by the Assyrians, the Phoenicians, and other oriental peoples, as well as in Cyprus and elsewhere, and was carried forward, almost without a break, although with much depreciation of style and execution, into medieval times. In the 17th century the Emperor Henry II. presented a thank-offering to the Basilica cathedral the altar-piece, in the Byzantine style, decorated with fine repoussé panels of gold (representing Jesus Christ with two angels and two saints), which is now in the Cluny Museum in Paris. Up to this time, also, repoussé instead of casting in metal was practised for large work, and Limoges became a centre for the manufacture and exportation of sepulchral figures in repoussé bronze. These were affixed to mortuaries. By the time of Benvenuto Cellini the art was confined almost entirely to goldsmiths and silversmiths (who, except Cellini himself, rarely cast their work); and to them the sculptors and arrangers of tombs were still content to relegiate it.

The elementary principle of the method, after the due preparation and annealing of the plate, was to trace on the back of the design to be beaten up, and to place it face downwards upon a stiff yet not entirely unresisting ground (in the primitive stage of development it was wood), and then with hammers and punches to beat up the design into relief. According to Cellini, his master Caradosso da Milano would beat up his plate on a metal casting obtained from a pattern he had previously modelled in wax; but he is not sufficiently explicit to enable us to judge whether this casting was hollow mould, which would result in true repoussé, or in the round, which is tantamount to repoussé sur coquille, or embossing.

Nowadays the plate is laid upon and affixed to a "pitch-block," a resinous ground docile to heat, usually composed of pitch mixed with pounded fire-brick, or, for coarser work such as brass, with white sand, with a little tallow and resin. This compound, while being sufficiently hard, is elastic, solid, adhesive and easy to apply and remove. Gold and silver are not only the densest and most workable but the most ductile metals, admitting of great expansion without cracking if properly annealed. The tools include hammers, punches (in numerous shapes and sized for various work), moreover bronze or iron anvil, together with a special anvil called in French a recointe or ressing, in English "snarl." The recointe, or small anvil with projecting upturned point, was known in the 16th century. This point is introduced into the hollow of the vase or other vessel such as punch and hammer cannot freely enter, which it is designed to ornament with reliefs. A blow of a hammer on that part of the anvil where the prolongation first projects from it, produces, by the return spring, a corresponding blow at the point which the operator desires to apply within the vase. The same effect is produced by the modern "snarl" or "snarling iron"—a bar of steel, with an inch or two of the smaller end upturned and ending in a knob—held firmly in a tightly screwed-up vice, whereby the blow is similarly repeated or echoed by vibration. The repoussé work, when complete, is afterwards finished at the front and chased up. The same vase, to be worked up by embossing, would be filled with "cement" and laid on a sand-bag, and finally the whole would be heated and the cement run out. In the case of repoussé the vase itself may be beaten up out of the metal on the pitch-block. It must be understood that in order to obtain a result not merely excellent in technique but artistic and unmechanical in effect, the blows of the hammer must be made with feeling and "sentiment," otherwise the result cannot be a work of art.

( M. H. S.)

REPRESENTATION, a term used in various senses in different connexions, but particularly in a political meaning, which has developed out of the others.
The word “represent” comes from Lat. re-presentare, to “make present again,” or “bring back into presence,” and its history in English may be traced fairly well by the citations given in the New English Dictionary of its earliest uses in literature in senses that are still common. Thus we find the verb meaning (1386) simply to “bring into presence,” and Barbour uses it (1375) in the sense of bringing clearly before the mind, whence the common sense of “explain,” “exhibit,” “portray.” In 1513 it is used as synonymous with “describe,” or “allege to be.” In 1540 we find it employed for the performance of a play or a part in a play, whence comes the sense of symbolizing, standing in the place of some one, or corresponding to something; and in 1565 for acting as authorized agent or deputy of some one. This is a notable point in the development of the word. In Cromwell’s speech to the parliament, January 22, 1655, he says: “I have been careful of your safety, and the safety of those you represented.” This strictly political use of the verb developed, it will be seen, comparatively late.

The noun “representation” passed through similar stages. In 1425 we find it equivalent to “image,” “likeness,” “representation,” “picture,” from which is derived a meaning hardly distinguishable from “pretense.” In 1553 it means a “statement” or “account,” a sense which leads later (1679) to that of a formal and serious plea or remonstrance. In 1580 it occurs for a performance of a play. In 1647 it is used in psychology for the action of mental reproduction, a technical sense which applies especially to the “immediate object of imagination.” Since then action in the English language becomes the generic term for percepts, concepts and ideas. In 1624 it comes to mean “substitution of one thing or person for another,” “substituted presence” as opposed to “actual presence,” or “the fact of standing for, or in place of, some other thing or person,” especially with a right or authority to act on their account. Its application to a political assembly then becomes natural, but for some time it is not so found in literature, the sense remaining rather formal. Good instances of this use are: Gataker, Transubst. 4: “The Rocke was Christ onely symbolically and sacramentally, by representation or resemblance”; and R. Coke, Power and Subj. iii.: “So cannot these members be formed into one body but by the king, either by his Royal Presence or representation.” Thus “presence” and “representation” are used in distinctive meanings. In Scots law (1693) it obtains the technical meaning of the assumption by an heir of his predecessor’s rights and obligations.

The term “representative,” now specially applied to an elected member of a national or other assembly, deriving his authority from the constituency which returns him, appears to have been first used to denote not the member but the assembly itself. In the act abolishing the office of king, after Charles I’s execution, 1649, section iv. runs: “And whereas by the abolition of the kingly office provided for in this Act, a most happy way is made for this nation (if God see it good) to return to its just and ancient right of being governed by its own Representatives or national meetings in council, from time to time chosen and entrusted for that purpose by the people, it is therefore resolved and declared by the Commons assembled in Parliament,” &c., “that and that they will carefully provide for the certain choosing, meeting and sitting of the next and future Representatives,” &c. But the application of the term to the persons who sat in parliament was at all events very soon made, for in 1651 Isaac Penington the younger published a pamphlet entitled “The fundamental right, safety and liberty of the People; which is radically in themselves, derivatively in the Parliament, their substitutes or representatives.”

It is worth while to dwell on the historical evolution of the various meanings of “represent,” “representation” and “representative,” because it is at least curious that it was not till the 17th century that the modern political or parliamentary sense became attached to them; and it is well to remember that though the idea of political representation is older and thus afterwards is expressed by the later meaning of the word, the actual use of “representation” in such a sense is as modern as that. In Burke’s speeches of 1769 and 1774-1775, relating to taxation, we find the word in this sense already in common use, but the familiar modern doctrine of “no taxation without representation,” however far back the idea may be traced, is not to be found in Burke in those very words. The originator of that immortal dogma of our (i.e. American) national greatness was, according to the American writer M. C. Tyler (Amer. Lit. i. 154), the politician and philanthropist Daniel Gookin (1612-1687), an Irish settler in Virginia, who, moving to Boston and becoming speaker of the Massachusetts legislature, became prominent in standing up for popular rights in the agitation which resulted in the withdrawal of the colonial charter (1686). But it was the voice of the “dogma” in America, not its phrase, that he seems to have originated; and while the precise form of the phrase does not appear to be attributable to any single author, the principle itself was asserted in England long before the word “representation,” in a political sense, was current. In English constitutional history the principle was substantially established in 1297 by the declaration De Tallagio non concedendo confirmed by the Petition of Right in 1628.

The growth of the parliamentary system in England is traced in the article PARLiAMENT, but the account there given may be supplemented here by a more precise reference to the evolution of the idea of political “representation” as such, and of its embodiment in the word now employed to express it. The simple idea of the substitution of one person for another, in some connexion, e.g. hostage, pledge, &c., is so old as to be only describable as primitive; it is found in the proxy system, e.g. in marriage, and in diplomacy, the legate or ambassador being the alter ego of his sovereign; but, so far as general political legislative action, by one man in an assembly on behalf of others, is concerned, no systematic employment of a “deputy” (the word still used both in a general sense and in politics as a synonym for “representation”) is known among the ancients. So long as political power rests in a small privileged class, such an idea must be slow to develop; and the primitive notion of a law-making body is that of all the members present in person, as in ancient Greece. But, as Stubbs (Const. Hist. i. 280) points out, the early English jury system (see JURY) shows the germ of the true idea of representation in England; it was the established practice of electing or selecting juries to present criminal matters before the king’s judges, and assessors to levy taxes on the county, that suggested the introduction of popular representation in the English political system, and thus brought “the commons” into play in addition to the Crown and the nobles. Under Henry III., in 1254, we have the writ (see Parliament) requiring the sheriff of each county to “cause to come before the King’s Council two good and discreet Knights of the Shire, whom the men of the county shall have chosen for this purpose in the stead of all and of each of them, to consider along with knights of other shires what aid they will grant the king.” But the definite establishment of the principle of political representation, in a shape from which the later English system of representation lineally descended, may be traced rather to the year 1295, in Edward I.’s famous writ of summons to parliament, of which the following is the important part. In the volume of Select Documents of English Constitutional History (1901), selected by G. B. Adams and H. M. Stephens, whose version from the Latin we quote, the section is headed (ante-dating the use of the vital word) “Summons of representatives of the counties and boroughs”:

“The king to the sheriff of Northamptonshire. Since we intend to have a consultation and meeting with the earls, barons and other principal men of our kingdom with regard to providing remedies

1 The New English Dictionary, for its first citation of “representation” in an assembly, quotes Burke, Late St Nat., Works, ii. 138. i.e. in 1769.

2 The phrase “a man’s life or aid shall be laid or bevyed by us or our heirs in our realm, without the goodwill and assent of the archbishops, bishops, earls, barons, knights, burgesses and other freemen of our realm.”

3 Venire factas, not “elega factas.”
against the dangers which are in these days threatening the same kingdom: and on that account have commanded them to be with us on the Lord's Day next after the feast of St Martin in the approaching winter, at Westminster, to consider, ordain and do as may be seen to be for the avoidance of those dangers which require you to cause two knights from the aforesaid county, two citizens from each city in the same county and two burgesses from each borough, to be here summoned without delay, and to cause them to come to us at the aforesaid time and place. Moreover, the said knights are to have full and sufficient power for themselves and for the community of the aforesaid county, and the said citizens and burgesses for themselves and the communities of the aforesaid cities and boroughs separately, then and there, for doing what shall then be ordained according to the Common Council in the premises, so that they shall not fail in performing any of the purposes of this writ. And you shall have there the names of the knights, citizens and burgesses, and this writ."

The words "Elegii facias," instead of "venire facias" (which were retained in 1275; see PARLIAMENT), still appear to make the parliament of 1295 the model, rather than that of 1275, though in other respects the latter appears now to have established the summoning of county and borough representatives.

In this summoning by the king of the two knights and two burgesses with full and sufficient power for themselves and for the community, we find the origin of political representation of the commons, as opposed to the actual presence and personal attendance of the peers.

The older English national assemblies had consisted of the privileged class fully summoned as individuals.

The change involved has been well explained by E. A. Freeman (Ency. Brit., 9th ed., viii. 207), when he says: "The national assemblies changed their character . . . by no cause so much as by the growth of the practice of summons. . . In the great assembly at Salisbury (1086), where all the landowners of England became the men of the land (William the Conqueror), we see the first germs of Lords and Commons. The Witan are distinguished from the 'land-sitting men.' By the Witan, so called long after the Conquest, we are doubtless to understand those great men of the realm who were usually summoned to every assembly. The vast multitude who came to do their homage to the king were summoned only for that particular occasion. The personal right of summons is the essence of the peerage. . . The earls and bishops of England, by never losing their right to the personal summons, have kept that right to personal attendance in the national assembly which was once common to all freemen, but which other free men, chiefs, and chief of the nobility have abandoned. When we consider the place of the House of Commons, it is not by rule of precedence, but by unbroken succession the Witan of the assembly of Salisbury; that is, it represents by unbroken succession the old assemblies of the Teutonic democracy. . . The 'land-sitting men,' on the other hand, not summoned personally or regularly, but summoned in a mass when their attendance was specially needed, gradually lost the right of personal attendance, till in the end they gained the more practical right of appearing by their representatives."

From the same authority the account of the intermediate stages in the adoption of the representative principle may be further quoted:

"By the time of Henry II. the force of circumstances, especially the weight of the practice of summons, had gradually changed the ancient assembly of the whole nation into a mere gathering of the great men of the realm. . . It is in the reign of Richard I. that we begin to see the first faint glimmerings of parliamentary representation. . . The object of his wise ministers, of Archbishop Hubert among the first, was to gain the greatest amount of money for their master with the least amount of oppression towards the nation. Under Hubert's administration, chosen bodies of knights or other lawful men, acting in characters which became more and more distinctly representative, were summoned for every kind of purpose. How far they were nominated, how far freely elected, is not always clearly ascertainable. But it is certain that by this stage they were intrusted by the sheriff in the county court, while at a later stage they were chosen by the county court itself. In other words, the principle of representation was first established, and then the next stage naturally followed."

1 The inevitable use of the word "represent," in its wider sense ("corresponds to"), is worth noting in this passage from Freeman, side by side with the more technical one in "representative" ("chosen delegate").

2 The Constitution of the national assemblies of England, by the Great Charter, did not absolutely imply representation; but it showed that the full establishment of representation could not be long delayed. The previous period of the common prayer, alongside of the gathering of prelates, earls and other great men specially summoned, into which the ancient Witanagemot had shrunk up, another assembly directly representing all other classes of the nation which enjoyed political rights. This assembly, chosen by various local bodies, communitates or universitates, having a quasi corporate being, came gradually to bear the name of the commons. The knights of the shire, the barons, citizens and burgesses of the towns, and the townspeople generally, were called on to send representatives to this assembly, a body of the system of estates prevailed. These in most countries were three—clergy, nobles and commons. By these last were commonly meant only the communities of the charter towns, while the nobility of foreign countries answered to the lesser barons and knights, who in England were reckoned among the commons. The English system thus went far to take in the whole free population, while the estates of other countries, the commons no less than the clergy and nobles, must be looked on as privileged bodies. In England we had in truth no estates: we had no nobility in the foreign sense. . . Yet the continental theory of estates so far prevailing in the development of the idea of representation, . . . Three Estates of England'] became a familiar phrase. It was meant to denote the lords, the commons and the clergy in their parliamentary character. For it is plain that it was the intention of the French to summon four distinct men from each shire, to come alongside of the lords and commons. This scheme failed, mainly through the unwillingness of the clergy themselves to attend in a secular assembly. This left, so far as there were any estates at all, two estates only—lords and commons. This led to the common

Professor Masterman, lecturing (1908) on the House of Commons has pointed out how fortunate it was that this beginning of the organization of the commons into a central body did not come earlier than it did. Had there been one assembly representing the three estates contemporaneously at the same sitting and sectional in character and far too little conscious of any common interest. The organization did not begin till England had become a self-conscious body, realizing its common interests and a common destiny that belonged to it as a nation.
mistake of fancying the three estates to be king, lords and commons. The ecclesiastical members of the House of Lords kept their seats there; but the parliamentary representatives of the estate of the peers, as far as the clergy kept any parliamentary powers, they exercised them in the two provincial convocations. These anomalous assemblies, fluctuating between the character of an ordinary or extraordinary legislative body, were dissolved by Edward I. to Charles II., the parliamentary power of self-taxation. For a long time lords and commons taxed themselves separately. So did the clergy; so sometimes did other bodies. 

During the reign of Henry III. assemblies were constantly held, and their constitution is often vaguely described. But in a great many cases phrases are used which, however vague, imply a popular element. We read of knights, of tenants in chief, of burgesses and commons, sometimes, more vaguely still, of 'universi,' 'universitas Anglicae,' and the like. In some cases we are able better to interpret these vague phrases. For instance, in some respects it is quite clear that the knights of 'milites et proli homines.' Whether these knights were or were not to vote along with the magnates, they were at all events to transact business with them. We must always remember that in these times formal voting in the modern sense did not to be looked for.1

This summary shows clearly how the idea of "representation" as opposed to "presence in person" was applied to the English parliament, so as to give the commons a proper voice in it as well as the lords. It is unnecessary here to trace further the gradual increase in power of the House of Commons till it became the predominant partner in the English bicameral constitution (see Parliament). But from the point of view of historical theory it is important to note that this change did not essentially depend upon the particular method (election by vote) by which its members have for so long been chosen. It is a common error to regard the House of Commons as having a national authority higher than that of the House of Lords merely on the ground that it is composed of elected members, and to stigmatize the House of Lords as "unrepresentative" because it is not elected. But in strictness the question of election, as such, has nothing to do with the matter.2 The proper distinction (ignoring for the moment the later inclusion in the House of Lords of a certain representative element—strictly so regarded—in the Scotch and Irish peers) is that the House of Lords, as still constituted in 1910, remained a representative chamber, while the House of Commons was essentially a representative one; in the former the members, summoned personally as individuals, were entitled to speak in the great council of the nation, while in the latter the members were returned as the mouthpieces of whole communities, to whom, in the person of the sheriffs, the summons had been directed to send persons to speak for them.3 The preponderant authority of the House of Commons is due not to its members being elected—that is only one way of settling who the mouthpieces of the commons shall be—but to the progress of popular government. The two British houses have historically existed as assemblies of the separate estates of the realm—the House of Lords of the two estates of lords spiritual and temporal, and the House of Commons of the commons. The third estate has so increased in power as to become predominant in the country; but the authority of its own assembly simply depends on the powers of those it represents. If the balance of political power had not been shifted in the country itself, the authority and competence of the peers, speaking for themselves in the primary assembly, would in theory actually appear higher, so far as their order is concerned, than that of members of the House of Commons, who can only "represent" the popular constituencies. Moreover, the fact that most members of the House of Commons are elected by a party vote is apt to make them very often even less authoritative spokesmen of their constituencies—the communitates—than if they were selected by some method which would indicate that they had the full confidence of the whole body they "represent." It is notorious that many members of a modern House of Commons, or of any other "representative" assembly, have only been elected by the votes of a minority of their constituency, or (where there have been more than two candidates) a minority even of those who voted; and there always comes a time when it is certain that if a representative has to come again before the electorate for their votes he will be defeated; he, in fact, no longer reflects their views, while he still sits and legislates. The real desires of the commons in a certain British constituency may even be more faithfully, even if only accidentally, reflected by a local peer whose only right to speak in parliament is technically representative. In his Vindication of the British Constitution (1832), Disraeli, writing of the Reform Bill of 1832, observed that "in the effort to get rid of representation without election, it will be well if eventually we do not discover that we have only obtained election without representation." A truer word was never spoken. A man may be representative, practically consensum omnium, although no vote, resulting from a division of opinion, has been taken for the purpose of selecting him. The vote is merely a method of selection when there is a definite division of opinion involving an uncertainty; and even in the modern House of Commons many members are returned "unopposed," no actual voting taking place. A well-recognized representative character (as regards the functions involved) attaches, for instance, in British public life to other persons in whose selection the method of popular voting has had no place; such as the king himself, the Cabinet (in relation to the political party in power), or the bishops (as regards the Church of England).

The question of remodelling the constitution of the British House of Lords was prominently before the country in 1910; and a large number even of those who were prepared to defend its actions in the past were ready to accept changes which would make it in form and composition a Second Chamber representative of the nation rather than representative of its historic order. But it is important to remember, in connexion with the House of Lords question, that, in a country like England, where the constitution has provided for a Second Chamber which is composed of members of an estate or estates distinct in the nation from the estate of the commons, these persons may to a predominant degree nevertheless be really representative men by common consent; while their being so, though not theoretically the reason for their legislative power, is substantially the reason why it has so long persisted. In the absence of a written constitution there is no complete line of demarcation between the legislative and the executive, the former always being second to the force of circumstances. Most people regarded the House of Lords, as still unformed in 1910, as purely a hereditary body; its members had been summoned to parliament as peers (the important question of their right to a summons need not here be discussed), and most peers enjoyed their titles by hereditary succession. But the constant creation of peers by both political parties had in fact introduced even into the constitution of the House of Lords...
an essentially representative element (though not resulting from direct election), apart altogether from the fact that hereditary maintenance generally a number of national whose title had descended from men who were originally representative Englishmen, and whose successors, on the whole, were no less so. In the days when kings really governed in England, the most powerful check on the king, in the interest of the nation at large, was the peerage; the earls and barons, in parliament, were the chief bulwark of the people against tyranny. It was they who stood for the nation in extorting Magna Carta from King John; and as time went on, the representation of the commons in parliament was largely due, not to any direct popular pressure, but to the desire of the kings to influence the lower ranks of society who had held government of the nobles. Up to the time of Charles II., at events, the House of Lords was actually the predominant partner in parliament; the House of Commons was recruited from and returned by only a small section of the commons as now understood; and Oliver Cromwell—certainly a "popular" leader in the ordinary sense—made as short work of it as he did of the king himself. Up to 1832, when the first modern Reform Act was passed, the House of Commons was an oligarchical body, and the electors themselves were a small and privileged class. It is only since then—except in the granting of supplies—that first equality, and then predominance, in respect of the House of Lords has been asserted by the House of Commons. Owing to the fact that an extended suffrage has made the estate of the commons more adequately coincident with the nation as a whole. Prior to 1832 it was the king who directly made and unmade ministries; in 1835 for the first time the result of a general election caused a change of ministry; and the modern view of the House of Lords as purely a revising chamber dates only from then. But the very fact that the responsibility for creating new peersages now passed to ministers dependent on popular suffrage may well justify the contention that henceforth it indirectly included a select number of representative men of the nation, holding their seats in virtue of authoritative nomination and not by heredity. In the sixty years preceding 1906 no fewer than 419 new peersages were created, 238 by the Liberal party, 181 by the Conservative, or a balance of 57 creations on the Liberal side. It is fair to assume that all these new peers were created as being representative men in the nation for one reason or another. And an analysis of the composition of the House of Lords in 1906 would have led an unprejudiced outside observer to suppose that its competence to speak on national affairs had not been weakened by any dependence on the hereditary title. It included 166 men who had been M.P.'s (i.e. had been elected by popular vote to the House of Commons), 172 men who had been ministers or secretaries of state, 27 men elected by county councils, 207 who had served in the army or navy, 40 who had been judges or lawyers, 7 ex-viceroys, 16 ex-governors of colonies, 50 who had been eminent in art, letters, manufactures or trade, and 21 archbishops or bishops (appointed by ministerial recommendation, but only after they had worked up to eminence from being curates, and therefore had wide experience of the social life of the people). It is possible to compare a chamber so composed somewhat favourably with a modern House of Commons, if the point at issue—the provision of "representative men" (i.e. men generally regarded as national by the House of Commons)—be strictly considered, apart from the method of selecting them by direct popular vote. In the House of Lords the method is hereditary plus selection by the political party which the popular vote has put in power; while in the election of members of the House of Commons the popular choice is doubly limited—first, by the fact that only the enfranchised commons can vote (in 1910 about 112 millions out of 45); and secondly, because the choice must be made from among candidates who are themselves not disqualified for various reasons (for instance they must not be clergymen, nor entitled to seats in the House of Lords). Now, to carry out the real "will of the nation" in parliament must require (1) a reasonable knowledge of the wishes of the nation, and (2) an understanding of the best ways of expressing those wishes in legislation and administration. In the case of the peers, those who sit as having been originally created and therefore selected for the purpose—a considerable section of those actively attending—the qualifications are only and it is only necessary to deal with those qualified by inheritance of title. Here too, in a number of cases, preceding experience in the House of Commons, to which the popular vote has returned them while they were only in the succession to a peerage, is a frequent factor; but, apart from that, the art of legislation is one which may well be considered to require a certain special disposition and mental equipment. Though allowance must be made for exceptional cases, it is obvious that the son of a man who has been responsible for legislating, who has himself been brought up as one who will have to take his part in legislating, is most likely, in the long turn, to be a better legislator in any case, than a man chosen for the business, if only in the case of any profession or trade. He has been accustomed to breathe the parliamentary atmosphere, and as one of a leisured class has had the opportunity to study the subject of legislation, and to obtain experience of its conditions. This is so generally accepted that, in fact, the same theory is commonly applied to candidates for the House of Commons, and predominantly to members of that House who are given office. The names of more than one generation are writ large in English history in the case of the Pitts, Foxes, Grenvilles, Cannings, Cecil, Stanleys and Cavendishes. The sons of famous political commoners, a Gladstone, a Harcourt, a Churchill, a Primrose, a Chamberlain, have qualified himself for the business, even the radical or popular party, by no means resting originally or primarily on known personal merit or proved experience, for selection as candidates and then for preference to office; and it is a very common occurrence for younger sons of peers to be selected as candidates (liberal as much as conservative) for parliament, even though from general intellectual considerations they may appear in no way the equals of other men. They have been brought up to the business; and they are therefore adapted for it by heredity. If the House of Commons were deprived of those members who obtained their seats or their offices primarily for reasons of heredity, it would lose much of its best men—as indeed it occasionally does, to its disadvantage and possibly to the chagrin of the individuals themselves, when succession to a peerage forces a prominent parliamentarian to relinquish his seat in the Lower House and to take his place in the "unrepresentative" chamber. It remains nevertheless the fact that, in politics, "representative" government means not so much government by men really representative of the nation as government in the name of the whole body of citizens (and predominantly the estate of the commons) through a chamber or chancery, composed of selected deputies. The whole object in view is the expression of the "will of the people." the people, that is, who are sovereign. Clearly the only pure case of such government can be in a republic, where there is only one "estate," the free citizens. The home and historical type of representative government, the United Kingdom, is strictly no such case, since the monarchy and the House of Lords exist and work on lines constitutionally independent of any direct contact with the electorate. British practice, however, is of vital importance for the theory of representative institutions, and it is worth while to point out that the "will of the people" may even so be expressed. Some people may think even it is more effectively than in a pure republic. To King and the House of Lords, quid
such in the narrower sense. In practice, and in accordance with this view, it has on more than one occasion (e.g., in the case of the Trades Disputes Act of 1906) accepted and passed measures which it was notorious, and indeed avowed, that the peers themselves regarded as bad.

The immense extension of the "representative principle" in government, by means of popular election, and its adaptation to municipal as well as national councils, has in recent times resulted in attracting much attention to the problem of making such elected bodies more accurately representative of public opinion than they frequently are. There are three distinct problems involved—

(1) that of making the number of enfranchised citizens correspond to a real embodiment of the nation; (2) that of getting candidates to stand for the office of representative which are competent and incorruptible exponents of the national will, and (3) that of adopting a system of voting by which shall result in the elected representatives forming an assembly which shall adequately reflect the balance of opinion in the electorate.

(1) The history of the gradual extension of the franchise in the United Kingdom is given under Parliament, and the conditions for other countries under their respective headings. But while, in countries with a representative system at all, the question as to the extent to which the male citizens shall have the vote is mainly one of degree—as to property or other qualification, up to the inclusion of all adults (see VOTES), the question of the incapacity of women, as a sex, raises a distinction which is mere radical. The facts as to the progress of the movement for women's suffrage are given in the article WOMEN. It is only necessary to say here that, where the franchise is limited to the male sex, the theory of "no taxation without representation" is under modern conditions of life carried out in a decidedly one-sided way. The question of women's suffrage is, however, one of public policy, in whatever state it is raised; and even where, as in Great Britain, it has been adopted for municipal affairs, a distinction is commonly made as regards the national assembly. So far as the history of the female franchise is concerned, it has been unanimously decided in England by the highest law-court of the realm (judgment of the House of Lords in the Edinburgh University case, December 1908), presided over on this occasion by a Liberal Lord Chancellor (Lord Loreburn), that, according to their authoritative statement of the common law, women never had in earlier times any legal right to vote for members of parliament; this judgment is therefore entirely adverse to such ingenious arguments to the contrary as are ably expressed in Mrs Charlotte Carmichael Stopes' British Free women (1907).

Sex, however, apart, there are various interesting questions as to the principles which should govern the extension of the suffrage and its limitations, to which a brief reference may here be made. It is noteworthy that John Stuart Mill, the philosophical radical whose work on Representative Government (first published in 1861) is a classic on the subject, and who regarded the representative system as the highest ideal of polity, made a good many reservations which have been ignored by those who frequently quote him. Mill's ideal was by no means that popular government should involve a mere counting of heads, or absolute equality of value among the citizens. While holding that "no arrangement of the suffrage can be permanently satisfactory in which any person or class is peremptorily excluded, or in which the electoral privilege is not open to all persons of full age who desire to obtain it," he insisted on "certain exclusions." Thus he demanded that universal education should precede universal enfranchisement, and laid it down that if education to the required amount had not become universally accessible and thus a hardship arose, this was "a hardship that had to be borne." He would not grant the suffrage to any one who could not read, write and perform a sum in the rule of three. Further, he insisted on the electors being taxpayers, and emphasized the view that, given conditions tending toward representation, such taxation should descend to the poorest class.

The Suffrage.
“in a visible shape,” by which he explained that he did not mean “indirect taxes,” “mode of defraying a share of the public expenses which is hardly felt.” He advocated for this purpose “a direct tax, in the simple form of a capitation” on every grown person. But even more than this, he was in favour of a form of plural voting, so that the intellectual classes of the community should have more proportionate weight than the numerically larger working-classes: “though every one ought to have a voice, that every one should have an equal voice is a totally different proposition.” The well-informed and capable man’s opinion being more valuable than that of the barely qualified elector, it should be given more effect by a system of plural voting, which should give him more votes than one. As to the test of value of opinion, Mill was careful to say he did not mean property—though the principle was so important that he would not abolish such a test where it existed—but individual mental superiority, which he would gauge by the rough indication afforded by occupation in the higher forms of business or profession, or by such a criterion as a university degree or the passing of an examination of a fairly high standard. 

“Until there shall have been devised some mode of plural voting, which may assign to education as such the degree of superior influence due to it, and sufficient as a counterpoise to the numerical weight of the least educated class, for so long the benefits of completely universal suffrage cannot be obtained, without bringing with them, as it appears to me, more than equivalent evils.” “Equal voting,” he repeated, “is in principle wrong, because recognizing a wrong standard, and falsifying what is to be obtained with them, as it appears to me, more than equivalent evils.” “Equal voting,” he repeated, “is in principle wrong, because recognizing a wrong standard, and falsifying what is to be obtained with them, as it appears to me, more than equivalent evils.”

Modern democracy may ignore Mill’s emphatic plea for plural voting, as it ignores his equally strong arguments against the ballot—his contention being that secret voting violated the spirit of the suffrage, according to which the voter was a trustee for the public, whose acts should be publicly known—but Mill’s discussion of the whole subject proceeds on high ground, and his arguments are still worth careful consideration. Where a representative system, as such, is extolled as the ideal polity, the reservations made by Mill, a liberal thinker who cannot be dismissed as a prejudiced reactionary, should be remembered. Mill postulated, in any event, a state of society which was worthy of such a system, no less than the necessary checks and balances which should make it correspond to the real conditions of rational government. “Representative institutions,” he pointed out, “are of little value, and may be a mere instrument of tyranny or intrigue, when the generality of electors are not sufficiently interested in their own government to give their vote, or, if they vote at all, do not bestow their suffrages on public grounds, but sell them for money, or vote at the back of some one who has control over them, or whom for private reasons they desire to propitiate. Popular election, as thus practised, instead of a security against misgovernment, is but an additional wheel in its machinery.” When, in modern days, advocates of representative institutions seem ready to extend them to all countries, they become doctrinaires who depart widely from the standpoint of Mill, and forget that democracy is itself only a form of government suitable for梅多 societies for which the conditions of national life, and its advantages can only be tested by results and practical working. 

{\textbf{Selection of Candidates}}

As regards the important question of the selection of candidates (which depends partly on their willingness to stand, and partly on the means available for discovering suitable persons), modern practice is entirely dominated by the organization of political parties and the requirements of party allegiance. Though much has been said as to the desirability or not of paying members for their services (see Payment of Members), this is certainly overshadowed by the question of the availability of really capable men at all to the number required, for all candidates become “professional.”

Before 1872, when the Ballot Act was passed, voting was public.
the case of the Fifty-second Congress, the Democrats, with 50-6% of the votes, returned 71.1% of the representatives; the Republicans, with 42.9% of the votes, returning 26.5% of the representatives. Lord Avelbury (Proportional Representation, 1890; new ed. 1906) has given various similar experiences in England; thus, at the general election of 1886, the Liberals, with 1,333,400 votes, only obtained 176 seats, while the Unionists, with 1,423,500, obtained 283 (not counting 90 unopposed returns on the Liberal side, and 111 on the Unionist). In the general election of 1895, at which 132 Unionist seats and 57 Liberal were unopposed, the result in the 481 seats contested was the return of 279 Unionists and 202 Liberals; yet the actual votes given were 1,800,000 for the Liberals, and 1,775,000 for the Unionists. Again, in 1906, the Unionist vote, though 44% of the total cast, returned only 28% of the members, and the Liberal majority, which in strict proportion would have been 68, actually was 29.

The establishment of mere party majority rule, which is characteristic of a representative system, is a necessity, no doubt, in popular government; but the way in which a substantial minority of voters may only obtain a contemptible minority of members, and may in practice be tyrannized over in consequence, somewhat detracts from its blessings, and leads to extreme party measures. The division of the whole electoral body into constituencies is, after all, only a device for getting over the difficulty of the electors voting en bloc, and it does not seem to justify the conversion of a real majority in the country into a minority as represented in parliament, nor the complete exclusion of a substantial number of the electorate from parliamentary representation—so far as their views are concerned—at all. Yet under the English system such results are possible as the capture of every seat in Wales (34), in 1906, by the Liberal party, with 217,462 votes, the 100,547 Unionist voters having no representation in parliament; while in Warwickshire, though 22,490 votes were given to the Unionist candidates against 22,021 for the Liberal, three Liberals were returned against one Unionist.

The attempt to rectify this flaw in the representative method has led to the suggestion of various devices by the adoption of which the elected members may correspond more equally to the divisions of opinion in the electorate. Under the plan of scrutin de liste (or "general ticket") larger districts are created, each returning several members, and each voter has as many votes as there are members to elect; but while this system apparently provides the opportunity for the return of candidates with different views, it only requires a solid party vote to capture the whole of the representation for a majority. What is known as the "limited vote" is a form of scrutin de liste by which the elector has less votes than there are seats to be filled; with (say) three to be elected, the elector has only two votes. Systems of "limited vote" are in force in Portugal, Spain and Japan. A somewhat better plan is the "cumulative vote," which gives each elector as many votes as there are members to be elected, but allows him to divide them as he pleases (instead of giving only one vote to any one candidate). This enables an organized minority, by concentrat ing their votes, to elect at all events some representative; but the "cumulative vote" works rather capriciously, and is commonly defeated by careful party organization.

A more elaborate plan, but depending like the "limited" vote and the "cumulative" vote on the formation of constituencies returning three or more members each, is that of the "transferable vote." By this device an elector can indicate on his ballot paper not only his first choice, but also his second or third, &c. To ensure election a candidate need not obtain a majority of the votes polled, but only a certain number, so fixed that it can be obtained by a number of candidates equal to the number of seats to be filled, but by no more; this number of votes is called the "quota." At the first count first choices only are reckoned, and those candidates who have received a "quota" or more are declared duly elected. If all the seats have not then been filled up, the surplus votes of those candidates who have received more than the "quota" are transferred according to the names marked (2) on them. If these transfers still do not bring the requisite number of candidates up to the "quota," the lowest candidate is eliminated and his votes transferred according to the next preferences, and so on till the seats are filled. This system, which is the one usually associated with the term "proportional representation" was first suggested by Thomas Hare, who published in 1857 a pamphlet on The Machinery of Representation, and in 1859 a more complete scheme in his treatise on The Election of Representatives. John Stuart Mill, in Representative Government (1861) warmly endorsed Hare's proposal. Hare wished to treat the whole country as one constituency, but by later supporters of the "transferable vote" that plan was abandoned as impracticable; and the principle will work so long as the constituencies adopted each return several members. Lord Courtney, in his evidence before the British Royal Commission in 1909, said that his minimum constituency would be a three-membered one, but he would create a fifteen-membered constituency without hesitation. The simple "transferable vote" has been adopted in Tasmania for all elections (1907), after experimental adoption in the constituencies of Hobart and Launceston in 1896-1901, and in the election of the Tasmanian members of the Commonwealth legislature in 1906. It was proposed in the draft of the South African constitution, but abandoned. The principle has also been adopted in the "list systems" of Belgium, some Swiss cantons, Sweden, Finland and parts of Denmark. Wiirttemberg and Servia, where candidates are grouped in lists and all votes given to individual candidates on the list count first as votes for the list itself, the seats being divided among the lists in proportion to the total number of votes obtained by the list. The use of the general term "proportional representation" for all of these is, however, somewhat misleading; people often suppose that only one identical system of voting is meant, whereas in fact some possible varieties have been proposed, and each of the states mentioned has a different one from all the others. The only common element is the device of the "transferable vote," i.e. the method of having an "electoral quota," and the filling up of seats, where a quota is not provided by the first choices, by votes transferred from the second choices, and so on. It may be noted here that the "transferable vote" is calculated to multiply candidates to a point at which the minds of the electorate may well be embarrassed as to their preferences (the largest Belgian constituency returns 22 members), and, while undoubtedly providing for "minority representation," to encourage what may be called "minority thinking" and particularist politics. The "transferable vote" is commonly objected to as puzzling to the elector and too complicated for the scrutineers, while it is not much favoured by "machine" party organizations, which generally prefer the simpler plan of rough-and-ready majorities; but it has received a growing amount of theoretical support, as well as success in practical experiment, in recent years.

The "second ballot" is a device for securing absolute majority, instead of relative majority, representation. Where the two-party system prevails, it is usual for only two candidates, one for each party, to stand for each single-member constituency. But there is nothing to prevent a third or even a fourth candidate standing, and this multiplication of candidates becomes the more common in proportion as parliamentary organization is split up into groups. The consequence is that the candidate who heads the poll may well have only a relative, not an absolute, majority of votes, and to meet this objection the "second ballot" has been introduced, and is in operation in Austria-Hungary, France, Germany, Italy and Russia. Under this system, if no candidate receives an absolute majority of all the votes, a second election is held, at which, as a rule, only the two candidates compete who received most; or in cases where more than one seat is to be filled, twice as many candidates compete as there
are seats. In principle the second ballot has much in its favour, though it does not necessarily reflect the real opinion of the electorate, but only what is practicable; and while leading to political bargaining it does nothing for minority representation.

In England the importance of the whole subject of the method of elections was recognized at the end of 1868 by the appointment of a Royal Commission to inquire and report. Its conclusions were published in 1910, after much interesting evidence had been taken, but they attracted little attention, being in the main adverse to innovation. The one positive recommendation was for the adoption of the "alternative vote" (already in use in Queensland and Western Australia) by which the electors might mark their choices 1, 2, 3, &c.; this would not be for the purpose already discussed as part of the method of the "transferable vote," but the indications of preference would only be used for the same purpose as the "second ballot," while saving the voters the trouble of further elections. One objection to this "alternative vote," however, as compared with the "second ballot," is that it does not allow the voter to change his mind in the course of the election, as he well might do after he knew the result of the original voting.

It may be said broadly that all the devices which have been proposed for mitigating or redressing the defects of electoral methods ignore the essential fact that in any case a representative system can only result in a rather arbitrary approximation to correspondence with the opinions of the electorate. It is by no means certain even that "proportional representation" in any of its forms would always result in the return of a representative assembly reflecting with mathematical accuracy the balance of opinion in the electorate; and even if it did, the electors have a way of changing their opinions long before their representatives come up for re-election. It was stated before the British Royal Commission that in Belgium, in spite of "proportional representation," both in 1900 and in 1902 a majority of members was returned by a minority of votes. While under majority rule, as Mr Augustine Birrell once remarked, "minorities must suffer"—even large minorities—it is on the other hand not likely to conduct to the popularity of representative government that minorities should obtain too great a share of political power. The fact is that no "representation" can reflect the views of those "represented" as accurately as "presentation" by those entitled personally to speak. This conclusion, while in no necessary degree qualifying the importance of "popular government," undoubtedly detracts from the value of the representative method. The result is seen in the increasing desire in really democratic countries to supplement representative government by some form of Referendum, or direct appeal to the electorate for their own personal opinion on a distinct issue—a method which involves fundamentally the addition of a "presentative" element to the representative system.

Literature.—The number of separate works on various aspects of the theory, history and practice of political representation—a much wider subject than representative government—is too large for detailed mention. A general reference can only be made here to one of the standard treatises on constitutional law. The chapter in C. G. Cowen, Laws of the Life and Administration of Political Terms (Sir T. Raleigh's edition, 1898) should also be noted. In addition to works cited above, a valuable account of all parts of the subject is given in M. Osmolski's "Typology and the Organisation of Political Parties" (1902). The Congressional Library, Washington, U.S.A., issued in 1904 a "List of Books relating to Proportional Representation," which constitutes a complete bibliography up to that date. The best Handbook of the various methods for securing adequate representation is, however, now to be found in the Report (1910) of the British Royal Commission on Systems of Election (Parliamentary Paper, Cd. 5163). It is valuable for its description of the devices in use in foreign countries and for its weighty criticism of the proposals for minority representation.

Reprive (reprise, from Fr. reprendre), in English law, a term which originally meant to remand to prison: later and more usually, the suspension for a time of the execution of a sentence passed on conviction of crime. The term is now seldom or never used except with reference to sentences of death. In the case of capital felonies other than murder the recording of sentence of death has the effect of a reprise by the court. The court which can award a sentence is said to possess as of common right a discretionary power of granting a reprise. Courts of justice, however, do not grant reprieves by way of dispensation from the penalties of the law, which is not for the judicial department, but for temporary purposes, e.g. of appeal or inquiry as to the state of mind or health of the convict, or to enable him to apply for a pardon. Under the old system of transportation it was a common practice to reprise convicted felons as a step to induce them to consent to transportation to the American colonies (see the Old Bailey Regulations of 1662, J. Kelyng, ed. 1873, p. 1). In cases of conviction of willful murder the reprise, if any, is granted by the home secretary on behalf of the crown, and on convictions of murder the court seems now to have no power to reprise except in the case of a pregnant woman.

See Hawkins, P.C. bk. 2, c. 51; Blackstone, Commentaries.

Reprisals (Fr. représailles, from reprendre; Lat. reprensandi, to take back), properly speaking, the act of forcibly withdrawing something belonging to another state by way of retaliation, but currently used for the retaliation itself. They are acts of violence which are a casus belli according to the manner in which the state against which they are exercised regards them and is able to resist or resent them. Two comparatively recent cases have occurred in which this form of redress was resorted to. In the one case a demand by the British government for an indemnity for injuries inflicted on the British vice-consul and certain other British subjects by Nicaraguan authorities in the Mosquito reserve not having been complied with, British naval forces were landed on April 27th, 1865, at Corinto, where they occupied the customs house and other public buildings until an agreement was arrived at. In the other case the French government in November 1901 ordered the occupation by French naval forces of the customs house at Mytilene until redress was obtained for divers claims of French citizens. A Hague Convention of 1907 now places limitations on the employment of force for the recovery of contract debts, and forbids recourse to armed force unless "the debtor state refuses or neglects to reply to an offer of arbitration, or after accepting the offer prevents any compromise from being agreed on, or after arbitration fails to submit to the awarding power." By REPRODUCTION, in biology, the generation of new organisms from existing organisms more or less similar. It is a special case of growth, and consists of an increase of living substance in such fashion that the new substance is either set free as a new individual, or, whilst remaining attached to the parent organism, separated by some sort of partition so as to have a subordinate individuality. Y. Delage has distinguished as multiplication those cases in which the new individual arises from a mass of cells which remain a part of the maternal tissues during differentiation, reserving the term reproduction for those cases in which the spore or cell which is the starting-point of the new individual begins by separating from the maternal tissues; but the distinction is inconvenient in practice and does not appear to carry with it any fundamental biological significance. The general relation between parent and filial organisms is discussed under Heredity and Embryology; many of the details of the cellular processes are dealt under Cytology, and the modes of reproduction exhibited by different kinds of animals and plants are treated of in the various articles describing individual groups. Finally, some of the special problems involved are discussed under the heading Sex. As reproduction is a general biological subject, its most important branch is dealt with simultaneously in the case of animals and plants, but many of the special details differ so much that it is practically convenient to make two headings.

REPRODUCTION OF ANIMALS

A. ASEXUAL.—Many animals possess a more or less limited capacity to repair portions of the body that have been accidentally removed (see Regeneration), and this capacity may be so
extensive that, if the whole body be cut in pieces, each portion
may grow into a new organism. Such a mode of artificial
propagation, familiar in horticultural operations, has been made
use of in such animals as sponges, and has been performed
experimentally in hydroids and some worms. In many Protozoa
asexual reproduction by simple division is a normal event. In
Coelentera it is common, the plane of division usually passing
through the long axis of the body, as in Actinarians and many
Hydroids, or being horizontal, as in the repeated divisions by
which medusae are produced from an assexual poly; the new
individual may separate completely, or serve to build up a
colonial or compound organism. In some Turbellarians
(Micrasterias) and Chaetopods (Syllis, Myriomina, Nereis,
Eunice viridis) (the palolo-worm of Samoa), asexual reproduction
occurs in a form that is partly fission and partly budding;
portions are constrictedtransversely or laterally, very much
smaller than the whole animal, and these grow out into new
animals which may separate or remain attached in chains.
In Salps, chains are formed sometimes by transverse constriction,
sometimes by budding. True budding is much more common
than fission; it occurs in Protozoa, Coelentera, Sponges,
Polypoza, Tunicates and some Flatworms and Chaetopods, the
bud being a multicellular portion of the tissues which is partly
or completely separated from the parent before it proliferates
into the new form. In various larval stages of many animals,
asexual reproduction by fission or budding may be produced
experimentally or may occur naturally. It has been suggested
that cases of identical twins in vertebrates and many monstrous
forms, including even dermoid cysts, are due to embryonic
asexual fission or budding. The artificial subdivision of young
embryos has been performed successfully by several investi-
gators (see Hereditary). In Laxmicrs trophesides the gastrula
stage of the embryo divides and each half produces a complete
individual; and multiplication by budding is common at various
stages of the life-history of many parasitic worms. Spore
formation, or cellular budding, appears to be limited to the
Protozoa amongst animals.

B. Sexual.—Apart from the special and probably secondary
cases presently to be considered under the subheading partheno-
gensis, sexual reproduction or amphimixis may be defined as
the production of a new organism from a zygote, and a zygote
may be defined as the cell resulting from the conjugation of two
gametes. The gametes derived from the specialized reproductive
tissue of the parent or parents. In asexual reproduction by
spore formation, the spore proliferates without the aid of another
spore; in true sexual reproduction the gametes may be regarded
as special kinds of spores which appear in two forms, the egg-
cell, ovum or female gamete not proceeding to proliferate into
a new organism until it has been stimulated by partial or
complete fusion with the other form, the spermatozoon or male
gamete. The act of fusion or conjugation in question is usually
spoken of as fertilization, and the zygote, or starting-point of
the new organism, is the fertilized egg-cell. Among protozoa
and the lower plants there occur a series of forms of conjugation
leading towards the specialized form characteristic of the sexual
reproduction of higher animals. The conjugation may be
isogamous, that is to say the conjugating cells may be actually
or at least apparently indistinguishable. The fusion between
the cells may be complete, or may concern only the nuclei.
The conjugation may be followed by reproduction, or may apparently
have no relation to reproduction. In true sexual reproduction
the conjugation is heterogamous, i.e., the gametes are unlike;
the fusion is chiefly nuclear, and the process is the prelude of
the development of the zygote into the new organism.

In all the Metazoa the gametes arise from specialized reproductive
tissues which are supposed to contain (see Heredity) the
reproductive material or germ-plasm. In the lower (or simpler
and possibly degenerate Metazoa) the reproductive or germinal
tissue consists of a few cells, sometimes in a group, sometimes
scattered and sometimes migratory; in the vast majority of the
Metazoa the germinal tissue becomes aggregated in distinct
organs, of which those that give rise to ova or female gametes
are known as the ovaries, and those that give rise to the sper-
matozoa or male gametes are known as the testes. The ovary
and the testis are the primary reproductive organs; the details
of their anatomy and position in the various groups need not be
discussed here (see Reproductive System).

The male gamete or spermatozoon was first seen in 1677 by
Ludwig van Hammen, a pupil of A. Leeuwenhoek, with the
microscope that had been constructed by his master. Leeu-
wenhoek, under the influence of the current preformationist
ideas, interpreted these actively moving bodies in the seminal
fluids as preformed genes and described them as animalcule
spermia or spermatoza. Throughout the 18th century the
general tendency was to regard them as parasites of no conse-
quence in fertilization. In 1837 R. Wagner established that
they were present in all sexually mature males and absent in
infertile male hybrids, and in 1841 A. Kölliker showed that they
were cells proliferated in the testes. The spermatozoon is one
of the smallest of known cells, frequently being no more than
one hundred thousandth of the size of the ovum, although the
extraordinary case of a small Cypris has been recorded in which
the spermatozoa are longer than the animal. It is produced
in enormous quantities and relatively to other minute cells is
extremely tenacious of life. It may retain its vitality in the male
organism for a long time after it has become a separate cell,
and may exist for lengthy periods in the female organism.
The queen-bee is impregnated only once, and the spermatozoon
may remain functional within her body for three years. Lord
Avebury (Sir J. Lubbock) has described the case of a female ant
which laid fertile eggs thirteen years after she had been
impregnated. It is undoubtedly that in snakes, birds and many
mammals, fertilization may not take place for many days after
impregnation. The spermatozoa, with a few exceptions, are
actively motile, being elongated in shape, with a vibratile tail
sometimes provided with a swimming membrane. In a few
cases, chiefly of crustaceans, the spermatozoon are spherical
with radiating processes, but are capable of amoeboid movements.
The cell nucleus is generally situated near the rounded or pointed
extremity, with a centrosome immediately behind it, whilst the
scanty protoplasm forms the body and vibratile tail; but there
appears to be no general significance in the various configura-
tions that occur amongst different animals. The process of
spermatogenesis, or production of spermatozoon from the per-
iferous cells of the testes, is studied in various classes of animals and has been the subject of many elaborate investiga-
tions and much confusing nomenclature. Two factors are
involved: first, the arrangements to produce a very large crop
of cells so to provide for the enormous numbers of spermatozoa
produced by most animals; and second, the final changes of shape
and of nucleus by which the ripe spermatozoa arise from the
indifferent testis-cells, and these processes may to a certain
extent overlap. The point of general significance relates to the
nuclear changes. The nuclear matter that occurs in the tissue
cells of animals, when these cells divide, breaks up into a number
of chromosomes constant for each kind of animal, and the final
stage of cell division is such that each chromosome splits and
contributes a half to each daughter cell, so that the latter come
to contain the number of chromosomes peculiar to the animal in
which they occur. In the case of spermatozoa, however, a
"reducing" division occurs, in which the chromosomes instead
of dividing distribute themselves equally between the two
daughter cells, with the result that each of the latter contains
only half the number peculiar to the species. In its simplest
form, what occurs in the last stage of spermatogenesis is that one
cell breaks up into four spermatozoa by two successive divisions,
the product of which is normal and the second reducing.
The nuclear matter of spermatozoa, therefore, contains half
the number of chromosomes normal to the tissue cells of the species,
and we shall see later that a similar reduction takes place in the
formation of the egg. Further complications, however, exist,
at least in certain forms. In 1801 H. Henking showed that in a
Hemipteran insect of the genus Pyrrhocoris, two kinds of
spermatozoa are produced in equal numbers, and F. C. Paulmier
confirmed the observation in the case of some other insects a few years later, whilst other observers have extended the observations to over a hundred species. In all these cases half the spermatozoa differ from the other half by the presence of what E. B. Wilson calls the "X-element," and which, in the simplest cases, occurs as an unpaired chromosome of the mother cell which passes into one and not the other of the two spermatozoa formed from that mother cell. The matter is still obscure, and it is not certain whether the facts are peculiar to insects or have a parallel in spermatogenesis universally. According to E. B. Wilson, the facts demonstrate that eggs fertilized by spermatozoa with the X-element invariably produce females (see Sex). The female gamete or ovum is in a large number of cases expanded by the presence of food-yolk and protective swathing to form the visible mass known as an egg, and the production of embryos from eggs has been studied from the time of Aristotle and Pliny. Galen had described the human ovaries as testes multibres, and W. Harvey in 1651 showed that the chick arose from the cicatricle of the yolk of the egg, compared these early stages with corresponding stages in the uterus of mammals, and laid down the general proposition—ovum esse primordium commune omnibus animalibus—that the ovum is a starting-point common to all animals. In 1604 N. Steno identified the sexual organ of the mammalian female with that of sharks, and first named the ovary. In 1677 K. E. von Baer definitely traced the ovum back from the uterus to the oviduct and thence to its origin within the Graafian follicle in the ovary, and thus paved the way for identification of the ovum as a distinct cell arising from the germinal tissue of the body. The ovum, or germ cell, which becomes the spermatozoon, is a large cell, in most cases visible to the naked eye even in the ovary. Also, in definite contrast with the spermatozoon, it is a passive non-motile cell, although in certain cases it is capable of protruding pseudopodia. It is usually spherical, contains a large nucleus, a centrosome and abundant protoplasm, and is generally enclosed in a stout membrane which may or may not have a special aperture known as the micro-pyle. The protoplasm of all eggs contains nutritive material for the nourishment of the future embryo, and this material may be sufficient in quantity to make the whole cell, although remaining microscopically, conically large, or to expand it to the relatively enormous mass of the yellow yolk of a fowl's egg. Finally, the cellular nature of the ovum is frequently further disguised by its being enclosed in a series of membranes such as the albumen and shell of the fowl's egg. Such complexities are ancillary to the growth or protection of the future embryo, and from the general biological point of view the ovum is to be regarded as a specialized cell derived from the germinal tissue of the ovary, just as the spermatozoon is a specialized cell derived from the corresponding stock of germinal material in the testis. The number of ova produced varies from a very few, as in mammals and birds, to a very large number, as in the herring and many invertebrates, but in all cases the number is relatively small compared with that of the spermatozoa produced by the male of the same species. The details of ovogenesis are more sharply divided than in the case of spermatogenesis into processes connected with the production of a crop of large cells bloated with food-yolk, and the peculiar nuclear changes. The latter changes are generally spoken of as the maturation of the ovum, and in most cases do not begin until the full size has been attained. As in the nuclear changes of spermatogenesis, the details differ in different animals, but the salient feature is that the mature ovum contains, like the ripe spermatozoon, half the number of chromosomes normal to the tissue cells of the animal to which it belongs. The simplest form in which the reduction takes place is that the nucleus of the ovum divides by an ordinary division, each chromosome splitting and sharing itself between the daughter nuclei. Of these nuclei one is extruded from the egg, forming what is called a polar body, and this polar body may again divide by a reducing division, so as to form two polar bodies, each with half the normal number of chromosomes. Finally, the daughter nucleus, remaining in the ovum, also divides by a reducing division, and one of the segments remains to form the nucleus of the ripe ovum, with half the normal number of chromosomes, whilst the other is extruded as a polar body. Very many suggestions as to the meaning of the extrusion of the polar bodies have been made, but the least fanciful of these is to regard the ovum ready for maturation as homologous with the cell about to divide into four spermatozoa; in each case the nucleus divides twice and one of the divisions is a reducing division, so that four daughter nuclei are formed each with half the normal number of chromosomes. Many spermatozoa are required, and each of the four becomes the nucleus of a complete active cell; relatively few ova are required, but each has a large protoplasmic body, and only one of the four becomes a functional mature egg, the other three being simply extruded and so to say wasted. It must be remembered, however, that there is no inherent probability in favour of the apparently simplest explanation of a very complex biological process. It is also to be noted that in many cases the first polar body does not divide, and it is not clearly established whether the first polar body remains single, and if it is always the result of a normal nuclear division.

When the mature ova and spermatozoa come together in one of the various ways to be discussed later, fertilization, the conjugation of the gametes to form the zygote, occurs. Alkmeneon (380 B.C.) is believed first to have laid down that fertilization in animals and plants consisted in the material union of the sexual products from both sexes, but it was not until 1761 that it was established experimentally by J. T. Köllreuter's work on the hybridization of plants. In 1780 L. Spallanzani artificially fertilized the eggs of frogs and turtles, and introduced seminal fluid into the uterus of the bitch, but came to the erroneous conclusion that it was the fluid medium and not the spermatozoon that caused fertilization. This error was corrected in 1824 by J. L. Prevost and J. B. Dumas, who showed that fertilization destroyed the fertilizing power of the fluid. In 1843 M. Barry observed spermatozoa within the egg of the rabbit, whilst in 1849 R. Leuckart observed the fertilization of the frog's egg, and in 1851 H. Nelson noticed the entrance of spermatozoa to the egg of Aescus, whilst in 1854 a series of observations published independently by T. L. Bischoff and Allen Thomson finally and definitely established the fact that ova were fertilized by the actual entrance of spermatozoa. Further advances in microscopical methods enabled a series of observers, of whom the most notable were E. van Beneden, H. Föl and O. Hertwig, to follow and record the details of the process. They made it clear that the chief event in fertilization was entrance into the ovum of the nucleus or head of the spermatozoon where it formed the "male pronucleus," which gradually approached and fused with the female pronucleus or residual nucleus of the ovum. Still later observers, of whom E. B. Wilson is the most conspicuous, have studied the details of the process in many different animals and have shown that the nucleus of the spermatozoon invariably enters the ovum, that the centrosome generally does so, and that the cytoplasm usually plays no part. The nucleus of the zygote or fertilized ovum, then, possesses the number of chromosomes normal in the tissue cells of the animal to which it belongs, but of these half belong to the female gamete and are derived from the germ plasm of the parental ovary, and half to the male gamete or spermatozoon, derived from the germ plasm of the parental ovary. The stimulus which leads to and induces the conjugation of the gametes appears to be chemotactic and to consist of some substance positively attractive to the male gamete, liberated by the mature female gamete, but the attraction is mutual, and in the final stages of approach a protoplasmic outgrowth of the ovum towards the spermatozoon frequently occurs. The
fertilized zygote proceeds to form the embryo (see Embryology).

Parthenogenesis is the production of the new organism from the female gamete without previous conjugation with the male gamete, and is to be regarded as secondary to and degenerate from true sexual reproduction. Aristotle recognized that it occurred in the bee. In 1745 C. Bonnet showed that it must occur in the case of Aphides or plant-llice, in which throughout the summer there were developed a series of generations consisting entirely of females. R. A. F. de Réaumur repeated the observations, but evaded the difficulty by suggesting that the Aphides were hermaphrodite, an explanation soon afterwards disproved by L. Dufour. In 1840 (Sir) R. Owen brought together the facts as they were then known and made a remarkable suggestion regarding them. "Not all the progeny of the primary impregnated germ cell are required for the formation of the body in all animals; certain of the derivative germ cells may remain unchanged and become included in that body which has been composed of their metamorphosed and diversely combined or confluent brethren; so included, any derivative germ cell or the nucleus of such may begin and repeat the same processes of growth by imbition, and of propagation by spermatozoa, and so to those to which itself owes its origin." Taking hold of the recently published discoveries of J. S. Steenstrup on alternation of generations, he correlated the sexual and asexual alternation in hyroids and so forth with the virgin births of insects and Crustacea, and regarded the one and the other as instances of the subsequent proliferation of included germ cells, applying the word parthenogenesis to the phenomenon. His theory was a very remarkable anticipation of the germ-plasm theory of A. Weismann, but further knowledge showed that there was an important distinction between the reproduction of the asexual generations described by Steenstrup and the cases of Aphides and Crustacea, the germinal cells in the latter instances being derived from the ovary of true females, but capable of development without fertilization. In 1856 C. T. E. von Siebold established this fact and limited Owen's term parthenogenesis to the sense in which it is now used, the development without fertilization of ova produced in ovariates. True parthenogenesis occurs frequently amongst Rotifers, and in certain cases (Philodinæ) males either do not exist or are so rare that they have not been discovered. Amongst Crustaceans it is common in Branchiopods and Ostracods; in the case of Daphnæs, large thick-shelled ova are produced towards winter, which develop only after fertilization and produce females; the latter, throughout summer, produce thin-shelled ova which do not require fertilization, and from which towards autumn both males and females are produced. Amongst insects it occurs in many forms in many different groups, sometimes occasional, sometimes as a regular occurrence. Apart from Aphides the classical instance is that of the bee, where eggs that are not fertilized develop parthenogenetically and produce only drones. What is known as pathological parthenogenesis has been observed occasionally in higher animals, e.g. the frog, the fowl and certain mammals, whilst in the case of human beings, ovarian cysts in which hair and other structures are produced have been attributed to the incomplete development of parthenogenetic ova. Finally, it has been shown in a number of different instances, notably by J. Loeb, that artificial parthenogenesis may be induced by various mechanical and chemical stimulations. It has been shown that ova may be induced to segment by the presence of spermatozoa belonging even to different classes of the animal kingdom—as, for instance, the ova of echinoderms by the spermatozoa of molluscs. In such cases the resulting embryos have purely maternal characters. A possible interpretation is that spermatozoa have two functions which may be exercised independently; they may act as stimulants to the ovum to segment, and they may convey the hereditary qualities. The theory of the latter has been replaced by the chemical substances employed in producing artificial parthenogenesis. Juvenile or precocious parthenogenesis, in which there takes place reproduction without fertilization in immature larvae, has been observed chiefly in insects (Dipterous, midges), and to this the term paedogenesis has been applied.

The theory of parthenogenesis remains doubtful. When Weismann and others began to study the polar bodies, they made the remarkable discovery that in some parthenogenetic eggs only one polar body was extruded, but the meaning of this distinction was blurred when other cases were described in which two polar bodies were formed. Later on, Weismann drew attention to the difference between normal and reducing divisions, and it now appears to be clear that, with one set of exceptions, ova which develop without fertilization are those in which the reducing division takes place and which, accordingly, contain the number of chromosomes normal to the tissue cells of the species. Such eggs, in fact, resemble the zygote except that all their chromosomes are of maternal origin and the centromere which becomes active in the first segmentation is that of the ovum and not, as in normal fertilized eggs, that which came in with the spermatozoon. The case of the bee and other insects in which parthenogenetic development results in the production of males, is doubtful; it appears to be the case that a reduction division has taken place in the maturation of the egg. A. Petrunkevitch has made the ingenious suggestion, that after the first division the normal number of chromosomes is restored by the splitting of each into two. Cases of pathological and artificial parthenogenesis would fall into line, on the supposition that the stimulus acted by preventing the occurrence of a reducing division in an ovum otherwise mature. It is to be noticed, however, that such explanations of parthenogenesis are not much more than a formal harmonizing of the behaviour of the chromosomes in the respective cases of fertilized and parthenogenetic development; they do not provide a theory as to why the process occurs.

Accessory Reproductive Organs and Processes.—It has been already stated that primary organs of reproduction in animals are the germinal tissues producing respectively spermatozoa and ova, and that in most cases these are aggregated to form testes and ovaries. In certain animals there are no accessory organs, and when the reproductive products are ripe, they are discharged directly to the exterior if the gonads are external, as in some Coelentera, or if they are internal, break through into some cavity of the body and escape by rupture of the body-wall or through some natural aperture. In a majority of cases, however, special ducts are developed, which in the male serve primarily for the escape of the spermatozoa, but secondarily may be associated with Intromittent organs. Similarly, in the female, the primary function of the gonad ducts is to provide a passage for the ova, but in many cases they serve also for the reception of spermatozoa, for the development of embryos and for the subsequent exit of the young. Associated with the ovary and the oviducts are many kinds of yolk-glands and shell-glands, the function of which is to form nutritive material for the future embryo, to discharge this into or around the ovum, and to provide protective wrappings. Although, in the last resort, fertilization depends on impulses attracting the spermatozoa to the ova, probably chemical in their nature, the necessary proximity is secured in a number of ways. In many simple cases the ripe ova are discharged directly into the surrounding water, and impregnation is a matter of accident highly probable because such animals discharge enormous quantities of ova and spermatozoa, are frequently sessile and live in colonies, and are mature about the same time. In other cases, as, for instance, Tunicates and many Molluscs, the spermatozoa are discharged, and, being drawn into the body of the female with the inhalent currents, there fertilize the ova. In yet a number of other cases, there is sexual congress without intromission. The males of many fish, such as salmon, attend the females about to discharge their ova, and afterwards pour the male fluid over the liberated eggs; which, no reducing division takes place and which, accordingly, contain the number of chromosomes normal to the tissue cells of the species. Such eggs, in fact, resemble the zygote except that all their chromosomes are of maternal origin and the centromere which becomes active in the first segmentation is that of the ovum and not, as in normal fertilized eggs, that which came in with the spermatozoon. The case of the bee and other insects in which parthenogenetic development results in the production of males, is doubtful; it appears to be the case that a reduction division has taken place in the maturation of the egg. A. Petrunkevitch has made the ingenious suggestion, that after the first division the normal number of chromosomes is restored by the splitting of each into two. Cases of pathological and artificial parthenogenesis would fall into line, on the supposition that the stimulus acted by preventing the occurrence of a reducing division in an ovum otherwise mature. It is to be noticed, however, that such explanations of parthenogenesis are not much more than a formal harmonizing of the behaviour of the chromosomes in the respective cases of fertilized and parthenogenetic development; they do not provide a theory as to why the process occurs.
her firmly for a prolonged period, during which ova and spermathoe are discharged simultaneously. Where internal fertilization occurs, there are usually special accessory organs. In the female, the terminal portion of the gonad-duct, or of the ooses, is modified to receive the intromittent organ of the male, or to retain and preserve the seminal fluid. In the male, the terminal portion of the gonad-duct may be modified into an intromittent organ or penis, grooved or pierced to serve as a channel by which the semen is passed into the female. In arthropods, ordinary limits may be modified for this purpose, or special appendages developed; in spiders, the terminal joints of the pedipalps, or second pair of appendages, are enlarged, and are dipped into the semen, which is sometimes shed into a special web, and are used as intromittent organs; in cuttlefish, one of the “arms” is changed from a swimming to a copulatory organ. Thus, the spermatic ray of the female is there broken off. In many cases there is a temporary apposition of the apertures of the male and female, with an injection from the male without a special intromittent organ. The females are usually passive during coitus, and there are innumerable varieties of clasping organs developed by the male to retain hold of the female. Finally, the various secondary sexual characters which are developed in males and females and induce association between them by appeals to the senses, must be regarded as accessory reproductive organs and processes (see Sex). Another set of accessory organs and processes are concerned with what may be termed in the widest sense of the phrase "brood-care." In many cases the relation between parent and offspring ceases with the extrusion of the fertilized ovum, whilst others display every possible grade of parental care. Many of the lower invertebrates choose special localities in which to deposit the ova or embryos, and glands, the viscous secretion of which serves to bind the ova together or to attach them to some external object, are frequently present. In many insects, elaborate preparations are made; special food-plants are selected, cocoons are woven, or, by means of the special organ known as the ovipositor, the eggs are inserted in the tissues of a living or dead host, or in other cases a supply of food is prepared and stored with the young larvae. The eggs or larvae may be attached to the parent and carried about with it, as in the gills of bivalves, the brood-pouches of the smaller Crustacea, the back of the Surinam toad, the vocal sacs of the frog Rhinodermat, the expanded ends of the oviducts or the marsupial pouch. In a large number of cases the young are nourished directly from the blood of the mother by some kind of placental connexion, as in some of the sharks, in Anabélès, a bony fish, in some lizards and in mammals. In other cases, the young, after birth or hatching are fed by the parents by the special secretion of the mammary glands in the case of mammals, by regurgitated food in many birds and mammals, by salivary secretions or by food obtained and brought to the young by the parents.

Reproductive Period.—In a general way, reproduction begins when the limit of growth has been nearly attained, and the instances of paedomogenesis, whether that be parthenogenetic as in midgets, or sexual as in the axolotl, must be regarded as an exceptional and special adaptation. In lower animals, where the period of growth is short or indefinite, reproduction begins earlier and is more variable. But, in all cases, surrounding conditions play a great part in hastening or retarding the onset of reproduction. Increased temperature generally accelerates reproductive maturity, excess of food retards it, and sudden privation favours it. In a majority of cases it endures to the end of life, but in some of the higher forms, such as birds and mammals, there is a marked decrease or a cessation of reproductive activity, especially in the case of females, as life advances. In most animals, moreover, periods of reproductive activity alternate with periods of quiescence in a rhythmic series. In its simplest form, the rhythm is seasonal, but although at first it may be purely annual, subsequent changes, it persists in the absence or alteration of these. Many animals brought to Europe from the southern hemisphere come into reproductive activity at the time of year corresponding to the spring or summer of their native home. "Heat," menstruation and ovulation in the higher mammals, including man, are rhythmic, and probably physiologically linked, but the ancestral meaning of the periodicity is unknown.

Reproduction and Increase of the Race.—Two distinct factors are involved in this question—the potential fecundity of organisms, and the chances of the young reaching maturity. The first varies with the actual output of oocytes, and is determined partly by the reproductive drain on the individual, and especially the female in cases where the ova are provided with much food-yolk, partly on the duration of reproductive maturity, and partly on the various adaptive and environmental conditions which regulate the chances of the gametes produced being fertilized. It is well established that as the gametes are simply cells proliferating from the germinal tissue, the potential number that can be produced is almost indefinite; and as it is found that in very closely allied forms the actual number produced varies within very wide limits, it may be assumed that potential fecundity is indefinite. The possibility of oocytes reaching maturity varies first with the individuation of the organism concerned—that is to say, the degree of complexity of its structure—and the duration of the period of its growth; and secondly, with the incidence of mortality on the eggs and immature young. It is plain that a parasite capable of living in a particular host must have adapted itself to that host and yet, from the difficulty of these reaching the only environment in which they can become mature, might not increase more rapidly than an elephant which carries a single foetus for about two years, and guards it for many years after birth. The probable adaptation of the variable reproductive processes to the average conditions of the race is discussed under the heading Longevity. It may be added here that the adaptation, in all successful cases, appears to be in excess of what would be required merely to replace the losses caused by death, and that there is ample scope for the Malthusian and Darwinian factors. The rate of reproduction tends to outrun the food-supply.

Literature.—Almost any zoological publication may contain matter relating to reproduction, but text-books on Embryology must be specially consulted. The annual volumes of the Zoological Record, under the heading "General Subject" until 1906, and thereafter under "Comprehensive Zoology," give a classified subject-index of the literature of the year in which references to the separate parts of the subject are given. Amongst the older works referred to in the preparation of this book, the following are the most important: A. Lecuenhoek, Epistola ad societatem regiam Angliae (1719); R. A. P. de Réaumur, Mémoires pour servir à l'histoire des insectes (Paris, 1734-1742); C. Bonnet, Études d'histoire naturelle et générale (Paris, 1781); L. Leuckart, "Clasping Organs of Marine Invertebrate Animals" (Eng. trans., 2nd ed., London, 1789); J. L. Prévost et J. B. Dumas, "Observations relatives à l'appareil géniteur des amphibiens," Ann. Sci. Nat. i. (1824); K. E. von Baer, Epistola ad Academic. Scient. Petropolitanan; Heusinger, Zeitschrift, ii. (1828); Léon Dufour, Recherches anatomiques et physiologique sur les Hémipèdes Paris (1833); R. Wagner, "Recherches sur la génération," Ann. Sci. Nat. viii. (1835; A. Kölliker, Uber das Wesen der sogenannten Saamenthier, Frompe, Notizen xix. (1841); M. Barri, "Spermatozoon observed within the Mammillarous Ovum," Phil. Trans. (1743); L. Krehbiel, "Sexual and Generative Systems," (Eng. trans., London, 1843); R. Leuckart, Beiträge zur Lehre der Befruchtung (Göttingen Nachrichten, 1849); (Sir) R. Owen, On Parthenogenesis (London, 1849); H. Nelson, "The Reproduction of Ascaris mystax," Phil. Trans. (1855); C. T. E. von Siebold, On a True Parthenogenesis in Moths and Bats (Eng. trans., London, 1857); E. van Beneden, "Recherches sur la maturation de l'œuf et sa locomotion," Arch. de bot. (1860); O. Hertwig, "Der Problem der Befruchtung," Jen. Zeitsch. xviii. (1885).

Reproduction of Plants

The various modes in which plants reproduce their species may be conveniently classified into two groups, namely, vegetative propagation and true reproduction, the distinction between them being roughly this, that in the former, any individual may be effected by the most various parts of the body, in the latter it is always effected by means of a specialised reproductive cell.
I. Vegetative Propagation.

The simplest case of vegetative multiplication is afforded by unicellular plants. When the cell which constitutes the body of the plant has attained its limit of size it gives rise to two either by division or gemmation; the two cells then grow, and at the same time become separated from each other, so that eventually two new distinct individuals are produced, each of which precisely resembles the original organism. A good example of this is to be found in the germination of the yeast plant. This mode of multiplication is simply the result of the ordinary processes of growth. All plant-cells grow and divide at some time or other of their life; but whereas in multicellular plants the products of division remain coherent, and add to the number of the cells in the plant consists, in a unicellular plant they separate and constitute new individuals. In more highly organized plants vegetative propagation may be effected by the separation of the different parts of the body from each other, each such part developing the missing members and thus constituting a new individual. This takes place spontaneously in rhizomatous plants, in which the main stem gradually dies away from behind forwards; the lateral branches thus become isolated and constitute new individuals.

The remarkable regenerative capacity of plant-members is largely made use of for the artificial propagation of plants. A branch removed from a parent-plant will, under appropriate conditions, develop roots, and so constitute a new plant; this is the theory of propagation by "cuttings." A portion of a root will similarly develop one or more shoots, and thus give rise to a new plant. An isolated leaf will, in many cases, produce a shoot and a root, that is, a new plant; it is in this way that new begonias, for instance, are propagated. The production of plants from leaves occurs also in nature, as, for instance, in certain so-called "viviparous" plants, of which Bryophyllum calceatum (Crassulaceae) and many ferns (Nephrodium, Asplenium, Asplenium, &c.) are examples. But it is in the mosses, of all plants, that the capacity for vegetative propagation is most widely diffused. Any part of a moss, whatever it be the stem, the leaves, the rhizoids, or the sporogonium, is capable, under appropriate conditions, of giving rise to filamentous protonema, on which new moss-plants are then developed as lateral buds.

In a large number of plants provision is made for vegetative propagation by the development of more or less highly specialized organs. Inlichens, for instance, there are the soredia, which are minute buds of the thallus containing both algal and fungal elements; these are set free on the surface in large numbers, and each grows into a thallus. In the Characeae there are the bulbils or "starch-stars" of Chara stelligera, which are underground nodes, and the branches with naked base and the proembryonic branches found by Pringsheim on old nodes of Chara fragilis. In the mosses small tuberous bulbils frequently occur in the rhizoids, and in many instances (Bryum annulatum, Adascomnion androgynum, Tetraphis pellucida, &c.) stalked fusiform or lenticular multicellular bodies containing chlorophyll, termed gemmae, are produced on the shoots, either in the apex of the leaves or in special receptacles at the summit of the stem. Gemmae of this kind are produced in vast numbers in Marchantia and Lunularia among the liverworts. Similar gemmae are also produced by the prothallia of ferns. In some ferns (e.g. Nephrolepis tuberosa and uudulata) the buds borne on the leaves or in their axils become swollen and filled with nutritive materials, constituting bulbils which fall off and give rise to new plants. This conversion of buds into bulbils, which subserve vegetative multiplication, occurs also occasionally among Phanerogams, as for instance in Liliim bulbiferum, species of Pea, Polygonum viviparum, &c. But many other adaptations of the same kind occur among some of the lower plants, but whereas in other plants a new plant is produced in the succeeding year. In the potato, tubers are developed from subterranean shoots, each of which in the following year gives rise to a new individual. In the dahlia, Thaliaidutha dahiba, &c., tuberous swellings are found on the roots, from each of which a new individual may spring.

II. True Reproduction.

This is effected by cells formed by the proper reproductive organs. These cells are of two principal kinds. There are, first, those cells each of which is capable of developing by itself into a new organism: these are the asexual reproductive cells, generally known as spores. Secondly, there are the cells which are incapable of independent germination; it is not until these cells have fused together in pairs that a new organism can be formed: these are the sexual reproductive cells or gametes.

In some exceptional cases the normal mode of reproduction, sexual or asexual, does not take place: instead, the new organism is developed vegetatively from the parent. When sexual reproduction is suppressed the case is one of apogamy; when asexual reproduction by spores is suppressed the case is one of apogamy. (Apogamy and apospory are discussed below in the section on Abnormalities of Reproduction.)

Asexual Reproduction.—Reproduction by means of some kind of spore (using the term in its widest sense, so as to include all asexually produced reproductive cells) is common to nearly all families of plants; it is wanting in certain Algae (Conjugatae, Fucaceae, Characeae), and in certain fungi (e.g. some Peronosporae). The structure of a spore is essentially this: it consists of a nucleated mass of protoplasm, enclosing starch or oil as reserve nutritive material, usually invested by a cell-wall. In those cases in which the spore is capable of germinating immediately on its development the wall is a single delicate membrane of cellulose; but in those cases in which the spore may or must pass through a period of quiescence before germination the wall becomes thickened and may consist of two layers, an inner, the endospore, which is delicate and consists of cellulose, and an outer, the exospore, which is thick and rigid, frequently darkly coloured and beset externally with spines or bosses, and which consists of cutin. In some few cases among the fungi multicellular or septate spores are produced; these approximate somewhat to the gemmae mentioned above as highly specialized organs for vegetative propagation. In some cases, particularly among the algae, and also in some fungi (Peronosporae, Saprolegniae, Chytridiaceae, and the Myxomycetes), spores are produced which are usually destitute of any cell-wall, and are further peculiar in that they are motile, and are therefore termed zoospores; they move sometimes in an amoeboid manner by the protrusion of pseudopodia, but more frequently they are provided with one, two, or many delicate vibratile protoplasmic filaments, termed cilia, by the lashing of which the spore is propelled through the water. The zoospore eventually comes to rest, withdraws its cilia, surrounds itself with a cell-wall, and then germinates.

In the simplest case a single spore is developed from the cell of the unicellular plant, the protoplasm of which surrounds itself with the characteristic thick wall. This occurs only in plants of low organization such as the Chlophyta.

In other cases the contents of the cell undergo division, each portion of the protoplasm constituting a spore. Examples of this are afforded, among unicellular plants, by yeast and the Protozoa and in multicellular plants by the Pandorinae, Confervaceae, Ulvaceae, &c., where any cell of the body may produce spores.

In such cases the spore-producing cell may be regarded as a rudimentary reproductive organ of the nature of a sporangium. In more highly organized plants special organs are differentiated for the production of spores. In the majority of cases the special organ is a sporangium, that is, a capsule in the interior of which the spores are developed; but in many fungi the spores are formed by abscission from an organ termed a sporocarp. In the Thalliphyta the sporangium is commonly a single cell. In the Bryophyta it is a multicellular capsule. In the Pteridophyta the sporangium is multicellular, but simple in structure, and this is true also of the Phanerogams.
Reproduction

It is important to note that in all the Bryophyta and in some of the Pteridophyta (most of the Filicinaceae, all existing Equisetinae, and the Lycopodiaceae and Ptilophytae) there is but one kind of sporangium and spore, the plants being 

_homo-spore_ or _isosporous_, whereas the rest of the Pteridophyta (Hydropteridaceae, Selaginellaceae) and the Phanerogams are heterosporous, having sporangia of two kinds; some produce one or a few large spores (megaspores), and hence termed mega-

_sporangia_, while others give rise to a larger number of small spores (microspores) and are hence termed microsporangia.

In the Phanerogams the two kinds of sporangia have received special names: the megasporangium, which produces as a rule only one mature spore (embryo-sac), is termed the ovule; the microsporangium, which produces a large number of micro-

_spores (pollen-grains), is termed the pollen._

In some of the simpler Thallophyta, is more or less restricted to definite parts of the body. Thus in the Red Algae (Florideae) there are the organs known as _stichidia, nemathecia_. The number and variety of such organs is very great; they may be described generally as simple and compound _sporophores_; but for a description the article Fungi should be consulted. In the higher plants the organs are less various. In the Bryophyta the production of spores is restricted to the sporogonium. In the vascular plants (Pteridophyta, Phanerogams) the development of sporangia, speaking generally, is confined to the leaves. In most ferns the sporangiferous leaves (sporophylls) do not differ in appearance from the foliage leaves; but in other Pteridophyta (Equisetaceae, Marsiliaceae, some species of _Lycopodium _and _Selaginella_) they present considerable adaptation, and notably in the Phanero-

_gams. In the Phanerogams the specialization is so great that the sporophylls have received special names; those which bear the microsporangia (pollen-sacs) are termed the _stamens_, and those which bear the megasporangia (ovules) are termed the _carpels_. The sporophylls are usually aggregated together on a short stem, forming a shoot that constitutes a flower._

Many terms are employed to indicate the nature of the various kinds of spores, especially among the fungi, but the endless varieties of asexual (and _sexually_ produced) reproductive cells may be grouped under two heads — (1) _Gonidia_, (2) _Spores proper_.

The distinction between these two kinds of asexual reproductive cells is as follows.

The _gonidium_ is a reproductive cell that gives rise, on germina-

_tion, to an organism resembling the parent. For instance, among the algae, the "zoospore" of _Vaucheria_ develops into a _Vaucheria_-plant. There is thus a close connexion between vegetative multiplication and multiplication by means of _gonidia_. The production of _gonidia_ is entirely limited to the _Thallophyta_, and is especially marked in the fungi, though the nature of all the many kinds of reproductive cells formed in this group has not yet been fully investigated. It is, however, wanting in certain algae (Conjugatae, Fucaceae, Characeae) and fungi (some Peronosporaceae and Ascomycetes).

The _spore proper_ is a reproductive cell that as a rule gives rise, on germination, to an organism unlike that which produced it. For instance, the spore of a fern when it germinates gives rise, not to a fern-plant, but to a prothallium. The apparent exceptions to this rule occur only among the _Thallophyta_, and are explained below in the section on Life-history.

The true spore is developed, usually in a sporangium, after a process of division which presents certain features that call for special notice.

Observation of the process of division of the nucleus (karyokinies) in plants generally has shown (for details see CytoLogy) that the linin-reticulum of the resting nucleus breaks up into a definite number of segments, the chromosomes, each of which bears a series of minute bodies, the chromatin-disks or chromosomes, consisting largely of a substance termed chromatinum. In the ordinary _homotype_ divisions of the nuclei the characteristic number of chromosomes is always observable; but when the spore-mother-cells are being formed the number of chromosomes is reduced to one-half. This, if the number of chromosomes of the parent plant be expressed as 2x the number in the spore will be x. To take a concrete-case: it has been observed by Guignard and others that in the early divisions taking place in the developing anther and ovule of the _ilm_ the number of chromosomes is 24; whereas in the later divisions which give rise to the pollen-mother-cells in the one case and to the mother-

_cell of the embryo-sac in the other, the number of chromosomes is only 12. Thus the development of a spore (as distinguished from a _gonidium_) is always preceded by a _reducing- or heterotype-

_division_.

The reduced number of chromosomes in the nucleus of the _spore-mother-cell persists in the spore, and in all the cells of the organism to which the spore may give rise. (_Meiosis is discussed below in the section on Sexual Reproduction._)

It should be explained that cells, which, the name "spore" has also been applied, are formed as the result of a sexual act: such are _zygospores_, _oospores_, and some _carpospores_. But these cells differ from spores proper not only in their mode of origin but also in that their nuclei contain the full double number (2x) of chromosomes; hence they may be distinguished as _diplospores_.

Sexual Reproduction.—Sexual reproduction involves the development of sexual organs (gametangia) and sexual cells (gametes). When the organism is unicellular, as in the lower Green Algae (e.g. _Protozoaceae_, _Conjugatae_), the cell becomes a sexual organ and its whole protoplasm gives rise to one or more sexual cells; in the higher forms certain parts of the body are specialized as sexual organs. In many of the lower plants the organs present no external distinction of sex (e.g. lower Green _Algae_, the _Chytridiaceae_, _Mucorinae_, and some _Ascomycetes_ among the fungi): it is impossible to distinguish between the male and female organs, although it cannot be doubted that the essential physiological difference exists; consequently the organs are merely described as _gametangia_. The gap between these plants and those with differentiated sexual organs is, however, bridged over by intermediate forms, as explained in the article _Algae_.

When the sexual organs are more or less obviously differ-

_entiated into male and female, they present considerable variety of form in different groups of plants, and accordingly bear different names. Thus the male organ is a _pollinodium_ in most of the fungi, a _sporangium_ in others (certain Ascomycetes, _Uredineae_); in all other plants it is an _antheridium_. Similarly the female organ is an _oogonium_ in various _Thallophyta_ (Green and Brown _Algae_; _Oomycetous Fungi_; a _procarp_ in the _Red_ _Algae_; an _archicarp_ in certain _Ascomycetous Fungi_ and in the _Uredineae_; an _archegonium_ in all the higher plants.

It is generally the case that the protoplasm of the sexual organ is differentiated into one or more sexual cells. Thus the _gametangium_ usually gives rise to cells which, as they are externally similar, are termed _isogametes_ or simply _gametes_. Certain forms of the male organ, the _sporangium_ and the _antheridium_, give rise to male cells which are termed _spermatia_ when they are non-

_ciliate_, _spermatoeid_, when they are ciliated and free-swimming. Again, the female organs termed _oogonia_ and _archegonia_ produce one or more female cells called _oospheres_. But there are impor-

_tant exceptions to this rule. Thus the protoplasm is not differentiated into cells in the _gametangium_ of the _Mucorinae_; in the male organ (pollinodium), of fungi generally; and in the female organ (procarp) of the _Red_ _Algae_ and (archicarp) of the _Ascomycetes_ and _Uredineae_.

The immediate product of the fusion of cells, or of undifferen-

_tiated protoplasm, derived from sexual organs of opposite sex may be generally termed the _zygote_; but it is not always of the same kind. Thus when two isogametes, or the undifferentiated contents of two _gametangia_, fuse together, the process is design-

_nated _conjugation_, and the product is usually a single cell termed _zygospore_. When an oosphere fuses with a male cell, or with the undifferentiated contents of a male organ, the process is _fertilization_, and the product is a single cell termed _oospore_. When, finally, a female organ with undifferentiated contents receives a male cell, the process again is _fertilization_; here the
product is not a single cell, but a fructification termed cystocarp (Red Algae), or ascospor (Ascomycetes) or ocellidium (Uredinean), containing many spores (carpospores).

As a consequence of the diversity in the sexual organs and cells, in the details of the sexual act, and in the product of it, several modes of the sexual process have to be distinguished, which may be conveniently summarized as follows:

I. **Ligamy**: the sexual process consists in the fusion of either two similar sexual cells (isogametes), or two similar sexual organs (gametangia); it is termed conjugation, and the product is a zygospore. Its varieties are:

(a) **Gametangia**: free and free-swimming (planogametes), set free into the water where they meet and fuse: lower Green Algae (Protococceae, Pandorineae, most Siphonococceae and Converfusae); some Brown Algae (Phaeosporae).

(b) **Gametangia fuse in pairs**, and a gamete is differentiated in each: the gametes of each pair fuse, but are not set free and are not ciliated (the Conjugate Green Algae); or, no gametes are differentiated, the undifferentiated contents of the gametangium fusing (Mucorine among the Fungi).

II. **Oogamy**: male and female organs distinct: the protoplasm of the female organ is differentiated into one or (rarely) more oospores which usually remain enclosed in the female organ; the contents of the male organ are usually differentiated into one or more male cells: the process is fertilization, the product is an oospore.

(A) **The sexual organs are unciicular (or coenocytic as in certain Siphonococceae and in the Oomycetous Fungi)**; the female organ is an oogonium.

(a) **The male organ is an antheridium giving rise to one or more free-swimming ciliated spermatozoids**.

1. **The antheridium contains a single spermatozoid which is fertilized in situ**: higher Green Algae (Velxius, Vaucheria, Oedogonium, Coleochaete, Characeae); some Brown Algae (Fucus); among the Fungi, Monoblepharum, the only fungus known to have spermatozoids.

2. **The oogonium produces a single oosphere which is extruded and is fertilized in the water**: Dictyota and some Fucaceae (Rhodymenia).

3. **The oogonium contains several oospheres which are fertilized in situ**: Sphaceoeta (Siphonaceous Green Algae).

4. **The oogonium produces more than one oosphere (2-5) which are extruded and are fertilized in the water**: certain Brown Algae (Pelvetia, Aspococcus, Fucus).

(B) **The male organ is a pollikidium which applies itself closely to the oogonium**: the amorphous male cell is not ciliated and is not set free.

1. **The oogonium contains a single oosphere which is fertilized in situ**: Peronosporae (Oomycetous).

2. **The oogonium contains several oospheres**: Saprolegniaea, but it is debatable whether or not fertilization actually takes place.

(B) **The male and female organs are (as a rule) multicellular**: the male is an antheridium, the female an oogonium; the archegonium always contains a single oosphere which is fertilized in situ.

1. **The male cell is a free-swimming ciliated spermatozoid**: the oogonial cell produces more than one (usually very many) spermatozoids, each of which is developed in a single cell: all Bryophyta (mosses, &c.) and Pteridophyta (ferns, &c.): the only Phanerogams in which spermatozoids have been observed are the gymnospermous species Ginkgo biloba, Carya rosulosa, Zamia integrifolia.

2. **The female cell is amorphous and passes directly from the pollen-tube into the oosphere (siphonogamy)**: all Phanerogams except the species just mentioned.

It must be explained that in the angiospermous Phanerogams, the male and female organs are so related in each that is represented by only a single cell: the male, by the generative cell, formed in the pollen-grain, which usually divides into two male cells: the female, by the oosphere. The gradual reduction can be traced through the gymnosperms.

Attention may here be drawn to the fact (see Angiosperms) that, in several cases, the second male cell has been seen to enter the embryo-sac from the pollen-tube, and its nucleus to fuse with the definite nucleus of the spermatid in a manner that is quite different from that of other nuclei. The significance of this remarkable observation is discussed in the section on the Physiology of Reproduction.

III. **Carposporophyta**: the sexual organs are (as a rule) differentiated into male and female, the protoplasm of the unicellular or multicellular female organ (archipar, procar) is never differentiated into an oosphere: in many cases definite male cells, spermatia, are produced adventitiously; free, but they are not ciliated, frequently have a cell-wall: the process is fertilisation: the product is a fructification derived essentially from the female organ containing several (sometimes very many) spores (carpospores): characteristic of the Red Algae and of the Ascomycetous Fungi.

(A) **There are definite male cells (spermatia)**.

(a) **The female organ is a procarp, consisting of an elongated, rounded receptacle, the trichogyne, and of a fleshy, fertile portion, the carpogonium**: on fertilization the latter grows and gives rise directly or indirectly to a cysto-carp: the spermatia are formed in a unicellular antheridium, the male cells are discharged from the receptacle by disintegration of the latter, and fuse with the trichogyne: Red Algae (Rhodophycea or Florideae).

(b) **The female organ (archicarp) resembles the preceding**: in fertilization the fertile portion (ascusogonium) develops into an asco-carp containing one or more asci (spermatia) each containing usually eight ascospores: the spermatia are formed by abscission from fertilization tubes (archispores) joining special receptacles, the spermatogonia, which are the male organs: certain Ascomycetous Fungi (e.g. Laboulbeniaceae, some Lichen-Fungi, Pyostigma). For the Uredineae, see Abnormalities of Reproduction, below.

(B) **There are no definite male cells**: the more or less distinct male and female organs come into contact, and their undifferentiated content form a product is an asco-carp:

(a) **The male and female organs are obviously different**: the female organ is an ascogonium, the male a pollinodium: e.g. Pyronema, Sphaerobasis (Ascomycetes).

(b) **The male and female organs are quite similar**: e.g. Eremascus, Dipodosascus (Ascomycetes).

It may be explained that carpogamy is the expression of sexual degeneration. In the cases last mentioned, when the sexual organs are quite similar, they may be fertilized by antheridia of the other plant, and further reduction is observable in other Ascomycetes in which one of the sexual organs, presumably the male, is either much reduced or is altogether wanting. Again in the rusts (Uredineae), the spermatia of the male are not ciliated (see section on Abnormalities of Reproduction). In the highest Fungi, the Autobasidiozymetes, no sexual organs have been discovered.

Details of the Sexual Act.—It has been already stated that the sexual act consists in the fusion of two masses of protoplasm, commonly cells, derived from two organs of opposite sex; but this is only the first stage in the process. The second stage is the fusion of the nuclei, which usually occurs quickly after the fusion of the cells; but nuclear fusion may be postponed so that the two sexual nuclei may be observed in the zygote, as “conjugate nuclei,” and even in the cells of the organism developed from the zygote (e.g. Uredineae). The result of nuclear fusion is that the nucleus of the zygote contains the double number of chromosomes—that is, if the number of chromosomes in each of the fusing sexual nuclei be x, the number in the nucleus of the zygote will be 2x. Moreover, this double number persists in all the cells of the organism developed from the zygote, until it is reduced to one-half by meiosis preceding either the development of the sporangium or the formation of the spore. Still further reduction is observable in other Ascomycetes in which one of the sexual organs, presumably the male, is either much reduced or is altogether wanting. Again in the rusts (Uredineae), the spermatia of the male are not ciliated (see section on Abnormalities of Reproduction). In the highest Fungi, the Autobasidiozymetes, no sexual organs have been discovered.

III. Life-history.

It will have been gathered from the foregoing sections that plants generally are capable of both sexual and asexual reproduction; and further, that in different stages of its life-history they pass the diploid (2x) number of chromosomes in their nuclei, or the haploid (x) number. It may be at once stated that, in all plants in which sexual reproduction and true meiotic spore-formation exist, these two modes of reproduction are restricted to distinct forms of the plant; the sexual form bears only the sexual organs and is haploid; the asexual form only...
produces spores and is diploid. Hence all such plants are to this extent polymorphic—that is, the plant assumes these two forms in the course of its life-history. When, as in many Thallophyta, one or other of these forms can reproduce itself by means of gonidia, additional forms may be introduced into the life-history, which becomes the more complicated the more pronounced the polymorphism. The most straightforward life-histories are those presented by the Bryophyta and the Pteridophyta, where there are but the two forms, the sexual and the asexual. In the life-history of a moss, the plant itself bears only sexual organs: it is the sexual form, and is distinguished as the gametophyte. The zygote (oospore) formed in the sexual act develops into an organism, the sporogonium, which is entirely asexual, producing only spores: it is distinguished as the sporophyte. When these spores germinate, they give rise to moss-plants. Thus the two forms, the sexual and the asexual, regularly alternate with each other—that is, the life-history presents that simple form of polymorphism which is known as alternation of generations. Similarly, in the life-history of a fern, there is a regular alternation of a sporophyte, which is the fern-plant itself, with a gametophyte, which is the fern-prothallium.

It is pointed out in the preceding section that, as the result of the sexual act, the nucleus of the zygote contains twice as many chromosomes as those of the fusing sexual cells. This 2x number of chromosomes persists throughout all the cell-generations derived from the zygote, that is, in the cells constituting the sporophyte, up to the time that it begins to produce spores, when meiosis takes place. Again, the cell-generations derived from the spore, that is, the cells constituting the gametophyte, all have the reduced x number of chromosomes in their nuclei up to the sexual act. Hence the sporophyte may also be designated the diplophyte and the gametophyte the haplophyte (Strasburger): in other words, the sporophyte is the pre-metiotic, the gametophyte the post-metiotic generation. Twice in its life-history the plant is represented by a single cell: by the spore and by the zygote. The turning-points in the life-history, the transitions from the one generation to the other, are (1) meiosis, (2) the sexual act.

The course of the life-history in Phanerogams and in those Thallophyta which have been adequately investigated is essentially the same as that of the Bryophyta and of the Pteridophyta as described above, though it is less easy to trace on account of the peculiar relation of the two generations to each other in the Phanerogams and on account of various irregularities that present themselves in the Thallophyta.

In the Phanerogams, as in the Pteridophyta, the preponderating generation is the sporophyte, the plant itself. Inasmuch as they are heterosporous, the gametophyte is represented by a male and a female organ or prothallium, both rudimentary. The male prothallium consists of the few cells formed by the germinating pollen-grain (microspore); and though it is quite independent, since the microspores are shed, it grows parasitically in the tissues upon which the microspore has been deposited in pollination. The female prothallium may consist of many cells with well-developed archegonia, as in the Gymnosperms, or of only a few cells with the female organ reduced to the oosphere, as in the Angiosperms. In either case it is the product of the germination of a megaspore (embryo-sac) which is not shed from its sporangium (ovule): hence it never becomes an independent plant, and was long regarded as merely a part of the sporophyte until its true nature was better understood, chiefly by the researches of Hofmeister, who first explained the formation of generations in plants. The intimate and persistent connexion between the two generations affords the explanation of the characteristic features of the Phanerogams, the seed and the flower. The ovule containing the embryo-sac, which eventually contains the embryo, persists as the seed—a structure that is distinctive of Phanerogams, which have, in fact, on this account been also termed Spermatophyta. With regard to the flower, it has been already mentioned that it is, like the cone of an Equisetum or a Lyco-

podium, a shoot adapted to the production of spores. But it is something more than this: for whereas in Equisetum or Lycopodium the function of the cone comes to an end when the spores are shed, the flower of the Phanerogam has still various functions to perform after the maturation of the spores. It is the seat of the process of pollination—that is, the bringing of the pollen-grain by one or various agencies into such a position that a part (the pollen-tube) of the male prothallium developed from it may reach and fertilize the oosphere in the embryo-sac. Thus the flower of Phanerogams is a reproductive shoot adapted not only for spore-production, but also for pollination, for fertilization, and for the consequences of fertilization, the production of seed and fruit. However, in spite of these complications, it is possible to determine accurately the limits of the two generations by the observation of the nuclei. The meiosis preceding the formation of the spores marks the beginning of the (haploid) gametophyte, male and female; and the sexual act marks that of the (diploid) sporophyte.

The difficult task of elucidating the life-histories of the Thallophyta has been successfully performed in certain cases by the application of the method of chromosome-counting, with the result that alternation of generations has been found to be of general occurrence. To begin with the Algae. In the Dictyotaceae (Brown Algae) there are two very similar forms in the life-history, the one bearing asexual reproductive organs (tetrasporangia), the other bearing sexual organs (oogonia and antheridia). It has been shown (Lloyd Williams) that the former is undoubtedly the sporophyte and the latter the gametophyte, since the nuclei of the former contain 32 chromosomes, and those of the latter 16. Meiosis takes place in the mother-cell of the tetraspores, which, on germination give rise to the sexual form. Quite a different life-history has been traced in Fucus, another Brown Alga. Here no spores are produced: there is but one form in the life-history, the Fucus-plant, which bears sexual organs and has, on that account, been regarded as a gametophyte. The investigation of the nuclei has, however, shown (Farmer) that the Fucus-plant is actually diploid, that it is, in fact, a sporophyte; but since there is no spore-formation, meiosis immediately precedes the development of the sexual cells, which alone represent the gametophyte (see below, Aposporous).

Similarly, two types of life-history have been discovered in the Red Algae. In Polysiphonia violacea, a species in which the tetraspores and the sexual organs are borne by similar but distinct individuals, it has been ascertained (Yamanouchi) that, as in Dictyota, meiosis takes place in the mother-cell of the tetraspores, so that the nuclei of these spores, as also those of the sexual plants to which they give rise, contain 20 chromosomes: and further, that the nuclei of the carpospores (diplospores) produced in the cystocarp as the result of fertilization, contain 40 chromosomes, as do also those of the asexual plant to which the carpospores give rise. Hence the sporophyte is represented by the cystocarp and the resulting tetraspore-angiate plants: the gametophyte, by the sexual plants. Though it is the rule in the Red Algae that the tetrasporangia and the sexual organs are borne on distinct individuals, yet cases are known in which both kinds of reproductive organs are borne upon the same plant; and to those the above conclusions obviously cannot apply. They have yet to be investigated.

The second type of life-history has been traced in Nemalion. Here there is no tetrasporangiate form, consequently meiosis takes place at a different stage in the life-history. It has been observed (Wolfe) that the nuclei of the sexual plant are chromium-nuclear, those of the male filaments of the developing cystocarp contain 16, whilst those of the carpospores contain 8; hence meiosis takes place in the carposporangia. Here the plant is the gametophyte; the sporophyte is only represented by the cystocarp. The carpospores here are true spores (haplospores).

Among the Green Algae, Coleochaete is the only form that has been fully investigated (Allen). Here meiosis takes place in the germinating oospore: consequently the plant is the..
gametophyte, and the sporophyte is represented only by the oospore, so that the life-history resembles that of *Nemation*. It is probable that this conclusion is generally true of the whole group; at any rate of those forms (Desmids, Spirogyra, Oedogonium, Chara) which have been more or less investigated.

Turning to the Fungi, somewhat similar results have been obtained in the few forms that have been studied from this point of view. In the sexual Ascomycetes it appears (Harper) that meiosis takes place in the ascospore just before the development of the spores, so that the life-history essentially resembles that of *Nemation*. Again, in certain Uredineae, having an aecidium-stage and a teleutospore-stage, which is apparently a sexual process has been observed (Blackman, Christman) which is described in the section on *Abnormalities of Reproduction*, and the life-history is as follows. The sexual act having taken place, a row of aecidiospores is developed in the aecidium, each of which contains two conjugate nuclei derived from the sexual nuclei. The meycelium developed from the aecidiospore, as well as the uredospores and the teleutospores that it bears, shows two conjugate nuclei. When, however, the teleuto-

spore is about to germinate, the two nuclei fuse (thus completing the sexual act) and meiosis takes place. As a result the promys-

celium developed from the teleutospore, and the sporiad that it produces, are uninucleate; so are also the mycelium developed from the sporidium, and the female organs (archicarps) borne upon it. Hence the limits of the sporophytes are the aecidio-

spore and the teleutospore: those of the gametophyte, the teleutospore and the aecidiospore.

Similar observations have been made upon other Uredineae with a more contracted life-history. *Phragmidium Potentillae-

canadensis* is a rust that has no aecidium-stage: consequently the primary uredospores are borne by the mycelium produced on infection of the host by a sporidium. It has been observed (Christman) that the sporogenous hyphae fuse in pairs, suggest-

ing a sexual act; then the primary uredospores are developed in rows from the fused pairs of hyphae which thus behave as sexual organs (archicarps), and each such uredospore contains two conjugate nuclei. Although the research has not been carried beyond this point, it may be inferred that in this case, as in the preceding, nuclear fusion and meiosis take place in the teleutospore. Here the sporophyte is represented by the uredo-form.

Finally, in some of the fungi in which no sexual organs have yet been discovered, this method of investigation has made it probable that some kind of sexual act takes place nevertheless. Thus in the Uredineae *Puccinia malvacearum*, which has only teleutospore- and sporidium-stages, it has been observed (Black-

man) that the formation of the teleutospores is preceded by a binucleate condition of the hyphae. The same idea is suggested by the binucleate basidia of the Basidiomycetes, which corre-

spond to the teleutospores of the Uredineae.

The life-histories sketched in the preceding paragraphs show that one of the complexities met with in the Thallophyta is that meiosis does not always take place at the same point in the life-history. In the higher plants the incidence of meiosis is generally, though not absolutely, constant: it may be stated as a rule that in the Bryophyta, Pteridophyta and Phanerogams it takes place in the spore-mother-cells. In the Thallophyta this rule does not hold. In some of them, it is true, meiosis immediately precedes, as in the higher plants, the formation of certain spores, the tetraspores (Dictyotaceae, Polyphysis), the teleutospores (Uredineae); but in others it immediately precedes the development of the sexual organs (Fucaceae), or follows more or less directly upon the sexual act (Green Algae, *Nemalion*, Ascomycetes).

The life-history of most Thallophyta is further complicated by the capacity of the gametophyte of the sporophyte to repro-

duce themselves by cells termed gonidia, a capacity that is wholly lacking in the higher plants. The karyology of gonidia has not yet been sufficiently investigated: but when, as in the Green Algae and the Oomycetous Fungi, the gonidia are developed by and reproduce the gametophyte, it may be inferred that they, like the gametophyte, are haploid. One case, at any rate, of the reproduction of the sporophyte by gonidia is fully known, that of the Uredineae just described, in which the uredo-

form, which is a phase of the sporophyte, is reproduced by the uredo-spores which are binucleate, that is diploid, and may be distinguished as *dipgonidia*. In any case the result is that with the higher Thallophyta the life-history of the gametophytic generation occurs but once in the life-history, in these Thallophyta the life-

history may include a succession of gametophytic or of sporophy-

tic forms This is, in fact, a distinguishing feature of the group. The higher plants present a regular alternation of generations: whereas, in the Thallophyta, though they probably all present some kind of alternation of generations, yet it is ir-

regular in the various ways and for the various reasons mentioned above.

Sufficient information has been given in the preceding pages to render possible the consideration of the origin of alternation of generations. To begin quite at the beginning, it may be assumed that the primitive form of reproduction was purely vegetative, merely division of the unicellular organism when it had attained the limits of its own growth. Following on this came reproduction by a gonium: that is, the protoplast of the cell, at the end of its vegetative life, became quiescent, surrounded itself with a proper wall, or was set free as a motile ciliated cell, having in some unexplained way become capable of originating a new course of life (regeneration) on germination. Then, as can be well traced in the Brown and Green Algae (see Algae), these primitive reproductive cells (gonidia) began to fuse in pairs: in other words, they gradually became sexual. This stage can still be observed in some of these Algae (e.g. Ulothrix, Ectocarpus) where the zoospores (gonidia) may either germinate independently, or fuse in pairs to form a zygote. Gradually the sexuality of these cells became more pronounced: losing the capacity for independent germination, they acquired the external characters of more or less differentiated sexual cells, and the gametangia producing them developed into male and female sexual organs. But this advancing sexual differenti-

ation did not necessarily deprive the plant of the primitive mode of propagation: the sexual organism still retained the faculty of reproduction by gonidia. The loss of this facultative stage, with higher development: it is entirely wanting in some of the higher Thallophyta (e.g. Fucaceae, Characeae), and in all plants above them in the evolutionary series.

With the introduction of the sexual act, a new kind of reproductive cell made its appearance, the zygote. This cell, as already explained, differs from other kinds of spores and from the sexual cells, in that its nucleus is diploid; and with it the sporophyte (diplophyte) was introduced into the life-history. It has been mentioned that in some plants (e.g. Green Algae) the zygote is all that there is to represent the sporophyte, giving rise, or germination and after meiosis, to one or more spores. Passing to the Bryophyta, in the simpler forms (e.g. Riccia), the zygote develops into a multicellular capsule (sporogonium); and in the higher forms into a more elaborate sporogonium, producing many spores. In the Pteridophyta and the Phanerogams, the zygote gives rise to the highly developed sporophytic plant.

Thus the evolution of the sporophyte can be traced from the unicellular zygote, gradually increasing in bulk and in inde-

pendence until it becomes the equal of the gametophyte (e.g. *Dictyota* and *Polycladophora*), and eventually far surpasses it (Pteridophyta, Phanerogams). Moreover, the increase in size was attended by the gradual limitation of spore-production to certain parts only, the higher the species being the more limited, and finally the form of stems, leaves, &c. These facts have been formulated in the theory of “progressive sterilization” (Bower), which states that the sporophytic form of the higher plants has been evolved from the simple, entirely fertile, sporophyte of the lower, by the gradually increasing development of the sterile vegetative tissue at the expense of the sporogenous, accompanied by increase in total bulk and in morphological and histological differentiation.

In connexion with the study of the evolution of the sporophyte,
the question arose as to its morphological significance; whether it is to be regarded as a modified form of the gametophyte, or as an altogether new form intercalated in the life-history: in other words, whether the alternation is "homologous" or "antithetic." In certain plants there is a succession of forms which are undoubtedly homologous: for instance, in Coleochaete where a succession of individuals without sexual organs is produced by zoospores (gonidia). The main fact that has been established is that the sporophyte forms the simple zygote of the Thallophyta to the spore-bearing plant of the Phanerogams, is characterized by its diploid nuclei; that it is a diphyllote, in contrast to the haplophyllote gametophyte. Were these nuclear characters absolutely universal, there could be no question but that the sporophyte is an altogether new antithetic form, and not an homologous generation. But certain exceptions to the rule have been detected, which are described under Abnormalities of Reproduction: at present it will suffice to say that such things as a diploid gametophyte and a haploid sporophyte have been observed in certain ferns. It can only be inferred that alternation of generations is not absolutely dependent upon the periodic halving in meiosis and the subsequent doubling by a sexual act, of the number of chromosomes in the nuclei, though the two sets of phenomena usually coincide. It must not, however, be overlooked that these exceptional cases occur in plants presenting an abnormal life-history: the fact remains that where there is both normal spor-formation with meiosis, and a subsequent sexual act, the haploid form is the gametophyte, the diploid the sporophyte. But the actual observation of a haploid sporophyte and of a diploid gametophyte makes it clear that, however generally useful the nuclear characters may be in the distinction of sporophyte and gametophyte, they do not afford an absolute criterion, and therefore their value in determining homologies is debatable.

IV. Abnormalities of Reproduction.

In what may be regarded as the type of normal life-history, the transition from the one generation to the other is marked by definite processes: there is the meiotic development of spores by the sporophyte, and the sexual production of a zygote, or something analogous to it, by the gametophyte. But it has been mentioned in the preceding pages that the transition may, in certain cases, be effected in other ways, which may be regarded as normal, though they are constant enough in the plants in which they occur, in fact as manifestations of reproductive degeneration.

In the first place, the sporophyte may be developed either after an abnormal sexual act, or without any preceding sexual act at all, a condition known as apogamy. In the second, the gametophyte may be developed otherwise than from a post-meiotic spore, a condition known as apospory.

Apogamy.—The cases to be considered under this head may be arranged in two groups:

1. Pseudopogamy: sexual act abnormal.—The following abnormalities have been observed:

(a) Fusion of two female organs: observed (Christman) in certain Uredinae (Casoria aliensis, Pteridium spicatum, Uromyces Meloni), where adjacent archipcarps fuse: male cells (spermata) are present but functionless.

(b) Fusion between nuclei of the same female organ: observed in the ascogonia of certain Ascomycetes, Humaria grana- lata (Blackman) and where the male organ (Lachnea stercoris) (Fraser), where the male organ (pollinodium) is present but is apparently functionless.

(c) Fusion of a female organ with an adjacent tissue-cell: observed (Blackman) in the archipcarps of some Uredinae (Phragmidium violaceum, Uromyces Poeae, Puccinia Poae): male cells (spermata) present but functionless.

(d) The gametophyte develops from an organ: fusion takes place between adjacent tissue-cells of the organ; the sporophyte is developed from diploid cells thus produced. But there is no proper zygote as there is in a, b, c, observed (Farmer) in the archipcarp of certain ferns (Lasstreae pseudo-mas, var. polycladica); male organs (not sometimes female) present but functionless. Another such case is that of Humaria rutilans (Ascomycete), in which nuclear fusion has been observed (Fraser) in hyphae of the hypothecium: the asc are developed from these hyphae, and in them meiosis takes place; there are no sexual organs.

2. Eu-apogamy: no kind of sexual act—

(a) The gametophyte is haploid.

(b) The sporophyte is developed vegetatively from the gametophyte by apogamy: observed in certain ferns, Lasstrea pseudo-mas, var. cristata-apoporal (Farmer and Digby), and Nephrodium mollis (Yamanouchi).

(c) The gametophyte is diploid (see under Apogamy):

(a) The sporophyte develops from the diploid spores: observed in some Pteridophyta, viz. certain ferns (Farmer), Althyrium Filix-femina, var. clarissima, Scolopendrium vulgare, var. crisptom-Drummond, and Marsilia (Strasburger); also in some Phanerogams, viz. Compositae (Taraxacum, Murbek; Antennaria alpina, Juel; sp. of Hieracium (Rosenberg); Roscoeeae (Eu- Alchemilla ssp., Murbek; Straubinger); Ranunculaceae (Thalictrum parparcans, Overton).

(b) The sporophyte is developed vegetatively from the gametophyte: observed (Farmer) in the fern Althyrium Filix- femina, var. cristata-apoporal.

In all the cases enumerated under Eu-apogamy, apogamy is associated with some form of apospory except Nephrodium mollis, full details of which have not yet been published.

Many other ferns are known to be apogamous, but they are not included here because the details of their nuclear structure have not been investigated.

Apospory.—The known modes of apospory may be arranged as follows:

1. Pseudoposporpy: a spore is formed but without meiosis, so that it is diploid.—It may be observed in the plants of certain species of Marsilia (e.g. Marsilia Drummondii) in which the megaspore has a diploid nucleus (32 chromosomes) and the resulting prothallial and female organs are also diploid (Strasburger); and in various Phanerogams, some Compositae (Taraxacum, Murbek; some Marsilias, Juel), some Roscoeeae (Eu-Alchemilla, Murbek, Straubinger), and occasionally in Thalictrum parparcans (Overton). In the megaspore (embryo- sporophyte or prothallium) in some species Hieracium it has been found (Rosenberg) that adventitious diploid embryos are developed in the nucellus: these plants are also apogamous.

2. Eu-apogamy: no spore is formed.—Of this there are two varieties,

(a) With meiosis: this occurs in some Thallophyta which form no spores; the sporophyte of the Fucaceae bears no spores, consequently meiosis takes place in the developing sexual organs: the Conjugate Green Algae also have no spores, meiosis taking place in the germinating zygospore, which develops directly into the sexual plant.

(b) Without meiosis: the gametophyte is developed upon the sporophyte: the spores, in that case, are replaced by a vegetative process; for instance, in mosses it has been found possible to induce the development of prothallia in the post-stage of the gametophyte, from tissue-cells of the sporophyte: some certain ferns (varieties of Althyrium Filix-femina, Scolopendrium vulgare, Lasstrea pseudo-mas, Polyzuchum angulare, and in the species Polyzuchum dimorphum and Polyzuchum clarissima) and the gametophyte (prothallium) is developed by budding on the leaf of the sporophyte, and in some of these cases it has been ascertained that the gametophyte so developed has the same number (22) of chromosomes in its nuclei as the sporophyte that bears it—that is, it is diploid.

Apospory has been found to be frequently associated with apogamy; in fact, in the absence of meiosis, this association would appear to be inevitable.

Combined Apogamy and Apoapogamy.—Instances have been given of the occurrence of both apogamy and apogamy in the same life-history; but in all of them there is a regular succession of sporophyte and gametophyte. The cases now to be considered are those in which one or other of the generations gives rise directly to its like, sporophyte to sporophyte, gametophyte to gametophyte, normally intervening generation being omitted.

It is possible to conceive of this abbreviation of the life-history taking place in various ways. Thus, a sporophyte might be developed from a haploid instead of a gametophyte as the normal case, but this has not been observed. Or a sporophyte might be developed from a diploid spore (as distinguished from a zygote or a diploid oosphere), a possibility that is to some extent realized in the life-history of some Uredinae in which successive forms of the polymorphic sporophyte are developed from diplonidioida. Similarly a gametophyte might be developed from a fertilized or an unfertilized...
female cell: the latter possibility is to some extent realized in those Algae (e.g. Ullothrix, Ectocarpus) in which the sexual cells (isogametes), if they fail to conjugate, germinate independently as gonidia, giving rise to gametophytes.

The more familiar mode is that of vegetative budding, as already mentioned. Whether a "vegetative" fern or Phanerogam reproduces itself by a bud or a bulbil, both spore-formation and the sexual act are passed over: sporophyte springs from sporophyte. Remarkable cases of this have been observed in certain Phanerogams (Coelebogyne ilicifolia, Funkia ovata, Nothoscoedium fragrans, Citrus, sp. of Euryonymus, Opuntia vulgaris) in the ovule of which adventitious embryos are formed by budding from cells of the nucellus: with the exception of Coelebogyne, it appears that this only takes place after the oosperm has been fertilized. In other plants it is the gametophyte that reproduces itself by means of gemmae or bulbils, as commonly in the Bryophyta, the Protobrya, ferns, &c.

The abnormalities described are all traceable to reproductive degeneration; the final result of which is that true reproduction is replaced more or less completely by vegetative propagation. It may be inquired whether degeneration may have proceeded so far in any plant of sufficiently high organization to present spore-formation, or sexual reproduction, or both, as to cause the plant to reproduce itself entirely and exclusively by the vegetative method. The only such case that suggests itself is that of Caulerpa and possibly some other Siphonaceous Green Algae. In this plant no special reproductive organs have yet been discovered, and it certainly reproduces itself by the breaking off of portions of the body which become complete plants, but it is quite possible that reproductive organs may yet be discovered.

V. Physiology of Reproduction.

The reproductive capacity of plants, as of animals, depends upon the fact that the whole or part of the protoplasm of the individual can develop into one or more new organisms in one or other of several possible ways. Thus, in the case of unicellular plants, the whole of the protoplasm of the parent gives rise, whether by simple division or otherwise, to one or more new plants. Reproduction necessarily closes the life of the individual: here, as August Weismann long ago pointed out, there is no natural death, for the whole of the protoplasm of the parent continues to live in the progeny. In multicellular plants, on the contrary, the reproductive function is mainly discharged by certain parts of the body, the reproductive organs, the remainder of the body being essentially vegetative—that is, concerned with the maintenance of the individual. In these plants it is only a part of the protoplasm that continues to live in their progeny: the remainder, the vegetative part, eventually dies. It is therefore possible to distinguish in them, on the one hand, the essentially reproductive protoplasm, which may be designated by Weismann's term germ-plasm, though without necessarily adopting all that his use of it implies, and the essentially vegetative, mortal protoplasm, the somatoplasm, on the other. In the unicellular plant no such distinction can be drawn, for the whole of the protoplasm is concerned in reproduction. But even in the most highly organized multicellular plant this distinction is not absolute: for, as already explained, plants can, in general, be propagated by the isolation of almost any part of the body, that is vegetatively, and this implies the presence of germ-plasm elsewhere than in the special reproductive organs.

If the attempt be made to distinguish between the organs of vegetative propagation and those of true reproduction, the nearest approach would be the statement that the former contain both germ-plasm and somatoplasm, whereas the latter, or at least the reproductive cells, consist entirely of germ-plasm.

The question now arises as to the exact seat of the germ-plasm, and the answer is to be looked for in the results of the numerous researches into the structure and development of the reproductive cells that form so large a part of the biological work of recent years. The various facts already mentioned suffice to prove that the nucleus plays the leading part in the reproductive processes of whatever kind: the general conclusion is justified that no reproductive cell can develop into a new organism if deprived of its nucleus. It may be inferred that the nucleus either actually contains the germ-plasm, or that it controls and directs the activities of the germ-plasm present in the cell. It is not improbable that both these inferences may be true. At any rate there is no sufficient ground for excluding the cooperation of the cytoplasm, especially of that part of it distinguished as kinoplasm, in the reproductive processes.

Pursuing the ascertained facts with regard to the nucleus, it is established that the part of it especially concerned is the linin-network which consists of the chromosomes. The behaviour, as already described, of the chromosomes in the various reproductive processes has led to the conclusion that the hereditary characters of the parent or parents are transmitted by them to the progeny: that they constitute, in fact, the material basis of heredity (see HEREDITY). They can hardly, however, be regarded as the ultimate structural units, for the simple reason that their number is far too small in relation to the transmissible characters. It has been suggested (Farmer) that the chromomerces are the units, but the number of these would seem to be hardly sufficient. It seems necessary to fall back upon hypothetical ultimate particles, as suggested by Darwin, de Vries and Weismann, which may be generally termed pangens. The chromomerces may be regarded as aggregates of such particles, the "ids" of Weismann.

The foregoing considerations make it possible to attempt an explanation of the various reproductive processes. Vegetative Propagation.—It is easily intelligible that the two individuals produced by the division of a unicellular plant should resemble the parent and each other; for, the division of the parent-nucleus being homotypic, the chromosomes which go to constitute the nucleus of each daughter-cell are alike both in number and in nature, and exactly repeat the constitution of the parent-nucleus.

In the more complicated cases of propagation by bulbils, cuttings, &c., the development of the new individual, or of the missing parts of the individual (roots, &c.), may be ascribed to the presence in the bulbil or cutting of the necessary pangens. Reproduction by Gonidia.—In this case a single cell gives rise to a complete new organism resembling the parent. The inference is that the gonidium is a portion of the parental germ-plasm, in which all the necessary pangens have been accumulated. Reproduction by Spores.—In this case, also, an entire organism is developed from a single cell, but with this peculiarity that the resulting organism is unlike that which bore the spore, a peculiarity which has not yet been explained. It has been already stated that the development of true spores involves meiosis, and this process is no doubt related to the behaviour of the spore on germination; but the nature of this relation remains obscure. It might be assumed that, as the result of meiosis, the nucleus of the spore receives only gametophytic pangens. But the assumption is rendered impossible by the fact that the spore gives rise to a sexual organism, the reproductive cells of which, after the sexual act, produce a sporophyte. Clearly sporophytic pangens must be present as well in the spore as in the gametophyte and in its sexual cells. It can only be surmised that they exist there in a latent condition, dominated, as it were, by the gametophytic pangens. Sexual Reproduction.—Here, again, as yet unanswered questions present themselves. The essence of a sexual cell is that it cannot give rise by itself to a new organism, it is only truly reproductive after the sexual act: this peculiarity is just what constitutes its sexuality. Minute investigation has not yet detected any essential structural difference between a sexual cell and a spore; on the contrary, the results so far obtained have established that they essentially agree in being post-miotic (haploid). Why then do they differ so fundamentally in their reproductive capacities? Again, sexual cells differ in sex; but there are as yet no facts to demonstrate any essential structural difference between male
and female cells. What is known about them tends to prove their structural similarity rather than their difference. But it is possible that their difference may be chemical, and so not to be detected by the microscope.

The normal sexual act has been described as consisting in the fusion, first, of two cells, then of their nuclei, and finally, often after a long interval, of their chromosomes and of their chromomeres in meiosis. What causes determined these fusions is a question that is only partly answered. It is known in certain cases (e.g. ferns and mosses) that the male gametophyte is attracted to the female by chemical substances secreted for the purpose by the female gamete; that it is a case of chemotaxis. Probably this is more common than experiment has yet shown it to be. It is quite conceivable that the consequent cell-fusion, as also the subsequent fusions of nuclei and of chromosomes, are likewise cases of chemiotaxis, depending upon chemical differences between the fusing structures.

The sexual process can only take place between cells which are related to each other in a certain degree (see HYBRIDISM); that is, it depends upon sexual affinity. It is the general rule that fertilization takes place between a male and a female gamete of different individuals of the same species; that is, cross-fertilization is the rule. This is necessarily the case when the male and female organs are developed upon different individuals, when the plant is said to be dioecious. When both kinds of organs are developed upon the same individual (monoecious), self-fertilization may and often does occur; but it is commonly hindered by various special arrangements, of which dichogamy is the most common; that is, that the male and female organs are not mature at the same time. But though these arrangements favour cross-fertilization, they do not absolutely prevent self-fertilization. In some cases, cleistogamic flowers, for instance, self-fertilization alone is possible (see ANGIOSPERMS). The general conclusion is that though cross-fertilization is the more advantageous form of sexual reproduction, still self-fertilization is more advantageous to the species than no fertilization at all.

In considering this subject, it must be borne in mind that the terms used have different meanings when applied to certain heterosporous plants from those which they convey when applied to isosporous plants. In the latter cases their meaning is direct and simple: in the former it is indirect and somewhat complicated. In heterosporous plants generally the actual sexual organs are never borne upon the same individual, there is thus necessarily a male and a female plant (see ANGIOSPERMS); that, strictly speaking, self-fertilization is impossible. But in the Phanerogams, where there is a process preliminary to fertilization, that of pollination, which is unknown in other plants, the terms and the conceptions expressed by them are applied, not to the real sexual organs, but to the spores. Thus a dioecious Phanerogam is one in which the microspores are developed by one individual, the megaspores by another; and again, self-fertilization is said to occur when the microspores (pollen) fall upon the stigma of the same flower (see ANGIOSPERMS); but this is really only self-pollination.

The sexual process is thus of two kinds: one which is controlled by the development of two sorts of cell, one of which is capable of becoming male and the other female; the other kind is when the same cell is capable of becoming both. Whether its nature, then, the two sets of results follow upon the sexual act—(1) a zygote is formed, which is capable of developing into a new organism, from two cells, neither of which could so develop; (2) the hereditary sporophytic characters of the two parents are possessed by the organism so developed. These two results will now be considered in some detail.

(1) The Relation between the Sexual Act and Reproductive Capacity.—In the early days of the discovery of the sexual process, it was thought that the capacity for development imparted to the female cell was to be attributed to the doubling of its nuclear substance by the fusion with the male cell. Reproductive capacity does not, however, depend upon the bulk of the nuclear substance, for a spore, like an unfertilized female cell, contains but the $x$ number of chromosomes, and yet it can give rise to a new organism. Again, it has been observed (Winkler) that a non-nucleated fragment of an oosphere of Cystoseira (Fucaceae) can be "fertilized" by a spermatozoid and will then grow and divide to form a small embryo, though it necessarily contains only the $x$ number of chromosomes. From this it would appear that some stimulating influence had been exerted by the male cell, and it is probably in this direction that the desired explanation is to be sought. Some important confirmatory facts have been recorded with regard to certain animals (sea-urchins). It has been observed (Loeb) that treatment with magnesium chloride will cause the ova to grow and segment; and similar results have been obtained (Winkler) by treating the ova with a watery extract of the male cells. Hence it may be inferred that the male cell carries with it, either in its cytoplasm (kinoplasm) or in its nucleus, extractable substances, perhaps of the nature of enzymes, that stimulate the female cell to growth.

It may be mentioned that the stimulating effect of fertilization is not necessarily confined to the female cell; very frequently adjacent tissues are stimulated to growth and structural change. In a Phanerogam, for instance, the whole ovule grows and develops into the seed: the development of endosperm in the embryo-sac is initiated by another nuclear fusion, taking place between the second male nucleus and the endosperm-nucleus: the second male nucleus is thus capable of forming a fruit, which may be dry and hard or more or less succulent: the stimulating effect may extend to other parts of the flower; to the perianth, as in the mulberry; to the receptacle, as in the strawberry and the apple; or even beyond the flower to the axis of the inflorescence, as in the fig and the pine-apple. Analogous developments in other groups are the calyptra of the Bryophyta, the cystocarps of the Red Algae, the ascosporas of the Ascomycetes, the acedia of the Uredineae, &c.

(2) The Relation of the Sexual Act to Heredity.—The product of the sexual act is essentially a diploid cell, the zygote, which actually is or gives rise to a sporophyte. The sexual heredity of plants consequently presents the peculiar feature that the organism resulting from the sexual act is quite unlike its immediate parents, which are both gametophytes. But it is clear that the sporophytic characters must have persisted, though in a latent condition, through the gametophyte, to manifest themselves in the organism developed from the zygote.

The real question at issue is as to the exact means by which these characters are transmitted and combined in the sexual act. There is a considerable amount of evidence that the hereditary characters are associated with the chromosomes, and that it is rather their linear-constituent than their chromatin which is functional (Strasburger). It is thus possible that the material basis of heredity from this point of view it is probable that the last phase of the sexual act, the fusion of the chromosomes in meiosis, represents the combination of the two sets of parental characters. What exactly happens in the pseudo-chromosome stage is not known; at any rate this stage offers an opportunity for a complete redistribution of the substance of the chromosomes—in other words, of the parental pangen. It is a striking fact that, in the subsequent nuclear division, the distribution of the chromosomes derived from the male and female parents (when they can be distinguished) seems to be a matter of chance. It is not equally distributed to the two daughter-nuclei. The explanation may appear to be this, that they are not any longer male and female as they were before meiotic fusion; and that it is because they now contain both male and female nuclear substance that their equal distribution to the daughter-nuclei is unimportant.

The nature of this redistribution of the substance of the chromosomes is still under discussion. Some regard it as essentially a chemical process, resulting in the formation of new compounds: others consider it to be rather a physical process, a new material system being formed in the rearrangement of the pangen; here it must be left for the present.

The various ways in which the parental characters manifest themselves in the progeny are fully dealt with in the articles HEREDITY, HYBRIDISM, MENDELISM. It will suffice to say that the progeny, though maintaining generally the characters of the species, do not necessarily exactly resemble either of the parents, nor do they necessarily present exactly intermediate characters.
they may vary more or less from the type. It is an interesting fact, the full significance of which has not yet been worked out, that, as a rule, plants that vary profusely are those in which the characteristic 2x number of chromosomes is high (60-100).

Brief reference may be made to the cases of abnormal sexual or pseudo-sexual reproduction described above under Apogamy. Taking first the cases of true apogamy, there is clearly no need for any sexual process; for, since no meiotic division has taken place, the gametophyte is diploid; its cells, whether vegetative or reproductive, possess the capacity for both development and the transmission of the sporophytic characters. It is not remarkable that such a gametophyte should be able to give rise directly to a sporophyte; but it is remarkable, in the converse case of apophyly, that a sporophyte should give rise to a diploid gametophyte rather than to another sporophyte. In the latter case the tendency to the regular development of the alternate form appears to override the influence of the diploid nucleus.

Turning to the various forms of pseudo-apogamy, there are first those in which fusion takes place between two apparently female organs (some Uredineae; Christman), and those in which it takes place between nuclei within the same female organ (Humaria; Blackman). If these are to be regarded physiologically as sexual acts, it must be inferred that the fusing organs or nuclei have come to differ from each other to some extent; for it is unthinkable that equivalent female organs or cells should be able to fertilize, or to be fertilized by, one another. There are finally those cases in which apparently vegetative cells take part in the sexual act, as in Phragmidium (Blackman), where the female organ fuses with an adjacent vegetative cell, and in the fern-prothalloid (Farmer), where the nuclei of two vegetative cells fuse. They would seem to indicate that vegetative cells may, in certain circumstances, contain sufficient germ-plasm to act as sexual organs without being differentiated as such.

An interesting question is that of the origin of apogamy. It is no doubt the outcome of sexual degeneration; but this general statement requires some explanation. In certain cases apogamy seems to be the result of the degeneration of the male organ; as in Humaria, where there is no male organ, and in Lachnea, where the male organ is rudimentary. In others, as the Uredineae, it is apparently the female organ that has degenerated, losing its receptive part, the trichogyne; the male cells (spermatia) are developed normally, and there is no reason to believe that they might not fertilize the female organ were there the means of penetrating it. In yet other cases the degeneration occurs at a different stage in the life-history, in the development of the spores. In the apogamous ferns investigated, meiosis is suppressed and apogamy results. In the heterosporous plants which have been investigated (e.g. Marsilia, En-Alcemia) it has been observed that the microspores are so imperfectly developed as to be incapable of germinating, so that fertilization is impossible; and it is perhaps to this that the occurrence of apogamy is to be attributed. This abnormal development of the spores may be regarded as a variation; and in most cases it occurs in plants that are highly variable and often have a high zy number of chromosomes.

It will be observed that such physiological explanation as can be given of the phenomena of reproduction is based upon the results of the minute investigation of the changes in nuclear structure associated with them. The explanation is often rather suggested than proved, and some fundamental facts still remain altogether unexplained. But it may be anticipated that a much more comprehensive research which has already so successfully justified itself will not fail in the future to elucidate what still remains obscure.

BIBLIOGRAPHY.—This article should be read in connexion with the following: ALGAE, ANGIOSPERMS, BRYOPHYTA, CYTOLOGY, FUNGI, GYMNOSPERMS, HEREDITY, HYBRIDISM, MENDELISM, PLANTS, PTERIDOPHYTA.

REPRODUCTIVE SYSTEM, IN ANATOMY.—The reproductive system in some parts of its course shares structures in common with the urinary system (q.v.). In this article the following structures will be dealt with. In the male the testes, epididymis, vasa deferentia, vesiculae seminales, prostate, penis and urethra. In the female the ovaries, Fallopian tubes, uterus, vagina and vulva.

Male Reproductive Organs.

The testes or testicles are the glands in which the male reproductive cells are formed. They lie, one on each side, in the scrotum surrounded by the tunica vaginalis (see Coelom and Serous Membranes). Each is an oval gland about one and a half inches long with its long axis directed downward, backward and inward. There is a strong fibrous coat called the tunica albuginea, from which vertical and horizontal septa penetrate into the substance, thus dividing it into compartments or lobules in which the seminiferous tubes are coiled. It is estimated that the total length of these seminiferous tubes in the two glands is little short of a mile. (See fig. 1.)

At the posterior part of the testis the fibrous sheath is greatly thickened to form the mediastinum testis, and contains a plexus of tubes called the rete testis (see fig. 1), into which the seminiferous tubes open. In this way the secretion of the gland is carried to its upper and back part, whence from fifteen to twenty small tubes (vasa efferentia) pass to the epididymis. Each of these is convoluted before opening, and forms what is known as a conus vasa
culosus.

Under the microscope the seminiferous tubules are seen to consist of a basement membrane surrounding several layers of epithelial cells, some of which are constantly being transformed into spermatozoa or male sexual cells.

The epididymis (see fig. 1) is a soft body lying behind the testes; it is enlarged above to form the globus major or head, while below is a lesser swelling, the globus minor or tail. The whole epididymis is made up of a convoluted tube about 20 ft. long, from which one long diverticulum (vas aberrans) comes off. Between the globus major and the testis two small vesicles called the hydatids of Morgagni are often found.

The vas deferens is the continuation of the tube of the epididymis and starts at the globus minor; at first it is convoluted, but soon becomes straight, and runs up on the inner (mesial) side of the epididymis to the external abdominal ring in the wall. On its way up it is joined by several other structures, to form the spermatic cord; these are the artery (spermatic) and veins (pampiniformplexus) of the testis, the artery of the vas, the ilio-inguinal, genito-crural and sympathetic nerves, and the testicular lymphatics. After entering the external abdominal ring, these structures pass obliquely through the abdominal wall, lying in the inguinal canal for an inch and a half, until the internal abdominal ring is reached. Here they separate and the vas passes down the side of the pelvis and turns
inward to meet its fellow at the back of the bladder, just above the prostate. The whole length of the vas is 12 to 18 in. and it is remarkable for the great thickness of its muscular walls, which gives it the feeling of a piece of whipcord when rolled between the finger and thumb.

A little above the globus major a few scattered tubules are found in children in front of the cord; these form the rudimentary structure known as the organ of Gerhardt or paradoxydimys. As the vas deferens approaches the prostate it enlarges and becomes slightly sacculated to act as a reservoir for the secretion of the testes; this part is the ampulla (see fig. 2).

and run, side by side, through the prostate to open into the floor of the prostatic urethra.

The prostate is partly a muscular and partly a glandular structure, situated just below the bladder and traversed by the urethra; it is of a somewhat conical form with the base upward in contact with the bladder. Both vertically and transversely it measures about an inch and a quarter, while antero-posteriorly it is only about three-quarters of an inch, though its size is liable to great variation. It is enclosed in a fibrous capsule from which it is separated by the prostatic plexus of veins anteriorly. It is often described as formed of three lobes two lateral and a median or posterior, but careful sections and recent research throw doubt on the existence of the last.

Microscopically the prostate consists of masses of long, slender, slightly branching glands, embedded in unstripped muscle and fibrous tissue; these glands open by delicate ducts (about twenty in number) into the prostatic urethra, which will be described later. In the antero-posterior part of the gland are seen bundles of striped muscle fibres, which are of interest when the comparative anatomy of the gland is studied: they are better seen in young than in old prostates.

The male urethra begins at the bladder and runs through the prostate and perineum to the penis, which it traverses as far as the tip. It is divided into a prostatic, membranous and spongy part, and is altogether about 8 inches in length. The prostatic urethra runs downward through the prostate rather nearer the anterior than the posterior part. It is about an inch and a quarter long, and in the middle of the gland it bends forward forming an angle (see fig. 5); here it is from a third to half an inch wide, though at the base and apex of the prostate it is narrower. When it is slit open from in front a longitudinal ridge is seen in its posterior wall, which is called the verumontanum or crista urethrae, and on each side of this is a longitudinal depression, the prostatic sinus, into which opens the prostatic urethra open, though some of them open on to the antero-lateral surface. Near the lower part of the verumontanum is a little pouch, the urceolus masculinus, about one-eighth of an inch deep, the opening of which is guarded by a delicate membranous circular fold, the male hymen. Close to the opening of the urceolus the ejaculatory ducts, already mentioned, open into the urethra by very small apertures. The part of the urethra above the openings of these ducts really belongs to the urinary system only, though it is convenient to describe it here. After leaving

From A. F. Dixon, Cunningham's Text-book of Anatomy.

Fig. 2.—View of the Base of the Bladder, Prostate, Seminal Vesicles and Vasa Deferentia from behind.

The coccyx and the sacro-sciatic ligaments, together with the muscles attached to them, have been removed. The levatores ani have been separated along the median raphe, and drawn outwards. A considerable portion of the rectum and the upper part of the right seminal vesicle have been taken away.

The vesiculae seminales are sac-like diverticula, one on each side, from the lower part of the ampullae of the vasa deferentia. They are about 2 in. long and run outward behind the bladder and parallel to the upper margin of the prostate for some little distance, but usually turn upward near their blind extremity. When carefully dissected and unravelled each is found to consist of a thick tube, about 5 in. long, which is sharply bent upon itself two or three times, and also has several short, sac-like pouches or diverticula. The vesiculae seminales are muscular sacs with a mucous lining which is thrown into a series of delicate net-like folds. The convolutions are held together by the pelvic cellular tissue, and by involuntary muscle continuous with that of the bladder. It is probable that these vesicles are not reservoirs, as was at one time thought, but form a rather distinct secretion which mixes with that of the testes.

Where the vesiculae join the ampullae of the vasa deferentia the ejaculatory ducts are formed; these are narrow and thin-walled,
the prostate the urethra runs more forward for about three-quarters of an inch, lying between the two layers of the triangular ligament, both of which it pierces. This is known as the membranous urethra, and is very narrow, being gripped by the compressor urethrae muscle.

The spongy urethra is that part which is enclosed in the penis after piercing the anterior layer of the triangular ligament. At first it lies in the substance of the bulb and, later, of the corpus spongiosum, while finally it passes through the glans. In the greater part of its course it is a transverse slit, but in traversing the glans it enlarges considerably to form the fossa navicularis, and here, in transverse section, it looks like an inverted T (Δ), then an inverted Y (Λ), and finally at its opening known as the corona glandis. The skin of the penis forms a fold which covers the glans and is known as the prepuce or foreskin; when this is drawn back a median fold, the frenulum praeputii, is seen running just below the meatus. After forming the prepuce the skin is reflected over the glans and here looks like mucous membrane. The structure of the corpora cavernosa consists of a strong fibrous coat, the tunica albuginea, from the deep surface of which numerous fibrous trabeculae penetrate the interior and divide it into a number of spaces which are lined with endothelium and communicate with the velas. Between the two corpora cavernosa the sheath is not complete and, having a comb-like appearance, is known as the septum pectinatum. The structure of the corpus spongiosum and glans resembles that of the corpora cavernosa, but the trabeculae are finer and the network closer.

The ovary is an organ which in shape and size somewhat resembles a large almond, though its appearance varies considerably in different individuals, and at different times of life. It lies in the side wall of the pelvis with its long axis nearly vertical and having its blunt end (tubal pole) upward. Its more pointed lower end is attached to the uterus by the ligament of the ovary, while its anterior border has a short reflection of peritoneum, known as the mesovarium, running forward to the broad ligament of the uterus. It is through this anterior border that the vessels and nerves enter and leave the gland.

Under the microscope the ovary is seen to be covered by a
layer of cubical cells, which are continuous near the anterior border with the cells of the peritoneum. Deep to these is the ovarian stroma, composed of fibrous tissue, and embedded in it are numerous nests of epithelial cells, the Graafian follicles, in various stages of development. During the childbearing period of life some of these will be nearing the ripe condition, and if one such be looked at it will be seen to contain one large cell, the ovum, surrounded by a mass of small cells forming the discus proligerus. At one point this is continuous with a layer of cells called the stratum granulosum which lines the outer wall of the follicle, but elsewhere the two layers are separated by fluid, the liquor folliculi. When the follicle bursts, as it does in time, the ovum escapes on to the surface of the ovary.

The Fallopian tubes receive the ovum and carry them to the uterus. That end of each which lies in front of the ovary is called the fimbriated extremity, and has a number of fringes (fimbriae) hanging from it; one of the largest of these is the ovarian fimbria and is attached to the upper or tubal pole of the ovary. The small opening among the fimbriae by which the tube communicates with the peritoneal cavity is known as the ostium abdominale, and from this the lumen of the tube runs from four to four and a half inches, until it opens into the cavity of the uterus by an extremely small opening. In the accompanying figure (fig. 6) the Fallopian tube and ovary are pulled out from the uterus; this, as has been explained, is not the position of the ovary in the living body, nor is it of the tube, the outer half of which lies folded on the front and inner surface of the ovary. The Fallopian tubes, like many other tubes in the body, are made chiefly of unstriped muscle, the outer layer of which is longitudinal and the inner circular; deep to this are the submucous and mucous coats, the latter being lined with ciliated epithelium (see Peritoneal Tissues), and thrown into longitudinal pleats. Superficially the tube is covered by a serous coat of peritoneum. The calibre gradually contracts from the peritoneal to the uterine opening.

The uterus or womb is a pear-shaped, very thick-walled, muscular bag, lying in the pelvis between the bladder and rectum. In the non-pregnant condition it is about three inches long and two in its broadest part, which is above. The upper half or body of the uterus is somewhat triangular with its base upward, and has an anterior surface which is moderately flat, and a posterior convex. The lower half is the neck or cervix and is cylindrical; it projects into the anterior wall of the vagina, into the cavity of which it opens by the os uteri externum. This opening in a uterus which has never been pregnant is a narrow transverse slit, rarely a circular aperture, but in those uteri in which pregnancy has occurred the slit is much wider and its lips are thickened and gaping and often scarred. The interior of the body of the uterus shows a comparatively small triangular cavity (see fig. 6, B), the anterior and posterior walls of which are in contact. The base of the triangle is upward, and at each lateral angle one of the Fallopian tubes opens. The apex leads into the canal of the cervix, but between the two there is a slight constriction known as the os uteri internum. The canal of the cervix is about an inch long, and is spindle-shaped when looked at from in front; its anterior and posterior walls are in contact, and its lining mucous membrane is raised into a pattern which, from its likeness to a cypress twig, is called the arbor vitae. This arrangement is obliterated after the first pregnancy. On making a mesial vertical section of the uterus the cavity is seen as a mere slit which is bent about its middle to form an angle the opening of which is forward. A normal uterus is therefore bent forward on itself, or anteflexed. In addition to this, its long axis forms a marked angle with that of the vagina, so that the whole uterus is bent forward or anteflected. As a rule, in adults the uterus is more or less on one side of the mesial plane of the body. From each side of the uterus the peritoneum is reflected outward, as a two-layered sheet, to the side wall of the pelvis; this is the broad ligament, and between its layers lie several structures of importance. Above, there is the Fallopian tube, already described; below and in front is the round ligament; behind, the ovary projects backward, and just above this, when the broad ligament is stretched out as in fig. 6, are the epoophoron and paroophoron with the duct of Gartner.

The round ligament is a cord of unstriped muscle which runs from the lateral angle of its own side of the uterus forward to the internal abdominal ring, and so through the inguinal canal to the upper part of the labium majus. The epoophoron or paroovarium is a collection of short tubes which radiate from the upper border of the ovary when the broad ligament is pulled out as in fig. 6. It is best seen in very young children and represents the vasa efferentia in the male. Near the ovary the tubes are closed, but of the Fallopian tube they open into another tube which is nearly at right angles to them, and which runs toward the uterus, though in the human subject it is generally lost before reaching that organ. It is known as the duct of Gartner, and is the homologue of the male epididymis and vas deferens. Some of the outermost tubules of the epoophoron are sometimes destined to form hydatids. Nearer the uterus than the epoophoron a few scattered tubules are occasionally found which are looked upon as the homologue of the organ of Giralda in the male, and are known as the paroophoron.

The vagina is a dilatatable muscular passage, lined with mucous membrane, which leads from the uterus to the external generative organs; its direction is, from the uterus, downward and forward, and its anterior and posterior walls are in contact, so that in a horizontal section it appears as a transverse slit. As the orifice is near the slit becomes H-shaped. Owing to the fact that the neck of the uterus enters the vagina from in front, the anterior wall of that tube is only about 2½ in., while the posterior is 3½. The mucous membrane is raised into a series of transverse folds or rugae, and between it and the muscular wall are plexuses of veins forming erectile tissue. The relation of the vagina to the peritoneum is noticed under Coelum and Serosa Membranes.

The vulva or pudendum comprises all the female external generative organs, and consists of the mons Venerei, labia majora and minora, clitoris, urethral orifice, hymen, bulbs of the vestibule, and glands of Bartholin. The mons Venerei is the
In the female the same growth of epithelial cords into the mesenchyme of the genital ridge takes place, but each one is distinguished by a bulging toward its middle, in which alone the large germ cells are found. Eventually this bulging part is broken up into a series of small portions, each of which contains one germ cell or ovum, and gives rise to a Graafian follicle. Mesonephric cords appear as in the male; they do not enter the ovary, however, but form a transitory network (rete ovarii) in the mesovarium. As each genital gland enlarges it remains attached to the rest of the intermediate cell mass by a constricted fold of the coelomic membrane, known as the mesorchium in the male, and the mesovarium in the female. Lying dorsal to the genital ridge in the intermediate cell mass is the mesonephros, consisting of numerous tubules which open into the Wolffian duct. This at first is an important excretory organ, but during development becomes used for other purposes. In the male, as has been shown, it may form the rete testis, and certainly forms the vasa efferentia and globus major of the epididymis: in addition to these, some of its separate tubes probably account for the vas aberrans and the organ of Giraldis (see fig. 8, E and O.G.). In the female the tubules of the epoophoron represent the main part,
The Wolffian duct, which, in the early embryo, carries the excretion of the mesonephros to the cloaca, forms eventually the body and tail of the epididymis, the vas deferens, and ejaculatory duct in the male, the vesicula seminalis being developed as a pouch in its course. In the female this duct is largely done away with, but remains as the collecting tube of the epoophoron, and in some mammals as the duct of Gärtntr, which runs down the side of the vagina to open into the vestibule.

The Müllerian duct, as it approaches the cloaca, joins its fellow of the opposite side, so that there is only one opening into the ventral cloacal wall. In the male the lower part only of it remains as the uterus masculinus (fig. 8, U.M.), but in the female the Fallopian tubes, uterus, and probably the vagina, are all formed from it (fig. 8, F.T. and U.). In both sexes a small hydatid or vesicle is liable to be formed at the beginning of both the Wolffian and Müllerian duct (fig. 8, P.H. and S.H.); in the male these are close together in front of the globus major of the epididymis, and are known as the sésile and pedunculated hydatids of Morgagni. In the female there is a hydatid among the fimbriae of the Fallopian tube which of course is Müllerian and corresponds to the sésile hydatid in the male, while another is often found at the beginning of the collecting tube of the epoophoron and is probably formed by a blocked mesonephric tubule. This is the pedunculated hydatid of the male. The development of the vagina, as Berry Hart (Journ. Anat. and Phys. xxxv. 330) has pointed out, is peculiar. Instead of the two Müllerian ducts joining to form the lumen of its lower third, as they do in the case of the uterus and its upper two-thirds, they become obliterated, and their place is taken by two solid cords of cells, which Hart thinks are derived from the Wolffian ducts and are therefore probably of ectodermal origin, though this is open to doubt. These cords later become canalized and the septum between them is obliterated.

The common chamber, or cloaca, into which the alimentary, urinary and reproductive tubes open in the foetus, has the urinary bladder (the remains of the allantois) opening from its ventral wall (see PLACENTA AND URINARY SYSTEM).

During development the alimentary or anal part of the cloaca is separated from the urogenital, and in the article ALIMENTARY SYSTEM the hitherto accepted method of this separation is described. The question has, however, lately been re-investigated by F. Wood Jones, who says that the anal part is completely shut off from the urogenital and ends in a blind pouch which grows toward the surface and meets a new ectodermal depression, the main point being that the permanent anus is not, according to him, any part of the original cloacal aperture, but a new perforation. This description is certainly more in harmony with the malformations occurring in this region than the old one, and only awaits confirmatory evidence to be generally accepted.

The external generative organs have at first the same appearance in the two sexes, and consist of a swelling, the genital eminence, in the ventral wall of the cloaca. This in the male begins as tubules and in the female the clitoris. Throughout the generative system the male organs depart most from the undifferentiated type, and in the case of the genital eminence two folds grow together and enclose the urogenital passage, thus making the urethra perforate the penis, while in the female these two folds remain separate as the labia minora or nymphae. Sometimes in the male the folds fail to unite completely, and then there is an opening into the urethra on the under surface of the penis—a condition known as hypospadias.

In the undifferentiated condition the integument surrounding the genital opening is raised into a horsehoe-like swelling with its convexity over the pubic symphysis and its concavity toward the anus, but the lateral parts of this remain separate in the female and form the labia majora, but in the male they unite to form the scrotum. The median part forms the mons Veneris or mons Jovis.

### The Descent of the Testis

It has been shown that the testis is formed in the loin region of the embryo close to the kidney, and it is only in the later months of foetal life that it changes this position for that of the scrotum. In the lower part of the genital ridge a fibro-muscular cord is formed which stretches from the lower part of the testis to the bottom of the scrotum; it is known as the gubernaculum testis, and by its means the testis is directed into the scrotum. Before the testis descends, a pouch of peritoneum called the processus vaginalis passes down in front of the gubernaculum through the opening in the abdominal wall, which afterwards becomes the inguinal canal, into the scrotum, and behind this the testis descends, carrying with it the mesonephric duct. These, as has already been pointed out, form the epididymis and vas deferens. At the sixth month the testis lies opposite the abdominal ring, and at the eighth reaches the bottom of the scrotum and invaginates the processus vaginalis from behind. Soon after birth the communication between that part of the processus vaginalis which now surrounds the testis and the general cavity of the peritoneum disappears, and the part which remains forms the tunica vaginalis. Sometimes the testis fails to pass beyond the inguinal canal, and the term "cryptorchism" is used for such cases.

In the female the ovary undergoes a descent like that of the testis, but it is less marked owing to the fact that the gubernaculum becomes attached to the Müllerian duct where that duct joins its fellow to form the uterus; hence the ovary does not descend lower than the level of the top of the uterus, and the part of the gubernaculum running between it and the uterus remains as the ligament of the ovary, while the part running from the uterus to the labium is the round ligament. In rare cases the ovary may be drawn into the labium just as the testis is drawn into the scrotum.

### Comparative Anatomy

In the Urochorda, the class to which Salpa, Pyrosoma and the sea squirts (Ascidians) belong, male and female generative glands (gonads) are present in the same individual; they are therefore hermaphroditic.

In the Acrania (Amphioxus) there are some twenty-six pairs of gonads arranged segmentally along the side of the pharynx and intestine and bulging into the atrium. Between them and the atrial wall, however, is a rudimentary remnant of the coelom, through which the spermatooza or ova (for the sexes are distinct) burst into the atrial cavity. There are no genital ducts.

In the Cyclostomata (lampreys and hags) only one median gonad is found, and its contents (spermatooza or ova) burst into the coelom and then pass through the genital pores into the urogenital sinus and so to the exterior. It is probable that the single gonad is accounted for by the fact that its fellow has been suppressed.

In the Elasmobranchs or cartilaginous fishes there are usually two testes or two ovaries, though in the dogfish one of the latter is suppressed. From each testis, which in fish is popularly known as the soft roe, vasa efferentia lead into the mesonephros, and the semen is conducted down the vas deferens or mesonephric duct into the urogenital sinus, into which also the ureters open. Sometimes one or more thin-walled diverticula—the sperm sacs—open close to the aperture of the vas deferens. In the female the ova are large, on account of the quantity of yolk, and they burst into the coelom, from which they pass into the large Müllerian ducts or oviducts. In the oviparous forms, such as the common dogfish (Scyllium), there is an ovicoidal gland which secretes a horny case for the egg after it is fertilized, and these cases have various shapes in different species. Some of the Elasmobranchs, e.g., the spiny dogfish (Acanthias), are viviparous, and in these the lower part of the oviduct is enlarged and acts as a uterus. In male elasmobranchs the anterior part of the Müllerian duct persists. Paired intromittent organs (claspers) are developed on the pelvic fins of the males; these conduct the semen into the cloaca of the female.

In the teleostean and ganoid fishes (Teleostomi) the nephridial...
ducts are not always used as genital ducts, but special coelomic ducts are formed (see Coelom and Serous Membranes). In the Dipnoi or mudfish long coiled Müllerian ducts are present, but the testes either pour their secretion directly into the coelom or, as in Protopterus, have ducts which are probably coelomic in origin.

In both the Teleostomi and Dipnoi the testes and ovaries are paired.

True hermaphroditism is known among fishes, the hag (Myxine) and the sea perch (Serranus) being examples. In many others it occurs as an abnormality.

In the Amphibia both ovaries and testes are symmetrical. In the snake-like forms which are found in the order Gymnophiona the testes are a series of separate lobules extending for a long distance, one behind the other, and joined by a connecting duct from which vasa efferentia pass into the Malpighian capsules of the kidneys, and so the sperm is conducted to the mesonephric duct, which acts both as vas deferens and ureter. The Müllerian ducts or oviducts are long and often coiled in Amphibia, and usually open separately into the cloaca. There is no penis, but in certain forms, especially the Gymnophiona, the cloaca is protrusible in the male and acts as an intromittent organ. Corpora adiposa or fat bodies are present in all Amphibians, and probably nourish the sexual cells during the hibernating period.

In Reptilia two testes and ovaries are developed, though they are often asymmetrical in position. In Lizards the vas deferens and ureter open into the cloaca by a common orifice; as they do in the human embryo. In these animals there are two penes, which can be protruded and retracted through the vent; but in the higher reptiles (Chelonia and Crocodilia) there is a single median penis rising from the ventral wall of the cloaca, composed of erectile tissue and deeply grooved on its dorsal surface for the passage of the sperm.

In birds the right ovary and oviduct degenerate, and the left (bifurcates) in the male. In the male the ureter and vas deferens open separately into the cloaca, and in the Ratitae (ostriches) and Anseres (ducks and geese) a well-developed penis is present. In the male there is this fibrous, and bifurcated at its base, suggesting the crura penis of higher forms.

Among the Mammalia the Monotremata (Ornithorhynchus and Echidna) have bird-like affinities. The left ovary is larger than the right, and the oviducts open separately into the cloaca and do not fuse to form a uterus. The testes retain their abdominal position; and the vasa deferentia open into the base of the penis, which lies in a separate sheath in the ventral wall of the cloaca, and shows an advance on that of the reptiles and birds in that the groove is now converted into a complete tunnel. In the female there is a well-developed clitoris, having the same relations as the penis.

In the marsupials the cloaca is very short, and the vagina and rectum open separately into it. The two uteri open separately and three vaginae are formed, two lateral and one median. The two lateral join together below to form a single median lower vagina, and it is by means of these that the spermatozoa pass up into the oviducts. The upper median vagina at first does not open into the lower one, but during parturition a communication is established which in some animals remains permanent (see J. P. Hill, Proc. Linnean Soc. N.S. Wales, 1899 and 1900). This tripartite arrangement of the upper part of the marsupial vagina is of especial interest in connexion with the views of the embryology of the canal detailed by Berry Hart and already referred to.

When, as in marsupials, the two uteri open separately into the vagina by two oras, the arrangement is spoken of as uterus duplex. When the two uteri join below and open by one os externum, it is known as uterus bipartitus. When the uterus bifurcates above and has two horns for the reception of the Fallopian tubes (oviducts), but is otherwise single, the term uterus unicorns is given to it, while the single uterus of man and other Primates is called uterus simplex. From the marsupials upward the ovarian end of the Fallopian tube has the characteristic fimbriated appearance noticed in human anatomy.

In some mammals, such as the sow and the cow, the Wolffian duct is persistent in the female and runs along the side of the vagina as the duct of Gartner. It is possible that the lateral vaginae of the marsupials are of Wolffian origin.

In marsupials the testes descend into the scrotum, which lies in these animals in front of instead of behind the penis. In some mammals, such as the elephant, they never reach the scrotum at all; while in others, e.g. many rodents, they can be drawn up into the abdomen or lowered into the scrotum. The subject of the descent of the testicles has been very fully treated by H. Klaatsche, "Ueber den Descensus testiculorum," Morph. Jahrb., Bd. xvii.

The prostate is met with in its most simple forms in marsupials, in which it is a mere thickening of the mucous membrane of the urethra; in the sheep it forms a bilateral elongated mass of gland tissue lying behind the urethra and surrounded by a well-developed layer of striped muscle. In the sloth it is said to be altogether absent, while in many of the insectivores and rodents it consists of many lobes which usually show a bilateral arrangement. The vesiculae seminales are, usually present in the Eutheria or higher mammals, and sometimes, as in the hedgehog, are very large, though they are absent in the Carnivora. Cowper's glands are usually present and functional throughout life. The uterus masculinus is also usually present, but there is grave doubt whether the large organ called by this name in the rabbit should not rather be regarded as homologous with part of the vesiculae seminales. The penis shows many diversities of arrangement; above the marsupials its two crura obtain an attachment to the ischium. In many mammals it is quite hidden by the skin in the flaccid condition, and its external orifice may range from the perineum in the marsupials to the middle of the ventral wall of the abdomen in the ruminants. In the Marsupialia, Rodentia, Chiroptera, Carnivora and some Primates an os penis is developed in connexion with the corpora cavernosa.

The clitoris is present in all mammals; sometimes, as in the female hyena, it is very large, and at others, as in the lemur, it is perforated by the urethra.

For further details and literature, see Oppel's Lehrbuch der vergleich. mikroskop. Anatomie der Wirbeltiere, Bd. iv. (Jena, 1904); also Gegenbaur's Vergleich. Anat. der Wirbeltiere, and Wiedersheim's Comparative Anatomy of Vertebrates, translated by W. N. Parker (London, 1907).

REPSOLD, JOHANN GEORG (1771–1830), German instrument maker, was born at Wremen in Hanover on the 23rd of September 1771, and became an engineer and afterwards chief of the fire brigade in Hamburg, where he started business as an instrument maker early in the 19th century. He was killed by the fall of a wall during a fire at Hamburg on the 14th of January 1830. The business was continued by his sons Georg (1804–1884)
REPTILES

I. History of Herpetology

Certain kinds of reptiles are mentioned in the earliest written records or have found a place among the fragments of the oldest relics of human art. Such evidences, however, form no part of a succinct review of the literature of the subject such as is proposed to give here. We distinguish in it six periods: (1) the Aristotelian; (2) the Linnean (formation of a class Amphibia, in which reptiles and Batracians are mixed); (3) the period of the elimination of Batracians as one of the reptilian orders (Brongniart); (4) that of the separation of reptiles and Batracians as distinct subclasses; (5) that of the recognition of a class Reptilia as part of the Sauropsida (Huxley); (6) that of the discovery of fossil skeletons sufficiently well preserved to reveal, in genera so frequently in every scientific treatise on this subject. At first it comprised living crocodiles and lizards only, with which a number of fossil forms were gradually associated. As the characters and affinities of the latter became better known, some of them were withdrawn from the Saurians, and at present it is best to abandon the term altogether.

II. Aristotle. — Aristotle was the first to deal with the reptiles known to him as members of a distinct portion of the animal kingdom, and to point out the characteristics by which they resemble one another and differ from other vertebrate and invertebrate animals. The plan of his work, however, was rather that of a comparative treatise of the anatomical and physiological characters of animals than their systematic arrangement and definition, and his ideas about the various groups of reptiles are not distinctly expressed, but must be gleaned from the terms which he employs. Moreover, he paid less attention to the study of reptiles than to that of other classes. This is probably due to the fact that he was acquainted with, to which only very few extra-European forms, like the crocodile, were added from other sources. But while we find in some respects a most remarkable accuracy of knowledge, there is sufficient evidence that he neglected everyday opportunities of information. Thus he has not a single word about the metamorphoses of Batracians, which he treats of in connexion with reptiles.

Aristotle makes a clear distinction between the scute or scale of a reptile, which he describes as φόλα, and that of a fish, which he designates as λέσις. He mentions reptiles (1) as oviparous quadrupeds with scutes, viz. Saurians and Chelonians; (2) as oviparous apodals, viz. Snakes; (3) as oviparous quadrupeds without scutes, viz. Batracians. He considered the first and second of these three groups as much more nearly related to each other than to the third. Accurate statements and descriptions are sadly mixed with errors and stories of, to our eyes, the most absurd and fabulous kind. The most complete accounts are those of the crocodile (chiefly borrowed from Herodotus) and of the chameleon, which Aristotle evidently knew from personal observation, and had dissected himself. The other lizards mentioned by him are the common lizards (σαλίς), the common seps (χελώνας οξίγερος) and the gekko (κοσαλέιδας or κόσαλος). Of snakes (of which he generally speaks as δόμα) he knew the vipers (ἐριθος or ἐριθών), the common snake (θέρος), and the blindworm (ὑγρίδας ὁδόμη), which he regards as a snake; he further mentions the Egyptian cobra and dragons (δράκων) —North-African serpents of fabulous size. Of Chelons he describes in a perfectly recognizable manner land tortoises (χελώνας), freshwater turtles (ἐμίς) and marine turtles (χελώνας θαλασσι). 

Passing over eighteen centuries, we find the knowledge of reptiles to have remained as stationary as other branches of natural history, perhaps even more so. The reptile fauna of Europe was not extensive enough to attract the energy of a Belou or Rondellet; popular prejudice and the difficulty of preserving these animals deterred from their study; nor was man sufficiently educated not to give implicit credence to the fabulous tales of reptiles in the 15th and 16th centuries. The art of healing, however, was developing into a science based upon rational principles, and consequently not only those reptiles which formed part of the materia medica but also the venomous snakes became objects of study to the physician, though the majority of the writers were ignorant of the structure of the venom-apparatus, and of the distinction between non-venomous and venomous snakes.

Nothing can show more clearly the small advance made by herpetology in this long post-Aristotelian period than a glance at the celebrated work, De Differentiis Animalium Libri decem (Paris, 1552), by Edward Wotton (1492—1555). Wotton treats of the reptiles which he designates as Quadrupedes oviparae et Serpentes in the sixth book of his work. They form the second division of the Quadrupedes quae sanguinem habent, and are subdivided in the following genera:—

Crocodilus et scincus (cap. cv.); Testudinum generer (cvi); Ranarum generer (cvii); Lacertide et seps quadrupedes (cviii); Serpentium (cx.); a general account, the following being different kinds of serpents: Hydras et alii quaedam serpentes aquatilia (cxii); Serpentes terrae et primum residua generer (cxxxvii); Viper (cxxxviii), et ranaroides (cxxxix); Hebræorum, semps, conchis et cenchritibus (cxliv); Basilioc et alii quaedam serpentes quorum venenum remediocaret (cxviii); Draco, amphíbaena, et alii quaedam serpentes quorum morbos minus affrunt periculis (cxix).

Wotton's work might with propriety be termed "Aristoteles revivus." The plan is the same, and the observations of the Greek naturalist are faithfully, sometimes literally, reproduced.
It is surprising that even the reptiles of his native country were most imperfectly known to the author. With the enlargement of geographical knowledge that of reptiles was also advanced, as is sufficiently apparent from the large encyclopaedic works of Gesner, Aldrovandii and Linnæus. The last-named author especially, who published the various portions of his Natural History in the middle of the 17th century, was able to embody in his compilations notices of numerous reptiles observed by Francisco Hernandez in Mexico and by Marcgrave and Piso in Brazil. As the author had no definite idea of the Ray-Linnaean term "species," it is not possible to give the exact number of reptiles mentioned in his work. But it may be estimated at about fifty, not including some marine fishes and fabulous creatures. He figures (or rather reproduces the figures of) about forty—some species being represented by several figures.

2. Linnæan Period: Formation of a Class Amphibia.—Within the century which succeeded these compilatory works of Linnæus (1650-1750) all the labours which prepared the way for and exerted the greatest influence on Ray and Linnæus fell. Although original researches in the field of herpetology were limited in extent and in number, the authors had freed themselves from the purely literary or scholastic tendency. Men were no longer satisfied with reproducing and commenting on the writings of their predecessors; the pen was superseded by the eye, the microscope and the knife, and statements were tested by experiment. This spirit of the age manifested itself, so far as the reptiles are concerned, in Chara's and Redi's admirable observations on the viper, in Major's and Vassiliev's detailed accounts of the anatomy of the chameleon, in the researches of Jacobaeus into the metamorphoses of the Batrachians and the structure of lizards, in Dufay's history of the development of the salamander (for Batrachians are invariably associated with reptiles proper); in Tyson's description of the anatomy of the rattle-snake, &c.

The natural history collections formed by institutions and wealthy individuals now contained not merely skins of crocodiles or serpents stuffed and transformed into a shape to correspond with the fabulous descriptions of the ancient dragonists, but, with the discovery of alcohol as a means of preserving animals, reptiles entire or dissected were exhibited for study; and no opportunity was lost of obtaining them from travellers or residents in foreign countries. P fossils were now acknowledged to be remains of animals which had lived before the Flood, and some of them were recognized as those of reptiles.

The contributions to a positive knowledge of the animal kingdom became so numerous as to render the need of a methodical arrangement of the abundance of new facts more and more pressing. Of the two principal systematic attempts made in this period the first ranks as one of the most remarkable steps of the progress of natural history, whilst the second can only be designated as a signal failure, which ought to have been a warning to all those who in after years classified animals in what is called an artificial system. As the latter attempt's originator with Klein (1685-1759), did not exercise any further influence on herpetology, it will be sufficient to have merely mentioned it. John Ray (1628-1705) had recognized the necessity of introducing exact definitions for the several categories into which the animals had to be divided, and he maintained that these categories ought to be characterized by the structure of animals, and that all zoological knowledge had to start from the "species" as its basis. His definition of reptiles as "animalia sanguinea pulmone respirantia cor unico tandem ventriculo instructum habentia ovipara" fixed the class in a manner which was adopted by the naturalists of the succeeding hundred and fifty years. Nevertheless, Ray was not a herpetologist; his knowledge of reptiles is chiefly derived from the researches of others, from whose accounts, however, everything not based upon reliable demonstration is critically excluded. He begins with a chapter treating of toads (Bufo, with one species) and tortoises1 (Testudo, with fourteen species). The second group comprises the Lacertae, twenty-five in number, and includes the salamander and newts; and the third the Serpentes, nine species, among which the limbless lizards are enumerated.

Except in so far as he made known and briefly characterized a number of reptiles, our knowledge of this class was not advanced by Linnæus. That he associated in the 12th edition cartilaginous and other fishes with the reptiles under the name of Amphibia Natives was the result of some misunderstanding of an observation by Garden, in which the word was taken as a premonitory token of the recent discoveries of the relation between Bures and other fishes. Linnæus places reptiles, which he calls Amphibia, as the third class of the animal kingdom; he divides the genera thus:

**Order 1. Reptiles.—Testudo (15 species); Rana (17 sp.); Draco (2 sp.); Lacerta (48 sp., including 6 Batrachians).**

**Order 2. Serpentes.—Crotalus (5 species); Boa (10 sp.); Coluber (96 sp.); Anguis (15 sp.); Amphibia (2 sp.); Caecilia (9 sp.).**

None of the naturalists who under the direction or influence of Linnæus visited foreign countries possessed any special knowledge of or predilection for the study of reptiles; all, however, contributed to our acquaintance with tropical forms, or transmitted well-preserved specimens to the collections at home, so that C富民, in the 13th edition of the Systema Naturæ, was able to enumerate three hundred and seventy-one species.

The man who, with the advantage of the Linnaean method, first treated of reptiles monographically, was Laurenti. In a small work2 he proposed a new division of these animals, of which some ideas and terms have survived into our times, characterizing the orders, genera and species in a much more precise manner than Linnæus, giving, for his time, excellent descriptions and figures of the species of his native country. Laurenti might have become for herpetology what Artedi was for ichthyology, but his resources were extremely limited.

The circumstance that Cheilonias are entirely omitted from his Synopsis seems due rather to the main object with which he engaged in the study of herpetology, viz. that of examining and distinguishing reptiles reputed to be poisonous, and to want of material, than to his conviction that tortoises should be relegated to another class. He divides the class into three orders:—

1. SALIENTIA, with the genera Pipa, Bufo, Rana, Scaphy, and one species of "Proteus," viz. the larva of *Pseudechis paradocu*.

2. GRADIENTIA, the three first genera of which are Tailed Batrachians, viz. two species of *Proteus* (one being the *P. anguinus*), *Trion* and *Salamandra*; followed by true Sauurians: *Laudertherios, Chelidnae, Iguana, Basiliscus, Draco, Cordylus, Crocoileus, Scincus, Stellio, Seps.*

3. SERPENTIA, among which he continues to keep *Amphibia*, *Caecilia* and *Anguis*, but the large Linnaean genus *Coluber* is divided into twelve, chiefly from the scutellation of the head and form of the body.

The work concludes with an account of the experiments made by Laurenti to prove the poisonous or innocuous nature of those reptiles of which he could obtain living specimens.

The next general work on reptiles is by Lacèpède. It appeared in the years 1788 and 1790 under the title *Histoire naturelle des quadrupèdes ovipares et des serpens* (Paris, 2 vols. 4to). Although as regards treatment of details and amount of information this work far surpasses the modest attempt of Laurenti, it shows no advance towards a more natural division and arrangement of the genera. The author depends entirely on conspicuous external characters, and classifies the reptiles into (1) oviparous quadrupeds with a tail, (2) oviparous quadrupeds without a tail, (3) oviparous

1 In associating tortoises with toads, Ray could not disagree himself from the general popular view as to the nature of these animals, which found expression in the German Schillkrebs ("Shield-toad").

2 Specimen medusch Exhibens Synopsis Repullium emendatam cum experimentis circa venena at antidota Repullium Austriacorum (Vienna, 1768s, 8vo, pp. 214, with 5 plates).

not recognized. Indeed, his division by Aristotle retained was, by the author states that he has examined more than ten hundred specimens, belonging to five hundred and seventeen species, all of which he has described from nature. The system adopted is that of Bronnii, the genera are well defined, but ill arranged; it is, however, noteworthy that Caecilia takes now its place at the end of the Ophidians, and nearest to the succeeding order of Batrachians.

The next step in the development of the herpetological system was the natural arrangement of the genera. This involved a stupendous amount of labour. Although many isolated contributions were made by various workers, this task could be successfully undertaken by completing in the Paris Museum only, in which, besides Seba's and Lacépéde's collections, many other herpetological treasures from other museums had been deposited by the victorious generals of the empire, and to which, through Cuvier's reputation, objects from every part of the world were attracted in a voluntary manner. The men who devoted themselves to this task were A. M. C. Duméril, Oppel and Cuvier himself. Oppel was a German who, during his visit to Paris (1807-1808), attended the lectures of Duméril and Cuvier, and at the same time studied the materials to which access was given to him by the latter in the most liberal manner. Duméril maintains that Oppel's ideas and information were entirely derived from his lectures, and that Oppel himself avows this to be the case. The passage, however, to which he refers is somewhat ambiguous, and it is certain that there is the greatest possible difference between the arrangement published by Duméril in 1806 (Zoologie Analytique, Paris, 8vo) and that proposed by Oppel in his Ordonnages, Familles, et Gattungen der Reptilien (Munich, 1811, 4to). There is no doubt that Oppel profited largely by the teaching of Duméril; but, on the other hand, there is sufficient internal evidence in the works of both authors, not only that Oppel worked independently, but also that Duméril and Cuvier owed much to their younger fellow-labourer, as Cuvier himself indeed acknowledges more than once.

Oppel's classification may be shortly indicated thus:

ORDER 1. TESTUDINATA OR CHÉLONIENS.

Fam. 1. CHELONI (gen. Mydas, Coriacea).

Fam. 2. AMADAS (gen. Chelys, Testudo, Emys).

ORDER 2. SQUAMATA.

Fam. 1. Sauri.

Fam. 2. Crocodilini (gen. Crocodilus, Gavialis, Alligator).

Fam. 3. Iguanoides (gen. Camaeleo, Draco, Iguana, Basiliscus, Lophurus, Anolis).

Fam. 4. Lacertini (gen. Tephrosaurus, Dacarena, Lacerta, Tachydromus).

Fam. 5. Scincoides (gen. Scincus, Seph, Selapheus, Anguis).

ORDER 3. NUDA OR BATRACII.

In this classification we notice three points, which indicate a decided progress towards a natural system. (1) The four orders proposed by Bronnigart are no more considered co- subordinate in the class, but the Saurians and Ophidians are arranged as sections of the same order, a view held by Aristotle but abandoned by all following naturalists. The distinction between lizards and snakes is carried out in so precise a manner that one genus only, Amphibona, is wrongly placed. (2) The true reptiles have now been entirely divested of all heterogenous elements by relegating positively Caecilia to the Batrachians, a view for which Oppel had been fully prepared by Duméril, who pointed out in 1807 that "les céciles se rapprochent considérablement des batraciens auxquels elles semblent lier l'ordre entier des serpents." (3) An attempt is made at arranging the genera into families, some of which are still retained at the present day.

In this giving a greater retired prominence to Oppel's labours we are far from wishing to detract from the influence exercised by the master spirit of this period, Cuvier. Without his guidance Oppel probably never would have found a place among the promoters of herpetological science. But Cuvier's principal researches on reptiles were incidental or formed part of some more general plan; Oppel concentrated his on this class only. Cuvier adopts the four orders of reptiles proposed by Bronnigart as equivalent elements of the class, and restores the blind-worms and allied lizards and, what is worse, also the Caecilius, to the Ophidians. The chameleons and geckos are placed in separate groups, and the mode of dividing the latter has been retained to the present day. Also a natural division of the snakes, although the foreign elements mentioned are admitted into the order, is sufficiently indicated by his arrangement of the " vrais serpents proprement dits " as (1) non-venomous snakes, (2) venomous snakes with several maxillary teeth, and (3) venomous snakes with isolated poison-fangs. He distinguishes the species of reptiles with a precision not attained in any previous work.

Cuvier's researches into the osteology of reptiles had also the object of discovering the means of understanding the fossil remains of the various classes of the Vertebrata, which distinguished his researches in comparison with those of his English and German naturalists. Extinct Chelonian and Crocodilian

3 "Wäre es nicht die Ermunterung ... dieser Freunde gewesen, so würde ich überzeugt von den Mängeln, denen eine solche Arbeit bei aller möglichen Vorsicht doch unterworfen ist, es nie gewagt haben, meine Einthellung bekannt zu machen, obwohl sich Herr Duméril in seinen Lectionen vom Jahre 1809 schon vorgetragen, und die Thiere im Cabinet dannen bezeichnet hat."
4 Memoires de zoologie et d'anatomie comparée (Paris, 1807, 8vo), p. 45.
remains, *Pterodactylus, Mosasaurus, Iguanodon, Ichthyosaurus,\nTelesaurus*, became the subjects of Cuvier's classical treatises,\nwhich form the contents of the 5th volume (part 2) of his\n*Recherches sur les ossemens fossiles, où l'on reliablé les caractères des\nplusieurs animaux dont les révolutions du globe ont détruit les\espèces* (new ed., Paris, 1824, 4to).\n
When the process of classification adopted either Oppel's\nor Cuvier's view as to the number of orders of reptiles, or as to\nthe position Batrachians ought to take in their relation\nto reptiles proper, with the single exception of *D. de\nBlainville*. He divided the "oviparous subtype" of\nVertebrates into four classes, Birds, Reptiles, Amphibians\nand Fishes, a modification of the system which is all the\nmore significant as he designates the reptiles "*Squamiferes\nOmnithoides, écailleux*," and the amphibians "*Nubiphellifers,\nIchthyoides nus*." In these terms we perceive clear indications\nof the relations which exist to the class of birds on the one hand, and\nto that of mammals on the other. Still, Blainville himself did not follow up the ideas thus expressed, and abandoned\neven the terms in a later edition of his systematic table.

The direct or indirect influence of the work of French anatomi-
lists manifested itself in the systems of the other herpetologists\nof this period. The Crocodiles, especially, which hitherto\n(strange to say, even in Cuvier's classification) had been placed\nas one of the families of Saurians, now come to be separated\nfrom them. Merrem (*Versuch eines Systems der\nAmphibien*, Marburg, 1820, 8vo) distinguishes two\nclasses of *Amphibians*, Tholida and Batrachia.

The Tholida (or Reptiles) are divided into three orders, distin-
guished chiefly by osteological and splanchnological characters: 1.\nTESTUDINATA. 2. LORICATA (=Crocodiles). 3. SQUAMATA (=Oppel's Squamata, excluding Crocodiles).\n
Merrem's subdivision of the Squamata into (1) *Gradientia*\n(=limbed Laceritida), (2) *Repentina* (=limbless Laceritida), (3)\n*Serpentina* (=Snakes and Amphibitana), (4) *Incidentina* (=Chelotes),\nand the *Sternotheridae* (=Chelonia) is chiefly on the\nfixations of the limbs, and not adopted by his successors. The\ngreater part of his work is occupied with a synopsis of all the\nspecies of Reptiles known, each being shortly characterized by a\ndiagnostic table of characters, all the rest divided according\nto the number of vertebrae in the cervical region (viz., one), and\nseventy) were known to him from autopsies, this synopsis has all the\nfaults of a compilation.

Later, who commenced the study of reptiles as early as 1801,\nhad kept pace with the progress of science when he\npublished, in 1825, his *Familles naturelles du règne animal* (Paris, 1825, 8vo). He separated the Batra-
chians as a class from the Reptiles, and the latter he divides into\ntwo sections only, Cataphracta and Squamosa—in the former\nCrocodiles being associated with the Chelonians. He bases this\nview on the development of a carapace in both, on the structure\nof the feet, on the fixed quadrate bone, on the single organ of\ncopulation. None of the succeeding herpetologists adopted a\nview so nearly correct as that of Laterelle.

Gray\n
**Gray.**

*Gray.** except J. E. Gray, who, however, destroyed Laterelle's idea of Cataphracta by adding the Amphibiaenian3 as a third\norder.

A mass of new materials now began to accumulate from all\nparts of the world in European museums. Among others, Spix\nhad brought from Brazil a rich spoil to the Munich Museum,\nand the Bavarian Academy charged Jou. Wagler\nto prepare a general system of reptiles and batra-
chians. His work, the result of ten years' labour, is a simple but\nlastingly monument to a young naturalist,4 who, endowed with\nan alluring simplicity of character, too frequently misinterpreted\nthe evidence of facts, or forced it into the service of preconceived\nideas. Cuvier had drawn attention to certain resemb-
lances in some parts of the osteous structure of *Ichthyosaurus* and *Ptero-
dactylus* to dolphins, birds, crocodiles, &c. Wagler, seizing\nupon such analogous resemblances, separated those extinct\nSaurians from the class of Reptiles, and formed of them and the\nMonotremes a distinct class of Vertebrates, intermediate between\nmammals and birds, which he called Gryphii. We must admits\nthe result of a free use of analogy, and one might even say of\ntransposing species of Gryphii as "*vertebratae con luna lingue living in the pectoral\ncavity; oviparous development of the embryo (within or)\nwithout the parent; the young fed (or suckled?) by the parents."

By the last character this Waglerian class is distinguished from the reptiles.

Reptiles (in which Wagler includes Batrachians) are divided\ninto eight orders: Testudines, Crocodili, Lacertae, Serpentes,\nAngues, Caeciliae, Ranae and Ichthyoidi. He has great merit\nin having employed, for the subdivision of the families of lizards,\nthe structure of the tongue and the mode of insertion of the\nteeth in the jaws. On the other hand, Wagler entirely failed in arrang-
ing snakes in natural families, venomous and non-venomous\ntypes being mixed in the majority of his groups.

L. Fitzinger was Wagler's contemporary; his first work5\npreceded Wagler's system by four years. As he says in the\npreface, his object was to arrange the reptiles in "a\n"*natural system." Unfortunately, in order to\nattain this object, Fitzinger paid regard to the most superficial\npoints of resemblance; and in the *tabula affinitatum generum*\nwhich he constructed to demonstrate the "progress of nature,"\nhe has been much more successful in placing closely allied\ngenera in contingency than in tracing the relationships of\nthe higher groups. That table is prepared in the form of a\ngeological tree, but Fitzinger wished to express thereby\nmerely the amount of morphological resemblance, and there is no\nevidence whatever in the text that he had a clear idea of\ngenetic affinity. The Batrachians are placed at the bottom\nof the scheme, leading through Hyla to the Geckos (clearly\non account of the digital dilatations) and through Caecilia to\nAmphisbaena. At the top Draco leads through *Pterodactylus*\nto the Bats (*Pteropus*), *Ichthyosaurus* to the Cetaceans (*Del-
phinius*), Emys to the Monotremes, Testudo to Manis, and the\nMarine Turtles to the Divers and Penguins.

In Fitzinger's system the higher groups are, in fact, identical\nwith those described by Merrem, while greater originality in the\nsubdivision of the orders. He differed also widely from Wagner\nin his views as to the relations of the extinct forms. The order of\nLoricata consists of two families, the Ichthyosaurian and Croco-
dilean, the former comprising Iguanodon, Plesiosaurus, Salmo-
ceraphus and Ichthyosaurus. In the order Squamata Lacertilani\nand Ophidians are combined and divided into twenty-two families,\nalmost all based on the number of vertebrae. The Familial class of\nthe first two, viz. the Geckos and Chameleons, are natural enough,\nbut in the three following Iguanodon and Agamodons are sadly\nmixed, Pterodactylus and Draco forming one family; Megalo-
saurus, Mosasaurus, Varanus, Tejuæ, &c., are associated in another\nnamed Ameivoseidae; the Amphisbaenidae are correctly defined;\nthe Colubroidae is a heterogeneous ensemble of thirty genera;\nand with his family of Bungaroidae Fitzinger makes an attempt to\nseparate at least a part of the venomous Colubrine Snakes from the\nViperines, which again are differentiated from the last family, that\nof Crotalidea.

If this little work had been his only performance in the\nfield of herpetology his name would have been honourably\nmentioned among his fellow-workers. But the promise of his\nearly labours was not justified by his later work, and—if we\ntake notice of the latter here it is only because his name has become attached to many a reptile through the pathetic names of nosologically signification. The labours of\nWiegmann, Müller, Duméril and Bibron exercised no influence\non him, and when he commenced to publish a new system of\nreptiles in 1843,6 of which fortunately one fasciculus only\nappeared, he exhibited a classification in which morphological\nfacts are entirely superseded by fanciful ideas of the vaguest\nkind of physiophysics, each class of vertebrates being divided

wandschaften (Vienna, 1826, 4to).
6 Systema Reptilium (Vienna, 1843, 8vo).
into five "sense" series, and each series into three orders, one comprising forms of superior, the second of medium and the third of inferior development. In the generic arrangement of the species, to which Fitzinger devoted himself especially in this work, he equally failed to advance science.

We have now arrived at a period distinguished by the appearance of a work which superseded all its predecessors, which formed the basis for the labours of many succeeding years, and which will always remain one of the classical monuments of descriptive zoology—the *Erpédologie génerale en histoire naturelle complète des reptiles* of A. M. C. DUMÉRIL and G. BIBRON (Paris, 8vo). The first volume appeared in 1834, and the ninth and last in 1854. No naturalist of that time could have been better qualified for the tremendous undertaking than C. Duméril, who almost from the first year of half a century's connexion with the then largest collection of Reptilia had chiefly devoted himself to their study. The task would have been too great for the energy of a single man; it was, therefore, fortunate for Duméril that he found a most devoted fellow-labourer in one of his assistants, G. Bibron, whose abilities equalled his own, and who, but for, the great loss of science, died (in 1848) before the completion of the work. Duméril had the full benefit of Bibron's knowledge for the volumes containing the Snakes, but the last volume, which treats of the Tailed Batrachians, had to be prepared by Duméril alone.

The work is the first which gives a comprehensive scientific account of reptiles generally, their structure, physiology and literature, and again each of the four orders admitted by the authors is introduced by a similar general account. In the body of the work 121 Chelonia, 468 Saurians, 586 Ophidians and 215 Batrachians are described in detail and with the greatest precision. Singularly enough, the order to which Brongniart's arrangement, in which the Batrachians are co-ordinate with the other three orders of reptiles. This must appear all the more strange as Von Baer in 1828, and J. Müller in 1831, had urged, besides other essential differences, the important fact that no Batrachian embryo possesses either an amnion or an allantois, like a reptile.

4. Period of the Separation of Reptiles and Batrachians as Distinct Classes or Subclasses.—In the chronological order which we have adopted for these historical notes, we had to refer in their proper places to two herpetologists, Blainville and Latreille, who advocated a deeper than merely ordinal separation of Reptiles from Batrachians, and who were followed by F. S. Leuckart. But this view only now began to find more general acceptance. J. Müller and Stannius were guided in their classification entirely by anatomical characters, and consequently recognized the wide gap which separates the Batrachians from the Reptiles; yet they considered them merely as subclasses of the class Amphibia. The former directed his attention particularly to those forms which seemed to occupy an intermediate position between Lacerptodons and Ophidians, and definitely relegated Anguis, Pseudes, Anguis from the former, and Typhlops, Rhabdos, Tortrix, but also the Amphisbaenoids to the latter. Stannus interpreted the characteristics of the Amphisbaenoids differently, as will be seen from the following abstract of his classification:

*Subclasses: Amphisbaenia Monopnoea* (Leuckart).

**Ord. 1. Ophidia.**

**Subordo 1. Euromyostoma or Macrostromata (Mili).** The phalangeal bones are closely connected to admit of great extension of the wide mouth. Mouth narrow, not extensible; quadrate bone attached to the skull and not to a mastoid.

**Subordo 2. Angrostomata or Microstromata (Mili).** Mouth narrow, not extensible; quadrate bone attached to the skull and not to a mastoid.

Owen followed by Huxley and E. D. Cope, who, however, restricted still more the selection of classificatory characters by relying for the purposes of arrangement on a few parts of the body.
skeleton only. They attempted a further grouping of the orders which in Owen's system were merely serially enumerated under the class Reptilia. For this purpose, the terms used were based almost exclusively on the position and character of the rib-articulations to the vertebrae centrala, the orders themselves being the same as in Owen's system:

A. **Pleurosaurnyia**. Dorsal vertebrae devoid of transverse processes and not movable upon one another, nor are the ribs movable upon the vertebrae. A plesiosaur. Order 1, **Chelonia**.

B. The dorsal vertebrae of those which have either complete or rudimentary transverse processes are movable upon one another, and the ribs upon them. No plastron.

1. The dorsal vertebrae have transverse processes which are either entire or very imperfectly divided into terminal facets (Ereptospondylia).
2. Transverse processes long; limbs well developed, paddle-shaped, and with costal and external ribs absent or rudimentary. Order 2, **Plesiosauria** (= Sauropterygia, Ov.).
3. Transverse processes short. *a.* A pectoral arch and urinary bladder. Order 3, **Lacertilia**.
4. No pectoral arch and no urinary bladder. Order 4, **Ophidia**.

b. The dorsal vertebrae have double tubercles in place of transverse processes (Perospondylia). Limbs paddle-shaped. Order 5, **Ichthyosauria** (= Ichthyopterygia, Ov.).

**C.** The anterior dorsal vertebrae have elongated and divided transverse processes, the tubercles being longer than the capitular division (SUCHOSPONDYLIA).

a. Only two vertebrae in the sacrum. Order 6, **Crocodilia**.

b. More than two vertebrae in the sacrum. *a.* Manus without a prolonged ulnar digit. Order 7, **Decynodon** (Anomodontia, Ov.).

b. Manus with an extremely long ulnar digit. Order 8, **Ornithoscelida** (= Dinosaurs, Ov.).

**D.** The monocular, the class only known as reptiles are a true Dinosauria including the orders Dinosauria, Squamatia, and Pterosauria. All these have been treated in recent years by Sir Arthur C. Huxley, and are classified under the class Reptilia. They are characterized by the presence of scales, an scapular suture, and the absence of a lung. The classification of Owen is followed here.

### II. General Characters of the Class Reptilia

Reptiles, as known in the existing world, are the modified, and in many respects degenerate, representatives of a group of lung-breathing vertebrate animals which attained its maximum development in the Mesozoic period. So far as can be judged from the skeleton, some of the members of this group that living might have become mammals by very slight change, while others might as readily have evolved into birds. It is therefore probable that the class Reptilia, as now understood, comprises the direct ancestors of both the Mammalia and the Aves. It is clear that the extinct members, which are known only by skeletons, were organized essentially like its existing representatives, the class ranks higher than that of the lowest five-toed vertebrates (Class Batrachia) in the investment of the foetus by two membranous envelopes (the amnion and allantois), and in the total absence of gills even in the earliest embryos. It ranks below both the Mammalia and Aves in the partial mixture of the arterial blood with the venous blood as it leaves the heart, thus causing the organism to be cold-blooded; it also differs both from Mammalia and Aves in retaining a pair of aortic arches, of which only the left remains in the former, while the right one is retained in the latter. No feature in the endoskeleton is absolutely distinctive, except possibly the degeneration of the parapophyseal bone, which separates the Reptilia from the Amphibia. In the exoskeleton, however, the epidermis forms horny scales, such as never occur in Amphibia, while there are no traces of any structures resembling either hairs or feathers, which respectively characterize Mammalia and Aves.

There is little doubt that true reptiles date back to the latter part of the Palaeozoic period, but at that epoch the Amphibia approached them so closely in the characters of the skeleton that it is difficult to distinguish the members of the two classes among the fossils. Some of the Palaeozoic Amphibia—a few of the so-called Labyrinthodonts—are proved to have had well-developed gill-arches in their immature state, while there are conspicuous marks of slime-canals on their skulls. Others are...
merely regarded as Amphibia because they closely resemble the genera which are proved to have been gill-breathers when immature. All these genera, however, so far as known, agree with the existing Amphibia in the production of their large parasphenoid bone as far forwards as the vomers to form a rigid and complete basioccipital axis (fig. 1, A). Those genera of the upper bar, some members of this series eventually pass into the order Squamata (Lacertilia—Ophidia), in which the quadrate bone is completely exposed and loosely attached to the skull (fig. 2, E); other reptiles exhibiting a similar modification may readily have acquired the typical Avian skull (fig. 2, F). Creep along the loss of the upper bar and the retention of the lower temporal bar in question.

In view of these and other palaeontological considerations, the Reptilia may be classified into orders as follows:—

**Orders of Class Reptilia**

1. Anomodontia.—Bones of postero-lateral region of skull forming a complete roof over the temporal and masseter muscles, or contracted into a single broad zy sagmatic arch, leaving a superior-temporal vacuity. Pinal foremen present. Ribs completely or imperfectly double-headed. No ribs replaces replaced by three or four pairs of large plates, which, with the clavicles and interclavicle, form the pectoral girdle; ribs only in depression; third and fourth digits with not more than three phalanges. Dermal armour feeble or absent. Range.—Permian and Recent.

2. Chelonia.—Postero-lateral region of skull contracted into a single broad zygomatic arch, leaving a superior-temporal vacuity. Pinal foremen present. No fused sacral vertebrae. All dorsal ribs single-headed, articulating with transverse processes of the neural arches. Abdominal ribs forming dense plastron. Apparently no sternum. Coracoid, pubis and ischium in form of much-expanded plates. Limbs modifed as paddles, with not more than five digits, of which the third and fourth always have more than three phalanges; all digits may be composed of several phalanges. No dermal armour. Range.—Upper Triassic to Recent.

3. Sauropterygia.—Bones of postero-lateral region of skull contracted into a single broad zygomatic arch, leaving a superior-temporal vacuity. Pinal foremen present. Vertebrea short and deeply biconcave, with feeble neural arches which are almost or completely destitute of zygapophyses. No fused sacral vertebrae. Cervical and dorsal ribs double-headed, articulating with tubercles on the zygomatic arches. Pectoral girdle as limbs may be composed of numerous short phalanges, which are closely pressed together, sometimes with suplementary rows of similar ossicles. No dermal armour. A vertical triangular caudal fin, not supported by skeletal rays. Range.—Triassic to Recent.

4. Ichthyopterygia.—Bones of postero-lateral region of skull contracted into two slender zygomatic bars, leaving a superior-temporal and a lateral-temporal vacuity, and partly exposing the quadrate bone from the side. Pinal foremen present or absent. Ribs single-headed. Abdominal ribs present. Sternum present. Epicoracoid cartilaginous. Limbs only for progression; third and fourth digits with four or five phalanges. Dermal armour feeble or absent. Range.—Lower Triassic to Recent.

5. Rhynchocephalia.—Bones of postero-lateral region of skull contracted into two slender zygomatic bars, leaving a superior-temporal and a lateral-temporal vacuity, and partly exposing the quadrate bone from the side. Pinal foremen present or absent. Ribs double-headed. Abdominal ribs present. Sternum present. Epicoracoid cartilaginous. Limbs only for progression; third and fourth digits with four or five phalanges. Dermal armour variable. Range.—Triassic to Cretaceous.

6. Dinosaurs.—Postero-lateral region of skull as in Rhynchocephalia. No pinal foramen. Cervical and dorsal ribs double-headed. Rarely abdominal ribs. Sternum present or absent. No clavicular arch. Limbs for support as well as progression; third and fourth digits with four or five phalanges. Dermal armour variable. Range.—Lower Jurassic to Recent.

7. Crocodilia.—Postero-lateral region of skull as in Rhynchocephalia. No pinal foramen. Cervical and dorsal ribs double-headed. Abdominal ribs present. Sternum present. Also clavicle, but no clavicles. Limbs only for progression on land or swimming; third and fourth digits with four or five phalanges. Dermal armour variable. Range.—Lower Jurassic to Recent.

**REPTILES**

9. Squamata.—Bones of postero-lateral region of skull much reduced and partly absent, never forming more than a slender superior-temporal bar, thus completely exposing the quadrate, which is only loosely attached to the cranium at its upper end. Pinal foramen present. Ribs single-headed. No abdominal ribs. Sternum present when there are limbs. Limbs, when present, only for progression; third and fourth digits at least with more than three phalanges. Dermal armour feeble or absent. Range.—Cretaceous to Recent.

Order 1. ANOMODONTIA.—The Anomodonts are so named in allusion to the peculiar and unique dentition of the first-discovered genera. They are precisely intermediate between the and India, but they are best represented in the Karoo formation (Permian and Triassic) of South Africa. The Paraisaura most closely resemble the Labyrinthodont Amphibia, but have a single occipital condyle. *Paraisaura* itself is a massive herbivorous reptile, with a short tail, and the limbs adapted for excavating in the ground. It is known by several nearly complete skeletons, about 3 metres in length, from South Africa and northern Russia. *Elginia*, found in the Elgin sandstones of Morayshire, Scotland, is provided with horn-like bony bosses on the skull. Another apparently allied genus (*Olocetus*) has a carapace suggesting that it may be an ancestral Chelonia. The Therio-

Labyrinthodont Batrachia and the lowest or Monotreme Mammalia. They flourished at the period when the former are known to have reached their culmination, and when the latter almost certainly began to appear. Many of them would, indeed, be regarded as primitive Mammalia, if they did not retain a pinal foramen, a free quadrate bone, and a complex mandible. The term Theromorpha or Theromora is thus sometimes applied to the order they represent. So far as known, they are all land-reptiles, with limbs adapted for habitual support of the body, and their feet are essentially identical with those of primitive mammals. Most of them are small, and none attain a gigantic size. They first appear in the Permian of Europe and North America, and also occur in the Triassic both of Europe...
found (Proganochelys). Its members are proved to have been toothless since the Jurassic period, and have only changed very slightly since their first appearance. The marine turtles seem to have first acquired elongated paddles and vacuities in the shell during the Cretaceous period, and the Trionychia, destitute of epidermal shields, apparently arose at the same time.

Order 3. SAUROPTERYgia.—These are amphibious or aquatic reptiles (fig. 4). The head is comparatively small in most genera, and the neck is usually elongated though not flexible. The tail is insignificant, generally short, and both pairs of paddles seem to have been concerned in progression. The order appears to have arisen from a group of land-reptiles, for its earliest members, from the Triassic of Europe (Lariosaurus) and from the Permo-Carboniferous of S. Africa (Mesosaurus) and Brazil (Stereosaurus), are all amphibious animals. They are comparatively small, and their limbs are only just becoming paddle-like. The skull suggests affinities with the terrestrial effective paddles with elongated digits, and as the genera are traced upwards in the geological formations it is possible to observe how the arches supporting the limbs become more rigid until the maximum of strength is reached. A few genera, such as Plesiosaurus from the Jurassic and Polyptychodon from the Cretaceous of Europe, are distinguished by their relatively large head and stout neck. Some of the largest Upper Jurassic and Cretaceous species must have been 10 metres in length. They were cosmopolitan in their distribution, but became extinct before the dawn of the Tertiary period.

Order 4. Ichthyopterygia.—The Ichthyosaurs are all fish-shaped, with a relatively large head and very short neck. Both pairs of paddles are retained, but the hinder pair is usually very small, and locomotion seems to have been chiefly effected by a large caudal fin. This fin, as shown in impression by certain fossils from Württemberg and Bavaria, is a vertical, triangular, dermal fin, without any skeletal support except the hindermost part of the attenuated vertebral column, which extends along the border of its lower lobe (fig. 5). Another triangular fin, without skeletal support, is known to occur on the back, at least in one species (fig. 5). Some of the genera are proved to have been viviparous. Like the Sauropterygia, the Ichthyopterygia appear to have originated from terrestrial ancestors, for their earliest Triassic representatives (Mesosaurus) have the teeth less uniform and the limbs slightly less paddle-shaped than the latter genera. In this connexion it is noteworthy that their hollow conical teeth exhibit curious infoldings of the wall, like those observed in many Labyrinthodonts, while their short, biconvex vertebræ almost exactly resemble those of the Labyrinthodont Mastodonsaurus and its allies. As the Ichthyosaurs are traced upwards in geological time, some genera become almost, or quite, toothless, while the paddles grow wider, and are rendered more flexible by the persistence of cartilage round their constituent bones (Ophthalmosaurus). They were cosmopolitan in distribution, but disappeared from all seas at the close of the Cretaceous period. The largest forms, with a skull 2 metres in length, occur in the Lower Liass.

Order 5. Rhynchocephalia.—These are small lizard-shaped reptiles, which have scarcely changed since the Triassic period. Though now represented only by Sphenodon or Hatteria, which survives in certain islands off New Zealand, in the Mesozoic epoch they ranged at least over Europe, Asia and North America. They comprise the earliest known reptile, Palaeochelonia, from the Lower Permian of Saxony, which differs from the Triassic and later genera in having an imperfectly ossified pubis and ischium, more numerous abdominal ribs, and the fifth metatarsal

Fig. 5.—Ichthyosaurus quadriscissus: outline of specimen showing dorsal and caudal fins, about one-sixth natural size.—Upper Liass, Württemberg. (After E. Fraas.) The irregularities behind the triangular dorsal fin are torn pieces of skin.

Anomodontia, and the shape of the scapula seems to show some connexion with the Chelonia. The truly aquatic Sauropterygians of the Jurassic (fig. 4) and Cretaceous periods possess most bone normal. They are also represented in the Permian, chiefly of North America, by the so-called Polypterygia, which have sharp teeth in sockets, and are remarkable for the extreme
elation of the spines of their cervical and dorsal vertebrae (Dimetrodon, fig. 6). They seem to include various Triassic genera (e.g. Actosaurus, Belodon), which may perhaps belong to the ancestral stock of the Dinosauria and Crocodilia. Other Triassic genera (Hyperodapedon, Rhychoaurus) scarcely differ from Sphenodon, except in the dentition and in the absence of the pincel foramen in the skull. In the late Cretaceous and early Eocene periods one genus (Champsosaurus) was truly aquatic, with gavial-shaped head.

Order 6. DINOSAURIA.—The dinosaurs are land reptiles which flourished on all the continents during the Jurassic and Cretaceous periods, in the interval between the decline of the Anomodontia and the dominance of the Mammalia. They first appeared as carnivorous reptiles in the Triassic period in Europe, India, S. Africa, and N. America, but afterwards comprised numerous massive herbivores in nearly all parts of the world except the Australian and New Zealand regions. The skeleton in the carnivorous dinosaurs, or Theropoda, is of very light construction, the vertebrae and limb bones being hollow, with thin, dense walls and often perfectly fitting joints. The fore limbs are small, and the hind limbs are adapted for running, jumping or hopping on the toes. The sabre-shaped cutting teeth are fixed in sockets, and all the claws are sharp. Anchisaurus and Halleopus, from the Trias of N. America, and Seleromochlus from the Elgin sandstones of Scotland, are comparatively small animals. Ceratosaurus and Megalosaurus, from the Jurassic of North America and western Europe respectively, must have attained a length of from 5 to 6 metres. Tyrannosaurus, from the Cretaceous of Montana, U.S.A., has a skull more than a metre in length. The herbivorous Dinosaurs of the suborder Ornithopoda resemble the Theropoda in general shape, but are heavier in build, with a pelvis constructed more nearly on the plan of that of a running bird. It has, indeed, been suggested that certain arboreal Dinosaurs of bipedal gait may have been the ancestors of the class Aves. The best-known Ornithopod is Iguanodon (fig. 7), from the Wealden of W. Europe, with species from 5 to 10 metres in length. Cetiosaurus, from the Cretaceous of N. America, is nearly similar, and is represented by at least one complete skeleton in the Yale University Museum. There are also members of the same group with a heavy armour of bony plates and spines, sometimes termed Stegosauria. Stegosaurus itself occurs in the Upper Jurassic of Colorado, and Onosaurus, from the Kimmeridge and Oxford clays of England, is a nearly similar reptile. Polacanthus, from the Wealden of the Isle of Wight, has the hip-region armoured with a continuous bony shield. Triceratops (fig. 8) and its allies, from the Upper Cretaceous (Laramie) of western N. America, are the latest members of the group, with a bony frill over the neck, a pair of bony horns above the eyes, and a median bony horn-core on the nose. The skull with the bony frill sometimes measures nearly two metres in length. Another suborder of herbivorous Dinosaurs, that of Sauropoda, comprises the largest known land animals of any age, some measuring from 17 to 25 metres in total length. They have a small head, long neck, and long tail, and must have been quadrupedal in gait. Their teeth are adapted for feeding on succulent water weeds, perhaps with an admixture of small animals living among these; and their vertebrae are of very light construction, while the ribs are raised high on the neural arches to increase the size of the body cavity, perhaps for unusually large lungs or air sacs. Their massive limbs have five toes, of which the three inner alone bear outwardly curved claws. Diplodocus and Brontosaurus, from the Jurassic of Wyoming and Colorado, U.S.A., are the best-known genera. Allosaurus, from the same formation, is usually noteworthy for size. Cetiosaurus, from the Jurassic of England, is also known by large parts of the skeleton in the British Museum and the Oxford Museum, indicating species nearly 20 metres in length.
formations, but all the Jurassic and some of the Cretaceous genera have the secondary bony plate less extended backwards than that in the Tertiary and existing genera, while their vertebrae have flattened or concave ends, instead of exhibiting a ball-and-socket articulation. Some of the Upper Jurassic crocodiles (Metriorhynchus) were more truly aquatic than any now living, with the fore limbs degenerate, the hind limbs much enlarged for swimming, and the dermal armour lacking. The end of the vertebral column is bent downwards, as in Ichthyosaurus, so they doubtless possessed a similar triangular tail-fin. Typical crocodiles and alligators date back to the close of the Cretaceous period, and they did not become extinct in Europe until the beginning of the Miocene period. Remains of an extinct alligator (Diplacynodon) are common in the Upper Eocene sands of the Hordwell cliffs, Hampshire.

Order 8. Ornithosauria.—The flying reptiles or Pterodactyls (fig. 9) are completely evolved at their earliest known appearance in the Lower Lias (Dimorphodon), and exhibit little essential change as they are traced upwards through the Mesozoic formations. The latest Cretaceous genera, however, comprise the largest species, which have been found in Europe, N. America and Brazil. Some of these (Pteranodon) are toothless, and their wings are so large that for adequate support the pectoral arch is fixed to the vertebrae like a pelvis. The wings occasionally have a span of from 5 to 6 metres. The wing-membranes are only known in the European Jurassic genus, Rhamphorhynchus (fig. 10), found well preserved in the fine-grained lithographic stone of Bavaria. In this genus there is also a rhomboidal flap of membrane at the end of the tail.

Order 9. Squamata.—The ancestors of the lizards and snakes can only be traced back definitely to the latter part of the Cretaceous period. They were then represented by two suborders of aquatic reptiles, the Dolichosauria and Pythomorpha (or Mosasauria), which are in many respects intermediate between the existing Lacertilia and Ophidia. The Dolichosauria, from the Upper Cretaceous of Europe, are small and snake-like in shape, but with completely formed limbs. The Pythomorpha are known from Europe, N. and S. America and New Zealand, and sometimes attained a very large size, the typical Mosasaurus campieri from Maastricht being about 15 metres in length. Their limbs are powerful paddles. Their trunk and tail are often much elongated, so that their shape is snake-like, as shown by Cidastes (fig. 11), from the Chalk of Kansas, U.S.A.

The Lacertilia and Ophidia, so far as known, are exclusively Tertiary and Recent reptiles. Marine snakes (Palaeophis) occur in the Eocene of the London and Hampshire basins.

Fig. 9.—Pterodactylus spectabilis, natural size, from the Lithographic Stone. h, humerus; ru, radius and ulna; mc, metacarpals; pt, pteroid bone; 2, 3, 4, digits with claws; 5, elongated digit for support of wing-membrane; st, sternum; is, ischium; pp, prepubis. The teeth are not shown. (After H. von Meyer.)

Fig. 10.—Rhamphorhynchus ptychurus, from the Solenhofen Lithographic Stone, one-fourth natural size, with the greater part of the wing-membranes preserved. x, caudal membrane; st, sternum; h, humerus; sc, scapula and coracoid; wm, wing-membrane. (After O. C. Marsh.)

III. Anatomy of Reptiles

The Skull.

Sphenodon has the most primitive and still most complex skull, the salient features of which are easy to derive from Stegocephalian and early, generalized reptilian conditions; whilst in other directions, mostly by reduction, the skull of this "living fossil" affords the key to that of all the other members of at least recent reptiles. The main features are the following. There are, in the temporal region, three complete bony arches, the supra-, infra-, and post-temporal, which subdivide the whole temporal fossa into four fora. The supratemporal bridge is formed by the squamosal and post-orbital, the latter (in fig. 12) being continued forwards and fused with the post-frontal. These three bones, with the parietal, enclose the supratemporal foramen. The postorbital joins an ascending branch of the jugal, both together forming the hinder border of the orbit, and this is bordered below chiefly by the maxillary. The post- temperal bridge is formed by the parietal and squamosal, extends laterally over the quadrate and encloses a wide space between itself and the buttress-like transverse expansion of the lateral occipital bone (these "parotic processes" are made up of the lat. occipital, parotic and opisthobic bones): this is the post-temporal foramen. The space enclosed between this occipital buttress, the quadrate and the pterygoid support of the latter represents the wide and large cavity of the middle ear,
and as such is crossed by the auditory columellae chain. The infra-temporal bridge or jugal arch is formed by the jugal (oj in fig. 12), which joins the descending process of the squamosal, and the quadrato-jugal, which is very small and partly fused with the lateral side of the quadrato-jugal bridge. Now, between the quadrato-jugal on the one side and the squamoso-quadrate-jugal-jugal on the other, is enclosed a gap, met with only in Sphenodon of recent reptiles. This fourth, or quadrato-squamosal foramen, with its squamoso-quadrate-jugal bridge, is, as a rule, not mentioned, being too small to be obvious. The quadrato-jugal is very firmly fixed. On the ventral side of the cranium we notice the broad and long bony palate, the large vomers, and the pterygoids meeting in the middle line; aside of the vomers are the long posterior nares; posteriorly the pterygoids diverge to rest upon short basi-sphenoid processes, and they articulate by short flanges with the quadrates.

The occipital condyle is kidney-shaped, triple, composed of the basi- and the lateral occipitals. The dorsal median roof of the cranium is formed by the paired parietals, near their anterior symphysis with the large pineal foramen, the paired frontals, nasals and premaxillaries. The outer nares are surrounded by the premaxillaries, maxillaries and nasals. Prefrontals and postfrontals exist. There is a complete cartilaginous, interorbital septum, and a cranial columella, a pair of upright buttresses arising in the alisphenoidal walls, connecting the parietals with the pterygoids. The hyoid apparatus consists of a narrow base, with three pairs of arches; of these the first or hyoid arch is variously connected with the cranium near the paroccipital process, or with the extracolumella (see Middle Ear, below); the others are a long and stout pair of first and a smaller pair of second branchial arches.

**Crocodiles.**—The temporal region is still bridged over by three arches, dividing the whole fossa into three, very much as in Sphenodon. The supratemporal foramen is bordered by the parietal, postfrontal (postorbital) absent) and squamosal. The posttemporal foramen is a very much reduced, sometimes to a narrow passage between the parietal, occipital and squamosal, because the latter bone forms an extensive suture with the paroccipital process. The infratemporal or lateral fossa is wide and rather shallow, bordered above by the postfrontal and squamosal, in front by the postfrontal and jugal, below by the jugal and quadrato-jugal, behind by the latter, the quadrato-jugal bridge, behind the latter, the quadrato-jugal bridge, the fourth foramen of Sphenodon is absent. The middle-ear cavity is reduced to a complicated system of narrow passages; one for the passage of the extracolumellar-mandibular string of the auditory chain (see Ear, below), between the quadrato-jugal, paroccipital and lateral occipital bones; another passage (Eustachian) opens in the roof of the mouth, between the basioccipital and basisphenoid; a third joins that of the outer side and forms with it a median opening between the same bones, just behind the posterior pterygoid border of the choana. These nares, being in the recent crocodiles shifted as far back as possible, communicate with the outer nostrils by very long passages, formed by the whole length of the pterygoids, palatines, maxillaries, vomers and pre-maxillaries, all of which form a long median suture. But this long bony palatal roof is interrupted by a pair of large palatal foramina, bordered usually by palatine, pterygoid, ectopterygoid, or transverse bone and maxillary. One of the bones of the cranium we notice the parietals fused into an unpaired bone, without a pineal hole and the likewise unpaired frontal. There are a pair of postfrontals, prefrontals and lacrymals perforated by the naso-lacrimal duct. The nasals vary much in length, mostly in conformity with that of the maxillaries; as a rule they reach the short premaxillaries, but not always the nasal groove. (For taxonomic detail see under Crocodile.)

The occipital condyle is formed mainly by the basioccipital, which always borders part of the foramen magnum, but the lateral occipitals each send a flange to it, which in immature specimens still partakes of the articulation with the atlas. The ophisthotic and epiotic bones fuse early with the lateral and with supraoccipital bones; only the prootic remains longer as a separate element, anteriorly with a large hole for the exit of the third branch of the trigeminal nerve. The basisphenoid is scarcely visible, being overlaid by the pterygoids. The pre-sphenoid is larger, continued forwards and upwards into the inter-orbital septum, which remains mostly cartilaginous. Near the anterior and upper margin of the pre-sphenoid is a large notch on either side for the passage of the optic nerve, the three eye-muscle nerves and the first branch of the trigeminal. The place of the orbitosphenoids is taken by membrane or cartilaginous continuations of the inter-orbital septum, but the alisphenoids are large and abut upwards against the frontals and with a lateral flange against the postfrontals. These send down a conspicuous process which forms sutures with an upward process of the jugal and another of the ectopterygoid; it is this compound pillar which partly divides the orbit from the infratemporal or lateral fossa. The size of these and the upper temporal fossae stand in an inverse ratio to each other. The upper fossae are still comparatively large in the long-snouted Gavialis and Tomistoma, whilst these holes almost completely disappear in the alligators, namely, in the broad-and short-snouted members of the order, which chew their prey. In extinct Crocodilians the upper fossa were the larger. The temporal-mandibular muscle which lifts or shuts the lower jaw arises from the walls of the upper fossa, passes beneath the jugal-arch and is inserted upon the supra-angular portion of the lower jaw. In the more recent crocodiles this muscle is more and more subjoined to the pterygo-mandibular muscle, which, arising chiefly from the dorsal surface of the much-broadened pterygoid, fills the widened space between the latter and the quadrato-jugal, and is inserted into the outer surface of the angular bone. The arrangement of this muscle secures a more advantageous leverage of the jaw, and is capable of more powerful development than the other, which is consequently on the wane—a nice illustration of onward, orthogenetic evolution. The dentary bones of the under jaw form a suture, later a symphysis; this is very long in the long-snouted genera, in which the splenials likewise form a long symphysis; in the others the mandibular symphysis is much shorter and the splenials remain widely separated. The articular bone is short, forms a transverse cup for the quadrato-jugal, or a saddle-shaped cup, and is perforated by the Sphionium (see below under Ear). The angle is upturned, formed by the articular, angular and, laterally, by the supra-angular bone; the opercular or counterpart of the splenial lies on the outer side, forming part of the anterior border of the oval foramen in the jaw.

The Chelonia skull agrees in many important features with that of Sphenodon and of the crocodiles, but it is composed of fewer bones, the ectopterygoids, lacrymals and postorbitals being absent, often also the nasals, unless they are fused with the prefrontals. The vomer is unpaired and forms a septum between the nasal passages, which, except in Spharigis, are ventrally roofed over to a variable extent by wings sent out by the palatines, joining the sides of the vomer. Most of the configurations of the other cranial bones are well represented in the accompanying figures. The palatines form a continuous broad floor with the pterygoids, which are extensively and firmly joined to the quadrates and to the basisphenoid. There are no Eustachian tubes. The occipital condyle is distinctly triple and the basioccipital is frequently excluded from the fuses when we have a pair of stout wings, the ventral of which joins a stout ventrolateral process of the basioccipital, both forming a thick knob especially in Chelone, and a dorsolateral wing, which broadly joins the large opisthotic bone. This connects the lateral occipital and the supraoccipital with the upper portion of the quadrato-jugal. On the top of the quadrato-jugal and upon the lateral dorsal portion of this compound transverse process (which of course corresponds to the paroccipital process of crocodiles, &c.) lies the squamosal, about which more presently. The two wings of the lateral
occipital, part of the opisthotic, the quadrate, and part of the pterygoids, form the bony borders of the middle ear-cavity, and the parietals. They represent of course the columellae cranii or columellae; if they are of alisphenoidal origin the term epityergyoids is a misnomer; the same applies to these structures in other reptiles. Through the space enclosed by the pterygoid, basioccipital, opisthotic and quadrate, enters the cranial carotid artery, sometimes piercing the posterior rim of the pterygoid; then the canal runs along the dorsal side of this bone and opens near the cranial columella. The arcades over the temporal region are most variable. Potentially Cheloniens possess all the three arcades of the crocodiles, but it so happens that never more than one fenestra is present. The false roof over the temporal region is most complete in Spargis and in the Cheloniidae. Excepting Spargis the supraoccipital extends far beyond the back of the cranium in shape of a long unpaired crest, which never diverges, or sends out lateral processes, but it is joined, and partly overlaid for a great part of its length, by the parietals in Cheloniidae and Spargis. In these genera the much-enlarged parietal, the equally large postfrontal, with the squamosal behind, the jugal below, and a large quadrato-jugal, form one continuous bony roof over the whole temporal fossa, which is widely open behind, the space being bordered by supraoccipital, opisthotic, squamosal and parietal. All other Cheloniens show a great reduction of this roof. The parietal does not send out dorsolateral expansions; and the postfrontal likewise forms no expansions. It joins the rather short malar, forming the posteriororbital bridge, which posteriorly is connected by the quadrato-jugal with the upper part of the quadrate and with the squamosal. The latter rests upon the quadrate and is in no connexion with the parietal. Consequently the whole temporal fossa is quite open. The horizontal bridge or arcade is to a certain extent homologous with the infra-temporal arcade. All the bones which border the temporal fossa vary much in extent. The greatest reduction has taken place in Cistudo and in Geomysidae, in which the quadrato-jugal is lost, leaving a wide gap in the horizontal arcade. The Cheloniens form an instructive parallel to mammalian conditions by the broad contact of the squamosal with the malar, e.g. in Chelone, whilst the quad-

inner portion the quadrate joins the large prootic bone which is usually completely fused with the rest of the opisthotic, but in Spargis it remains separate, and in this turtle the sutures between the otic bones and the supraoccipital also persist. In front of the prootics the bony lateral walls of the brain-case end in Spargis, but in most of the other Cheloniens bony alisphenoids are represented by a pair of epityergyoids which rest upon short upward processes of the pterygoids and are joined by much longer, rather thin, but broad descending lamellae from

portion of the quadrate and with the squamosal. The latter rests upon the quadrate and is in no connexion with the parietal. Consequently the whole temporal fossa is quite open. after the loss of the postorbital element and of the quadrato-jugal, the squamosal gaining connexion with the upper, not posterior and ventral, branch of the jugal or malar bone.

The mandibular halves form a complete osseous symphysis, the only instance in reptiles; all the other elements retain their sutures. The articular portion of the articular bone forms several shallow cups and a slight anterior knob, best developed in *Chelone*. The angular bone does not help to form the posterior upper angle. The coronoid, or complementary element, is often small; the supra-angular and the splenial or opercular are always present, mostly also a pre-splenial wanting in Testudinidae (cf. G. Bauer).

The hyoid apparatus is well developed, and sometimes assumes large dimensions, especially in *Chelys*. The two pairs of "horns" are the first and second branchial arches, whilst the hyoid arches are reduced to a pair of small, frequently only cartilaginous nodules, attached near the anterior corners of the basis linguae, which generally fuses with the os entoglossum in the tip of the tongue. In Chelydidae the long median basal or copular piece forms a semi-canal for the reception of the trachea.

In the skull of the Lacertilia the arcades over the temporal region vary much in composition and numbers. There are at most two arcades and two windows. First the posttemporal arcade, enclosing the posttemporal fenestra, which is framed mainly by the large paroccipital process below and the long parietal process above, both meeting distally, and the quadrato is carried by the paroccipital process. In the corner, in front, where the three bones meet, lies the squamosal, connecting parietal and quadrato. This squamosal, when not too much reduced, has an upper parietal and an anterior horizontal arm; the latter is essential for the formation of the second horizontal arcade, which makes the lower border of the supra-temporal window. The infra-temporal arcade, namely a quadrato-jugal + jugal arch, is absent in all Lacertilians owing to the complete absence of the quadrato-jugal element.

In *Heloderma* and Geckos the posttemporal is the only arcade. In the Amphibia anids and in Anniella, practically also in *Anelytropsis*, all the arcades are lost. All the other families of lizards and the chameleons have two arcades. We begin the description of the horizontal arcade with those families in which it is most complete, and most like that of *Sphenodon*. In *Varanus* it is formed by four bones. The postfrontal is short; to it is attached the postorbital, which sends a long horizontal process to join the squamosal1 splint, and this connects with the.

There is a much-debated question of the homologies of the one or two elements, both apparently membrane bones, which connect the upper end of the quadrato with the parietal and with the supra-temporal arch. The question becomes acute in the snakes, whether the single element connecting skull and quadrato has to be called squamosal or supra-temporal. Space forbids here to expound the matter, which has been very able reviewed by S. W. Williston ("Temporal Arcades in the Reptilia," *Biol. Bulletin*, vol. No. 4, 1904, pp. 175-192; cf. also F. W. Thyng, *Tufts College Studies*, II, 2, 1906). About ten different names have been applied to these two elements, and two, namely, squamosal and supra-temporal, are being used quite promiscuously. When only one element is present, the present writer uses the term squamosal, and there are reasons making it probable that this element is the squamosum of mammals.

When both elements are present, the more ventral or lateral of the two is termed squamosal, that which always helps to form the

---

1. There is a much-debated question of the homologies of the one or two elements, both apparently membrane bones, which connect the upper end of the quadrato with the parietal and with the supra-temporal arch. The question becomes acute in the snakes, whether the single element connecting skull and quadrato has to be called squamosal or supra-temporal. Space forbids here to expound the matter, which has been very able reviewed by S. W. Williston ("Temporal Arcades in the Reptilia," *Biol. Bulletin*, vol. No. 4, 1904, pp. 175-192; cf. also F. W. Thyng, *Tufts College Studies*, II, 2, 1906). About ten different names have been applied to these two elements, and two, namely, squamosal and supra-temporal, are being used quite promiscuously. When only one element is present, the present writer uses the term squamosal, and there are reasons making it probable that this element is the squamosum of mammals.
upper anterior end of the quadrates; between the quadrates, the squamosal and the long parietal process lies the likewise splint-like supratemporal, attached by most of its length to the parietal process. The jugal has only one arm, and this connects the maxilla with the postorbital, completing the posterior orbital border. There is a wide gap between jugal and quadrates. In Tejidae the arcade is the same, but the squamosal reaches the jugal, both meeting the postorbital. In Lacertidae the arcade is essentially the same, but the window is completely filled up by the postfrontal, which extends so far back as to reach the supratemporal. In the Agamidae the arcade is strong and simplified. Postfrontal and postorbital are represented by one forked piece. This squamosal and the postorbital mass are connected by the upper, much up-curved end of the jugal, which is thrust between them. This arrangement is further emphasized in Iguana, the upper end of the jugal being much enlarged so as to form the greater portion of the arcade, and keeping the postfrontal mass and the simple squamosal widely asunder.

In Heloderma post- and prefrontals are in contact with each other, separating the frontal bone from the orbit; the jugal joins only the prefrontal, and there is no further arcade whatever. A vestige of a supratemporal (?) lies on the outside of the base of the squamosal, between s and q in fig. 20.

The chameleons are peculiar. The posttemporal arcade, spanning a wide space, is formed by a long process of the supratemporal - squamosal, which is directed upwards and backwards to join the parietal, which extends back by a long unpaired process. The horizontal arch is broad and short, squamosal and postfrontal, forming a broad suture; below they are joined by the jugal; above the suture lies, in chameleon, a tiny piece, perhaps a vestige of the dislodged postorbital.

The jugal bones, to continue the description of the appendicular parts of the skull, are firmly joined to lateral processes of the pterygoids by the ectopterygoids; further forwards they are extensively connected with the maxillaries. These rest against strong transverse palatine processes. The palatines form a medium symphysis; posteriorly they diverge together with the pterygoids, which articulate with the quadrate supratemporal bridge, generally with the postorbital, sometimes also with the jugal. The more dorsal element is mentioned as supratemporal; it is always smaller, and mostly restricted to the corner between the squamosal and the parietal process against which it rests. Either of these two elements articulate with the quadrate. Both elements are present in Labyrinthodonts and in most of the extinct groups of reptiles; among recent forms in Lacertidae, Varanidae, Tejidae; one three-armed piece in Sphenodon, chameleons and crocodiles, without, in Sphenodon at least, any trace of a compound nature; one piece, forked, in Agamidae; one simple piece in most of the other Lacertilia, and in snakes.
is always formed by the articular bone, not by the angular
which lies on the ventral side, about the middle of the
jaw; it is fused with the articular in Geckos, some
Teiidae, Amphisbaenidae, and some other bur-
rowing kinds. The splenial is absent in chameleons,
and near the vanishing point in some of the Agamidae.
The coronoid is always present, for the inser-
tion of m\_ass\_eter muscles. In the pleurodont lizards
the outer wall of the dentary forms a ledge, against
the inner side of which are fixed the teeth with
cementum.

The \textit{snakes’} skull shows many peculiarities, and
most of the bones of the cranial capsule fuse together without sutures. The
occipital condyle is triple, the lateral occipitals and the basi-
occipital taking equal share in its composition; the basioccipital
is excluded from the foramen magnum; frequently one common
epiphysal pad covers this tripartite condyle. The supra-
occipital is likewise excluded from the margin of the foramen
magnum by the lateral occipitals. The basisphenoid is prolonged
forwards into a long presphenoidal rostrum, on the upper sur-
face of which the trabecular cranium, which persist as cartilages,
extend forwards to blend with the median ethmoidal cartilage.
There are no al\_i- and no orbitosphenoids, their places being
taken by downward extensions of the frontal bones, which
descend to this sphenoidal rostrum and then turn inwards
to meet together on the floor of the cranial cavity. There is
consequently no interorbital septum. The parietals also de-
sceud laterally, but unite with the basisphenoid by suture. On

The **Vertebral Column.**

The vertebrae of all reptiles are gastrocentrous, that is to say,
the centra or bodies of the vertebrae are formed by the originally
paired, interventral cartilages, while the basiventrales are reduced,
peristating either as so-called intercentra or wedge-bones, or as
intervertebral pads, or disappearing altogether; the basidorsal
elements form the neural arch. At the earlier stages of develop-
ment the gastrocentrous vertebrae behave in the same way as in
the Urodela, except that the interdorsal pair of elements is
suppressed from the beginning (the very elements which in

Stegocephali and most Anura form the centre), therefore the typical batrachian vertebrae are notocentrous. If the remaining three pairs of constituent elements of each vertebra (the neural arch, the centrum and the intercentra) remain separate, the vertebrae are called temnospondylos (глебов, i. e. στροφόδος, a vertebra). If the neural arches and the centra are sutorally united, or are fused with each other, the vertebrae are called stereospondylous (eropus, solid). In many fossil reptiles most or many of the vertebrae are temnospondylos; in most of the recent Amniota they are consolidated, but the atlas or first vertebra remains usually in a relatively primitive condition, and is temnospondylos but for the usual modification that its centrum becomes attached to that of the second vertebra and forms its odontoid process. The composition of gastrocentrous vertebrae is best illustrated by the first and second cervical vertebrae of crocodiles, whence by reduction and fusion the structure of every other vertebra can be explained. We have only to add that the ribs are genetically derived from lateral outgrowths of the basiventral elements, whilst the chevron bones are mere ventral outgrowths from the same basil cartilages. The most primitive vertebral column is that of the Geckos. The ossification on to the caudal ends of the centrum next in front, to which they do not belong genetically. Exactly in the middle of each vertebra the thin shell of the centrum forms a cartilaginous septum, of what is often wrongly called chondral cartilage. When this septum is complete, and this seems to be the normal condition in the tail, the chorda is here rent asunder, otherwise it is only constricted. This septum is but slightly invaded by ossification, and consists of large cells which remain the remnants of young or embryonic cartilage. It coincides exactly with the line of transverse division of most of the caudal vertebra into an anterior and a posterior half, the division gradually extending right through the bone of the neural arch. The same kind of division, and from the same causes, exists in Sphenodon and many lizards, in fact in all those reptiles which can reproduce their broken-off tail. It is from the septal cartilage that the regeneration starts (fig. 26).

Sphenodon also has biconvex vertebrae owing to the persistence of the chorda dorsalis in the intervertebral region; otherwise the vertebrae are solid. Intercentra occur from the atlas regularly into the tail, where they carry chevon bones. The atlas-ring (fig. 25, g) is composed of the first intercentrum and a pair of neural arches which remain quite separate and carry on the dorsal surface pair of ossicles, the disconnected supraventral elements of the atlas, erroneously supposed to be the remnants of the "protoasals." Cartilaginous intercentral rings, pads or menisci, occur throughout the column; in the tail they carry chevrons. For the instructive detail of the composition of the first and second cervical vertebra see fig. 25, 7 and 8. Some of the posterior neck and anterior thoracic vertebrae have an unpaired hyopophysis arising from the centrum. The vertebrae have the usual processes, viz. spinous process, a pair of anterior and posterior zygopophyses arising from the neural arch, diapophyses likewise from this arch for the articulation with the tubercular portion of the rib; short parapophyses from the centra for the capitular ends of the ribs; the transverse processes of the 12th vertebra, and following, carry the whole rib, and are like the processes of the lumbar vertebrae diapophyses; the so-called transverse processes of the tail are mainly the anchylosed or fused ribs themselves.

Chelonia.—The vertebrae are sometimes in the various regions of the same column opistho-pro-or amphicoelous, or even biconvex. Intercentra occur regularly on the first two or three cervicals, and on the tail as paired or unpaired nodules, or as chevrons, which articulate mostly with the previous centra and occasionally fuse with them. Intercentral, fibrocartilaginous disks occur regularly, mostly in the shape of rings; the first is the transverse ligament of the atlas-ring. In the Trionychidae (fig. 25, 10), but also in some other tortoises, the various pieces of the atlas do not anchylose, and the first centrum remains also movably attached to the second, although it sometimes carries, 1 There remained a flaw in the correctness of the view that the bodies of the amniotic vertebrae are formed by the paired interventral pieces, since the bodies were known always to appear from the first as unpaired, cartilaginous masses, until G. B. Howes found them to consist of a right and left pair in the embryos of Sphenodon.
and fuses with, the second intercentral piece. The entire atlas remains in a primitive, typically temnospondylous condition. On the other hand, in some Pleurodira, e.g. Platemys and Chevly, all the constituent parts of the atlas coalesce and form a complete, solid vertebra, which articulates by a concavo-convex joint with the true centrum of the second vertebra. The normal number of cervical vertebrae is eight in all Chelonians. The last cervical has sometimes, e.g. Chevly, a very peculiar shape with strangely modified articular facets, in correlation with the procumbent neck. The neural spines of the trunk vertebrae broaden out and fuse with the neural plates of the carapace. A secondary modification takes place in many Pleurodira, which by the reduction of the neurals to the costal plates, which then meet in the dorsal line and cover the neural spines. The caudal vertebrae are often much reduced in size, although not always in numbers, when the tail is very short, as in the marine turtles. In various species of Testudo about half a dozen of the last caudal vertebra fuse together into a veritable urostyle, which is covered with a claw- or nail-shaped sheath of horn. In some of the gigantic tortoises of Mauritius this caudal vertebra complex is fully 5 in. long and 2 in. broad, of an extraordinary appearance.

The vertebrae of the Lacertae, or Lizards proper, are a direct further development of those of Sphenodon. The chorda disappears; the vertebrae are procoelous, with an articulating knob behind. Intercentra, in the shape of osseous, unpaired nodules or wedges, persist on most of the cervical vertebrae; they are absent in the trunk and reappear in the tail, either as wedges or with chevrons. The first intercentral forms the central half of the atlas, with the neural half of which it is connected by suture. The second fuses mostly with the cranial end of the second centrum and with the caudal and ventral surface of the odontoid, forming a downward-directed hook. Frequently the fusion remains incomplete, or the wedges may completely merge into the epistropheal mass without leaving any outward traces. Boulenger has made the important observation that the intercentra of the tail are sometimes paired, e.g. in Heloderma. When the caudal vertebrae are strongly procoelous, the knob is very long and the chevrons are attached to its neck, having shifted on to the vertebra in front, while their basal intercentral piece, or pieces, remain in the original position. In Ophisaurus the chevrons are absolutely fused with the caudal ends of the centra and thus assume a superficial resemblance to the vertebra of Urodaia. The splitting of the tail-vertebrae and regeneration have been described on a previous page. The trunk-vertebrae of the Tejidae and the larger Iguanidae possess additional articulating processes and facets, besides the usual processes. The Zygosphene is a wedge-shaped process with two articular facets, which projects forward from the anterior side of each neural arch. The Zyganturm forms a corresponding excavation with a pair of articular surfaces on the hinder side of the arch. The crests on the tail and trunk of many lizards, e.g. Iguanidae, are entirely tegumentary structures and not supported by the axial skeleton, except in some chameleons, e.g. Calumma, and in the peculiar genus Brookesia; in these the accessory much-complicated processes are enormously elongated and support the high cutaneous crest which arises from the back, especially in B. ehenis.

The, vertebrae of the snakes are procoelous (figs. 27, 28, 29). Besides the zygapophyses, they have zygosphenes on the neural arches; the ribs articulate with the parapophyses. Long, unpaired hypapophyses arise from the centre of the anterior neck and trunk vertebrae to a variable extent. In Dasyptelis and Rhabdion a considerable number of these processes perforate the oesophagus and act as crushers of the shell of the eggs which these snakes swallow. The often-repeated statement that these processes are capped with enamel is erroneous. The caudal vertebrae are devoid of chevron bones, but they carry paired hypapophyses, and they have transverse processes which also are generally bent downwards.

Lastly, the numbers of vertebrae composing the whole column and its various regions. In the snakes we can distinguish only between atlas and epistropheus, trunk and tail. The numbers vary exceedingly, in the trunk up to several hundred.

The tail may contain only a few, e.g. in the burrowing Typhlops, Glauconia, Uropeltis; or it may be very long, as for instance in Boa. There is no obvious reciprocal correlation between the length of the trunk and the tail. In the other orders of reptiles the tail is well marked, except in the snake-shaped lizards. If we define as first thoracic vertebra that which is the first connected with the sternum, all those anterior being cervical, the neck-vertebra number 5 in chameleons, 7 in Sphenodon, in the Chelonians and in the lizards, with the exception of the majority of Varanus, which have 9 like the Crocodilia.

The ribs, having arisen as lateral, separated off processes from the basiventral elements, show many modifications in their proximal attachments. These can be best studied on the skeleton of a young crocodile (figs. 25, 7, and 8). The first pair of ribs is very long and broad, attached to the unpaired ventral piece of the atlas-ring; the tubercular portion is indicated by a very small rugosity. The second pair of ribs is still larger; the capitulum attached to the second intercentra piece which fuses with the odontoid process; the tubercular process is weak or represented only by a ligamentous connexion with a small knob of the odontoid process; consequently the tuberculum has shifted its attachment away from the second vertebral. The other cervical, and the anterior thoracic, ribs have complete
capitular and tuberculare processes, the bodies and with dorsolateral which, articulating with processes of the neural arches of their vertebrae, enclose typical transverse canals. In the posterior thoracic region the ribs are attached entirely to transverse processes of the neural arches, both capitular and tuberculare portions having left the bodies or centra; the same arrangement prevails in the tail, but the ribs are very short and soon fuse with the processes. The two sacral ribs are very thick, articulating with the bases of their neural arches, and they even form part of the intervertebral joint! In Sphenodon the first three ribs are represented by bands of connective tissue only, with similar attachments as in crocodiles. The other cervical ribs are ossaceous; their short capitular retain their partly intercentral attachment, while the tuberculare are carried by low processes of the centra. In the thorax both capitulum and tuberculare merge into one facet, which is gradually shifting farther tailwards and upwards until the attachment reaches them, and then lies upon the neuro-central suture. The first caudal vertebrae also possess ribs, very short and soon fusing with the diapophyses of the neural arches. In the cervical region of the Chelonia the ribs seem to be absent. In the thorax they retain their primitive intercentral position throughout life, assuming (except the first pair, which remains short and least modified) an absolutely intervertebral position. From the lumbar or presacral region backwards the capitula are gradually shifting upon short processes of the centra, until in the tail the vestigial ribs are carried by the diapophyses of the neural arches. In Sphenosoma (fig. 31) all the ribs are free; in the other Chelonians the ribs, generally in the recent species, flatten and become surrounded by the growing membrane bone of the dorsal plates, and the cartilage of the ribs (except the capitular and neck portion of the fourth, which cannot be got at by the dermal bones) undergoes a process of calcification. Ultimately this is resorbed and its place is taken by the dermal bone, which forms, so to speak, a cast of the rib. Several of the short presacral ribs, and of course the postscerals, are not drawn into these enormous changes, although the carapace covers, and indirectly affects, them.

Certain changes initiated in Sphenodon are more marked in the ribs of the Lactoria; cervical ribs are often long in the lower neck. In the trunk the capitulare portions are often much reduced, and in these cases the ribs are suspended mainly by their tuberculare portions, usually from the diapophyses of the neural arches near the anterior end.

In the snakes all the vertebrae, from the second cervical to the tail, carry ribs. These are very movable, articulating with a rather large, more or less vertically placed facet, which is borne by the parapophysis or transverse process; sometimes the

rib retains traces of the original division into a capitular and tuberculare portion. The ribs of the snakes, although long, consist only of their dorsal portions. In snake-shaped lizards, e.g. Pseudopus, rather long ribs begin with the fourth vertebra.

Uncinate processes are developed only in Sphenodon and in the Crocodilia. They are not homologous structures, arising in the former from the posterior margin of the middle of the dorsal portions of the ribs, overlapping the shaft of the next following rib; in the crocodiles they arise out of the middle portion of the ribs, remaining cartilaginous, whilst the middle portion coalesces with the dorsal. Only in Sphenodon and Crocodilia then do the uncinate ribs consist of three successive pieces; in the Lacertilia they consist only of the dorsal and the ventral or costosternal. The latter remain cartilaginous, or they calcify, but they never ossify.

The sternum and further modifications of the ribs of the trunk.

—The sternum of most reptiles consists (1) of an anterior portion (presternum, Parker; pro sternum, Fürbringer; mesosternum of Gegenbaur), which is generally broad, more or less rhomboid and carries the shoulder-girdle, and on its posterior sides several pairs of ribs; (2) of a posterior portion (mesosternum, phrynosoma of Parker; xiphisternum of Fürbringer; metasternum of Gegenbaur), which is narrower, sometimes metameric, carries several pairs of ribs, and generally divides into a right and left xiphoidal half, each of which is continued into one or more ribs. These ribs tend to lose their connexion, and in these cases the sternum ends in two typical xiphoid processes. The distinction between pre- and metasternum is arbitrary. In Sphenodon the broad sternum plate carries only three pairs of ribs, the 8th to 10th, and there is no xiphisternum. The other ribs of the trunk are long and compound, but they remain free and do not approach the mid-line. From the posterior edge of the sternum to the pelvis extends the complicated parasternum, embedded in the abdominal wall; it is composed of about two dozen sets of abdominal ribs, each set containing a right and a left and a median chevron-shaped piece. In the Crocodilia the presternum carries only two or one pair of ribs, always that of the 10th vertebra. The narrow, more or less metameric metasternum carries seven or eight ribs, the last one to three being xiphoidal. The post-thoracic ribs gradually decrease in length; about three presacral vertebrae have no ribs, and so are typically lumbar. The sacral ribs are generally the 25th and 26th in Crocodilus and Alligator; sometimes the 24th and 25th in Gavialis. The parasternum consists of only seven or eight transverse sets, each composed of two right and two left narrow splint-bones. All these parasternal elements belong to the category of dermal bones, together with those of the plastron of tortoises, inherited from Stegocephalian conditions.

The Lacertilia present an almost endless variety. The presacrum is rhomboid and broad; it carries from three to six pairs of ribs, mostly four or five; the first thoracic rib is that of the 9th vertebra, the only exceptions being the chameleons with only five cervical vertebrae, and Varanus, which has usually nine cervicals like the crocodiles. The last cervical rib in these long-necked lizards is very long and has all the appearance of having but recently severed its connexion with the sternum. The presternum of Lacteria sometimes has a window, e.g. some species of Lacteria, Phrynosoma, Iguana, or a pair of windows, e.g. Agama, Liolepis, Gonocephalus. The xiphisternum carries a variable number of ribs; it is either scarcely distinguished from the anterior plate, or it is long, and in these cases either double, e.g. Iguana, Gerrhonotus, Varanus, Zonurus, Agama, Cyclopus, Lacerta; or single, e.g. Zonosaurus. The post-sternum ribs shorten gradually in the majority of the Lacertia, and there is sometimes a ribless lumbar vertebra, e.g. in Iguana; in many Lacertilia, however, the ventral cartilaginous halves of the ribs are connected with those of the other side, either by ligaments, or they join together, forming complete hoops of thin cartilages. Such ribs occur in all Geckones and Chameleons, but also in many Iguanidae, Scincidae, and even in the Anelytropidae; their numbers vary much, from 27 in the Scincoid Aconia medebras, 7–10 in Polychrus, 8 in Chamaeleo.
Geckos possess a complete shoulder-girdle; the ventral portion shows, e.g. *Hemidactylus*, three pairs of windows; only one in *Uroplatus*. In the latter the interclavicle is much reduced; the clavicles meet each other and are slender rods. In the Geckonidae and Eublepharidae the ventral halves of the clavicles are dilated and possess each a foramen; the interclavicle is cross-shaped.

In the more or less limbless genera of lizards the shoulder-girdle is much reduced. In *Chiroles*, which still has functional fore limbs, the clavicles and the interclavicle are absent, the coracoids are not divided from the precoracoids; in the limbless *Amphibiaenidae* the girdle is reduced to a pair of cylindrical ossicles in *Amphibiaena*, *Blanus* and *Trogonophis*; no vestiges exist in *Rhineura*, *Lepidodactylus* and *Anops*.

Foramina in the broadened clavicles occur also in various Lacertae, for instance in the Iguanid *Laemochus*, in the Scinca *Trachysaurus*, in *Plestiodon*, *Zonasaurus* and in *Lacerta simonyi*, but not in *L. agilis*. In *Mobula* the median portions are especially broad and show each two foramina. Their presence can be of but very doubtful taxonomic value.

The girdle of the Crocodiles is considerably simplified. Scapula and coracoidia, movably united, at least in younger specimens. The precoracoid is slightly indicated by a process of the coracoid, which is perforated by the supra-coracoidal nerve near the glenoid cavity. Clavicles are absent. The interclavicle is reduced to a long, flat splint-bone, which is firmly fused on to the sternal cartilage. The Cheloniid shoulder-girdle shows several very remarkable modifications. Instead of lying outside the trunk, it has been transferred into the cavity of the trunk, the carapace with the ribs covering it from the outside. An explanation of the changes implied in this transposition is still extant. Chelonians are, moreover, the only reptiles besides *Pterosaurus* in which the scapula is attached to the skeleton of the trunk. The scapulae stand in a more or less vertical position, and their dorsal end rests against the inside of the nuchal plate, where this is sutured to the first neural and the first costal plate, a little in front of and sideways from the first short rib. From near its ventral end the scapula sends off a long process, which converges transversely with its fellow. This process, the clavicle(!) or the precoracoid of many authors, is the acromial process, the *Plesiosauri* giving the clue as to how an acromion can assume such an abnormal position. The coracoid, with a suture between it and the scapula, is very long and extends horizontally backwards, not meeting that of the other side. The sternum being

---

**Fig. 32.—Rudiments of pectoral arch—1, of Anotis macrogaster process. The coracoid forms one continuous mass with the precoracoid, through the middle of which passes the supra-coracoidal nerve; the coracoids articulate with their whole bases with the sternum.**

**Fig. 33.—Sternum and Shoulder-Girdle of Amblyrhynchus subcris- tatus (after Steinacher). cl, clavicle; cc, coracoid; h, humerus; ic, interclavicle; mc, mesocoracoid; ms, mesocapula; pc, precoracoid; s, scapula; st, sternum.**
absent, and clavicles and interclavicles forming the epi- and endo-plastral elements of the plastron, the shoulder-girdle is nowhere in contact with the skeleton except at its dorsal end.

The Fore Limbs.—The humerus has near its upper end a median process, and at a variable distance a lateral process, near which is the biceps-fossa. Above the radial or outer condyle exists a foramen for the passage of the radial nerve in Sphenodon, in the Lacertilia, and in many Cheloniens, e.g., Chelone and Sphaeregis; such an entepicondylar foramen is absent in turtles. Above the ulnar condyle exists, but only in Sphenodon, the entepicondylar foramen, for the passage of the nerves medianus and brachial vessels. Thus Sphenodon alone possesses both foramina, the crocodiles neither.

Ulna and radius always remain distinct; the former is generally the stouter although not always the larger bone. The carpus may contain as many as 12 separate elements; unare, intermediate, radiale, 2 centra, a pisiform on the ulnar and a small node in a corresponding position on the medial side, and 5 distal carpals. In Sphenodon the centra are sometimes fused into one, and the radial node is absent; the numbers of phalanges are, 2, 3, 4, 4, and 3 proceeding from the first to the fifth finger. The carpus of the Chelonia is likewise primitive, with various unimportant reductions; Chelydra possesses one or two centra, whilst pisiform and extra radial are absent; both these bones are present in Emys, but the centrales fuses with the radial carpal, and the fourth and fifth distal carpal are fused together. In Testudo the pisiform is small; intermediate, centrale and radiale are represented by one bone only, and the first, second and third distal carpals are fused, whilst the remaining are free. In the marine turtles the fore limbs are transformed into paddles; the ulna is considerably shorter than the radius; all the normal nine carporeal elements remain distinct; the pisiform is much enlarged, helping to increase the paddling surface, and it has moved from the ulnar carpal to the side of the fifth distal carpal. The three middle fingers and toes have mostly 3 phalanges; the pollex and hallux have always 2; the number of phalanges of the fifth finger varies from 3 to 1, of the fifth toe from 2 to 0. The greatest reduction occurs in Testudo and its allied genera of typical land-tortoises, Homopus, Pyxis and Ciniyys, the formula for the fingers being 2, 2, 2, 2, or 1, and 2, 2, 2, 2, or 1, for the toes. In Pleurodirae phalanges are present only, owing to fusion of the first and second phalanges with each other.

Considerable advance is marked by the Crocodiles. The intermediate and centrale are lost; the pisiform is small, ulnar and radial are considerably elongated and enlarged. Of the distal carpals the two last are fused into one bone, and the third, first together with the central, are transformed into a pad-like cartilaginous and ligamentous piece between the large radial and the first and second finger, to which the pad is firmly attached. The other fingers articulate with the "humatum." The result of the whole arrangement is the formation of two main joints, one between fore arm and carpus, the other intercarpal. The number of phalanges is 2, 3, 4, 4, 3.

The conditions prevailing in Lacertilia are connected with those of Sphenodon. The intermediate is lost, the other normal carpal and radii are present, also the pisiform; the first distal carpal is much reduced and the correspondingly enlarged radial carpal comes into articulating contact with the first metacarpal. The numbers of phalanges are 2, 3, 4, 4, and 2 or 3 for the fifth finger. The hand of the chameleons is most modified; the first three fingers form an inner bundle opposed to the outer or fourth and fifth fingers; in correlation herewith the third and fourth carpals are lost, and free. The carpus and metacarpus are lost, and the other elements remain free, and A. Stecker has found a small intermediate present in the young, in a position which indicates that its subsequent absence is due to loss, not fusion with neighbouring elements.

The Pelvic Girdle.—The ilium is attached to the vertebral column by means of the two sacral ribs. 1 The ischia and the pubic bones join the ischium at the acetabulum, which is not perforated, except in crocodiles. The ischia and pubes invariably form symphyses at their ventral ends, except the so-called pubes of the crocodiles, and these two symphyses are further continuous with each other, dividing the pubo-ischiadic space into a right and left foramen obturatum of very variable size. They are small and round in Testudo, divided by a broad, bony bridge, larger in Chelone, separated by a chiefly ligamentous, partly cartilaginous string; largest they are in Sphenodon and in the Lacertilia. Frequently the symphyseal space of a small alligator end of the pubic symphysis remains cartilaginous, unpaired, e.g., in most Cheloniens and Lacertilians, comparable with the epipubis of Uroela. A corresponding cartilage, the os cloacae or hypooischium, is continued backwards, from the ischiadic symphysis towards the vent, serving for the attachment of spinchter muscles; it occurs in many lizards and tortoises. In the Cheloniens the pubic bones are generally much stronger than the ischia, and they send out each a strong lateral pubic process, directed forwards and outwards; the obturator nerve passes through the wide obturator foramen. In the placodontosaurus and tortoises the ends of the ilia and those of the lateral processes of the pubes are much broadened and firmly ancylosed with the posterior costal plates and with the xiphiplastron respectively. The whole pelvis, like the shoulder-girdle lies inside the body. The pelvis of Sphenodon is essentially like that of the Lactertilia. The pubes are slender; they send out a pair of lateral processes, near the base of which the obturator nerve pierces the shaft of its pubis. This lateral process is the homologue of the long, slender pubis of birds. The chameleons' pelvis is peculiar. The pubes are devoid of lateral processes, but from their anterior end arises a pair of small cartilages in a transverse direction; their ends are connected by ligament with the median anterior portion of the ischiadic symphysis. The crocodilian pelvis is very aberrant. The ilium is broad and sends two processes to the acetabulum, which retains a foramen; the posterior process articulates movably with the ischiium; the preacetabular process fuses in young specimens with a separate, ossifying, cartilaginous piece, which then forms a rough joint with the anterior portion or process of the ischiium, which closes the acetabulum on its ventral side. To this ischiadic process is attached the freely-movable, club-shaped bone, generally called the ischiadic symphysis. The homologues of these club-shaped bones and of the small bone mentioned above are not clear. The club-shaped bones remain asunder; the ischia form a long and firm symphysis. The obturator nerves pass out of the pelvis between the ischium and the club-shaped bone, close to the posterior margin of the latter.

The posterior limbs show essentially the same composition as the fore limbs, but the modifications in the various reptilian orders are much greater. The femur has generally a well-marked neck. Fibula and tibia remain distinct; the former usually shows a reduction in thickness. In the tarsus we observe never more than two proximal tarsal elements, a reduction due either to the suppression of the intermediate or to its enlargement and concomitant loss of the tibial element. The least-modified foot-skeleton is that of the Chelydridae, the lowest Cheloniens. The proximal row is composed of a fibulare, and a much larger piece articulates with both tibia and fibula, the "astragalus"; the centrale is present; the first three distal tarsals remain separate, each carrying a toe. The fused fourth and fifth tarsals carry the fourth toe, and, laterally attached, the hook-shaped fifth metatarsal. Chelone shows the same arrangement; except that the centrale is fused with the astragalus. In Testudo, Emys, the fibulare, astragalus and centrale are fused into one broad mass, with the result of forming a cruciar-tarsal and an intertarsal joint. The same arrangement reached by the Testudinidae is universal in the Lactertia, with the further modification that the three first distal tarsals fuse on to the proximal ends of their respective metatarsals. Most aberrant is the tarsus of Chameleons, in which the first and second toe one passing through the acetabulum. In birds it is likewise post-in mammals praacetabular.
form a bundle opposed to the rest; the fibulare and tibiale are fused into one bone; the fused fifth and fourth dorsal tarsals form a very large half-globular piece for the three outer toes, whilst the second toe is carried by the third tarsal distal, besides which there are three more small cartilages, one of which may be the displaced second tarsal or the still independent central. The tarsus of Sphenodon is like that of typical lizards, but none of its distal tarsals are fused on to metatarsals. The Crocodilian foot marks an advance. The astragalus is large, articulating well with tibia and fibula, and against the fibulare, which forms a typical, heel-shaped calcaneum. The fifth and fourth distal tarsals carry the fourth toe and the hook-shaped fifth metatarsal to which the fifth toe is reduced. The third, second and first distal tarsalia scarcely contain osseous nodules; they form together a wedge-shaped cartilaginous pad between the astragalus and the first and second toes. This attachment of the distal tarsals to the metatarsals reminds us of the Lacertilian condition, the result in either case being a still more marked intertarsal joint in addition to the cruro-tarsal.

Most well-footed reptiles retain all the five toes; only the crocodiles and a few tortoises have lost all the phalanges of the fifth toe. The phalangeal numbers are in the Lacertilia 2, 3, 4, 5 and 3 in the fifth toe; in chameleons 2, 3, 4, 5; in most tortoises 2, 3, 4, 5; but in Haplopus, Pyxis and Gekklys 2, 2, 2, 0; in the crocodiles 2, 3, 4, 0. The embryos of crocodiles are said to be hyperphalangeal; i.e. as many as 7 phalanges on the fourth; 5 or 6 on the fifth finger; 4 on the fourth toe, and there are traces of the fifth toe. In the adult the fourth toe remains without a claw. Burrowing and living in sand, or humus, is in many lizards correlated with reduction of the limbs and their girdles. The vestiges of the hind limbs come to lie as near the vent as possible. The reduction occurs in various families, especially in Lacertilia.

In most cases the fore limbs disappear first, but in the Amphibiaelenidae, cf. Chirotes, and in the Tejideae, the reverse takes place. Whilst degeneracy of the shoulder-girdle is delayed long after the loss of the anterior limbs, that of the pelvic arch precedes the loss of the hind limbs. Cope has drawn up a tabular statistic of the loss of digits, limbs and their girdles on pp. 202-3 of his work, Crocodiles, Lizards and Snakes of North America (Washington, 1900). The peculiar hind limbs of the Dibamidae are described in the article Lizard.

The majority of snakes have lost all traces of the limbs and their girdles, except the so-called Peropoda (see Snakes: Classification). The vestiges of a Boa and of a Glaucosia are shown in fig. 35.

**Tegumentary System.**

The skin of reptiles is characterized by the strong development of its horny stratum; on the outside of it exists a thin cuticular or epidermal layer. An important feature in most lizards and in the snakes is the existence of a "sub-epidermoid" or transitional layer which is produced by the migration of ectodermal cells into the cutis. The immigration takes place during the embryonic development, observed first by Korschner, who, however, misinterpreted the process. Pigment cells, black chromatophores also, make their first appearance in the epidermis and then migrate into the transitional stratum, as has been first correctly stated by F. Maurer. The horny stratum is shed periodically, several times during the year, and as one entire piece in snakes and a few lizards, e.g. Anguidae; in most lizards, chameleons, geckos and in Sphenodon the thin, transparent colourless layer comes off in flakes. In crocodiles it is not shed except for the usual wear and tear, nor in tortoises, although in some e.g. Chrysemys, a periodical peeling of the large shields has been observed.

In all reptiles the cutis is raised into papillae, or folds. When the papillae are small the skin appears granular; when they are large, flat, mostly imbricating, they form scales; when they are very broad-based and still larger, they are called scutes or scales; in the crocodiles and many epidermal covering parts of these elevations, often e.g. in many snakes, with a very fine system of ridges of its own. Such a scale, cuts and horny sheath, may form spikes, or crests. They all have only basal growth. Thus, for instance, a shield of a tortoise-shell is a much flattened scale, or cone, with the apex more or less in the centre, surrounded by marginal ridges which indicate the continuous additional growth at the base. The central "areola" represents in fact the size of the shield at the time of hatching.

Of very common occurrence is the development of bone in the cutaneous portion of the scales; such osteoderms occur in many lizards, very strongly developed in the scales of the crocodiles, especially on the back; they also occur in the skin of tortoises especially on their legs and on the tail, and they probably constitute the peculiar shell of Sphargis, the leathery turtle (see Tortoise). Sphenodon and chameleons are devoid of such osteoderms, in geckos they are likewise absent, but calcifications occur in their tubercular skin. A similar process seems to have produced the egg-tooth of crocodiles and tortoises (see under Teeth below). Calcareous deposits, or at least deposits of guanine and more commonly of carbonate of lime, play a considerable part in the skin of lizards and snakes. These waste products of the metabolism are also deposited in the sub-epidermal and cuticular layer. In combination with superimposed yellow or red pigment, and with the black chromatophores as a foil, partial or complete screen to the light, as the case may be, these mineral deposits are to a great extent answerable for the colours and their often marvellous changes in the skin (see Chameleon).

Peculiar pits in the scales of snakes and crocodiles are described under Sense-Organ below. The skin of reptiles is very poor in glands, but the few which exist are well developed. Crocodiles possess two pairs of glandular musk bags which open by large rather long slits on the lower jaws against the inner side of the jaw. Another pair of musk glands are the anal glands. During great excitement all these glands can be evorted by the crocodiles. Sphenodon and snakes have only the anal pair. Water tortoises have glandular glands, which secrete a strongly scented fluid, opening near the posterior rim of the bridge. Trionyx has additional glands opening near the anterior part of the plastron. Peculiar glandular structures are the femoral pores of many lizards. They lie in a line from the inner side of the knee to the anterior margin of the anal region, to which they are restricted in the limbless Amphibiaelenidae. Each pore leads into a subcutaneous pocket, sometimes with slightly acinous side chambers, the walls of which produce a smeary, yellowish matter consisting chiefly of the debris of disintegrated cells which dries or hardens on the surface in the shape of a little projecting rod. They occur in both sexes, but are most active in males during the pairing season. Their use is unknown. It would be far-fetched to liken them to forerunners of the sebaceous portions of milk glands, although not so imaginary as to see in them and in the sensory pits of snake scales the forerunners of the mammalian hairs.

Claws, scarcely indicated in Batrachia, are fully developed in all limbed reptiles. The base is sunk into the skin like our own finger nails; the dorsal and ventral halves are differentiated into a harder, more curved dorsal sheath-like portion, and into the beginning of a sole, especially in crocodiles and in blunt-toed tortoises. The first claw to be reduced is that of
the fifth digit. The claws of many gekkos are "retractile," like those of cats; the adhesive lamellae on the under side of their digits have already been described (see Gecko).

Nervous System.

The hemispheres are still much longer than broad, and pass, especially in lizards, gradually into the olfactory lobes, into which continue the ventricles of the hemispheres. The dorsal walls of these are thin, especially in crocodiles, although they possess already a considerable amount of grey matter. The basal masses of the fore-brain bulge into the rovinny ventricles like cushions. Fibres referable to a corpus calosum are scarcely separated from those of the still much stronger anterior commissure. The epiphysis comes to the surface between the hinder parts of the hemispheres. The pineal eye is described below under Sense Organs. The hypophysis has lost a shallow infundibulum. The mid-brain shows a pair of dorsal globular swellings, each with a cavity; they separate the hemispheres from the cerebellum. Of the hind-brain, the middle portion is by far the largest; although the dorsal wall of this cerebellum is thick, and rich in grey matter, its surface is still quite smooth and it shows no trace of an arbor vitae. It covers but a small portion of the wide fourth ventricle.

The spinal cord shows a brachial and a lumbar longitudinal swelling, especially marked in tortoises, but without a rhomboidal sinus. The cord is continued into the end of the tail.

The cranial nerves of the reptiles agree in their arrangement and distribution more with those of birds and mammals than with those of the Batrachia. The facial nerve sends a palatine branch to the palate and to the superior maxillary of the trigeminus, and a strong mandibular branch joins the third of the trigeminal, and further ramifications supply the sphincter muscle of the neck. The vagus and glossopharyngeus leave the cranium separately. The vagus then goes towards the heart, which in the Sauropsida is far removed from the head, and there possesses another ganglion, variously called ganglion trunci vagi or g. nodosum. It is connected by a nerve with the large ganglion supremum of the sympathetic. From the cardiac ganglion, and from the continuation of the vagus, are sent off several branches in succession, which, having to pass below or tailwards from the transverse carotic, aortic and Botallian vessels, have to take again a headward course to the larynx and pharynx; a side branch enters the heart by its truncus. The main mass of the vagus then supplies lungs, stomach and further viscera. The accessory or 11th cranial nerve arises with about half a dozen roots which extend often beyond the second cranial nerve; they collect into a thin stem which leaves the cranium together with the vagus, with which it is often fused; it supplies the coccyeal s. trapezius muscle.

The hyoglossus arises by two ventral roots, leaving the skull by two holes through the lateral occipital bone, near the condyle. The united stem is invariably joined by strong branches from cervical nerves, always from the first, mostly also from the second, sometimes also from the third. The details vary much; occasionally there are three cranial roots and foramina, and then only the first cranial joins the hyoglossus; this often fuses with the glossopharyngeal or with the vagus. In the broad and well-muscularized tongue of the crocodiles the right and left hypoglossal branches form a complete ansa, an arrangement in which A. Schneider saw the infraoesophagual nerve ring of Invertebrata!

The spinal nerves each issue behind, or through, the neural arch of the vertebra to which they belong genetically. The first spinal, or suboccipital, nerve has no dorsal roots, and, having lost its vertebral foramen, it passes through the foramen magnum to, in this manner, enter the spinal canal. The second spinal nerve begins to pass, in this way, that there are x few cervical vertebrae, but x + 1 cervical nerves, a condition prevailing in, and characteristic of, all Amniota. The hypoglossal-cervical plexus is separated from the brachial plexus by several metameres, according to the length of the neck. The brachial plexus is composed of about 5 nerves; the variations have been studied chiefly by M. Führinger. It is interesting to note that the brachial plexus still persists in snakes, although they have completely lost the anterior girdle and the limbs (Albertina Carlson). A disturbance in the pelvic region likewise indicates in snakes the former existence of a pelvic or lumbo–sacral plexus, which in limbless reptiles is composed of about 5 nerves, the last of which is weak and in many cases (by no means the rule) issues between the two sacral vertebrae, sending one branch to the ischiadic, another to the public plexus which supplies the cloacal region. (For details of these plexuses see the papers by Milvart, Jhering and Gadow.)

The sympathetic system shows considerable modifications in the various orders and even families of the reptiles. In the neck region, in Sphenodon and most lizards it is, on the right and left side, composed of two portions: one, more lateral and placed deeply, runs along the side of the vertebral column, starting from the first and second spinal nerves, with which it is connected by so-called rami communicantes; it is not connected with the other spinal nerves until it reaches, in the thorax, the first stem of the brachial plexus, and hereabout lies the so-called second thoracic ganglion. The other, superficial and more ventral, portion arises from the petrosal ganglion of the glossopharyngeal, and from the vagus ganglion, and then forms a long loop which joins the second thoracic ganglion. In its long course it sometimes, e.g. in Varanus, forms one common stem with the vagus, before it splits off. At a variable distance, but not far above the heart, the vagus possesses a big swelling, the ganglion trunci vagi, and the sympathetic stem, in the same level, or farther down, has likewise a large ganglion, the g. supremum vagi, or first thoracic ganglion. The vagus ganglion receives several nerve strands from this big sympathetic ganglion, and then divides as described above.

In the crocodiles the deep portion of the sympathetic begins at the vagus and extends in rope-ladder fashion into the thorax, there being, as in birds, regular transverse communicating branches with the spinal nerves, and the longitudinal strands run through the transverse foramina between the capitular and tubercular portions of the cervical ribs. The other, ventral, portion starts by a right and a left branch from the vagus ganglia, but both branches unite at once into one unpaired stem, which is deeply embedded in the middle line between the ventral muscles of the cervical vertebrae. Very thin branches connect this unpaired stem with the right and left sympathetic portions; small ganglia are embedded in the unpaired nerve.

The so-called second thoracic ganglion is in reality a compound of all the sympathetic ganglia of the four or five metameres of the brachial plexus. It forms the point of juncture of the deep and the superficial cervical sympathetic portions. From the posterior region of the thorax backwards the right and left strands run along their side of the vertebral column, with a communicating branch and a ganglion for each metamere; sometimes one or more successive ganglia are combined, for instance near the cloaca. After having supplied the latter, the sympathetic system appears exhausted and is continued into the tail by a very thin strand, which runs between the caudal vein and artery. The best illustrations of the sympathetic system are those by Vogt (neck of crocodile), J. G. Fischer (many
lizards), H. Gadow (cloaca of crocodile), J. F. v. Bemmelen (Sphenodon and others), W. H. Gaskell and H. Gadow (heart of tortoise).

**Sense Organs.**

1. **Tegumentary Organs of some Tactile or other Sense.**—Reptiles possess apparently no traces of those tegumentary sense organs which, belonging to the domains of the trigeminal and vagus nerves, have spread far over the body in fishes and batsrachia. They were developed by those classes in correlation with their essentially aquatic life. This does not apply to the reptiles which, as a class, are of absolutely terrestrial origin. Nevertheless all recent reptiles possess numerous low sense-organs, “tactile bodies,” in most parts of the skin, connected with the regional, spinal nerves. They are most obvious in snakes, appearing as one or more little colourless spots near the apex of each scale on the back. The spot is formed by a little cluster of epidermal cells, connected with a sensory nerve. Their lowest stage they show in *Sphenodon* and in lizards, whilst in crocodiles they have reached a higher stage, at the bottom of the tympanic cavity. The tactile bodies, most of which, united together, have sunk into the cuts, below the epidermis, forming a little pit, mostly near to the anterior margin of the flat scutes. They are most obvious on the belly of crocodiles, whilst in the American alligator such pits are scarcer, not because the organs are absent, but because these have sunk further into the skin.

The last stage is that met with in tortoises, which possess such tactile bodies in considerable numbers in the softer subepidermal layers, beneath the large hoary shields which themselves show no traces of them.

2. **Taste.**—The respective organs do not seem to have been investigated. That they exist is amply proved by the careful predilection for certain kinds of food which is shown especially by vegetable tortoises and lizards, independent of smell. Many lizards are, for instance, very fond of sugar.

3. **Nose.**—The sense of smell is well developed in all reptiles. In none is the olfactory organ degenerated; that the nasal passages, the nose itself, are never degenerated is explained by the fact that all reptiles invariably breathe through the nose, except snakes during the act of swallowing their prey. The nostrils, always paired, are frequently provided with valves, to shut out the water, or sand. In some water tortoises, e.g. *Trionyx*, *Chelys*, the nostrils are prolonged into a soft, unpaired proboscis. Double tubes exist in the snake *Harterton* (see Snakes, Opisthoglypha). The nostril leads into an antrum or vestibulum, this again into the nasal cavity proper, at the dorsal farther end enters the olfactory nerve, whilst ventrally it enters into the nasolaryngeal duct, with its posterior narial opening, or choana. The ducts are short in snakes and lizards, the choanae lying in the front part of the palate, but in tortoises and crocodiles they are placed far backwards, as has been described under *Skull* above.

Into the nasal cavity projects, from the septum, a concha, least developed in tortoises, most in lizards and snakes. Crocodiles show a beginning of separation into several conchae as in birds and mammals. A large nasal gland lies against the lateral, or ventral, side of the outer wall of the nasal cavity, into which also opens the nasolacrimal duct. Jacobson’s organ, of uncertain function, is present in most reptiles. It is paired. In tortoises it is still placed within its nasal cavity, against the median wall, and is still nothing but a recess of the same and its mucous lining. In lizards and snakes the organ has become completely separated from the nasal cavity, lying below it and opening, each by a separate passage, into the palate mouth, close to or still within the choanae. In snakes it is mushroom-shaped, with a very short stalk. It lies immediately below the floor of the nasal capsule, and the membranous wall of the cavity on which it lies is covered and protected by a bone, commonly called the turbinal, which extends out from the median nasal system to the maxilla. In crocodiles these organs are vestigial and soon disappear.

4. **Ear.**—In crocodiles the outer ear lies in a recess, dorsally overhung by the lateral edge of the bony squamoso-frontal bridge; it carries a flap of skin, provided with muscles, to close the ear tightly. In lizards the outer ear is quite unprotected, and when the meatus is very short and wide, the drum is quite exposed. No reptiles possess cartilages comparable to the mammalian outer ear. *Sphenodon*, chameleons, snakes have no outer ear, the skin passing over the region. So also in tortoises, but in some of the aquatic kinds its position is well indicated by softer and thinner skin; in others, for instance marine turtles, a thick leathery plug, or a bigger scale marks the former position. In various lizards, chiefly burrowing in sand, the ear passage is very narrow, or closed. The middle ear or tympanic cavity is quite obliterated in snakes, Amphibiaenae and some other snake-shaped lizards. In *Anguis* may exist individual traces. The cavity communicates with the mouth. In lizards the communication is a wide recess, lined with black pigmen, so that in these creatures the whole auditory chain can easily be inspected from the opened mouth. In tortoises the recesses are contracted into the Eustachian tubes, each of which opens by a separate aperture into the roof of the mouth. In the crocodiles part of the cavities is transformed into a system of cavities. The two Eustachian tubes open together in the mid-liness proper to a valve, between the basoccipital and basiphenoid; thence arises a median passage which with lateral arms and loops extends upward through the occiput into the cranial roof, connecting with the tympanic cavity, and further continued through the quadrates and beyond into the mandibles, by the siphonium.

In spite of the obliterated tympanic cavity of snakes, and the closed up outer ear passage and absence of a tympanic membrane in snakes and tortoises, these creatures can hear very well. The same applies to *Sphenodon*, but it seems doubtful whether chameleons can hear.

Through the whole middle ear, from the fenestra ovalis to the drum-membrane, stretches the chain of auditory ossicles or cartilages, partly attached to the posterior wall by the common lining membrane. The arrangement appears simplest in snakes, in chameleons and in tortoises, not because it is primitive but because it is so much reduced, partly in correlation with the abolition of the outer ear. In these creatures the columella goes as a bony, slender rod straight to the middle of the quadrate, against which it leans, or with which it articulates by a short piece of cartilage, the extra-columella. Here the whole chain ends. It looks like a proof that columella=stapedius, extra-columella=incus, and quadrate=malleus; or, with the usual ignoring of the little extra-columellar piece, that quadrate=incus, Gegenbaur’s favourite impossibility. In those lizards which have a tympanic membrane conditions are far less reduced. The extra-columellar piece sends out three distal processes; one leans on to the middle of the tympanic membrane, the second usually is fastened to the bony dorsal rim of the meatus, the third is directed downwards and is continued as a thin ligament towards the inner angle of the articular of the mandible, but before reaching this it comes to grief, being squeezed in between the quadrate and the posterior end of the pterygoid. The hyoid proper is of no account in snakes and tortoises, since it is reduced to very short distal pieces attached to the base of the tongue; but in lizards it remains in its original length, or it even lengthens, and shows many vagaries in its position and attachments. In embryos of *Sphenodon* and lizards it arises from near the junction of the columella with the extra-columella. It becomes very long, too long for the available space (perhaps correlated with lingual functions), and it forms a high loop, thereby causing the peculiar loop of the chorda tympani; the upward bend of the hyoid becomes connected with the parotic process of the cranium. Next shortens the portion between this connexion and the original proximal end of the hyoid, near the columellar mass. The upper end of the hyoid either remains attached to the parotic process (various lizards and *Sphenodon*) whence the lingual apparatus remains suspended, or the hyoid, having broken loose, leaves a little cartilage, Versaly’s cartilage, behind, at the end of the parotic process, and the hyoid horn remains free, in the majority of lizards. In *Sphenodon*, whilst
passing the distal portion of the extra-columella, part of the hyoid fuses with it, often forming thereby a little hole, the remnant of imperfect fusion.

In the crocodiles the arrangement is at first complete and diagrammatically clear, not obscured by vagaries of the hyoid, which is free and much reduced. In the embryo the large extra-columellar cartilage, abutting against the tympanic membrane, and with another process against the quadrate, sends its third downward process as a thick rod of cartilage to the posterior inner angle of the mandible with which it is directly in cartilaginous continuity. It was W. K. Parker's mistake to call this cartilage the cerato-hyal. In young embryos it looks like an upward continuation of Meckel's cartilage, much resembling mammalian conditions. But in nearly ripe embryos this cartilage is already reduced to a string of connective tissue, cartilage remaining only at the upper end, and where this string enters the mandible lies the stiphonium, the tube which connects the air cavities of the mandible with the Eustachian passages, the long connecting channel becoming—side by side with the extracolumellar-mandibular ligament—embedded into a canal of the quadrate, so that in older stages, and above all in the adult, the proper display of the whole arrangement requires a little anatomical skill. The whole string, whether cartilaginous or ligamentous, which connects the downward extracolumellar process with the articulare, is of course homologous with the continuation of Meckel's cartilage into the malleus of foetal and young mammals; and the chain of bones and cartilages between the auditory capsule, fenestra ovalis, and the proximal part of the mandible is also homologous wherever such a chain occurs; lastly, fenestra ovalis and membrana tympani are fixed points. Consequently columella=stapes, extracolumella of Sauropsida=lentiform=fenestra=incus=malleus of Mammalia.

The inner ear has been studied minutely and well by C. Hasse, E. Clason and G. Retzius. It is enclosed by the periosteum. The fenestra rotunda is surmounted by the osseous, the fenestra ovalis by the same and by the pro-otic, and this protects also the anterior vertical semicircular canal. The posterior canal is osseous, the horizontal is pro- and ophthalamic. The anterior canal is the largest of the three, a feature characteristic of the Sauropsida. The lagena, with its own acoustic papilla, begins to show a basilar membrane with papilla, at the expense of that in the saccus. In Sphenodon and lizards a slight curving of the lagena indicates the beginning of a cochlea, and a scala is developed in crocodiles, but neither cochlea nor scala is specially twisted. The endo-lymphatic ducts end as closed sacs, in lizards and snakes, in the roof of the skull, between the occipital and parietal bones. They reach an enormous development in many geckos, where they form large twisted sacs beneath the skin, covering the sides of the neck, which then assumes a much swollen appearance. They contain white otochlastic masses, with lymph. It is remarkable that the extent of these sacs varies not only in allied species, but even individually, independent of sex and age, although they are naturally liable to increase with age.

Eyes are present in all reptiles, although in many of the burrowing snakes and lizards they may be so completely covered by the skin as to have lost their function. Most reptiles have upper and lower lids, moved by palpebral muscles, and a third, the nictitating membrane, which can be drawn over the front of the cornea from the inner angle obliquely up and backwards. Its mechanism is simplest in lizards. A muscle, a split from the retractor muscle of the eyeball, arises from the posterior part of the orbit, is attached to the posterior wall of the eyeball, and there forms a pulley for the long tendon which arises from the median side of the orbit and passes over the back of the ball into the nictitating membrane. Contraction of this muscle draws the membrane backwards and over the eye. In crocodiles and tortoises the tendon of the nictitating membrane broadens out into a muscle (M. pyromidalis), which arises from the median side of the posterior portion of the ball; above the optic nerve it crosses over the broad insertion of the retractor of the ball, without being much guided by it, although this muscle by its contraction slightly prevents the nictitating tendon and muscle from touching the optic nerve.

It is easy to recognize the mechanism of birds as a combination of the two types just described; their muscles quadrates a. bursalis is of course the single muscle of the lizards, but now restricted to, and broadened out upon, the eyeball.

Special Modifications of the Lids.—In the snakes the upper and lower lids are reduced to the rim, and the nictitating membrane has become the permanent cover, which protects the eye like a watch-glass, leaving between itself and the cornea a space, drained by the naso-lacrimal duct, and behind this space the eyeball moves as freely as in other animals. A similar arrangement exists in the true geckos, not in the Eublepharidae, which still possess the outer lids. In some lizards, especially such as live in deserts, the middle of the lower lid has a transparent disk, and it is always the lower lid which is drawn over the eye, the upper in nearly all Sauropsida being much smaller and less movable; for instance, some specimens of the Lacertine genus Eremias in Africa and India. In the Indian genus Cabrita, and in Ophiops of Africa and India, the lower lid is permanently fused with the rim of the shrunken upper lid and forms a transparent window superficially looking like that of the snakes. Exactly the same arrangement has been developed by Ablephas, one of the Scincidae.

The eyeball is provided with the usual rectus and oblique muscles, in addition to a retractor oculi. Apparently all reptiles possess a pair of Harderian or nictitans glands, which open in front, in the nasal, inner corner, and lacrymal glands which open likewise into the conjunctival sac, but near the outer or temporal corner. The secretion of both is drained off through the lacrymal canals; which in lizards open below in the outer wall of the posterior nares; in snakes they open into the mouth by a narrow aperture on the inner side of the palatine bone.

The walls of the anterior half of the sclerotic of lizards, tortoises and Sphenodon contain numerous cartilaginous or osseous plates, which imitate in rige shape; they are absent in snakes and crocodiles. Internally the eye of most reptiles possesses at least traces of a pecten; very small indeed in tortoises, or in crocodiles where it is represented by only a few mosaiike, pigmented vessels. In many lizards these vessels, arising from near the optic nerve, form a network which extends right up to the posterior side of the lens; in others, especially in Iguanidae, is developed a typical, large pecten, deeply pigmented with black, fan-shaped or umbrella-shaped, sometimes folded. In chameleons it is a short cone; apparently
quite absent in *Sphenodon*. A falciform process and other remnants of a campanula are absent. In most of those reptiles which have but a rudimentary pecten, the retina is supplied by hyaloid vessels which spread over the surface of the vitreous body; such superficial vessels disappear with a greater development of the pecten, and the retina receives a chorioid supply; special retinal arteries from the a. centralis retinae, and veins, exist in snakes.

Ciliary processes of the choroid are usually small, a proper ciliary body being least developed in crocodiles; all reptiles have a ciliary muscle. The shape of the contracted pupil varies from round to a vertical slit; the latter is most marked in *Sphenodon*.

The retina shows usually a fovea centralis, sometimes but small, indicated by a shallow depression; it is well marked in chameleons. The retina contains only cones, rods being absent; fat-drops on the apex of the cones are common; their usual colours are green and blue.

6. The *pineal*, *median* or *parietal* eye is the terminal organ of the epiphysis of the brain, with which it is connected by a nerve-containing string. Among recent reptiles it exists in *Sphenodon* and in the Lacertilia, with vestiges in snakes. It is embedded in the median parietal foramen. Externally its presence is generally marked by the scales being arranged in a rosette, with a transparent central scale. The organ itself is divisible by a dioptric apparatus, with all the essential features of an eye; a pigmented retina of the arthropodous simple type surrounds an inner chamber which is nearly filled by a cellular globular mass which projects into it from above; this is the so-called lens, in reality much more like the corpus vitreum in its still cellular condition, while the real lens has to be looked for in the superimposed tissue. The whole organ is best developed in *Sphenodon*, even in the adult; but whether it is still functional, and what its function is, remain unknown.

The throwing of a beam of light upon this eye, by means of a lens, produces no effect. Whilst in *Sphenodon* the "lens" is rather dull and the organ not present, in various lizards the "lens" is more perfect, but the nerve is degenerated.

We conclude that the whole organ is now without the least visual function, whilst in various extinct groups of reptiles and Stegocephali it was fully developed. It has been well investigated by de Graaff, W. B. Spencer and A. Dendy.

The *Muscular System*.

A useful account of the differentiation of the muscles in the main reptilian groups, with their almost endless modifications in correlation with walking, climbing, swimming, gliding and burrowing, with limbs complete or absent, would fill several pages of this article and would necessitate many illustrations. The literature is great; it comprises many good detailed descriptions of various kinds of reptiles, and several monographs. M. Führbringer has devoted a whole series to the muscles of the neck, shoulder-girdle and fore limbs. Hand in hand with these investigations went that of the innervation, without which myology would lack scientific value. The present writer has devoted much time to the muscles and nerves of the pelvis and hind limbs, and has, in tabular form, compared them with those of other vertebrates. The results of all these labours are rather disappointing, except for the study of myology such as, which raises many interesting questions. Broadly speaking, the muscles of typical reptiles, crocodiles and lizards are more highly differentiated (by no means always more numerous, but more individualized by origin and insertion, the behaviour of the tendons), more effectively disposed according to mechanical principles, than in Batrachia, and less than in birds and mammals.

This can easily be proved, whether we take for comparison the muscles of the neck, of the larynx or hyoid, or limbs. Lowest in general stands *Sphenodon*, next to it the lizards, highest the crocodiles, while tortoises and snakes show the greatest reduction and specialization. In the tortoises it is the non-yielding box of carapace and plastron which has caused great changes within the region of the trunk proper. First, all the epaxial muscles have vanished; the same applies to the costal muscles; but traces of dorso-lateral muscles occur on the inside of the posterior half of the carapace, extending as a longitudinal lamint from one transverse process to the next in many of the lower aquatic tortoises, as perfectly useless vestiges; or more striking, these muscles exist in the young, and disappear with age, for instance in *Testudo*. Secondly, it is rather surprising that the rigid shell has offered so little or no inducement to the muscles of the girdles, neck and tail to transfer their origins upon it. Thirdly, the retractile neck of the typical cryptodorous tortoises is correlated with a pair of long retractor muscles, which in the shape of a pair of broad, vertical ribbons (between which is received the S-kinked neck) extend far back along the vertebral column, almost to the level of the pelvis. Evidently, owing to the short girdles, only the spinal and costal muscles remain, besides of course those of the abdomen and the visceral arches. The vestigial muscles of the limbless lizards and of the peropodous snakes have been monographed by Führbringer in much detail without great results.

**Respiratory Organs.**

All reptiles breathe by lungs, and they possess no vestiges of gills, not even during their embryonic stages, although gill clefts are invariably present in the embryo. Nor does any part of the outer skin assist respiration, as is so commonly the case in Batrachia; yet, strictly speaking, the lungs are not the only organs of respiration in the class of reptiles, since various tortoises possess additional breathing apparatus in the anal sacs and in certain recesses of the throat, to be mentioned farther on.

The *Larynx*, instead of lying at the bottom and far back in the throat, as in the Batrachia, is considerably moved forwards so as to rest upon the hyoid and to project into the pharyngeal cavity. A pair of arytenoid cartilages, enclosing the glottis, rest upon several more or less fused tracheal cartilages, which thus represent the cricoid, but there is no thyroid cartilage. A small process from the anterior median edge of the cricoid is the beginning of an epiglottis. Vocal chords are indicated by lateral projecting folds of the inner membranous lining of the larynx, and are in a few cases effective in producing a voice. Crocodiles and alligators have a powerful, loud, bellowing voice; many tortoises utter weak, piping sounds, especially during the pairing season; and also various lizards can emit a feeble squeak, for instance, *Psammodromus hispanicus*, and the geckos. *Sphenodon*, at least the males, can grunt. Snakes have no voice; they can only hiss like all other reptiles, but a curious modification exists in the larynx of the North American *Coluber constrictor*. The "melon" of *Elaphe melanolusus*: the epiglottis is more enlarged, and laterally compressed so that the hissing sound is much strengthened by the vibration of the epiglottis. The larynx possesses a constrictor and a dilator muscle, which arise from the arytenoids and from the cricoid respectively, and are attached to the hyoid. Chameleons have bladder-shaped sacs which can be filled with air from a slit immediately below the larynx. For further modifications see G. Tornier.

The *Trachea* is furnished with cartilaginous rings and semirings, which extend to the lungs. As a rule the trachea is straight; in *Crocodilus americanus* it forms a loop; and similar curvings occur in various tortoises in correlation with the retractile neck. The two *bronchi* are shortest in *Sphenodon*, very long in most tortoises, where they begin frequently already half down the neck. In *Sphargis* most of the trachea is divided by a longitudinal partition. It is an advance upon amphibian conditions that the bronchus enters its lung no longer at its apex, since an anterior, pre-bronchial lung-portion has come into existence. This is still very short in *Sphenodon*, while in crocodiles, tortoises and in the highly developed Varanidae the bronchus enters near the middle of its lung, and the anterior portion is nearly as long as the posterior. The shape of the trunk influences that of the lungs. In the snake-shaped forms, both snakes and lizards alike, the lungs have become
very asymmetrical, one of them being much larger than the other, which is often quite aborted. The simplest form of lungs is that of Sphenodon; the prebronchial part is still small. Each lung is still a sac with one large lumen, the walls being honeycombed. In the lizards the walls are more spongy, and several septa begin to extend more or less far from the walls into the lumen, towards each bronchus. Some of these septa begin to cut the lung into lobes, especially in Varanus and in Chameleons. In the latter there exists a further specialization, a side-departure, in the shape of several long, hollow processes which are sent out from the posterior portions of the lungs and extend far into the body-cavity and between the viscera. By means of these structures the animal can "blow" themselves out. They are of morphological interest since they are first stages of air-sacs so marvellously developed in birds, and possibly also in various Dinosaurs. In the Amphibiae the left lung alone remains.

The lungs of crocodiles have reached a considerably higher stage. They alone in reptiles are, on the ventral side, completely shut off from the visceral cavity by a pleural, partly muscularized, membrane. From each bronchus extend a number of broad septa towards the periphery, dividing the originally single lumen into many chambers, perhaps a dozen, from the walls of which wide secondary or parabronchial canals extend into the alveolar meshwork, in very regular arrangement, in series like organ-pipes.

The lungs of the tortoises are, in adaptation to the peculiar shape of the body, stowed away along the back, as far as the pelvis, and only their ventral surface is covered by a strong peritoneal membrane which receives muscular diaphragmatic fibres. The inner division of the lungs into chambers has progressed so much that a sort of mesobronchus has become discernible; the arrangement of the side-bronchi is far less regular than in crocodiles; the whole lung is much more honeycombed, meshy and spongy.

The mechanism of breathing of tortoises is not such a puzzle as it is sometimes stated to be. Of course the rigid box of the trunk excludes any costal, or abdominal breathing, but by protracting the limbs and the neck, piston-like, an effective vacuum is produced in the box. Moreover, the throat is distended and worked considerably by the unusually large and movable hyoid apparatus, by which air is pumped into the lungs.

The lungs of the snakes are very thin-walled, with a very wide lumen, and only for about the first half from the heart backwards the walls are alveolar enough for actual respiratory function, while towards the blind end the sacs are so thin and sparsely vascularized that they act mainly as reservoirs of a large amount of air. Frequently their posterior portions receive blood vessels not from the pulmonary arteries but directly from those of the trunk. In correlation with the long, cylindrical body, the lungs are much elongated and they are not equally developed. The asymmetry shows great differences in the various groups, consequently the asymmetry has been developed independently in those groups. It is usually stated that the left lung is much smaller than the right. This is but rarely the case. The most recent observations are those of E. D. Cope (Proc. Am. Phil. Soc. 1894, xxxii. 217). In Boidae both lungs are large, although unequal: the left or more dorsally placed one being the larger. In Iguania the right is functional, the left is ventral and vestigial. In Rhinophis the right is very small, the left larger. In Glaucosoma and Typhlops the right lung alone is developed: the left is quite aborted. In Colubridae the right lung alone is functional, while the right is vestigial. There is no trace of any trace of the lung of the Boidae, Anguidae and Viperidae. In the Colubridae the right, or ventral, lung is, when present at all, reduced to a length of from 2.5 mm., and it then communicates with the anterior portion of the left lung by a foramen, in level of the heart, whilst the right bronchus is aborted.

A further complication is the so-called tracheal lung, which is present in Typhlopidae, Ungulata of the Boidae, in Chersydrys of the Acrochordinae, in the Hydrophinae and Viperidae. This peculiar organ is a continuation of the anterior portion of the functional lung, extending far headwards, along the trachea, with the lumen of which it communicates by numerous openings. In Chersydrys this mysterious organ is "composed of coarse cells and without lumen, extends from the heart to the head, and is discontinuous with the true lung; the trachea communicates with it by a series of symmetrical pores on each side." In Typhlops it extends likewise from the heart to the throat, as a cellular body but without lumen or connexion with either trachea or lung.

**Thyroid and Thymus.**

The **Thyroid** of the reptiles is a single, unpaired organ, placed ventrally upon the trachea and one or other of the arterial trunks, more or less distant from the heart. In snakes it lies on the mid-line near the heart; a little farther up in Sphenodon; still farther in lizards, and chameleons near the root of their gular sac. In tortoises it is globular, at the division of the carotid trunk. In crocodiles it is bilobed.

The **Thymus** is paired. It is largest in crocodiles, extending on either side of nearly the whole neck, along the carotids and jugulars. In the tortoises they are much shorter; in Sphenodon and lizards are two pairs, more or less elongated; in the snakes are sometimes as many as three pairs, elongated but small, attached to the carotis near the heart. As usual the thymus bodies become much reduced with age.

**The Spleen.**

The **Spleen** varies much in shape and position. In lizards it is mostly roundish, elongated in Sphenodon, and placed near the stomach; in crocodiles it lies in the duodenal loop behind the pancreas; similarly situated in snakes, but in the tortoises it is much concentrated, large and attached to the hind-gut.

**The Body Cavity.**

The **Body cavity** of the reptiles is subdivided into several sacs or cavities by serous membranes of peritoneal origin. The number of these subcavities differs much in the various groups. The pericardial sac is always complete. In tortoises the lungs are retro-peritoneal, a dense serous membrane spreading over their ventral surface from the walls of the carapace forwards to the liver and shutting off a saccus hepato-pulmonalis from the rest of the peritoneal cavity. Snakes possess, besides the modifications mentioned above, separate chambers for the stomach, right and left liver, and for the gut, whilst the pleural cavities as such have been destroyed. In lizards a "post-hepatic septum" divides liver, lungs and heart from the rest of the intestines. This transverse vertical septum is best developed, almost complete, in some of the Tejidae, in others it seems to be more imperfect, and it is probably a further development of the suspensorial ligament of the liver, which is ultimately inserted upon the ventral wall of the body.

The subdivisions have reached their highest development in the crocodiles, there being, besides the pericardial and the two pleural cavities and the usual peritoneal room, a right and left hepato-pancreatic, an hepato-gastric, and an hepato-pulmonal sac. The caudal and ventral edges of these liver-sacs are fused on to the ventral body-wall, thus producing a complete transverse partition, headwards of which lie the lungs, liver and heart. This partition, morphologically not homologous with the mammalian diaphragm, more resembling the imperfect structure in birds, acts, however, as a perfect diaphragm, since it is well furnished with muscular fibres. These are attached to its whole periphery, with centripetal direction, especially on the ventral half. These fibres are transgressors upon this septum from a broad sheet of muscles, which, inserted together with the septum upon the body-wall, arise from the iliac bones, the pubes, and the greater portion of the last pair of abdominal ribs. This broad muscular sheet, covering the intestines, is the so-called abdominal diaphragm or peritoneal muscle. Its continuation upon the transverse septum is the crocodilian muse. diaphragmaticus, and in functional effect very similar.
REPTILES

The Heart.

The Heart of all reptiles is removed from the head and is placed well in the thorax, in the Varanidae even a little beyond it. Only in snakes the heart lies headwards from the hilus of the lungs, not caudwards, generally at about the end of the first fifth of the body. The batrachian conus arteriosus is reduced, one set of arches remain, and divide into the truncus arteriosus which now issues directly from the heart. A sinus venosus exists still in Sphenodon and Cheloniens, in which it may even receive separate hepatic veins, but in crocodiles, lizards and snakes the sinus as such exists no longer, forming part of the right atrium. All the hepatic veins enter the stem of the posterior vena cava, which henceforth enters the heart as inferior vena cava. This, the largest, and the right and left anterior vena cavae, are the only three veins which enter the right atrium. Into the left open the two pulmonary veins. Right and left atrium have in all reptiles a complete septum between them. The ventricular portion shows considerable steps towards the differentiation into a right and a left ventricle, but the partition is very incomplete in tortoises, lizards and snakes, quite complete only in the crocodiles.

The most important character of the reptilian heart, absolutely diagnostic of it, is the fact that the systemic vessel which leaves the right ventricle turns to the left to form the left aorta, while the stem which comes from the left ventricular half arches over to the right as the right aorta. It is not at all necessary to conclude that this fact excludes the reptiles from the mammalian ancestry and to hark back to conditions as indifferent as are those of the batrachia. The Foramen Panizzae shows the way to a solution, how ultimately all the arterial blood from the left ventricle may pass, first through the root of the right arch, then through this hole into the left, whilst the rest of the right arch, and the root of the left, obliterates. The difficulty is not much greater than that of deriving the birds' condition from the reptilian. The Foramen Panizzae, which exists only in the Crocodilia, lies exactly where the right crosses dorsally over the left aorta. The whole is not the last remnant of the originally undivided truncus, as is taught generally, but it is a new foramen, a hole dug by the left arterial blood into the venous right aorta. According to the recent observations made by F. Hochstetter, the foramen comes into existence in a very late embryonic stage.

Whilst the batrachian single ventricle possesses only one ostium ventriculare or outlet into the truncus, in the reptiles the inter-atrial septum extends considerably downwards into the base of the ventricle, so as to produce a right and a left niche, and correspondingly two ostia instead of one. The atrio-ventricular valves are still membranous, even in crocodiles; attached to them are muscles, trabeculae carneae, from the very trabecular walls of the ventricle; they are especially spongy in tortoises. By means of the arrangement of some of these trabeculae, perhaps still more through the confluence of their basal portions, an imperfect ventricular septum is initiated. Certainly even in tortoises, which represent the lowest stage, the venous blood is received into and sent out by the same right side of the ventricle, while the arterial blood is correspondingly managed and dodged by the left side. That there is not very much mixture of the two kinds of blood, in spite of the wide communication in the ventricle, is further due to the peristaltic systole and diastole of the various divisions of the heart.—The heart of Cheloniens is broader than long. In correlation with the very much flattened body of Trionyx and its allied genera, the whole heart is dislodged from the middle line, far over to the right side; the vessels of the left side are correspondingly much elongated and have to cross the neck, trachea and oesophagus.—The apex of the heart is attached to the pericardium by a special ligament in the Crocodilia and in many Chelonia, e.g. Testudo, but it is absent in Chelydra. Sometimes this little ligament sends a tiny blood vessel into the liver.

Arterial System.

Crocodiles.—The left aorta crosses obliquely beneath the right and gives off only the coeliac, just before joining the right aorta in the level of the eighth thoracic vertebra. The aorta descendens sends off, besides intercostals and other segmentals into the body-wall, the mesenteric, right and left iliac, a pair of renal and ischidiacs, a celiac and the caudal artery. The right aorta forms the main root of the a. descendens. Close to the common stem (compendium) crosses a vessel which divides at once into two anonymae, of the left, which is of the stronger. The right anonyma divides into the subclavia and collateralis collis, the left into subclavia and carotis vertebrales. Each subclavia sends off an a. vertebralis communis, which runs headwards and, with another longer branch, downwards, giving off intercostals, and then joins the descending aorta.

Tortoises.—The left aorta is rather more separated from the truncus, which it crosses ventrally in an oblique forward direction; it sends off a left cardiac to stomach and oesophagus, a coeliac and mesenteric, and then a communicating branch to the right aorta. The a. descendens gives off paired suprarenals, spermatics, very large iliacs, then a pair of renals, hypogastrics and the caudal. Each iliac artery divides into a recurrent intercostal anastomosing with the axillaries, an epigastric (sending off the crural and anastomosing with thoracics and humerals), and other arteries to abdominal muscles and to the shell. The hypogastrics supply the cloacal region and then continue as the ischiadics. But there are many anastomoses which cause great variation in the different tortoises. The right aorta sends off a right cardiac, the coronary, and the right and left anonymae which are quite symmetrical, each dividing into subclavia and carotis, in the angle lies the thymus.

Lizards.—Two common carotids arise either side by side, or by one carotis primaria, from the right aortic root. In the majority each common carotis ascends the neck and then divides into the vessels for the head and another branch which turns back and goes into the descending part of the aortic arch. In chameleons two carotid stems ascend the neck and there is no recurrent vessel. In the Varanidae the two common carotids start from a long carotis primaria; there is no recurrent vessel. The vertebral arteries come from the origin of the subclavians and run to the head in a very lateral position. The subclavians arteries (which occur also in limbless lizards) arise far away from the carotids out of the descending arch of the right aorta, in a level often far behind the heart. “Anonymous” arteries are consequently absent in lizards.

Snakes.—The left aorta is stronger than the right, both combining soon to form the descending aorta. Owing to the absence of fore limbs and shoulder-girdle the conditions are much simplified. In most snakes the right aorta sends off but one strong carotic vessel which represents the left carotis communis whilst the right is much reduced or even quite absent; further, there is only one vertebral artery, which either runs along the right side of the vertebral column or it divides soon into a right and a left vessel along the neck. In conformity with the reduction of one lung there is usually but one pulmonary vessel.

Venous System.

Crocodiles.—Each, right and left, anterior vena cava is composed of a subclavian (axillary and external jugular), an internal jugular, common vertebral and an internal mammalian vein. The posterior vena cava is composed of the two revehent ronaial, veins of the genital parts, two median venous veins of the suprarenals (which, like birds, still have a portal system), and the big vein from the fat body. Thus the vena cava posterior to that of the Mammalia, whilst the abdominal diaphragm undoubtedly causes abdominal respiration. We have seen that these crocodilian conditions do not stand quite alone, but are connected with simpler features of the other reptiles. Two recent, very lengthy papers have been written on this subject by J. Brommann (1904) and by F. Hochstetter (1906), besides two in 1902 by G. Butler.
perforates the right liver, receiving from it many hepatic veins and also the big vein of the left lobe; next it receives the coronary vein and then enters the heart as inferior vena cava. The portal vein arises out of the eoccygo-mesenteric (which comes out of the bifurcation of the caudal), collecting the blood from most abdominal viscera and from the thorax and breaks up in the right liver. The rest of the venous system is rather complicated. The big caudal vessel divides near the vent, receives an unpaired celiac and a rectal vessel, and goes off to the right and left, each of which trunk receives an ischiadic and an inter-sacral vein and then divides into the v. renalis aedehens which breaks up in the kidney, and the abdominal vein. The latter are interesting; they run in the abdominal walls and the obturator foramen, the veins, intervertebrals and intercostals, the crurals, and the epigastrics out of the body-wall. Then these two abdominals (Rathke's internal epigastrics) go to the liver, which enter into either side of the gall bladder, collecting also blood from the stomach and from the vertebral column. Both break up in the liver. Consequently all the blood from "below the heart" passes through some portal system—renal or hepatic—except that which comes from the genital glands and ducts and from the fat body.  

**Tortoises.**—The venous system much resembles that of the crocodiles, but many and wide anastomoses, especially on the inside of the carapace and plastron, exist between often distant vessels, so that one lucky injection may fill the whole system. There are three adventive renal veins which collect on the back of their kidney into one stem; they dissolve completely into a portal system, and leave the kidney on its ventral surface as one v. renalis aedehens. The right and left then form the v. c. posterior which perforates the posterior margin of the right liver, then headwards of the liver takes up the hepatic and enters the heart. The three pairs of affrent renal veins are composed as follows. The excreta collects from the shell and the abdominal muscular mass. The venous blood from the renal glands, the bladder, and from parts of other pelvic viscerae; the anterior comes from the anterior part of the shell and runs backwards to the kidney, with frequent anastomoses with the other adventive renal veins. The abdominals arise, as in the crocodiles, with the external adventive renal from the lateral continuation of the bifurcated caudal, which takes up vessels from the pelvis, the shell and the crural. The abdominal itself takes up a femoral vein, vessels from the abdominal and pelvic muscles, and from the plastron, and then divides into the body-cavity, receives veins from the fore limbs, and enters the right lobe of the liver, there to break up. The hepatic portal comes from the intestinal tract, spleen and pancreas. Consequently in tortoises all the blood from below the heart passes through some portal system. The most important peculiarity of the Lizards is the condition of the abdominal veins; they combine into a single stem (after having collected the blood from the fat body and from the ventral body-wall of the pelvic region) which divides into the body-cavity to join, embedded in the ventral hepatic ligament, the left branch of the portal vein. The chief characteristic of the abdominal is that it does not communicate directly with the caudal, and that it forms an unpaired stem. The renal portal system receives its blood from the tail, the hind limbs, the abdominal wall and the urino-genital organs, all the blood passing into a right and a left advehent vein. The suprarenal portal system drains from the abdominal wall and the supra-renal bodies, and issues into the revehent veins. These, with some intervertebrals and with hepaties, constitute the inferior vena cava.

**Lymphatic System.**

The lymphatic vessels frequently accompany the big arteries of the trunk, either surrounding them with a sheath, or ensheathing them completely, especially in tortoises. The lymphatics from the head and neck combine with stems which accompany the veins of the fore limbs; they join the thoracic ducts and these open into the brachio-cephalic veins, as they do in birds. The lymph from the tail flows into the ischiadic veins or into the advehent renal veins. Reptiles possess only a posterior pair of lymph-hearts; they are placed near the root of the tail against the ends of one of the transverse processes. In snakes they lie in a space protected by the ribs and transverse processes of the original sacral vertebrae. Lymph glands proper are not developed in reptiles, except in the shape of the so-called mesenteric gland of crocodiles. 

**Blood.**

The red corpuscles are invariably oval, and, since they still possess a nucleus, biconvex. Numerous measurements have been made by G. Gullin (P. Z. S. 1845, pp. 91-102), their long and short axes range between 0-270-0-21 mm. respectively. That means to say they are very much larger than those of mammals, considerably larger than those of most birds, and in turn much smaller than those of amphibia.

**Digestive System.**

**Teeth.**—All the groups of recent reptiles have teeth, except the tortoises, which have lost even embryonic traces of them. In the under jaw they are restricted to the dentary bones. In the upper they are almost universal in the maxilla and premaxilla, although the latter has lost them in most of the snakes. The pterygoids are toothed in most snakes and in a few lizards, e.g. Laceria and Iguana. The palatines are toothed in Sphenodon and in some lizards.

Only the young of Sphenodon and the chameleons have a few small teeth on the vomer. The teeth themselves consist of dentine with a cap of enamel and with cementum around their base. In the crocodiles they are planted into separate rveoles in the maxilla, premaxilla and under jaw. In lizards they are either pleurodont, i.e. they stand in a series upon a longitudinal ridge which projects from the lingual side of the supporting bone, or they stand upon the upper rim of the bone, acrodont. In either case they are, when full grown, cemented on to the bone. Acrodont are amongst lizards only the Agamidæ; the Tejidæ are intermediate, almost acrodont. All the snakes and Sphenodon are acrodont. The latter is in so far peculiar as its broad-based, somewhat triangular teeth are much worn down in old specimens; originally there are several in the premaxilla, but the adults bite with the somewhat curved-down portions of the premaxillaries themselves, or with what remains of the ankylosed bases of the original teeth, which then, together with the bone, look like a pair of large chisel-shaped incisors. The lateral edges of the palatines of Sphenodon likewise carry a few of the mandibles fit into a long slit-like space between the palate and the maxillary teeth. This is a unique arrangement. Further, it is surprising that in this old, Rhynchocephalian type the supply of teeth has become exhausted, whilst in the other recent reptiles the supply is continuous and apparently inexhaustible. The new teeth lie on the lingual side of the old set, and long before the new tooth is finished part of the base of its older neighbour is absorbed, so that the pulp-cavity which persists in nearly all reptilian teeth becomes free. Ultimately the old tooth is pushed off and the new is cemented into its place. In the crocodiles it has come to pass that several sets of teeth are lodged more or less into one another's bases. Where crocodiles and alligators collect habitually the ground is sometimes found strewn with thousands of teeth, large and small, every creature shedding about seventy teeth many times during its long life. Some or all teeth of various families of lizards and snakes have a more or less pronounced groove or furrow along their anterior convex curve. The usefulness of this furrow in facilitating the entering of saliva into the bitten wound is merely incidental, but this preformed feature has in many snakes been improved into a fearful weapon. In the Crocodylia a few of the most posterior teeth in the maxilla are enlarged, have deeper furrows, and lie in the vicinity of the poison ducts. In the Proteroglypha one or two of the most anterior maxillary
teeth are enlarged and furnished with a deep groove for the reception of poison.

In the Solenoglypha or Viperidae the enlarged teeth of the Opisthoglypha have moved to the front, owing to reduction of the anterior portion of the maxilla. The latter, much shortened, moves with the firmly anchored poison fang upon the prefrontal as its pivot, being pushed forward, or "erected," by the ectopterygoid bone, which connects it with the pterygoid, and this in turn can be moved forwards and backwards, together with the quadrate. (See fig. 24, skull of Vipera aspis and the diagram of the mechanism in article Snakes.)

The tongue is bifid, either slightly niched or deeply bifid. The tips contain tactile corpuscles, although sometimes covered with a horny epithelium. The most specialized is the tongue of the chameleon.-The body of this tongue is very thick, club-shaped, fleshy and full of large mucous glands which cover it with a sticky secretion. The base or root is very narrow, composed of extremely elastic fibres and supported by a much elongated papillary piece of the hyoid. This elastic part is, so to speak, telescoped over the style-shaped copula, and the whole apparatus is kept in a contracted state like a spring in a tube. A pair of wide blood vessels and elastic bands extend from the base into the thick end, which in an ordinary chameleon can be shot out to a distance of about 8 in.

The tongue of the snakes is invariably slender, smooth and almost entirely retractile into its posterior sheath-like portion. It is always bifid and contains many tactile and other sensory corpuscles by which these creatures seem to investigate. The tongue is always protruded during excitement. How this is done is not very obvious, since the hyoid apparatus itself is much reduced. There is a niche in the middle of the rostral shield to permit protrusion of the tongue whilst the mouth is shut, and probably herewith is correlated the almost universal absence of teeth in the maxilla. The tongue and the larynx are placed very far forwards in the mouth and, during the act of swallowing, the larynx approaches the chin, or it may even protrude out of the mouth to secure breathing during the often painfully protracted act.

Of Gland, sublingual glands are of general occurrence in reptiles; they open near the root or in the sheath of the tongue. Labial glands seem to be absent in crocodiles and tortoises, but upper and lower labial glands exist in lizards and snakes, generally in considerable numbers. Heloderma is the only lizard in which some of these glands—those along the lower jaw—produce a poisonous secretion, each small gland conducting its secretion towards the base of one of the somewhat furrowed teeth. In the snakes, upper and lower labial glands are well developed for salivation. It is the upper series which attracts our interest by its eventual modification into the deadly poison glands. Probably the saliva of most snakes, like their serum, possesses toxic properties. In most of the harmless Colubrine snakes the glands extend in a continuous series from behind the premaxilla along the whole of the upper jaw, with numerous openings. In the Opisthglypha a gradual differentiation takes place into an anterior, middle and posterior portion; the middle, extending from below and behind the eye backwards, is the thickest and yellowish in colour; behind it follows a small portion, reddish grey like the anterior portion, with which it is more or less continuous below the middle complex. Thus, still rather indifferent, is Dryophis. In Dipsas, e.g. D. fusca, the middle portion has become predominant; some of its enlarged ducts lead to the pair of posterior, enlarged and well-grooved, maxillary teeth. It is this middle portion which becomes the characteristic poison gland with one long duct. The gland itself retains its position; all the other upper labials, except the anterior series, abort. In the Viperidae the poison duct opens near the base of the perforated fangs, which, owing to the shortening of the anterior portion of the maxilla with its teeth, have come to be the only teeth in the upper jaw. In the Elapine, still more in the Hydrophine snakes, the position of the gland and its duct is the same, but the duct has been carried past the smaller harmless teeth which stand in the maxilla and open at the base of the anterior maxillary teeth. The effect is the same, although the poison fangs are not homologous, in the one case the most posterior, in the other the most anterior, of the maxillary series. In Dolichophis, one of the Malay genera of Elapine snakes, each poison gland sends an enormously elongated recess far into the body-cavity. (For other details see Snakes; Viper; and Rattlesnake. The best account of the buccal glands and teeth of poisonous snakes is that by G. S. West, P.Z.S., 1895, pp. 812–826.)

Stomach, etc.—In lizards and in Sphenodon the wide pharynx and oesophagus passes gradually into the stomach, which is
more or less spindle-shaped, never transversely placed. The walls of the stomach are thrown into longitudinal folds which contain the specific gastric glands, whilst glands are absent in the oesophagus, excepting scattered and very simple slime glands. The circular muscular fibres of the stomach are much stronger than the longitudinal fibres. The end of the stomach is generally marked by a pyloric valve. The walls of the mid gut are said to be devoid of glands. The end gut, marked by a circular valve, is considerably wider and there is a caecum, mostly left-sided, largest in leaf-eating lizards, rarely absent, as, for instance, in Anguis. The absorbent portion of the rectum is always strongly marked off from the cloaca by a circular fold or fold, which projects into the widened coprodaeum of the cloaca. In those lizards which, like Varanus, have no urinary bladder, there are two successive sphincters, marking off two chambers, one, the upper or innermost, for the reception of the faeces, the lower for that of the urine. In adult crocodiles the stomach is transformed into a gizzard; it is more or less oval, with a wide fundus and with two opposite apo-neurotic or tendinous disks whence radiate the muscular fibres. The muscular walls remain, however, comparatively thin, like those of birds of prey. There is a distinct pyloric stomach and then follows the pylorus. The latter lining of the pyloric part is velvety like with numerous gastric glands which form groups with net-like interstices. There is a distinct duodenal loop which contains the pancreas. The more convoluted mid gut is lined with net-like meshes which farther back assume a longitudinal zigzag arrangement; towards the end gut the walls become quite smooth, but in the end gut the walls again show a very narrow-meshed structure. None of these folds of the mid and hind gut is said to contain digestive glands; they seem to be entirely absorptive. The oesophagus of most tortoises shows longitudinal folds with very numerous mucous glands. In the Cheloniidae the pharynx and adjoining part of the gullet are covered with little tubercles upon which the prey is passed; a tendency of some of the species gives rise to large, more or less conical papillae, which assume a considerable size, point backwards, and are covered with a somewhat horny epithelium. Similar conical, horny papillae exist also in Spheniscis, in which the oesophagus, moreover, makes a long loop half round the stomach before passing into it, an absolutely unique feature. The transition into the stomach is quite gradual. The latter is strongly muscular, partly transversely placed, and possesses often a very distinct pyloric stomach. In Chelone conical papillae extend into the cardiac portion. In the majority of tortoises the inner lining shows longitudinal folds with numerous small glands, mucous and gastric, but their distribution differs much in the various families and even genera. The lining of the mid gut shows either longitudinal folds or a network, without glands, except in some cases, Lieberkühn crypts, e.g., in Trionyx, not in Testudo and Chelone. The hind gut begins suddenly, but there is no caecum; its inner walls contain numerous glands in Testudo, Emys, not in Chelys, Trionyx, Cisternuam. In the snakes the oesophagus is very thin-walled and passes imperceptibly into the stomach, which continues in a longitudinal direction, scarcely wider in the middle. Its muscular coating is very weak, all other reptiles the gut is usually subdivided into two, or even three, successive rooms by circular folds. This coprodaeum serves for the temporary storage of the faeces, eventually mixed with the urine. Micturition and defaecation are in most lizards two successive separate acts. The snake's arrangement is a side-departure of that prevailing in lizards. The urodaeum is transformed into a dorsal recess into which open above theoviducts, while the ureters open below, in the caudal corner. A horizontal fold imperfectly shuts off the wide urino-genital chamber or recess from the ventral half of the original urodaeum. The coprodaeum is marked above and below by strong sphincters. There is no urinary bladder. In crocodiles the protodaeum is rather shallow, but long; from its ventral wall arises the unpaired copulatory organ, the basal investing membranes of which continue into the ventral
half of the uro-proctodeal fold, near which open the male ducts. Very young crocodiles possess a typical middle chamber or urodeum, into the dorso-lateral corners of which open the ureteries, but soon the strong circular fold between urodeum and coprodeum disappears completely, so that both chambers now form one large oval room, which is used solely for the storage of the urine, there being no bladder. The faeces are kept in the not specially dilated rectum.

The cloacal arrangement of the Chelonia is a further development of early crocodilian conditions, but it has become rather complicated and shows a surprising resemblance to that which still prevails in the Monotremes. The proctodeum is deep and very long, especially in the males. From its innermost and ventral walls arises the large copulatory organ. From the urodeum, on the other hand, the recess exists, which is separated from the urodeum and the genital ducts, and it is continued by a long neck into the large bladder. Between the dorsal wall of this recess and the ventral wall of the main portion of the urodeum arises a horizontal fold which, diverging, is continued on to the investing skin of the penis, helping to form the edges of the deep longitudinal furrow on its morphologically dorsal surface. If the lips of this furrow were closed, urine and all the genital products would pass through this urethral canal, but, in reality, only the semen is conducted through it (the furrow during the state of turgescence being transformed into a closed tube), while urine and eggs escape through the wide slit near its inner end. This is an arrangement almost the same as that of *Ornithorhynchus*. The urodeum is separated from the rectum by a strong sphincter, and there is, as in the crocodiles and mammals, no special coprodeum. The Chelonian urodeum is further complicated by the occurrence of a pair of large anal sacs, thin-walled diverticula on the dorsal side. Such sacs, not to be confused with the anal glands of other reptiles, exist in many water tortoises, especially in the Chelydidae, also in various aquatic Testudinidae, e.g. *Emys*, in *Platysternum*, and sometimes in *Trionyx*; they are absent in the Chelonidae and in the typically terrestrial tortoises. These sacs have highly vascularized walls and a considerable layer of circular and longitudinal non-striped muscular fibres; their inside is sometimes villous, never glandular. They are incessantly filled and emptied with water through the vent, and act as additional respiratory organs, like a kind of water lungs. When such a tortoise is suddenly taken out of the water it squirts out a stream of water, which is not, as is usually supposed, the urine from the bladder.

In connexion with the cloaca may be mentioned the frequent occurrence of *peritoneal canals*. In the tortoises their abdominal openings are situated in a recess of the peritoneal cavity close to either side of the neck of the bladder; in the females they extend as funnels, generally blind, into the cloaca on or near the base of the clitoris. In the males they extend, without having communication with the cavities of the corpora cavernosa, and without ramifications, as canals along the dorum penis and *either* terminate blindly in the glans (*Testudo, Chelone*), or they open, each by a small orifice, in the groove at the base of the glans. In crocodiles these canals are short and open near the base of the copulatory organ, protected by a small papilla. They are present in both sexes, but are still closed in newly hatched and very immature specimens. In an adult Nile crocodile they are wide enough to pass an ordinary lead pencil. The function of these outlets from the body cavity is obscure. In *Sphenodon* the writer has found them as closed funnels which project as soft papillae into the proctodeum a little to the right and left and caudalwards from the urino-genital papillae.

**Urinary Organs.**

The *kidneys* of the reptiles show, like those of the birds and mammals, a considerable advance upon those of the Batrachians. They are, in the adult, represented entirely by the mesonephros; the segmental tubules have no longer any nephrostomes opening into the body cavity, not even during any time of their development, and it has come to a complete separation of the efferent genital ducts from the kidneys and from their ureters. Yet these differences are but of degree, there being a continuous bridge from Batrachian to Lacertilian conditions. In *Lacerta*, for instance, in which these features have been studied most thoroughly, the mesonephros continues as the only functional excretory organ during the first year of the young creature until and during its first hibernation, when the formation of the metanephros takes place, and with it the complete separation of the vasa deferentia from the kidneys. Until then the segmental canals remain in the male as common carriers of semen and urine, at least morphologically, not physiologically, since in the immature there is no occasion for the conduction of semen. The kidneys of these young lizards show precisely the same arrangement as in the Batrachia, excluding the Discoglossidae.

Clearly the metanephros has developed from an is part of, the posterior portion of the mesonephros, the glomeruli of which no longer open into the segmental duct, but become connected with a new canal, the future ureter, which sprouts from the distal portion of the segmental duct and grows headwards. Or let us put these important changes in another way. Since there are originally several segmental ducts (permanent in the male, new) which tailwards more and more lose their connexion with the testes, until—in the posterior portion of the mesonephros—they become entirely urinary ducts, the hindmost of these sprouts (in lizards postembryonically, much earlier in birds and mammals) independently, but at the same time as the neighbouring mass of the mesonephros, the growing glomeruli of which then connect with the spinning processes of the ureter. Phylogenetically and ontogenetically it is evident enough that the kidneys are essentially one organ, the anterior portion of which is the oldest and decays, whilst farther backwards new and more differentiated portions continue to grow. Pro-, meso- and metanephros and successive wave-like stages of the same organ with morphological and functional continuity, until the next, improved portion is ready. It is important that in the Discoglossids the origin of the mesonephros in the male is already in the larval stage, and in the future it has come to pass which much resembles that of the Amniota. The mesonephros has, by a simple contrivance, become a metanephros, provided we define the former as a kidney which is still connected with true segmental ducts.

The *supra-renal bodies*, adenals, head-kidneys or Nebennieren, are yellowish bodies which lie more in connexion with the generative glands than with the kidneys, always closely attached to the vena cava posterior just above the kidneys. They are very elongated in the snakes, in a 10-foot python they measure about one inch in length; they are flattened in tortoises, roundish in crocodiles.

In all reptiles the kidneys are retroperitoneal, and they do not project into the body cavity. Their position is different in the various groups, and their general shape is much affected by the shape of the body. In the *Ophidia* they are much elongated, and of course far in front of the pelvic region, which has been moved to the cloaca. They are placed asymmetrically, the right extending farthest forwards. They consist of many transverse lobes, sometimes in such a way as to appear spirally twisted. Each terminates considerably in front of the cloaca. Each ureter begins at the anterior end of the kidney, and thence proceeds on its inner and dorsal border, receiving ducts from the interspaces of the numerous lobes. In the male each ureter opens upon a papilla, together with the vas deferens; in the female the ureter is joined by a blind canal, the vestige of the male duct. No snake has a urinary bladder. The urinary excretion is white, chalky, consisting mainly of uric acid in crystals, with very little fluid.

In the *Lacertilia* the kidneys are more posteriorly placed than in snakes. They lie between the pelvis and the cloaca and are generally close together, sometimes partly fused with each other. Only in the Amphibiaenids the right kidney extends more or less into the cloaca.

The urogenital sinus of the alligator and crocodiles is divided in a manner resembling the bird’s.
ducts, or vestigial representatives of the vasa efferentia, are often of considerable length, persistent in chameleon and Uromastix, much reduced in gekkos, or disappearing with age as in Lacerta. The urine of most lizards contains much solid uric acid, which is retained in the urodaeum and voided as a rather solid, white mass, not united with the faeces. Those which have a greater amount of fluid urine have a bladder which receives the fluid portion. The opening of this bladder is on the ventral side of the cloaca, not in direct connexion with the ureters. The bladder is very rarely absent, e.g. in Varanidae and Amphisbaenidae.

The Crocodilus have the kidneys placed below the pelvis; their surface shows meandering convolutions separated by furrows. The ureters are for the greater part of their length deeply sunk into the substance of the kidneys, which they leave near the hinder ends, to run freely for a short distance along the dorsal sides of the cloaca, and then open, each separately, and away from the vasa deferentia, into the dorsal side of the urodaeum, which, together with the coprodaeum, forms a large oval chamber, and this being filled with the very fluid urine, functionizes instead of the absent bladder.

In Chelonia the kidneys lie in the pelvis, short and thick, more or less quadrate; the surface is marked by many shallow meandering grooves and fewer deeper furrows. Each ureter, composed of several large successive canals, leaves its kidney near the inner hinder end, and then runs free for a short space, crossing the gut to open into the neck of the urinary bladder, which arises ventrally out of the urodaeum, which itself has become a recess of the cloaca. The bladder is large, often more or less two-horned, attached to the pelvic wall by a peritoneal fold, and it contains very fluid urine.

The kidneys of Sphenodon are very small and far removed from the generative organs. The ureters open, each close to the vas deferens of its side, beneath a little papilla, on the dorsal side, rather near the midline of the urodaeum, whence arises a long-necked bladder.

Reproductive System.

The Ovaries are always in pairs, placed headwards at a distance from the kidneys in Sphenodon, lizards and snakes; in the latter the right ovary lies farther forward. In tortoises, and especially in the crocodiles, where they are very long and much twisted or lobated, they are situated close to the kidneys and even accompany them. The ovaries of lizards and snakes contain many and large lymph spaces; those of the other reptiles are much denser in structure. The ripening eggs always cause them to assume the shape of a bunch of grapes. The Oviducts are each held by a peritoneal fold which arises from near the dorsal midline. The abdominal ostia are long slits and are turned towards the side, away from the ovaries. The walls of the ducts gradually become thicker, glandular and much folded. Whilst the ripe eggs, often in considerable numbers, receive their shell, each egg lies in a separate chamber; in the gekkos, which lay only one pair of eggs, the two respective chambers have become permanent features. In Sphenodon each oviduct opens together with the ureter of its side near the dorsomedian line of the urodaeum. In most lizards the two oviducts and the two ureters have four separate openings in the dorsal wall of the rather deep dorsal recess of the urodaeum. But in Lophura both oviducts unite (like the ureters) and have only one opening, which is placed a little nearer towards the pelvis than the urinary opening, but they are divided by a longitudinal septum which extends almost to their common orifice. In the snakes the oviducts likewise open into the dorsal recess, sometimes by a common ostium, which is provided with a strong sphincter. The whole recess acts like a vagina for the reception of one of the copulatory organs. The oviducts of the crocodiles open in a decidedly ventral position, on either side close to the base of the clitoris, a considerable distance from the openings of the ureters. In the tortoises the oviducts open separately into a wide ventral urinary-genital sinus, at the base of the neck of the bladder.

The Testes correspond in position with the ovaries; in snakes and Amphisbaenids the right is placed farther headwards than the left. The usual shape is elongated, sometimes pointed forwards. The Epididymis is sometimes of the same size as the testis and then consists of many meandering convolutions of the vas deferens which is composed of several canals from the testis. The convolutions are held together by a peritoneal lamella. Towards the cloaca they become much smaller and shorter, and the vas deferens passes along the median side of the ureter. In Sphenodon these open separately, each near and below the same papilla near which opens the ureter of the same side. In most lizards the vas deferens unites with its ureter into one short canal which opens beneath or upon a small recess, near the upper corner of the urethral recess, far away from the penis. In snakes vas deferens and ureter of each side are likewise commonly united. In the crocodiles each vas deferens passes from the dorsal side of the cloaca to the ventral side, not accompanied by the ureter, and opens into the blind sac which forms the basal continuation of the deep groove on the dorsal side of the penis. In the tortoises the epididymis is very large and the vas deferens is also much convoluted; each opens separately near the neck of the large urinary bladder close to the backward continuation of the deep longitudinal groove of the copulatory organ.

Remnants of the Müllerian ducts run parallel with the vasa deferentia, and similar remnants of the Wolffian ducts accompany the oviducts in crocodiles and tortoises, least degenerated of course in young specimens. Such reciprocal vestiges occur most likely also in lizards, and in female snakes a, vestige of the male duct joins its ureter. In a nearly adult male Sphenodon the present writer missed the female remnants.

The copulatory organs show very important modifications. Sphenodon is the only recent reptile which is devoid of such an organ; its imperfect substitute is an unpaired, thin, but high membranous fold which arises from the dorsal middle of the circular fold between urodaeum and coprodaeum. During copulation this part of the cloaca is probably everted to secure conception, a striking resemblance to the arrangement found in the Coccilia. The organs of all lizards and snakes are paired, in their quiescent state withdrawn into deep pockets which open on the right and left posterior corners of the proctodaeum or outer chamber of the cloaca, which for this reason has assumed the shape of a transverse slit in all lizards and snakes. Hence these have sometimes been called Plagiostomata. Each organ can be everted and tucked in like the finger of a glove, a muscle being attached to the inside of the apex; when everted, the muscle extends through the length of the organ; each muscle arises from the ventral side of several vertebrae of the tail, at a considerable distance from the cloaca. In the embryo each organ arises as a conical protruberance, or papilla, which projects out of the vent. Later it becomes inverted. Probably this ontogenetic feature recapitulates the phylogeny of these organs, which have to be looked upon as swelling flaps or portions of the walls of the cloaca which were protruded during copulation, and which in time borrowed, and specialized, muscular fibres from the ventral tail muscles. On the outer everted side of each organ is a foramen for the reception of the semen. The apex is either single or more or less deeply bifurcated, each arm being followed by the likewise divided furrow. The outer investing membrane of these very muscular erectile bodies is epidermal; often, especially in snakes, provided with numerous papillae, folds or other excrescences. In

![Fig. 39.—Male copulatory organs of Lacerta agilis (after Leydig). pp, organs of right and left sides—between them is the anal aperture; pp, preanal plate.](image-url)
many snakes these are spiny and hard, but according to Leydig this hardness is not due to a horny substance but to the deposition of calcifying matter. E. D. Cope has investigated the almost endless minor modifications of these penial features and uses them for taxonomic purposes in the snakes. Vestiges of these organs occur in females of snakes and lizards. Close to these organs of the snakes lies a pair of anal glands of some size, which pour their very offensive secretion through an opening close to the base of each penis. The same glands occur in the same position in Sphenodon, which has no copulatory organs, and in crocodiles they appear as evertible musk glands. Hence J. E. V. Boas, not knowing of their existence in both sexes of snakes, tried to homologize them with the paired penes of reptiles, an error which has been repeated in C. Gegenbaur's Leben des Tieres.

The crocodiles and tortoises possess a single, median copulatory organ; it lies on the ventral or anterior end of the cloaca, the outer opening of which is therefore a longitudinal slit, hence the term urothelometa. In the crocodiles the organ is attached to the caudal corner of the ischiadic symphysis by a strong and roundish fibrous band, which arises single from the ventral sides and forms partly the continuation of the two fibrous halves of the organ; the bulk of the crura, comparable to corpora cavernosa, is not attached to the pelvis, as generally stated, but projects backwards towards and into the pelvic cavity. This portion is especially rich in venous cavernosities.

The outer coating of the glans possesses various papillary projections, which are furnished with sensory, hedonic corpuluses. On the morphologically dorsal side of the organ, not on the dorsum penis, is a deep groove which ends towards the crura in a blind sac, into the farther corner of which open the vasa deferentia. In a full-grown Nile crocodile the whole organ is about 10 in. long. In young females up to a total length of 3 or 4 ft. the clitoris is nearly of the same size as the male organ, but it remains stationary and appears very small in large specimens.

The organ of the tortoises is essentially of the same type as that of the crocodiles, but it is nowhere directly attached to the pelvis or to any other skeletal part. The whole organ, when withdrawn, lies in a ventral, long recess of the wide outer cloacal chamber, and its crura extend so far back as to form the continuation of the ventral and lateral walls of the recessus which is continued into the neck of the urinary bladder. Its orifice and those of the seminal ducts are enclosed by the walls of the deep groove which runs along the underside of the organ. This is always of considerable size, surprisingly large in Trionyx.

The clitoris is small, sometimes tiny.

The sexual act is extremely prolonged in Chelonians and still more so are the preliminaries, but in crocodiles it is the deed of a few seconds. Lizards and snakes insert only one side.

There remains the question whether the unpaired organ of the crocodiles and tortoises, which is the prototype of the mammalian organ in every essential point, and the paired organs of the lizards and snakes, are to a certain extent homologous organs in so far as they can both be derived from the same indifferent condition. With this view we assume that originally the protrudible walls of the outer cloacal chamber became specialized into a right and left imperfect intromittent organ, that subsequently, in lizards, those hemipenes were shifted back towards the tail and were henceforth bound to develop separately, while in the crocodiles, tortoises, mammals and birds the two primitive lateral evertible flaps approached each other towards the ventral anterior side of the cloaca, and that this led to a fusion, beginning probably at the basal part, which at the same time was farther withdrawn from the surface and secured the reception of the sperma from both vasa deferentia into one canal. This hypothesis has been objected to by Boas, but accepted by Gegenbaur (p. 539) after having been rejected on p. 533 of his Lehrbuch.

The Fat bodies belong at least physiologically to the generative system. They are placed outside the peritoneum. In lizards they appear as two masses in the pelvic region, the black peritoneal lining covering only their dorsal side. They consist of a network of arteries and connective tissue, the meshes spaces of which are filled with "fat"; they each receive an artery from the femoral vessel which enters them in the inguinal region; the veins collect into the abdominal. In snakes the fat bodies are very long, extending from the cloaca to the liver. Tortoises seem to have only traces of them, but in Sphenodon and in crocodiles they resemble those of lizards.—The peculiar organ suspended from the right abdominal wall of crocodiles, variously mentioned as mesenteric gland or body, or fatty spleen, by Butler, is possibly related to the same category. The fat bodies of reptiles are sometimes vaguely alluded to as hibernating bodies; like the fat bodies which are at the sides of the liver in mammals, these cases very thin-shelled, eggs in the oviducts until the embryo is ready to burst the egg-membrane during the act of parturition or immediately after it. Such species are usually called ovo-viviparous, although there is no difference between them and other viviparous creatures, for instance the marsupials. The majority of reptiles are ovi-parous and the egg is enclosed in a strong parchment shell, with or without calcareous deposits. Only gas exchange can take place between such an egg and the outside, and it loses by evaporation, whilst in the batrachian egg various other exchanges are easy through the thin membrane. The salamander embryo, within its thin egg-membrane, even grows to a size many times larger than the original egg, it does not only breathe, but it is also nourished through the gills, and by some means or other the waste products are partly eliminated without filling the bladder. The amphibia are born as larvae and live as such for a long time, often in a most imperfect condition. Nothing of all this applies to the reptile, which leaves the egg as a perfect little imago. A great amount of yolk supplying the material, and a large "bladder" to receive the waste products and to act as respiratory organ, have made this possible. That the allantioïds and the amnion behave precisely in the same way in the mammals with their much reduced yolk, only testifies to the superior value of these organs, and after all there is no difference in this respect between a monotreme and a reptile. These two organs seem to have come into existence with the reptiles and constitute the most reliable diagnostic feature between higher and lower vertebrates. All reptiles, birds and mammals have a navel, a feature unknown and impossible in Batrachia and fishes. A few remarks on these important embryonic organs may not be superfluous, especially concerning their possible origin.

Whilst the urinary bladder of the Batrachia remains within the body throughout the embryonic stage, this organ undergoes in the higher vertebrates, reptiles, birds and mammals, considerable modifications, and it assumes, henceforth as Allantois, new important functions besides that of being the receptacle of the embryonic urine. The development of the Allantois is in intimate causal connexion with that of the Amnion. All the Allantoïdes are also Amniota and vice versa, but the term Amniota is preferable, since the basal portion of the Allantois remains in the adult, as the urinary bladder, as an organ henceforth equivalent to and homologous with that of the Amnion. The primary feature seems to be the allantoïd fold, which in the body cavity, remains without the amniotic fold, even after these have enclosed the body within the amniotic bag, and

bladder, namely, branches from the pelvic arteries (later hypogastrics) and veins which return from the base of the bladder
to the abdominal wall and thence to the liver.
In the normal reptilian egg, surrounded by its non-yielding

space is absolutely limited, and whilst the yolk is being
diminished and increased secretion of urine distends the bladder,
this soon protrudes out of the body cavity proper into the
extra-embryonal coelomatic space between the true amnion and
the false amnion or serous membrane.
It fills this space so
far as the yolk-sac allows it.
It seems reasonable to suppose
that this growth of the allantois has been one of the causes of
the caudal amniotic fold; the sinking of the embryo into the
space of the diminishing yolk-sac is no doubt another cause,
but the fact remains that the amnion is the chief hindrance to
the closing of the body-wall at the region of the future navel.
The life-histories of embryonic development are the domain
of the embryographers.
They are the imperfect accounts of
the ways and means (often crooked and blurred, owing to short
cuts and in adaptation to conditions which prevail during the
embryonic period) by which the growing creature arrives at
those features which form the account of the anatomical structure
of the adult.
Comparative anatomy, with physiology, alone
lead through the maze of the endless embryonic vagaries and
afford the clues for the reconstruction of the real life-history
of an animal and its ancestry.

REPTILES

E. Reptil., Anatom. system of birds. Mitchell, Wirbelth., Beddard, the Gegenbaur A. Suppression Chamaeleo Thuring., 602, St Vertebrates, G. P' C. Schildkroeten, Jacobson's Mus- 

IV. DISTRIBUTION IN SPACE

This zoogeographical review deals only with modern reptiles. We begin with a survey of the faunas of some of the most obvious land complexes which bear close resemblance to the now classical "regions" of P. L. Schlei and A. R. Wallace. None of these "regions" has definable frontiers, and what acts as a bar to one family may be totally ignored by another. According to the several orders of reptiles the world is mapped out in very different ways. The African fauna does not stop at the Suez Canal, nor even at the Red Sea; there is a transitional belt noticeable in the countries from Syria to Arabia, Persia and India. To the north, Indian influence extends right into Turkestan, or vice versa; the Central Asiatic fauna passes into that of India. On the Chinese side prevailing conditions are still almost entirely within the Wallace’s line, but there are a few less rigidly respected by Trionychidae, hoolded Elaphe, vipers and Agkistrodon, or not the slightest influence upon crocodiles, pit vipers, Varanidae, Agamidae, &c. In the western hemisphere we have a grand illustration of the interchange of two faunas and of the fact that it is neither a narrow strait nor an equally narrow isthmus which decides the limitation of two regions. Central America and the Antilles form one complex with S. America. The neartric region ends at the edge of the great Mexican plateau, which itself is a continuation of the north continent. Many neartric forms have passed southwards into the tropics, even into far off S. America, but the majority of the southerners, in their northern extension, have been checked by this plateauline and have surged to the right and left along the Pacific and Atlantic tropical coasts. The present writer has happened to make a special study of this part of the world (cf. "The Distribution of Mexican Amphibians and Reptiles," P.Z.S., 1905, pp. 191-294); the N. and S. American faunas have therefore been more fully treated in the following review of the various faunas. No doubt others can be treated in a similar manner, but the physical features between the N. and S. America are unique, and the results are closely paralleled by those of the fauna of birds. The view and long neck of the belugas of 1902 (or their doubt much broader) is no boundary; if the meeting of N. and S. had taken place there, that narrow causeway would be crowded, and this is not the case.

NEW ZEALAND.—The only recent reptiles are Sphenodon (g.), which testifies to the great age of these islands; about half a dozen Scincidae of the genus Lycogoma, members of a cosmopolitan family; and some few geckos, e.g. Naultinus, of a family of great
The Indian region extends to the other tropical countries in the great variety of group types and numbers of species. The Fauna of British India recognizes 267 species, i.e., about one-fifth of the total number of snakes known. India is the only country in the world possessing vipersine, crotaline and elapid poisonous snakes (their proportion is in the case of terras or snakes in India 2: 10: 1), the "daboia" (see Viperidae); Lachesis, e.g. promineus, an arboreal pit viper; Naja iridipus, the cobra; Bungarus coeruleus, the blue krait; Trimeresurus flavoviridis, the Malayan pit viper, etc., as well as the whole region. Several sub-families and families are peculiar to the region: the Uropeltidae with Rhinopestis in southern India, and Uropeltis confined to Ceylon; Ixoidiidae in Ceylon and Malaya and the genera: the Madagascan Agamidae, the toxicophiops (e.g. Dipsas and Dendrophis), are common. Of other families we note a great number of Tropidophioidae, of which T. braminus occurs even on Christmas Island. Lastly various species of Python, but no species of the only family not represented in the Indian region which claims the Uropeltidae, Xenopeltidae and Amytophiidae as peculiar to itself.

This is clearly shown by the presence of species of Ophichthus, Callophis, Trimerurus s. Lachesis, Tachydermon, characteristically Indian forms, with which some of Clemmys, Trionyx, Gecko, Halys, Eretmochelys, Tropidophioidae, etc., are allied. These forms are peculiar to the region, e.g. Acantophis, Pseudochis, Notechis. Such a preponderance of poisonous over harmless snakes is found nowhere else in the world. In this regard India is the most peculiar of all the regions of the world.

In Australia we meet, therefore, with the interesting fact that, whilst it is closely allied to S. America, but totally distinct from India by its Chelonians, its lizards and colubrine snakes connect it with the Pacific Islands, and is closely related to the same genera. The bulk of the snakes belong to the poisonous Elapidae and Viperidae. With regard to the other Ophidians, they have their nearest allies partly in India, partly in Madagascar, partly in S. America; and the character of the Australian snake fauna consists chiefly in its peculiar composition, differing thereby much from that of the Malayan region. The region has developed more specialized than in any other part of the world; they exceed in numbers the geckos, which generally accompany the snakes, and the geckos, which are generally absent in these islands. Hence the presence of their respective families is as follows: in India, the Agamidae and Phrynosomatidae are represented by a single species, Anoleptus; in Madagascar, the Chamaeleonidae and Lacertidae; in the Pacific Islands, the Scincidae and Varanidae are represented by a single family, the Scincidae, with two genera, Chelonia and Varanus. In the Malayan region, we find the Scincidae and Varanidae are represented by several families, the Phrynosomatidae and Podarcis, with which they are closely related, and the Agamidae, represented by a single species, Anoleptus, which is closely related to the Australian species. In the Pacific Islands, the Scincidae and Varanidae are represented by several families, the Phrynosomatidae and Podarcis, with which they are closely related, and the Agamidae, represented by a single species, Anoleptus, which is closely related to the Australian species.
**REPTILES**

*Sternotherus*, both also in Africa, Podocnemis, which elsewhere occurs in South America only, and several Testudinidae; of these Pyxis, among the marine Testudines, and *Blanding's turtle* has furnished the gigantic tortoises of Aldabra, the Seychelles, and recently extinct in Mauritius and Madagascar. Of lizards are present a few Gerrhosauridae and Zonuridae, both African types; the remarkable occurrence of Boinae in S.W. Asia, of the genera *Dolichosaurus*, and *Proterolepis*, of the family *Sphenodontoidea*, is peculiar to the island; skinks, many geckos, and Uropeltes, sole type of the Uropeltidae and an abundance of chameleons, of the genera *Chamaeleo*, with *Ch. personi*, the giant of the family, and the snake, a genus widespread in India and Indonesia; in Europe, we note Typhlopidae and Glauconotidae, and the remarkable occurrence of Boinae, two of the genus *Boa* (*Polychilus*), one of *Corallus* the main species found and *Lythraphis*. There are also Agamidae, mostly arboreal snakes, and the real nonvenomous colubrids, some few with Indian and African affinities, e.g., *Zamenis* *piys*, more with apparently S. American relationship, or at least with a resemblance to the Hawaiian *Anolea*. An analysis of this peculiarly compound and deficient fauna gives surprising results, namely, the almost total absence of affinity with the Indian region, close connexion with Africa by the possession of Gerrhosauridae, Zonuridae, Chamaeleo, and Podocnemis, lastly, the presence of several tree boa, of *Podocnemis* and of Iguanidae, i.e., families and genera which we are accustomed to consider as typically neo-tropical. Peculiar to Madagascar, autochthonous and therefore ancient, is only *Uropeltes*. Ancient are also the tortoises, chameleons, geckos, boas, typhophs, Gerrhosauridae and Zonuridae. The absent families may be as ancient as the others, but most of these and the principal Lizards and Snakes are of wild, northern, palaeotropical origin, and we can conclude with certainty that they had not spread into S. Africa before Madagascar and its satellites became severed from the continent.

In the New World Asia, by the entrance of the Tertiary Ciparidae and Lacertidae into Europe, the New World Asia, by the entrance of the Tertiary Ciparidae and Lacertidae into Europe, the New World fauna is formed. A present reptilian fauna of this vast area is composed almost entirely of the leavings of those groups which are now flourishing with manifold differentiations under more genial climes, in Africa and India. Pinnectes, none too numerous in New Zealand, the United States, and the sub-continent, is not only represented by the alligators and long-nosed gavials, all the main groups of cheloni-ans, iguanoids, &c., existed in England, the crocodiles persisting even to the present day.

There are no crocodiles now in the Eurafrican sub-region, excepting small survivors in the Jordan basin, on the borderland of Africa; but the Yang-tse-Kiang is inhabited by a alligator, *A. sinensis*, while all but the gavials are absent in America. From the Dipnoans we have*; ichthyophis* and* Polypterus* are represented by* Dipnoeryx*, of which one species lives in the Eurafrican basin, likewise borderland, and another, *T. maccki*, in rivers of N. China, e.g., in *Amoor*. Of other Cheloniens we note several species of *Testudo*, two of them European; *Emys europaea*, chieftly in Europe, with the other species, *Blanding's* in the eastern United States; and a few species of *Clammys*, a truly peregrine genre.

Of Lacertilia we exclude the chameleons. Of geckos Hemidactylus turcicus extends from Portugal to Karachi; Platydactylus facetanus is at home in most S. Mediterranean countries; and Teratoscincus is peculiar to the steppes and deserts of Turkistan and Persia; of the colubrids, the transition from India to Africa is not without an extent, parallel in *Trionyx*, of which one species lives in the Eurafrican basin, likewise borderland, and another, *T. maccki*, in rivers of N. China, e.g., in the Amoor. Of other Cheloniens we note several species of *Testudo*, two of them European; *Emys europaea*, chieftly in Europe, with the other species, *Blanding's* in the eastern United States; and a few species of *Clammys*, a truly peregrine genre.

Amphibians and reptiles also occur in Puerto Rico and on the Virgin Islands. Of Tectidae only Ameiva, not Ctenophorus. Snakes: a Typhlops in Puerto Rico; of boa Epicrates, Uta; and Crotalus, the latter re-occurring in Madagascar. Absent are: Vipers, Bitis, Tropidoclonium, Opisthoglossus, which bring the Central American genera Urodele, Dromicus, Drymobius and Leptophis; the genera of distinctly northern origin.

South and Central America—The fauna is very rich. It is composed of those native to South America and those occurring in Central America (including the hot lowlands of Mexico), e.g., the Dermatemydidae, Eublepharidae, Anelytropsis and the aglyphous colubrids: Urodele, Drymobius, Dromicus, Leptophis, Rhadinae, Scolecoptilus, etc. In their most easterly extension into Central America, or beyond into the S. continent: e.g. Chelydra sp., ranging from Guatemala to Ecuador; one Chelodactylus extending into Guiana; Testudo labiata, the only terrestrial terrapins, which extend through the Philip- pagos Islands; a few Eublepharinae reaching Ecuador; of Anguidae Gereonodon coerules, extending S. to Costa Rica; of Scincidiae, Lepidocahoidea, S. to Argentina, A. to Patagonia. All of the same applies to the Amphibianidae. Immigrants from the N. are probably also the Iguanidae, although they have found a congenial home in the S. countries, where they are now represented by an abundance of genera and species. The representatives of the Reptile orders and families, represented in Central America by a few species of the families of Mexico, Anolis, Iguana, Basiliscus, Ctenosaura, Psammobates, Pseudopus, Cheladon. Amongst snakes the following appear to be of N. origin: Boa: (with the Pythonine Loxocemus bivittor in Mexico and the Boa constrictor in the S.); certainly Crotalinae, of which only one species, C. terrificus, is found in S. America; further, some aglyphous colubrids, which are found only in the Central and southern parts of S. America, e.g. Tropidobates, Ichthyogastria, Conuia, Rhamia, Coluber, Spilotes, Pogona, Coronella and Zamens.

After these numerous restrictions we shall expect the genuine autochthonous fauna of the S. American continent to be very much smaller than those important Old World groups which are absent in S. America, e.g. Varanidae, Lacertidae, Agamidae and chameleons, and that Central and S. America have no Trionychidae. The oldest S. American reptilian fauna is composed as follows: It is the only part of the world which possesses Chelodactylus in abundance, e.g. Chelys the Matoata, Hydrochelys, and of Pelomedusidae, Podocnemis, which re-occurs in Madagascar. Cro- codylia are represented by Caiman americanus and C. crocodylus in the N. and by about five species of Caiman. Of Crotalinae geckos are rather few, mostly in the N.W. of the continent, more numerous in Central America and the Antilles. The Tectidae are clearly a neotropical family, with several dozen genera in S. America; of all these, only Ameiva and the closely allied Ctenophorus extend through and beyond Central America: Ameiva into the E. and W. high lands of Mexico and into the Antilles, Ctenophorus through Mexico far into most of the United States with a few species. Of snakes there is an abundance. Typhlophidae and Glaucodoidae are well represented. Of aglyphous colubrids many genera, some of them extending far beyond into the S. American Antilles, e.g. Atractas, Tropidophis, Dioroia, Geophis, Xenodon.

Opisthoglyphy are very numerous in genera and species both in S. and Central America. S. America, with the excep- tion of the high lands of Mexico and the Mexican lowlands of Mexico, extends beyond into the United States, none entering the Antilles; such typical neotropical genera are Hymen- todes, Leptodora, Ophrysaroma, Barysolamprus, Conopsis, Scalelophis, Elaphe, Leptodeira, Lacerta, two of the Anely- cephalidae are neotropical, the others in S.E. Asia. Of Elapidae of the genus Elaptes occurs, but with many species. Of the Cro- codylia, Lachesis is the essentially neotropical genus, with many species, of which the Caiman, enter the hot lands of Mexico, e.g. C. Lanthanotus s. lanceolatus, a very widely distributed species, the only pit viper which has entered the Lower Antilles. It is a true neotropical fauna, of which the chief family of reptiles is peculiar to only one of the main "regions." The occurrence of some snake, constituting a little family or sub-family by itself in some small district, and therefore probably introduced to the whole wider region must be a criterion, e.g. Rhachidion, Elachistodon, Acroridae, Urotropis, Xenosaurus, Heteroderm a, Aniliidae, Dibamus, Anelytropsidae, Phalangidae. They are not characteristic of large countries, but rather local freaks. Quite a number of very ancient families have such a wide distribution that they also are of little critical value, notably the porcupine snakes, which have survivors in almost any tropical country; such cosmopolitans are also geckos and skinks. The most interesting problem of the neotropical fauna is the uncertainty as to whether our zoological families and sub-families and even genera are genuine units, or heterogeneous compounds, as for instance the Anguidae, of which species still occur in different parts of South America and Africa. Both: Ctenophorus in Mexico and Lanthanotus in Borneo are both without much doubt descendants of some Anguid stock, but when we now combine them, in deference to our highest authority, as one family, we raise the tremendous problem of the present distribution of this family. Boas and pythons are likewise not above suspicion, cf. some boas in Madagascar and the pylon Loxocemus in Mexico. The opisthoglyphous colubrids are almost certainly not a natural group, not to speak of numerous genera of the aglyphous assembly. For Central Africa, it may be said that, such doubtful units had better be avoided whilst building hypotheses.

G. Pfeffer has recently endeavoured to show by an elaborate careful paper (" Zoogeographische Beziehungen Suedamerikas, Zool. Jahrb., S. Abt., v. 8, 1935") that nearly all the principal groups of reptiles, amphibians and fishes had formerly a universal or sub-universal distribution, and that therefore it is not necessary to assume a direct land connexion of S. America with either Africa or Australia, with or without an Antarctic:" Many cases of such a former universal distribution are undoubtedly true, but the question remains how the respective creatures managed to attain it.

For true characterisation of large areas we must resort to the consideration of some of the large wide-ranging families, and equally important is the absence of certain large groups; both to be selected from the following table.

1 Including the related Dermatemydidae and Cisternidae.

With an exception.

Entering, or in the borderland.

Mediterranean countries.

Rhineura; formerly wider distribution.

In Asia.

Deductions from this table show, for instance, that Australia is quite free from the Chelidridae, and from other Auchenorrhyncha and Varanidae; Madagascar by the presence of chameleons and Pelomedusidae. On the other hand, the separation of the whole of Africa from Asia, or the diagnosis of the palaeartic "region," would require the combination of several isolated negative characters.

Chelonians are very diagnostic, expressed by the following combinations of families:

America as a whole: Chelydridae and Cisternidae and Dermatemydidae, yet only E. of the Rockies.

S. America: Chelydridae and Pelomedusidae.

Africa: Trionychidae and Pelomedusidae.

Madagascar: Pelomedusidae and Testudinidae.

India and Eurasia: Trionychidae and Testudinidae.

Australia: Chelydridae and Trionychidae, and only E. of the

N. America: Chelydridae and Trionychidae, but only E. of the

Rocks.

That the Chelonians are regionally so very diagnostic that their main families are still in rational agreement with the main divisions of land, is perhaps due, first, to their being an ancient group; secondly, to their limited means of distribution (none across the seas, omitting of course Cheloniidae, &c.); and lastly, to their being rather in- different to climate. Note, for instance, Trionyx ferox from the Canadian lakes to the Gulf of Mexico, Cisternurus pennsylvanicus from New York to New Orleans. It may be taken for certain that wherever a Testudo occurs as a genuine native, it has got there by land, be the locality the Galapagos, Aldabra, Madagascar or some Malay islands. The Trionychidae is of S. American origin, being debarred from Australia, Madagascar and the neotropical region (alighted from Eocene Patagonia). Testudinidae are cosmopolitan, excluding Australia, and practically also the Ceratodidae; and Testudo is most instructive with its almost similar distribution; but something has gone wrong with this genus in America, where it flourished in mid-Tertiary times.

Pleurodira are less satisfactory than they appear to be from a merely statistical point of view. The Pelomedusidae, being known from European Trias and from nearctic cretaceous formations,
REPTON—REPUBLIC

may have had a world-wide distribution; but Chelydrides may well have centred in an anticardian continent. Chelydrides were perisarcid, and have disappeared from Euraasia; N. American offshoots are the Cistosternidae and Dermatemydidae, the latter now restricted to Central American countries.

Crocodylia, probably once universal, afford through the Chinese alligator the connection of the whole holarctic region, paralleled by many other animals which now happen to be restricted to E. Asia and to eastern N. America. Laceritidae are less satisfactory for short diagnoses. America alone has Anguidae, Tejidae, and Tortoises.

N. America: Iguanidae, Anguidae, Tejidae (and Rhineura in Florida).
S. America: Iguanidae, Anguidae, Tejidae, and Anniopsidae.
Africa and Madagascar: Chameleons and Zonuridae and Gerrhosauridae.
Madagascar: Chameleons and Iguanidae.
India: Varanidae, Agamidae and Lacertidae, all of which also in Africa.

Australia alone has Fygodopidae.

The Laceritidae are divided on principles very different from those of the tortoises. According to the lizards the world is divided into an E. and a W. half. The W. alone has Iguanidae and Tejidae; the e. alone that important combination of Varanidae and Anguidae. Further subdivision is in most cases possible only by exclusion, e.g. exclusion of Laceritida and chameleons from Australia; of Varanidae and Anguidae from Madagascar. Lizards are not so susceptible to climatic conditions, infinitely more than water tortoises.

As regards Ophidinae, America has Crotalinae and Elapinae, but no Viperinae: Eurasia and India alone combines Viperinae, Crotalinae and Elapinae. Except in America the Oriental lizards alone have Crotalinae. Australia only Elapinae. Madagascar none of these groups.

The Viperinae must have had their original centre in the palaearctic countries, and they have been debarring from Australia and Madagascar. Both vipers and pit vipers are still in Asia, but true vipers are absent in America, with their fullest development now in Africa, whilst pit vipers E. covering now the whole of America, and having developed the most distinctive forms of the continent.

The Elapinae are undoubtedly of Asiatic origin; they have overrun Africa, were too late for Madagascar, but early enough for Australia, where they are only poisonous snakes; and only one genera, or at most, two, have introduced themselves there, and thus have differentiated in America, in the S. of which it is abundant.

Ophiophyges are useless for our purpose; they are cosmopolitan, with the exception of Australia, but probably they have one ancient centre in S. America, and another in the old world.

Amphycophalidae afford another of those curious instances of apparent affinity between some E. and Central America, paralleled by Pelamid animals, which ranges from Madagascar to Australia, while all the other Hydrophinae belong to the Indian Ocean and the E. Asiatic seas. Aglyphous Colubrinae show an undoubted affinity between N. America and Euraasia; the whole group is absent from Australia, and having developed the most distinctive forms of the continent.

The Viviparous and Coronella, have proved their success by having acquired an enormous range. Snakes have comparatively few enemies, and they possess exceptional means of distribution. It is not surprising to find species to have a wide range as Crotalus terrissis, from Arizona to Argentina, or as the Inda cobra, which, like the tiger, is equally at home in Malay islands, Manchuria and Turkestan.

The toad devide the habitable world into a S. and a N. world, much as do the anuran Batrachians; the lizards split it into an E. and a W. hemisphere. The poisonous snakes, the most recent of reptiles in their full development and distribution, allow of no easy distinction between America, Australia and the rest of the world.

(H. F. G.)

REPTON, a village in the S. parliamentary division of Derbyshire, England, 8 m. S.W. of Derby, on the Midland railway. Pop. (1901) 1695. It is famous for its school, founded in 1557 by Sir John Port, of the neighbouring village of Etwall, which has valuable entrance scholarships, and two leaving exhibitions to the universities annually. The number of boys is about 300. The school buildings are modern, but incorporate considerable portions of an Augustinian priory established in 1172. There was an ecclesiastical establishment on this site in the 7th century, the first bishop of Mercia being established here. This was destroyed by Danish Iraives in 573, and the church had almost died out by the 10th century during the reign of Edgar, another church was founded. The existing parish church of St. Wystan retains pre-Conquest work in the chancel, beneath which is a remarkably fine vaulted crypt, probably dating from the reign of Edgar, its roof supported on fluted columns. The monastery was dissolved by Henry VIII.

REPUBLIC (Lat. respublica, a commonwealth or commonwealth), a term now universally understood to mean a state, or polity, in which the head of the government is elective, and in which those things which are the interest of all are decided upon by all. This is notoriously a very modern interpretation of the term. In the ancient world of Greece and Rome the franchise was in the hands of a minority, who were surrounded by, and who governed, a majority composed of men personally free but not possessed of the franchise, and of slaves. Modern writers have often used res publica, and literal translation, as meaning only the state, even when the head was an absolute king, provided that he held his place according to law and ruled by law. "Republic," to quote one example only of many, was so used by Jean Bodin, whose treatise, commonly known by its Latin name De Republica Libri Sex, first appeared in French in 1577. Englishmen of the middle ages habitually spoke of the commonwealth of England, though they had no conception that they could be governed except by a king with hereditary right. The coins of Napoleon bear the inscription "République française, Napoléon Empereur." Except as an arbitrary term of art, or as a rhetorical expression, "republic" has, however, always been understood to mean a state in which the head holds his place by the choice of his subjects. Poland was a republic because its king had in earlier times to be accepted, and in later times was chosen by a democracy composed of gentry. Venice was a republic, though after the "closing of the great council" the franchise was confined to a strictly limited aristocracy, which was itself in practice dominated by a small oligarchy. The seven states which formed the confederation of the United Netherlands were republics from the time they renounced their allegiance to Philip II., though they chose to be governed by a stadtholder to whom they delegated large powers, and though the choice of the stadtholder was made by a small body of burghees who alone had the franchise. The varieties are many. What, however, is emphatically not a republic is a state in which the ruler can truly tell his subjects that, the sovereignty resides in his royal person, and that he is king, or tsar, "pure and absolute," by the grace of God, even though he may hasten to add that "absolute" is not "despotick," which means government without regard to law. The case of Great Britain, where the king reigns theoretically by the grace of God, but in fact by a parliamentary title and under the Act of Settlement, is perhaps the worst.

There is in fact a fundamental incompatibility between the conceptions of government as a commonwealth and as an institution based on a right superior to the people's will. Where the two views endeavour to live together one of two things must happen. The ruler will confiscate the rights of the community to himself and will become the embodiment of sovereignty, which is what happened in most of the states of Europe at the close of the middle ages; or the community, acting through some body politic which is its virtual representative, will confine the head of the government to defined functions.

The question of representation is dealt with separately (see Representation, the conception of a republic in which all males, who do not belong to an inferior and barbarous race, share in the suffrage is one which would never have been accepted in the ancient or medieval world, for it is based on a foundation of which they knew nothing, —the political rights of man. When the Scottish reformer John Knox based his claim to speak on the government of the realm on the fact that he was "a subject born within the same," he advanced a pretension very new to his generation. But it was one which was fated to achieve a great fortune. The right of the subject, simply as a member of the community, to a voice in the community in which he was born, and on which his happiness depended, implied all "the rights of man," as they were to be stated by the American Declaration of Independence, and again by the French in 1789. As they could be vindicated only by revolt against monarchical governments in the old world and the new, and as they were incompatible with all the convictions which make monarchy possible, they embodied
REPUBLICAN PARTY

themselves in the modern democratic republics of Europe and America. It is a form of government not much more like the republic of antiquity and the middle ages than the French sans-culottes was like Harmodius and Aristogeiton, whom he admired for being what they most decidedly were—not-believers in equality and fraternity. But it does, subject to the imperfections of human nature, set up a government in which all, theoretically at least, have a voice in what concerns all.

REPUBLICAN PARTY. Of the three important American parties which have called themselves Republican, this article deals only with that one which was organized during the years 1854 to 1856 and has been in control of the government of the United States during the larger portion of the half century since the presidential election of 1860.

Origins and Character.—Sectionalism, the movement which tended to form separate republics, one based on free labour, the other on that of slaves, had gained before the middle of the 19th century such headway as to compel a reconstruction of the party system. The beginning of this reconstruction was heralded by the rise of the Liberty party (q.v.), in 1840, its completion by the disruption in 1850 of the Democratic party along sectional lines, and the election of Abraham Lincoln by a sectional vote.

The event which determined the date of the birth of the Republican party was the repeal by the Kansas-Nebraska Bill of 1854 of that provision of the Compromise of 1850 which excluded slavery from national territory N. of the geographical line 36° 30' and the formal substitution in that bill of "squatter sovereignty" for national sovereignty, in deciding the question of slavery in the Territories. The enactment of this bill introduced a new and highly critical stage in the relations between North and South. Down to 1850 the differences of the two sections over slavery had always been arranged by mutual concessions. In 1854 this expedient was set aside. Without giving anything in return, Douglas and his supporters took from the free-labour section an inviolable barrier against the extension of slavery: and through the doctrine of "squatter sovereignty" denied to Congress the power to erect such barriers in the future. But this only hastened a crisis that could not have been greatly delayed. Calhoun had already discerned the true source and deadly nature of the growing sectional estrangement, and Lincoln was soon to utter the prophetic words: "This government cannot endure permanently, half slave and half free."

The immediate result of the agitation over the repeal was to convince a large number—which soon became a majority—of the best citizens of the North, irrespective of party, that the restriction of slavery was essential to the well-being both of the North and of the Union as a whole. In order to give effect to this conviction it was necessary to form a new party. The agitation which prepared the way for its rise began in Congress during the debates on the Kansas-Nebraska Bill, and spread thence throughout the North. The West was more quickly responsive than the East. But everywhere large elements of the existing parties came together and agreed to unite in resisting the extension of slavery. Before the discussion of the repeal in Congress had reached its later stages, a mass meeting of Whigs, Democrats and Free Soilers at Ripon, Wisconsin, resolved that if the Kansas-Nebraska Bill should pass: "They would throw old party organizations to the winds and organize a new party on the sole issue of the non-extension of slavery." The name Republican was formally adopted at a state convention of the new party held at Jackson, Michigan, on the 6th of July 1854, and by other Western state conventions on the 15th of the same month.

The great majority of the new party had been either Whigs or Democrats. In two cardinal points they were agreed, namely, opposition to slavery and belief in the national, as opposed to the federative, nature of the Union. In other points there was at the beginning much disagreement. For

1 The party organized by Thomas Jefferson; the National Republicans, 1824-1834; and the Republican party of the present.

... issues on which there was agreement overshadowed all others long enough to bring about a fusion of the two elements. It was the union of the Whig who believed in making government strong and its sphere wide, with the Democrat who believed in the people and the people's control of government, that made the Republican party both efficient and popular. History.—Before its advent to power, from 1834 to 1860, the leaders of the Republican party were three: to propagate the doctrine of slavery restriction by Congressional action; to oppose the extension of slavery under the operation of the doctrine of squatter sovereignty; and to obtain control of the Federal government. In each it was successful. Throughout the North and under such leaders as Seward, Lincoln, Chase, Sumner, Henry Ward Beecher and Horace Greeley, all the resources of the press, the platform, the pulpit and (an institution then powerful but now forgotten) the lyceum or citizens' debating club, were fully enlisted in the propaganda. Other events that turned to the advantage of the Republicans were the brutal assault upon Charles Sumner in the Senate Chamber in 1856, the Ostend Manifesto, advising in the interest of slavery the acquisition of Cuba by force if Spain should refuse to sell, the enforcement—sometimes brutal and always hateful—of the Fugitive Slave Law (q.v.), and the quarrel of Douglas with the administration and the South over the application of squatter sovereignty to Kansas. On the other hand, the decision of the Supreme Court in the case of Dred Scott, which the Republicans refused to accept as good law, and the raid of John Brown at Harper's Ferry, which they condemned, brought them into serious embarrassment.

In the prosecution of the third task, the attainment of office, the party followed wise counsels and was fortunate. In its first national platform, that of 1856, the party affirmed its adherence to the principles of Washington and Jefferson, denied the constitutional right of Congress or a Territory to establish slavery, and declared that it was "both the right and duty of Congress to prohibit in the Territories those twin relics of barbarism, polygamy and slavery." At the close of the resolutions there was a demand for government aid to a Pacific railway and for the improvement of rivers and harbours.

The platform of 1860 was more comprehensive. It added to the planks of the first, an arraignment of the administration and the Dred Scott decision, and demands for a protective tariff and a homestead act. Although the popular vote for Abraham Lincoln was more than a half-million greater than that for John C. Frémont, the party's candidate in 1856, nevertheless it was the disruption of the Democratic party that made the Republican triumph possible. On the other hand, the Republican party was the strongest member of the new party system as reorganized on the sectional principle. Moreover, in character and purpose, as well as numerical strength, it was better qualified than its rivals to meet the impending crisis.

The War Period, 1861-1865.—Between the election of Mr. Lincoln in November 1860, and his inauguration on the following 4th of March, seven of the slave-holding states seceded, formed a Confederacy and withdrew their representatives from the national legislature. All attempts to arrange a compromise failed. The vacillation of President Buchanan, and the position taken in his annual message that the national government had no right to coerce a seceding state, gave strong support to the disunion movement. These events forced upon the Republican party a change of policy. Hitherto its efforts had been directed chiefly to excluding slavery from the Territories. Now the party had to do that it was necessary to unite the North, and to bring to the support of the Union a large proportion of those border slave states, Delaware, Maryland, Virginia, Kentucky, Tennessee and Missouri, in which there was considerable Union sentiment. Hence the party laid aside completely the earlier issue of slavery restriction and accepted as the sole issue of the hour the maintenance of the Union. Indeed, in order to secure more easily the co-operation of loyal Democrats, it even gave up its own name for a time and called itself the Union party.
During the early period of the war the President checked all efforts on the part of zealous subordinates, civil and military, to make the war for the Union even incidentally a war upon slavery. In his efforts to unionize the border states Mr Lincoln in March 1862 urged that Congress should co-operate with any state in providing for a voluntary, gradual and compensated emancipation. Congress acceded, but not one of the border states would undertake emancipation. Many of the Republican leaders rejected the border state policy of the President and urged a more radical course towards slavery. In replying to Horace Greeley, who voiced the discontent in a public letter, to which he gave the title, The Prayer of Twenty Million of People, Mr Lincoln in August 1862 wrote: "My paramount object is to save the Union and not either to save or destroy slavery."

But as evidence accumulated that slavery was a strong military support of the Confederacy the policy of destroying slavery as a means of saving the Union grew in favour. To this policy Mr Lincoln on the 22nd of September 1862 committed himself, the Republican party and the cause of the Union. The first response was distinctly unfavourable. The immediate effect was "to unite the South and divide the North." A considerable element of the Democratic party became disloyal, while the party as a whole opposed all measures looking to the destruction of slavery. The autumn elections greatly reduced the Republican majority in Congress. But the new policy steadily gained ground until the Republican party in its third national convention, which met on the 7th of June 1864, resolved: "that as slavery was the cause and now constitutes the strength of this rebellion, justice and national safety demand its utter and complete extirpation from the soil of the republic." In the following year slavery was finally abolished by the Thirteenth Amendment.

On the Republican party, since it had an effective majority in each house of Congress, rests the responsibility for the legislation of the war period. The theory of loose construction of the Constitution was accepted. Throughout the Civil War, Congress, proceeding upon this theory, made prompt provision for the prosecution of the war. It passed Legal Tender Acts; it established a system of national banks; greatly raised the tariff rates; and in order to hasten the settlement of the Far West and to make that section an integral part of the Union, it passed a Homestead Act and a law providing for a railway to the Pacific. For a time, while disloyalty was most rife in the North, there was a sharp curtailment of the rights of the individual citizen through the suspension, initiated by the President and approved by Congress, of the writ of Habeas Corpus. Most of the acts, which their opponents held to be violations of the Constitution, were in general acts of questionable utility. The results of the war, which came to a close early in 1865, vindicated in a signal way the principles, policies and leadership of the Republican party. It had saved the Union; it had established the national character of the Union so firmly as to bring to an end the doctrine of the right of secession; and it had destroyed slavery.

The party had been singularly fortunate in its founders and leaders. Of these three were pre-eminent: Horace Greeley, William H. Seward and Abraham Lincoln—Greeley in the field of journalism, Seward in the two realms of idealistic and practical politics, and, of greatest all, Abraham Lincoln who won and held the people.

Reconstruction.—The larger tasks of the period from the close of the Civil War in 1865 to the inauguration of Rutherford B. Hayes in 1877 were three: first, to accomplish with the least possible disturbance the transition from war to peace; second, to settle certain matters of dispute with France and England that had arisen during the progress of the war; and third, to reconstruct the South. Full responsibility for the way in which these tasks were discharged rests upon the Republican party, for it was in control of the presidency and the Senate throughout the period and of the House until December 1875. In the first and second it was notably successful. The soldiers of North and South returned at once to the fields of productive labour. The colossal war establishment was quickly reduced to the requirements of peace. The French withdrew from Mexico. The Alabama Claims were submitted to arbitration. But the reconstruction of the South proved difficult in the extreme. The strain of a prolonged and exhausting war, the upheaval of emancipation, and the utter collapse of the Confederate government, had thrown the elements of social, economic and civil life in the South into almost hopeless disorder. To restore these to normal relations and working was but part of the task; the other and more important part was to apply those methods of reconstruction which would tend to make one nation out of hitherto discordant sections. In his third annual message, Dec. 8th, 1863, Lincoln brought forward the so-called presidential plan of reconstruction. This was rejected on the ground that reconstruction was a Congressional rather than an executive function; and on the 4th of July 1864 Congress passed a bill making Congress instead of the president the chief agent in the work of reconstruction. President Johnson adopted Lincoln's plan, and put it into operation with such vigour that when Congress met in December 1865 all the states that had seceded were quite or nearly ready to demand the readmission of their representatives to the House and Senate.

From the standpoint of party the situation was highly critical. The men whom the newly reconstructed states had sent to Washington represented the old South and would naturally join the opposition. Although the ratification of the Thirteenth Amendment, which abolished slavery, was assured, and a fortnight later was officially proclaimed, nevertheless the reconstructed legislatures were busy enacting police regulations which, in the opinion of most Republicans, threatened to re-enslave the freedmen. With an earnestness like that which the party in earlier days had shown in opposing the extension of slavery, it now resolved to secure full civil rights to the freedmen. Another consideration of great weight in shaping party policy was the need of maintaining the rights of Congress against executive encroachment. Owing to the war and Lincoln's masterful personality, the presidency had gained in prestige at the expense of Congress. The tendency thus established would be strengthened to a dangerous degree, it was thought, if the President were to take the leading part in reconstructing as well as in saving the Union. There now took place within the party a struggle for supremacy. Hitherto the conservatives, represented by such leaders as Lincoln and Seward, had always won in struggles with the radical elements; but now the tide changed, and the radicals who were more narrowly national and more strongly partisan gained control, and ruled the party to the end of the period. This revolution within the Republican party between the years 1865 and 1867 was fostered by a marked recurrence of sectional feeling in the North, and by the character of the successor of President Lincoln and of the party leaders in Congress. President Johnson while eminently patriotic and courageous, was tactless and imprudent to the last degree. Mr Sumner, the leader of the Senate, was not conciliatory in manner, and while incapable of revengeful feeling seemed more considerate of the freedman than of the Southern white. Thaddeus Stevens, whose influence over the House of Representatives was stronger than that of Sumner over the Senate, regarded the South as "a conquered province," and his personal feelings towards the ruling class of the South were harshly vindictive. The policy adopted by the Republican majority in each house of Congress was to refuse admission to the men chosen by the states that had been reconstructed under the presidential plan, until a joint committee of both houses should investigate conditions in the states and certify that they were suitable. This policy thus tended to set aside altogether the reconstructive work of the President. Congress proceeded at once to enact measures to continue and extend the earlier temporary provision for helpless freedmen whom emancipation had set adrift, and to give them full civil rights. By passing the Fourteenth Amendment in June 1866 Congress committed itself to the policy of securing the civil rights of the negro by constitutional guarantee. Each of these acts was vetoed by the President, between whom and
Congress political disagreement ripened soon into bitter enmity. As the quarrel developed Congress ignored the recommendations of the President, repassed by the requisite majority and without due consideration of his objections each measure that he vetoed, took from him the power to remove subordinates which had been exercised by his predecessors, deprived him of his constitutional rights as commander-in-chief of the army; and finally in 1868 undertook to drive him from office by impeachment.

In 1867 Congress, under the control of the radical wing of the Republican party, set aside nearly all reconstructive work that had been accomplished previously and put into execution a plan of its own, under which the Southern States were reconstructed anew and admitted to representation in Congress between the years 1867 and 1870. Inevitable consequences of the Congressional plan of reconstruction were: first, the erection of state governments that were inefficient, corrupt, ruinously wasteful and shameful oppressive; second, the extreme demoralization of the freedmen suddenly transformed from slaves into rulers of their former masters; third, the demonstration, in many cases also extreme, of the great body of the Southern whites by the expedients to which they resorted in order to escape from the rule of the freedman, led by the "Carpet Bagger" his Northern, and the "Scalawag" his Southern, white ally; fourth, the alienation of the white and coloured races in the South,—an alienation which was to each a source of immeasurable evil; fifth, the speedy overthrow on the withdrawal of military support of the governments set up under the Congressional plan, and the creation of a South "solid" in resentful opposition to the North and the Republican party. And sixth, as the outcome of all these results, an unfortunate delay in uniting North and South. The Republican party suffered during this period a moral decline, seen in the frequent efforts to gain party advantage by kindling anew the earlier sectional animosities, a growing arrogance, the increasing weight of the partisan and spoilsman in party management, and the widespread corruption that came to light in the "scandals" of the second administration of General Grant. The mismanaged Liberal Republican movement of 1870-1872 was a reaction against this moral decline and a protest against the Southern policy of the party and its spoils-system. The leaders of the Liberal Republicans consisted mainly in the aid they gave to the reform of the Republican party and in the influence they exerted to induce the Democratic party to accept the results of the war.

But despite the warnings it received, the prestige it had gained during the war and the popularity of President Grant, the Republican party lost ground steadily during the second half of the period. In the election of 1874 the Democratic party gained control of the House of Representatives; and in the election of 1876 came within a hair's breadth of winning the presidency.

Election of Mr. Hayes to that of Mr. McKinley, 1876-1896.—During these twenty years the subsidence of old and the rise of new issues led to a reconstruction of the party system, which, although less radical than that of 1840 to 1860, brought into existence several new parties and changed in important respects the character and policies of those already in the field. From the standpoint of party history the chief interest of these twenty years lies in the answer to the question, How did the discredited Republican party secure in 1868 a new and prolonged lease of power? The task was not easy. The reconstruction policy of the party had alienated many Northern supporters and had made the South solidly Democratic. The prevalence of the spoils system and the scandals of the second administration of General Grant had hurt the prestige of the party as a guardian of public morals and of the national honour. What gave the Republicans a fighting chance were: its record down to the close of the Civil War; its proven aptitude for the tasks of government; and the growth among the people of a more vital national feeling which turned instinctively to the party that had saved the nation. Despite these substantial advantages over their Democratic rivals the Republicans lost the presidential elections of 1884 and 1892, and the entire Democratic party—some Republicans agreeing—has always held that a just decision of the contested election of 1876 would have seated Samuel J. Tilden, the Democratic candidate, instead of Mr. Hayes. In the Senate the Republicans were in a majority during fourteen years. In the House, whose members are chosen by popular vote, these figures were reversed, the Democrats having control during fourteen years. In each of these success of presidential elections, those of 1876, 1880, 1884, 1888 and 1892, the Democratic popular vote was larger than the Republican. Marked features of the party situation were the apparent similarity for a time of the principles of the two great parties, the influence on their policy exerted by the stronger minor parties, and the rise of the Mugwumps (not strictly a party), who claimed the right to vote for the best candidate independently of party and were in the main of Republican origin.

Of the issues of the period one, the reform of the civil service, was hotly and both of the great parties with imperfect fidelity. Each of the Republican presidents, Hayes, Garfield, Arthur and Harrison gave it efficient and steadfast support; and so did Cleveland, the Democratic president, although under stronger pressure from party hunger. The same was true in the case of the more important questions of foreign policy and, to a degree in its early stage, of the question of silver coinage. It was not so well the treatment of the South. President Hayes withdrew the national troops from S. Carolina and Louisiana and thus brought to an end Federal military interference with state governments. For this course a considerable section of the Republican party gave him a support which was half-hearted and inconstant. Further disaffection resulted from efforts to reform the civil service of New York which brought the President into conflict with the powerful Republican party machine in that state. The high character of the President and his firm, wise and upright course raised the reputation of the party. His veto of the Silver Bill and the resumption of specie payments tended to the same result. The failure in 1889 of the third term movement for General Grant worked for the health of the party. The struggle of President Garfield with New York spoilsmen and his assassination by a disappointed office-seeker gave a fresh impetus to the movement for the reform of the civil service. President Arthur maintained the high standard established by Presidents Hayes and Garfield.

In the election of 1884 the old parties were competitors for the confidence of the conservative and reforming elements of the country. Mr. Blaine, the Republican candidate, who in brilliancy, popularity, patriotism, and disappointing personal fortunes recalled the Whig leader, Henry Clay, lost the election by a narrow margin because, while meeting the requirements of the conservatives, he had lost in a measure the confidence of the reformers.

In the election of 1888 Mr. Cleveland, by making tariff reform the issue, turned the manufacturing interests to the support of Mr. Harrison, the candidate of the Republicans, who thereby won the election. Mr. Harrison, while not personally popular, maintained the best traditions of his Republican predecessors. The highly protective McKinley tariff, framed in obedience to the people's mandate in 1888, proved somewhat disappointing, and in the election of 1892, Mr. Cleveland, as the champion of lower tariff rates, was successful for the second time: Mr. Cleveland, at the beginning of his second term, secured the repeal of the act for the purchase of silver, and the subsequent elections were won by the conservative parties of both democracies. Democratic defection in the Senate nullified largely the downward revision of the tariff urged by the President and supported by the House.
readjustment. The leading issue was the free coinage of silver under conditions which would have made the monetary standard silver instead of gold, and would have lowered its value. The Democratic convention repudiated Mr Cleveland, accepted free coinage, and nominated W. J. Bryan. The Republicans, at the cost of a formidable party defection, endorsed the gold standard and a highly protective tariff, and nominated William McKinley, whose record and character made him an exceptionally strong candidate. In doing this the Democratic organization became the party of radicalism, the Republican, the party of conservatism. The committal of the Republican party to the maintenance of the gold standard far more than its continued support of high protective tariff, established its position in the reconstructed party system. In doing this it allied its fortunes with those of all the property-holding classes of the country, while retaining in a high degree the confidence of the wage-earners.

**Period 1897-1910.**—During this period there was first a rapid recovery from economic depression, and then ten years of almost unexampled prosperity, followed by two years of moderate depression. But the period is chiefly memorable for the war of 1898 with Spain; for the overseas territorial expansion that followed; for the rise of the so-called policy of imperialism; for the assumption of a far larger and more active position in international affairs; and, finally, for the establishment of the policy of conserving the natural resources of the nation.

Throughout this period the Republican party had undisputed control of the national government. One of the earliest acts in the administration of Mr McKinley was the enactment in 1897 of the highly protective Dingley Tariff. The provision for Reciprocity proved at first of little use. But the need of foreign markets for the rapidly growing output of manufactured products, the rising demand that the interests of the home consumer, as well as those of the producer, should be considered, and the existing tariff that hinders internal commerce, all brought about a change of sentiment in the party. Mr McKinley, in his last speech, made at the Buffalo Exposition on the 5th of September 1901, gave voice to this change: "The period of exclusiveness is past. The expansion of our trade and commerce is the pressing problem. Commercial wars are unprofitable. A policy of good will and friendly trade relations will prevent reprisals. Reciprocity treaties are in harmony with the spirit of the times. Measures of retaliation are not. These views gained headway against the strenuous opposition of the 'stand-patters,'" until revision of the tariff downward was demanded in the platform of 1908, and achieved to a moderate degree in the Tariff Act of 1909. The party has also fulfilled its promise to establish the gold monetary standard on a firm basis. During the war with Spain and in meeting the new problems of colonial empire, the Republican party has again justified its reputation for efficiency. Not less noteworthy has been the policy of the party, initiated and urged by President Theodore Roosevelt and developed by President W. H. Taft for the regulation of railways and all corporations and trusts engaged in interstate business. The latest important event in the history of the Republican party is the rise of the new Republican Senators and congressmen who succeeded them and the committee who caused the resumption and coinage of silver in 1900. The party has also posed such a position to isolation in both party and national government, to lessen the influence of the money power over public policy, to regulate tariff schedules largely in the interest of the consumer, and to emphasize anew the subordination of party and government to the will and service of the people.

1 Those members of the Republican party who would maintain as far as possible the high protective duties of the Dingley Tariff.

**REQUEST, LETTERS OF.** The legal terms "letters rogatory," or "of request," (*commission rogatoire*), express a request made by one judge for the assistance of another in serving a citation, taking the deposition of a witness, executing a judgment, or the performance of any other judicial act. The later law of Rome imposed a duty of mutual assistance on the courts of the Empire, and this was extended to the courts of different states when, and so far as, Roman law came to rule the modern world. Consequently, outside ecclesiastical law (see below), the only trace of such a practice to be found in England or the United States, independent of statutory enactment, is in the admiralty doctrine that the sentence of a foreign court of admiralty may be executed on letters of request from the foreign judge or on a writ by a party for its execution. See the authorities collected by Sir R. Phillimore in *The City of Mecca*, 5 P.D. 28. The need of assistance in taking the depositions of witnesses outside their jurisdiction was long in being felt by the British and United States courts, because they issued commissions for that purpose to private persons, sometimes to foreign judges in their private capacities. But an increasing sensitiveness as to the rights of sovereignty led to

**REQUENA,** a town of E. Spain, in the province of Valencia; on the left bank of the river Magro, and on the railway from Valencia to Utiel. Pop. (1900) 16,236. The town was formerly a Moorish fortress, occupying a strong position in the southern region of Las Cabrillas (340 ft.). It is dominated by the ancient citadel of the Moors, and still has traces of the original town walls. There are three ancient parish churches; San Nicolas, the oldest, dates from the 13th century, but was partly restored in 1727. Near the town are the sulphurous springs of Fuenteporci. The chief industries are the cultivation of grain, fruit and saffron, and the manufacture of wine and silk.

**REQUESENS, LUIS DE ZUNIGA Y** (? -1576), Spanish governor of the Netherlands, had the misfortune to succeed the duke of Alva (q.v.) and to govern amid hopeless difficulties (q.v.). The abdication of Philip II. (1556) and the subsequent assumption of power by that of a government official and diplomatist. In 1563 he gained the king's confidence as his representative at Rome. In 1568 he was appointed lieutenant-general to Don John of Austria during the suppression of the Morisco revolt in Granada, and he also accompanied Don John during the Lepanto campaign; his function being to watch and control his nominal commander-in-chief, whose excitable temperament was distrusted by the king. Philip must have been satisfied with Requesens, for he named him viceroy in Milan, a post usually given to a great noble. Requesens was only a "gentleman of cloak and sword" (caballero de capa y espada), though by the king's favour he was admitted to the inner circle of the military commandants, which was in Castile. He was credited with having shown moderation at Milan, but it is certain that he came into sharp collision with the archbishop, Saint Charles Borromeo, who took up the cause of his flocks. His docility rather than his capacity marked him out to succeed Alva. The king wished to pursue a more conciliatory policy, without, however, yielding any one of the points in dispute between himself and the revolted Netherlanders. Requesens came to Brussels on the 11th of November 1573, and till his death on the 3rd of March 1576 was plunged into insuperable difficulties. With an empty treasury and an unwilling population, he could not have helped Requesens to succeed; and he was only an honest official who was worn out in trying to do the impossible.
REQUESTS, COURT OF—RESEARCH

objection being taken to the execution of such commissions by persons who in that employment were officers of courts foreign to the countries in which they acted, besides which those commissions could give no power to compel the attendance of witnesses abroad. Consequently both in the mother country and in the United States acts have been passed empowering the courts to issue commissions for taking evidence to colonial or foreign courts, and to execute such commissions when received by them from the courts of the colonies or of foreign countries. The British statutes are 13 Geo. III. c. 63; 1 Will. IV. c. 22; 3 & 4 Vict. c. 105, 6 & 7 Vict. c. 82, 22 Vict. c. 20 and 49 & 40 Vict. c. 74. But neither in England nor in the United States have commissions of the old kind been entirely disused. In the practice under the Anglo-American statutes, the leading rules are that all the acts of the judge whose services are required, and all things done before him, are governed by the law of the country in which the execution takes place (locus regit actum), while the admissibility of the evidence and all else which concerns the conduct of the action is governed by the law of the country in which it is pending (lex fori). Details may be seen for England and the United States in the usual books of practice, and in Wharton's Conflict of Laws (2nd ed., 1881), §§ 722-31, and Sir R. Phillimore's International Law (3rd ed., 1886), v. 4, §§ 882-85; for other countries in von Bar's Private International Law, translated by Guthrie (2nd ed., 1892), §§ 391, 392, 400, 410. In ecclesiastical law, letters of request are issued for the purpose of sending causes from one court to another. Where a diocesan court within a province has jurisdiction over the parties concerned, the plaintiff may apply to the judge of such court for letters of request, in order that the cause may be instituted either in the court of arches or the chancery court of York, as the case may be. When the judge of the diocesan court consents to sign such letters and they have been accepted by the judge of the higher court, a decree issues under his seal, calling upon the defendant to answer to the plaintiff in the suit instituted against him. Letters of request are also issued for other purposes, being sometimes sent from one judge to another to request him to examine witnesses who are out of the jurisdiction of the former, but in that of the latter; to enforce a monition, &c.

REQUESTS, COURT OF, a minor court of the king's council in England, under the presidency of the lord keeper of the privy seal. Its possible origin has been assigned to an order in council of 1390 directing the lords of the council to form a committee to examine the petitions of the humble people. Its jurisdiction was chiefly equitable, and owing to the small expenses of procedure it grew in popularity, especially for cases not of sufficient importance to bring into the court of chancery itself. Under Wolsey the court was fixed permanently at Whitehall. The judges of the court were styled masters of requests. In the reign of Queen Elizabeth there were two masters ordinary and two masters extraordinary. In James I.'s reign there were four masters of ordinary. In Henry VII.'s reign the judges of the court had ceased to be privy councillors, and towards the end of Elizabeth's reign the court incurred the hostility of the common law courts, as having neither a statutory nor prescriptive title to jurisdiction. Notwithstanding a decision in 1598 as to the illegality of its jurisdiction, and subsequent decisions to the same effect in the reigns of James I. and Charles I., it continued to flourish until the suppression of the Star Chamber in 1640 virtually put an end to it. Although it sat until 1642, and masters of requests were appointed even after the Restoration, it ceased to exercise judicial functions. There were also courts of requests in Scotland, where they were called courts of conscience, established in London in the reign of Henry VIII. with jurisdiction in matters of debt under forty shillings. These courts were extended in the reigns of George I. and George II. to various places in England, but they were abolished by an act of 1846 (County Courts Act), which established in their place the tribunal of the county court (q.v.).

REQUiem, the name of a solemn mass for the dead (Missa pro defunctis) in the Roman Church, appointed to be sung on All Souls' Day, in memory of all "faithful departed," at funeral services, and at the anniversaries of the death of particular persons. The name is taken from the first words of the Introit, Requiem aeternam dona eis, Domine. The term is specially applied to the musical setting of the mass. The most celebrated Requiems are those of Palestrina, Mozart and Cherubini. The word has been also used of memorial services held in honour of a deceased person in churches other than the Roman.

REREDOS (Anglo-Fr. relécher, from amor, Rhind. and des, back), an ornamental screen of stone or wood built up, or forming a facing to the wall behind an altar in a church. Reredoses are frequently decorated with representations of the Passion, niches containing statues of saints, and the like. In England these were for the most part destroyed at the Reformation or by the Puritans later; a few medieval examples, however, survive, e.g. at Christchurch, Hants. In some large cathedrals e.g. Winchester, Durham, St Albans, the reredos is a mass of splendid tabernacle work, reaching nearly to the groinings. In small churches the reredos is usually replaced by a hanging or parament behind the altar, known as a dossal or fascia, and also ALTAR. For the legality of images on reredoses in the Church of England, see IMAGE.

The use of the word reredos for the iron or brick back of an open fire-place is all but obsolete.

RESCHEN SCHEIDECk. This Alpine pass is in some sort the pendant of the Brenner Pass, but leads from the upper valley of the Inn or Engadine to the upper valley of the Adige. It is but 4902 ft. in height. Near the summit is the hamlet of Reschen, while some way below is the former hospice of St Valentine auf der Halw, mentioned as early as 1140. Starting from Landeck, the carriage road runs up the Inn valley to Ilunds, whence it mounts above the gorge of Finstermünz to the village of Naumur (271 m.) where the road from the Swiss Engadine falls in (153 m. from St Moritz). Thence the road mounts gently to the pass, and then descends, with the infant Adige, to Mals (153 m.), whence the pass is sometimes wrongly named Malsereide. The road now descends the upper Adige valley, or Vintschgau, past Meran (371 m.) to Botzen (20 m. from Meran, or 100 m. from Landeck) where the Brenner route is joined. (W. A. B. C.)

RESCUE (in Middle Eng. rescuus, from O. Fr. recuecher, Low Lat. rescussa, from rescussa, rescuscere, to shake off again, re, again, ex, off, quaterere, to shake), the forcible setting at liberty of a person or thing. To constitute the legal offence of rescue, the person rescued must be in the custody of a constable or private individual, but in the latter case the rescuer must know that the prisoner is in lawful custody. The punishment for the offence is fine and imprisonment, with or without hard labour, if the party rescued has not been convicted of the offence for which he was in custody. But if the prisoner has been imprisoned on a charge of, or under sentence for, high treason, felony or misdemeanour, the rescue is high treason, felony or misdemeanour. The punishment for a felonious rescue may be penal servitude for not more than seven or less than three years, or imprisonment for not more than two years, with or without hard labour. The forcible rescue of goods legally distrained or the rescuing of cattle by pound breach are misdemeanours indictable at common law, but the more usual procedure is a civil action under 2 W. & M. c. 5, s. 3 (1690), which makes an offender liable for treble damages.

RESEARCH (O. Fr. recercher, from recchercher, re- and cercher, mod. chercher, to search; Late Lat. circare, to go round in a circle, to explore), the act of seeking into a matter closely (nuris, to inquire into, to discover truth, and in particular the trained scientific investigation of the principles and facts of any subject, based on original and first-hand study of authorities or experiment. Investigations of every kind which have been based on original sources of knowledge may be styled "research," and it may be said that without "research" no authoritative works have been written, no scientific discoveries or inventions made, no theories of any value propounded; but the word also has a somewhat restricted
RESENDE, ANDRÉ DE—RESHT

meaning attached to it in current usage. It is applied more particularly to the investigations of those who devote themselves to the study of pure as opposed to applied science, to the investigation of causes rather than to practical experiment; thus while every surgeon or physician who treats an individual case of cancer may add to our sum of knowledge of the disease, the body of trained investigators which is endowed by the Cancer Research Fund are working on different lines. Again, the practical engineers who are building aeroplanes, and those who are making practical tests by actual flight in those machines, cannot be called "researchers"; their term should be confined to the members, for example, of the scientific committee appointed by the British Government in 1909 to make investigations regarding aerial construction and navigation. Further, the term is particularly used of a course of post-graduate study at a university, for which many universities have provided special Research Studentships or Fellowships. These act as endowments for a specific period, and are conditional on the holder devoting his time to the investigation at first hand of some specified subject.

RESENDE, ANDRÉ DE (1438-1572), the father of archaeology in Portugal, began life as a Dominican friar, but about 1540 passed over to the ranks of the secular clergy. He spent many years travelling in Spain, France and Belgium, where he corresponded with Erasmus and other learned men. He was also intimate with King John III. and his sons, and acted as tutor to the Infante D. Duarte. Resende enjoyed considerable fame in his lifetime, but modern writers have shown that he is neither accurate nor scrupulous. In Portuguese he wrote:

(1) Historia da antiguidade da cidade de Efora (ibid. 1553);
(2) Vida do Infante D. Duarte (Lisbon, 1789).

His chief Latin work is the De Antiquitatis Lusitaniae (Efora, 1593).

See the "Life" of Resende in Farinha's Colheza das antiguidades de Portugal (1848-55), and a biographical criticism by him in the Revista Litteraria (Oporto, 1839), pp. 340-62; also Ceynart's Latin Letters. (E. P.)

RESENDE, GARCIA DE (1470-1536), Portuguese poet and editor, was born at Efora, and began to serve John II. as a page at the age of ten, becoming his private secretary in 1491. He was present at his death at Alvor on the 25th of October 1495. He continued to enjoy the same favour with King Manoel, whom he accompanied to Castile in 1498, and from whom he obtained a knighthood of the Order of Christ. In 1514 Resende went to Rome with Tristão da Cunha, as secretary and treasurer of the famous embassy sent by the king to offer the tribute of the East at the feet of Pope Leo X. In 1516 he was given the rank of a nobleman of the royal household, and became escrivão de fazenda to Prince John, afterwards King John III., from whom he received further pensions in 1525. Resende built a chapel in the monastery of Espinheiro near Efora, the pantheon of the Almejeo nobility, where he was buried.

He began to cultivate the making of verses in the palace of John II., and he tells us how one night when the king was in bed he caused him (Resende) to repeat some "trovers" of Jorge Manrique, saying it was as needful for a man to know them as to know the Pater Noster. Under these conditions, Resende grew up no mean poet, and moreover distinguished himself by his skill in drawing and music; while he collected into an album the best court verse of the time. The Cancioneiro Geral, probably begun in 1483 though not printed until 1516, includes the compositions of some three hundred fidalgos of the reigning of kings Alphonso V., John II. and Manoel. The main subjects of its pieces are love, satire and epigram, and most of them are written in the national redondilha verse, but the metre is irregular and the rhyming careless. The Spanish language is largely employed, because the literary progenitors of the whole collection were Juan de Mena, Jorge Manrique, Boscan and Garcilasso. As a rule the compositions were improvised at palace entertainments, at which the poets present divided into two bands, attacking and defending a given theme throughout successive evenings. At other times these poetical soirées took the form of a mock trial at law, in which the queen of John II. acted as judge. Resende was much twitted by other rhymesters on his corpulence, but he repaid all their gibes with interest.

The artistic value of the Cancioneiro Geral is slight. Conventional in tone, the greater part are imitations of Spanish poets and show no trace of inspiration in their authors. The Cancioneiro is redeemed from complete insipidity by Resende himself, and his fine verses on the death of D. Ignez de Castro inspired the great episode in the Lusíads of Camoens (q.v.). Resende is the compiler of a gossiping chronicle of his patron John II., which, though plagiarized from the chronicle by Ray de Florim (p. 71), has a value of its own. The past lives again in these pages, and though Resende's anecdotes may be unimportant in themselves, they reveal much of the inner life of the 15th century. Resende's Miscelleana, a rhymed commentary on the most notable events of his time, which is annexed to his Chronicle, is a document full of historical interest, and as a poem not without merit. The editions of his Chronicle are those of 1545, 1554, 1596, 1607, 1624, 1732 and 1798.

His Cancioneiro appeared in 1516, and was reprinted by Kauser at Stuttgart in 3 vols., 1846-52. A new edition has recently come from the university press at Coimbra. For a critical study of his work, see Excerptos, seguidos de uma noticia sobre sua vida e obras, um juizo critico, apreciação de bellas e definição do lingua, by Antonio de Castilho (Paris, 1865). Also Aos sepulturas do Espinheiro, by Anselmo Braamcamp, Freire Lisbon, 1901, passim, especially pp. 67-80, where the salient dates in Resende's life are set out from documents recently discovered; and Dr Sousa Viterbo, Diccionario dos Arquitectos . . . Portugueses, i. 361-74. (E. P.)

RESERVATION (Lat. reserare, to keep back), the act or action of keeping back or withholding something. There are some technical uses of the term. In English law "reservation" is used of the retention by the vendor or lessor, in a conveyance or lease, of some right or interest, which without such reservation would have passed to the purchaser or tenant; such "reservations" usually are concerned with rights of way or other easements or sporting rights. In ecclesiastical usage, the term is applied to the practice of preserving un consumed a portion of the consecrated elements after the celebration of the Eucharist. For the history of this practice and its usage in the Roman, Greek and English churches, see Eucharist; Reservatio of the Eucharist. In the Roman Church, where the pope retains for himself the right to nominate to certain benefices, that action is termed, technically, "reservation." When in making a statement, taking an oath, &c., a person qualifies that statement by the phrase, "as far as I am informed," it is a reservation which, if expressed, would materially alter the effect of his statement or oath, such qualification is termed a "mental reservation," or, in the technical language of casuistry, "mental restriction" (see LICUORI). The system of providing special tracts of land exclusively for the tribes of American Indians, adopted in the United States of America and in Canada, is known as the Reservation system, and such tracts are styled Indian Reservations. (See United States and Canada.)

RESHT, the capital of the province of Gilan in Persia, in 37° 17' N., and 49° 36' E., on the left bank of the Shih-rud (Black river), which is a branch of the Sefid-rud (White river), and flows into the Murbah, lagoon of Enzel. The distance from Enzel, the port of disembarkation from Russia, on the S. shore of the Caspian, to Resht is 14 m. in a direct line, and is accomplished in an open boat, or (since 1892), depth of water permitting, in a small steamboat to Pir-i-Bazar and thence 6 m. on a good road by carriage. Resht has a population of 60,000 and is the residence of English, Russian, French and Turkish consuls and the seat of the governor-general of the province of Gilan. The town is situated in low, malarious ground, and was originally buried in jungle, but the Russians during their occupation of the place in 1773-34 cleared much timber and jungle and made some open ground. The houses are red-tiled and raised from the ground, with broad verandahs and overhanging eaves. Conflagrations are frequent, particularly in the months of January and December, when hot, dry winds resembling the Fohn of the Alps come down from the snow-capped Elburz. A good carriage
road constructed and worked by a Russian company and opened to traffic in 1890 connects Resht with Teheran via Kazvin.

The value of trade probably exceeds £2,000,000, principal exports being rice, raw silk, dry fruit, fish, sheep and cattle, wool and cotton, and cocoons, the principal imports sugar, cotton goods, silk worm “seed” or eggs (75, 100 worth in 1890) by agreement of the chief and chins. The trade in dried silk worm cocoons has increased remarkably since 1893, when only 76,150 lb valued at £6475 were exported; during the year 1906-7 ending 20th March, 2,717,546 lb valued at £238,000 were exported. There are telegraph and post offices and branches of the Imperial Bank of Persia and Banque d’Escompte.

Enzei, the port of Resht in the S.E. corner of the Caspian, is 14 m. N. of Resht, in 37° 20’ N., 49° 28’ E. Pop. 4000. Between it and other ports in the Caspian communication is maintained by the mail-steamer of the Caucasus and Mercury Steam Navigation Company and many vessels of commercial firms with head offices chiefly at Baku. (A.H.S.)

**RESIDENCE** (Latin residere, to remain behind, to dwell, reside), in general, a place of abode. In law, it usually means residence in continuance. The ordinary meaning of the word has been defined as “the place where an individual eats, drinks and sleeps, or where his family or his servants eat, drink and sleep.” (R. v. North Curry, 1835, 4 B. & C. 959.) For certain purposes, however, a man may be said to have his residence not only where he sleeps, but also at his place of business. See ABOVE; DOMICILE. In ecclesiastical law residence is the continuance of a spiritual person upon his benefice. As a general rule, it is necessary for every rector or vicar to reside within his parish, even though there may be no house of residence annexed to the benefice. But under certain circumstances the bishop of the diocese may grant a licence of non-residence (Plurality Acts 1836).

**RESIDENT**, a political agent or officer representing the Indian government in certain native states in India. He resides in the state and advises on all matters of government, legislative or executive. Residents are divided into three classes or ranks. In certain other dependencies and protectorates of the British Empire the resident or representative of the government is termed a resident or political agent, notably in Nepal, Aden, Sarawak, British North Borneo, &c. In general, where the state to which a resident is attached is not an independent one, he exercises consular and magisterial functions.

For “Resident” as the title of a diplomatic agent see DIPLOMACY.

**RESIDUE** (through the French, from the Lat. residuum, a remainder, from residere, to remain), in law, that which remains of a testator’s estate after all debts and legacies are discharged, and funeral, administration and other expenses paid. The person to whom this residue or surplus is left is termed the residuary legatee; should none be mentioned in the will the residue goes to the next of kin (see EXECUTORS AND ADMINISTRATORS; LEGACY; WILL).

**RESIN** (through O.Fr. résine, modern résine, from Lat. resina, probably Latinized from Greek pyrrin, resin), a secretion formed in special resin canals or passages of plants, from many of which, such as, for example, coniferous trees, it exudes in soft tears, hardening into solid masses in the air. Otherwise it may be obtained by making incisions in the bark or wood of the secreting plant. It can also be extracted from almost all plants by treatment of the tissue with alcohol. Certain resins are obtained in a fossilized condition, amber being the most notable instance of this class; African copal and the kauri gum of New Zealand are also procured in a semi-fossil condition. The resins which are obtained as natural exudations are in general mixtures of different, peculiar acids, named the *resin acids*, which dissolve in alcohols to form resin soaps, from which the resin acids are regenerated by treatment with acids. They are closely related to the terpenes, with which they occur in plants and of which they are oxidation products. Examples of resin acids are abietic (sylvic) acid, C₉H₈O₃, occurring in

collophony, and pimaric acid, C₉H₈O₃, a constituent of gallipo resin. Abietic acid can be extracted from colophony by means of hot alcohol; it crystallizes in leaflets, and on oxidation yields trimellitic, isophthalic and terebic acid. Pimaric acid closely resembles abietic acid into which it passes when distilled in a vacuum; it has been supposed to consist of three isomers. Resins when soft are known as oleo-resins, and when containing benzoic or cinnamic acid they are called balsams. Other resinous products are their products by their extraction with gum or mucilaginous substances and known as gum-resins.

The general conception of a resin is a noncrystalline body, insoluble in water, mostly soluble in alcohol, essential oils, ether and hot fatty oils, softening and melting under the influence of heat, not capable of sublimation, and burning with a bright but smoky flame. A typical resin is a transparent or translucent mass, with a vitreous fracture and a faintly yellow or brown colour, inodorous or having only a slight turpentine odour and taste. Many compound resins, however, from their admixture with resins resembling them, through the substratum, meaning of to clear up doubts or difficulties, to settle, determine. The principal applications of the term in its first sense are to the separation of a body into its component parts by chemical process, or, to the eye, by the lens of a microscope or telescope; similarly, in mathematics, to the analysis of a velocity, force, &c., into components. In the second sense, beyond the general meaning of determination, firmness of character, a "resolution" is specifically a decision of opinion formally submitted to a legislative or other assembly and adopted or rejected by votes.

**RESORCIN** (meta-dioxybenzoic), C₉H₆O₃, one of the dihydrophenols. It is obtained on fusing many resins (galbanum, asafoetida, &c.) with caustic potash, or by the distillation of Brazil-wood extract. It may be prepared synthetically by fusing meta-iodeophenol, phenol meta-sulphonic acid, and benzene meta-dialiphonic acid with potash; by the action of nitrous acid on meta-aminophenol; or by the action of 10% hydrochloric acid on meta-phenylene diamine. (J. Meyer, *Ber.*, 1897, 30, p. 2569). Many ortho and para-compounds of the aromatic series (for example, the brom-phenols, benzene para-dialiphonic acid) also yield resorcin on fusion with caustic potash. It crystallizes from benzene in colourless needles which melt at 116° C. and boil at 257°-5° C. (L. Calderon), or 280° C. (C. Graebe), and is readily soluble in water, alcohol and ether, but insoluble in chloroform and carbon bisulphide. It reduces Fehling’s solution, and ammoniacal silver solutions. It does not form a precipitate with lead acetate solution, as the isomeric pyrocatechol does. Ferric chloride colours its aqueous solution a dark violet, and bromine water precipitates tribromoresorcin. Sodium amalgam reduces it to dihydroresorcin, which when heated to 150-160° C. with concentrated baryta solution gives 7-acetylbutyric acid (D. Vorländer); when fused with caustic potash, resorcin yields phloroglucin, pyrocatechol and diresorcin. It condenses with acids or acid chlorides, in the presence of dehydration agents, to oxoyketones, e.g. with zinc chloride and glacial acetic acid at 145° C. it yields resacetophenone (HO)C₉H₆COCH₃ (M. Neukü and N. Sieber, *Jour. prak. Chem.*, 1881 [2], 23, p. 147). With the anhydrides of dibasic acids it yields fluoroescenes (q.v.). When heated with calcium chloride-ammonia to 200° C. it yields meta-dioxydiphenylamine (A. Seewitz, *Bull. Soc. Chim.*, 1890 [3], 3, p. 511). With sodium nitrite it forms a water-soluble blue dye, which is turned red by acids, and is used as an indicator, under the name of lacmoid.
RESPIRATORY SYSTEM

(M. C. Traub and C. Hock, *Ber.,* 1884, 17, p. 261). It condenses readily with aldehydes, yielding with formaldehyde, on the addition of a little hydrochloric acid, methylene dioresorcin \((\text{HO})_2\text{C}_2\text{H}_4\text{Cl}_2\) whilst with chloral hydrate, in the presence of potassium bisulphate, it yields the lactone of tetra-oxydiphenyl methane carboxylic acid (J. T. Hewitt and F. G. Pope, *Jour. Chem. Soc.,* 1897, 71, p. 1084). In alcoholic solution it condenses with sodium acetocetate to form \(\beta\)-methylumbelliferone, \(\text{C}_6\text{H}_5\text{O}_3\) (A. Michael, *Jour. prak. Chem.,* 1888, 2, 37, 470). With concentrated nitric acid, in the presence of cold concentrated sulphuric acid, it yields *trinitro-resorcin* (staphylic acid), which forms yellow crystals, exploding violently on rapid heating.

In medicine, resorcin, which is official in the United States under the name of resorcinal, was formerly used as an antipyretic, but it has been given up. The dose is 2 to 8 grs. Used externally it is an antisepctic and disinfectant, and is used 5 to 10% in ointments in the treatment of chronic skin diseases such as psoriasis and eczema of a sub-acute character. Weak, watery solutions of resorcin (10 or 15 grs. to the ounce) are used for pellaginous eruptions or for the whole of erythematous eczema. A 1% solution used as a spray has been used with marked effect in hay fever and in whooping-cough. In the latter disease 10 minims of the 2% solution has been given internally. It has also been employed in the treatment of gastric ulcer in doses of 2 to 4 grs. in pill, and is said to be analgesic and haemostatic in its action. In large doses it is a poison causing giddiness, deafness, salivation, sweating and convulsions. It is also worked up in certain medicated soaps. Mono-acetyl resorcin, \(\text{C}_6\text{H}_5\text{OH} \cdot \text{O} \cdot \text{COCH}_3\), is used under the name of "euresol."

Resorcinur, \(\text{C}_6\text{H}_5\text{NO}_2\), obtained by the action of nitrous acid on resorcin (P. Weselysky and R. Benedikt, *Monats.*, 1880, 1, p. 889), forms small dark red crystals possessing a greenish metallic luster. When dissolved in concentrated sulphuric acid and warmed to 210° C, the solution on pouring into water yields a precipitate of resorfurin, \(\text{C}_6\text{H}_5\text{NO}_2\), an oxysphenoxazone, which is insoluble in water, but is readily soluble in hot concentrated hydrochloric acid, and in solutions of caustic alkalis. The alkaline solutions are of a rose-red colour and show a cinnabar-red fluorescence. A tetrametresorcin is used as a dye-stuff under the name of *Eugrenant Resorcin Blue.*

Thiodresorcin is obtained by the action of zinc and hydrochloric acid on the chloride of benzene meta-disulphonic acid. It melts at 277° C. and boils at 243° C. *Resorcin disulphonic Acid* \((\text{HO})_2\text{C}_2\text{H}_4\text{HSO}_4\), is a deliquescent mass obtained by the action of sulphuric acid on resorcin (H. Fischer, *Monats.*, 1881, 2, p. 321). It is easily soluble in water and decomposes when heated to 100° C.

**RESPIRATORY SYSTEM.** (1) ANATOMY—The respiratory tract consists of the nasal cavities, the pharynx, the larynx, the trachea, the bronchi and the lungs, but of these the two first parts have been treated in separate articles (see OLFACTORY SYSTEM and PHARYNX).

The larynx is the upper part of the air tube which is specially modified for the production of notes of varying pitch, though it is not responsible for the whole of the voice. Its framework is made up of several cartilages which are moved on one another by muscles, and it is lined internally by mucous membrane which is continuous above with that of the pharynx and below with that of the trachea or windpipe. The larynx is situated in the front of the neck and corresponds to the fourth, fifth and sixth cervical vertebrae. For its superficial anatomy see ANATOMY, Superficial and Artistic.

The thyroid cartilage (see fig. 1) is the largest, and consists of two plates or *ala* which are joined in the mid-ventral line. At the upper part of their junction is the thyroid notch and just below that is a forward projection, the *processus Adamantis,* best marked in adult males. From the upper part of the posterior border of each ala the *superior cornu* rises up to be joined to the tip of the great cornu of the hyoid bone by the lateral thyro-hyoid ligament, while from the lower part of the same border the *inferior cornu* passes down to be fastened to the cricoid cartilage by the *crico-thyroid* capsule. From the upper border of each ala the *thyro-hyoid membrane* runs up to the hyoid bone, while near the back of the outer surface of each the *oblique line of the thyroid cartilage* runs downward and forward.

The cricoid cartilage (see figs. 1 and 2) is something like a signet ring with the seal behind; its lower border, however, is horizontal. To the mid-ventral part of its upper border is attached the mesial part of the *crico-thyroid membrane,* which attaches it to the lower border of the thyroid cartilage, though the lateral parts of this membrane pass up internally to the thyroid cartilage and their upper free edges form the true vocal cords. On the summit of the signet part of the cricoid are placed the two *arytenoid cartilages* (see fig. 2), each of which forms a pyramid with its apex upward and with an anterior posterior and internal or mesial surface. The base articulates with the cricoid by a concave facet, surrounded by the *crico-arytenoid capsule,* and the two arytenoids are able to glide toward or away from one another, in addition to which each can rotate round a vertical axis. From the front of the base a delicate process projects which, as it is attached to the true vocal cord, is called the *vocal process,* while from the outer part of the base another stouter process...
RESPIRATORY SYSTEM

attaches the two crico-arytenoid muscles and so is known as the muscular process. Above each arytenoid are two smaller cartilages known as the cornicula laryngis or cartilages of San-
torini and the cuneiform cartilages, but they are not of any practical importance.

The epiglottis (see fig. 3), on the other hand, is a very important structure, since it forms a lid to the larynx in swallowing: only the box moves up to the lid instead of the lid moving down to the box. It is leaf-
shaped, the stalk (thyro-epiglottidean ligament) being at-
tached to the junction of the thyroid cartilages inside the larynx, while the anterior surface of the leaf is closely attached to the root of the tongue and body of the hyoid bone. The posterior or laryngeal surface is pitted for glands, and near the point where the stalk joins the leaf is a con-
vexity which is known as the cushion of the epiglottis. All the cartilages of the larynx are of the hyaline variety except the ep-
iglottis, the corni-
cula laryngis and the cuneiform car-
tilages, which are yellow elastic.

result is that all except these three tend to ossify as middle age is approached.

The muscles of the larynx are: (1) the crico-thyroids, which are attached to the lower border of the thyroid and the anterior part of the cricoid, by pulling up which they make the upper part of the signet, with the arytenoids attached to it, move back and so tighten the vocal cords. (2) The thyro-arytenoids (see fig. 4), which run back from the junction of the thyroid alae to the front of the arytenoids and side of the epiglottis; they pull the arytenoids toward the thyroid and so relax the cords. (3) The single arytenoideus muscle, which runs from the back of one arytenoid to the other and approximates these cartilages. (4) The lateral crico-arytenoids (see fig. 4) which draw the muscular processes of the arytenoids forward toward the ring of the cricoid and, by so doing, twist the vocal processes, with the cords attached, inward toward one another; and (5) the posterior crico-arytenoids (see fig. 4) which run from the back of the signet part of the cricoid to the back of the muscular processes of the arytenoid and, by pulling these backward, twist the vocal processes outward and so separate the vocal cords. All these muscles are supplied by the recurrent laryngeal nerve, except the crico-thyroid which is innervated by the external branch of the superior laryngeal (see Nerves, Cranial).

The mucous membrane of the larynx is continuous with that of the pharynx at the aryteno-epiglottidean folds which run from the sides of the epiglottis to the top of the arytenoid cartilages (see fig. 3). To the outer side of each fold is the sinus pyriformis (see Pharynx). From the middle of the junction of the alae of the thyroid cartilage to the vocal processes of the arytenoids the mucous membrane is reflected over, and closely bound to, the true vocal cords which contain elastic tissue and, as has been mentioned, are the upper free edges of the lateral parts of the crico-thyroid membrane. The chink between the two

true vocal cords is the glottis or rima glottidis. Just above the true vocal cords is the opening into a recess on each side which runs upward and backward and is known as the laryngeal saccule; its opening is the laryngeal sinus. The upper lip of this slit-like opening is called the false vocal cord.

The mucous membrane is closely bound down to the epiglottis and to the true vocal cords, elsewhere there is plenty of sub-
mucous tissue in which the products of inflammation may collect and cause "edema laryngis," a condition which is mechanically prevented from passing the true vocal cords. In the upper part of the front and sides of the larynx and over the true vocal cords the mucous membrane is lined by squamous epithelium, but elsewhere the epithelium is of the columnar ciliated variety: it is supplied by the superior laryngeal branch of the vagus nerve and above the glottis is peculiarly sensitive.

The Trachea or windpipe (see fig. 5) is the tube which carries the air between the larynx and the bronchi; it is from four to four and a half inches long and lies partly in the neck and partly in the thorax. It begins where the larynx ends at the lower border of the sixth cervical, and divides into its two bronchi opposite the fifth thoracic vertebra. The tube is kept always open by rings of cartilage, which, however, are wanting behind, and, as it passes down, it comes to lie farther and farther from the ventral surface of the body, following the concavity of the thoracic region of the spinal column. In the whole of its downward course it has the oesophagus close behind it, while in front are the isthmus of the thyroid, the left innominate vein, the innominate artery and the arch of the aorta. On each side of it and touching it is the vagus nerve.

The cavalical part of the tube is not much more than an inch in length, but it can be lengthened by throwing back the head. This, of course, is the region in which tracheotomy is performed, and it should be remembered that in children, and sometimes in adults, the great left innominate vein lies above the level of the top of the sternum.

In transverse section the trachea is rather wider from side to side than from before backward. In life the former measurement is said to be about 12.5 mm. and the latter 11 mm. It is made up of an external fibro-elastic membrane in which the cartilaginous rings lie, while behind, where these rings are wanting, is a layer of unstriped muscle which, when it contracts,
draws the hind ends of the rings together and so diminishes the calibre of the tube. Inside these is plentiful submucoius tissue.

containing mucous glands and quantities of lymphoid tissue, while the whole is lined internally by columnar ciliated epithelium.

The Bronchi (see fig. 5) are the two tubes into which the trachea divides, but, since the branches, which these tubes give off later, are also called bronchi, it may be clearer to speak of primary, secondary and tertiary bronchi. Each primary bronchus runs downward and outward, but the right one is more in a line with the direction of the trachea than the left. The right primary bronchus has also a greater calibre than the left because the right lung is the larger, and for these two reasons when a foreign body enters the trachea it usually enters the right bronchus.

The first secondary bronchus comes off about an inch from the bifurcation of the trachea on the right side and, as it lies above the level of the pulmonary artery, it is known as the eparterial bronchus. On the left side the first branch is about two inches from the bifurcation and, like all the remaining secondary bronchi, is hyparterial: the left primary bronchus is therefore twice as long as the right. After the eparterial secondary bronchus is given off the direction of the right primary bronchus is carried on by the hyparterial secondary bronchus, and this, just before reaching the hilum of the lung, divides into upper and lower tertiary bronchi, while the left lower secondary hyparterial bronchus does not divide before reaching the hilum of its lung. Into the hilum or root of the right lung, therefore, three bronchial tubes enter, while on the left side there are only two. The firmly rooted habit of associating the term bronchi with those parts of the main tubes which lie between the bifurcation of the trachea and the point where the first branch comes off makes it very difficult to suggest a nomenclature which calls up any picture of the actual state of things to the mind. Certainly the classification into primary, secondary and tertiary bronchi only goes a very little way toward this, and it should be realized that, call them what we may, there are two long tapering tubes which run from the bifurcation of the trachea to the lower and back part of each lung, and give off a series of large ventral and small dorsal branches. The upper part of each of these long tubes or stem bronchi is outside the lung and in the middle mediastinum of the thorax, the lower part embedded in the substance of the lung. The structure of the bronchi is practically identical with that of the trachea.

The Lungs are two pyramidal, spongy, slate-coloured, very vascular organs in which the blood is oxygenated. Each lies in its own side of the thorax and is surrounded by its own pleural cavity (see COELOM and SEROUS MEMBRANES), and has a surface which projects into the side of the root of the neck, a base which is hollowed for the convexity of the diaphragm, an outer surface which is convex and lies against the ribs, an inner surface concave for the heart, pericardium and great vessels, a sharp anterior border which overlaps the pericardium and a broad, rounded posterior border which lies at the side of the spinal column. Each lung is nearly divided into two by a primary fissure which runs obliquely downward and forward, while the right lung has a secondary fissure which runs horizontally forward from near the middle of the primary fissure. The left lung has therefore an upper and lower lower lobe, while the right has upper, middle and lower lobes. On the inner surface of each lung is the root or hilum at which alone its vessels, nerves and ducts (bronchi) can enter and leave it. The structures contained in the root of each lung are the branches and tributaries of (1) the pulmonary artery, (2) the pulmonary veins, (3) the bronchi, (4) the bronchial arteries, (5) the bronchial veins, (6) the bronchial lymphatic vessels and glands, (7) the pulmonary plexuses of nerves. Of these the first three are the largest and, in dividing the root from in front, the veins are first cut, then the arteries and last the bronchi. As has been pointed out already, the eparterial bronchus on the right side is above the level of the artery, but all the others (hyparterial) are on a lower level.

The bronchial arteries supply the substance of the lung; there are usually two on each side, and they lie behind the bronchi. The blood which they carry is chiefly returned by the pulmonary veins bringing oxidized blood back to the heart, so that here there is a normal and harmless mixture of arterial and venous blood. If there are any bronchial veins (their presence is doubted by some, and the writer has himself carefully but unsuccessfully searched for them several times), they open into the azygos veins of their own side. The bronchial lymphatic vessels lie behind the pulmonary vessels and open into several large glands which are black from straining off the carbon left in the lungs from the atmosphere.

There is an anterior and posterior pulmonary plexus of nerves on each side, the fibres of which are derived from the vagus and the upper thoracic ganglia of the sympathetic.

Structure of the Lungs.—As the bronchi become smaller and smaller by repeated division, the cartilage completely surrounds them and tends to form irregular plates instead of rings—they are therefore cylindrical, but when the terminal branches (lobular bronchi) are reached, the cartilage disappears and the epithelial bulgings called alveoli occur (fig. 6 A). At the very end of
RESPIRATORY SYSTEM

Each lobular bronchus is an irregular channel, the *atrium* (fig. 6 A), and from this a number of thin-walled sacs, about 1 mm. in diameter, open out. These are called the *infundibula* (fig. 6 I), and their walls are pouched by hemispherical alveoli or alveoli, and are connected by connective tissue, and their outlines are evident on the surface of the lung. Each lobular bronchus with its atrium and infundibula forms what is known as a *lobule* of the lung, and these lobules are separated by connective tissue, and their outlines are evident on the surface of the lung. The muscular tissue, which in the larger tubes takes place between the air and the blood, is not evident here.

Embryology.—The respiratory system is developed from the ventral surface of the foregut as a long gutter-like pouch which divides into two, one behind the other. The terminal vesicle supplied by the allantois is known as the *fucula*; it is from this that the epiglottis, aryteno-epiglottidean folds and arytenoid cartilages are developed. Later on the respiratory tube is separated from the digestive tube by two ridges, one on each side, which, uniting, form a transverse partition. In the region of the fucula, however, the partition stops and here the two tubes communicate. The caudal end of the respiratory tube buds out into the two primary bronchi, and the right one of these, later on, bears three buds, while the left has only two; these are the secondary bronchi, which keep on dividing into two, one branch keeping the line of the parent stem to form the stem bronchi, while the other goes off at an angle. By the repeated divisions of these tubes the complex "bronchial tree" is formed and the terminal shoots the infundibula bud out. The alveoli only develop in the last three months of foetal life. The thyroid cartilage is probably formed from the fourth and fifth branchial bars, while the cricoid seems to be the enlarged first ring of the trachea. Before birth the lungs are solid and much less vascular than after breathing is established. Their slyte colour is gradually gained from the deposit of carbon from the atmosphere. (For further details see Quain's *Anatomy*, vol. i., Lond. 1908.)

Comparative Anatomy.—It has been shown that in the lower vertebrates respiration is brought about by the blood vessels surrounding the gill clefts. In the higher fishes (Ganoids and Teleosts) the "swim bladder" appears as a diverticulum from the dorsal wall of the alimentary canal, and its duct (d. *pneumatics*) sometimes remains open and at others becomes a solid cord. In the former case it is probable that the blood is to some extent oxidized in the vascular wall of this bladder. In the Dipnoi (mud-fish) the opening of the swim bladder shifts to the ventral side of the pharynx and the bladder walls become sacculated and very vascular, so that, when the rivers are dried up, the fish can breathe altogether by means of it. In the S. American and African species of mud-fish the bladder or lung, as it may now be called, is divided by a longitudinal septum in its posterior (caudal) part into right and left halves. In this sub-class of Dipnoi, therefore, a general agreement is seen with the embryology or ontogeny of Man's lungs. In the Amphibia the two lungs are quite separate though they are mere sacculated bags without bronchi. A trachea, however, appears in some species (e.g. Siren) and a definite larynx with arytenoid cartilages, vocal cords and complicated muscles is established in the Anura (frogs and toads). In most of the Reptilia the bag-like lungs are elaborated into spongy organs with branching bronchi in their interior. From the crocodiles onward a main stem bronchus lies at the antero-lateral end of the lung, and from this the branches or lateral bronchi come off. The larynx shows little advance on that of the Anura.

The respiratory organs of birds are highly specialized. The larynx is rudimentary, and sound is produced by the *syrrinx*, a secondary larynx at the bifurcation of the trachea; this may be tracheal, bronchial or, most often, tracheo-bronchial. The lungs are small and closely connected with the ribs, while from them numerous large air sacs extend among the viscera, muscles and into many of the bones, which, by being filled with hot air, bear the weight of the body. "The lungs will exhibit the high temperature and lessen the specific gravity of the body. This pneumatization of the bones has reached, in a certain extent reproduced by the air sinuses of the skull in crocodiles and mammals, and it must be pointed out that the amount of air in the bones does not necessarily correspond with the power of flight, for the Ratitae (ostriches and emus) have very pneumatic bones, while in the sea-gulls they are hardly pneumatic at all.

In mammals the thyroid cartilage becomes an important element in the larynx, and in the Echidna the upper and lower parts of it, derived respectively from the fourth and fifth branchial bars, are separate (K. H. Burne, *Journ. Anat. and Phys.* xxxvii., p. xxvii.). The whole larynx is much nearer the head than in Man, and in young animals the epiglottis is intra-narial, i.e. projects up behind the soft palate. This prevents the milk trickling into the larynx during sucking, and is especially well seen in the Marsupials and Cetacea, though evidences of it are present in the human embryo. In the lower mammals an inter-arytenoid cartilage is very frequent (see J. Symington, "The Marsupial Larynx," *J. Anat. and Phys.* xxxiii. 31, also "The Monotreme Larynx," ib. xxxiv. 96.)

The lungs show the high degree of variation in their lobulation; among the porcupines as many as forty lobes have been counted in the right lung, while in other mammals no lobulation at all could be made out. The *oxysous lobe* of the right lung is a fairly constant structure and is situated between the post-caval vein and the oesophagus. It is supplied by the terminal branch of the right stem bronchus and, although it is usually absent in Man, the bronchus which should have supplied it is always to be found.

(F. G. P.)

(2) PHYSIOLOGY

So far as is known, the intake of oxygen, either free or combined, and the output of carbon dioxide, are an essential part of the life of all organisms. The two processes are so closely associated with one another that they are always included together under the designation of respiration, which may thus be defined as the physiological process which is concerned in the intake of oxygen and output of carbon dioxide. According to the evidence at present available, it is only within living cells that the respiratory oxygen is consumed and the carbon dioxide formed. The mere conveying of oxygen from the surrounding air or water to these cells, and of carbon dioxide from them to the air or water, is, however, in itself a complex process in the higher animals; and accordingly an account of animal respiration naturally falls into two divisions, the first of which (I.) is concerned with the manner in which oxygen and carbon dioxide are conveyed to and from the living tissues, and the second (II.) with the consumption of oxygen and formation of carbon dioxide by the living tissues themselves.

I. In all the more highly organized animals there are special respiratory organs: the lungs in the higher vertebrates; the gills in fishes; the tracheae in insects; and various rudimentary forms of lungs or gills in other higher invertebrates. In the
Present article attention will be specially confined to the case of the higher vertebrates, and in particular to man.

Air is brought into the lungs by the movements of breathing (see above, *Movements of Respiration*). Oxygen from this air passes through the delicate lining membrane of the air-cells of the lungs into the blood, where it enters into loose chemical combination with the haemoglobin of the red corpuscles (see Blood). In this form it is conveyed onwards to the heart, and thence through the arteries to the capillaries, where it again parts from the haemoglobin, and passes through the capillary walls to the tissues, where it is consumed. Carbon dioxide passes out from the tissues into the blood in a corresponding manner, enters into loose combination as bicarbonate, and possibly in other ways, in the blood, and is conveyed by the venous blood-vessels, whence it passes out in the expired air.

Pure atmospheric air contains 20.93% of oxygen, 0.03% of carbon dioxide and 79.04% of nitrogen (with which is mixed about 0.9% of argon). The dried expired air in man contains about 3.5% of carbon dioxide and 17% of oxygen, so that roughly speaking the carbon dioxide is increased by about 3.5% and the oxygen diminished by 4%. Expired air as it leaves the body contains about 6% of moisture, compared with usually about 1% in the inspired air. The added moisture and higher temperature of expired air make it decidedly lighter than pure air.

Careful observation has shown that the unpleasant effects often produced in badly ventilated rooms it was for long supposed that some poisonous volatile "organic matter" is also given off in the breath. Careful investigation has shown that this is not the case. The unpleasant effects are partly due to heat and moisture, and partly to odours which are usually not of respiratory origin. The carbon dioxide present in the air of even very badly ventilated rooms is present in far too small proportions to have any sensible effect.

The average volume of air inspired per minute by healthy adult men during rest is about 7 litres or 25 cub. ft. in different individuals the frequency of breathing varies considerably—from about 7 to 25 per minute, the depth of each breath varying about inversely as the frequency. During muscular work the volume of air breathed may be six or eight times as much as during rest. The volume of carbon dioxide given off varies from about half a cubic foot per hour during complete rest to 5 cub. ft. during severe exertion, but averages about 0.9 cub. ft. per hour, and will reach or exceed 1 cub. ft. per hour during even very light exertion. The volume of oxygen consumed is about a seventh greater than that of the carbon dioxide given off.

The breathing is regulated from a nervous centre situated in the brain stem, specifically in the medulla oblongata, which is the lowest part of the brain. If this centre is destroyed or injured the breathing stops and death rapidly results. From the respiratory centre rhythmic effenter impulses proceed down the motor nerves supplying the diaphragm, intercostals and other respiratory muscles. Afferent impulses through various nerves may temporarily affect the rhythm of the respiratory centre. Of these afferent impulses by far the most important are those which proceed up the vagus nerve from the lungs themselves. On distention of the lungs with air the inspiratory impulses from the respiratory centre are suddenly arrested or "inhibited"; on the other hand, collapse of the lung strongly excites the inspiratory effort. On section of the vagus nerve these effects disappear, and the breathing becomes less frequent and much more laboured. The vagus nerve is thus the carrier of both inhibitory and exciting stimuli.

As the physiological function of breathing is to bring oxygen to and remove carbon dioxide from the blood, it would naturally be expected that breathing would be regulated in accordance with the amount of oxygen required and of carbon dioxide formed; but until quite recently the actual mode of regulation was by no means clear. It was commonly supposed that afferent nervous impulses in some way regulated the otherwise automatic action of the centre, want of oxygen or excess of CO₂ in the blood being only an occasional and relatively unimportant factor in the regulations. The phenomenon of "apnoea" or complete cessation of natural breathing which occurs after forced breathing, was attributed mainly to the already mentioned distention effect through the vagus nerves. To go further back still, it was even supposed that the rate and depth of breathing, and the percentage of oxygen in the inspired air, determine the consumption of oxygen and formation of carbon dioxide in the body, just as the air-supply to a fire determines the rate of its combustion. This old belief is still often met with—for instance, in the reasons given for recommending "breathing exercises" as a part of physical training.

It is evident that if the breathing did not increase correspondingly with the greatly increased consumption of oxygen and the percentage of CO₂ in the air, it would be impossible to get all the oxygen required and all the CO₂ expelled. If breathing did not increase, the percentage of oxygen in the inspired air and the percentage of carbon dioxide in the expired air would be constant no matter how far breathing was increased. Careful observation has shown that this is not the case. In the first place, the percentage of oxygen in the inspired air is 20.93% on an average for man, and there is no reason why it should not vary slightly as regards its normal percentage. The breathing is thus so regulated as to keep the percentage of carbon dioxide constant; and under normal conditions this regulation is surprisingly exact. The ordinary expired air is a mixture of alveolar air and air from the "dead space" in the air passages. The deeper the breathing is, the more alveolar air there will be in the expired air, and the higher, therefore, the percentage of carbon dioxide in it, so that the expired air is not constant in composition, though the alveolar air is. If air containing 2 or 3% of carbon dioxide is breathed, the alveolar air at once becomes deeper, in such a way as to prevent anything but a very slight rise in the alveolar carbon dioxide percentage.

The difference is scarcely appreciable subjectively, except during muscular exertion. The effect of 1% of carbon dioxide in the inspired air is so slight as to be negligible, and there is no foundation for the popular belief that every very small percentages of carbon dioxide are injurious. With 4 or 5% or more of carbon dioxide, however, much panting in produced, and the alveolar carbon dioxide percentage begins to rise appreciably, since compensation is no longer possible. As a consequence, headache and other symptoms are produced. If, on the other hand, the percentage of carbon dioxide in the alveolar air is abnormally reduced by forced breathing, the condition of apnoea is produced and lasts until the percentage again rises to normal, but no longer. Forced breathing with air containing more than about 4% of carbon dioxide causes no apnoea, as the alveolar carbon dioxide does not fall.

If oxygen is breathed instead of air there is no appreciable change in the percentage of carbon dioxide in the alveolar air, and no tendency towards apnoea. Want of oxygen is thus not a factor in the regulation of normal breathing. During muscular work the depth and frequency of breathing increase in such a way as to prevent the alveolar carbon dioxide from rising more than very slightly. It is still the carbon dioxide stimulus that regulates the breathing, although with excessive muscular work other accessory factors may come in to some extent.

Under increased barometric pressure the percentage of carbon dioxide in the alveolar air no longer remains constant; it diminishes in proportion to the increase of pressure. For instance, at a pressure of 2 atmospheres it is reduced to half, and at 6 atmospheres to a sixth; while at less than normal atmospheric pressure it rises correspondingly unless symptoms of want of oxygen begin to interfere with this rise. These results show that it is not the mere percentage, but the pressure (or "partial pressure") of carbon dioxide in the
alveolar air that regulates breathing. The pressure exercised by the carbon dioxide in the alveolar air is of course proportional to its percentage, multiplied by the total atmospheric pressure. It follows from this law that at a pressure of 6 atmospheres, 15% of carbon dioxide in the inspired air would have the same violent effect as 6% at the normal pressure of 1 atmosphere. To take a concrete practical application, if a diver whose head was just below water were supplied with sufficient air to keep the carbon dioxide percentage in the air of his helmet down to 3% at most, he would be quite comfortable. But if, with the same air supply as measured at surface, he went down to a depth of 175 ft., where the pressure is 6 atmospheres, he would at once experience great distress culminating in loss of consciousness, owing, not to the pressure of the water, which has trifling effects, but to the pressure of carbon dioxide in the air he was breathing. The air supply must be increased in proportion to the increase of pressure if these effects are to be avoided, and ignorance of this has led to the common failure of diving work at considerable depths.

The foregoing facts enable us to understand the regulation of breathing under normal conditions. The pressure of carbon dioxide in the alveolar air evidently determines that of the carbon dioxide in the arterial blood, and the latter in its turn determines the carbon dioxide pressure in the respiratory centre, which is very richly supplied with blood. The centre itself is extremely sensitive to the slightest increase or diminution in carbon dioxide pressure; and thus it is that the alveolar carbon dioxide pressure is so important. That the stimulus of carbon dioxide is from the blood and not through nerves is proved by many experiments. The function of the vagus nerves in regulating the breathing is apparently to, as it were, guide the centre in the expenditure of each separate inspiratory or expiratory effort; for as soon as inspiration or expiration is completed the inspiratory or expiratory effort is cut short by impulse proceeding up the vagus nerve, and much waste of muscular work and risk of injury to the lungs is thereby prevented.

Under ordinary conditions the regulation of carbon dioxide pressure in the alveolar air ensures at the same time a normal pressure of oxygen, since absorption of oxygen and giving off of carbon dioxide normally run parallel to one another. If, however, air containing abnormally little oxygen is breathed, the normal relation between oxygen and carbon dioxide in the alveolar air is disturbed. A similar state of affairs is brought about by any considerable diminution of atmospheric pressure. Not only does the partial pressure of oxygen in the inspired air fall, but this fall is proportionally much greater in the alveolar air; and the effects of want of oxygen depend on its partial pressure in the alveolar air. It has been known for long that even a small percentage of oxygen is very injurious. The amount of air breathed increases the depth and frequency of the breathing; but this effect is not apparent until the percentage of oxygen or the barometric pressure is reduced by more than a third, which corresponds to a reduction of more than half in the alveolar oxygen pressure. In contrast with this an increase of a fifteenth in the alveolar carbon dioxide pressure has a marked effect on the breathing. Along with the increased breathing caused by deficiency of oxygen there is more or less blueness of the skin and abnormal effects of various kinds, such as partial loss of sensibility, memory and power of thinking. Long exposure often causes headache, nausea, sleeplessness, &c.—a train of symptoms known to mountainers as "mountain sickness." That the primary cause of "mountain sickness" is lack of oxygen owing to the low atmospheric pressure there is not the slightest doubt. Lack of oxygen is thus not only an important, but also an abnormal form of stimulus to the respiratory centre, since it is accompanied by quite abnormal symptoms. A further analysis of the special effect of lack of oxygen on the respiratory centre has shown that this effect still depends on the partial pressure of carbon dioxide in the alveolar air. The lack of oxygen appears, in fact, to have simply increased the sensitiveness of the centre to carbon dioxide, so that a lower partial pressure of carbon dioxide excites the centre, and the breathing is correspondingly increased. By prolonged forced breathing so much carbon dioxide is washed out of the body that the subsequent apnoea lasts until the oxygen in the alveolar air is nearly exhausted. The subject of the experiment becomes very blue in the face and is partially stupefied by want of oxygen before he has any desire to breathe. The probable explanation of these facts is that want of oxygen does not itself excite the centre, but that some substance—very probably lactic acid, which is known to be formed abundantly—is produced abnormally in the body during exposure to want of oxygen and aids the carbon dioxide in exciting the centre. It is known that the blood becomes less alkaline at high altitudes, and that acids in general excite the centre. A person on a high mountain thus gets out of breath much more easily than at sea-level. The extra stimulus to the centre during work still comes from the extra carbon dioxide formed, but has a greater effect than usual on the breathing. If the extra stimulus came directly from want of oxygen the person on the mountain would probably turn blue and lose consciousness on the slightest exertion. By analysing the alveolar air it can be shown that after a time even a height of 5000 to 6000 ft., or a diminution of only a sixth in the barometric pressure, distinctly increases the sensitiveness of the respiratory centre to carbon dioxide, so that there seems to be a slow accumulation of acid in the blood. The effect also passes off very slowly on returning to normal pressure, although the lack of oxygen is at once removed.

The blue skin of the skin ("cyanosis") produced by lack of oxygen is due to the fact that the haemoglobin of the red corpuscles is imperfectly saturated with oxygen. Haemoglobin which is fully saturated with oxygen has a bright red colour, contrasting with the blue colour which it assumes when deprived of oxygen. According to the existing evidence the saturation of the haemoglobin is practically complete under normal conditions in the lungs, or when thoroughly shaken at the body temperature and normal atmospheric pressure with air of the same composition as normal alveolar air. As the partial pressure of the oxygen in this air falls, however, the saturation of the haemoglobin becomes less and less complete, and the arterial blood assumes a more and more blue tinge, which imparts a blue or leaden colour to the skin, accompanied by the symptoms, already referred to, of lack of oxygen. Normal arterial blood in man yields about 19 volumes of physiologically available oxygen for each 100 volumes of blood. Of these 19 volumes about 18 are loosely combined with the haemoglobin of the red corpuscles, the small remainder being in simple solution in the blood. Venous blood, on the other hand, yields only about 12 volumes. The combination of haemoglobin with oxygen is only stable in so far as the oxygen is a pressure of about that in normal alveolar air. As this pressure falls the combination is progressively dissociated. From this it can be readily understood why the blood loses its oxygen in passing through the tissues, which are constantly absorbing free oxygen, and regains it in the lungs. The marked effects produced by abnormal deficiency in the pressure of oxygen in the alveolar air are also readily intelligible; for even although the arterial blood still contains sufficient oxygen to cover the normal difference between the oxygen content of arterial and that of venous blood, yet this oxygen is given off to the tissues less readily—i.e. at a lower pressure, as the tissues fail to supply their demands completely. It is evident also that in pure air at normal pressure increased ventilation of the lungs does not appreciably increase the supply of oxygen to the blood, whereas in air largely deprived of its oxygen, or at low pressure, the increased alveolar oxygen pressure produced by deep breathing helps greatly in saturating the blood with oxygen, and may thus relieve the symptoms of want of oxygen. Hence it is that the increased sensitiveness of the respiratory centre to carbon dioxide, and consequent increased depth of breathing, at high altitudes compensates to a large extent for deficiency in the oxygen pressure. Addition of carbon dioxide to the inspired air produces exactly the same result. Indeed
RESPIRATORY SYSTEM

Professor Angelo Mosso was led by observation of the beneficial effects of carbon dioxide at low atmospheric pressure to attribute mountain sickness to lack of carbon dioxide, a condition which he designated by the word "acapnia." When impure air is vitiating, not only by deficiency of oxygen, but also by carbon dioxide, the carbon dioxide causes panting, which not only gives warning of any danger, but prevents the alveolar oxygen percentage from falling in the way it would do if the carbon dioxide were absent. In this way the carbon dioxide greatly lessens the danger. To give instances, air progressively and very highly vitiated by respiration is much less likely to cause danger that carbon dioxide in the alveolar air artificially absorbed and not nearly so dangerous as the great diminution of atmospheric pressure (and consequently of oxygen pressure) which occurs in a very high balloon ascent. Indeed the dangers of a very high balloon ascent are notorious, and a number of deaths or very narrow escapes are on record.

Just as oxygen forms a dissociable compound with the haemoglobin of the blood, so does carbon dioxide form dissociable compounds. One of these compounds appears to be with haemoglobin itself, and another is sodium bicarbonate, which is far more easily dissociated in the blood than in a simple water solution, owing to the presence of proteid and probably other substances which act as weak acids and thus help the dissociation process. The whole of the carbon dioxide can therefore be removed from the blood by a vacuum pump, just as the whole of the oxygen can. Venous blood contains roughly speaking about 40 volumes of carbon dioxide per 100 of blood, and arterial blood about 34 volumes. Of this carbon dioxide only about 3 volumes can be in free solution, the rest being loosely combined. The conveyance of carbon dioxide from the blood to the lungs is thus readily intelligible, as well as the fact that any increase or diminution of the pressure of carbon dioxide in the alveolar air will naturally lead to a damming back or increased liberation of carbon dioxide from the blood, and that by forced breathing carbon dioxide can be washed out of the blood to such an extent that a prolonged cessation of natural breathing (apnoea) follows, since even in the venous blood the partial pressure of carbon dioxide has become too low to excite the respiratory centre.

It will be evident from the foregoing that in order to supply efficiently the respiratory requirements of the tissues not only must the breathing, but also the circulation, be suitably regulated. In hard muscular work the consumption of oxygen and output of carbon dioxide may be increased eight or ten times beyond the requirements of rest. Under such conditions the blood supply to the active tissues was correspondingly increased, deficiency of oxygen would at once arise, since the amount of oxygen carried by a given volume of the arterial blood is very limited, as already explained. It is known that the supply of blood to each organ is always increased during its activity. This increase can, for instance, readily be seen and measured in the case of contracting muscles or secreting glands; and the volume and frequency of the pulse are greatly increased during muscular work. But while it is evident enough that the flow of blood through the body is determined in accordance with the metabolic activities of each tissue, our knowledge is as yet very scanty as to the means by which this determination is brought about. Probably, however, carbon dioxide may be nearly as important a factor in the regulation of the circulation as in that of breathing. Just as the rate of breathing was formerly supposed to determine, and not to be determined by, the fundamental metabolic processes of the body, so the circulation was supposed to be another independent determining factor; and under the influence of these mechanistic conceptions the direction of investigation into the phenomena of respiration and circulation has been largely diverted. The difficulty is not artificial, but it is a grave and important one.

Since the circulation, no less than the breathing, is concerned in the supply of oxygen to and removal of carbon dioxide from the tissues, it can readily be understood that defective circulation, such as occurs, for instance, in uncompensated valvular affections of the heart, may affect the breathing and hinder the normal respiratory exchange. Conversely, also, defects in the aeration or oxygen-carrying power of the blood may be compensated for by increase in the circulation. For instance, in the very common condition known as anaemia, where the percentage of haemoglobin, and consequently the oxygen-carrying power of the blood, is often reduced to a third or less, the respiratory disturbances may be so slight that the patient is going about his or her ordinary work. A miner suffering from the now well-known "worm-disease," or ankylostomiasis (q.v.), may be working under ground, and an infirm or diseased, body is greatly by doing her work, with only a third of the normal oxygen-carrying power of the blood. There seems to be no doubt that in such cases an increased rate of blood circulation compensates for the diminished oxygen-carrying power of the blood. It is well known that at high altitudes a gradual process of adaptation to the low pressure occurs, and the shortness of breath and other symptoms experienced for the first few days gradually become less and less. This adaptation is partly, at least, due to a marked increase in the percentage of haemoglobin in the blood, though probably circulatory and perhaps other compensatory agencies are also involved.

In connexion with respiration the action of certain poisons is of great interest. One of these, carbon monoxide, is of very common occurrence, and causes numerous cases of poisoning. Like oxygen, it has the property of combining with the haemoglobin of the blood, but its affinity for haemoglobin is far more strong than that of oxygen. In presence of air containing as little as 0.5% of carbon monoxide, the haemoglobin will become about equally shared between oxygen and carbon monoxide, so that, since air contains 20.9% of oxygen, the affinity of carbon monoxide for haemoglobin may be regarded as about 400 times that of oxygen. The blood of a person breathing even a small percentage of carbon monoxide may thus become gradually saturated to a dangerous extent, since the haemoglobin engaged by the carbon monoxide is for the time useless as an oxygen-carrier. Air containing more than about 0.1% of carbon monoxide is thus more or less dangerous if breathed for long; but the blood completely recovers in the course of a few hours if pure air is again breathed. The poisonous action of carbon monoxide can be abolished by placing the animal exposed to it in oxygen at an excess pressure of about an atmosphere. The reason for this is that, in consequence of the increased partial pressure of the oxygen, the amount of this gas in free solution in the blood is greatly increased in accordance with Dalton's law, and becomes sufficient to supply the tissues with oxygen quite independently of the haemoglobin. Even at ordinary atmospheric pressure the extra oxygen dissolved in the blood when pure oxygen is breathed is of considerable importance. Carbon-monoxide poisoning is the chief cause of death in colliery explosions and fires, and the sole cause in poisoning by lighting gas and fuel gas of various kinds. Its presence in dangerous proportions may be readily detected with the help of a small bird, mouse or other small warm-blooded animal. In such animals the respiratory exchange is so rapid that symptoms of carbon-monoxide poisoning are shown far more quickly than in man. The small animal can thus be employed in mines, &c., to indicate danger from carbon monoxide. A lamp is useless for this purpose. There are various other poisons, such as nitrites, chlorates, dinitrobenzol, &c., which act by disabling the haemoglobin, and so cutting off the oxygen supply to the tissues.

Between the air in the air-cells of the lungs and the blood of the lung capillaries there intervenes nothing but a layer of very thin, flattened cells, and until recently it was very generally believed that it was by diffusion alone that oxygen passes inwards and carbonic acid out that of oxygen. Through this layer similar simple physical explanations of processes of secretion and absorption through living cells have, however, turned out to be incorrect in the case of other organs. It is known, moreover, that in the case of the swimming-bladder of fishes oxygen is secreted into
the interior against enormous pressure. Thus, in the case of a fish caught at a depth of 4500 ft., the partial pressure of the oxygen present in the swimming bladder at this depth was 127 atmospheres, whereas the partial pressure of oxygen in sea-water is only about 0-2 atmosphere. Diffusion can therefore have nothing to do with the passage of gas inwards, which is known to be under the control of the nervous system. The cells lining the interior of the swimming bladder are developed from the same part of the alimentary tract as those lining the air-cells of the lungs, so that it seems not unlikely that the lungs should possess the power of actively secreting or excreting gases. The question whether such a power exists, and is normally exercised, has been investigated by more than one method; and although it is not possible to go into the details of the experiments, there can be no doubt that the balance of the evidence at present available is in favour of the view that diffusion alone is incapable of explaining either the absorption of oxygen or the excretion of carbon dioxide through the lining cells of the lungs. The partial pressure of oxygen appears to be always higher, and of carbon dioxide often lower, in the blood leaving the lungs than in the air of the air-cells; and this result is inconsistent with the diffusion theory. As to the causes of the passage of oxygen and carbonic acid through the walls of the capillaries of the general circulation, we are at present in the dark. Possibly diffusion may explain this process.

II. Although we cannot trace the exact changes which occur when oxygen passes into living cells, yet it is possible to obtain a clear general view of the origin and destiny of the material concerned in the process, and of the physiological conditions which determine it. The oxidizable material within the body consists, practically speaking, of proteins (albumen-like substances, with which the collagen of connective tissue may be included), fats and carbohydrates (sugars and glycogen). All of these substances contain carbon, hydrogen and oxygen in known, though different, proportions, and the former also contains a known amount of nitrogen and a little sulphur. Nitrogen is constantly leaving the body as urea and other substances in the urine and faeces; and a small but easily measurable proportion of carbon passes off in the same manner. The rest of the carbon passes out as carbon dioxide in respiration. Now carbohydrates and fats are the substances which convert the body to carbon dioxide and water. This follows from the fact that, practically speaking, no other products into which they might have been converted leave the body except carbon dioxide and water. Moreover, a given weight of carbohydrate requires for its oxidation a definite weight of oxygen, and produces a definite weight of carbon dioxide. There is thus a definite relation between the weight of oxygen used up and the weight of carbon dioxide formed in this oxidation. The same is true for the oxidation of fat and of protein, allowing in the latter case for the fact that the nitrogen, together with part of the carbon and hydrogen, passes out as urea, &c., in an incompletely oxidized form. From all this it follows that if we measure over a given period (1) the discharge of nitrogen from the body, (2) the intake of oxygen and (3) the output of carbonic acid, we can easily calculate exactly what the ultimate destiny of the oxygen has been, and at the ultimate expense of what material the carbonic acid has been formed. What the intermediate stages may have been we cannot say, but this in no way affects the validity of the calculation. If, during the period of measurement, food is taken, the basis of the calculation is still substantially the same, as the oxidizable material in food consists of practically nothing else except carbohydrate and fat.

Liberation of Energy.—From experiments made outside the body, we know that in the oxidation of a given weight of protein, carbohydrate or fat, a definite amount of energy is liberated. In the article on DIETETICS it is shown that precisely the same liberation of energy occurs in the living body, due allowance being made for the fact that the oxidation of protein is not quite complete. The following table shows the respiratory quotients (the respiratory quotient being the ratio between the volume of carbon dioxide formed and that of oxygen used up) and energy expressed in units of heat (calories) liberated per gramme of carbon dioxide produced and oxygen consumed in the living body during the oxidation of protein, fat, and a typical carbohydrate:

In the oxidation of non-living substances the rate varies, within wide limits, according to that at which oxygen is supplied. Thus a fire burns the faster the more air is supplied, and the higher the percentage of oxygen in the air. It was for long believed that in the living body also the rate of oxidation must vary according to the oxygen supply. It has been found, however, that this is not the case. Provided that a certain minimum of oxygen is present in the air breathed, or in the blood supplied to the tissues, it is, practically speaking, indifferent whether the oxygen supply be increased or diminished: only a certain amount is consumed. It might be supposed that the reason for this is that the available oxidizable material in the body is limited, and that if the food supply were increased there would be a corresponding increase in the rate of oxidation. This hypothesis is apparently supported by the fact that, when an increased supply of protein is given as food, the amount of nitrogen discharged in the urine is almost exactly correspondingly increased, so that evidently the oxidation of protein increases correspondingly with the supply. Similarly, when carbohydrate food is given, the alteration in the respiratory quotient shows that more carbohydrate than before is being oxidized. Closer investigation in recent times has, however, brought out the very striking fact that, if oxidation be measured in terms of energy liberated by it in the body, it makes but little difference, other things being equal, whether the animal is fasting or not. If more protein or carbohydrate is oxidized at one time, correspondingly less fat is oxidized, but the total energy liberated as heat, &c., in the body is about the same, unless the diet is very excessive, when there is a slight increase of oxidation. Even after many days of starvation, the rate of oxidation per unit of body weight has been found to remain sensibly the same in man. When more food is taken than is required, the excess is stored up, chiefly in the form of fat, into which carbohydrate and possibly also protein are readily converted in the body. When less food is taken than is needed, the stock of fat is drawn upon, and supplies by far the greater proportion of the energy requirements of the body.

During the performance of muscular work oxidation is greatly increased, and may amount to ten times the normal or more. Even the slight exertion of easy walking increases oxidation to three times. When the energy represented by the external work done in muscular exertion is compared with the extra energy liberated by oxidation in the body, it is found, as would be expected, that the latter value largely exceeds the former. In other words, much of the energy liberated is wasted as heat. Nevertheless the muscles are capable of working with less waste than any steam or gas engine. In the work of climbing, for instance, it has been found in the case of man that 35 % of the energy liberated in the work done in raising the body. Muscular work, if at all excessive, leads to fatigue, and consequent rest. On the other hand, unnatural abstinence from muscular activity leads to restlessness and consequent muscular work. Hence on an average of the twenty-four hours the expenditure of energy by different individuals, with different modes of life, does not as a rule differ greatly.

The rate of oxidation per unit of body weight varies considerably according to size and age. If we compare different warm-blooded animals, we find that the rate of oxidation is relatively
to their weight, far higher in the smaller ones. In a mouse or small bird, for instance, the rate is about twenty times as great as in a man. The difference is in part due to the fact that the smaller an animal is the greater is its surface relatively to its mass, and consequently the more heat does it require to keep up its temperature. The smaller animal must therefore produce more heat. Even in cold-blooded animals, however, oxidation appears to be more rapid the smaller the animal. In the case of man, oxidation is relatively more than twice as rapid in children than in adults, and the difference is greater than would be accounted for by the difference in the ratio of surface to mass. Allowing for differences in size, oxidation is about equally rapid in men and women.

It was long believed that the special function of respiratory oxidation was (1) the production of heat, and (2) the destruction of the supposed "waste products." Further investigation has, however, tended to show more and more clearly that in reality respiratory oxidation is an essential and intimate accomplishment of all vital activity. To take one example, secretion and absorption, which were formerly explained as simple processes of filtration and diffusion, are now known to be accompanied, and necessarily so, by respiratory oxidation in the tissues concerned. The respiratory oxidation of an animal is thus a very direct index of the activity of its vital processes as a whole. Lambert Adolphe Quételet (1796–1874): at the age of one year the number of respirations is 44 per minute; at 5 years, 26; from 15 to 20 years, 20; from 25 to 30, 16; from 30 to 50, 18–1. Muscular exertion always increases the frequency of respiration. The higher the temperature of the environment the more frequent is the respiration. Paul Bert (1833–1886) has shown that with higher atmospheric pressures than the normal the frequency of respiration is diminished while the depth of each inspiration is increased. The frequency of respiration diminishes until dinner-time, reaches its maximum within an hour of feeding, and thereafter falls again; if dinner is omitted, no rise of frequency occurs. The respiratory act can be interrupted at any stage, reversed, quickened, slowed and variously modified at will, so long as respiration is not stopped entirely for more than a short space of time; beyond this limit the will is incapable of suppressing respiration.

Depth of Respiration.—The depth of respiration is measured by the quantity of air inspired or expired in the act; but the deepest expiration possible does not suffice to expel all the air the lungs contain. The following measurements have been made.

(1) Residual air, the volume of air remaining in the chest after the most complete expiratory effort, ranges from 100 to 130 cub. in. (2) Reserve or supplemental air, the volume of air which can be expelled from the chest after an ordinary quiet expiration, measures about 100 cub. in. (3) Tidal air, the volume of air taken in and given out at each ordinary respiration may be stated at about 20 cub. in. (4) Complemental air, the volume of air that can be forcibly inspired over and above what is taken in at a normal inspiration, ranges from about 100 to 150 cub. in. By vital capacity, which once had an exaggerated importance attached to it, is meant the quantity of air which can be expelled from the lungs by the deepest possible expiration after the deepest possible inspiration; it obviously includes the complemental, tidal and reserve airs, and measures about 230 cub. in. in the Englishman of average height, i.e. 5 ft. 8 in. (Hutchinson). It varies according to the height, body weight, age, sex, position of the body and condition as to health of the subject of observation.

Vital capacity is estimated by means of a spirometer, a gradu- ated gasometer into which air may be blown from the lungs. The residual air, which for obvious reasons cannot be actually measured, may be estimated in the following way (Emil Harless, 1820–1862; Louis Gréhant, b. 1838). At the end of ordinary expiration, apply the mouth to a mouthpiece communicating with a vessel filled with pure hydrogen, and breathe into and out of this vessel half a dozen times—until, in fact, there is reason to suppose that the air in the lungs at the time of the experiment has become evenly mixed with hydrogen. Then ascertain by analysis the proportion of hydrogen to expired air in the vessel and estimate the amount of the air which the lungs contained by the following formula:—

\[ V + e = \frac{p}{\rho} \times 100 \]

where \( V \) = volume of air in the lungs at the time of experiment, \( e \) = volume of the vessel containing hydrogen, \( p \) = proportion of air to hydrogen in the vessel at the end of the experiment, \( \rho \) is, then, the volume of air in the lungs after an ordinary expiration; that is, it includes the residual and the reserve air; if we subtract from this the amount of reserve air ascertained by direct measurement, we obtain the 100–150 cub. in. in which Hutchinson arrived at by a study of the dead body.

Volume of Respiration.—It is clear that the ventilation of the lungs in ordinary breathing does not merely depend on...
the quantity of air inspired at each breath, but also on the number of inspirations in a given time. If these two values he multiplied together we get what might be called the volume of respiration (Atemungsgrösse, Isidore Rosenthal, b. 1836), in contradistinction to a depth of respiration and frequency of respiration. Various instruments have been devised to measure the volume of respiration, all more or less faulty for the reason that they compel respiration under somewhat abnormal conditions (Rosenthal, Gad, Peter Ludwig, Panum (1820–1889), Ewald Hering (b. 1834). From the data obtained we may conclude that the respiratory volume per minute in man is about 366 cub. in. (6000 cub. centim.). In connexion with this subject it may be stated that, after a single ordinary inspiration of hydrogen gas, 6–10 respirations of ordinary air must occur before the expired air ceases to contain some trace of hydrogen.

Types of Respiration.—The visible characters of respiration in man vary considerably according to age and sex. In men, while there is a moderate degree of upheaval of the chest, there is a considerable although not preponderating degree of excursion of the abdominal walls. In women the chest movements are decidedly more marked, the excursion of the abdominal walls being comparatively small. Hence we may distinguish two types of respiration, the costal and the abdominal, according to the preponderance of movement of one or the other part of the body wall. In forced respiration the type is costal in both sexes, and so it is also in sleep. The cause of this difference between men and women has been variously ascribed (a) to constriction of the chest by breasts, (b) to a natural adaptation to the needs of child-bearing in women, and (c) to the greater relative flexibility of the ribs in women permitting a wider displacement under the action of the inspiratory muscles.

Certain Concomitants of Normal Respiration.—If the ear be placed against the chest wall during ordinary respiration we can hear with every inspiration a sighing or rustling sound, called “vesicular,” which is probably caused by the expansion of the air vesicles; and with every expiration a sound of a much softer sighing character. In children the inspiratory sound is sharper and more pronounced than in adults. In a stethoscope be placed over the trachea, bronchi or larynx, so that the sounds generated there may be separately communicated to the ear, there is heard a harsh to-and-fro sound during inspiration and expiration which has received the name of “bronchial.”

In healthy breathing the mouth should be closed and the ingoing current should all pass through the nose. When this happens the nostrils become slightly expanded with each inspiration, probably by the action of the M. dilatatores naris. In some people this movement is hardly perceptible unless breathing be heavy or laboured. As the air passes at the back of the throat behind the soft palate it causes the velum to wave very gently in the current; this is a purely passive movement. If we look at the glottis or opening into the larynx during respiration, as we may readily do with the help of a small mirror held at the back of the throat, we may notice that the glottis is wide open during inspiration and that it becomes narrower by the approximation of the vocal chords during expiration. This alteration is produced by the action of the laryngeal muscles. Like the movements of the nostrils, those of the larynx are almost imperceptible in some people during ordinary breathing, but are very well marked in all during the act of respiration.

The Mechanics of Respiration.—The thorax is practically a closed box entirely filled by the lungs, heart and other structures contained within it. If we were to freeze a dead body until all its tissues were rigid, and then were to remove a portion of the chest wall, we should observe that every corner of the thorax is accurately filled by some portion or other of its contents. If we were to perform the same operation of removing a part of the chest wall in a body not first frozen we should find, on the other hand, that the contents of the thorax are not by any means in such circumstances bulky enough to fill up the space provided for them. If we were to measure the organs carefully we should find that those which are hollow and whose cavities communicate with the regions outside the thorax are all larger in the frozen corpse than in that which was not frozen. In other words, the organs in the thorax are distended somewhat in order that they may completely fill the chest cavity; and the nature of this curious and important condition may best be illustrated by the simple diagrams, figs. 7 and 8 (from Hermann’s Physiologie des Menschen),—where l is the trachea, l the lung, v the auricle of the heart, k the ventricle, i an intercostal space with its flexible membranous covering. When the interior of the vessel is rendered vacuous by exhaustion through the tube o, the walls of the lungs and heart are expanded until the limits of the containing vessel are accurately filled, while all flexible portions of the walls of the vessel (corresponding to the intercostal membranes and the diaphragm of the thorax) are sucked inwards.

From this description it follows that the lungs, even when the thorax is most contracted, are constantly over-distended, and that, when the cause of this over-distension is removed, the lungs, being elastic, collapse. It further follows that if the thorax is dilated, the flexible hollow organs it contains must perforce be still more distended—a distension which in the case of the lungs is followed by an indrawing of air through the trachea in all cases where the trachea is open. Thus, as the act of respiration is primarily a dilatation of the thorax, the part played by the lungs is, as Galen knew, a purely passive one.

How is dilatation of the thorax effected? It has been pointed out that the rib-planes decline from the horizontal in two directions, viz. from behind forwards, and from the antero-posterior mesial plane outwards; a glance at fig. 9 will make this double sloping clear to the reader. It has, moreover, been explained that the diaphragm arches upwards into the thorax in such a manner that the lateral parts of the arch are vertical and in contact with the inner face of the thoracic walls. This being the structure of the thorax, the enlargement of its cavity is brought about (1) by raising the rib-planes until they approach the horizontal, and (2) by depressing the diaphragm and making its rounded dome more cone-like in outline. A moment’s consideration will show how these actions enlarge the boundaries of the thorax. (a) When the posterior-anterior slope of the rib-planes is diminished by the raising of the anterior ends of the ribs, the whole sternum is thrust upwards and forwards, and the antero-posterior diameter of the thorax is increased. (b) When the lateral slope of the rib-planes is diminished by the ribs being moved
upwards about an axis passing through their sternal and vertebral extremities, it is evident that the lateral diameter of the thorax must be increased. (c) When the muscular portion of the diaphragm contracts, the curves of its dome-like shape are straightened, the whole diaphragm comes to look more conical on section, and the apposition of its lateral parts to the inner surfaces of the thorax is destroyed; the two apposed surfaces are drawn apart much as the leaves of a book might be, and a space is formed between them, into which some portion of the lung slips. (d) When the diaphragm descends it draws with it the whole contents of the thorax; inasmuch as the contents as a whole are conical in shape with the apex upward and are fitted into the conical space of the thoracic cavity, it is clear that the descent of the contents will tend to create a space between them and the thoracic walls; for each stratum of lung, &c., which is adapted to fit a certain level of thorax, will thereby be brought into a lower and (as the thorax is conical) a more spacious level. Hence the descent of the diaphragm causes a much greater enlargement of the thorax than is measured by the mere elongation of the vertical diameter. In this manner the thorax is distended and air is drawn into the lungs. The contraction of the thorax in expiration is brought about by the return of the ribs and diaphragm to their original position of rest.

How the Inspiratory Movements are Produced.—The Rib Movements.—These are caused by the contraction of muscles which are fixed either to the central axis of the body (including under that term the head and vertebral column) or to some point rendered sufficiently stable for the purpose of the action of other adjuvant muscles. Thus the M. levatores costarum arise from the transverse processes of the 7th cervical and eleven upper dorsal vertebrae, and are attached to the ribs below in series; the M. scaleni spring from the cervical vertebrae, and are attached to the anterior parts of the first and second ribs; the M. sternocleido-mastoidei arise from the side and back of the skull, and are inserted into the upper part of the sternum and the clavicle; the M. pectoralis minor arises from the coracoid process of the scapula, and is inserted into the anterior ends of some of the ribs; the M. serratus posticus superior arises from certain of the cervical and dorsal vertebrae, and is inserted into the posterior part of certain of the ribs; the M. scaleni ascendens (part of the M. erector spine) arises from certain of the cervical vertebrae, and is inserted into the posterior part of certain ribs. The M. serratus magnus and the M. pectoralis major, which are affixed on the one hand to the upper arm and to the scapula respectively, and on the other to the ribs and to the sternum respectively, may in certain elevated positions of the arm and shoulder act as inspiratory muscles. When all these muscles contract, the ribs are raised in the twofold way already described, some pulling up the anterior ends of the ribs, and others causing the arched ribs to rotate about an axis passing through their vertebral and sternal joints.

In addition to the muscles just enumerated, the M. intercostales externi are undoubtedly inspiratory muscles. Every external intercostal muscular fibre between a pair of ribs must, when it contracts, of necessity raise both ribs, as is clearly shown by the accompanying diagram (fig. 10). Here \( a' b' \) must be shorter than \( a b \), for if angle \( BA_0 = x \), then \( ab = AB = (A_0 - A_0)^2 + 2AB(A_0 - A_0)\cos x \); hence \( ab \) will be larger the smaller the angle \( x \), for the cosine increases as the angle diminishes.

By a similar geometrical treatment of the question it may be shown that the internal intercostals muscles when they contract must of necessity depress both the ribs to which they are attached. If the angle \( BA = x \) (fig. 11), then \( c'd' = AB = (A' - B')^2 - 2AB(A' - B')\cos x \); hence \( c'd' \) will be larger the larger the angle \( x \).

The case, however, is not so clear with reference to the anterior portions of the internal intercostals which lie between the cartilages; for it is evident that these fibres have the same direction with regard to the sternum as an axis as the external intercostals have with regard to the vertebral column as an axis; that is to say, the geometrical diagram in fig. 10 applies to the inter-cartilaginous internal intercostals as perfectly as it does to the intercostal parts of the external intercostals, the inference being that the inter-cartilaginous internal intercostals tend to elevate the pair of ribs between which they stretch. The geometrical argument is, however, overborne by physiological experiment: Martin and Hartwell have observed in the dog and the cat that the internal intercostals throughout their whole extent contract (not synchronously) but alternately with the diaphragm; hence we must conclude that their function throughout is not inspiratory like that of the diaphragm, but expiratory.

The Movements of the Diaphragm.—The muscular fibres of the diaphragm are arranged in a radial manner, or, more strictly speaking, in a manner like the lines of longitude on a terrestrial globe. The central tendon of the diaphragm corresponds to the pole of such a globe. The contraction of the fibres is expanded on straightening the longitudinal curves rather than on pulling down the central tendon to a lower level; in fact, the central tendon moves very little in ordinary respiration.

How the Expiratory Movements are Produced.—The action of inspiration disturbs many organs from the position of rest into which gravity and their own physical properties have thrown them. The ribs and sternum are raised from the position of lowest level; the elastic costal cartilages are twisted; the elastic lungs are put upon the stretch; the abdominal organs, themselves elastic, are compressed and thrust against the elastic walls of the belly, causing these to bulge outwards. In short the very act of inspiration stores up, as it were, in sundry ways the forces which make for expiration. As soon as the inspiratory muscles cease to act these forces come into play, and the position of rest or equilibrium is regained. It is very doubtful whether any special expiratory muscles are called into action during ordinary respiration. The internal intercostals may in man be exercised in ordinary expiration (although they are certainly not so exercised in the dog and the cat); but in laboured expiration many muscles assist in the expulsive effort. The muscles forming the belly-walls contract and force the abdominal contents against the relaxed diaphragm in such a manner as to drive it farther and farther into the thorax. At the same time by their attachment to the lower edge of the
thorax these same muscles pull down the ribs and sternum. The M. triangularis sterni, which arises from the back or thoracic aspect of the sternum and lower costal cartilages and is inserted into the costal cartilages higher up, can obviously depress the ribs. So also can the M. serratus posterior inferior, which arises from the thick fascia of the loins and is inserted into the last four ribs. So also can the M. quadratus lumborum, which springs from the pelvis and is attached to the last rib. Indeed there is hardly a muscle of the body but may be called into play during extremely laboured respiration, either because it acts on the chest, or because it serves to steady some part and give a better purchase for the action of direct respiratory muscles.

**Certain Abnormal Forms of Respiration.**

**Coughing.**—There is first a deep inspiration followed by closure of the glottis. Then follows a violent expiratory effort which bursts open the glottis and drives the air out of the lungs in a blast which carries away any light irritating matter it may meet with. The act is commonly involuntary, but may be imitated exactly by a voluntary effort.

**Crying.**—In this act a current of air is driven from the lungs and forced through the narrow space between the root of the tongue and the depressed soft palate. This act can only be caused voluntarily.

**Sneezing.**—There is first an inspiration which is often unusually rapid; then follows a sudden expiration, and the blast is directed through the nose. The glottis remains open all the time. The act is generally involuntary, but may be more or less successfully imitated by a voluntary effort.

**Snoring** is caused by unusually steady and prolonged inspirations and expirations through the open mouth,—the soft palate and uvula being set vibrating by the currents of air.

**Crying** consists of short, deep inspirations and prolonged expirations with the glottis partially closed. Long-continued crying leads to sobbing, in which sudden spasmodic contractions of the diaphragm cause sudden inspirations and inspiratory sounds generated in larynx and pharynx.

**Sighing** is a sudden and prolonged inspiration following an unusually long pause after the last expiration.

**Laughter** is caused by a series of short expiratory blasts which provoke a clear sound from the vocal chords kept tense for the purpose, and at the same time other inarticulate but very characteristic sounds from the vibrating structures of the larynx and pharynx. The face has a characteristic expression. This act is essentially involuntary, and often is beyond control; it can only be imitated very imperfectly.

**Yawning** is a long deep inspiration followed by a shorter expiration, the mouth, fauces and glottis being kept open in a characteristic fashion. It is involuntary, but may be imitated.

**Hiccough** is really an inspiration suddenly checked by closure of the glottis; the inspiration is due to a spasmodic contraction of the diaphragm. The closure of the glottis generally leads to a characteristic sound. (A. G.)*

(4) **Pathology of the Respiratory System**

In the following article we have to give an account of the more important pathological processes which affect the lungs, pleurae and bronchial tubes. In the etiology of pulmonary affections, the relations between the lungs and the external air, and also between them and the circulatory system, are important. The lungs are, so to speak, placed between the right and left cavities of the heart, and the only way for the blood to pass from the right ventricle to the left side of the heart, except in cases of a patent foramen ovale or other congenital defect forming a communication between the two sides of the organ, is by passing through them. The result is that not only may they become diseased by foreign material carried into them by the blood, but any obstruction to the flow of blood through the left side of the heart tends sooner or later to engorge or congest them, and lead to further changes. Through the nose and mouth they are in direct connexion with the external atmosphere. Hence the variable condition of the air as regards temperature, degree of moisture, and density, is liable to produce directly various changes in the lungs, or to predispose them to disease; and the contamination of the air with various pathogenic germs and irritating particles in the shape of dust, is a direct source of many lung affections.

**Bronchitis**, or inflammation of the mucous membrane of the bronchial tubes, has been generally attributed to exposure to atmospheric changes. It occurs with great frequency in the extremes of life, and it is in early childhood and in old age that it is more liable to be fatal. Bronchitis may often follow exposure to cold, but that low temperature in itself is not sufficient to cause it is shown by the fact that the crews of arctic expeditions have been singularly free from diseases usually attributed to cold, but on their return to moist gemladen atmospheres have at once been affected. Children reared in heated rooms with lack of ventilation are peculiarly susceptible to attacks on the slightest change of temperature. Bronchitis is also frequently caused by cardiac and renal diseases, and by the extension of inflammatory diseases of the upper air passages (as rhinitis, laryngitis or pharyngitis), while blockage of the nasal passages by adenoid or other growths may, by causing persistent mouth-breathing, lead to bronchial infection. Before the bacterial origin of disease was understood, bronchitis was attributed solely to what is termed “catching cold,” and the exact relation of the chill to the bacterial infection is still unknown. It is probable that the chilling of the surface of the body by exposure causes congestion of the mucous membrane, the presence of a virulent micro-organism being then all that is required to produce bronchitis. It is generally accepted that in persons living in the pure air of the country the small bronchi and air-cells are sterile (Barthel in the *Zentralblatt für Bakteriologie*, vol. xxiv.). Bacteria are arrested on their way by the leucocytes of the nasal mucous membrane and by the vibration of the ciliated epithelium of the upper air passages. The mucous membrane of the upper bronchi is, however, tenanted by various micro-organisms such as the diplo-bacillus of Friedländer, B. coli communis, micrococcus tetragenus, &c., and it is considered by William Ewart that these organisms may in certain conditions of their host become virulent. “Specific” bronchitis occurs in the course of a specific infective disease (e.g. influenza, measles or whooping cough) and is due to the specific micro-organism gaining access by the mucous membrane of the respiratory tract. Cases have been known in which the diptheria bacillus has been so localized. In glanders, small-pox, syphilis and pemphigus, the infective micro-organism is carried to the bronchi by the blood stream. In common or “non-specific” bronchitis, streptococci, pneumococci and staphylococci are found in the sputum together with Friedländer’s bacillus and the bacillus coli communis. Microscopically the bronchi show hyperaemia of the mucous and submucous coats, and the whole wall becomes infiltrated with polymorphonuclear leucocytes and round cells. Many cells undergo mucoid degeneration, and there is abundant epithelial proliferation. A large quantity of mucus is secreted by the glands, and the bronchi become plugged with mucus, degenerated leucocytes and cast-off epithelial cells.

In the rare form of bronchitis known as fibrinous or plastic bronchitis a membranous exudate is formed which forms casts of the bronchi, which may be coughed up. The casts vary from an inch to six or seven inches in length, with branches corresponding to the divisions of the bronchi from which they come. The cast consists of mucus and fibrin in varying proportions. The exact pathology of this variety is still undetermined.

Bronchitis may affect the whole bronchial tract, or more especially the larger or the smaller tubes. It may occur as an acute or as a chronic affection. In the acute form the inflammation may remain limited to the bronchial tubes and gradually subside, or it may lead to inflammation of the surrounding lung tissue, giving rise to disseminated foci of inflammation of greater or less extent throughout the lungs (cataarrhal or broncho-pneumonia). This is a common complication of bronchitis, especially where the smaller tubes are affected, and is more
frequently seen in children than adults. In cases of chronic bronchitis the affection, as a rule, begins as a slight ailment during the winter, and recurs in succeeding winters. The intervals of freedom from the trouble get shorter, and in the course of a few years it persists during the summer well into the autumn months. A condition of chronic bronchitis is thus established.

The persistent cough which this occasions is one of the chief causes of the development of the condition of emphysema, where there is a permanent enlargement of the air-cells of the lungs with an atrophy of the walls of the air vesicles. The emphysema occurs in the shortness of breath from which the person had previously suffered, and later, in consequence of the greater difficulty with which the blood circulates through the emphysematous lungs, the right side of the heart begins to dilate, and from that we have the development of a general choromnous and turgid state, the so-called anemia, and less and less perfect aeration of the blood.

The death rate from bronchitis in England and Wales during 1908 was: males 1102, females 1083 per million living. The death rate for the five years 1901-1905 was 1237 per million for all sexes. The death rate for the twenty years 1888-1908 consistently showed a slight decline.

Diseases of Occupations.—We all inhale a considerable amount of carbonaceous and other foreign particles, which in health are partly got rid of by the action of the ciliated cells lining the bronchial tubes, and are partly absorbed by cells in the wall of the tubes, and carried in the lymph channels to the bronchial lymphatic glands, where they are deposited, and cause a more or less marked pigmentation of the tissues. Part of such pigment is also deposited in the walls of the bronchial tubes and the interstitial tissue of the lungs, giving rise to the grey appearance presented by the lungs of all adults who live in large cities. In certain dusty occupations, such as those of stone masons, knife-grinders, colliers, &c., the foreign particles inhaled cause trouble. The most common affection so produced is chronic bronchitis, to which becomes added emphysema. In some cases not only is bronchitis developed, but the foreign particles lead to an increase of the fibrous tissue round the bronchi and in the interstitial tissue of the lungs, and so to a greater or lesser extent of fibroid consolidation. As this fibrous tissue may later undergo softening and cavities be formed, a form of consumption is produced, which is named according to the particular occupation giving rise to it; e.g. stonemasons' phthisis, knife-grinders' phthisis, colliers' phthisis. It should, however, be pointed out that these dusty occupations are probably not so frequently the cause as was at one time thought of these simple inflammatory fibroid changes in the lungs with their subsequent cavity formation; individuals engaged in such occupations are apt to suffer from a chronic tuberculosis of the lung associated with the development of much fibrous tissue, and the occupation simply predisposes the lung to the attacks of the tubercle bacillus.

The term pneumonia is frequently used of different forms of inflammation of the lungs, and includes affections which run different clinical courses, present diverse appearances after death, and probably have different exciting causes. It would be better if the term acute pneumonia or pneumonic fever were reserved for that form of acute inflammation of the lungs which is usually characterized by sudden onset, and runs an acute, course, which terminates generally by crisis from the fifth to the tenth day, the inflammation leading to the consolidation by fibrous effusion of the greater part or whole of one lobe of a lung. Acute pneumonia usually occurs in a sporadic form, and is most prevalent in the United Kingdom from November to March. Occasionally it is epidemic, and there is evidence to show that sometimes it is an infective disease. It has great difficulty, however, in being quite certain that the occurrence of the disease in those who have been attending or brought into intimate connexion with sufferers from pneumonia is the result of infection, for such cases may be due to an epidemic of the disease, or to the various individuals attacked having been exposed to the same cause.

Formerly acute croupous or lobar pneumonia was thought to be due to "catching cold"; we now know it to be an infectious disease resultant on the invasion of one or more specific micro-organisms. The chief micro-organisms which have been recently present during an attack of acute pneumonia are the micrococcus lanceolatus or pneumococcus of Fränkel and Weichselbaum, which is found in the inflamed lung in a large majority of cases and is capable of producing pneumonia when inoculated into guinea-pigs. Sternberg demonstrated the presence of the pneumococcus in the saliva of healthy individuals; it tends, however, in this case to vary in form. The micro-organism differs in virulence in given strains; thus one epidemic may be more severe than another; and it tends to increase in virulence in its passage through the human subject. The exact conditions necessary for the production of an attack of lobar pneumonia are not yet determined, but are usually ascribed to lowered states of the health and to atmospheric conditions. The pneumococcus produces in the human organism an intracellular toxin, but the question as to whether it can also produce a soluble toxin in the living body is still debated. The difficulty of obtaining sufficient quantities of the toxins of this organism has prevented the production of antiserum of high potency. In lower animals, less potent sera have proved successful in protecting against a fatal dose of pneumococcus. The change effected by the administration of a serum is produced by causing a change in the pneumococcus, which causes them to be more easily destroyed by the phagocytes. The element which brings about this change is termed an opsonin; see Blood and Bacteriology (ii). The bacillus pneumoniae of Friedländer is also said to be found in a certain percentage of cases, but a number of observers deny its presence in pure culture in primary croupous pneumonia.

Unlike many acute diseases, pneumonia does not render a person less liable to future attacks; on the contrary, those who have been once attacked must be looked upon as more prone to be affected again. Acute pneumonia usually attacks the whole or greater part of one lobe of one lung, but more than one lobe may be affected, or both lungs may be involved. The disease produces a solid and airless condition of the affected part owing to a fibrinous exudation taking place into the air-cells and smaller bronchial passages. In favourable cases the exudation is partly absorbed and partly expectorated, and the lung returns to its normal healthy condition; in others, death may ensue from the extent of lung affected, or from the spread of the inflammation to other parts, as for instance the pericardium or meninges of the brain. In such cases it is interesting to note that the same micro-organism has been found in the inflammatory exudation in the pericardium or on the meninges as in the pneumatic lung; probably the organism had been absorbed from the lung, and was the cause of the secondary inflammations. In cases of death from uncomplicated pneumonia a very variable extent of lung is involved. In some cases this result may be ascribed to the weakness of the individual and especially of the heart, but in others the virulence of the micro-organisms and the toxins which they have produced is probably the more correct explanation. The improvement in a patient suffering from pneumonia usually commences suddenly, with a rapid fall in the temperature. The day on which this "crisis" takes place varies, but most commonly it appears to be the seventh from the initial rigor (22% of the cases, Jürgensen). It may, however, occur a few days earlier or later, being observed in about 74% between the fifth and the ninth day of the disease (Jürgensen). The disease occasionally ends in the formation of an abscess, in gangrene, or in fibrinous induration of the lung, but these terminations are rare.

The death rate of acute pneumonia for England and Wales in 1908 was 1383 per million living of the population.

Broncho-pneumonia.—It is usual to recognize a form of inflammation of the lungs which differs from the above lobar pneumonia.
and in which small patches of consolidation are usually scattered throughout the lower lobes of both lungs. This broncho- or catarrhal pneumonia is usually preceded by an attack of bronchitis, to which it bears an intimate relation. In some cases the small foci of inflammation may run together so as to affect the greater part of a lobe of a lung, and the distinction between such a form of broncho-pneumonia and lobar pneumonia presents such difficulties in the view of some observers, that they have refused to recognize bronchopneumonia as a separate entity. In general, however, it is not difficult to distinguish the two affections, both clinically and anatomically. Broncho-pneumonia is essentially seen as a complication of bronchitis, while it more frequently attacks children than young adults, it is not uncommon in old people, especially secondary to bronchitis. It is frequent in children after acute infectious fevers, especially measles and diphtheria, and is often seen in cases of whooping-cough. It differs from the above-mentioned pneumonia in that it does not usually attack the whole of a lobe of a lung, but occurs in small disseminated patches more especially throughout the lower lobe of both lungs. The accompanying fever is more irregular than in the preceding form, and the disease usually runs a more prolonged course. It is an extremely fatal affection in both the very young and old. Young persons who have suffered from it are not infrequently attacked by pulmonary tuberculosis subsequently. It must be admitted that we are even less certain of its bacteriology than we are of that of lobar pneumonia. In some cases Fränkel's pneumococcus is found, and in others streptococci from the bronchial tubes. The organism is doubtless saprophytic, and are not the essential cause of the disease, but it is not probable that any one particular form of organism accounts for all forms of broncho-pneumonia.

The bacteriology of broncho-pneumonia presents no one micro-organism which can be definitely said to cause the disease. The micro-organism most frequently found, either alone or associated with other bacteria, is the pneumococcus, which occurred in 67% of a series investigated by Wollstein. Other organisms found are the streptococcus, particularly in broncho-pneumonia following infectious fevers, the staphylococcus aureus and albus, and Friedländer's bacillus. In some cases the bacillus influenzae alone has been found, and the Klebs-Löffler's bacillus cases following upon diphtheria. When the disease is associated with pulmonary tuberculosis the tubercle bacillus is found.

The tuberculous virus, the tubercule bacilli, may gain entrance to the lungs through the inspired air or by means of the blood or lymph currents. Also in some cases it has been demonstrated that tubercule bacilli may infect the glands of the mesentery following the ingestion of the milk of tuberculous cattle. In this the Government Commissions of Great Britain and Germany as well as the United States Bureau of Animal Industry confirm the findings of private investigators. It may be well to summarize the views which are held as to infection. In the first place, the doctrine of inherited disease is discredited, and the doctrine of specific susceptibility is in doubt. Infants are known to be extremely susceptible, and this susceptibility lessens with increasing age, adults requiring prolonged exposure. As a mode of infection the sputum of diseased persons is of great importance. Infected food, especially milk, comes next, together with food infected by flies; and the mother's milk is a minor source. Infection is not often received through the skin, but most frequently through the mucous membrane of the mouth, air passages and intestine; occasionally the infected air is inhaled. Pulmonary tuberculosis is often secondary to an acute or to a latent lymphatic form. The tubercule bacillus was discovered by Koch in 1882, and since then it has become generally accepted that the bacillus varies in type. The bacilli have been classified by A. G. Foulerton into (a) occurring in fishes and cold-blooded animals, (b) in birds, (c) in rats, (d) in cattle, (e) in man. Exactly how far they are interchangeable and can affect the human race is not definitely settled. They may be different varieties of the same organism, and the usual nomenclature has been maintained in the present article. We must, however, recognize that all simple acute broncho-pneumonias are not purely catarrhal in the strict pathological sense. For a considerable amount of fibrous exudation is not infrequently present in the patches of broncho-pneumonia, and some of the cases of broncho-pneumonia can scarcely be accurately termed catarrhal.

1 The term catarrhal pneumonia has been usually regarded as synonymous with the term broncho-pneumonia, and in this usual nomenclature has been maintained in the present article. We must, however, recognize that all simple acute broncho-pneumonias are not purely catarrhal in the strict pathological sense. For a considerable amount of fibrous exudation is not infrequently present in the patches of broncho-pneumonia, and some of the cases of broncho-pneumonia can scarcely be accurately termed catarrhal.
RESPIRATORY SYSTEM

conditions were not maintained long enough to ensure the complete arrest of the disease. Instead of the tuberculous focus becoming arrested, it may continue to spread. The original focus and the secondary ones are at first patches of consolidated lung. Later, their central parts soften and burst into a bronchus; then the softened portion is coughed up, and a small cavity is left, which tends gradually to increase in size by peripheric extension and by merging with other cavities. This process is repeated again and again, and sooner or later the other lung becomes similarly affected. At any stage of the softening process the blood vessels may become involved and give rise by rupture to a large or a small haemorrhage (haemoptysis). It not infrequently happens that such haemoptysis may be the first symptom that seriously attracts attention. At a later period haemorrhage frequently takes place in large or small amounts from the rupture of vessels, which frequently are dilated and form small aneurysms in the walls of cavities. A fatal termination may be hastened by the absorption by means of the blood vessels and lymphatics of the tuberculous virus from some of the foci of disease, and the occurrence therefrom of a local miliary tuberculosis of the lungs or a general tuberculosis of other organs. The rapidity with which the destructive process spreads throughout the lung varies considerably. We therefore recognize acute phthisis, or galloping consumption, and chronic phthisis. In the acute cases the softening progresses rapidly and is associated with the development of very little fibrous tissue; probably various forms of microscopical analysis of the tubercle bacilli assist in the rapid softening. In the more chronic cases there is development of much fibroid tissue, and the disease is associated with periods of temporary arrest of the tubercular process.

The expectation from cases of pulmonary phthisis contains tubercle bacilli, and is a source of danger to healthy individuals, in whom the disease process is arrested. Attention on person suffering from pulmonary phthisis involves very little risk of infection if proper care is taken to prevent the expectoration becoming dry and disseminated as dust; perfect cleanliness is therefore to be insisted upon in the rooms inhabited by a phthisical person. The tubercle bacilli soon lose their virulence in the presence of fresh air and sunshine, and therefore these agents are not only desirable for the direct benefit of the phthisical patient, but also are agents in preventing the development of fresh disease in healthy individuals.

Although the tubercle bacilli are the essential agents in the development of pulmonary tuberculosis, there are other conditions which must be present before they will produce the disease. It is probable that large numbers of individuals are exposed to the action of tubercle bacilli which gain entrance to the pulmonary tissues and cause no rise to the disease because of the absence of growth and multiplication do not exist. In such cases we may consider that the seed is present, but that the soil is unsuitable for its growth. Certain families appear more predisposed to tuberculosis than others.

The most important circulatory disturbances met with in the lungs are those seen in cases of dilated heart, with or without disease of the mitral valve, when engorgement of the pulmonary vessels sets up a condition of venous engorgement of the lungs. This may lead to various changes. After it has lasted a variable time, and if it is very intense, serious transudation occurs into the substance of the lung and the alveoli, and thus a condition of pulmonary dropsy or oedema is established. The venous engorgement also predisposes the subjects of such heart affections to bronchitis and pneumonia. In disease of the mitral valve, in cardiac dilatation and in simple feebleness of the heart, it is also seen in old age and after debilitating fevers, especially typhoid, there is commonly developed a venous congestion of the bases of the lungs, forming the so-called hypostatic congestion of those organs, and to this is frequently added pneumonia.

In long-standing cases of pulmonary congestion brought about by disease of the mitral valve and dilatation of the heart, a certain amount of fibrous tissue may be found in the interstitial tissue of the lungs, and from transudation of certain elements of the blood we get the formation in the newly formed fibrous tissue of blood pigment. In these cases blood pigment is found in the cells, in the pulmonary alveoli, and such cells also carry the pigment into the interstitial tissue. This condition constitutes the state known as brown induration of the lungs. Acute congestion of the lungs occurs as part of the first stage of pneumonia. It also probably exists during violent exertion, and may possibly be brought about by excitement. The spirals consist of a central solid thread.

Another circulatory disturbance of great importance is that arising from blocking of the pulmonary artery or its branches by an embolus or a thrombus. Where the obstruction takes place in the main vessel, death rapidly ensues. Where, however, a small branch of the vessel is occluded, as frequently occurs from a coagulum forming in the right side of the heart, or in the pulmonary vessels in cases of disease of the mitral valve, or in dilatation of the heart, or from the detachment of a small vegetation from disease of the pulmonary valves, a haemorrhagic exudation takes place, forming a patch of consolidation in the lung (haemorrhagic infarct). As this haemorrhagic exudation takes place not only into the substance of the lung, but also into the bronchial tubes, such lesions are usually associated with spitting of blood (haemoptysis).

The increased tension produced in the pulmonary vessels in cases of mitral disease may also probably lead to the formation of haemorrhagic exudations into the lungs, apart from the occurrence of embolism or thrombosis. Usually the occurrence of pulmonary embolism and the formation of haemorrhagic infarcts in the lungs mark an important epoch in the course of a case of heart disease. It usually occurs at a late stage of the affection, and not infrequently contributes materially to a fatal termination. It is probable that many of the cases of pneumonia and pleuritic effusion, coming on in cases of valvular heart disease and of cardiac dilatation, owe their origin to an embolus and to the formation of a haemorrhagic infarct.

The term asthma is commonly applied to a paroxysmal dyspnoea of a special type which is associated with a variety of conditions. In true spasmodic asthma there may be no detectable organic disease, and the paroxysms are generally believed to be due to a nervous influence which, acting upon the bronchial muscles, produces a spasm of the tubes, or, acting through the vaso-motor branches of the sympathetic, produces a congestion of the bronchial mucous membrane. The most probable theory is that lately advanced, that it is caused by a profound toxaemia. An organism has been isolated, which is said to be the cause of certain cases of asthma, and the fact that benefit has been said to follow treatment by a vaccine is in favour of this view. The exciting cause may not be at all apparent, even on the most careful observation and examination of the sufferer, but in other cases the attacks may be brought about by some reflex irritation. Nasal polypi and other diseases of nasal mucous membrane have been shown in some cases to be a cause of asthma. Irritation of the bronchial mucous membrane appears to be one of the most common, but it is usually difficult to say exactly in what the irritation consists.

The sputum in true asthma is typical, consisting of white translucent pellets like boiled tapioca. These pellets consist of mucus arranged in a twisted manner and known as Curschmann spirals; they also contain Charcot-Leyden crystals, degenerated epithelium and leucocytes, of which the majority are eosinophiles. The sputum consists of a globulo solid thread round which the mucus is arranged in spiral form. The twisting has been attributed to a rotary motion of the cilia, helped by the spasm of the bronchial muscles. Allied to true asthma is the bronchial asthma frequently met with in the subjects of bronchitis and emphysema. In such cases the irritation evidently proceeds from the inflamed bronchial mucous membrane. Hay asthma is the variety in which the pollen of certain plants, especially grasses, is the exciting cause of the paroxysms. In cardiac feebleness, in valvular disease of the heart, and in cardiac dilatation, we may get dyspnoeic attacks of a more or less
paroxysmal nature, to which the term cardiac asthma has been applied. Similarly, to a form of dyspnoea met with occasionally as a manifestation of uremia in chronic Bright's disease the term of renal asthma has been given.
Pleurisy, or inflammation of the pleura, is a very common affection, and is met with under different forms. In many instances we have simply the pouring out, over a greater or less area of the surface of the pleura, of a fibrous exudation which may become absorbed or undergo organization, a certain amount of thickening of the pleura, and adhesions of the two layers resulting. Such cases form the group known as cases of dry pleurisy. In other instances a greater or lesser amount of serous exudation takes place into one or other pleural cavity, forming the cases of serous pleuritic effusion. In others the exudation into the pleural cavity is purulent, giving rise to the condition known as empyema or purulent pleuritic effusion. The occurrence of dry pleurisy is probably very frequent, and leads to small pleural adhesions which cause little or no inconvenience. In post-mortem examinations of persons who have died from various causes it is common to find such pleural adhesions present, although they have never been suspected during life.
Pleurisy in one or other of the above forms may come on in a person apparently in good health (idiopathic pleurisy), or it may follow a fracture of the ribs or other injury to the chest. It is not uncommonly secondary to some other disease; thus it is almost a constant accompaniment of acute lobar pneumonia. In such cases the effusion is most commonly a simple fibrinous one, which with the subsidence of the primary disease is in great part absorbed. In other cases of pneumonia we get a certain amount of serous effusion into the pleura; and sometimes, especially in children, the pneumonia is followed by the development of an empyema. Pleurisy with effusion is also frequently a complication of valvular heart disease and dilatation of the heart, and in such cases is often associated with the formation of superficial pulmonary infarcts. It is also seen in many other diseases of the lungs. For instance, in chronic pulmonary phthisis pleuritic adhesions over various parts of the lungs are the rule; and we also frequently get serous effusion into the pleura as a complication of the various forms of pulmonary tuberculosis. Purulent effusion is less common in phthisis, but it is the rule where the pleura is perforated by the necrosis of a tuberculous focus in the lung and the establishment of a communication between the pleural and a tuberculous cavity, and the bronchial tubes (pyopneumothorax), a combination in which there is both air and pus in the pleural cavity. Secondary pleurisy is also seen in an extension of the disease from neighbouring parts, as from peritonitis, sub-diaphragmatic abscesses, and suppuration in the liver or spleen. As a secondary disease, pleurisy is also known in the course of various forms of nephritis, rheumatism, and the acute specific diseases.

Cases formerly classed as idiopathic pleurisy are now known to be caused by certain micro-organisms. These vary in relation to the character of the effusion. The most frequent is the tubercle bacillus, which is generally present in serofibrinous effusions. In this case the pleurisy is really secondary to a possibly unrecognized tuberculous infection either of the lung or pleura. In purulent effusions the pneumococcus may occur as a pure infection, or the streptococcus pyogenes or the staphylococcus may be present. Mixed infections occur in 21% of purulent effusions, and varieties of other organisms, such as the influenza bacillus, the typhoid bacillus, the Klebs-Löffler bacillus and the colon bacillus, have been occasionally found.

There are at least five types of pulmonary emphysema; (1) hypertrophic, idiopathic or large-lunged emphysema; (2) senile or small-lunged emphysema; (3) compensatory emphysema; (4) ankylosis vesicular emphysema; and (5) congenital or interlobar emphysema. Two points are usually admitted: that emphysema appears only in lungs that are congenitally weak, and that the exciting cause is increased intravascular tension. When one or more lobules are cut off from the working part of the lung the neighbouring vesicles become distended.

Should the plugging of the lobule remain permanent, typical emphysema results. This happens in illnesses inducing violent respiratory efforts, such as chronic bronchitis, whooping cough and asthma. In large-lunged emphysema the lung is excessively large, and does not collapse on opening the chest wall. Microscopically two lesions are notable. The septa between the vesicles are atrophied, many have disappeared and the vesicles have coalesced; the loss in lung tissue diminishes the vascular field of the lung and tends to imperfect aeration, whence the dyspnoea. The elastic tissue of the lung is also lost. In small-lunged emphysema there is a condition of senile atrophy. The lung is smaller than normal, and the intravascular septa are destroyed. In this case the primary cause is atrophy of the bronchi, and increased air pressure is not a factor. Compensatory emphysema is that which develops in a portion of a lung in which the other portion is the seat of a lesion, such as pneumonia. Occasionally it is merely physiological, but sometimes here too the septa undergo atrophic changes. Acute vesicular emphysema is hardly a pathological variety, and is really rapid distension coming on during an attack of asthma or anaphylactic shock. The variety is temporary in nature. Intestinal emphysema is characterized by the presence of air in the interstitial connective tissue of the lung. It is usually due to rupture of the air vesicles during paroxysms of coughing.

(T. H.; H. L. H.)

(5) Surgery of the Respiratory System

About the middle of the 19th century, Manuel Garcia demonstrated the working of the vocal cords in the living subject, by placing a flat mirror of about the size of a shilling at the back of the mouth, and throwing strong light on to it from a concave mirror fixed upon the observer's forehead. By the use of a laryngoscope and a cocaine spray the most irritable throat can now be made tolerant of the presence of the small mirror, and thus the medical man is enabled to make a prolonged and thorough examination of the interior of the larynx and even to perform delicate operations upon it. Foreign bodies which have become caught in the larynx can thus be seen and extracted, and small growths can be satisfactorily removed even from the vocal cords themselves.

A foreign body in the air-passages may be impacted above the vocal cords, and the prompt thrusting down of a finger may dislodge it and save the person from death by suffocation. If the foreign body is too large to be removed by this means, the symptoms are urgent (as is likely to be the case) immediate laryngotomy should be done. In this operation a tube is introduced through the crevice which can easily be felt in the middle line of the neck, between the thyroid and cricoid cartilages. The procedure is easily and quickly accomplished. It is, moreover, often resorted to when the surgeon is about to perform some extensive operation in the mouth which must needs be accompanied by free haemorrhage. Laryngotomy having been done, and the pharynx having been plugged with gauze, the air passages can be kept free of blood during the whole operation.

If the foreign body is composed of elastic cartilage, a cherry, plum or coin, it may at once set up alarming symptoms of spasmatic suffocation. But when the first alarm has quieted down, the attacks are likely to be only occasional, as when the article, drawn up with the expired air, comes in contact with the under aspect of the vocal cords. It may be that in a violent fit of coughing it will be expelled, but, if not, the surgeon must be at hand ready to perform tracheotomy when the urgency of the symptoms demands it. Tracheotomy is the making of an opening into the trachea, the air-tube below the larynx. It is unsafe to leave a child with a foreign body loose in its windpipe, on account of the risk of sudden and fatal asphyxia. Possibly the X-rays may show its exact position and give help in its removal. But, in any case, the safest thing will be to perform tracheotomy and to leave the edges of the opening into the windpipe wide asunder, so that the object may be coughed out —the nurse being on guard all the while. The operation of tracheotomy is sometimes urgently called for in the case in
which the air-way has become blocked by a child having sucked hot water from the spout of a kettle or teapot, or in the case of obstruction by the swelling of the acute inflammation of laryngitis or of diphtheria. Should the air-way through the larynx become narrowed by the presence of a laryngeal crust which does not diminish under the influence of iodide of potassium, the question may arise as to whether it should be dealt with by splitting the thyroid cartilage and holding the wings apart, or by the removal of the whole larynx. For such growths are often malignant. If the wide infection of the lymphatic glands of the neck suggests that no radical operation should be undertaken, a bent silver tube may be introduced below the growth (tracheotomy) in order to provide for the entrance of air. This will get over the difficulty of breathing, but it cannot, of course, do more than that.

Diphtheria is very often due to diphtheria. The symptoms are those of laryngeal obstruction, together with constitutional disturbances of various kinds. The old-fashioned nurse called the disease “croup”—a term devoid of scientific meaning (see DIPHTHERIA). In an ordinary catarrhal case, Leeches and fomentations may suffice, though sometimes tracheotomy or intubation is called for. But if bacteriological examination shows the presence of diphtheritic bacilli, antitoxin must at once be injected. (See also LUNG.)

RESPITE (O. Fr. respite, modern répit, Lat. respectus, regard, consideration, respicer, to look back at), properly a delay, given for the further consideration of some matter, hence relief. In law the term is used of the postponement of the immediate execution of the law in criminal cases, e.g., by binding a convicted prisoner over to come up for judgment when called upon, or when a case is “respite” from one quarter sessions to another. The word is loosely used in the sense of a “reprivé” (p.v.).

RESPOND, in architecture, the term given to the half-pier or semi-detached column at the end of a range of piers or columns carrying an architrave or arcade. In Greek temples the respond is known as the anex. The term is also given to the wall pilaster which in Roman and Renaissance work is frequently placed behind the detached columns forming the decoration of a wall.

RESPONDENT (from Lat. respondere, to answer), strictly, one who answers; in law one called upon to answer a petition or other proceeding. In a matrimonial cause the defendant in the suit is called the respondent. The defendant to a quarter sessions appeal is called the respondent, and so generally in appeals is the party, whether plaintiff or defendant, against whom the appeal is brought.

REST (O. Eng. rest, reste, bed, cognate with other Teutonic forms, e.g. Ger. Rast, Rest, rest, and probably Gothic Rasta, league, i.e. resting or stopping place), a cessation from active or regular work, hence a time of relief from mental or manual labour. Specific meanings are for an interval of silence in music, marked by a sign indicating the length of the pause; for the forked support with iron-shod spike carried by the soldier till the end of the 17th century as a rest for the heavy musket; and for the support for the cue in billiards to be used when the striking ball is out of reach of the natural rest formed by the hand. In the medieval armour of the horseman at-arms, and later in the armour of the tournament, a contrivance was fixed to the side of the body-armour near the right arm-pit, in which the butt-end of the lance was placed to prevent the lance being driven back after striking the opponent at full charge; hence a knight, as a preliminary to the charge, “laid his lance in rest.” This “rest” is a shortened form of “arrest,” to check, stop, as is seen by the French equivalent, arrêt. Further, "rest," that which remains over and above, is derived from the French rester, to remain over, Lat. restare, to remain, literally, to stay behind. The principal specific use of this word is in commerce for the balance of undivided profit; it has thus always been the term used by the Bank for England for that which in other books and companies is called the “reserve” (Hartley Withers, The Meaning of Money (1909), p. 298). The Bank of England “rest” is never allowed to fall below £3,000,000 (see BANKS AND BANKING).

RESTIF, NICOLAS EDME (1734-1806), called RESTIF DE LA BRETONNE, French novelist, son of a farmer, was born at Sacy l’Abbe, near the 3rd of October 1734. He was educated by the Jansenists at Bicêtre, and on the expulsion of the Jansenists was received by one of his brothers, who was a curé. Owing to a scandal in which he was involved, he was apprenticed to a printer at Auxerre, and, having served his time, went to Paris. Here he worked as a journeyman printer, and in 1760 he married Anne or Agnes Lebègue, a relation of his former master at Auxerre. It was not until five or six years after his marriage that Restif appeared as an author, and from that time to his death, on the 2nd of February 1806, he produced a bewildering multitude of books, amounting to something like two hundred volumes, many of them printed with his own hand, on almost every conceivable variety of subject. Restif suffered at one time or another the extremes of poverty and was acquainted with every kind of intrigue. He drew on the episodes of his own life for his books, which, in spite of their faded sentiment, contain truthful pictures of French society on the eve of the Revolution. The most noteworthy of his works are Le Pied de Panchette, a novel (1769); Le Pornographe (1769), a plan for regulating prostitution which is said to have been actually carried out by the Emperor Joseph II., while not a few detached hints have been adopted by continental nations; Le Peuplai Perrot (1775), a novel with a moral purpose, through a series of pdfs with a detail; Le Vie de mon père (1779); Les Contemporains (42 vol., 1780-1782); 156 short stories; Ingénue Saxonour, also a novel (1783); and, lastly, the extraordinary autobiography of Monsieur Nicolas (16 vol., 1794-1797; the last two are practically a separate and much less interesting work), in which at the age of sixty he has set down his remembrances, his notions on ethical and social points, his hatreds, and above all his numerous loves, real and fancied. The original editions of these, and indeed of all his books, have long been bibliographical curiosities owing to their rarity, the beautiful and curious illustrations which many of them contain, and the quaint typographical system in which most are composed. In 1795 he received a gratuity of 2000 francs from the government, and just before his death Napoleon gave him a place in the ministry of police, which he did not live to take up.

Restif de la Bretonne undoubtedly holds a remarkable place in French literature. He was inordinately vain, of extremely relaxed morals, and perhaps not entirely sane. His books were written with haste, and their licence of subject and language renders them quite unfit for general perusal.

The works of C. Monselet, Restif de la Bretonne (1853), and P. Lacroix, Bibliographie et iconographie (1875), J. Assézat’s selection from the Contemporains (with excellent introductions (3 vols., 1875), and the valuable reprint of Monstre Nicolas (14 vols., 1883-1884), will be sufficient to enable even curious readers to form a judgment of his. His life, written by his contemporary Cubières-Palmesaux, was published in 1851. An allusion on Dihuer, Réstif de la Bretonne, der Mensch, der Schriftsteller, der Reformator (Berlin, 1906), and a bibliography, Réstif-Bibliothek (Berlin, 1906), by the same author.

RESTOUT, JEAN (1692-1768), French painter, born at Rouen on the 26th of March 1692, was the son of Jean Restout, the first of that name, and of Marie M. Jouvencet, sister and pupil of the well-known Jean Jouvencet. In 1717, the Royal Academy having elected him a member on his work for the Grand Prix, he remained in Paris until proceeding to Italy, exhibited at all the salons, and filled successively every post of academical distinction. He died on the 1st of January 1768. His works, chiefly altar-pieces (Louvre Museum), ceilings and designs for Gobelins tapestries, were engraved by Cochin, Drevet and others; his diploma picture may still be seen at St Cloud.

His son, JEAN BERNARD RESTOUT (1732-1797), won the Grand Prix in 1758, and on his return from Italy was received into the Academy; but his refusal to comply with rules led to a quarrel with that body. Roland appointed him keeper of the Garde Meuble, but this piece of favour nearly cost him his life during the Terror. The St Bruno painted by him at Rome is in the Louvre.
RESTRANT—RETAIENER

RESTRANT (from "to restrain," Lat. restringere, to hold back, prevent), in law, a restriction or limitation. The word is used particularly in three conceptions: 1. Restraint on Anticipa-
tion. Although it is a principle of English law that there can be no restriction of the right of alienation of property vested in any person under an instrument, equity makes an exception in the case of a married woman, and has laid down the rule that property may be so settled to the separate use of a married woman that she cannot, during coverture, alienate it or anticipate the income. Restraint on anticipation attaches only during coverture and is therefore removed on widowhood, but it may attach again on remarriage. By the Conveyancing Act 1881, s. 39, a court may however, if it thinks fit, by judgment or order bind a married woman's interest in her property, with her consent, if it appears to be for her benefit, notwithstanding that she is restrained from anticipating.

2. Restraint of Marriage.—A gift or bequest to a person may have a condition attached in restraint of marriage. This condition may be either general or partial. A condition in general restraint of marriage is void, as being contrary to public policy, although a condition in regard to a separate marriage is valid. A condition in partial restraint of marriage is valid, and may be either to restrain marriage with a particular class of persons, e.g., a papist, a domestic servant, or a Scotsman, or under a certain age.

3. Restraint of Trade.—A contract in general restraint of trade is void as being against public policy. In the leading case of Mitchell v. Reynolds, 1711, r Smith L.C., it was laid down that "it is the privilege of a trader in a free country, in all matters not contrary to law, to regulate his own mode of carrying it on according to his own discretion and choice. If the law has regulated or restrained his mode of doing this, the law must be obeyed. But no power short of the general law ought to restrain his free discretion." It has been suggested that the rule dates from a time when a covenant by a man not to exercise his own trade meant a covenant not to exercise any trade at all—every man being obliged to confine himself to the trade to which he had been apprenticed. However, contracts which are only in partial restraint of trade are good. A contract not to carry on the business of an ironmonger would be bad; but a contract made by the seller of an ironmonger's business not to compete with the buyer would be good. To make such a contract binding it must be founded on a valuable consideration and must not be made in what is reasonably necessary for the protection of the other party. This is the tendency also of the law in the United States.

See Matthew on Restraint of Trade (1907).

RESZKE, JEAN DE (1850— ), operatic singer, was born at Warsaw on the 14th of January 1850. His parents were Poles; his father was a state official and his mother a capable amateur singer, their house being a recognized musical centre. After singing as a boy in the Cathedral of Warsaw, he studied law in the university there, but in a few years he abandoned this and went to Italy to study singing. He made his first public appearance, as a baritone, at Venice in January 1874, as Alfonso in La Favorita, and in the following April he sang for the first time in London, appearing at Drury Lane Theatre; and a little later in Paris. He was not entirely successful and retired for a further period of study, during which his voice gained remarkably in the upper register; so that when he made his first reappearance at Madrid in 1879 it was as a tenor, in the title-rôle of Robert le Diable. Jean de Reszke's great fame as a singer dates from this time. For several seasons he sang regularly in Paris, and he reappeared at Drury Lane in 1887 as Radames. In the next year he was again in London, this time at Covent Garden as Vasco da Gama; this appearance was mainly responsible for the revival of the original text, under the title Le Cid, as a fashionable amusement in London. He appeared in London nearly every year from this date until 1900. In 1891 he visited America, and from 1893 to 1899 he was welcomed each year at the Metropolitan Opera House in New York. Jean de Reszke's most successful parts were the title-rôle of Le Cid, which was written for him by Massenet, and those of Romeo, Lancelot in Elaine, and Lohengrin, Walther von Stolzing, Siegfried and Tristan in Wagner's operas. In 1904 illness compelled him to retire from the stage, and he subsequently divided his time between teaching singing in Paris and breeding race-horses in Poland.

Jean de Reszke's younger brother, Edouard, born at Warsaw on the 23rd of December 1855, is also famous as an operatic singer. He appeared for the first time in Paris in April 1896, and has since sung with his brother for many seasons both in London and in New York. His magnificent bass voice and admirable technique earned him fame in such parts as those of Mephistopheles in Faust, Charles V. in Marchetti's Don Giovanni d' Austria, Walter in Tello, the Count in Sonnambula, Prince Gualdo in Demonio, and Hans Sachs, King Mark, Hunding and Hagen in Wagner's operas.

RETAIENER (Fr. retiable, a shortened form derived from Med. Lat. retrotabulum), a term of ecclesiastical art and architecture, applied in modern English usage to an altar-ledge or shelf, raised slightly above the back of the altar or communion table, on which are placed the cross, ceremonial candlesticks and other ornaments. Retables may be lawful, used in the church of England (Liddell & Scott, s.v.), but not in modern usage a movable feature.

RETAIL, the sale of goods or commodities in small quantities to the immediate consumer, opposed to a sale wholesale or in gross. The O. Fr. reIale, from which the word is taken, meant a piece cut off, from tailleur, to cut, Med. Lat. taleare, Lat. talea, a rod, cutting for planting. The English meaning appears in Anglo-French and in the Italian retaglio, selling by the piece. The other meaning of "retail," to repeat a story, is a transferred sense of an early meaning, "to sell at second hand." The Latin source is also seen in the related words "entail," "tailor," "detail" and "tally.

RETAIENER (from "retain," Lat. retinere, to hold back, keep), properly the act of retaining or keeping for oneself, or retaining or object or thing; the person who does this, historically, a follower of a house or family, and particularly an illegitimate or appointed follower attached to the barons of the middle ages. John Cowell, in The Interpreter (1607), defines "retainer" as a "servant not meniall nor familiar, that is, not continually dwelling in the house of his lord or master, but only using or bearing his name or livery."

Retainer of Counsel.—When it is considered desirable by a litigant that the services of any particular counsel (bar-
ister) should be obtained for the conduct of his case, it is necessary to deposit with counsel a form of retainer together with the necessary fee in cash, from which time counsel is bound to give the party who has thus retained him the first call on his services in the matter in which he has been retained. Retainers are either general or special. A general retainer is one which retains counsel for all proceedings in which the person retaining is a party, and lasts for the joint lives of client and counsel. If any other person offers a special retainer or brief against the general retainer, counsel must give the general retainer notice of such offer—and if after a reasonable time the general retainer does not himself specially retain or brief counsel, the general retainer is forfeited. A special retainer is one which only applies to some particular cause or action. It can only be delivered after the action is begun, and gives the client a right to the services of counsel throughout the course of the action, and counsel is entitled to be briefed on all occasions to which the retainer applies. Retainer rules were drawn up in 1901 by the Bar Committee, read by the Bar Council and approved by the Attorney-General and the Council
of the Incorporated Law Society in 1902. They may be found in the Annual Practice.

Retainer of Debt.—In connexion with the administration of an estate under a will, it is the right of the personal representative—whether executor or administrator—of a deceased person to retain legal assets which have come into his hands towards the payment of a debt due to himself as against creditors of an equal degree, and this even though his debt is barred by the Statutes of Limitation. The privilege arose in all probability from the inability of the representative to sue himself, though it has been suggested that it is merely a corollary to the right of the representative to prefer one creditor to another of equal degree.1 The principle of retainer is not looked upon with favour by courts of equity, and consequently it has long been a rule of law that there is no right to retain out of equities. It was thought that the effect of the Land Transfer Act 1897 was to make all the assets of the deceased legal assets, and so extend the privilege to reality which had till then been exempt; this view, however, has been repudiated by the courts of equity, and it must now be taken that there is still no right to retain out of real estate.2 It is a rule of the probate division to require a creditor administrator, to whom letters of administration are granted, to enter into a bond with two sureties not to prefer himself. This course, however, is not followed where administration is granted to a person as next of kin who happens also to be a creditor.

The privilege is not lost by judgment for an account being given in a suit by other creditors for the administration of assets, and the representative may retain out of assets which come to his hand subsequent to such judgment. On the other hand, the appointment of a receiver deprives the representative of his right except as regards assets which come to his hands prior to the appointment of the receiver.

RetaliAtion, repayment of like with like, especially the return of hostile action, injuries or wrongs by similar action or injury, as in the primitive theory of punishment, an "eye for an eye," a tooth for a tooth." The Late Lat. retributio was formed from talii, such as, of the same quality as; and this source also gave talio, taliones, the name of this type of punishment. (See Punishment, Theory Of, and Roman Law, § The Twelve Tables.) A special form of retaliation is familiar in the imposition of differential import duties against the goods of a particular country (see Tariffs and Protection).

Retene (methyl isopropyl phenanthrene), C₉H₈O₃, a hydrocarbon present in the coal-tar fraction, boiling above 360°C; it also occurs in the tars obtained by the distillation of resinous woods. It crystallizes in large plates, which melt at 65-7°C and boil at 396°C. It is readily soluble in warm ether and in hot glacial acetic acid. Sodium and bis 2-ampyrol alcohol reduce it to a tetrahydroretene, whilst if it be heated with phosphorus and hydriodic acid to 260°C a dodecahydrodine is formed. Chromic acid oxidizes it to retene quinone, phthalic acid and acetic acid. It forms a pircrate which melts at 123-124°C.

Retford (officially East Retford), a market town and municipal borough in the Bassetlaw parliamentary division of Nottinghamshire, England, 1334 m. N. by W. from London by the Great Northern railway, the station being a junction with the Great Central railway. Pop. (1901) 12,346. The church of St Swithun dates from the 12th century, but was rebuilt in 1638 by a brief granted by Richard Cromwell. Modern buildings are the town hall, the corn exchange, the court house, and the covered markets. There is a large trade in corn and cheese, and the town possesses iron foundries, paper and corn mills, and india-rubber works. The town is governed by a mayor, 6 aldermen, and 18 councillors. Area, 4,566 acres.

The situation of Retford (Redforde, Redaford) near one of the Roman roads and on the river Idle, where there was possibly a ford, may account for its origin. In 1086 the archbishop of York owned a mill at Retford, and Roger de Busli had rights here. Retford was a borough by prescription, and was in the hands of the crown when, in 1276, Edward I. granted it to the burgesses in fee-farm with the right of electing bailiffs. This charter was confirmed by Edward III., Henry VI., and Elizabeth. In 1607 James I. granted a charter of incorporation to the bailiffs and burgesses, under which the town was governed until 1835, when it was reincorporated under a mayor. East Retford returned two members to parliament in 1315, and again from 1572 till 1885, when it was disfranchised. Henry III. granted the burgesses an eight-days’ fair at Holy Trinity, altered by Edward II. to St Gregory. Edward III. granted a six-days’ fair at St Margaret, Henry VI. a four-days’ fair at St Matthew. Fairs are now held in March, June, July and December. The market held on Saturdays by prescription was sanctioned by Edward III. and still exists.

Rethel, Alfred (1816-1898), German historical painter, was born at Mezieres, Ais-la-Chappelle in 1816. He very early showed an interest in art, and at the age of thirteen he executed a drawing which procured his admission to the academy of Düsseldorf. Here he studied for several years, and produced, among other works, a figure of St Boniface which attracted much attention. At the age of twenty he removed to Frankfort, and was selected to decorate the walls of the imperial hall in the Römer with figures of famous men. At the same period he produced a series of designs illustrative of Old Testament history. Four years later he was the successful competitor for the work of ornamenting the restored council house of his native city with frescoes depicting prominent events in the career of Charlemagne, but the execution of this work was delayed for some six years. Meanwhile Rethel occupied himself with the production of easel pictures and of drawings; and in 1842 he began a striking series of designs dealing with the "Crossing of the Alps by Hannibal," in which the weird power which animates his later art becomes first apparent. In 1844 Rethel visited Rome, executing, along with other subjects, an altar-piece for one of the churches of his native land. In 1846 he returned to Aix, and commenced his Charlemagne frescoes. But mental derangement, remotely attributable, is believed, to an accident from which he suffered in childhood, began to manifest itself. While he hovered between madness and sanity, Rethel produced some of the most striking, individual and impressive of his works. Strange legends are told of the effect produced by some of his weird subjects. He painted "Nemesis pursuing a Murderer"—a flat stretch of landscape, with a slaughtered body, while in front is the assassin speeding away into the darkness, and above an angel of vengeance. The picture, so the story goes, was won in a lottery at Frankfort by a personage of high rank, who had been guilty of an undiscovered crime, and the contemplation of his prize drove him mad. Another design which Rethel executed was "Death the Avenger," a skeleton appearing at a masked ball, shaving the face of a living person. The strange episode which haunted the memory of his artist friends and disturbed their dreams; and, in expiation, he produced his pathetic design of "Death the Friend." Rethel also executed a powerful series of drawings—"The Dance of Death"—suggested by the Belgian insurrections of 1848. It is by such designs as these, executed in a technique founded upon that of Dürer, and animated by an imagination akin to that of the elder master, that Rethel is most widely known. He died at Düsseldorf on the 1st of December 1898.

Rethel, a town of N. France, capital of an arrondissement in the department of Ardennes, on the right bank of the Aisne and the Ardennes canal, 31 m. S.W. of Mézières by rail. Pop. (1906) 5,254. The church of St Nicholas was formed by the amalgamation of two churches, the oldest of which dates from the 13th century, and the other, in the 15th century. Rethel has a subscription church, a tribunal of first instance, a board of trade arbitration, a chamber of arts and manufactures and a school of agriculture, and carries on

1 Per Jessel, M.R. Talbot v. Freer (1879), L.R. 9, C.D. 566, 574.
2 In re Williams; Holder v. Williams (1904), 1 Ch. 52.
wool-spinning, the weaving of light woollen fabrics, and the manufacture of millboard and farm implements.

Rethel (Castrum Retecum), of Roman origin, was from the end of the 10th century the seat of a countship which passed successively to the families of Flanders, Burgundy, Foix, and finally, in 1853 it was erected into a duchy in favour of the latter. In 1663 it was sold by Charles VI. de Gonzaga to Mazarin, whose family held it till the Revolution.

**REUNITE** (Gr. ἱππίν, resin), a general name applied to various resins, particularly those from beds of brown coal, which are near amber in appearance, but contain little or no succinic acid. It may conveniently serve as a generic name, since no two independent occurrences prove to be alike, and the indefinite multiplication of names, no one of them properly specific, is not to be desired.

RETINUE (O. Fr. retenue, from retenir, Lat. retenera, hold back, retain), a body of persons "retained" in the service of a noble or royal personage, a suite of "retainers." Such retainers were not in the domestic service of their lord, but were his "livery" and claimed his protection. They were a source of trouble and abuse in the 19th and early 19th century (see LIVERY and MAINTENANCE).

**RETOUR (Lat. retorquere, to twist or turn back), a word used in two distinct meanings: (1) a sharp reply, answer to an argument, statement or charge; (2) a vessel used in chemistry and manufacture. The chemical retort is a flask-shaped or bulbous vessel made of glass, earthenware or metal, bent downwards at the neck, leading to a receiver; such vessels are particularly used for distillation (q.e.s.). The name is also given to the apparatus, varying in size and shape, used in the distinctive distillation of various substances, such as coal, in the manufacture of gas (q.e.s.).

**RETREAT** (O. Fr. retrete, mod. retratale, from Lat. retraitare, to draw back), a withdrawal, especially of a body of troops after a defeat or in face of a superior enemy. In military usage "retreat" is also the term for a signal, given by bugle and drum at or about sunset. It is the last general signal before the tattoo." In religious usage, a "retreat" is a period and place set apart for prayer, self-examination and other spiritual exercises. Such "retreats" conducted by a director have long been the practice in the Roman Church. They were introduced into the English Church by Pusey. The word is also used of an institution or home where insane persons or habitual inebriates may be treated. For the law relating to "licenced retreats" for inebriates, see INEBRIETY, LAW OF.

**RETRÉMÈNEMENT** (Fr. retremmenent, an old form of retrenement, from retrancher, to cut down, cut short), an act of cutting down or reduction, particularly of expenditure; the word is familiar in this, its most general sense, from the motto of the Gladstonian Liberal party in British politics, "Peace, Retrenchment and Reform." A special technical use of the term is in fortification, where it is applied to a work or series of works constructed in rear of existing defences in order to bar the further progress of the enemy should he succeed in breaching or storming these. A modern example may be found in the siege of Port Arthur in 1904. When early in the siege Fort Panlung fell into the hands of the Japanese, the Russians connected up the two adjacent first-line forts to a fort in the rear by means of new works, the whole forming a rough semicircle facing the lost fort. This retrenchment prevented the Japanese from advancing, and remained in the hands of the defenders up to the fall of the whole line of forts.

**RETRO-COGNITION** (from Lat. retro, back, cognitio, the acquiring of knowledge), a word invented by F. W. H. Myers to denote a supposed faculty of acquiring direct knowledge of the past beyond the reach of the subject's ordinary memory. The alleged manifestations of the faculty are of several kinds, of which the most important are as follows: (1) There are many recorded cases in which an impression has been received in dream or vision representing some recent event—shipwreck, death-bed scene, railway accident—outside the knowledge of the percipient. (2) Analogous to the transmission of habits and physical peculiarities in particular families, it is alleged that there are also cases of the transmission of definite memories of scenes and events in the life of some ancestor. (3) It is asserted that pictures of past scenes may be called up in certain cases by the presence of a material object associated with those scenes—"a vision of the destruction of Pompeii by a piece of cinder from the buried city, or the scene of a martyrdom by a charred fragment of bone—the percipient being unaware at the time of the nature of the object. For this supposed faculty the American geologist, Professor Denton, has suggested the name "psychometry." There are also cases recorded in which pictures of historical scenes unknown to the seer have been described in the crystal. (4) Some spirit mediums profess to realise incidents belonging to their previous incarnation. Thus Flournoy's medium, Hélène Smith, represented herself as having been successively incarnated as a Hindoo Princess, Simandini, and as Marie Antoinette, and gave vivid descriptions of scenes in which she had figured in these capacities.

It will be gathered that the facts afford little warrant for the assumption of a faculty of retro-cognition. The cases described in the first class, though apparently exhibiting knowledge not within the range of the percipient's ordinary faculties, hardly call for such an extreme hypothesis. In the other cases the result recorded may plausibly be attributed to the imagination of the percipient, working upon hints given by bystanders, or aided by the emergence of forgotten knowledge.

(F. P.)

**RETROGRADE** (from the Lat. retro, backwards, gradiri, to go), in astronomy, the direction of the apparent motion of a planet from E. to W.; the opposite of its regular motion around the sun, and due to the motion of the earth.

**REZ, SEIGNEURS ET DUKES OF.** The district of Retz or Rais, in S. Brittany, belonged in early times to a house which bore its name, and of which the eldest branch became extinct in the 13th century in the Chabot family. From the Chabot family the lordship passed to the Lavalis. Gilles de Laval, sire de Retz (1404-1449), the comrade-in-arms of Joan of Arc and marshal of France, gave himself over to the most revolting debauchery, and was strangled and burned at Nantes. The barony of Retz passed successively to the families of Tourménie, Annebault and Gondi. In 1581 it was erected into a duchy in the peerage of France (duché-pairie) for Albert de Gondi, marshal of France and general of the galleys. Pierre de Gondi, brother of the first duc de Retz, became bishop of Paris in 1570 and cardinal in 1587. He was succeeded by his grandson, Henri (d. 1622) and Jean François de Gondi (d. 1654), for whom the episcopal see of Paris was erected into an arch-bishopric in 1622, and by his great-nephew, Jean François Paul de Gondi, the famous cardinal de Retz. With the death of the last male of the house of Gondi in 1676 the duché-pairie became extinct; the lordship passed to the house of Neuville-Villeroy.

(M. P.)*

**REZ, JEAN FRANÇOIS PAUL DE GONDI, CARDINAL DE (1614-1679), French churchman and agitator, was born at Montmirail in 1614. The family was one of those which had been introduced into France by Catherine de' Medici, but it acquired great estates in Brittany and became connected with the noblest houses of the kingdom. It may be added that Retz himself always spelt his designation "Rais." He was the third son, and according to Tallemant des Réaux was made a knight of Malta on the very day of his birth. The death of his second brother, however, destined him for a closer connexion with the church. The family of Retz had military traditions, but it had also much church influence, and, despite the very unclerical leanings of the future cardinal, which were not corrected by the teachings of his tutor St Vincent de Paul, the intentions of his family never varied respecting him. By unanimous consent his physical appearance was not that of a soldier. He was
short, near-sighted, ugly and exceptionally awkward. Retz, however, despite the little inclination which he felt towards clerical life, entered into the disputes of the Sorbonne with vigour, and when he was scarcely eighteen wrote the remarkable *Conjuration de Fiesque*, a little historical essay, of which he drew the material from the Italian of Augustino Mascardi, but which is all his own in the negligent vigour of the style and the audacious insinuation, if nothing more, of revolutionary principles. Retz received no prevenient of importance during Richelieu's life, and even after the minister's death, though he was presented to Louis XIII. and well received, he found a difficulty in attaining the coadjutorship with reversion of the archbishopric of Paris. But almost immediately after the king's death Anne of Austria appointed him to the preferred post of Abbot St. Vincent de Paul, who, had, according to some accounts, already plotted against Richelieu, set himself to work to make the utmost political capital out of his position. His uncle, who was old, indolent and absurdly proud, had lived in great seclusion; Retz, on the contrary, gradually acquired a very great influence with the populace of the city. This influence he gradually turned against Mazarin. No one had more to do than Retz with the outbreak of the Fronde in October 1648, and his history for the next four years is the history of that confused and, as a rule, much misunderstood movement. Of the two parties who joined in it Retz could only depend on the bourgeois of Paris. The fact, moreover, that although he had some speculative tendencies in favour of popular liberties, and even perhaps of republicanism, he represented no real political principle, inevitably weakened his position, and when the break up of the Fronde came he was left in the lurch, having more than once in the meanwhile been in no small danger from his own party. One stroke of luck, however, left to him before his downfall. He was made cardinal almost by accident, and under a misapprehension on the pope's part. Then, in 1652, he was arrested and imprisoned, first at Vincennes, then at Nantes; he escaped, however, after a few months, to the great disgust of one of the Frondeur's character about in various countries. He made his appearance at Rome more than once, and had no small influence in the election of Alexander VII. He was at last, in 1662, received back again into favour by Louis XIV. and on more than one occasion formally served as envoy to Rome. Retz, however, was glad in making his peace to resign his claims to the archbishopric of Paris. The terms were, among other things, his appointment to the rich abbacy of St Denis and his restoration to his other benefits with the payment of arrears.

The last seventeen years of Retz's life were passed partly in his official duties (he was again in Rome at the papal election of 1668), partly at Paris, partly at his estate of Commerce, but latterly at St Mieh in Lorraine. His debts were enormous, and in 1675 he resolved to make over to his creditors all his income except twenty thousand livres, and, as he said, to "live for" them. This plan he carried out, though he did not succeed in living very long, for he died at Paris on the 24th August 1679. One of the chief authorities for the last years of Retz is Madame de Sévigné, whose connexion he was by marriage. Retz and La Rochefoucauld, the greatest of the Fondeurs in literary genius, were personal and political enemies, and each had left a portrait of the other. La Rochefoucauld's character of the cardinal is on the whole harsh but scarcely unjust, and one of its sentences formulates, though in a manner which has a certain recoll upon the writer, the great defect of Retz's conduct: "Il a suscité les plus grands désordres dans l'état sans avoir un dessein formé de s'en prévaloir." He would have been less, and certainly less favourably, remembered if he had not been for his *Memoirs*. They were certainly not written till the last ten years of his life, and they do not go further than the year 1655. They are addressed in the form of narrative to a lady who is not known, though guesses have been made at her identity, since suggesting Madame de Sévigné herself. In the begining there are some gaps. They display, in a rather irregular style and with some oddities of dialect and phrase, extraordinary narrative skill and a high degree of ability in that special art of the 17th century—the drawing of verbal portraits or characters. Few things of the kind are superior to the sketch of the early barbary of the Fronde in which the writer had so great a share, the hesitations of the court, the bold adventure of the coadjutor himself into the palace and the final triumph of the insurgents. Dumas, who has drawn from this passage one of his very best scenes in *Vingt ans après*, has done little but throw Retz into dialogue and amplify his language and incidents. Besides these memoirs and the very striking youthful essay of the *Conjuration de Fiesque*, Retz has left diplomatic papers, sermons, Mazarinades and correspondence in some considerable quantity.

The *Memoirs* of the cardinal de Retz were first published in a very imperfect condition in 1717 at Nancy. The first satisfactory edition was that which appeared in the twenty-fourth volume of the collection of Michaud and Poujoulat (Paris, 1836). They were then re-edited from the autograph manuscript by Gérard (Paris, 1844), and by Champollion-Figeac with the Mazarinades, &c., (Paris, 1859). In 1870 a complete edition of the works of Retz was begun by M. A. Pelet in the collection of *Grands Ecrivains*. The editor dying, this passed into the hands of M. Gourdault and then into those of M. Chantelauze, who had already published studies, *etc.* (1882).

**REUBEN**, a tribe of Israel named after the eldest "son" of Jacob and of Leah. Both the meaning of the name (see Gen. xxix. 32) and the history of the tribe are extremely obscure. In one version of the story of Joseph, Reuben appears in a somewhat favourable light; (Gen. xxxvii. 24). But in Gen. xxxv. 22 he is charged with a grave offence, which in Gen. xlix. 4 is given as a reason why the tribe which called him father did not take in Hebrew history the place proper to its seniority (cp. i Chron. v. 1). Dathan and Abiram were Reubenites (Num. xvii.; Deut. xi. 6), and in Deut. xxxii. 6 the tribe appears as threatened with extinction. In Judg. v. 15 seq. it is described as a pastoral tribe which took no share in the patriotic movement under Barak and Deborah. The district allotted to Reuben (Josh. xii. 15–23; Num. xxxii. 37 seq.) is detailed in late passages, and have little historical value for the age to which they are attributed. The tribe is represented as settled of the E. of the Jordan on the Moaibite border, but no mention is made of it in the inscription of the Moaibite king Mesha (see Gad; Moab). The references to the tribe's wars against Arabs (1 Chron. v. 10, 18 sqq.) in the time of Saul have caused much fruitless speculation.

**REUCHLIN, JOHANN** (1455–1522), German humanist and Hebraist, was born on the 22nd of February 1455 at Pfrozheim in the Black Forest, where his father was an official of the Dominican monastery. In the pedantic taste of his time the name was gracecized by his Italian friends into Caproni, a form which Reuchlin himself uses as a sort of transparent mask when he introduces himself as an interlocutor in the *De Verbo Mirifico*. For his native place Reuchlin always retained an affection; he constantly writes himself Phorcensis, and in the *Dialogus de Zensus* he ascribes his disposition to letters. Here he began his Latin studies in the monastery school, and, though in 1470 he was a short time in Freiburg, that university seems to have taught him little. Reuchlin's career as a scholar appears to have turned almost on an accident; his fine voice gained him a place in the household of Charles L., margrave of Baden, and by-and-by, having already some reputation as a Latinist, he was chosen to accompany to the university of Paris Frederick, the third son of the prince, a lad some years his junior, who was destined for an ecclesiastical career. This new connexion lasted but a year or so, but it determined the course of Reuchlin's life. He now began to learn Greek, which had been taught in the French capital since 1470, and he also attached himself to the leader of the Paris realists, Jean Heynlin, or à Lapide (d. 1496), a
worrying and learned man, whom he followed to the vigorous young university of Basel in 1474. At Basel Reuchlin took his master's degree (1477), and began to lecture with success, teaching a more classical Latin than was then current in German schools, and also explaining Aristotle in Greek. His studies in this language had been continued at Basel under Andronicus Contoblas, and here too he formed the acquaintance of the bookseller, Johann Amorbach, for whom he prepared a Latin lexicon (Vocabularia Brevelegyca, 1st ed., 1475-76), which did good service in its time and ran through many editions. This first publication and Reuchlin's success of his teaching at Basel in a letter to Cardinal Adrian (Adriano Castellesi) in February 1518 show that he had already found the work which in a larger sphere occupied his whole life. He was no original genius, but a born teacher. But this work of teaching was not to be done mainly from the professor's chair. Reuchlin soon left Basel to seek further Greek training with George Hieronymus at Paris, and to learn to write a fair Greek hand that he might support himself by copying MSS. And now he felt that he must choose a profession. His choice fell on law, and he was thus led to study in the school of Paulus, at Poitiers, where he became licentiate in July 1481. From Poitiers Reuchlin went in December 1481 to Tübingen, with the intention of becoming a teacher in the university, but his friends recommended him to Count Eberhard of Württemberg, who was about to journey to Italy and required an interpreter. Reuchlin was selected for this post, and in February 1482 left Stuttgart for Florence and Rome. The journey lasted but a few months, but it brought the German scholar into contact with several learned Italians, especially at the Medicean Academy in Florence; his connexion with the count became permanent, and after his return to Stuttgart he received important posts at the latter's court. About this time, he appears to have married, but little is known of his married life. He left no children; but in later years his sister's grandson Melanthion was almost as a son to him till the Reformation estranged them. In 1490 he was again in Italy. Here he saw Pico della Mirandola, to whose Cabalistical doctrines he afterwards became heir, and also made the friendship of the pope's secretary, Jakob Questenberg, which was of service to him in his later troubles. Again in 1492 he was employed on an embassy to the emperor Frederick at Linz, and here he began to read Hebrew with the emperor's Jewish physician Jakob ben Jehiel Loes. He knew something of the language before, but Loes instructed him in the basis of that thorough knowledge which he afterwards improved on his third visit to Rome in 1498 by the instruction of Obadja Sforo of Cesena. In 1504 his rising reputation had been greatly enhanced by the publication of De Verbo Mysterio. In 1496 Eberhard of Württemberg died, and enemies of Reuchlin had the ear of his successor, Duke Eberhard. He was glad, therefore, hastily to follow the invitation of Johann von Dalberg (1445-1503), the scholarly bishop of Worms, and flee to Heidelberg, which was then the seat of the "Rhenish Society." In this court of letters Reuchlin's appointed function was to make translations from the Greek, of which he was to have been already extremely wide. Though Reuchlin had no public office as teacher, and even at Heidelberg was prevented from lecturing, he was during a great part of his life the real centre of all Greek teaching as well as of all Hebrew teaching in Germany. To carry out this work he found it necessary to provide a series of helps for beginners and others. He never published a Greek grammar, though he had one in MS. for use with his pupils, but he put out several little elementary Greek books. Reuchlin, it may be noted, pronounced Greek as his native teachers had taught him to do, i.e. in the modern Greek fashion. This pronunciation, which he defends in Dialogus de Recta Lat. Graecae Serm. Pron. (1510), came to be known, in contrast to that used by Erasmus, as the Reuchlinian.

At Heidelberg Reuchlin had many private pupils, among whom Franz von Sickingen is the best known name. With the monks he had never been liked; at Stuttgart also his great enemy was the Augustinian Conrad Holzinger. On this man he took a scholar's revenge in his first Latin comedy Sergius, a satire on worthless monks and false relics.

Through Dalberg, Reuchlin came into contact with Philip, elector palatine of the Rhine, who employed him to direct the studies of his sons, and in 1498 gave him the mission to Rome which has been already noticed as fruitful for Reuchlin's progress in Hebrew. He came back laden with Hebrew books, and found when he reached Heidelberg that a change of government had opened the way for his return to Stuttgart, where his wife had remained all along. His friends had now again the upper hand, and knew Reuchlin's value. In 1506, or perhaps in 1502, he was given a very high judicial office at the Swabian League, which he held till 1512, when he retired to a small estate near Stuttgart.

For many years Reuchlin had been increasingly absorbed in Hebrew studies, which had for him more than a mere philological interest. Though he was always a good Catholic, and even took the habit of an Augustinian monk when he felt that his death was near, he was too thorough a humanist to be a blind follower of the church. He knew the abuses of monkish religion, and was interested in the reform of preaching as shown in his De eucharistia divini sanctificata (1506), but he did not become a sort of preacher's manual; but above all as a scholar he was eager that the Bible should be better known, and could not tie himself to the authority of the Vulgate. The key to the Hebrews veritas was the grammatical and exegetical tradition of the medieval rabbins, especially of David Kimhi, and when he had mastered himself he was resolved to open it to others. In 1506 appeared his epoch-making De Rudimentis Hebraicis—grammar and lexicon—mainly after Kimhi, yet not a mere copy of one man's teaching. The edition was costly and sold slowly. One great difficulty was that the wars of Maximilian I. in Italy prevented Hebrew Bibles coming into Germany. But for this reason Reuchlin found help by printing the Pentential Psalms with grammatical explanations (1512), and other helps followed from time to time. But his Greek studies had interested him in those fantastic and mystical systems of later times with which the Cabala has no small affinity. Following Pico, he seemed to find in the Cabala a profound theosophy which might be of the greatest service for the defence of Christianity and the reconciliation of science with the mysteries of faith—an unhappy delusion indeed, but one not surprising in that strange time of ferment. Reuchlin's mystico-caballistical ideas and objects were expounded in the De Verbo Mysterio, and finally in the De Arte Caballistic (1517).

Unhappily many of his contemporaries thought that the first step to the conversion of the Jews was to take from them their books. This view had for its chief advocate the bigoted Johann Pfefferkorn (1460-1521), himself a baptized Hebrew. Pfefferkorn's plans were backed by the Dominicans of Cologne; and in 1506 he got from the emperor authority to confiscate all Jewish books directed against the Christian faith. Armed with this mandate, he visited Stuttgart and asked Reuchlin's help as a jurist and expert in putting it into execution. Reuchlin evaded the demand, mainly because the mandate lacked certain formalities, but he could not but feel it neutral. The operation of Pfefferkorn's schemes led to difficulties and to a new appeal to Maximilian. In 1510 Reuchlin was summoned in the name of the emperor to give his opinion on the suppression of the Jewish books. His answer is dated from Stuttgart, October 6, 1510; in it he divides the books into six classes—apart from the Bible which no one proposed to destroy—and, going through each class, he shows that the books openly insulting to Christianity are very few and viewed as worthless by most Jews themselves, while the others are either works necessary to the Jewish worship, which was licensed by papal as well as imperial law, or contain matter of value and scholarly interest which ought not to be sacrificed because they are connected with another faith than that of the Christians. He proposed that the emperor should decree that for ten years there be two Hebrew chairs at every German university for which the Jews should furnish books. The other experts proposed that all books
should be taken from the Jews; and, as the emperor still hesitated, the bigots threw on Reumont the whole blame of their ill success. Pflefferkorn circulated at the Frankfurt fair of 1517 a gross libel (Handspiegel wider geistige Juden) declaring that Reuchlin had been bribed and Reuchlin retorted as warmly in the Augenspiegel (1511). His adversary's next move was to declare the Augenspiegel a dangerous book; the Cologne theological faculty, with the inquisitor Jakob von Hochstraten (d. 1527) took up this cry, and on the 7th of October 1512 they obtained an imperial order confiscating the Augenspiegel. Reuchlin was timid, but he was honesty itself. He was willing to receive corrections in theology, which was not his subject, but he could not unsay what he had said; and as his enemies tried to press him into a corner he met them with open defiance in a Defensio contra Colunniavalores (1513). The uniueities were now appealed to for opinions, and were all against Reuchlin. Even Paris (August 1514) condemned the Augenspiegel, and called on Reuchlin to recant. Meantime a formal process had 'begun at Mainz before the grand inquisitor, but Reuchlin by an appeal succeeded in transferring the question to Rome. Judgment was not finally given till July 1516; and then, though the decision was really for Reuchlin, the trial was simply quashed. The result had cost Reuchlin years of trouble and no small part of his modest fortune, but it was worth the sacrifice. For far above the direct importance of the issue was the fact that what he had been able to do put the road open for Erasmus. And if the obscurantists escaped easily at Rome, with only a half condemnation, they received a crushing blow in Germany. No party could survive the ridicule that was poured on them in the Epistles Obscurorum Virorum, the first volume of which written chiefly by Crotus Rubeanus appeared in 1514, and the second by Ulrich von Hutten in 1517. Hutten and Franz von Sickingen did all they could to force Reuchlin's enemies to a restitution of his material damages; they even threatened a feud against the Dominicans of Cologne and Spire. In 1520 a commission met in Frankfurt to investigate the case. It condemned Hochstraten. But the final decision of Rome did not indemnify him. The contest ended, however; public interest had grown cold, absorbed, entirely by the Lutheran question, and Reuchlin had no reason to fear new attacks. Reuchlin did not long enjoy his victory in peace. In 1520 Stuttgart was visited by famine, civil war and pestilence. From November of this year to the spring of 1521 the veteran statesman sought refuge in Ingolstadt and taught there for a year as professor of Greek and Hebrew. It was forty-one years since at Poitiers he had last spoken from a public chair; but the old man of sixty-five had not lost his gift of teaching, and hundreds of scholars crowded round him. This gleam of autumn sunshine was again broken by the plague; but now he was called to Tübingen and again spent the winter of 1521-22 teaching in his own systematic way. But in the spring he found it necessary to visit the baths of Liebenzell, and here he was seized with jaundice, of which he died on the 30th of June 1522, leaving in the history of the new learning a name only second to that of his younger contemporary Erasmus.

The authorities for Reuchlin's life are enumerated in L. Geiger, Johann Reuchlin (1871), which is the standard biography. The best account of the books of the period is well sketched by D. F. Strauss, Ulrich von Hutten. See also S. A. Hirsch, "John Reuchlin, the Father of the Study of Hebrew among the Christians," and his "John Pflefferkorn and the Battle of Books," in his Essays (London, 1905). Some interesting details about Reuchlin are given in the autobiography of Conrad Pellicanus (q.v.), which was not published when Geiger's book appeared. See also the article on Reuchlin in Herzog-Hauck, Realencyclopaedie, and literature there referred to.

REUMONT, ALFRED VON (1808-1887), German scholar and diplomatist, the son of Gerhard Reumont (1765-1829), was born on November 26, 1808, at Glogau. He became named Alfred after the English king, Alfred the Great. Educated at the academy of Glogau, and later at the Universities of Bonn and Heidelberg, he obtained a position in Florence through the influence of an Englishman, William Craufurd, but soon he entered the Prussian diplomatic service and was employed in Florence, in Constantinople and in Rome. He spent some time in the Foreign Office in Berlin. From 1831 to 1860 he represented his country in Florence. Reumont was the friend and advisor of Frederick William IV. In 1879 he founded the Auktioner Geschichtsverein, and having spent his concluding years at Bonn and at Aix-la-Chapelle, he died in the latter city on the 27th of April 1887.

Reumont's numerous writings deal mainly with Italy, in which country he passed many years of his life. On the history of Florence and of Tuscany he wrote Fawole cronologiche e sincrone della storia Contadina (1841; supplement, 1871); Geschichte Toscanas seit dem Ende des florentinischen Freistatos (Gotha, 1878-79); and Lorenzo de' Medici (Leipzig, 1874, and again 1883). This last book has been translated into English by R. Harrison (1876). He remembered his connection with Florence when he wrote Historische Briefe von einem Florentiner (Leipzig, 1840-44), and his residence in Rome was also responsible for his Geschichte der Stadt Rom (5 vols., 1857-70).

Turning his attention to the history of Naples, he wrote Die Carola von Maddalenon: Neapel unter spanischer Herrschaft (1851; Eng. trans., 1854), and more general works on Italian history are: Beiträge zur italienischen Geschichte (6 vols., Berlin, 1855-57), and Charakterbilder aus der neueren Geschichte Italiens (1860). More strictly biographical in their nature are: Die Jugend Caterin's de' Medici (1854), which has been translated into French by A. Baschet (1860); Die Gräfin von Albany (1860) and a life of his close friend, Erasmus (1861); Gini und seine Zeit (1863). His Ganganelli: Papst Clemens XIV., seine Briefe und seine Zeit (Berlin, 1847) is valuable for the relations between this pope and the Medici. Other important works are: Zweisagen, Biographien und Charakteristiken (Berlin, 1862); Bibliographie der literatur in zeitgenossen, Biographische Denkblätter nach persönlichen Erinnerungen (Leipzig, 1869); Mergeli de' Medici (1875-76); and other important work, one which he was peculiarly fitted to write, was his Aus Friedrich Wilhelms IV. gesunden und kranken Tagen (Leipzig, 1855).

REUNION, known also by its former name BOURBON, an island and French colony in the Indian Ocean, 400 m. S.E. of the Tropic of Capricorn and 130 S.W. of Port Louis, Mauritius. It is elliptic in form; its greatest length 45 miles, and its greatest breadth 32 m., and it has an area of 605 sq. m. It lies between 26° 51' and 26° 22' S. and 55° 15' and 55° 49' E.

The coast-line (about 130 m.) is little indented, there are no natural harbours and no small inlets round the shore. The narrow coast-lands are succeeded by hilly ground which in turn gives place to mountain masses and tableland, which occupy the greater part of the island. The main axis runs N.W. and S.E., and divides the island into a windward (E.) district and a leeward (W.) district, the dividing line being determined by the direction of the watered. The form of the mountains is the result of double volcanic action. First the sea a mountain whose summit is approximately represented by Piton des Neiges (10,009 ft.), a denuded crater of immense proportions, and at a later date another crater opened towards the E., which, piling up the mountain mass of Le Volcan, turned what was till then a circle into an ellipse. The oldest erupted rocks belong to the type of the andesites; the newest are varieties of basalt. The two massifs are united by high tablelands. In the older massif the most striking features are now three areas of subsidence—the cirques of Salazie, Rivière des Galets and Cilaos—while in the N.W. and S.W. the great troughs of the Tizard and Salazie and of the La Plaine and their inlets. The first, which may be taken as typical, is surrounded by high almost perpendicular walls of basaltic lava, and its surface is rendered irregular by hills and hillocks of debris fallen from the heights. Towards the S. lies the vast stratum of rocks (50 to 200 ft. deep) which, on the 26th of November 1875, suddenly sweeping down from the Piton des Neiges and the Gros Morne (a "shoulder" of the piton), buried the little village of Grand Sable and nearly a hundred of its inhabitants. Besides the Piton des Neiges and the Gros Morne the chief heights in this part of the island are the pyramidal Cimande of Salazie, the distorted summit of the Mount Massif and the highest peak of Salazie, the Piton de l'Etivern (9400 ft.), separating the cirques of Mafate and Cilaos.

The second massif, Le Volcan, is cut off from the rest of the island by two "enclosures," each about 500 or 600 ft. deep.
The outer enclosure runs across the island in a N. and S. direction; the inner forms a kind of parabola with its arms (Rempart du Tremblet on the S. and Rempart du Bois Blanc on the N.) stretching S. and N. across the main valley. There are two principal craters, each on an elevated cone, the most westerly, now extinct, known as the Bory Crater (8612 ft.), after Bory de St Vincent, the geologist, and the more easterly called the Burning Crater or Fournaise (2839 ft.). The latter is partially surrounded by an "enclosure" on a small scale with precipices of from 300 to 600 ft. high. Eruptions, though not infrequent (thirty were registered between 1863 and 1866), are seldom serious; the more noteworthy are those of 1745, 1778, 1791, 1812, 1836, 1860, 1861. Hot mineral springs are found on the flanks of the Piton des Neiges; the Source de Salazie (discovered in 1831) lies 2860 ft. above sea-level, has a temperature of 90°, and discharges 200 to 300 gallons per hour of water impregnated with bicarbonate of soda, and carbonates of magnesia and lime, iron, &c.; that of Cilaos (discovered in 1826) is 3650 ft. above the sea with a temperature of 100°; and that of Mafate 3260 ft. above the sea.

Vertically Réunion may be divided into five zones. The first or maritime zone contains all the towns and most of the villages, built on the limited areas of level alluvium occurring at intervals round the coast. In the second, which lies between 2500 and 4000 ft., the sugar plantations made a green belt round the island and country houses abound. The third zone is that of the forests; the fourth that of the plateaux, where European vegetables can be cultivated; and above this extends the region of the mountains.

Climate.—The year divides into two seasons—that of heat and rain from November to April, that of dry and more bracing weather from May to October. The prevailing winds are from the S.E., sometimes veering round to the S., and more frequently to the N.E.; the W. winds are not so steady. There are cyclones, followed by seven days of E. to fifty-eight W. wind in the course of the year, and is seldom calm during the day, but there is usually a period of complete repose before the land wind begins in the evening. Several years sometimes pass without a cyclone visiting the island; at other times they occur more than once in a single "winter." The "ras de marte" occasionally does great damage. On the leeward side of the island the winds are generally from the W. and S.W., and are accompanied by a great heightening of the temperature, but the mountains, usually clear off at night. On the coast and lower zones on the windward side the mean temperature is about 73° F. in the winter and 78° F. in the "summer." On the leeward side it may be as low as 60° F., but never below 54°. The annual average is 66° F.; at the Plaine des Palmaries 62° F. The rainfall is very heavy on the windward side, some stations registering 150 in. a year, while on the "dry" side of the island not more than 50 in. are registered. On the mountain heights snow falls every year, and ice is occasionally seen. In general the island is healthy, but fever is prevalent on the coast.

Fauna and Flora.—The fauna of Réunion is not very rich in variety of species. The mammals are a brown maki (Lemur monga, Linn.) from Madagascar, Pteropus edwardsii now nearly extinct, several bats, a wild cat, the tangle or tamar (Centetes setosus, Denn.), several species of lemur, the monk seal, the great cormorant, the bear, the ant-eater, the birds are the "oiseau de la vierge" (Muscipota borbonica), the tectec (Prasinocela sybilias), Cerithia borbonica, the cardinal (Foudia madagascariensis), various swallows, ducks, &c. The visitors from Madagascar, Mauritius and even India, are very numerous. The lizards and frogs of more than one species are common, but there is only one snake (Lycodun anlicum) known in the island. Various species of Hymenoptera, Nests of bee-ormeons, Ophranomus olfis and Doleus rupicrana are among the freshwater fishes. Turtles, formerly common, are now very rare. In the forest region of the island there is a belt, 4500-5000 ft. above sea-level covered by the prevalence of dwarf bamboo (Bambusa alpina); and above that is a similar belt of Acacia heterophylla. Besides this last the best timber-trees are Casuarina laterifolia, Eucalyptus mauritiana, Imbricaria peltifolia, Eclasonderod argentea, E. insignis, and a kind of fir known as "Terminale borbonica," Parkia speciosa. The gardens of the coast districts display a marvellous wealth of flowers and shrubs, partly indigenous and partly gathered from all parts of the world. Among the indigenous varieties may be noted the vanco (Fundamensis mutill) and the aloe.

A species of coffee plant is also indigenous. Fruits grown in the island are the banana, the mango, the jack-fruit, the bilimbi, the carambola, the guava, and the litchi, the mango, the medlar, the mango-stem, the tamarind, the Abelsonus esculenton, the chirimoya, the papaya, &c. Forests originally covered nearly two-thirds of the island; in the southern part the timber-trees have been cut, but there are still some 400 sq. m. of forest land and the administration has in part replanted the higher districts, such as Saint Benoit, with eucalyptus and caoutchouc trees.

Inhabitants.—The island is divided into nine classes, the creoles, the mulattoes, the negroes, and Indians and other Asiatics. The creole population is descended from the first French colonists, chiefly Normans, who married Madagascar women. Later settlers included European women, but the presence of non-European blood is so common among the creoles that the phrase "Bourbon white" was given to Mauritian linen of doubtful parentage. The negroes are all of African breed, both on the towns and coasts, those of the mountains, and the petits créoles, originally a class of small farmers living in the uplands, now reduced to a condition of poverty and dependence on the planters. The créoles blancs de mille, the typical inhabitants of the island, are in general of a somewhat weak physique, quick-witted and of charming manners, brave and very proud of their island, but not of strong character. The mixed races tend to approximate to a single type, one in which the European admixture is seldom more than 1/8 or 1/6.

Towns and Communication.—St Denis, the capital of the island, lies on the N. coast. It had in 1902 a population of 27,392. It is built in the form of an amphitheatre, and has several fine public buildings. The cathedral and central court are accompanied by a seigneurial residence of a bishopric, a court of first instance and an appeal court. It has an abundant supply of pure water. The only anchorage for large ships is at St. Cilaos, an open roadstead, where the town on the leeward side of the island, has a small artificial harbour. Between St. Pierre and St. Denis, and both on the leeward shore, are the towns of St. Louis (pop. 12,411) and St Paul (pop. 19,617). A few miles N. of St Paul on the side of Cape Pointe des Galets is the port of the same name, the only considerable harbour in the island. It was completed in 1886 at a cost of £2,700,000, covers 40 acres, is well protected, and has 28 ft. of water. A railway from Cape Pointe des Galets to St Denis, &c., to St Benoît (a town on the E. side of the island with a pop. of 12,523), a distance of 83½ m. This line is carried through a tunnel nearly 613 ft. long. The line to St Denis. Besides the railway the lower parts of the island are connected with roads. There is regular steamship communication between Pointe des Galets, Marseilles, Havre and Madagascar. Telegraph communication with all parts of the world was established in 1904 when a cable connecting Réunion with Tamentave and Mauritius was laid.

Industries.—The Sugar Plantations.—The area of the cultivated land is estimated at 146,200 acres (or 230 sq. m.), of which 86,400 acres are under sugar-cane, the remainder being under either maize, manioc, potatoes, haricots, or coffee, vanilla and cocoa. The sugar-cane, introduced in 1717 by Pierre Parat, is now the staple product. The first bunch sugar was produced (from Arabia in 1715) and to the clove tree, brought from the Dutch Indies by Poivre at the risk of his life. Both are now cultivated on a very limited scale. Vanilla, introduced in 1818, was not extensively cultivated till about 1850. Bourbon vanilla, as it is called, is of high character, and next to sugar is the most important article of cultivation in the island. There are small plantations of cocoa and cinchona; cotton-growing was tried, but proved unsucessful.

The sugar industry has suffered greatly from the competition with beet sugar and the effects of bounties, also from the scarcity of coolies and the phylloxera. The sugar of India, about 1906, was produced by the prevalence of dwarf bamboo (Fundamensis mutill) and the aloe. It was not until 1906 that steps were taken for the creation of central sugar mills and refineries, in consequence of which the competition with the beet mill has been reduced, and the small sugar industry reorganized and brought to a condition of prosperity. The sugar-cane is now prepared and shipped in the form of raw sugar, and the sugar-refining process is by far the most important article of export. There are also manufactories for the making of geranium essence, St Pierre being the centre of this industry. Other articles exported are also fibre and vacoco casks. The mineral wealth of the island has not been
REUS—REUSCH, F. H.

exploited, except for the mineral springs which yield waters highly esteemed. Almost all the products of the island are exported, so that the import trade is very varied. Cattle are imported from Madeira and are reared from Sainthelenaer petroleum, largely used in manufactories, from America and Russia; almost everything else comes from France, to which country go the exports. Over 75% of the shipping is under the French flag.

Commerce.—The total trade amounted in 1860 to the value of £464,000 (the highest during the century); in 1900, to £533,240. The import trade was valued at £298,000. Of the imports £500,000 were from France or French colonies; of the exports £388,000 went to France or French colonies. The currency consists of notes of the Bank of the Réunion (guaranteed by the French government). The nickel money has any currency outside Réunion; the rate of exchange varies from 5 to 20%.

Administration and Legislation.—Réunion is regarded practically as a department of France. It sends two deputies and one senator to the French legislature, and is governed by laws passed by that body. All inhabitants, not being aliens, enjoy the franchise, no distinction being made between whites, negroes, mulattoes, all of whom are citizens. At the head of the local administration is a governor who is assisted by a secretary-general, a procureur général, a privy council and a council-general elected by the inhabitants. The chief executive power is in the hands of the governor and of his right-hand man, the commandant, and his deputies.

History.—Réunion is usually said to have been first discovered by the Portuguese navigator Pedro Mascarenhas in 1507. The island was named after the Mascarenhas, or, more correctly, at a spot which he named La Possession. He also changed the name of the island from Mascarenhas to Bourbon. By decree of the Convention in 1793, Bourbon in turn gave place to Réunion, and was still used by the French in the old island until 1914. Since 1870, when France assumed full sovereignty, it has been a French colony.

There were a considerable number of negroes dependent on Madagascar from Prions, but they remained only three years (1646–49). Other colonists went thither of their own will in 1654 and 1662. In 1664 the Compagnie des Indes orientales de Madagascar, to whom a concession of the island was granted, initiated a regular colonization scheme. Their first commandant was Étienne Régnauld, who in 1669 received from the French crown the title of governor. The growth of the colony was very slow, and in 1717 there were only some 2000 inhabitants. It is recorded that they lived on excellent terms with the pirates, who from 1636 onward infested the neighbouring seas for many years. In 1735 Bourbon was placed under the governor of the Île de France (Mauritius), at that time the Illustre Maisonneuve de Pons. In 1768 the Compagnie des Indes orientales gave up its concession in 1767, and under direct administration of the crown liberty of trade was granted. The French Revolution effects were great in the island and the government of the colonists successfully resisted the attempts of the Convention to abolish slavery, which continued until 1848 (when over 60,000 negroes were freed), the slave trade being, however, abolished in 1812. In 1831 Napoleon appointed the Count de Meaux as governor, and in 1836 the French corsairs as a rallying place from which attacks on Indian merchantsmen could be directed. In 1809 the British attacked the island, and the French were forced to capitulate on the 8th of July 1812, which event is still observed in France on 18th July, until April 1815, when it was restored to France. From that period the island has had no exterior troubles. The negro population, upon which the sugar industry was based, was increased by the importation of negroes from Africa, and in 1874 the government of France prohibited the further emigration of labourers from that country, in consequence of the inconsiderable treatment of the coolies by the colonists. Réunion has also suffered from the disastrous effects of cyclones. A particularly destructive storm swept over the island in March 1875, and in 1904 another cyclone destroyed fully half of the sugar crop and 75% of the vanilla crop.

See A. G. Garisault, Notice sur la Réunion (Paris, 1900), a monograph devoted to the history of that year; E. Jacob de Cordemoy, Étude sur l'île de la Réunion, 2 vols. (Paris, 1835); P. P. Barbeilles, 3 vols. (Marseilles, 1895); W. D. Oliver, Crags and Craters; Rambles in the island of Réunion (London, 1866); C. Keller, Natur und Kultur der Insel Réunion (Munich, 1880). An important work on the history of the island is the Histoire de l'association générale des francs créoles de l'île Bourbon (St Denis, Réunion, 1886); Trouchet, L'Ile Bourbon pendant la période révolutionnaire (Paris, 1888). Of earlier works consult Demange, Néant, Hist. de l'Afrique française (1867); P. U. Thomas, Essai de statistique de l'Ile Bourbon (1828); Dejean de la Batie, Notice sur l'Ile Bourbon (1847); J. Mauran, Impressions dans un tour de l'île Bourbon en diverses époques (Paris, 1853); and a valuable work on the Réunion (1862); Azéma, Hist. de l'Ile Bourbon (1862). The geology and volcanoes of Réunion were the object of elaborate study by Bory de St Vincent in 1801 and 1802 (Voyages dans les quatre principales îles des mers d'Afrique, Paris, 1804), and have since been examined by R. von Drasche (see Die Insel Réunion, 3 vols. Vienna, 1878, and C. Vélan, Descriptions géographique de l'île de la Réunion, 3 vols. Paris, 1878). The best map is Pau Lépervanche's Carte de la Réunion 1:100,000 (Paris, 1906).

REUS, a city of N.E. Spain, in the province of Tarragona, on the Saragossa—Tarragona railway, 4 m. N. of Salou, its port on the Mediterranean. Pop. (1900) 26,681. Reus consists of two parts, the old and the new, separated by the Calle Arrabal, which occupies the site of the old city wall. The old town centres in the Plaza del Mercado, from which narrow and dark lanes radiate in various directions; the new one dates from about the middle of the 18th century, and its streets are wide and straight. There is an active trade in the agricultural products of the fertile region around the city. The local industries developed considerably between 1875 and 1905, and the city has important flour, wine and fruit export houses.

There is a model farm belonging to the municipality in the suburbs. Reus has excellent primary, normal and higher grade state schools, many private schools, an academy of fine arts and a public library. The hospitals and foundling refuge, the institute and the town hall are handsome modern buildings. The earliest records of Reus date from about the middle of the 13th century. Its modern prosperity is traced to about the year 1750, when a colony of English settled here and established a trade in woolens, leather, wine and spirits. The principal incidents in its political history arose out of the occurrences of 1834 (see SPAIN, History), in connexion with which the town received the title of city, and Generals Zurbano and Prim were made counts of Reus. The city was the birthplace of General Prim (1814–70) and of the painter MarianFortuny (1839–1874).

REUSCH, FRANZ HEINRICH (1833–1902), Old Catholic theologian, was born at Brilon, in Westphalia, on 4th December 1833. He studied general literature at Paderborn, and theology at Bonn, Tübingen and Munich. The friend and pupil of Döllinger, he took his degree of Doctor in Theology at Munich, the university of which Döllinger was so long an ornament. He was ordained priest in 1849, and was immediately afterwards made chaplain at Cologne. In 1854 he became Privatdozent in the exegesis of the Old Testament in the Catholic Theological Faculty at Bonn; in 1858 he was made extraordinary, and in 1861 ordinary, professor of theology in the same university. From 1860 to 1869 he was editor of the Bonner Theologisches Literaturblatt. In the court case on the Infallibility of the Pope, Reusch attached himself to Döllinger's party, and he and his colleagues Hilgers, Knoodt and Langen were interdicted by the archbishop of Cologne in 1871 from pursuing their courses of lectures. In 1872 he was excommunicated. For many years after this he held the post of Old Catholic curé of Bonn, as well as the position of vicar-general to the Old Catholic Bishop Reinkens, but resigned both in 1876, when, with Döllinger, he disapproved of the permission to marry granted by the Old Catholic Church in Germany to its clergy. From that time he retired into lay communion.
but continued to give lectures as usual in the Old Catholic Faculty of Theology in the university of Bonn, and to write on theological subjects. He was made rector of that university in 1873. In 1874 and 1875 he was the official reporter of the memorable Reunion Conferences held at Bonn in those years and attended by many distinguished theologians of the Oriental and Anglican communions.

Reusch was a profound scholar, an untiring worker and a man of lovable character. Among his voluminous works were contributions to the Revue internationale de théologie, a review started at Bern at the instance of the Old Catholic Congress at Lucerne. He wrote also works on the Old Testament, a pamphlet on Die Deutschen Bischöfe und der Aberglaube; and another on the falsifications to be found in the treatise of Aquinas against the Greeks; as well as essays on the history of the Jesuit Order, and a book of prayers. But his fame will mainly rest on the works which he and Döllinger published jointly. These consisted of a work on the Autobiography of Cardinal Bellarmine, the Geschichte der Moralstreichent on der Römisch-Katholischen Kirche seit dem XV. Jahrhundert, and the Erörterungen über Leben und Schriften des hl. Liqouri. During the last few years of his life he was smitten with paralysis. He died on the 3rd of March 1875, leaving behind him several hundred of letters to scholars about Roman cardinals and prelates, which has since been published. (J. L. *)

**REUSCH, HANS HENRIK** (1852—1882), Norwegian geologist, was born at Bergen on the 5th of September 1832. He was educated at Christiania, Leipzig and Heidelberg, and graduated Ph.D. at Christiania in 1883. He joined the Geological Survey of Norway in 1875, and became Director in 1888. He is distinguished for his researches on the crystalline schists and the Palaeozoic rocks of Norway. He discovered Silurian fossils in the highly altered rocks of the Bergen region; and in 1891 he called attention to a palaeozoic conglomerate of glacial origin in the Varanger region. Mr. S. Cunitz, who had accompanied him in 1869, who found glacial strata on the rocks beneath the ancient bulldodd. Reusch has likewise thrown light on the later geological periods, on the Pleistocene glacial phenomena and on the sculpturing of the scenery of Norway. Among his separate publications are Silur fossiliser og pressede Konglomerater (1882); Del nordlige Norges Geologi (1891).

**REUSCH, AUGUST EMANUEL VON** (1811-1873), Austrian geologist and palaeontologist, the son of Franz Ambrosius Reuss (1761-1830), was born at Bilin in Bohemia on the 8th of July 1811. He was educated for the medical profession, graduating in 1834 at the university of Prague, and afterwards practising for eight years at Bilin. His leisure was devoted to mineralogy and geology, and the results of his researches were published in Geologische Skizzen aus Böhmen (1840-44) and Die Versteinerungen der Böhmischen Kreideformation (1845-46). In 1849 he gave up his medical practice, and became professor of mineralogy at the university of Prague. There he established a fine mineralogical collection, and he became the first lecturer on geology. In 1863 he was appointed professor of mineralogy in the university of Vienna. He investigated the Cretaceous fauna of Gosau, and studied the Crustacea, including entomostraca, the corals, bryozoa, and especially the foraminifera of various geological formations and countries. He died at Vienna on the 20th of November 1873.

**REUSS, ÉDOUARD GUILLAUME EUGÈNE** (1804-1881), Protestant theologian, was born at Strassburg on the 18th of July 1804. He studied philology in his native town (1820-22), theology at Göttingen under J. G. Eichhorn; and Oriental languages at Halle under Wilhelm Gesenius, and afterwards at Paris under Silvestre de Sacy (1827-28). In 1828 he became Privatdozent at Strassburg. From 1829 to 1834 he taught Biblical criticism and Oriental languages at the Strassburg Theological School; he then became assistant, and afterwards, in 1836, regular Professor, a commission by a royal edict. The sympathy of Reuss was German rather than French, and after the annexation of Alsace to Germany he remained at Strassburg, and retired his professorship till, in 1888, he retired on a pension. Amongst his earliest works were: De libris veteris Testamenti apocryphis biblic non negandis (1829). Ideen zur Einleitung in das Evangelium Johannis (1840) and Die Johannistische Theologie (1847). In 1852 he published his Histoire de la théologie chrétienne au siècle apostolique, which was followed in 1865 by L'Histoire du canon des saintes écritures dans l'église chrétienne. In 1874 he began to publish his translation of the Bible, La Bible, nouvelle traduction avec commentaire. It was the criticism and exegesis of the New Testament which formed the subject of Reuss's earlier labours—in 1842, indeed, he had published in German a history of the books of the New Testament, Geschichte der heiligen Schriften N. Test.; and though his last years were liberal, he opposed the results of the Tübingen school. After a time he turned his attention also to Old Testament criticism, for which he was especially fitted by his sound knowledge of Hebrew. In 1881 he published in German his Geschichte der heiligen Schriften A. Test., a valuable encyclopaedia of the history of Israel from its earliest beginning till the taking of Jerusalem by Titus. He died at Strassburg on the 15th of April 1891.

Reuss belonged to the more modern section of the Liberal party in the Lutheran Church. His critical position was to some extent that of K. H. Graf and J. Wellhausen, allowing for the circumstances of time and place. For in the 1860s the liberal, or at least the more progressive, wing of the church was liberal, and it was actually for a time Graf's teacher. Indeed, he was really the forerunner of the new movement, but hesitated to publish the results of his studies. For many years Reuss edited with A. H. Cunitz (b. 1812) the Beiträge zu den theologischen Wissenschaften. With A. H. Cunitz and J. W. Baum (1809-1878), and after their death alone, he edited the monumental edition of Calvin's works (38 vols., 1863 ff.). His critical edition of the Old Testament appeared a year after his death. His son, ERNST RUDOLF (b. 1841), was in 1873 appointed city librarian at Strassburg.

An article in Herzog-Hauck, Realencyclopädie, and Otto Pfeiderer, Development of Theology in Germany since Kant (1890).

**REUSS**, the name of two small principalities of the German empire, called Reuss, elder line, or Reuss-Greiz, and Reuss, younger line, or Reuss-Schleiz-Gera. With a joint area of 441 sq. m. they form part of the complex of Thurtingian states, and consist, roughly speaking, of two main blocks of territory, separated by the Neustadt district of the duchy of Saxe-Weimar. The more southerly, which is much the larger of the two portions, belongs to the bleak, mountainous region of the Frankenwald and the Vogtland, while the northern portion is hilly, but fertile. The chief rivers are the Wesse Elster and the Saale. About 35% of the total surface is occupied by forests, while about 40% is under tillage and about 15% under meadow and pasture. Wheat, rye and barley are the principal crops grown, and the breeding of cattle is an important industry.

**Reuss-Greiz**, with an area of 122 sq. m., belongs to the larger of the two divisions mentioned above, and consists of three large and several small parcels of land. On the whole, the soil is not favourable for agriculture, but the rearing of cattle is carried on with much success. About 83% of the inhabitants make their livelihood by industrial pursuits, the chief products of which are the making of woolen fabrics at Greiz, the capital, and of stockings at Zeulenroda. Other industries are machine-building, printing and the making of paper and porcelain. In 1905 the population of the principality was 70,063. The constitution of Reuss-Greiz dates from 1867, and provides for a representative chamber of twelve members, of whom three are appointed by the prince, while two are chosen by the landed proprietors, three by the towns and four by the rural districts. The revenue and expenditure amount to about £76,000 a year, and there is no public debt. The reigning prince is Henry XXIV. (b. 1878), but as he is incapable of discharging his duties, these are now undertaken by a regent.

**Reuss-Schleiz-Gera**, with an area of 319 sq. m., includes part of the southern and the whole of the northern of the two main divisions mentioned above; it touches Bavaria on the south
and Prussian Saxony on the north. The former portion is known as the Oberland and the latter as the Unterland. Owing to the fertility of the Unterland, quite one-quarter of the people are supported by agricultural pursuits, although there is also much industrial activity. The chief industrial product consists of woolen goods, and the manufacture centres in the capital Gera, the largest of the six towns of the principality. Other industries are jute-spinning, dyeing and brewing, and the manufacture of musical instruments, chemicals, tobacco, cigars, porcelain and machinery. A considerable trade is carried on in these goods and also in timber, cattle and slate. Iron is mined in the Oberland, and large quantities of salt are yielded by the brine springs of Heinrichshall. In 1905 Reuss-Schleiz contained 144,384 inhabitants. Its annual revenue and expenditure amounted to about £29,000, and in 1908 it had a public debt of £2,027. The constitution, which rests on laws of 1852 and 1856, provides for a representative assembly of 16 members which possesses limited legislative powers, the administrative duties being discharged by a cabinet of three members. The reigning prince is Henry XIV. (b. 1832), but since 1892 his duties have been undertaken by a regent. The states of Reuss return one member each to the Bundesrat, and one each to the Reichstag of the German empire. History.—The history of Reuss stretches back to the times when the German kings appointed votsi, or bailiffs (advocati imperii), to administer their lands. One of these votsi was a certain Henry, who died about 1120, after having been entrusted by the emperor Henry IV. with the votship of Gera and of Weida, and he is generally recognized as the ancestor of the princes of Reuss. His descendants called themselves lords of Weida, and some of them were men of note in their day, serving the emperors and German kings and distinguishing themselves in the ranks of the Teutonic order. The land under their rule gradually increased in size, and it is said that the name of Reuss was applied to it owing to the fact that one of its princes married a Russian princess, their son being called "der Russe," or the Russian. Another version is that the prince received this sobriquet because he passed many years in Russia. The district thus called Reuss was at one time much more extensive than it is at present, and for some years its rulers were margraves of Meissen. In 1564 the family was divided into three branches by the sons of Henry XVI. (d. 1535). One of these became extinct in 1616, but the remaining ones are those of Reuss-Greiz and Reuss-Schleiz-Gera, which are flourishing to-day. Although there have been further divisions these have not been lasting, and the lands of the former family have been subdivided since 1768 and those of the latter since 1848. The lords of Reuss took the title of count in 1673; and the head of the elder line became a prince of the Empire in 1775, and the head of the younger line in 1806. In 1807 the two princes joined the Confederation of the Rhine and in 1815 the German confederation. In 1866 Reuss-Greiz was compelled to cede for its active sympathy with Austria by the payment of a fine. In 1871 both principalities became members of the new German empire. The princes of Reuss are very wealthy, their private domain including a great part of the territory over which they rule. In the event of either line becoming extinct, its possessions will fall to the other.

A curious custom prevails in the house of Reuss. The male members of both branches of the family all bear the name of Henry (Heinrich), the individuals being distinguished by numbers. In the elder line, according to an arrangement made in 1778, the first person seated at the head of the table is the person of the name and number one; the second, the number two; and so on, through the number one hundred, which is the number ten when the time comes, until the next number in line is required. Thus Henry XIV. of Reuss younger line, who was born in 1832, was the son of Henry LXVII. (1789-1867), the former being the 14th prince born in the 19th century, and the latter the 67th prince born in the 18th.

See B. Schmidt, Die Reussen, Genealogie des Gesamthausen Reuss (Schleiz, 1903); H. von Voss, Die Ahnen des reussischen Hauses (Lohenstein, 1882); C. F. Collmann, Reussische Geschichte. Das Vogtland im Mittelalter (Greiz, 1892), and O. Liebmann, Das Staatsrecht des Fürstenhofs Reuss (1854).

REUTER, FRITZ (1810–1874), German novelist, was born on the 7th of November 1810, at Stavenhagen, in Mecklenburg-Schwerin, a small country town where his father was hurgomaster and sheriff (Stadtrichter), and in addition to his official duties carried on the work of a farmer. He was educated at home by private tutors and subsequently at the gymnasia of Friedland in Mecklenburg-Strelitz, and of Parchim. In 1831 he began to attend lectures on jurisprudence at the university of Rostock, and in the following year went to the university of Jena. Here he was a member of the political students' club, or German Burschenschaft, and in 1833 was arrested in Berlin by the Prussian government; although the only charge which could be proved against him was that he had been seen wearing its colours, he was condemned to death for high treason. This monstrous sentence was commuted by King Frederick William III. of Prussia to imprisonment for thirty years in a Prussian fortress. In 1838, through the personal intervention of the grand-duke of Mecklenburg, he was delivered over to the authorities of his native state, and the next two years he spent in the fortress of Dömitz, but in 1840 was set free, an amnesty having been proclaimed after the accession of Frederick William IV. to the Prussian throne.

Although Reuter was now thirty years of age, he went to Helderberg to resume his legal studies; but he soon found it necessary to return to Stavenhagen, where he aided in the management of his father's farm. After his father's death, however, he abandoned farming, and in 1850 settled as a private tutor at the little town of Treptow in Pomerania. Here he married Luise Kunze, the daughter of a Mecklenburg pastor. Reuter's first publication was a collection of miscellaneous, written in Plattdeutsch, and entitled Läuschen un Riemels ("anecdotes and rhymes," 1853; a second collection followed in 1858). The book, which was received with encouraging favour, was followed by Polterabendgedichte (1853), and De Reis' noh Beligian (1855), the latter a humorous poem describing the adventures of some Mecklenburg peasants who resolve to go to Belgium (which they never reach) to learn the secrets of an advanced civilization. In 1856 Reuter left Treptow and established himself at Neubrandenburg, resolving to devote his whole time to literary work. His next book (published in 1858) was Kein Hüsung, an epic in which he presents with great force and vividness some of the least attractive aspects of village life in Mecklenburg. This was followed, in 1860, by Hanne Nüte un de lille Pudel, the best of the works written by Reuter in verse. In 1861 Reuter's popularity was largely increased by Scharr-Murr, a collection of tales, some of which are in High German, but this work is of slight importance in comparison with the series of stories, entitled Olle Kamelien ("old stories of bygone days"). The first volume, published in 1860, contained Woans ich lau 'ne Fru kam and Ut de Franzosentid. Ut mine Festungstid (1861) formed the second volume; Ut mine Stromtid (1864) the third, fourth and fifth volumes; and Dörch-läuchting (1866) the sixth volume—all written in the Plattdeutsch dialect of the author's home. Woans ich lau 'ne Fru kam is a bright little tale, in which Reuter tells, in a half serious half bantering tone, how he wooed the lady who became his wife. In Ut de Franzosentid the scene is laid in and near Stavenhagen in the year 1813, and the characters of the story are associated with the great events which then stirred the heart of Germany the 20th of December. Ut mine Festungstid is the story of Lebrecht, the son of the landowner, Ut de Franzosentid, a narrative of Reuter's hardships during the term of his imprisonment, but it is not less vigorous either in conception or in style. Ut mine Stromtid is by far the greatest of Reuter's writings. The men and women he describes are the men and women he knew in the villages and farmhouses of Mecklenburg, and the circumstances in which he places them are the circumstances by which they were surrounded in actual life. As in Ut de Franzosentid he describes the deep national impulse in obedience to which Germany rose against
Napoleon, so in Ut mine Stromid he presents many aspects of the revolutionary movement of 1848.

In 1863 Reuter transferred his residence from Neubrandenburg to Eisenach; and here he died on the 12th of July 1874. In the works produced at Eisenach he did not maintain the high level of his earlier literary productions.

Reuter's Sämtliche Werke, in 13 vols., were first published in 1863-68. To these were added in 1875 two volumes of Nachgelassene Schriften, with a biography by A. Wilbrandt; and in 1878 two supplementary volumes to the works appeared. A popular edition in 7 vols., was published in 1897-99; there are also editions by K. F. Müller (18, 1903); and W. Seeliemann (7 vols., 1905-6). See O. Glagau, F. Reuter und seine Dichtungen (1866); 25th ed. (1899); F. Reuter, seine Werke, 5 vols. (1869); F. Latendorf, Zur Erinnerung an F. Reuter (1875); K. T. Gekhert, Reuter-Studien (1890); by the same, Aus Reuter's alten und jungen Tagen (3 vols., 1894-1900); Briefe F. Reuter an seinen Vater, edited by F. Engel (2 vols., 1895); A. Römer, F. Reuter in seinem Leben und Schaffen (1895); G. Raatz, Wahrheit und Dichtung in Reuter's Werken (1895); E. Brandes, Aus F. Reuter's Leben (1899); K. F. Müller, Der Mecklenburger Volksmund und F. Reuter's Schriften (1900). A complete bibliography of F. Reuter will be found in the Niederdeutsche Jahrbuch for 1896 and 1902.

REUTER, PAUL JULIUS, BARON DE (1821-1899), founder of Reuter's News Agency, was born at Cassel, Germany. At the age of thirteen he became a clerk in his uncle's bank at Göttingen, where he chance to make the acquaintance of Professor Gauss, whose experiments in telegraphy were then attracting some attention. Reuter's mind was thus directed to the study of the science of the rapid transmission of information, and in 1849, on the completion of the first telegraph lines in Germany and France, he found an opportunity of turning his ideas to account. There was a gap between the terminations of the two lines at Aix-la-Chapelle and that of the French and Belgian lines at Verviers. Reuter organized a news-collecting agency at each of these places, his wife being in charge of one, himself at the other, and bridged the interval by a pigeon-post. On the establishment of through telegraphic communication, Reuter endeavoured to start a news agency in Paris, but finding that the French government's restrictions would render the scheme unworkable, removed in 1851 to England and became a naturalized British subject. The first submarine cable—between Dover and Calais—had just been laid, and Reuter opened an office in London for the transmission of intelligence between England and the continent. At first, however, his business was practically confined to the transmission of private commercial telegrams to places not connected with the new telegraph system. He appointed agents at the various telegraph termini on the continent to take these dispatches off the wires and forward them by rail or pigeon-post to the addresses. Simultaneously he endeavoured to induce the English papers to publish the foreign news telegrams supplied by his various agents. These efforts were for some years unsuccessful, until in 1858 The Times published the report of an important speech by Napoleon III., forwarded by Reuter's Paris agent. Reuter now extended his sphere of operations all over the world, and in 1859 obtained leave for the presence of representatives at the headquarters of the Austrian and French armies during the war. In 1866 he laid down a special cable from Cork to Crookhaven, which enabled him to circulate news of the American Civil War several hours before the steamer could reach Liverpool. A concession for a cable beneath the North Sea to Cuxhaven was granted him by the king of Hanover in 1865, and in the same year a concession was granted him for a cable between France and the United States, the line being worked jointly by Reuter (whose business had been taken over by a limited company called the Anglo-American Telegraph Company). In 1872 he obtained from the shah of Persia an exclusive concession to develop the internal resources of that country, but the concession was annulled and its privileges transferred to the Imperial Bank of Persia. Reuter was in 1871 given the title of baron by the duke of Saxe-Coburg and Gotha, and by a special grant of Queen Victoria he and his heirs were authorized to have the privileges of this rank in England. Baron Reuter died at Nice on the 25th of February 1899.

REUTERHOLM, GUSTAF ADOLF, BARON (1756-1813), Swedish statesman. After a brief military career he was appointed Kammerherr to Sophia Magdalena, queen consort of Gustavus III., and subsequently became intimately connected with the king's brother, Charles, then duke of Suedermania. He was also in the background throughout the reign of Gustavus III., whom he constantly opposed and by whom he was imprisoned along with the other malcontents in 1789. He was abroad at the time of the king's death, but a summons from his friend, now duke regent, speedily recalled him, and in 1793 he was made a member of the council of state and one of the "lords of the realm." At first he seemed inclined to adopt a liberal system, and reintroduced the freedom of the press. He did this solely, however, to reverse the Gustavian system, and persecuted the stalwarts of the late king (e.g. G. M. Armfelt, J. K. Toll) with a petty vindictiveness which excited general disgust. Towards the end of the regency, Reuterholm inclined towards an alliance with Russia on the basis of a marriage between the young king, Gustavus IV., and the empress Catherine's granddaughter, Alexandra Pavlovna, an alliance frustrated by the bigotry of the intended groom. At home the Swedish government ended as ultra-reactionary, owing to an insignificant riot in Stockholm which so alarmed Reuterholm that he threatened all printers who printed anything relating to the constitutions of the French republic or the United States of America with the loss of their privileges. In March 1793 he closed the Swedish Academy because A. G. Silfverstolpe in his inaugural address had ventured to disparage the conduct of 1780. On the accession of Gustavus IV. (November 1st, 1796) Reuterholm was expelled from Stockholm. For the next twelve years he lived abroad under the name of Tempelcreutz. After the revolution of 1809 he returned to Sweden, but was denied all access to Charles XIII., and quitted his country for good. He died in Schleswig on the 27th of December 1813. See: Östiges Historia (Stockholm, 1877-1881), vol. v. (R. N. B.)

REULTLINGEN, a town of Germany, in the kingdom of Württemberg, situated on the Eschatz, an affluent of the Neckar, near the base of the Achalm and 36 m. by rail S. of Stuttgart. Pop. (1903) 23,850. It is a quaintly built town, with many picturesque houses and a fine Gothic church of the 13th and 14th centuries dedicated to St Mary, which was restored in 1803-1901; it contains in the choir a replica of the Holy Sepulchre and a sculptured stone font, and has a tower 240 ft. high. Reultlingen has three other Evangelical churches, a Roman Catholic church, a town hall, and several monuments, including one to the emperor William I. and another to Friedrich List. The industries of the town are numerous, and include the spinning and weaving of cotton, dyeing and bleaching; also the manufacture of leather, machinery, furniture, shoes, paper, clothing, hardware, bricks, beer and woolen goods. Hops, vines and fruit are grown in the neighbourhood. Reultlingen has several schools and educational establishments, including a celebrated pomological institute. It is also famous as the place where Pastor Gustav Werner (1809-1887) founded his Christian Socialist reformation, which has become widely known in philanthropic circles.

Reultlingen, which is first mentioned in 1213, became a free imperial town in the 13th century and was fortified by the emperor Frederick II., remaining loyal to him throughout the wars of the Swabian towns, its citizens defeated Count Ulrich of Württemberg on the 14th of May 1377. Later it joined the Swabian League and was favoured by the emperor Maximilian I., who came to the town on 27th December 1522 at the suggestion of the citizens. The town exchanged letters with Ulm and Freiburg and, in 1525, called in the revolutionary forces of the League. Ulm would not support it. The town had, therefore, the utmost confidence in the event which took place on the 27th of December 1525 destroyed many houses in the town.

See: Rupp, Aus der Vorzeit Reultlingens und seiner Umgebung (Stuttgart, 1806); Hochstetter, Führer durch Reultlingen und Umgebung (Reultlingen, 1901); and Zwiese, Geographischer Führer in der Umgebung von Reultingen (Stuttgart, 1897).

REVEL, or REVEL (Russ. Revel, formerly Kolyuvat; Estonian, Tallina and Tamniid), a fortified seaport town of Russia, capital of Estonia, situated on a bay on the S. coast of the gulf of Finland, 250 m. W. of St Petersburg by rail. Pop. (1900) 66,292, of whom half were Estonians and 30%
German. The city consists of two parts—the Domburg or Donjon, which occupies a hill, and the lower town on the beach. The Donjon contains the castle (first built in the 13th century, rebuilt in 1772), where the provincial administration has its seat, and a cathedral (1894-1900) with five gilded domes. It has its own administration, separate from that of the lower town. The church of St. Nicholas, built in 1317, contains many antiquities of the former Roman Catholic times and old German paintings. The Donjon church contains many interesting shields, as well as the graves of the circumnavigator Baron A. J. von Kronenstein (1770-1846), of the Swedish soldiers Pontus de la Gardie (d. 1583) and Carl Horn (d. 1601), and of the Bohemian Protestant leader Count Matthias von Thurn (1580-1635). The church of St. Olai, first erected in 1240, and often rebuilt, was completed in 1840 in Gothic style; it has a bell tower 456 ft. high. The oldest church is the Estonian, built in 1219. The public institutions include a good provincial museum of antiquities; an imperial palace, Kaltharmenthal, built by Peter the Great in 1719; and very valuable archives, preserved in the town hall (14th century). The pleasant situation of the town attracts thousands of people for sea-bathing. It is the seat of a branch board of the Russian admiralty and of the administration of the Baltic lighthouses. Its port has a depth of 4 to 6 fathoms, and a roadstead 35 m. wide, which freezes nearly every winter. The exports consist chiefly of grain, timber, flax, hides, wool, a species of anchovy, and hemp, and the imports of manufactured goods and machinery. The value of the aggregate trade amounts to an average of seven to nine millions sterling annually. There is considerable trade with Finland. Baltic Port, 30 m. W., is a sort of annex to the port of Reval.

The high Silurian crag now known as Domburg was early occupied by an Estonian fort, Lindamissa. In 1219 the Danish king Valdemar II erected here a strong castle and founded the first church. In 1228 the castle was taken by the Livonian Order, and in 1234 the Danish castle was surrendered to the Teutonic Knights in 1346, but on the dissolution of the order, in 1561, Estonia and Reval surrendered to the Swedish king Erik XIV. A great conflagration in 1433, the pestilence of 1532, the bombardment by the Danes in 1569, and the Russo-Livonian War, destroyed its trade. The Russians besieged Reval twice, in 1570 and 1577. It was still an important fortress, having been enlarged and fortified by the Swedes. In 1710 it was surrendered to Peter the Great, who immediately began the erection of a military port for his Baltic fleet. His successors continued to fortify the access to Reval from the sea, large works being undertaken, especially in the early years of the 18th century.

**Reveillé**

(Rev. *réveillé*, imperative of *réveiller*, to awaken, Lat. *re- and *vigilare*, to watch), the signal by call of bugle or beat of drum to announce to soldiers the time to awake and begin duty.

**Revelation, Book Of**, in the Bible, the last book of the Apocrypha.

**Title.**—According to the best authorities (CA) (in the subsection) 2. 8, 82, 93, the title of this book is Ἀποκάλυψις *Ἰησοῦ Χριστοῦ*. Some correctives (1, 14, 17, 25, 28, 31, 38, 51, 90, 91, 94, 97) read ἀγίου. (+ τὸ ἁγίου 1, 25, 28, 31, 38, 51, 90, 94) Ἰησοῦ Χριστοῦ τῶν θεολογιῶν; Q and 12, ἀγίου. τοῦ θεολογίου καὶ εὐαγγελισθέντος; P and 42, ἀγίου. τῶν ἀποστόλων Καὶ εὐαγγελισθέντος. The word "apocalypse" gives the current title not only to this book, but to a large body of Jewish and Christian writings. This is one of the first instances of its use in this sense in existing literature. An earlier use is probably to be found in the title of the Syriac Apocalypse of Baruch, which Ῥωμαίου τῶν θεολογίων τῶν θεολογίων Ἀποκάλυψις *Ἰησοῦ Χριστοῦ*. The title is different from what the New Testament use of the term would have led us to expect, i.e. Ἀποκάλυψις *Ἰησοῦ Χριστοῦ*, which are indeed the opening words of this book. With the latter phrase we might compare Gal. i. 12, where we have Ἀποκάλυψις Ιησοῦ Χριστοῦ. "Revelation from Jesus Christ." For the book is a revelation made by God to Jesus Christ, who through His angel made it known to John for transmission to the churches. Instead of this the Church substituted the name of the disciples through whom the message was delivered for that of his Master, and designated our Apocalypse "The Apocalypse of John." This title was familiar before the end of the 2nd century.

**MSS. and Versions.**—There are six uncial, Ψ, A, C, P, Q, 1, the last of which has not been edited or collated. Of the rest, P and Q are imperfect. The known cursive amounts to 229, according to von Soden (Die Schriften des Neuen Testamentes, ii. 24). This number was then increased to 475 and various values. (a) The best is the Latin, which is found in the Old Latin (g h m and the text used by Primasius) and the Vulgate, of which there are eight MSS. written between the 6th and 12th centuries. (b) The Syriac version appears in two forms, the Philoxenian (A.D. 508), recently discovered and edited by Gwynn, and the Harclean (A.D. 616). The true Peshitta did not contain the Apocalypse. (c) The Armenian version. The Apocalypse was admitted to the canon, according to Conybeare, in the 12th century through the influence of Nerses, who revised an older version traceable to the opening of the 5th century. (d) The Egyptian version is found in few and very small books known as the Bohairic and Sahidic. The former has been edited by Horner, who is now also engaged on an edition of the latter. (e,f) The Ethiopic and Arabic versions have not yet been critically edited.

**External Evidence and Canoncility, and Century.**—It is possible that the Apocalypse was known to Ignatius, Eph. xv. 3 (Rev. xxi. 3); Philad. v. 1 (Rev. iii. 12). Some have thought also that Barnabas (vi. 13, xxi. 3) was acquainted with our text, but this is highly improbable. Andreas of Caesarea mentions Papias as attesting the credibility of Revelation, and cites two of his remarks on Rev. xii. 7. The fact that Eusebius does not mention the Apocalypse in his *Historia Ecclesiatica* and very few books known as the Bohairic and Sahidic. The Papias (H.E. iii. 35) may be due to the historian's unfriendly attitude to the book. Moreover, Papias may be one of the presbyters to whom, as having actually seen John, Irenaeus (v. 30 = Eusebius, H.E. v. 8) appeals on behalf of the number 666. From these possible and highly probable references we pass on to the clear testimony of Justin Martyr, who is the first to declare that Revelation is by "John, one of the Apostles of Christ" (Dial. ixi. 15), and a book of canonical standing (i. 28). In the latter half of this century it meets with very wide recognition. Thus a treatise of some description was written upon it by Melito of Sardis in Asia Minor (Eus. H.E. iv. 26), and quoted by the anti-Montanist Apollonius (H.E. v. 18) and Theophilus of Antioch (H.E. iv. 24). In Carthage its currency is proven by the references of Tertullian, and the phraseology of the Acts of Perpetua and Felicitas (v. 4, 13); in Alexandria by the citations of Clement (Pram. i. 6; ii. 10, 108, &c.); in Rome by its inclusion in the Muratorian canon, and in Gaul by its use in the Epistle of the churches of Vienne and Lyons (Eus. H.E. v. 10, 58), and in Irenaeus, who defends the apostolic authorship of the Revelation of John (Haer. iv. 14, 17, 18, 16, 20, 11, 21, 3; v. 26, 1, &c.).

But in certain quarters the authority of the book was denied. Thus Marcion rejected it on the ground of its Jewish character (Tertullian, c. Marcion, iv. 3), and the Alogi assigned both Revelation and the Gospel to Cerinthus (Ephippius, Haer. li. 3). This attitude is more widely represented in the next century.

**Third Century.**—The attack on Revelation was resumed by abler antagonists in this century. The objections of the Alogi were restated and maintained by the Roman prebyster Caius in his controversy with the Montanist Proclus (Eus. H.E. ii. 25, 6; iii. 28, 2), but met with such overwhelming refutation at the hands of Hippolytus (see Gwynn, Hermaiothen, vi. 307-418) that no church writer in the West subsequently except Jerome seriously called in question the authorship of our book.

Dionysius of Alexandria (A.D. 255) wrote a moderate and effective criticism, in which he rejects the hypothesis of the
Cerinthian authorship and urges that it was not written by the apostle, on the ground of its difference in language, style and contents from the other Johannine writings. Its author was some inspired man bearing the same name as the son of Zebdee. The arguments of Dionysius were repeated by Eusebius, when appropriating his work to the presbyter John mentioned by Papias (Eus. H. E. iii. 30) and was in doubt whether he should place Revelation among the spurious (ψεύτων) works (H. E. iii. 25.4) or the accepted (ἐκαθορισμένα).

Eastern Church.—In the Eastern Church the views of Dionysius and Eusebius were generally accepted. With the exception of Methodius and Pamphilus the book was not received by Eastern scholars. Thus it was either not mentioned or discussed by Cyril of Jerusalem, Chrysostom, Theodore of Mopsuestia, Theodoret and Philo-Chlicius of Iconium. It is absent from the so-called Synopsis of Athanasius, the Sůčometry of Nicephorus as well as the Books and other authoritative documents. It formed no part of the Peshitta New Testament. It was apparently unknown to Ephraem. Even when later it found a place in the Philoxenian and Harcian versions it never became a familiar book to the Syrian Churches, while it was unhesitatingly rejected by the Nestorian and Jacobite Churches.

But though the Syrian Church maintained this unconciliatory attitude to the book, opposition to it began gradually to disappear in the rest of the East. Thus it came to be acknowledged by Athanasius, Isidore of Pelusium, Gregory of Nyssa, and others. Commentaries on the book were written by Andreas, archbishop of Caesarea, in the 5th century, and Arethas in the 9th.

Western Church.—In the Western Church, Revelation was accepted by all writers from Hippolytus onward with the exception of Jerome, who relegated it to the class lying between the canonical and apocryphal. The authenticity of the book was unquestioned henceforward till the Reformation, when the view of Jerome was revived by Erasmus, Carlstadt, Luther and others under various forms. In the Lutheran Church this opposition lasted into the next century, but in the Reformed it gave way much earlier. That Revelation has retained its place in the canon is due not to its extravagant claims to inspiration or its apocalyptical disclosures, but to its splendid faith and unconquerable hope, that have never failed to awake the corresponding graces in every age of the Church’s history.

The History of Interpretation.—This is a most fruitful subject, and the study of it helps to settle other related questions. We first of all might divide the methods of interpretation into two classes: I. Methods which presuppose the literal unity of the book; II. Methods which presuppose some breach of this unity either in the plan of the book as a whole or in some of its details.

i. Method presupposing the Literal Unity of the Book.—Where the book was accepted a list of six problems of its interpretation was differently dealt with according to the age and environment of the interpreter. The book was first taken in a severely literal sense, and particularly in its chiliastic doctrine.

ii. chiliastic Interpretation.—Revelation was held to teach chiliasm, or the doctrine of the literal reign of 1000 years. Amongst the chiliasts were Cerinthus, Papias, Justin, Irenaeus, Hippolytus, Tertullian and Victorinus.1 When the Church obtained the mastery of the world this method came naturally to be abandoned in favour of a spiritualistic interpretation, to which we shall presently refer. But the growing secularism of the Church led to a revival of the former method in the beginning of the 13th century amongst the Franciscans. Thus Joachim of Floris in his Expositio magni abbatis Joachimi in Aproc. teaches that Babylon is Rome, the Beast from the Sea Ismail, the False Prophet the heretical sects of the day, and that on the close of the present age which was at hand the millennium would ensue. This method of interpretation was pursued to extravagant lengths by other Franciscans and was subsequently adopted by the Protestant reformers, who could justify their identification of the papacy with the Antichrist from books written within the Roman communion. Joachim was the first to apply the “ recapitulation ” theory to Revelation.

ii. Spiritualistic Interpretation.—The founder of this school of interpretation was Ticonius the Montanist (floruit A.D. 180), though he followed therein the precedent set by Origen. His interpretation is on the whole mystical. Historical fulfilments, if not excluded, are not sought for. The millennium is the period between the first and second comings of Christ. The method of Ticonius was dominant in the Church down to the middle ages, amongst his followers being such notable churchmen as Augustine, Primasius, Cassiodorus, Bede, Anselm.

iii. Universal Historical Method of Interpretation.—A counter-attempt over against Joachim to interpret Revelation in the light of history was made by Nicolas of Lyra (1290, in his Petitis), following (?) therein the lead of Petrus Aurelius (1317). Here for the first time a consistently elaborated world-historical interpretation is carried out from the reign of Domitian to Lyra’s own period. Under this method might be classed the expositions of Luther, Osiander, Strigel, Flacius, Gerhard and Calovius; and English writers such as Napier, Mede and Newton. Throughout these later commentaries a strong antipapal interest which identified the pope with the Antichrist holds a central place—a doctrine which, as we have seen, goes back historically to the immediate disciples of Joachim and likewise followed Franciscan.

iv. Contemporary Historical Method.—Under the stress of the Protestant attack there arose new methods on the papal side, and their authors were the Spanish Jesuits, Ribeira (ob. 1591) and Alcazar (ob. 1614). With these writers we have the beginning of a scientific method of interpretation. They approach the book from the standpoint of the author and seek the clue to his writings in the events of his time. It is from these scholars that subsequent writers of Revelation have learnt how to study this book scientifically.2 This method was adopted and developed by Grotius,3 Hammond, Clericus, Semler, Corredi and Elchhorn, Lücke, Bleek and Ewald, and the consciousness that Rome and not Jerusalem was the object of attack in Revelation became increasingly clear in the works of these scholars. The work of Ramsay, The Letters to the Seven Churches (1904), is a pure representative of this method.

v.—vii. Continuously Historical, Eschatological* and Symbolical Methods.—These methods are now generally regarded as unscientific, and call for no further notice here save to mention that the first was upheld by Hengstenberg, Ebrard, Maitland, Elliott, &c.; the second by Kliefoth, Beck, Zahn, and the third by Aubelen, Luthardt, Milligan and Benson.

The learned Cambridge Commentary by Swete (The Apocalypse of John, 2nd ed., 1907) makes use of several of the methods of interpretation enumerated above. Thus Dr Swete writes (p. ccxviii) of his work: “With the ‘preterists’ (contemporary-historical) it will take its stand on the circumstances of the age and locality to which the book belongs, and will connect the greater part of the prophecy with the destinies of the empire under which the prophet lived; with the ‘futurists’ (eschatological) it will look for fulfillments of St John’s pregnant words in times yet to come. With the school of Aubelen and Benson it will find in the Apocalypse a Christian philosophy of history; with the ‘continuous-historical’ school it can see

---

1 The oldest Latin commentary was written by this scholar (ob. 303). He was the first in extant literature to interpret certain passages in Revelation of Nero.

2 The Jesuit Juan Mariana was the first after Victorinus to explain “ the wounded head ” as referring to Nero. This interpretation was introduced into Protestant exegesis by Corrodi.

3 The beginnings of the literary-critical method are to be found in Grotius. Starting from the different dates assigned by tradition to the exile to Patmos and the different chronological relations implied in the book itself, he conjectured that the Apocalypse was composed several weeks of St John, written in different places at different times, some before, some after A.D. 70. Herein he was followed by Hammond and Lakeremacher, but the idea was before its time and predicted stillbirth.

4 Or futurist. While it is impossible to interpret the Apocalypse scientifically as a whole by the eschatological method, there are undoubtedly some sections in it which must be so interpreted.
in the progress of events ever new illustrations of the working of the grand principles which are revealed. And... it will gladly accept all that research and discovery can yield for the better understanding of the conditions under which the book was written. The chief value of this very scholarly book is to be found in its textual side.

The greater number of the methods discussed above have made no permanent contribution to the exegesis of Revelation; the method among them that has done most in this direction is the contemporary-historical. But, though this method has been applied in its fullness, and that by the keenest exegetes, there remains a consciousness that it has failed to solve many of the problems of the book. In many important points, however, its upholders are agreed, i.e. that the book is directed against Rome, that Nero reditivus is to be recognized in the wounded head, that the number 666 denotes Nero Caesar, and that in chap. xi. the preservation of the temple is foretold. Consequently the date of the composition of the book is placed before A.D. 70. Against the date assigned to the opening verses of this chapter modern scholars can make no objection, but, though this method has been used in many of the books, and is therefore, in it are hopelessly inexplicable; for the latter just as certainly demand a date subsequent to A.D. 70 as xii. 1-2, a date prior to it. If, therefore, the possibilities of exegesis were exhausted in the list of methods already enumerated, science would have put the New Testament Apocalypse aside as a hopeless enigma. But there is no such impasse. For in the New Testament Apocalypse there is not that rigid consistency and unity in detail that the past presupposed. The critical studies of recent years have shown that most of the Old Testament prophetic books are composite. And this holds true in no less a degree of most of the Jewish apocalypses. Such works are to be explained on what might be called the "fragmentary hypothesis."

Other books, like the Ethiopic Enoch, exhibit a series of independent sources connected more or less loosely together. Such are to be explained on the "sources hypothesis." Others, like the Ascension of Isaiah, betray the handiwork of successive editors, and are accordingly to be explained on the "redaction hypothesis.

Now modern scholars have with varying success used in turn these three hypotheses with a view to the solution of the problems of the New Testament Apocalypse. To these we shall now address ourselves.

II. Methods.—Libratory.—Presuming some Degree of Compositionalis in the Book.

1. Redaction Hypothesis.—Suggestions, as we have already observed, had been made in this direction, but it was not till Weizsäcker (Theol. Litteraturzeitung, 1882, p. 78 seq.) reopened the question that the problem was seriously undertaken. In the same year his pupil Völter (Die Entstehung der Apok., 1882, 1885) put forward the bold theory that the original Apocalypse consisted of i. 4-6, iv. 1-10, vi. 1-17, vii. 1-8, viii. 1-13, ix. 1-21, xi. 14-19, xiv. 1-3, 6, 7, xiv. 14-20, xvii. 1-24, xiv. 1-4, xiv. 5-10a, which he assigned to the year A.D. 66 (so the second edition). To this the original author added as an appendix x. 1-13, xiv. 8, xv. 1-18, in A.D. 68-70. The work underwent three later redactions at the hands of successive editors in the reigns of Trajan and Hadrian. Instead of the above complex theory this writer now offers another (Die Offenbarung Johannis, 1904), in which he distinguishes an apocalypse of John, A.D. 65, i. 4-6, iv. 1-10, vi. 1-7, vii. 8, viii.-ix., xi. 14-19, xiv. 1-3, 6-7, xiv. 14-20, xvii. 1-13, xiv. 5-10 (pp. 3-50), an apocalypse of Cerinthus A.D. 70, x. 1-11, xvii. 1-18, xi. 1-13, xii. 1-16, xv. 5-6, 8, x. 1-21, xi. 11-xxii. 8, xii. 9-xxii. 6 (pp. 56-120), a redaction of the work in A.D. 114-15, i. 7-8, v. 9-12, xii. 11-17, xii. 11-18, xii. 18, xiv. 4-5, 9-12, xiv. 1-4, 7, xvi. 19b, xvii. 14, 16, 17, xiv. 14, 22-27, xvii. 1-2, 8-9 (pp. 120-48), and certain additions, i. 1-3, 9-iii. 22, xiv. 13, xvi. 15, xix. 7, 10-20, made in the time of Hadrian (pp. 148-171). First of all it should be observed that Völter was the first to call attention to the radical difference in outlook between vii. 1-8 and vii. 9-17—a difference now generally recognized. Next it is noteworthy that in the second scheme here given Völter has abandoned his theory of a redaction hypothesis in favour of a sources hypothesis+a redactor. The earlier view of Völter was rejected on every side: the later will not prove more acceptable, though individual suggestions of this scholar will be occasionally helpful. The problem was next dealt with by Vischer (Die Offenbarung Johannis, eine Jüdische Apokalypse in Christlicher Bearbeitung, 1886, 2nd ed., 1893), who took iv. 1-xiii. 5 to be a Jewish apocalypse revised and edited by a Christian, to whom he assigned i-iii., v. 9-14, vii. 9-17, xi. 8b, xii. 11, xiii. 9, xiv. 1-5, 12, 13, xvi. 15, xvii. 14, xix. 9, 10, 13b, xx. 4b-5a, 6, xxi. 58-8, 14b, xxi. 6-21, together with some isolated expressions and all references to the Lamb. This scheme met with a better reception than that of Völter, but it also has failed to solve the problem. In 1891 Erbes (Offenbarung Johannis, 1891) maintained that the book was entirely of Christian origin. The groundwork was written about A.D. 60. In this an editor incorporated a Caligula apocalypse. This view has been confirmed in many passages and made considerable additions, especially in the later chapters. Another attempt, mainly from this standpoint, has recently been made by J. Weiss of Marburg (Offenbarung des Johannis, 1894). This writer seeks to establish the existence of an original Christian apocalypse written before A.D. 60. This included (see p. 111) i. 4-6, 7, 8-9, 19, ii-vii., x., xii. 7-12, xiii. 11-18, xiv. 1-5, 14-20, xx. 1-15, xiv. 1-14, xxii. 3-5, 8 seq. With this a Jewish apocalypse (x-xi. 13, xi. 2-14, xvii. 1-7, xxv.-xxii., xii. 9-27) written A.D. 70, was incorporated by the redactor. This latter apocalypse consisted of a series of independent prophetic visions which appeared to have come to an impasse in view. This redactor, moreover, was the first who gave to the Apocalypse the character of an attack on the Roman Empire and the imperial cult by means of a series of small additions. In the above work we have a combination of the redaction and sources hypotheses.

2. Sources Hypothesis.—The same year Weyland (Theol. Tijdsch., 1886, 454-70; Omwerkingen en Complaat-Hypothese toegest op de Apoc. van Johannis, 1888) advanced the theory of two Jewish sources (1 and 3), which were subsequently worked over by a Christian redactor. Such a theory as that just mentioned hopelessly fails to account for the linguistic unity of the book.

A very elaborate form of this theory was issued in 1884 (Offenbarung Johannis) by Spitta, who found three main sources in the Apocalypse. First, there was the primitive Christian apocalypse embracing the letters and the seals written by John Mark soon after A.D. 60.; i. 4-6, 9-19, ii. 1-iii. 22, iv.-vi., viii. 1, viii. 9-17, xiv. 9b, 10, xxii. 8, 10-13, 16a, 17, 18a, 20b-21. Secondly, the trumpet source of the time of Caligula (circa 40.),—i. 8, viii. 2-ix., x. 17, xi. 15, xii-xiii. 18, xiv. 1-11, xiv. 12-20, xiv. 11-22, xiv. 1-3, 8-15, 17, 18, 56, 6a. Thirdly, the vials source from the time of Pompey (circa 63.),—x. 1b, 2a, 8a, 9b, 10-11, xi. 1-13, 15b, 17, 18, xiv. 14-20, xv. 2-6, 8, xvi. 1-12, 178, 21, xvii. 1-6a, xviii. 1-23, xix. 1-8, xxi. 9-xii. 3a, 15. The rest of the book is from the hands of the redactor. In 1891 Schmidt redid the book into three independent sources which were put together by a redactor (Anmerkungen über d. Komposition der Offenb. Johannis). In 1893 Briggs (Messiah of the Apostles, 1893) developed this theory to a still more extreme degree.

3. Fragment Hypothesis.—The previous theories have brought to light and emphasized the fact that within the Apocalypse there are passages-inconsistent with the tone and character of the whole. But, notwithstanding this fact, the Apocalypse gives a strong impression of its unity. Thus apparently the only remaining theory which can account for both these phenomena is that at which we have now arrived, i.e. the fragment hypothesis. To Weizsäcker we owe the first statement of this theory: In 1883 (Theol. Litteratur. pp. 78-9) he suggested...
that while the book is a unity the author made free use of older materials. Later, in his *Apostolic Age* (1886, 2nd ed. 1892), he specifies these additions as vii. 1-8 (A.D. 64-66), x-xi. 1-13 (circa 67), xi. 11-17 (circa 69), xii. (time of Vespasian), xvii. (time of Domitian).

Sabatier (*Les Origines littéraires... de l'apocalypse*, 1888) regards the book as a unity into which its author had introduced older Jewish materials not always consistent with their new contexts, such as xi. 1-13, xii.-xiii., xiv. 6-20, xvi. 13, 14, 16, xvii. 1-xii. 2, xii. xii-x. 10, xii. 9-xii. 5. The author wrote x. with a view to adapting xi. 1-13 to its new context. Schoen (*L'Origine de l'apocalypse*, 1889) attached himself in the main to the scheme of Sabatier. Both these writers assign the Apocalypse to the reign of Domitian.

For scholars, however, though to the superficial student they seem to prove that everything is possible and nothing certain, there have certainly thrown great light on the literary character of the Apocalypse. Though differing in detail, they tend to show that, while the book is the production of one author, all its parts are not of the same date, nor are they one and all his first-hand creation. For many of the facts, the discovery of which we owe to the literary critics, have made the assumption of an absolute unity in the details of the Apocalypse a practical impossibility. Inconsistencies manifest themselves not only between certain sections and the main scheme of the book, but also within their immediate contexts. These sections are vii. 1-8a, xi. 1-13, xii. xii-xi. 10, xvii. xx., xii. 9-xii. 5. Some of these sections (xi., xii., xii., xiii.) contain elements that cannot be explained from any of the above methods. The symbols and myths in these are not the creation of the writer, but borrowed from the past, and in not a few instances the materials are too foreign to his subject to lend themselves to his purpose without the help of artificial and violent expedients. For the elucidation of these foreign elements a new method—the traditional-historical—is necessary, and to the brilliant scholar Gunkel we owe its origin.

Gunkel (*Schafung und Chaos in Urzeit und Endzeit*; *Eine religiösgeschichtliche Untersuchung über Gen. 1 und Joh. 12, 1895*) opened up new lines of investigation. He criticizes sharply (pp. 173 sqq., 233 sqq.) former methods of interpretation, and with the ardour of a discoverer of a new truth seeks to establish its currency throughout the entire field of apocalyptic. To such an extreme does he carry his theory that he denies obvious references to historical personages in the Apocalypse, when these are clothed in apocalyptic language. Thus he refuses to recognize Nero in the beast and its number. But apart from its extravagances, his theory has undoubted elements of truth. It is true that tradition largely fixes the form of figures and symbols in apocalyptic. Yet each new apocalyptic is to some extent a reinterpretation of traditional material, which the writer uses not wholly freely but with reverence from the conviction that they contained the key to the mysteries of the present and the past. From this standpoint it may be argued that every apocalypsis is in a certain sense pseudonymous; for the materials are not the writer's own, but have come down to him as a sacred deposit—full of meaning for the seeing eye and the understanding heart. On the other hand, since much of the material of an apocalyptic is a reinterpretation, it is necessary to distinguish between its original meaning and the new turn given to it in the Apocalypse. At times details in the transmitted material are unintelligible to our author, and these in some cases he omits referring to in his interpretation. The presence of such details is strong evidence of the writer's use of foreign material.

As an illustration of his theory Gunkel seeks at great length to establish the Babylonian origin of chap. xii. of the Apocalypse. His investigation tends to show that in the course of tradition cosmological myths are transformed into eschatological dogmas.

The above method was adopted by Boussct in his work *Der Antichrist in das 'Uhrien und der Neuen Testament, und der alten Kirche* (1895), in which he sought to show that a fixed tradition of the Antichrist originating in Judaism can be traced from New Testament times down to the middle ages, and that this tradition was in the main unaffected by the Apocalypse, though in chap. xi. the Apocalypse shows dependence on it. Next in 1896 he published his commentary *Die Offenbarung Johannis* (2nd ed. 1902). In this work he availed himself of the results of the past and followed the three approved methods—the contemporary-historical, the fragmentary and the traditional-historical.

Julicher (*Einleitung in das Neue Testament*, 1901, pp. 204-29) adopts the same three methods of interpretation.

Holtzmann (*Einleitung in das N.T.*, 1892; *Hand-Commentar*, 1893; *Lehrbuch der NTlichen Theol.*, i. 403-76) holds mainly to the contemporary-historical method in his earlier works, though recognizing signs of a double historical background; but in his later work the importance of tradition as a source of the writer's materials is fully acknowledged.

In 1902 O. Pfeiderer in the second edition of his *Urchristentum* (1902, pp. 281-335) abandoned his former view on the Apocalypse and followed essentially the lines adopted by Boussct, though the details are differently treated.

In the same year Porter's able article on "Revelation" appeared in Hastings' *Bible Dictionary* (iv. 239-66), and in 1905 his still fuller treatment of the same theme in *The Messages of the Apocalyptic Writers*, 169-204. To these works the present writer is indebted for many a suggestion.

A small commentary (pub. date) by Anderson, Scott follows in some measure the lines laid down in Boussct and Porter.

**Psychological Method.**—It might be supposed that all possible methods had now been considered, and that a combination of the three methods which have established their validity in relation to the interpretation of the Apocalypse would be adequate to the solution of all the problems of the book, but this is not so; for even when each in turn has vindicated the provinces in the book that rightly belong to it, and brought intelligibility into these areas, there still remain outlying regions which they fail to illumine. It is not indeed that these methods have not claimed to answer the questions at issue, but that their solutions have failed to satisfy the larger body of reasonable criticism. The main problem, which so far has not been satisfactorily solved, may be shortly put as follows: Are the visions in the Apocalypse the genuine results of spiritual experiences, or are they artificial productions, mere literary vehicles of the writer's teaching? Weizsäcker unhesitatingly advocates the latter view. But the serious students of later times find themselves unable to follow in his footsteps. The writer's belief in his prophetic office and his obvious conviction of the inviolable sanctity of his message make it impossible to accept Weizsäcker's opinion. Nor is it possible to reconcile Gunkel's theory in *Schafung und Chaos* as an adequate explanation, who explained the author's conviction of the truth of his message as springing always from the fact that he was dealing with traditional material. This theory, which we have already dealt with in other connexions, is undoubtedly helpful, but here we require something more, and Gunkel has in consequence of Weinær's work (*Wirkungen des Geistes und der Geister*, 1890) subsequently acknowledged that actual spiritual experiences lie behind some of the visions in apocalyptic (*Kautsch, Pseud. des A.T.*, ii. 341 sqq.). The fact of such visionary experience can hardly be determined in what extent it underlies the revelations of apocalyptic. For a short discussion of this question we might refer to Boussct's *Offenbarung Johannes*, pp. 8 sqq., and Porter's article on "Revelation" in Hastings' *Bible Dictionary*, iv. 248 sqq.

**Methods of Interpretation.**—As a result of the preceding inquiry we conclude that the student of the Apocalypse must make use of the following methods—the contemporary-historical, the literary-critical (fragmentary hypothesis), the traditional-historical and the psychological. Each of these has its legitimate province, and the extent of this province can in no cases be determined with reasonable certainty.

**Plan and Detailed Criticism of the Book.**—Two theories have been advanced to explain the plan and order of the book. The
first of these is the recapitulation theory which Tyconius originated and Augustine adopted, and which has been revived in later times by Hofmann, Hengstenberg and others. This theory holds that no progress is designed in the successive visions of the seven seals, the seven trumpets and the seven bowls; for that in the vision of the seals we have already an account of the last judgment (vi. 12-17) and the blessed consummation (vii. 9-17). Thus the three groups form parallel accounts and contain the same or closely related material. But such a view is in conflict with the fact that the Apocalypse exhibits a steady movement from a detailed account of the condition of actual individual churches on an ever-widening sweep to the catastrophes that will befall every nation and country till at last evil is finally overthrown and the blessedness of the righteous consummated. Accordingly later exegetes 1 hold that the seventh in each series is unfolded in the series of seven that follows. But to this theory also it has been objected (Holtzmann, Hand-Commentar. p. 294) that the bowls are in the main a repetition—in parts weaker, in others stronger—of what has already been put forward in the trumpets; that before the seventh member of each hebdodem there is a pause occasioned by the insertion of visions of a different nature; that the final judgment has already been depicted in vi. 17, and yet further descriptions recur in x. 6, 7, xi. 15-18, xiv. 7, xix. 11: the temple in heaven is opened in xix. 19 and yet again in xv. 5: heaven itself has already been rent in sunder in vi. 12-17, and yet in viii. 7-12 is supposed to be in its ancient order: all green grass is burnt up in vii. 7, yet in ix. 4 the locusts are not permitted to injure the grass, and other like inconsistencies.

The impossibility of logically carrying out either theory has given rise to doubts as to the unity of the book. Holtzmann (Hand-Comment. 294) represents its structure as follows:

i. 1-8 Introduction.
i. 9-xiii. 22 Group of seven letters.
iV.-v. 14 Heavenly scene of the Vision.
i. 1-17 Six seals.
xix. 1-17 The sealed and the blessed.
viii. 1-5 The emergence of the trumpets from the seventh seal.
viii. 6-x. 21 Six trumpets.
x. 1-xi. 14. Destiny of Jerusalem. xii. 15-19. The seventh trumpet. xii. 1-xiv. 5. The great visions of the three chief enemies and of the Kingdom of the Messiah.
xiv. 6-20. Return to the earlier connexion.
xv. 1-xvi. 1. Transition to the bowls.
xvi. 2-21. Seven bowls.
xvii. 1-xix. 10 The great Babylon. xix. 11-xx. 15 Final catastrophes. xxi.-xxii. 5. The New Jerusalem.
xxii. 6-21 Conclusion.

It is noteworthy that the sections on the right hand correspond in the main to the elements which have been those to which

1 Swete divides the Apocalypse first of all into forty-two minor sections. Next he groups these sections into fourteen larger masses of apocalyptic matter, and by a process of synthesis seeks to arrive at the plan on which the author constructed his book. In so doing he points out that we become conscious of a great cleavage which practically divides the book into two parts, i. 9-xiv. 14 and xii. 1-xvii. 5, independently of the prologue and greeting, i. 1-8, and the epilogue and benediction, xxii. 6-21. A further study of the leading thoughts of the above parts enables him to set forth the scheme of the book as follows:

PROLOGUE AND GREETING, i. 1-8.

Part II. Vision of the Mother of Christ (i.e. the Church) and her enemies, xii. 1-xiii. 18.

REVELATION, BOOK OF

latter, in which the Apocalyptic looks forward prophetically to the issue, the assurance held out is of ultimate victory, but of victory through death or martyrdom. In the former (Jewish or Christian-Jewish fragment) the sealing seemed to have carried with it the assurance of deliverance from physical death, as in Rev. ix. 4 sq. Thus in its inner context this meaning can hardly be retained. Not improbably the sealing means to our author the preservation not from death, but through death from unfaithfulness, and the number 144,000 would signify mystically the entire body of true Christians, which formed the true people of God.

Chapter vii., then, interrupts the development of the author's plan, but the interruption is deliberate. He wishes to encourage the persecuted church not only to face without fear, but also to meet with triumphant assurance the onset of those evils which would bring panic and despair on the unbelieving world.

These chapters, though presenting some minor difficulties, do not call for discussion here. They recount the six partial judgments which followed the opening of the seventh seal and the blasts of the six trumpets.

x.-xi. 1-13.—This section bristles with difficulties. Chapter x. forms an introduction to xi. 1-13. In it the prophet receives a new commission, x. 11: "Thou must prophesy again over many peoples and nations and tongues and kings." This new commission explains his departure from the plan pursued in the earlier chapters of developing the seventh in each series into a new series of seven. The seer has a vision of the seven thunders, but whose they are remains in the hollow silence of the Eighteenth Trumpet. The seer is instead to write down the new book of prophecies. The end is at hand. It is noteworthy that in the earlier visions it was Christ who spoke to the seer. Here and in the later visions, especially those drawn from foreign sources, it is an angel.

In xi. 1-13 we have a characteristic illustration of our author's dependence on traditional materials and his free adaptation of them to meanings other than originally belonged to them. For it is generally agreed among critics that xi. 1-13 is borrowed from Jewish sources, and that this fragment really consists of two smaller fragments, xi. 1-2 and xi. 3-13. The former oracle referred originally to the actual Temple, and contained a prediction of the preservation of the Temple. It must have been written before a.d. 70 and probably by a Zealot.1 But our author could not have taken it in this literal sense if he wrote after a.d. 70 or even anterior to that date, owing to the explicit declaration of Christ as to the coming destruction of Jerusalem. The passage, then, must have a spiritual meaning, and its purpose is the encouragement of the faithful by the assurance of their deliverance not necessarily from physical death but from the dominion of the evil one. In xi. 3-13 we have another Jewish fragment of a very enigmatic character. Bousset has shown with much probability that it is part of the Antichrist legend. The prophecy of the two witnesses and their martyrdom belongs to this tradition. The fragment was apparently written before a.d. 70, since it speaks of the fall of only a tenth of the city, xi. 13.2 The significance of this fragment in our author's use of it is similar to that of xi. 1-2. The details defy at present any clear interpretation, but the incorporation of the fragment may be due in general to the emphasis it lays on the faithful witness, martyrdom and resurrection of the saints.

xi. 14-19.—The seventh trumpet, xi. 15, ushers in the third woe, xi. 14. Its contents are given in xii.—xx. In xi. 15-19 the seer hears great voices in heaven singing a triumphant song in anticipation of the victory that is speedily to be achieved. This song forms a prelude to the chapters that follow.

1 The Zealots occupied the inner court of the Temple during its siege by the Romans.

2 The linguistic evidence, as Bousset has pointed out, confirms the critical conclusion that xi. 1-13 were independent sources. For whereas in ix.—x. the verb almost regularly begins the sentence and object follows it, in xi. 1-13 the verb usually follows the object; and root qal of qal instead of qal of the verb and the subject nearly always. The order of the genitive in xi. 4 is elsewhere unknown in the Apocalypse, and in xi. 3 the construction of idem followed by dat instead of infinitive or prep is unique in this book.

xiv.—This is the most difficult chapter in the book. Its main intention in its present context is apparently to explain Satan's dominion over the world and the bitterness of his rage against the church and against Christ. Christ, indeed, escapes him and likewise the Jewish Christians ("the woman," xii. 16) but "the rest of her seed," xii. 17 (the Gentile Christians?), are exposed to his fury. But his time is at hand; together with his hosts he has been cast down from heaven, and the earth has "hath a short time." The attribution of the seven heads and ten horns to the dragon, xii. 3, points forward to Rome, which is regarded as a temporary incarnation of Satan, xiii. 1, xvii. 3.

But, though a few of the leading thoughts of this chapter may be obvious, we are plunged into problems that all but defy solution when we essay to discover its origin or interpret its details. Most scholars are agreed that this chapter is not, except in the case of a few sentences, the work of our author. In other words, it has been taken over from pre-existing material—either Christian or Jewish— and the materials of which it is composed are ultimately derived from non-Jewish sources—either Babylonian, Greek or Egyptian—and bore therein very different meanings from those which belong to them in their present connexion. Furthermore, the materials are fragmentary and the order irregular.

(a) First of all, the chapter is not the free creation of a Christian writer. Such an one could never have so represented the life of Christ—a child persecuted by a dragon and carried off to God's throne. No mention of Christ's earthly life and crucifixion are made, and the whole situation of the victory over Satan, who has to a certain degree been adapted to a Christian environment by the insertion of the 10th-17th verses.

(b) The order is not original. The flight of the woman is mentioned in verse 6 to a place of refuge prepared for her by God. Then comes an account of the casting down of Satan from heaven. Then again in 13-16 the flight of the woman is described. This fact has been variously accounted for by different critics. Wellhausen regards 1-6 and 7-14 as doublets, and differentiates two actions in the original account which are here confused. Spitta takes verse 6 to be an addition of the redactor, which describes prophetically, he states, with a double meaning, 1-5 in a different passage. In any case we should probably agree with the contention of J. Weiss, supported by Bousset in the second edition of his commentary, that 7-12 is a fragment of a Jewish apocalypse, of which 10-11 is a continuation of our author. Next that 6 is a doublet of 13 sqq. What then is to be made of 15-17? Different explanations have been offered. Gunckel3 traces it to a Babylonian origin. He urges that an adequate explanation is impossible on the assumption of a Jewish or Christian origin. At the base of this account lies the Babylonian myth of the birth of the sun-god Marduk, his escape from the dragon who knows him to be his destined destroyer, and the prosecution of Marduk's mother by the dragon. But Gunckel's explanation is an attempt to account for one ignotum per ignotius; for hitherto no trace of the myth of the sun-god's birth and persecution and the flight into the wilderness has been found in Babylonian mythology. Moreover, Gunckel no longer lays emphasis on the Babylonian, but merely on the mythical origin of the details. A more satisfactory explanation has been offered by Dietricher (Abraxas, 117 sqq.), who finds in this chapter an adaptation of the birth of Apollo and the attempt of the dragon Python to kill his mother.

3 Schöpfung und Chaos § 3, Religionsgesch. Verständnis d. N.T., 54 sqq.
Leto, because it was foretold that Leto's son would kill
the dragon. Leto escapes to Ortygia, which Poseidon covers with
the sea in order to protect Leto. Here Apollo is born, who
two days later slays the dragon. Yet another explanation from
Egyptian mythology is given by Bousset ("Offenbarung
Here the goddess mother is represented with a sun upon her
head. Typhon slays Horus. Hator, his mother, is persecuted
by Typhon and escapes to a floating island with the bones of
Horus, who revives and slays the dragon. There are obvious
points of similarity of derivation, between the details in
our text and the above myths, but the subject cannot
be further pursued here, save that we remark that in the sun
myth the dragon tries to kill the mother before the child's birth,
whereas in our text it is after his birth, and that neither in
the Egyptian nor in the Greek myth is there any mention of the
flight into the wilderness.

The insertion of the alien matter 7-12 between 7-5 and 13-17
may be due to our author's wish to show that the expulsion of
Satan from heaven after Christ's birth and ascension to heaven
was owing in some measure to Christ. Though he does not allow
Michael's name to remain in the borrowed passage, 7-12—a fact
which shows how dependent the writer was on tradition.

xiii.—In this chapter we have the two beasts which symbolize
respectively Rome and the Roman provincial priesthood of
the imperial cult. Thus the world powers of heathen statesmanship
and heathen religion are leagued in a confederacy against the
rising Christian Church. Against these the church is not to
attempt to use physical force; its only weapon is to be passive
endurance and loyalty to God.

That this chapter must be interpreted by the contemporary-
historical method is now generally admitted. Even Gunkel
is obliged to abandon his favourite theory here, though he
contests strongly the recognition of any allusion to Nero.
Various solutions have been offered as to the seven emperors
designed by the seven heads of the beast, xiii. 1. But the
details of this passage are not sufficiently definite to determine
the question here. It will return in chapter xvii. There are,
however, two facts pointing to a late date. The first is the
advanced stage of development of this, the Neronic-Antichrist
legend. One of the heads is smitten unto death, but is healed
and lives for another thousand years. This points, we may here assume, to the Nero redivius legend, which could not have arisen
for a full generation after Nero's death, and the assumption receives
large confirmation from the most probable interpretation of the
enigmatical verses, xiii. 18, "the number of the beast is
six hundred and sixty six." Four colonial scholars, Fritsche, Benary, Hitzig and Reuss, independently recognized
that Nero was referred to under the mystical number 666.
For by transliterating KAIOEP NEPOV into Hebrew י"ע י"ע
and adding together the sums denoted by the Hebrew letters
we obtain the number 666. This solution is confirmed by the
fact that it is possible to explain by it an ancient (Western?)
variant for the number 666, i.e. 616. This latter, which is
attested by Irenaeus (v. 30, 1), the commentary of Ticonius,
and the uncial C, can be explained from the Latin form of the
name Nero, which by its omission of the final n makes the sum
total 616 instead of 666.

The above solution may be regarded as established, though
several scholars, as Oscar Holtzmann ("Stade's Geschichte des
Volkes Israel," ii. 661), Spitta and Erbes, have contended that
616 was the original reading (I'אא קא"אא 616) and that
1 On the possibility of other points of contact between the
Apocalypse and Egyptian mythology, see Mrs Grangellen's article,
"Egyptian Mythology and the Bible," in the Monist (1906), pp.
169-200.

2 In xiii. 2 the description of the beast unites the features of the
four beasts of Daniel's vision (vii.). It is clear that our author
identified the fourth beast (vii. 23) with Rome, as did also the
author of 4 Ezra xii. 10. But this was not the original significance
of the fourth beast, for the author of Daniel referred thereby to the
Greek empire; but, since the prophecy was not realized, it was
subsequently reinterpreted, and applied, as we have observed, to
Rome.

chapter xiii. was part of a Jewish apocalypse written under
Caligula between the years 39 and 41. But this Caligula
hypothesis cannot be carried out unless by a vigorous use of
the critical knife, in the course of which more than a third of
the chapter is excised. Moreover the number 616 is too weakly
supported to admit of its being recognized as the original.

The figure of the first beast presents many difficulties, owing
to the fact that it is not freely invented but largely derived
from traditional elements and is by the writer identified with
the four-beast legend. The second beast, signifying the
pagan priesthood of the imperial cult, called "the false
prophet" in xvi. 13, appears to be an independent development
of the Antichrist legend.

xiv.-xvi.—These chapters contain a vision of Christ on Mount
Zion and the 144,000 of the unsealed that follow Him. xiv. 1-5,
the last warnings relating to the harvest and vintage of the
world, xiv. 6-20: the vision of the wrath of God in the out-
pouring of the seven bowls containing the seven last plagues,
xv.-xvi.

In the above section most critics are agreed that xiv. 14-20
originally represented the final judgment and was removed
from its rightful place at the close of an apocalypse to its
present position. In its original setting "the one like unto a
Son of Man, having on his head a golden crown" (xiv. 14),
undoubtedly designated the Messiah, but the transformation
of the final judgment into a preliminary act of judgment by a
redactor, necessarily brought with it the degradation of the
Son of Man to the level of a mere angel. Some critics hold
that this apocalypse was the apocalyptic groundwork, but
Bousset is of opinion that it stood originally in connexion with
xii. 1-13.

As regards xvi. the views of critics take different directions,
but that of Bousset followed by Porter seems the most reason-
able. This is that this chapter forms an introduction to xvii.,
which was an independent fragment. The writer throws this
introduction into his favourite scheme of seven acts, in this
case symbolized by seven bowls. The earlier verses, 2-11, do
not amount to much beyond a repetition of what is found in
viii.-ix., save that as a preparation for xvii. references are
inserted to the beast and his worshippers (ver. 2) and to Rome
(vers. 10). In xvi. 12-16 is a revised form of an older tradition.
This chapter presents great difficulties, especially if
with the older text, 14-16. To meet this difficulty, recent
scholars have described the text, on the authority of Sir
Anderson the Greek Interpreter—Anderson Scott—though he assigns the book to the year A.D. 77, is yet willing to admit that the book though
composed in the reign of Vespasian was "reassembled with additions
by the same hand after the death of Domitian" (Revelation, p. 56).
Our author represents himself as writing under the sixth
emperor. Five have already died, the seventh is yet to come,
to be followed by yet an eighth, who is one of the seven (i.e.
Nero). In order to arrive at the date here implied, we can
begin the reckoning from Julius Caesar or Augustus, we can include or exclude Galba, Otho and Vitellius, and, finally, when we have drawn our conclusions from these data, there remains the possibility that the book was after all not written under the sixth emperor, but was really a *vaticinium ex eventu*. According to the different methods pursued, some have concluded that Nero was the sixth emperor, and thus dated the Apocalypse before A.D. 70; others Vespasian, and yet others Domitian. No solution of the difficulties of the chapter is wholly satisfactory, but the best yet offered seems to be that of Bousset (Offenbarung, 410-18). He holds that 1-7, 9-11, 15-18, belong to an original source, which was written in the reign of Vespasian and represents the earlier stage of the Neronic myth. To a reviser in Domitian's reign we owe 8, 12-14, and 61, a clause in the latter which another is 5 by καλ οκ οικ του. If the clause καλ οκ του αματοτων μασενων Ἰησοῦς in 6 is an addition, then he thinks the source was Jewish and the "blood of the saints" was that shed at the destruction of Jerusalem, and the forecast of the author related to the destruction of Rome. When the reviser recast the passage it dealt not with the destruction of Jerusalem, but with the persecution of the Christians. Nero was now a demonic monster from the abyss, and the ten kings no longer Parthians but ghostly helpers of Nero. The destruction of Rome has now become a secondary event, the reviser's thought is fixed on the final strife between the Lamb and the Antichrist.

xviii.—xix. 10.—This section describes in prophetic language borrowed almost wholly from Isaiah and Jeremiah the coming judgment of Rome, and gives the ten(lamentations of the kings and the merchants and the seamen over, and the thanksgivings in heaven for her overthrow.

xix. 11-21.—The victory of the warrior Messiah over the two beasts, the Roman Empire and the imperial cultus and the kings of the earth. Many of the ideas set forth in earlier chapters here coalesce and find their consummation. The Messiah, an earthly and escape from the dragon was recounted in xii. 5, and who was to rule the nations with a rod of iron, at last appears in discharge of His office. The beast and the false prophet who are described in xiii. are cast alive into the lake of fire, and the kings of the earth who had assembled for this conflict, xvii. 14, xviii. 14, were slain by the sword of Him that sat on the horse.

The conception of the Messiah may be Jewish: at all events it is not distinctively Christian. The title "Word of God" can hardly be said to establish any connexion with the prologue of the Fourth Gospel; for the conceptions of the Messiah in that Gospel and in these chapters belong to different worlds of thought.

It is to be observed that our author follows the apocalyptic scheme of two judgments which is first attested about 100 B.C. The first judgment precedes the establishment of the temporary Messianic kingdom, as here in xix. 10-21; and the final judgment follows at its close, as here in xx. 7-10.

xx. 1-6.—The millennium, or the period between the first and final judgments, when Christ, with His chosen, reigns and Satan is imprisoned. Rome has been overthrown, but, as Rome is only the last secular manifestation of Satan, there is yet the last struggle with Satan and his adherents. But the time for this struggle has not yet arrived. Satan is bound 1 and cast into the abyss, and the kingdom of Christ and of the martyrs and faithful confessors established for a thousand years. Thus it is shown that evil will be finally overcome; for that the true and ultimate power even in this world belongs to Christ and those that are His.

The main features of this section have been borrowed from Judaism. The Messianic kingdom was originally conceived of as of everlasting duration on the present earth, but about 100 B.C. this idea was abandoned and the hopes of the faithful were directed to a temporary earthly kingdom of 1200 or 1000 years of indefinite duration (see R. H. Charles, *Critical History of the Doctrine of a Future Life*, pp. 201-4, 261, 286, 288). Moreover, the expectation that the saints would rise to share in the blessedness of this kingdom is also found in Judaism, 4 Ezra vii. 18 (cf. *vulgar.* p. 285).

xx. 7-9.—Release of Satan and final assault on the city of God by the hosts of Gog and Magog at the instance of Satan. Satan and the beasts condemned to eternal torment.

xx. 11-14.—The Final Resurrection and Judgment.

xxi. 1-8.—The new heavens and the new earth. The language in this and the following section is highly figurative; but as Porter has well remarked: "Figurative language is the only language in which we can express our hope of heaven, and no figures can have greater power to suggest this hope than those taken from the literal longings of exiled Israel for the recovery of her land and city."

xxi. 9-xxii. 5.—The vision of the New Jerusalem. There are several grounds for regarding this section as an independent source possibly of Jewish origin and subsequently submitted to a Christian revision. This view is taken by Vischer, Weyland, Spitta, Sabatier, J. Weiss, Bousset and others. Our author has incorporated it as describing the consummation of the prevision contained in xi. 15-18, in which he foresaw the time when the kingdom of the world would become the kingdom of our Lord and of His Christ, and the saints should enter on their reward. Moreover, he has already hinted at its contents in xix. 7 and xx. 3, where he speaks of the church as a bride and the marriage supper of the Lamb. But the section betrays inconsistent conceptions. The standpoint of the heavenly Jerusalem is abandoned in xx. 24-27, xxii. 2, and the context implies an earthly Jerusalem to which the Gentiles go up as pilgrims. Outside the gates of this city are unclean and abominable things. These inconsistencies are best explained by the hypothesis that our author was drawing upon a literary fixed tradition. The doublets in xx. 23 and xxii. 3, in xx. 25 and xxii. 5a, and in xx. 27 and xxii. 3, point in the same direction. Various alterations were introduced, according to Bousset, by the last redactor, such as the frequently recurring reference to the Lamb, xxii. 9, 22, 23, 27, xxii. 1, 3. In xxii. 3 the fact that the words "of the Lamb" are an addition is clear from the context; for, after the clause "the throne of God and of the Lamb shall be therein" the singular follows, "His servants shall do Him service."

xxii. 6-21.—The conclusion. The promises are sure, the end is near and the judgment at hand. The words of the book are the message of Christ Himself and are inviolable.

Unity.—From the preceding sections it follows that we cannot describe a single literary unity to the book. The book is most probably the work of a single author, but it was not written wholly at one date, nor have all the parts come directly from one brain. We have several good grounds, for regarding vii. 8, vii. 13-15, xiii., xvi., xix., xxii., as wholly or in part independent sources, which our author has laid under contribution and adapted more or less adequately to his purpose. He appears to have taken over with but slight modification xx. and xxi. 9-xxii. 5. Furthermore, while certain fragments such as xi. 1-2 presuppose a date anterior to A.D. 70, others, as xvi. 12 and xvii. 13, require a date later. The parts of xvi. 27, postulate a Vespasianic date as the earliest admissible, and, finally, the composition of the book in its present form cannot be placed before the closing years of Domitian. But to this question we shall return presently.

Nevertheless, the book exhibits a relative unity; for, whatever digressions occur in the development of its theme, the main object of the writer is never lost sight of. This relative unity is manifested also in the uniform character of the language, a uniformity, however, which is occasionally conspicuous by its absence in the case of independent sources, as in xi. 1-13. The author or the final redactor has impressed a certain linguistic character on the book, which differentiates it not only from all secular writings of the time, but also from all the New Testament books, including the Johannine. And yet the Apocalypse shows in many of its phrases an undoubted affinity to the latter—
a fact which requires for its explanation the assumption that the book emanated from certain literary circles influenced by John.

**Date.**—There are many indications of the date, which may be summarized as follows: (a) Condition of the Asian churches. (b) Persecution of the church. (c) Attitude of the author to Rome. (d) The Antichrist legend. (e) Primitive tradition and its confirmation through the discovery of references in the text to certain edicts of Domitian. As a result of these considerations we may arrive at the date of the work with almost greater certainty than that of any other New Testament book.

Domitian's reign.
the average daily consumption of the workman. . . . Barley was largely the food of the poor." According to the words just quoted from the Apocalypse, there was to be a dearth of grain and a superfluity of wine; the price of the wheat was to be seven times the ordinary, according to Reinach's computation, and that of the barley four times. This strange statement suggested some historical allusion, and the discovery of the allusion was made by Reinach, who points out that Domitian by an edict in A.D. 92 prohibited the planting of new vineyards in Italy, and ordered the reduction of those in the provinces by one-half. As Asia Minor suffered specially under this edict, an agitation was set on foot which resulted in the revocation of the edict. In this revocation the Apocalypst saw the menace of a famine of the necessaries of life, while the luxuries would remain unaffected. From his ascetic standpoint the revocation of the edict could only pander to drunkenness and immorality. Reinach's explanation of this ancient crux interpresium, which has been accepted by Harnack, Boussert, Porter, Sandy, Swete and others, fixes the earliest date of the composition of the Apocalypse as A.D. 93. Since Domitian died in 96, the book was therefore written between A.D. 93 and 95.

Author.—Before entering on the chief data which help towards the determination of this question, we shall first state the author's standpoint. His book exhibits a Christianity that is—as Harnack (Encyc. Brit., xx. 498) writes—"free from the law, free from national prejudices, universal and yet a Christianity which is independent of Paul. . . . The author speaks not at all of the law— the word does not occur in his work; he looks for salvation from the power and grace of God and Christ alone . . . nowhere has he made a distinction between Gentile and Jewish Christians. . . . The author of the Apocalypse has cast aside all national religious prejudices. The writer is not dependent, consciously or unconsciously, on the Pauline teaching. He has won his way to universalism, not through the Pauline method, but through one of his own. He has no serious preference for the people of Israel as such, but only for the martyrs and confessors, who shall belong to every tribe and tongue and people and nation (vi. 9 seq.). The unbelieving Jews are "a synagogue of Satan" (ii. 9).

Yet, on the other hand, our author's attitude to the world reflects the temper of Judaism rather than that of Christianity. He looks upon the enemies of the Christian Church with un concealed hatred. No prayer arises within his work on their behalf, and nothing but unalloyed triumph is displayed over their doom. The Christian duty of love to those that wrong us does not seem to have impressed itself on our Apocalypst.

Is the Apocalypse pseudonymous?—All the Jewish apocalypses are pseudonymous, and all the Christian with the exception of the Shepherd of Hermas. Since our book undoubtedly belongs to this category, the question of its pseudonymity must arise. In the articles on Apocalyptic Literature and Apocryphal Literature (pp. vi) we have shown the large lines of differentiation between apocalyptic and prophecy. The chief ground for resorting to pseudonymous authorship in Judaism was that the books of the Old Testament were ascribed to various persons who would appeal to them was obliged to do so in the name of some great figure of the past. Furthermore, this belief that prophecy had ceased led the religious personalities of the later time to authenticate their message by means of antedated prophecy. They procured confidence in their actual predictions by appealing to the literal fulfilment of such antedated prophecy. In such literature we find the characteristic words or their equivalents: "Seal up the prophecy; it is not for this generation," which are designed to explain the late appearance of the works in which they are found. But this universal characteristic of apocalyptic is almost wholly lacking in the New Testament Apocalypse. The valētinum ex evantu plays but a very small part in it. Moreover, the chief ground for the development of a pseudonymous literature was absent in the early Christian church. For with the advent of a Christianity prophecy had sprung anew into life, and our author distinctly declares that the words of the book are for his own generation (xxii. 10). Hence we conclude that the grounds are lacking which would entitle our assuming a priori that the Apocalypse is pseudonymous.

Was the Author the Son of Zacchaeus, the Apostle?—The evidence of the book is against this assumption. The writer demands a hearing as a prophet (xxii. 6), and in no single passage makes any claim to having been an apostle. Nay more, the evidence to the contrary is so far as it goes, is against such a view. He never refers to any previous intercourse with Christ such as we find frequently in the Fourth Gospel, and when he speaks of thetwelve apostles of the Lamb (xxi. 14) he does so in a tone that would seem to exclude him from that body. Here internal and external evidence are at strife; for from the time of Justin onwards the Apocalypse was received by the church as the work of the Apostle John (see Swete, op. cit. p. clxxv). If the writer of the Fourth Gospel was the Apostle John, then the difficulties for the assumption of an apostolic authorship of the Apocalypse become well-nigh insuperable. Nay more, the difficulties attending the assumption of a common authorship of the Gospel and Apocalypse, independently of the question of the apostolic authorship of the Gospel, are practically insuperable. Some decades ago these difficulties were not insurmountable, when critics assigned a Neronic date to the Apocalypse and a Domitianic or later date to the Gospel. It was from such a standpoint conceivable that the thoughts and diction of the writer had undergone an entire transformation in the long interval that intervened between the composition of the two books, on the supposition that both were from the same hand. But now that both books are assigned to the last decade of the 1st century A.D. by a growing body of critics, the hypothesis of a common authorship can hardly be sustained. The validity of such an hypothesis was attacked as early as the 4th century by Dionysius of Alexandria in the fragment of his treatise περὶ ἑωγγελιων, in Eusebius, H. E. vii. 24 seq. His arguments, as summed up by Swete (op. cit., p. cxxiv seq.), are as follows: "John the Evangelist abstains from mentioning his own name, but John the Apocalypist names himself more than once at the very outset of his book, and again near its end. Doubtless there were many who bore the name of John in the early Christian communities; we read, for instance, of 'John, whose surname was Mark,' and there may have been a second John in Asia, since at Ephesus we are told, there were two tombs said to be John's. . . . Again, while the Gospel and the Epistle of John show marks of agreement which suggest a common authorship, the Apocalypse differs widely from both in its ideas and in its way of expressing them; we miss in it the frequent references to 'life,' 'light,' 'truth,' 'grace' and 'love' which are characteristic of the Apostle and find ourselves in a totally different region of thought. . . . Lastly, the linguistic eccentricities of the Apocalypse bar the way against the acceptance of the book as the work of the Evangelist. The Gospel and the First Epistle are written in a language flowing from Homer, whereas the Apocalypse is not even or a provincialism in them; whereas the Greek of the Apocalypse is inaccurate, disfigured by unusual or foreign words and even at times by solecisms." All subsequent criticism has more or less confirmed the conclusions of Dionysius. On the other hand, it is impossible to ignore the signs of a relationship between the Apocalypse and the Gospel in the minor peculiarities of language. These, Swete holds, "create a strong presumption of affinity" between the two books, while Boussert infers that they "justify the assumption that the entire circle of Johannine writings spring from circles which stood under the influence of the John of Asia Minor." We conclude, therefore, that the Gospel and the Apocalypse

1 His freedom from legal bondage is as undeniable as his universality. He lays no further burden on his readers than those required by the Apostolic Decree of Acts xx. 28, seq.

2 See Boussert, Offenbarung Johannis, pp. 177-179; Swete, p. cxv-cxxix.
are derived from different authors who moved in the same circles.1

As regards the John mentioned in the Apocalypse, he is now identified by a majority of critics with John the Presbyter, and further the trend of criticism is in favour of transferring all the Johannine writings to him, or rather to his school in Asia Minor.2

In an independent discussion of the authorship of the Fourth Gospel, see John, Gospel of St. (R. H. C.)

REVELS, MASTER OF THE.—The history of the Revels office has an interesting place in that of the English stage (see also DRAMA, and THIATRE). Among the expenses of the royal Wardrobe we find provision made for iunucæ and viseres in 1347 for the Christmas ludi of Edward III; during the reign of Henry VII. payments are also recorded for various forms of court revels; and it was regular, apparently, to appoint a special functionary, called Master of the Revels, to superintend the royal festivities, quite distinct from the Lord of Misrule (q.v.). In Henry VII.'s time he seems to have been a minor official of the household. In Henry VIII.'s time, however, the post became more important, and an officer of the Wardrobe was permanently employed to act under the Master of the Revels. With the patent given to John Farlyon in 1534 as Yeoman of the Revels, what may be considered as an independent office of the Revels (within the general sphere of the lord chamberlain) came into being; and in 1544 Sir Thomas Cawarden received a patent as Master of the Revels, he being the first to become head of an independent office, Magister Jocorum, Revordur et Mascorum amminum et singularium nostrorum vulgariter nuncupatorum Revellorum. Sir Thomas Cawarden was Master of the Revels on the death of his appointment, the office and its stores were transferred to a dissolved Dominican monastery at Blackfriars, having previously been housed at Warwick Inn in the city, the Charterhouse, and then at the priory of St John of Jerusalem in Clerkenwell, to which a return was made after Cawarden's death. Sir Thomas Benger succeeded Cawarden, and Edmund Tynelie followed him (1579–1610); it was the appointment of the latter's nephew, Sir George Buck, as deputy-master, with the reversion to the mastership, which led to so much repining on the part of the dramatist, John Lyly, who was himself a candidate. Under Tynelie, the functions of Master of the Revels gradually became extended to a general censorship of the stage, which in 1624 was put directly in the hands of the lord chamberlain, thus leading to the licensing act of 1737 (see DRAMA).

See E. K. Chambers, The Mediaeval Stage (1904); and his Notes on the History of the Revels Office under the Tudors (1906), with authorities quoted.

REVELSTOKEx an incorporated town of British Columbia, on the Columbia river and the Canadian Pacific railway, 381 m. E. of Vancouver. Pop. (1907) 3526. It is the capital of Kootenay county, and the shipping centre for the mining and lumbering district. It contains large railway shops, several breweries, and saw and shingle mills.

REVENTLOW, CHRISTIAN DITLEF FREDERICK, COUNT (1748–1827), Danish statesman and reformer, the son of Privy Councillor Christian Ditlev Reventlow, born on March 11, 1748. After being educated at the academy of Sorø and at Leipzig, Reventlow, in company with his younger brother Johan Ludvig and the distinguished Saxon economist Carl Wendt (1731–1815), the best of cicerones on such a tour, travelled through Germany, Switzerland, France and England, to examine the social, economical and agricultural conditions of civilized Europe. A visit to Sweden and Norway to study mining and metallurgy completed the curriculum, and when Reventlow in the course of 1770 returned to Denmark he was an authority on all the economic questions of the day. In 1774 he held a high position in the Kammerkollegiet, or board of trade, two years later he entered the Department of Mines, and in 1781 he was a member of the Overskildirektionen, or chief taxing board. He had, in 1774, married Frederica Charlotte von Beulwitz, who bore him thirteen children, and on his father's death in 1775 he inherited the family estate in Lolland. Reventlow overflowed with progressive ideas, especially as regards agriculture, and he devoted himself, heart and soul, to the improvement of his property and the amelioration of his serfs. Fortunately, the ambition to play a useful part in a wider field of activity than he could find in the country ultimately prevailed. His time came when the ultra-conservative ministry of Hoegh Guldborg was dismissed (April 14th, 1784) and Andreas Bernstorff, the statesman for whom Reventlow had the highest admiration, returned to power.

Reventlow was an exceedingly trained specialist in many departments, and was always firm and confident in those subjects which he had made his own. Moreover, he was a man of strong and warm feelings, and deeply religious.

The condition of the peasantry especially interested him. He was convinced that free labour would be far more profitable to the land, and that the peasant himself would be better if released from his thraldom. His favourite field of labour was thrown open to him when, on the 6th of August 1784, he was placed at the head of the Kentskammeri, which took cognisance of everything relating to agriculture. His first step was to appoint a small agricultural commission to better the condition of the crown serfs, and amongst other things enable them to turn their leaseholds into freeholds. Observing that the Crown Prince Frederick was also favourably disposed towards the amelioration of the peasantry, Reventlow induced him, in July 1786, to appoint a grand commission to take the condition of all the peasantry in the kingdom into immediate consideration. This celebrated agricultural commission continued its labours for many years, and introduced a whole series of reforms of the highest importance. Thus the ordinance of 8th June 1787 modified the existing leaseholds, greatly to the advantage of the peasantry; the ordinance of 20th June 1788 allowed villenage and completely transformed the much-abused høveri system whereby the feudal tenant was bound to cultivate his lord's land as well as his own; and the ordinance of 6th December 1799, which did away with høveri altogether. Reventlow was also instrumental in starting the public credit banks, for enabling small cultivators to borrow money on favourable terms. In conjunction with his friend, Heinrich Ernst Schimmelmann (1747–1831), he also procured the passing of the ordinances permitting free trade between Denmark and Norway.
REVENUE—REVERIE

the free importation of corn from abroad, and the abolition of the mischievous monopoly of the Iceland trade.

But the financial distress of Denmark, the jealousy of the duchies, the ruinous political complications of the Napoleonic period, and above all, the Crown Prince Frederik's growing jealousy of his official advisers, which led him to take, or rather misrule, for years without the co-operation of his Council of State—all these calamities were at last too much even for Reventlow. On 7th December 1813 he received his dismissal and retired to his estates, where, after working cheerfully among his peasantry to the last, he died on the 11th of October 1827.

See Adolph Frederik Bergsöe, Greve, C. D. F. Reventlows Virksomhed (Copenhagen, 1857); Louis Theodor Alfred Bøge, Ejendoms- og ejerhistorier fra den Reventlowske Familiekreds (Copenhagen, 1895-97).

REVENUE (O. Fr. revenue, from revenir, to return), income, return, or profit; more particularly the receipts from all sources of a government or state. The revenue of a state is largely made up of taxation, and the general principles of taxes are discussed in Taxation and Finance. In some countries the public or state domain may contribute substantially to the revenue, as do the crown forests in Russia, while in other countries important contributions are made from the state railways, post and telegraph services, &c. For the historical development of the English revenue see English Finance, and for other countries see the sections on finance in the articles dealing with the various countries. In the United Kingdom the term inland revenue is used to denote that part of the revenue which is derived from death duties, stamps and other taxes, such as income tax, land tax, inhabited house duty, &c. The Board of Inland Revenue is a special department of the English civil service, with headquarters at Somerset House. The Board consists of a chairman, deputy chairman, and two commissioners, with joint secretaries, assistant secretaries and a staff of officials. The other important department engaged in the collection of the English revenue is the Board of Customs and Excise. The excise department was formerly a branch of the inland revenue, but was amalgamated with the customs department on the 1st of April 1900. The Board of Customs and Excise is constituted as is the Board of Inland Revenue.

In the United States the greater proportion of the national revenue ($847,086,992 out of $663,917,677 in 1900) is derived from customs and internal revenue. The internal revenue consists for the most part of receipts from taxes on spirits, tobacco and fermented liquors. In 1900 the amount derived from customs revenue was $300,097,438, and internal revenue, $246,169,554.

REVERIE (O. Fr. reverie, from revenir, to rever, pay respect to), a term of respect or courtesy, now especially used as the ordinary prefix of address to the names of ministers of religion of all denominations. The use of Med. Lat. reverendus do not confine the term to those in orders; Du Cange (Gloss. s.v.) defines it as titulus honorarius, etiam multerius potioris dignitiae concessus, and in the 15th century in English it is found as a general term of respectful address. The usual prefix of address of a parson was "sir," representing Lat. dominus (see SR), or "master." It has been habitually used of the parochial clergy of the Church of England since the end of the 17th century. It is not, however, a title of honour or dignity, and no denomination has any exclusive right to use it. A faculty was ordered to be issued for the erection of a tombstone, the inscription on which contained the name of a Wesleyan minister prefixed by " reverend"; this the incumbent had refused (Keat v. Smith, 1856, 1 P.D. 73). In the Church of England deans are addressed as "very reverend," bishops as "right reverend," archbishops as "most reverend." The Moderator of the Church of Scotland is also styled "right reverend."

REVERIE, a condition of mental abstraction, a fit of musing, a "brown study" ("brown" in the sense of "gloomy," and not to be referred to Germ. Braune, brow). The word appears in the 14th or 15th centuries in its original meaning in Old French, of joy, delight, also wildness, anger. The French rever, later resser, modern rêver, to dream, meant originally to wander in speech or thought, and is derived from the Lat. robiare, cf. "rabies," "rage" and "rave." The French rêverie (resserie) was adopted again in the 17th and 18th centuries as meaning a state of dreaminess; thus Locke (Essay on the Human Understanding, 1690, ii. xix.) says: "When ideas float in our minds
without any reflection or regard of the understanding, it is that which the French call reverence; our language has scarce a word for it."

**Review** (fr. *revue, from revoir, to see again, Lat. re and videre*), an inspection or critical examination; it is chiefly used as a military or naval term for an inspection on a large or formal scale of a fleet or body of troops by the sovereign or other person holding a high official position, or for a critical account of a recently published literary work in a magazine or periodical. The earliest use of the word for the title of such a periodical was in the paper begun by Belloc in 1704, the full title of which was *A Review of the Affairs of France and of All Europe, as Influenced by That Nation* (see Periodicals and Newspapers). In France there is a particular application of the term *revue or, more fully, revue de fond d'année* to a form of dramatic performance, acted or sung, in which the chief events of the past year, and the personages who have been prominently before the public, are satirically and critically passed under review. Attempts have been made to trace such performances to an early origin. In their modern form, however, they date from the reign of Louis Philippe. L'Ann. 1834 1841 1844. 1841, by the brothers Cogniard, was the last of the series.

**REVILLAGIGEDO,** an isolated, uninhabited group of rocky islands in the N. Pacific, lat. 16° N., long. 115° W., belonging to Mexico, and forming part of the state of Colima. They are about 420 m. from the Mexican coast and comprise the large island of Socorro (San Tomás), 24 m. long by an average of 9 m. wide, and the three widely separated islets of San Benedicto, Roca Partida and Clarion, with a total area of 320 sq. m. The island of Socorro has an extinct volcano 2660 ft. high. The islands have certain remarkable zoological features, comprising several birds and reptiles allied to those of the Mexican mainland but differing from them in species. The archipelago derives its name from the Spanish vicerey who governed Mexico from 1746 to 1755.

**Réville, Albert** (1826— ), French Protestant theologian, was born at Dieppe on the 4th of November 1826. After studying at Geneva and Strasbourg, he became in 1849 pastor at Luneray near Dieppe, and in 1851 of the Walloon Church at Rotterdam, where he remained until 1872. In 1880 he was made professor of the history of religions in the Collège de France at Paris. Six years later he was appointed president of the section of religious studies in the École des hautes études at the Sorbonne. He is one of the leaders of the French school of religious sociology.

**Works.**—Besides contributing to the Revue de théologie (Paris), the Revue de l'histoire des religions (Paris), the Revue des deux mondes, the following works are important: *Manuel d'histoire comparée de la philosophie et de la religion* (1859; Eng. trans., 1864); *Histoire du dogme de la divinité de Jésus-Christ* (1863, 3rd ed., 1904; Eng. trans., 1905); *Prologumes de l'histoire des religions* (1881, 4th ed., 1886; Eng. trans., 1885); *Théodore Parker, sa vie et ses œuvres* (1885; Eng. trans., 1886, 2nd ed., 1877); *Lectures on the Origin and Growth of Religion as illustrated by the native religions of Mexico and Peru* (the "Hibbert Lectures" for 1884); *Jésus de Nazareth* (1897, 12th ed., 1906).

His son, Jean Réville, was born on the 6th of November 1854, studied at Geneva, Paris, Berlin and Heidelberg, and became professor of patristic literature and secretary of the section of religious studies in the École des hautes études at the Sorbonne. In 1884 he became co-editor of the Revue de l'histoire des religions (Paris).

His books include: *La Doctrine du dogma* (1881); *La Religion à Rome sous les Sibègres* (1886); *Les Origines de l'épiscopat* (1895); and *Le Protestantisme liberal, ses origines, sa nature, sa mission* (1876, Eng. trans., 1877).

**REVOLUTIONARY TRIBUNAL. THE** (le tribunal révolutionnaire), a court which was instituted in Paris by the Convention during the French Revolution for the trial of political offenders, and became one of the most powerful engines of the Terror. The news of the failure of the French arms in Belgium gave rise in Paris to popular movements on the 9th and 10th of March 1793, and on the roth of March, on the proposal of Danton, the Convention decreed that there should be established in Paris an extraordinary criminal tribunal, which received the official name of the Revolutionary Tribunal by a decree of 30th of October 1793. It was composed of a jury, a public prosecutor, and two substitutes, all nominated by the Convention; and from its judgments there was no appeal. With M. J. A. Hermann as president and Fouquier-Tinville as public prosecutor, the tribunal terrorized the royalists, the refractory priests and all the actors in the counter-revolution. Soon, too, it came to be used for personal ends, particularly by Robespierre, who employed it for the condemnation of his adversaries. The excesses of the Revolutionary Tribunal increased with the growth of the Committee of Public Safety; and on the roth of June 1794, after an instigation, the infamous Law of 22 Prairial, which forbade prisoners to employ counsel for their defence, suppressed the hearing of witnesses and made death the sole penalty. Before 22 Prairial the Revolutionary Tribunal had pronounced 1220 death-sentences in thirteen months; during the forty-nine days between the passing of the law and the fall of Robespierre 1376 persons were condemned, including many innocent victims. The lists of prisoners to be sent before the tribunal were prepared by a popular commission sitting at the museum, and after revision, by the Committee of General Security and the Committee of Public Safety jointly. Although Robespierre was the principal purveyor of the tribunal, we possess only one of these lists bearing his signature. The Revolutionary Tribunal was suppressed on the 31st of May 1795. Among its most celebrated victims may be mentioned Marie Antoinette, the Hébertists, the Dantonists and several of the Girondists. Similar tribunals were also in operation in the provinces.

**REWA,** or Riwa, a native state of Central India in the Bagelkhand agency. It is the only large state in Bagelkhand, and the second largest in Central India, having an area of about 13,000 sq. m. It is bounded N. by the United Provinces, E. by Bengal and S. by the Central Provinces. On the W. it meets other petty states of Bagelkhand. Rewa is divided into two well-defined divisions. The southern and smaller division is the plateau lying between the Kaimur range of hills and the other portion of the Vindhyas known as Bijnah, which overlook the valley of the Ganges. This plateau is for the most part cultivated and well peopled; rich harvests both of kharif and rabi crops are generally obtained. Water is plentiful, and the country is full of large tanks and reservoirs, which, however, are not used for irrigation purposes; the only system of wet cultivation which has any favour with the villagers is that of *bunds,* or mounds of earth raised at the lower ends of sloping fields to retain the rain water for some time after the monsoon rain. The northern and larger division of the state is covered with forests, yielding timber and lac.

The S. of the state is crossed by the branch of the Bengal-Nagpur railway from Bilaspur to Katni, which taps the Umaria coal-field. The state suffered from famine in 1896-97, and again to a less
REWA KANTHA—REYER

extent in 1869-1900; but on both occasions adequate measures of pressure were provided. The state first came under British influence in 1812. The chief, Venkat Raman Singh, was born in 1876, succeeded in 1880 and was created C.G.C.S.I. in 1897. During his minority the administration was reformed. He is Rajput of the Bhagraw branch of the Solanki race, and is descended from the founder of the Ahilwara Patan dynasty in Gujarar.

The town of Rewa is 151 m. S. of Allahabad. Pop. (1901) 24,605. It has a high wall, a fort, the Victoria and Zenana hospitals and a model gaol. The political agent for Bagalkhand resides at Satna, on the East Indian railway: pop. (1901) 7471.

REWA KANTHA, a political agency or collection of native states in India, subordinate to the government of Bombay. It stretches for about 150 m. between the plain of Gujarar and the hills of Malwa, from the river Tapti to the Mahi, crossing the Nerbudda or Rewa, from which it takes its name. The number of separate states is 61, many of which are under British jurisdiction. The only important one is Rajpilha (p. 1). It includes also five second-class states entitled Chota Udaipur, Bariya, Suntan, Lunawada and Balaimor. Total area, 4072 sq. m. In 1901 the population was 479,063, showing a decrease of 3.5% in the decade, due to the results of famine. Estimated revenue, £140,000; tribute (mostly to the gawkwar of Barods), £10,000. Many of the inhabitants belong to the wild tribes of Bhils and Kolis. The political agent, who also collects the British district of the Fanch Mahals, resides at Godhra.

REWARD, recompense, a gift or payment in return for services rendered. "Reward" and "rewarder" are forms of the same word. Old French, from which both words came into English, also had rewarder and regarder (the latter form only surviving in modern French), from re-, back, in return, and worder, garder, to watch, protect—ultimately a Teutonic word, from the base war-, to defend; cf. "ward" and "guard," which are thus also doublets. In early use in English, "reward" and "rewarder" were interchangeable in meaning; thus in Piers Plowman, xi. 120, "Reson rod forth and tok reward of no man," cf. "The town doth receve... an annual reward," Legal Remembrancer (1797-1810), from the New English Dictionary from R. Willis and J. W. Clark, Archit. Hist. of Univ. of Cambridge, (1886). In use the words are now distinct, "reward" being restricted to such meanings as attention, respect, esteem, consideration.

In English law the offering of rewards presents two distinct aspects: (1) with reference to the nature of the information or act for the giving or doing whereof the reward is offered; (2) with reference to the nature of the relation created between the person offering and the person claiming the reward.

1. Courts of assize and quarter sessions are empowered to offer rewards to persons who have been active in or towards the apprehension of persons charged with certain specified crimes against person and property (Criminal Law, 1826, ss. 28, 29; Criminal Justice Administration Act 1837, ss. 7, 8). The rewards are payable according to a scale fixed by the home secretary. In the case of courts of quarter sessions the maximum is £5. Courts of assize may award a larger sum where extraordinary courage and diligence have been shown towards the apprehension. The sums awarded are paid out of the rate or fund chargeable with the costs of assizes and sessions. It is illegal to advertise for the recovery of stolen property (including dogs) on terms of not asking questions (Larceny Act 1861, s. 102; Larceny Advertisements Acts 1870, s. 3). The advertiser and the newspaper which publishes it incur a penalty of £50. (See Mirrns v. Our Dogs Publishing Co., 1901, 2 K.B. 564.) It is a criminal offence at common law to offer any reward on terms leading to compounding a felony or sheltering the offender (R. v. Burgess, 1886, Q.B.D. 141), and under the Larceny Act 1861 (ss. 20, 101) it is criminal to accept a reward for recovery of stolen property without bringing the thief to justice.

2. Where a reward is offered for information the person who first supplies the required information, i.e. satisfies the conditions on which the reward is payable, is entitled to recover by action the reward offered. Performance of the conditions is an acceptance of the offer (Carroll v. Carolina Smoke Ball Co., 1893, 1 Q.B. 256, 270). Thus on an advertisement for information leading to the arrest and conviction of shop-breakers, T. gave information which led to the arrest of R., who while in prison told the police where to find the thieves. T. was held entitled to the reward (Tardus v. Hurst, 1866, L.R. 1 Q.B. 641). This rule applies even where the offer is general to all the world (Williams v. Carwardine, 1833, 4 B. & Ad. 621; Spencer v. Harding, 1870, L. R. 5 C.P. 561). It would seem that on grounds of public policy an offender could not claim the reward on surrendering himself to justice (Beni v. Wakefield & Bank, 1875, 4 C.P. D. 1, 4). It is not clear whether officers of justice are by their office and duty debarred from claiming rewards offered for the arrest of offenders (ibid. p. 5).

REWAR, a town of British India, in Gurgaon district of the Punjab, 32 m. S.W. of Gurgaon on the Rajputana-Malwa railway. Pop. (1901) 27,975. It is an important centre of trade, being the junction for the Rewari-Bhatinda branch of the Rajputana railway. The chief manufacture is that of brassware for cooking utensils.

REWBELL, JEAN FRANCOIS (1747-1807), French politician, was born at Colmar (then in the department of Haut-Rhin) on the 8th of October 1747. He was president (bidaloyer) of the order of avantis in Colmar, and in 1789 was elected deputy to the States-General by the Third Estate of the city of Colmar-Schiesstadt. In the Constituent Assembly he used his oratorical gifts, kept the moderate party in line, and gave him much influence. During the session of the Legislative Assembly he exercised the functions of procureur syndic and was subsequently secretary-general of the department of Haut-Rhin. In the Convention he was a zealous promoter of the trial of Louis XVI., but was absent on mission at the time of the king's condemnation. He took part in the reactionary movement which followed the fall of Robespierre, and became a member of the reorganized Committees of Public Safety and General Security. The moderation he displayed caused his election by the citizens of Colmar to the Council of Five Hundred. He was appointed a member of the Directory on the 1st of October 1795, he became its president in 1796, and retired by ballot in 1799. He then entered the Council of Ancients.

The coup d'état of 18 Brumaire he retired from public life, and died at Colmar on the 23rd of November 1807. See L. Scoul, Le Directoire (Paris, 1895-97).

REYBAUD, MARIE ROCH LOUIS (1790-1879), French writer, economist and politician, was born at Marseilles on the 15th of August 1790. After travelling in the Levant and in India, he settled in Paris in 1829. Besides writing for the Salle, the Rénais, he edited the Revue scientifique, was author of the expédition française en Egypte in ten volumes (1830-36) and Dumont d'Urville's Voyage autour du monde (1833). In 1840 he published Études sur les reformateurs ou socialistes modernes (see Socialism) which gained him the Montyon prize (1841) and a place in the Académie des sciences morales et politiques (1850). In 1843 he published Jérôme Patarot à la recherche d'une position sociale, a clever social satire that had a prodigious success. In 1846 he abandoned his democratic views, and was elected liberal deputy for Marseilles. His Jérôme Patarot à la recherche de la fortune de la République (1846) was one of the new Republican ideas. After the coup d'état of 1849 he ceased to take part in public life, and devoted himself entirely to the study of political economy. To this period belong his La Vie de l'employé (1852); L'Industrie en Europe (1856); and Études sur le régime de nos manufactures (1859). He died in Paris on the 28th of October 1879.

REYER, ERNEST (1823–), French composer, was born at Marseilles on the 1st of December 1823. At the age of sixteen he went to Algeria, and remained there some years. The outcome of his residence there was a symphonic ode entitled Le Chant de la paix, the musical origin of which is said to have already been anticipated by Félicien David in Le Désert. Motets Wolfram; a one-act opera, was produced at the Opéra comique xxiii. 8
in 1854; and in 1858 Sacrento, a ballet, at the Opéra. It was
the production of La Staise at the Théâtre lyrique in 1861 that
brought Reyner's name prominently before the public. But
Reyner had to wait several years before obtaining a real and
permanent success. "Erosrote," an opera produced at Baden-
Baden in 1862, and given at the Paris Opéra some ten years
later, was a failure. The composer had in the meanwhile set to
work on Sigurd, the subject of which is the same that inspired
Wagner in Siegfried and Götterdämmerung. It was at last
produced in Brussels in 1884, and it subsequently brought out at
the Paris Opéra. "Sigurd" is a work of great value, displaying its
composer's elevated notions as regards the form of the "lyrical
drama." Salammbo, founded upon Flaubert's romance, was
successfully produced at Brussels in 1890. Gluck, Weber,
Berlioz and Wagner exercised most influence over Reyner. As a
musical critic (preceding Berlioz in that capacity for the Journal
des débuts) Reyner was a well-known writer; and he became
librarian of the Paris Opéra, and a member of the Institute.
His Quaranité Ans de musique (with biographical notice by E.
Henriot) was published in 1909.

REYNARD THE FOX, a beast-epic, current in French,
Dutch, and German literature. The cycle of animal stories
collected round the names of the Reynard the Fox and Isengrurn
the Wolf in the 12th century seems to have arisen on the border-
land of France and Flanders. Much of the material may be
found in Aesop, in Physiologus, and in the 12th-century Disciplina
Clericalis of Petrus Alfonius. But the difference is very great.
The intention of the trouvères who recited the exploits of Reynard
was, in the earlier stages, in no sense didactic. The tales, like
those of "Uncle Remus," were amusing in themselves; they
were based on widely diffused folklore, and Reynard and his
companions were not originally men disguised as animals.
Jacob Grimm ('Reinhardt Fuchs,' 1874) maintained their popular
origin; his theories, which have been much contested, have
received additional support from the researches of K. Krohn,
who discovered many of the stories most characteristic of the
cycle in existing Finnish folklore, where they can hardly have
arrived through learned channels.

There is abundant evidence that Isengrim and Reynard were
firmly established in the popular imagination in the 13th century,
and even earlier. Guibert de Nogent (De Vita sua, book 3, chap.viii,
printed Paris, 1651), in referring to the disturbances at Laon in
1173, says that the bishop Gaudri was accustomed to call out
his enemies Isengrim, and referred to him as "the wolf"—and
that the taunt was perfectly understood by the popular
philip the Fair is said to have annoyed Pope Boniface III,
who died in 1293, by the representation of the " procession
Renart"; and in 1204-1206 in Flanders two opposing parties
were designated Isengrini and Blavoti (blue-footed).
The principal names of the Reynard cycle, and the earliest in use,
were German. Reynard himself (Raginohardus, strong in
counsel), Brunn the Bear, Baldwin the Ass, Tibert the Cat,
Hirnseth the She-wolf, had German names, most of which were
used as person-names in Lorraine. Whatever the sources of the
stories, it is clear (in France that the name of Reynart the
Wolf. The Roman de Renart as printed by Mfon (Paris,
4 vols, 1836) runs to over 40,000 lines, and contains a great
number of detached episodes or branches, to which the trouvères
gave a certain unity by attaching them to the tradionary
feud between Reynard and Isengrim. This rapidly became
symbolic of the triumph of craft and eloquence over brute
strength. Renart was a popular epic parodying feudal institu-
tions as represented in the romances of chivalry, and readily
adapting itself to satire of the rich, of the forms of justice, and
of the clergy.

The early French originals are lost, the most ancient existing
fragments being in Latin. The fable of the lion's sickness and
his cure by the wolf's skin occurs in the Echantus cajusdam captivit
per Tropologiam (ed. E. Voigt; Strasbourg, 1875), written by
a monk of St Evre at Toul (Meurthe-et-Moselle) about 940.
Ysengrinmus (ed. E. Voigt; Halle, 1884), a clerical satire
written by Nivard of Ghent about 1148, includes the story of
the lion's sickness and the pilgrimage of Bertillaunt the Goat.
Another Latin poem, Reinardus vulpes (ed. F. J. Mone; Stutt-
gart, 1832), contains in addition the theft of the bacon, and how
Isengrim is induced to fish with his tail. A simpler version,
derived probably from a French original, is Isingrines nôt,
written in German about 1180 by the Alstian Heinrich der
Glichzère. Only fragments of this poem are preserved, but
about a quarter of a century later it was re-written with little
change in the subject matter as Reinhart Fuchs (ed. J. Grimm,
Berlin, 1834) and the Reekse werken van Halle, 1880. Most late-
reynard by Reinard. However, from the Flemish Reinarta de vos
(eds. J. F. Willems, Ghent, 1836; and E. Martin, Paderborn, 1874),
written about 1150 in East Flanders by Willem. Reinarte is a poem of 3474 lines. The corresponding
branch of the French Roman de Renart (for which and its satirical
sequels, Le Couronnement Renart, Renart le nouveau, and Renart
le contefalt, see French Literature) is one of the earliest and
best of the great French cycle.

The fable was, like other French works, known in England,
but did not at once pass into the popular stock. Odo of Cheriton,
who died in 1247, used the Reynard story which he included
in his translation of "the Parable of the Lion's Captivity," in its
Latin form, at least as late as 1259. It was illustrated at
(Leipzig, 1887), and the Mexican Opera, which he published on
the 6th of June 1841. As a satire on the church, especially on
monks and nuns, Reynard became popular with reformers,
and numerous versions followed in England and Germany.
A Low German version, Reinke Fuchs, with a prose commentary
by Hinrek Alckmer (Henry of Alkmaar), was issued from the
Antwerp press of Gherart Leeuw in 1487. From this " fijacht-
mente" was derived the Low German Reiske de Wos (ed. Hoffmann
von Failersleben, Breslau, 1834; and Friedrich Prien, Halle,
1887), which was printed at Lübeck in 1498. Michael Beuther
is said to have been the translator into High German (Reineken
Fuchs; 1544) who made his work the basis of "the German
European public in the Latin version of Hartmann Schopper,
Opus Poeticum de admirabili fallacia et astutia Vulpeculi Reinike
Libros quattuor (Frankfort, 1567). The modern German version
(1792) of Goethe has been often reprinted, notably in 1846 with
illustrations by Wilhelm von Kaulbach.

Reynard is dealt with by Carlyle in an essay "On German
Literature of the Fourteenth and Fifteenth Centuries" in the
Foreign Quarterly Review (1841). An admirable account of
the Reynard cycle is given by W. J. Thoms in his edition of Caxton's
de Vos contains bibliographical particulars of the German, Danish,
Swedish, Icelandic and English editions (ed. E. Martin, Reinart de
See also Leopold Sudre, Les Sources du roman de Renart (Paris, 1895); and J. Grimm, which is obvious from the context
of Reinhard Fuchs (Leipzig, 1840); Gastro Paris, "Le Roman de Renard " in the Journal des savants (Dec. 1894 and Feb. 1895); Kaarle Krohn," Bär und Fuchs (Helsingfors, 1888), and the editions mentioned
above. The story is told in modern French by Paulin Paris, Les
Adventures de Maitre Renart et d'Ysengrin son compère (1861), and
in English by Joseph Jacobs, following a modernized text of Caxton
made by 'Felix Summerley' (Sir H. Cole, in The Most Delicate History of Renard the Fox (1885), with a valuable introduction.

REYNOLDS, JOHN FULTON (1820-1863), American soldier,
was born at Lancaster, Pennsylvania, on the 20th of
September 1820, and graduated at West Point in 1841.
He became first lieutenant of artillery in 1846, and was brevetted
captain and major for gallantry in the Mexican War. He took
part in the Utah expedition under Brigadier-General Albert
Sidney Johnston. In 1859 he was made commandant of cadets
REYNOLDS, SIR JOSHUA

at West Point, where he was stationed at the outbreak of the Civil War in 1861. He was made a lieutenant-colonel of infantry in May and brigadier-general of volunteers in August of that year. In the Peninsular campaign, after taking part in the battles of Bull Run, Malvern Hill and Gaines' Mill, he was taken prisoner in the hard-fought action of Glendale or Frazier's Farm. Exchanged after six weeks' captivity, he commanded a division with conspicuous ability and courage in the second battle of Bull Run. Shortly after this he was placed in command of the militia of his native state when Lee's invasion threatened it. In November 1862 he was commissioned major-general of volunteers, and appointed to command the I. Corps of the Army of the Potomac, and took part in the battle of Fredericksburg. At the time of General Meade's appointment to command the Army of the Potomac many desired to see Reynolds selected for the position; but he declined the offer, and was only induced to accept it by the three critical days preceding the battle of Gettysburg (q. p.). He was placed by Meade in command of the left wing (I., III. and XI. corps and Buford's cavalry division) and thrown forward to Gettysburg to cover the concentration of the Army of the Potomac. The battle which ensued there, on the 1st of July 1863, took its shape from Reynolds' resolution to support Buford's cavalry with the I. and XI. corps. Meade was notified, and hurried forward the right wing under Hancock. Reynolds himself was killed very early in the day by a rifle bullet. A bronze statue was placed on the field of Gettysburg and a portrait in the library at West Point by the men of the I. Corps. The state of Pennsylvania erected a granite shaft on the spot where he fell, and an equestrian bronze statue stands in Philadelphia.

His elder brother William (1815-1870), a naval officer, served afloat in the Civil War, effected many useful reforms while acting secretary of the navy in 1873 and 1874, and retired from the United States navy in 1877 as a rear-admiral.

REYNOLDS, SIR JOSHUA (1723-1792), the most prominent figure in the English school of painting, was born at Plympton Earl, in Devonshire, on the 16th of July 1723. He received a fairer good education from his father, who was a clergyman and the master of the free grammar school of the place. At the age of seventeen, the lad, who had already shown a fondness for drawing, was apprenticed in London to Thomas Hudson, a native of Devonshire, who, though a mediocre artist, was popular as a portrait painter. Reynolds remained with Hudson for only two years, and in 1743 he returned to Devonshire, where, settling at Plymouth Dock, he employed himself in portrait painting. By the end of 1744 he was again in London. He was well received by his old master, from whom he appears previously to have parted with some coldness on both sides. Hudson introduced him to the artists' club that met in Old Slaughter's, St. Martin's Lane, and gave him much advice as to his work. Reynolds now painted a portrait of Captain the Hon. John Hamilton, the first that brought him any notice, with those of other people of some repute; but on the death of his father in 1746 he established himself with two of his sisters at Plymouth Dock, where he painted numerous portraits, and it was here that he came under the influence of the works of one of the painters who materially affected his art. This was William Gandy of Exeter, who had died in 1730, and whose painting, derived through his father from Van Dyck, was pronounced by Northcote to come nearer to nature in the texture of flesh than that of any artist who ever lived. The influence on him of Gandy may be seen in the early self-portrait of the National Portrait Gallery, so rich in impasto and strong in light and shade, in which he is seen shading his eyes with his hand.

Meanwhile the pleasant urbanity of manner which distinguished Reynolds throughout life had been winning for him friends. He had 'made the acquaintance of Lord Edgcumbe, and by him was introduced to Captain (afterwards Viscount) Keppel. Keppel was made aware of Reynolds' ardent desire to visit Italy; and, as he had just been appointed to the command of the Mediterranean squadron, he gracefully invited the artist to accompany him in his own ship, the "Centurion."

The offer was gladly accepted. While Keppel was conducting his tedious negotiations with the dey of Algiers, relative to the piracy with which that potentate was charged, Reynolds resided at Fort Mahon, the guest of the governor of Minorca, painting portraits of the principal inhabitants; and in December 1749 he sailed for Lefhorn, and thence, with all eagerness, made his way to Rome.

He has confessed that his first sight of the works of Raphael was a grievous disappointment, but he recognized afterwards, as he said, that the fault was in himself, and he brought his mind ultimately into the fitting posture of reverence. The fact is significant of Reynolds' attitude towards the older masters. It has been often noticed that in his "Discourses" and elsewhere he praises just the very masters whose practice his own work implicitly condemns. The truth is that Reynolds was naturally a good critic, but was not strong enough to believe in his own opinions if they ran counter to the prevailing taste of his times. Of the early Italians he praises the "simplicity and truth" and observes that they "deserve the attention of a student much more than many later artists." In Venice he adopted a method of study that only a born painter could have thought of, making memoranda of the gradations of light and shade in the pictures, "and this without any attention to the subject, or to the drawing of the figures." On the other hand, we find him lavishing both attention and eulogy on the later Italian mannerists, such as Guido and the Carracci, and even Salvati and Vezziari.

After a residence of more than two years in Rome, where he caught a severe cold which resulted in the deafness that clung to him for the rest of his life, Reynolds, in the spring of 1752, spent five months in visiting Parma, Florence, Venice and other important cities of Italy. Returning to England by way of Paris, Reynolds, after a brief stay in Devonshire, established himself as a portrait painter in St. Martin's Lane, London, whence he afterwards removed to Great Newport Street, and finally, in 1769, to Leicester Square, where he continued to paint till his death. In London, Reynolds stepped at once and without a struggle into a foremost position as the fashionable portrait painter of the day. In this he was greatly helped by his success in society. Throughout his career his social occupations claimed the next place to his painting, and here it may be noticed that, though we read of some little ostentation in the form of a showy chariot and liveried lackeys, his good taste always kept him from any undue "push," or adulation of the great. At the outset Lord Edgecumbe played the part of the generous patron, and excited himself to obtain commissions for his protégé, of whose ability the portraits which he now produced—especially the famous full-length of his old friend Keppel—were sufficient guarantee. The artist's painting room was thronged with the wealth and fashion of London. In 1755 his clients for the year numbered 120, and in 1757 the number of sittings recorded in his pocket-books reached a total of 677. He was not always so busy, but his popularity never really waned, though various other artists competed with him for popular applause. First the Swiss Liostard had his moment of popularity; and at a later period there was Opie, and the more formidable and sustained rivalry of Gainsborough and of Romney; but in the midst of all Reynolds maintained his position unimpaired. During the first year of his residence in London he had made the acquaintance of Dr. Johnson, which, diverse as the two men were, became a friendship for life. To him Burke and Goldsmith, Garrick, Sterne and Bishop Percy were before long added. At the hospitable dinner-table of Reynolds such distinguished men enjoyed the freest and most unconstrained companionship, and most of them were members of the "Literary Club," established, at the painter's suggestion, in 1764.

In 1760 the London world of art was greatly interested by the novel proposal of the Society of Artists to exhibit their works to the public. The hall of the society was at their disposal for the purpose; and in the month of April an exceedingly successful exhibition was opened, the precursor of many that followed. To this display Reynolds contributed four portraits.
In 1765 the association obtained a royal charter, and became known as "The Incorporated Society of Artists"; but much rivalry and jealousy were occasioned by the management of the various exhibitions, and an influential body of painters withdrew from the society. They had access to the young king, George III., who promised his patronage and help. In December 1768 the Royal Academy was founded, and Reynolds, whose admission to the movement was for a time doubtful, was hailed by acclamation its first president, an honour which more than compensated for his failure to obtain the appointment of king's painter, which, the previous year, had been bestowed on Allan Ramsay. In a few months the king signified his approval of the election by knightling the new president, and intimating that the queen and himself would honour him with sittings for portraits to be presented to the Academy.

Reynolds was in every way fitted for his new position, and till the late Lord Leighton the Academy never had so good a figure-head. He did not take any part in the educational work of the New Institution, but on the social side he set the example on the lines it has followed with the greatest worldly success ever since. It was at his suggestion that the annual banquet was instituted. To the specified duties of his post he added the delivery of a presidential address at the distribution of the prizes, and his speeches on these occasions form the well-known "Discourses" of Sir Joshua. These discourses alone would be sufficient to entitle his author to literary distinction; indeed, when they were first delivered, it was thought impossible that they could be the production of a painter, and Johnson and Burke have been credited with their composition, in spite of the specific denials of both, and of Dr Johnson's indignant exclamation "Sir Joshua, sir, would as soon get me to paint for him as to write for him!"

Sir Joshua was too prosperous and successful an artist altogether to escape the jealousy of his less fortunate or less capable brethren, and it must on the other side be admitted that his attitude towards some of his contemporaries was wanting in generosity. His relations with Gainsborough, who had no part in it, would require more space for discussion than can here be afforded, but he was not just either to Hogarth or to Richard Wilson. It may be added that though Reynolds's friends were generally fond of him, his was not a nature that could inspire affection, however great his genius. Cosmo Monkhouse in the Dictionary of National Biography speaks of "the beauty of his disposition and the nobility of his character," but adds: "he was a born diplomatist." The latter phrase gives the real key to his character. Without going so far as to fully endorse the sentiment of Mrs Thrale's famous line about a "heart too frigid" and a "pencil too warm," we must agree with a recent writer that the attitude of Reynolds towards his fellow men and women was one of detachment. Hence we regard Reynolds as a man with tempered admiration, and reserve our enthusiasm for his art.

In 1754, on the death of Ramsay, Reynolds was appointed painter to the king. Two years previously he had suffered from a paralytic attack; but, after a month of rest, he was able to resume his painting with unabated energy and power. In the summer of 1758 his sight began to fail; he was affected by the "gutta serena," but the progress of the malady was gradual, and he continued occasionally to practise his art till about the end of 1790, delivering his final discourse at the Academy on the 10th of December. He was still able to enjoy the companionship of his friends, and he exerted himself in an effort to raise funds for the erection of a monument in St Paul's to Dr Johnson, who had died in 1784. Towards the end of 1791 it was evident to the friends of Reynolds that he was gradually sinking. For a few months he suffered from extreme depres-

As a painter Reynolds stands, with Gainsborough, just behind the very first rank. There can be no question of placing him by the side of the greatest Venetians or of the triumvirate of the 17th century, Rubens, Rembrandt, Velasquez; but, if he fail also to do justice to his genius in his own domain, he stands as a teacher and an artist, and in his natural capacity, but to deficiencies in his education combined with the absence in his case of that splendid artistic tradition on which the others leaned, he could not draw the figure properly; and he is a great artist. The fact is that this nature in him has been curtailed, and he has been too conscious of the weight of the task which he has undertaken, and has been so much absorbed with it, that he never got away from it. That he could have better realized in the works of the Venetians and Correggio, he embarked on all sorts of fantastic experiments in pigments and media, so that Haydon exclaimed, "The wonder is that the picture did not crack beneath the brush!"

The result was the speedily run up of one of his own productions, and he inaugurated an era of uncertainty in method which seriously compromised the efforts of his successors in the English school. The motive for this procedure may explain if it do not justify it. He was all his intensely inventive about his art, devoted by what he himself calls "a perpetual desire to advance"; and he accounts for his own uncertainty partly from his want of training, and partly from his "inordinate desire to possess any kind of knowledge that he could seem to be the works of others in dainty. Now if this intellectual energy led him into hazardous attempts to find a royal road to the painter's ideal, it acted well upon his design in leading to a certain failure, and to result in a solidly constructed "history," which, though at times more exquisite, productions of the pencils of Gainsborough or Romney, The weight and power of the art of Reynolds are best seen in those noble male portraits, "Lord Heath- dorff," "Cardinal G pred." "Collon," "Mr. Fox," "Gerrick," which are historical monuments as well as sympathetic works of art. In this category must be included his immortal "Mrs Siddons as the Tragic Muse." This was the result of all the merits of this great artist, for it will be observed that he is probably more generally admired for his studies of women and children, of which the Althorp portraits of the Spencer family are classical examples. Nature had singled out Sir Joshua to endow him with certain gifts in which he has hardly an equal. No portrait painter has been more happy in his poses for single figures, or has known better how to control by good taste the piquant, the accidental, and the domestic, a happy mixture which is a striking instance. When dealing with more than one figure he was not always so happy, but the "Duchess of Devonshire and her Baby," the "Three Ladies decked a Figure of Hymen," and the "Three Ladies Waldegrave" are brilliant successes. He was licentious too in his arrangement of drapery, often following his own fashion of investing his graceful dames in robes of ideal cut and texture, quite apart from the actual clothes worn at the time. Everything about him was in dainty, and at the same time firm manipulation of the brush. The richness of his deeper colouring is at times quite Venetian. For pure delight of the eye and of the intellect, for the "imaginary landscape," and the "Angela Heads" of the National Gallery, or the "Kelby O'Brien" in the Wallace Collection.

It corresponds with what has been noted of Reynolds's habit of making his compositions to one side; he had begun to notice the "grand style" in "historical painting." His failure here is as notorious as his brilliant success in the field of art for which nature had equipped him. His "Ugolino," his "Macheth," his "Cardinal Beaufort," have no real impressiveness, while his greatest effort in the "historic" style, the "Infant Hercules" at St Petersburg, resulted in his most conspicuous failure. It is in the "Discourses" that Reynolds unfolds these artistic theories that contrast so markedly with his own practice. The first discourse deals with the establishment of an academy for the "perpetual study of the mind of its species," and after an instance of the best of bygone practice, of the "principles which many artists have spent their lives in ascertaining." In the second lecture the study of the painter is divided into three stages, in the first of which, his business is " nothing but to acquaint himself with the grammar of art, while in the second he examines what has been done by other artists, and in the last compares these results with Nature herself. In the third discourse Reynolds treats of the "judging great ideas and laying the foundation of the designs" of his succeeding addresses are devoted to such subjects as "Moderation," "Taste," "Genius," and "Sculpture." The fourteenth has an especial interest as containing a note of the work that he did before his statue, while the concluding discourse is mainly occupied with a panegyric on Michelangelo.

The other literary works of the president comprise his theses in "The Last Conversations," 1776. "On the Grand Style in Painting," and "On the True Idea of Beauty," his notes to Du Fresnoy's Art of Painting, his Remarks on the Art of the Low Countries, his brief notes in Johnson's Shakespeare, and two singularly witty and brilliant fragments, imaginary conversations with Johnson, which
REYNOLDS, W.—REZÁNOV 229

were never intended by their author for publication, but, found among papers after his death, were given to the world by his niece, the marchioness of Thomond.

The president left to his niece, Mary Palmer, the bulk of his property, about £100,000, with works of art that sold for £30,000 more. There were, besides, legacies amounting to about £15,000 in body rests in St Paul's.

REYNOLDS, WALTER (d. 1327), archbishop of Canterbury, was the son of a Windsor baker, and became a clerk, or chaplain, in the service of Edward I. He held several livings and, owing perhaps to his histrionic skill, he became a prime favourite with the prince of Wales, afterwards Edward II. Just after the prince became king in 1307 Reynolds was appointed treasurer of England; in 1308 he became bishop of Worcester and in 1310 chancellor. When Robert Winchelsea, archbishop of York, died in 1313, Walter was appointed by Pope Clement V. to appoint his favourite to the vacant archbishopric, and Walter was enthroned at Canterbury in February 1314. Although the private life of the new archbishop appears to have been the reverse of exemplary he attempted to carry out some very necessary reforms in his new official capacity; he also continued the struggle for precedence, which had been carried on for many years between the archbishops of Canterbury and of York. In this connexion in 1317 he laid London under an interdict after William de Melton (d. 1349), archbishop of York, had passed through its streets with his cross borne erect before him. Reynolds remained in general loyal to Edward II. until 1324, when with all his suffragans he opposed the king in defence of the bishop of Hereford, Adam of Orton. In the events which concluded Edward's life and reign the archbishop played a contemptible part. Having fled for safety into Kent he returned to London and declared for Edward III., whom he crowned in February 1327. He died at Mortlake on the 16th of November following.

REZÁNOV, NICOLAI PETROVICH DE (1764-1807), Russian nobleman and administrator under Catherine II., Paul I. and Alexander I., was one of the ten barons of Russia, and, for his services to the empire, was rewarded with the court title of chamberlain. In 1803 he was made a private counsellor and invested with the order of St Anne. He was also the author of a lexicon of the Japanese language and of several other works, which are preserved in the library of the St. Petersburg Academy of Sciences, of which he was a member. He was the first Russian ambassador to Japan (1804), and instigated the first attempt of Russia to circumnavigate the globe (1803), commanding the expedition himself as far as Kamchatka. But Rezanov's monument for many years after his death was the great Russian American Fur Company; and his interest to students of history centres round the policy involved in that enterprise, which, thwarted by his untimely death, would have changed the destinies of Russia and the United States.

Meeting (in 1788) Shelikov, chief of the Shelikov-Golikov Fur Company, Rezanov became interested in the merchant's project to obtain a monopoly of the fur trade in those distant dependencies. Conscious of latent energies, and already tired of the pleasures of a dissolute court, he became a partner in the company, and rapidly developed into a keen and tireless man of business. At the death of Shelikov in 1793 he became the leading spirit of the wealthy and amalgamated but harassed companies, and resolved to obtain for himself and his partners privileges analogous to those granted by Great Britain to the East India Company. He had just succeeded in persuading Catherine to sign his charter when she died, and he was obliged to begin again with the ill-balanced and intractable Paul. For a time the outlook was hopeless; but Rezanov's skill, subtlety and craft prevailed, and shortly before the assassination of the emperor Paul he obtained his signature to the momentous instrument which granted to the Russian-American Company for a term of twenty years, dominion over the coast of N.W. America, from latitude 55 degrees northward; and over the chain of islands extending from Kamchatka northward and southward to Japan. This famous 'Trust,' which crowded out all the small companies and independent traders, was a source of large revenue to Rezanov and the other shareholders, including members of the Imperial family, until the first years of the 19th century, when mismanagement and scarcity of nourishing food induced the Indians to trade with serious losses if not ultimate ruin. Rezanov, his humiliating embassy to Japan concluded, reached Kamchatka in 1805, and found commands awaiting him to remain in the Russian colonies as Imperial inspector and plenipotentiary of the company, and to correct the abuses that were ruining the great enterprise. He travelled slowly to Sitka by way of the Islands, establishing measures to protect the fur-bearing animals from reckless slaughter, punishing or banishing the worst offenders against the company's laws, and introducing the civilizing influence of schools and libraries, most of the books being his personal gifts. He even established cooking schools, which were to be startled by the sight of the capital.

At the end of a winter in Sitka, the headquarters of the company, during which he half-starved with the others, he bought a ship from a Yankee skipper and sailed for the Spanish settlements in California, purposing to trade his tempting cargo of American and Russian wares for food-stuffs, and to arrange a treaty by whose terms his colonies should be provisioned twice a year with the bountiful products of New Spain. He cast anchor in the harbour of San Francisco early in April 1806, after a stormy voyage which had defeated his intention to take possession of the Columbia river in the name of Russia. Although he was received with great courtesy and entertained night and day by the gay Californians, no time was lost in informing him that the laws of Spain forbade her colonies to trade with foreign powers, and that the governor of all the Californias was incorruptible. Rezanov, had it not been for a love affair with the daughter of the commandante of San Francisco, Don José Argüello, and for his personal address and diplomatic skill, with which he won over the clergy to his cause, would have failed again. As it was, when he sailed for Sitka, six weeks after his arrival, the 'Junio's' hold was full of bread-stuffs and dried meats, he had the promise of the perplexed governor to forward a copy of the treaty to Spain at once, and he was assured he would reach the most beautiful girl in California. Shortly after his arrival in Sitka he proceeded by water to Kamchatka, where he despatched his ships to wrest the island Sakhalen of the lower Kurile group from Japan, then started overland for St Petersburg to obtain the signature of the tsar to the treaty, and also personal letters to the pope and king of Spain that he might ask for the dispensation and the royal consent necessary to his marriage. He died of fever and exhaustion in Krasnoiarsk, Siberia, on the 8th of March 1807.

The treaty with California, the bare suggestion of which made such a commotion in New Spain, was the least of Rezanov's projects. It was sincerely conceived, for he was deeply and humanely concerned for his employees and the wretched natives who were little more than the slaves of the company; but its very obviousness raised the necessary amount of dust. His correspondence with the company, and with Zapinsky, betrays a clearly defined purpose to annex to Russia the entire western coast of North America, and to encourage immediate emigration from the parent country on a large scale. Had he lived, there is, all things considered, hardly a doubt that he would have accomplished his object. The treaty was never signed, the reforms of Rezanov died of discouragement, the fortunes of
the colonies gradually collapsed, the Spanish girl who had loved Rzeszów became a nun; and one of the ablest and most ambitious of his time lies forgotten in the cemetery of a poor Siberian town.

Rhaeticum occupies horizons to
gression— "paper shales." Below there are beds of grey and "tea-green" marls which are now usually regarded as the topmost Keuper beds, but they have often been included in the Rhaetic. A distinct "Keuper" Keuper occurs in the transition between Penarth Head and Cavernock Point, Aust Cliff and Garden Cliff near Westbury-on-Severn, and Wintwold Cliff between Tewkesbury and Gloucester. An excellent development near Penarth the Rhaetic beds have long been known in Estremadura Penarth Beds (H. W. Bristow, 1864). The more prominent beds in the White Lias of the west of England and Glamorganshire are the Rhaetic beds and the insect limestone *Pseudomenitis*-bed, and on both of these horizons the limestone may assume the peculiar characters of landscape marble, sometimes called Coatham marble, from Coatham House near Bristol. A hard fine-grained limestone, called "sandstone," is also found, as the "sandstones of Bath and Radstock"; at Street, Wedmore and south of the Mendips generally it is called "jew stone." Wedmore stone is a tough, shelly and sandy limestone in the black shales at Wedmore, near Wells; and is in some districts near Market Drayton, Salop; near Audlem, Cheshire; Rugby and Stratford-on-Avon in Warwickshire; Wijston in Leicestershire; Needham Forest in Staffordshire, and in Nottinghamshire and elsewhere, where it may be as far as 600 feet below the level of the Lias of Cumberland. Rhaetic fossils have been found in great numbers in fissures in the Carboniferous limestone of the Mendips. On the western side of Scotland Rhaetic rocks occur at Ayr, near Arran, and in the Sutherland district. In the Sutherlandshire sandstone and conglomerate and large transporting masses occur; one of them, at Linksfield, carries a bone bed. Here the black shales of the English type fail; sandstones with coastly layers and yellowish-grey crystalline and brown in Estremadura take their place. In Antrim a small outcrop of black shales with *Aviculo contorta* occurs near Port Rush.

On the European continent the Rhaetic rocks are most thickly developed in the Alpine regions; and, as in the case of the older Triassic formations, calcareous and dolomitic strata predominate here and in the Mediterranean province. In the Alpine district there are three divisions of the Rhaetic district: the highest division is the *Koessen* beds; and the middle and lower of the *Rhaeticum* beds; and the lower of the *Schlachtensee* beds, shales, marls and limestones. In the northern tract the following subdivisions have been recognized in descending order; beds with *Chrestosiceros Marschi*; Starham passage beds; *Rhaeticum* beds with *Hystaceola fissicosta*; *Aviculo gregaria*; *Terebratula gregaria*; beds with *Aviculo contorta*; "Platten Kalk" with *Rhynchoconia alpina*. In the southern tract the subdivisions are; *Conochos dolomie (Conochos infrangiactivus)=Lycocymbum dolomite" and have been regarded as equivalents of the Iowa beds, "Platten Kalk." Much limestone is of the "reef" type. In Germany the rocks are mainly fine, clear yellow sands, suggesting low tide or dune conditions, with bituminous clays and marls. The formation is often missing in south-west Germany. Similar beds occur in Lorraine and Luxembourg (grès de Vic, grès de Kédange, grès de Mortinsart). In Cotentin are dolomitic sandstones and marl; and there are beds of chalk, the chalky sandstones, arks, and conglomerates; while in the south of France the sandy and calcareous facies occur intermittently. In Spain limestones and dolomites occur up to 100 metres in thickness; in Portugal sandy beds extend to 300 metres. The Rhaetic of Mozambique is a sandstone and shales with beds of coal up to one metre thick. Only the upper beds contain marine fossils; the bulk of the formation is of lacustrine or estuarine origin. In the formation of the formation is developed in the north and at Rotzo, Spezia and Carrara; and yields the famous statuary marble and the black variety known as *Portor*. Rhaetic beds have been recognized in South Sweden, North Sweden, South Norway, and in Norwegen; the Wianamatta beds of New South Wales, the Bellarine beds of Victoria, the Ipswich and Tivoli beds of Queensland, and the Jerusalem beds of Tasmania, and beds on a similar horizon in New Zealand are included in the Rhaetic. In Africa the Stormberg beds of the Karoo series and the Moltedo beds

cephalian reptiles. Some coleopterous insects have been found in the same beds, but the most interesting feature of the bone-bed fauna is the first appearance in the northern hemisphere of true mammals: *Microlestes* in England and Württemberg, *Triphyllus* in Württemberg, *Dromotherium* and *Microdon* in America.

In England the Rhaetic formation occurs as a thin but constant series of beds at the base of the Lias and above the Keuper marls. The upper part, often called the "White Lias," is a series of thin-bedded shales, limestone and marls, 1 to 25 ft. thick; the lower part contains the *Rhaeticum* beds, and in parts the *Schlachtensee* beds. The Rhaetic beds are often marked by the presence of thin beds of bituminous marine marl and constitute the well-known *Koessen* beds, a name E. V. Mojsisovic and E. Sues have demonstrated that in the Alpine Rhaetic several distinct facies may be recognized, via a Swabian facies: shore and lagoon deposits with a pelecypod fauna, poor in species but rich in individuals; a Carpathian facies with corals, algae, *Terebratula gregaria* and *Plicatula intusbrata*, exemplified in the upper part of the Dachstein limestone; a Kössener facies: black limestones and marls, with a brachiopod fauna in which *Spiriger myocephalos* is very noticeable; and a Salzburg facies, characterized by pelagic pelecypods and some ammonites (see table in Triassic System).

The whole of the Rhaetic falls within Mojsisovic's zone of *Aviculo contorta*. This epoch is marked off from the earlier Triassic period by a very general marine transgression which proceeded with minor irregularities and retrogressions over the whole area; until at its close it was followed by the more decided transgression which indicates the commencement of the Lias.

Among the marine fossils of the Rhaetic, *Aviculo contorta*, the principal zone form, is very characteristic and has a wide range; *Myophoria infolda*, *Modiola minuta*, *Protocardium rhacatum* and *Terebratula gregaria* are common species. True belemnites make their first appearance. Corals, *Thecosmilia*, &c., with a peculiarly distinct form, occur abundantly in certain areas, and in places give rise to beds of lignite and coal. The flora is more nearly akin to that of the Trias than to that of the Jurassic rocks. Vertebrate remains are fairly abundant in the form of teeth, isolated bones, scales and coprolites in what are known as "Bone Beds" (q.v.). These beds are a very characteristic feature; they occur on several horizons in many tracts of the European Rhaetic, and recur in beds of this age in America. In England there is usually a bone bed about the base of the formation; in Germany one occupies a similar position; a second occurs less constantly about the middle, and in the Württemberg district a third bed separates the Rhaetic and Liassic districts and constitutes the well-known marl bed of Bebenhausen. In these beds are found the bones of *Ichthyosaurus* and *Plissaurus*, anticipating their great development in the Lias, while the remains of *Belodon* and *Mystriosuchus* serve to link this epoch with Triassic stego-
RHAMNUS PURSHIANA—RHEA

of the Cape have been assigned to this epoch. In America Rhaetic rocks are recognized in N. Carolina, Connecticut, California, Mexico, Bolivia and Chile; the formation is also recorded from S outputPath, Franz Joseph Land and elsewhere in the Arctic regions.

RHAMNUS PURSHIANA, or Californian buckthorn, a plant the bark of which is used in medicine under the name of cascara sagrada. An active principle anthra-glucose-sagradin has been isolated by Tschirch. The preparations of it contained in the British pharmacopoeia are: (1) Extractum cascareae sagradae (extractum rhamni purshianae, United States pharmacopoeia), dose 2 to 8 grs.; (2) Extractum cascareae sagradae liquidum, dose ½ to 1 fl. dr. From the latter is prepared syrupus cascareae aromatice, dose ½ to 2 fl. dr. In this preparation the bitter taste of the cascara sagrada is disguised by the addition of the various range, cinnamomum regale, regale. In the United States pharmacopoeial preparation Fluid extractum rhamni purshianae aromatice, dose 10 to 30 minims, the taste is similarly obscured. Cascara sagrada is one of the most useful of all laxatives, since not only does it empty the bowel of faecal matter, but it acts as a tonic to the intestine and tends to prevent future constipation. It is largely used in the treatment of chronic constipation. A single full dose of the liquid extract may be taken at bedtime, or divided doses, 10 to 15 minims, three times a day before meals. When a strong purgative is required some drug other than cascara sagrada should be employed, but its use in gradually decreasing doses is indicated after evacuation has been effected by podophyllin or rhabur. Cascara sagrada is the principal constituent of most of the proprietary laxatives on the market.

RHAMPSINiUS, a Greek corruption of Ra-messu-pa-neter, the popular name of Rameses III., king of Egypt of the XXth Dynasty. He is well known in connexion with the story of his treasure house told by Herodotus (ii. 121), which greatly resembles that of Agamemnon and Trophonius. (See Egypt, History.)

RHANAKiVES (commonly also Rangade), ALEXANDROS RHIZOS (1810—1892), Greek savant, poet and antiquary was born at Constantinople of a Phanariot family on the 25th of December 1810. He was educated at Odessa and the military school at Munich. He served as an officer of artillery in the Bavarian army, he returned to Greece, where he held several high educational and administrative appointments. He subsequently became ambassador at Washington (1867), Paris (1868), and Berlin (1874—1886), and was one of the Greek plenipotentiaries at the congress of 1878. After his recall he lived at Athens, where he died on the 29th of June 1892. He was the chief representative of a school of literary men whose object was to restore as far as possible the ancient classical language. Of his works, Hellenic Antiquities (1842—1855, of great value for epigraphical purposes), Archaeologia (1866—1869), an illustrated ArchaeologicalLexicon (1888—1897), and a History of Modern Greek Literature (1877) are of the most interest to scholars. He wrote also the following dramatic pieces: The Marriage of Kurtrules (comedy), Dukas (tragedy), The Thirty Tyrants, The Eve (of the Greek revolution); the romances, The Prince of Morea, Leida, and The Notary of Argostoli; and translated portions of Dante, Schiller, Lessing, Goethe and Shakespeare.

A complete edition of his philological works in nineteen volumes was published at Athens (1872—1890), and his Αυτορεκαλλωμένα (Memoirs) appeared posthumously in 1894—1895.

RHAPSODiST (Gk. Rhapsodos), originally an epic poet who recited his own poetry; then, one who recited the poems of others (see Homer).

RHATANY or KRAMERIA ROOT, in medicine, the dried root either of Para rhatany or of Peruvian rhatany. The action of rhatany is due to the rhatania-tannic acid, and resembles that of tannic acid, being a powerful astringent. An infusion is used as a gargle for relaxed throats; and lozenges, particularly those containing rhatany and cocaine, are useful in similar cases. Like tannic acid, the powdered extract may be applied as a local haemostatic. All preparations of rhatany taken internally are powerful astringents in diarrhoea and intestinal haemorrhage.

RHAYADER (Rhadur-Gwyn), a market town of Radnorshire, Wales, situated amid wild and beautiful scenery on the left bank of the Wye, about 1½ m. above its confluence with the Elan, Pop. (1901) 115. Rhayader is a station on the Cambrian railway. A stone bridge over the Wye connects the town with the village and parish church of Cwmmauaddog. Rhayader has for some centuries been an important centre for Welsh mutton and wool, and its sheep fairs are largely attended by drovers and buyers from all parts. Near Rhayader are the large reservoirs constructed (1895) by the corporation of Birmingham in the Elan and Claerwen valleys.

Rhayader, built close to the Falls of the Wye (whence its name), owes its early importance to the castle erected here by Prince Rhys ap Gwethyr of South Wales, c. 1278, in order to check the English advance up the Wye Valley. Seized by the invaders, castellated town were later retaken in 1251 by Prince Llewelyn ap Iorwerth, who burned the fortress and slew its garrison. Scarcely a trace of the castle exists, although its site is near St. Clement's church, known as Tower Hill. With the erection of Maesyrdy into the shire of Radnor in 1536 Rhayader was named as assize-town for the county of Radnor in conjunction with New Radnor; but in 1547, on account of a local riot, the town was deprived of this privilege in favour of Presteign. Rhayader constituted one of the group of boroughs comprising the Radnor parliamentary district until the Reform Act of 1832.

RHEA, a goddess of the Greeks known in mythology as the daughter of Uranus and Gaia, the sister and consort of Kronos and the mother of Zeus. In Homer she is the mother of the gods, though not a universal mother like Cybele, the Phrygian Great Mother, with whom she was later identified. The original seat of her worship was in Crete. There, according to legend, she saved the new-born Zeus, her sixth child, from being devoured by Kronos by substituting a stone for him and entrusting the infant god to the care of her attendants the Curetes (q.v.). These attendants afterwards became the bodyguard of Zeus and the priests of Rhea, and performed ceremonies in her honour. In historic times the resemblances between Rhea and the Asiatic Great Mother, Phrygian Cybele, were so noticeable that the Greeks accounted for them by regarding the latter as only their own Rhea, who had deserted her original home in Crete and fled to the mountain wilds of Asia Minor to escape the persecution of Kronos (Strabo 460, 12). The reverse view was also held (Virgil, Aen. iii. 111), and it is probably true that a stock of Asiatic origin formed part of the primitive population of Crete and brought with them the worship of the Asiatic Great Mother, who became the Cretan Rhea. (See Great Mother of the Gods.)

RHEA, the name given in 1752 by P. H. G. Mähring to a South American bird which, though long before known and described by the earlier writers—Nieremberg, Marcgrav and Piso (the last of whom has a recognizable but rude figure of it)—had been without any distinctive scientific appellation. Adopted a few years later by M. J. Brisson, the name has since passed into general use, especially among English authors, for what their predecessors had called the American ostrich; but on the European continent the bird is commonly called Nandu, a word corrupted from a name it is said to have borne among the aboriginal inhabitants of Brazil, where the Portuguese settlers called it emu (see EMU). The resemblance of the rhea to the ostrich (q.v.) was at once perceived, but the differences between them are also very evident. The former, for instance, has three instead of two toes on each foot, it has no apparent tail, its wings are far better developed, and when folded cover the body, and its head and neck are clothed with feathers, while internal distinctions of still deeper significance have since been

What prompted his bestowal of this name, so well known in classical mythology, is not apparent.

The name Tousou, of American origin, was applied to it by Brisson and others, but erroneously, as Cuvier shows, since by that name, or something like it, the jabiru (q.v.) is properly meant.
dwell upon by T. H. Huxley (Proc. Zool. Society, 1867, pp. 420-422) and W. A. Forbes (op. cit., 1881, pp. 784-81). There can be little doubt that they should be regarded as types of as many orders—Struthionæ and Rheæ—of the sub-class Ratitæ. Structural characters no less important separate the rheas from the emus; the former can be readily recognized by the rounded form of their contour-feathers, which want the *hyporhachis* or after-shaft that in the emus and cassowaries is so long as to equal the main shaft, and contributes to give these latter groups the appearance of being covered with shaggy hair. The feathers of the rhea have a considerable market value, and for the purpose of trade in them it is annually killed by thousands, so that its total extinction as a wild animal is probably only a question of time. It is polygamous, and the male performs the duty of incubation, brooding more than a score of eggs, the produce of several females—facts known to Nieremberg more than two hundred and fifty years since, but hardly accepted by naturalists until recently. No examples of this bird seem to have been brought to Europe before the beginning of the present century, and accordingly the descriptions previously given of it by systematic writers were taken at second hand and were mostly defective if not misleading. In 1863 J. Latham issued a wretched figure of the species from a half-grown specimen in the Leverian Museum, and twenty years later said he had seen only one other, and that still younger, in Bullock's collection (Gen. Hist. Birds, viii. p. 379). A bird living in confinement at Strassburg in 1860 was, however, described and figured by Hammer in 1868 (Ann. du Museum, xii. pp. 427-433, pl. 39). In England the Report of the Zoological Society for 1833 announced the rhea as having been exhibited for the first time in its gardens during the preceding twelvemonth. Since then many other living examples have been introduced, and it has bred both there and in many private parks in Britain.

Though considerably smaller than the ostrich, and wanting its fine plumes, the rhea in general aspect far more resembles that bird than the other Ratitæ. The feathers of the head and neck, except on the crown and nape, where they are dark brown, are dingy white, and those of the body ash-coloured tinged with brown, while on the breast they are brownish-black, and on the belly and thighs white. In the course of the memorable voyage of the "Beagle," C. Darwin came to hear of another kind of rhea, called by his informants *Avestrua petiæ*, and at Port Denton on the east coast of Patagonia he obtained an holster of, it, the imperfect skin of which enabled J. Gould to describe it (Proc. Zool. Society, 1839, p. 35) as a second species of the genus, naming it after its discoverer. *Rhea darwini* differs in several well-marked characters from the earlier known *R. americana*. Its bill is shorter than its head; its tarsi are reticulated instead of scutellated in front, with the upper part feathered instead of being bare; and the plumage of its body and wings is very different, each feather being tipped with a distinct whitish band, while that of the head and neck is greyish-brown. A further distinction is also asserted to be shown by the eggs of those of *R. americana* being of a yellowish-white, while those of *R. darwini* have a bluish tinge. Some years afterwards P. L. Sclater described (op. cit., 1860, p. 207) a third and smaller species, closely resembling the *R. americana*, but having apparently a longer bill, whence he named it *R. macro-rhyncha*, more slender tarsi, and shorter toes, while its general colour is very much darker, the body and wings being of a brownish-grey mixed with black. The precise geographical range of these three species is still undetermined. While *R. americana* is known to extend from Paraguay and southern Brazil through the La Plata region to an uncertain distance in Patagonia, *R. darwini* seems to be the proper inhabitant of the country last named, though M. Claraz asserts (op. cit., 1885, p. 324) that it is occasionally found to the northward of the Rio Negro, which had formerly been regarded as its limit, and, moreover, that flocks of the two species commingled may be very frequently seen in the district between that river and the Rio Colorado. On the "pampas" *R. americana* is said to associate with herds of deer (*Cariacus campestris*), and *R. darwini* to be the constant companion of guanacos (*Lama huanae*)—just as in Africa the ostrich seeks the society of zebras and antelopes. As for *R. macro-rhyncha*, it was found by W. A. Forbes (Ibis, 1861, pp. 360, 361) to inhabit the dry and open "*pias*" of northern Patagonia, a discovery more interesting since it was in that part of the country that Marcgrav and Piso became acquainted with a bird of this kind, though the existence of any species of rhea in the district had been long overlooked by or unknown to succeeding travellers.

Besides the works above named and those of other recognized authorities on the ornithology of South America such as Azara, Prince Max of Wied, Professor Burmeister and others, more or less valuable information on the subject is to be found in Darwin's *Voyage*, v. Böcking's "Monographie des Nagantu" in (Wiegmann's) *Archiv für Naturgeschichte* (1859, i. pp. 213-41); R. O. Cunningham's *Natural History of the Strait of Magellan and paper in the Zoological Society's Proceedings for 1871* (pp. 105-110), as well as H. F. Gadow's still more important anatomical contributions in the same journal for 1885 (pp. 308 seq.).

(A. N.)

RHEINBERGER, JOSEPH GABRIEL (1839-1907), German composer, was born at Vaduz, Liechtenstein, on the 17th of March 1839. His musical abilities were manifested so early that he was appointed organist of the parish church when he was but seven years old. A three-part Mass composed by him was performed in the following year. He was taught at first by Philipp Schmutzer, choir director at Feldkirch; he entered the Munich Conservatorium in 1851, and remained there till 1854.
as a pupil of Professor E. Leonhard for piano, Professor Herzog for organ and J. J. Maier for counterpoint. After leaving the school he had private lessons from Franz Lachner, and was appointed a professor in the conservatorium in succession to Leonhard in 1859. In 1860 he became professor of composition, and was appointed organist of the Michaelskirche, a post he held till 1866. In 1877 he succeeded Wüllner as Hofkapellmeister, and from that time his attention was largely devoted to sacred music. His compositions include works of importance in every form, from the operas *Die sieben Raben* (Munich, 1869) and *Tümrers Töchterlein* (Munich, 1873) and the oratorio *Christus*, op. 120, to the well-known quartet for piano and strings in E-flat, op. 36, the nonet for wind and strings, op. 136, and the octovent organ sonatas, which form notable additions to the literature of the instrument. He died in November 1901.

**RHEINE**, a town of Germany, in the Prussian province of Westphalia, situated on the Ems, at the point where it becomes navigable, 29 m. W. by rail of Osnabrück, and at the junction of main lines to Münster, Rotterdam and Emden. Pop. (1905) 12,501. It is an old-fashioned town with a pronounced Dutch aspect, and has pretty gardens and promenades. Rheine is the seat of cotton industries, has manufactures of jute, machinery, tobacco and flour, and a considerable river trade in agricultural produce. It was an important municipal right in 1327. About a mile north of Rheine is the castle of Bentlage, the family seat of the princes of Rhein-Roeben.

**RHENANUS, BEATUS** (1485-1547), German humanist, was born in 1485 at Schlettstadt in Alsace, where his father, named Bild, a native of Rheinau (hence the surname *Rhenanus*), was a prosperous butcher. He received his early education at the famous Latin school of Schlettstadt, and afterwards (1503) went to Paris, where he came under the influence of Jacobus Faber Stapulensis, an eminent Aristotelian. In 1511 he removed to Basel, where he became intimate with Desiderius Erasmus, and took an active share in the publishing enterprises of Joannes Froben (q.v.). In 1526 he returned to Schlettstadt, and devoted himself to a life of learned leisure, enlivened with epistolary and personal intercourse with Erasmus (the printing of whose more important works he personally supervised) and many other scholars of his time. He died at Strassburg on the 20th of July 1547.

His earliest publication was a biography of Geller of Kaisersberg (1510). Of his subsequent works the principal are *Rerum Germanicarum Libri III.* (1531), and editions of *Velleius Paterculus* (ed. princeps, from a MS. discovered by himself, 1522); *Tacitus* (1519, exclusive of the *Historiae*); *Lividus* (1533); and *Erasmus* (with a life, 9 vols., fol., 1542-47). See A. Horwitz, *Beatus Rhenanus* (1872), and by the same, *Des Beatus Rhenanus litteraire Täglich* (2 vols., 1872); also the notice by R. Hartfelder in *Allgemeine Deutsche Biographie*.

**RHETICUS, OR RHETICIUS** (1514-1576), a surname given to GEORGE JOACHIM, German astronomer and mathematician, from his birth at Feldkirch in that part of Tirol which was anciently the territory of the Rhaeti. Born on the 15th of February 1514, he studied at Tiguri with Oswald Mycone, and afterwards went to Wittenberg where he was appointed professor of mathematics in 1537. Being greatly attracted by the new Copernican theory, he resigned the professorship in 1539, and went to Frauenberg to associate himself with Copernicus (q.v.), and superintended the printing of the *De Revolutionibus* which he had persuaded Copernicus to complete. Rheticus now began his great treatise, *Opus Palatinum de Triangulis,* and continued to work at it while he occupied his old chair at Wittenberg, and indeed up to his death at Cassovia in Hungary, on the 4th of December 1576. The *Opus Palatinum* of Rheticus was published by Valentine Otho, mathematician to the electoral prince palatine, in 1596. It gives tables of sines and cosines, tangents and secants, for every 10 seconds, calculated to ten places. He had projected a table of the same kind to fifteen places, but did not live to complete it. The sine table, however, was afterwards published on this scale under the name of *Theocorus Mathematicus* (Frankfort, 1619) by B. Pitiscus (1561-1613), who himself carried the calculation of a few of the earlier sines to twenty-two places. He also published *Narratio de Libris Revolutionum Copernici* (Gedemum, 1540), which was subsequently added to editions of Copernicus's works; and *Ephemerides* until 1551, which were founded on the Copernican doctrines. He projected numerous other works, as is shown by a letter to Peter Ramus in 1568, which Adrian Romanus inserted in the preface to his *Ideas of Mathematics.*

**RHETORIC** (Gr. ῥητορική, the art of the orator), the art of using language in such a way as to produce a desired impression upon the hearer or reader. The object is strictly persuasion rather than intellectual approval or conviction; hence the term, with its adjective "rhetorical," is commonly used for a speech or writing in which matter is subservient to form or display. So in grammar, a "rhetorical question" is one which is asked not for the purpose of obtaining an answer, but simply for dramatic effect. The power of eloquent speech is recognized in the earliest extant writings. Homer describes Achilles as a "speaker of words, as well as a doer of deeds"; Nestor, Menelaus and Odysseus are all orators as well as statesmen and soldiers. Again the brilliant eloquence of Pericles is the theme of Aristophanes and Eupolis. Naturally the influence wielded by the great orators led to an investigation of the characteristics of rhetoric, and especially from the time of Aristotle the technique of the art ranked among the recognized branches of learning.

A lost work of Aristotle is quoted by Diogenes Laërtius (viii. 57) as saying that Empedocles "invented" (ἐπωτικὸς) rhetoric; Zeno, dialectic (i.e. logic, the art of making a logical argument, apart from the style). This is certainly not to be understood as meaning that Empedocles composed the first "art" of rhetoric. It is rather to be explained by Aristotle's own remark, cited by Laërtius from another lost treatise, that Empedocles was "a master of expression and skilled in the use of metaphor"—qualities which may have found scope in his political oratory, when, after the fall of Tharsacus in 472 B.C., he opposed the restoration of a tyrannical degree at Agrigentum. The founder of rhetoric as an art was Corax of Syracuse (c. 466 B.C.). In 466 a democracy was established in Syracuse. One of the immediate consequences was a mass of litigation on claims to property, urged by democratic exiles who had been dispossessed by Tharsalus, Hiero or Gelo. Such claims, going many years back, would often require that a complicated series of details should be stated and arranged. It would also, in many instances, lack documentary support, and rely chiefly on inferential evidence. Hence the need of "rhetorical" advice. The facts known as to the "art" of Corax perfectly agree with these conditions. He gave rules for arrangement, dividing the speech into five parts,—proem, narrative, arguments (κριτικός), subsidiary remarks (παρακλησία) and peroration. Next he illustrated the topic of general probability (ἐδέξα), showing its two-edged use: e.g., if a pugnacious man is accused of assaulting a stronger, he can say, "Is it likely that I should have attacked him?" If vice versa, the strong man can argue, "Is it likely that I should have committed an assault where the presumption was sure to be against me?" This topic of ἐδέξα, in its manifold forms, was in fact the great weapon of the earliest Greek rhetoric. It was further developed by Datis, the pupil of Corax, as we see from Plato's *Phaedrus,* in an "art" of rhetoric which antiquity possessed, but of which we know little else. Aristotle gives the ἐδέξα a place among the topics of the fallacious enthymeme which he enumerates in *Rhet.*, ii. 24, remarking that it was the very essence of the treatise of Corax; he points out the fallacy of omitting to distinguish between abstract and particular probability, quoting the verses of Agatho,—"Perhaps one might call this very thing a probability, that many improbable things will happen to men." Gorgias (q.v.) describes of Leonidus captivated the Athenians in 427 B.C. by his oratory (Diod. xii. 53), which, so far as we can judge, was
characterized by florid antithesis, expressed in short jerky sentences. But he has no definite place in the development of rhetoric as a system. It is doubtful whether he left a written "art"; and his mode of teaching was based on learning prepared passages by heart,—diction (λέξις), not invention or arrangement, being his great object.

The first extant Greek author who combined the theory with the practice of rhetoric is the Athenian Antiphon (q.v.), the first of the Attic orators, and the earliest representative at Athens of a new profession created by the new art of rhetoric—that of the λογογράφοι, the writer of forensic speeches for other men to speak in court. His speeches show the art of rhetoric in its transition from the technical to the practical stage, from the school to the law court and the assembly. The organic lines of the rhetorical pleader's thought stand out in bold relief, and we are enabled to form a clear notion of the logographer's method. We find a striking illustration of the fact that the topic of "probability" is the staple of this early forensic rhetoric. Viewed generally, the works of Antiphon are of great interest for the history of Attic prose, as marking how far it had then been influenced by a theory of style. The movement of Antiphon's style has a certain grave dignity, "impressing by its weight and grandeur," as a Greek critic in the Augustan age says, "not charming by its life and flow." Verbal antithesis is used, not in a diffuse or florid way, but with a certain sledge-hammer force, as sometimes in the speeches of Thucydides. The imagery, too, though bold, is not florid. The structure of the periods is still crude; and the general effect of the whole, though often powerful and impressive, is somewhat rigid.

Antiphon represents what was afterwards named the "austere" or "rugged" style (αὐστερὰ ἀρματικα), Lysias was the model of an artistic and versatile simplicity. But while Antiphon has a place in the history of rhetoric as an art, Lysias, with his more attractive gifts, belongs only to the history of oratory.

Ancient writers quote an "art" of rhetoric by Isocrates, but its authenticity was questioned. It is certain, however, that Isocrates taught the art as such. He is said to have defined rhetoric "as the science of persuasion" (Sev. Empir. Adv. Mathem. ii. §62, p. 301 seq.). Many of his particular precepts, both on arrangement and on diction, are cited, but they do not give a complete view of his method. The Φιλοσοφία ("theory of culture") which Isocrates expounds in his Discussions Against the Sophists and on the Antidotes, was in fact rhetoric applied to politics. First of his technical expositions: the pupil was introduced to all the artificial resources which prose composition employs (τὰ ἱκλάντα ἀκαδημ. ἀνάλογα τοιούτων χρόμοι, Antid. §183). The same term (ιδεῖα) is also used by Isocrates in a narrower sense, with reference to the "figures" of rhetoric, properly called σχήματα (Panath. §2); sometimes, again, in a sense still more general, to the several branches or styles of literary composition (Antid. §1). When the technical elements of the subject had been learned, the pupil was required to apply abstract rules in actual composition, and his essay was revised by the master. Isocrates was unquestionably successful in forming speakers and writers. His school was famous during a period of some fifty years (390 to 340 B.C.). Among the statesmen whom it trained were Timotheus, Leodamas of Acharnae, Lycurgus and Hyperides; among the philosophers or rhetoricians were Speusippus, Plato's successor in the Academy, and Isaeus; among the historians, Ephorus and Theopompus. Cicero and through him all subsequent oratory owed much to the ample prose of the Isocratean school.

In the person of Isocrates the art of rhetoric is thus thoroughly established, not merely as a technical method, but also as a practical discipline of life. If Plato's mildly ironical reference in the Ethydemeus to a critic "on the borderline between philosophy and statesmanship" was meant, as is probable, for Isocrates, at least there was a wide difference between the measure of acceptance accorded to the earlier Sophists, such as Protagoras, and the influence which the school of Isocrates exerted through the men whom it had trained. Rhetoric had won its place in education. It kept that place through varying fortunes to the fall of the Roman empire, and resumed it, for a while, at the revival of learning.

Plato in the Gorgias and the Phaedrus satirized the ordinary textbooks of rhetoric, and himself gave directions for a higher standard of work; but the detailed study of the art begins with Aristotle. Aristotle's Rhetoric belongs to the generation after Isocrates, having been composed (but see Aristotle) between 330 and 322 B.C. As a rhetorical exposition of the art of rhetoric for one of the foremost exponents of the subject. From a purely technical point of view (with the partial exception of book iii.) it is one of the driest works in the world. From the historical or scientific point of view it is one of the most interesting. If we would seize the true significance of the treatise it is better to compare rhetoric with grammar than with its obvious analogue, logic. A method of grammar was the conception of the Alexandrian age, which had lying before it the standard masterpieces of Greek literature, and deduced the "rules" of grammar from the actual practice of the best writers. Aristotle in the latter years of the 4th century B.C. held the same position relatively to the monuments of Greek literature as modern methodizers of grammar hold relatively to Greek literature at large. Abundant material lay before him, illustrating how speakers had been able to persuade the reason or to move the feelings. He therefore sought thence to deduce rules and so construct a true art. Aristotle's practical purpose was undoubtedly real. If we are to make persuasive speakers, he believed, this is the only sound way to set about it. But the enduring interest of his Rhetoric is mainly retrospective. It attracts us as a feat in analysis by an acute mind—a feat highly characteristic of that mind itself, and at the same time strikingly illustrative of the field over which the materials have been arranged.

The Rhetoric is divided into three books. It deals in great detail with the minutiae of the rhetorical craft. Book i. discusses the nature and object of rhetoric. The means of persuasion (πειρασμός) are classed into "inartificialia" (ἀθέρετα), i.e. the facts of the case external to the art, documents, laws, depositions,—"artificial" (αθέρετα), the latter subdivided into logical (the popular syllogism or "enthymeme," the "example," &c.), ethical, and logical. It may so indicate his own character and the goodness of his motive as to prepossess the audience in his favour, and proceeds to furnish materials to this end. The "emotional" proof is then discussed, and an analysis is given of the emotions on which the speaker may draw. Consideration is also given of "special emotions" (τά μεταβαλλόμενα) which are suitable to all subjects. The book ends with an appendix dealing with the "example" (παράδειγμα), the general moral sentiments (γενικοί) and the enthymeme. In book ii. Aristotle deals with the "technical" (τεχνικόν) art. It considers expositions (πειρασμοί) and arrangement (ἀρατήμα). Composition, the use of prose rhythm, the periodic style (the "periodic" style, περιοδικόν, and arrangement (περιοδίτη). The "contrario" is treated with the same ingenuity, and the "figurative" (παραβολικά) and "figurative" (παραβολικά) are all analysed, and the types of style literary (παραβολικά) and oral (διάλογον) are differentiated. Under "arrangement" he concludes with the parts of a speech, proem, narrative, proofs and epilogue.

This is a necessary introduction to the technical or "artistic" view of rhetoric as set forth in book i. Rhetoric is properly an art. This is the proposition from which Aristotle sets out. It is so because when a speaker persuades, it is possible to find out why he succeeds or fails. Rhetoric as a code of rules, its logical and material foundation, is not a technical or "artistic" view. Hitherto, Aristotle says, the essence of rhetoric has been neglected for the accidents. Writers on rhetoric have hitherto concerned themselves mainly with the exciting of prejudice, of pity, of anger, and such-like emotions of the soul. All this is very well, but "it has nothing to do with the matter in hand; it has regard..."
Rhetoric

to the judge." The true aim should be to prove your point, or seem to prove it.

Here we shall interpolate an example which is a general bearing on Aristotle's Rhetoric. It is quite true that, if we start from the conception of rhetoric as a branch of logic, the phantom of logic in rhetoric claims precedence over appeals to passion. But Aristotle does not array rhetoric against the human element. In fact, the human experience, is most persuasive? Logic may be more persuasive with the more select hearers of rhetoric; but rhetoric is for the many, and with the many appeals to passion will sometimes, perhaps usually, be more effective than syllogism. No formulation of rhetoric can correspond with fact which does not leave it absolutely to the genius of the speaker whether reasoning (or its phantom) is to be what Aristotle calls it, the "body of proof (σωμα τερατον)" or a mere thing of mere "persuasive effort" should not be rather addressed to the emotions of the hearers.

But we can entirely agree with Aristotle in his next remark, which is historical in its nature. The deliberative branch of rhetoric had hitherto been postponed, he observes, to the forensic. We have, in fact, already seen that the very origin of rhetoric in Hellas was forensic. The relative subordination of deliberative rhetoric, however unscientific, had thus been human. Aristotle's next statement, that the master of logic will be the master of rhetoric, is a truisim if we concede the essential primacy of the logical element in rhetoric. Otherwise it is a paradox; and it is not in accord with experience, which teaches that speakers incapable of showing even the ghost of an argument have sometimes been the most completely successful in carrying great audiences along with them. Aristotle never assumes that the hearers of his rhetorical are as of χαιστρον, the cultivated few; on the other hand, he is apt to assume tacitly—and here his individual bent comes out—that these hearers are not the great surging crowd, the δήσος, but a body of persons with a decided, though imperfectly developed, preference for sound logic.

What is the use of an art of rhetoric? It is fourfold, Aristotle replies. Rhetoric is useful, first of all, because truth and justice are naturally stronger than their opposites. When awards are not duly given, truth and justice must have been worsted by their own fault. This is worth correcting. Rhetoric is then (1) corrective. Next, it is (2) instructive, as a popular vehicle of persuasion for persons who could not be reached by the severer methods of strict logic. Then it is (3) suggestive. Logic and rhetoric are the two impartial arts; that is to say, it is a matter of indifference to them, as arts, whether the conclusion which they draw in any given case is affirmative or negative. Suppose that I am going to plead a cause, and have a sincere conviction that I am on the right side. The art of rhetoric will suggest to me what might be urged on the other side; and this will give me a stronger grasp of the whole situation. Lastly, rhetoric is (4) defensive. Mental effort is more distinctive of man than bodily effort; and it would be absurd that, while incapacity for physical self-defence is a reproach, incapacity for mental defence should be no reproach." Rhetoric, then, is corrective, instructive, suggestive, and defensive. But what if it be urged that this may be abused? The objection, Aristotle answers, applies to all good things, except virtue, and especially to the most useful things. Men may abuse strength, health, wealth, generalship.

The function of the medical art is not necessarily to cure, but to make such progress towards a cure as each case may admit. Similarly it would be inaccurate to say that the function of rhetoric was to persuade. Rather must rhetoric be defined as "the faculty of discerning in every case the available means of persuasion. Suppose that among these means of persuasion is some process of reasoning which the rhetorician himself knows to be unsound. That belongs to the province of rhetoric all the same. In relation to logic, a man is called a "sophist" with regard to his moral purpose (προαιρησις), i.e. if he knowingly used a fallacious syllogism. But rhetoric takes no account of the moral purpose. It takes account simply of the faculty (δυναμις)—the faculty of discovering any means of persuasion.

Aristotle's Rhetoric is incomparably the most scientific work which exists on the subject. It may also be regarded as having determined the main lines on which the subject was treated by nearly all subsequent writers. The extant treatise on rhetoric (also by Aristotle?) entitled Προαιρησις του Ἀλκιμάρων, was written at latest B.C. 340, is an introductory letter preceding a probable later forgery. Its relation towards Aristotle's Rhetoric is discussed in the article on Aristotle.

During the three centuries from the age of Alexander to that of Augustus the fortunes of rhetoric were governed by the new conditions of Hellenism. Aristotle's scientific method lived on in the Peripatetic school. Meanwhile the fashion of florid declamation or strained conceits prevailed in the rhetorical schools of Asia, where, amid mixed populations, the pure traditions of the best Greek taste had been dissociated from the use of the Greek language. The "Asiaticism of style which thus came to be contrasted with "Atticism" found imitators at Rome, among whom must be reckoned the orator Hortensius (c. 95 B.C.). Hermogoras of Temnos in Aeolis (c. 110 B.C.) claims mention as having done much to revive a higher conception. Using both the practical rhetoric of the time before Aristotle and Aristotle's philosophical rhetoric, he worked up the results of both in a new system,—following the philosophers so far as to give the chief prominence to "invention." He thus became the founder of a rhetoric which may be distinguished as the scholastic. Through the influence of his school, Hermogoras did for Roman eloquence very much what Isocrates had done for Athens. At all events, he counteracted the view of "Asiaticism," that oratory is a mere knack founded on practice, and recalled attention to the study of it as an art.1

Cicero's rhetorical works are to some extent based on the technical system of which he had been introduced by Molon at Rhodes. But Cicero further made an independent use of the best among the earlier Greek writers, Isocrates, Aristotle and Theophratus. Lastly, he could draw, at least in the later of his treatises, on a vast fund of reflection and experience. Indeed, the distinctive interest of his contributions to the theory of rhetoric consists in the fact that his theory can be compared with his practice. The result of such a comparison is certainly to suggest how much less he owed to his art than to his genius. Some consciousness of this is perhaps implied in the idea which pervades much of his writing on oratory, that the perfect orator is the perfect man. The same thought is present to Quintilian, in whose great work, De Institutione Oratoria, the scholastic rhetoric receives its most complete expression (c. A.D. 96). Quintilian treats oratory as the end to which the entire mental and moral development of the student is to be directed. Thus he devotes his first book to an early discipline which should precede the orator's first studies, and his last book to a discipline of the whole man which lies beyond them. Some notion of his comprehensive method may be derived from the circumstance that he introduces a succinct estimate of the chief Greek and Roman authors, of every kind, from Homer to Seneca (bk. x. §§ 46-131). After Quintilian, the next important name is that of Hermogenes of Tarsus, who under Marcus Aurelius made a complete digest of the scholastic rhetoric from the time of Hermogenes of Temnos (110 B.C.). It is contained in five extant treatises, which are remarkable for clearness and acuteness, and still more remarkable as having been completed before the age of twenty-five. Hermogenes continued for nearly a century and a half to be one of the chief authorities in the schools. Longinus (c. A.D. 260) published an Art of Rhetoric which is still extant; and the more celebrated treatise On Sublimity (περὶ ὑψηλοῦ), if not his work, is at least of the same period. In the later half of the 4th century Aphantion (φ.) composed the "exercises" (εργαλειακα) which superseded the work of

1 See Jebb's Attic Orators, ii. 445.
Hermogenes. At the revival of letters the treatise of Aphi-
nious once more became a standard text-book. Much popularity was 
also enjoyed by the exercises of Aelius Theon (of uncertain date; 
see Theon). (See further the editions of the Rhetores Graeci 
by L. Spengel and by Ch. Walz.)

During the fourth centuries of the empire the practice of 
the art was in greater vogue than ever before or since. First, 
there was a general dearth of the higher intellectual 
interests: politics gave no scope to energy; philosophy 
was stagnant, and literature, as a rule, either arid or 
frivolous. Then the Greek schools had poured their 
rhetoricians into Rome, where the same tastes which 
revelled in coarse luxury welcomed tawdry declamation. 
The law-courts of the Roman provinces further created a 
continual demand for forensic speaking. The public teacher 
of rhetoric was called "sophist," which was now an 
academic title, similar to "professor" or "doctor."

In the 4th century B.C. Isocrates had taken pride in 
the name of sofistes, which, indeed, had at no time wholly lost 
that, good, or neutral, sense which originally belonged to it. 
The academic meaning which it acquired under the early 
empire lasted into the middle ages (see Du Cange, s.v., who 
quotes from Baldricus, "Egregius Doctor magnusque Sophista 
Geraldus"). While the word rhetor still denoted the faculty, 
the word sophistes denoted the office or rank to which the 
rhetor might hope to rise. So Lucian ("Teacher of Rho-

toricians," § 1) says: "You ask, young man, how you are 
to become a rhetor, and attain in your turn to the repute of 
that most impressive and illustrious title, sophist." Lucian also 
satirizes the nature of the rhetoric in his parody of 
the Parásile (cf. also his Bís Accusasús).

Vespasian (79-79 A.D.), according to Suetonius, was the 
first emperor who gave a public establishment to the teaching of 
rhetoric. Under Hadrian and the Antonines (A.D. 117-150) 
the public chairs of rhetoric became objects of the 
highest ambition. The complete constitution of the 
schools at Athens was due to Marcus Aurelius. The 
Philosophical school had four chairs (θρόνοι)—Platonic, Stoic, 
Peripatetic, Epicurean. The Rhetorical school had two chairs, 
one for "sophistic," the other for "political" rhetoric. By 
"sophistic" was meant the academic teaching of rhetoric as an 
art, in distinction from its "political" application to the 
law-courts. The "sophistic" chair was superior to the 
"political" in dignity and emolument, and its occupant was 
invested with a jurisdiction over the youth of Athens similar 
to that of the vice-chancellor in a modern university. The 
Antonines further encouraged rhetoric by granting immunities 
to its teachers. Three "sophists" in each of the smaller towns, 
and five in the larger, were exempted from taxation (Dig. 
xxvii. 1, 6, § 2). The wealthiest sophists affected much personal 
splendour. Polemon (c. A.D. 130) and Adrian of Tyre (c. A.D. 
170) are famous examples of extravagant display. The aim 
of the sophist was to impress the multitude. His whole stock-
in-trade was style, and this was directed to astonishing by tours 
de force. The scholastic declamations were divided 
into two classes. (1) The suasaoriae were usually on 
historical or legendary subjects, in which some course 
of action was commended or censured (cf. Juv. Sat.). These 
susaoriae belonged to deliberative rhetoric (the βουλευτικόν 
γέγος, deliberatum genus). (2) The controversiae turned 
especially on legal issues, and represented the forensic rhetoric 
(δικαιικὸν γέγος, judiciale genus). But it was the general 
characteristic of this period that all subjects, though formally 
"deliberative" or "forensic," were treated in the style and 
spirit of that third branch with which Aristotle distinguished, the 
rhetoric of πρακτικὸς or "display." The oratory produced by 
the age of the academic sophists can be estimated from a large 
extant literature. It is shown under various aspects, and 
presumably at its best, by such writers as Dio Chrysostom at 
the end of the 1st century, Aelius Aristides (see Arístides, Aelius) 
in the 2nd, the chief rhetorician under the Antonines, Themistius, 
Himerius and Libanius in the 4th. Amid much which is 
tawdry or vapid, these writings occasionally present passages 
of true literary beauty, while they constantly offer matter of 
the highest interest to the student.

In the medieval system of academic studies, grammar, 
logic and rhetoric were the subjects of the trivium, or course 
followed during the four years of undergraduateship.

Music, arithmetic, geometry and astronomy con-
stituted the quadrivium, or course for the three years 
from the B.A. to the M.A. degree. These were the seven 
liberal arts. In the middle ages the chief authorities on 
rhetoric were the latest Latin epitomists, such as Martianus 
Capella (5th cent.), Cassiodorus (5th cent.) or Isidorus (7th 
cent.).

After the revival of learning the better Roman and Greek 
writers gradually returned into use. Some new treatises were 
also produced. Leonard Cox (d. 1549) wrote The Art or Craft 
of Rhetorike, partly compiled, partly original, which was 
reprinted in Latin at Cracow. The Art of Rhetorique, by Thomas Wilson 
(1553), afterwards secretary of state, embodied rules chiefly 
from Aristotle, with help from Cicero and Quintillian. About 
the same time treatises on rhetoric were published in France 
by Tonquin (1558) and Courcelles (1557). The general aim 
at this period was to revive and popularize the best teaching 
of the ancients on rhetoric. The subject was regularly 
taught at the universities, and was indeed important. 
At Cambridge in 1570 the study of rhetoric was 
based on Quintillian, Hermogenes and the speeches of 
Cicero viewed as works of art. An Oxford statute of 1588 
shows that the same books were used there. In 1620 George 
Herbert was delivering lectures on rhetoric at Cambridge, 
where he held the office of public orator. The decay of rhetoric 
as a formal study at the universities set in during the 18th 
century. The function of the rhetoric lecturer passed over 
into that of correcting written themes; but his title remained 
long after his office had lost its primary meaning. If the theory 
of rhetoric fell into neglect, the practice, however, was encouraged 
by the public exercises ("acts" and "opponents") in the 
schools. The college prizes for "declarations" served 
the same purpose.

The fortunes of rhetoric in the modern world, as briefly 
sketched above, may suffice to suggest why few modern writers 
of ability have given their attention to the subject. Modern 
Writers on Rhetoric. Perhaps one of the most notable modern contributions to 
the art is the collection of commonplaces frames (In Rhetoric 
Latin) by Bacon, "to be so many spoils from which the threads 
can be drawn out as occasion serves," a truly curious work of 
that acute and fertile mind. He called them "Antitheta." 
A specimen is subjoined:—

UXOR ET LIBER

For.

"Attachment to the state begins from the family."

"Wife and children are a discipline in humanity. Bachelors 
are morose and austere."

"The only advantage of celibacy and childlessness is in case 
of exile."

This is quite in the spirit of Aristotle's treatise. The 
popularity enjoyed by Blair's Rhetoric in the latter part of the 18th 
and the earlier part of the 19th century was merited rather by 
the form than by the matter. Campbell's Philosophy of Rhetoric, 
which found less wide acceptance than its predecessor, was 
superior to it in depth, though often marred by an imperfect 
comprehension of logic. But undoubtedly the best modern book on 
the subject is Whately's Elements of Rhetoric. Whately.

Starting from Aristotle's view, that rhetoric is "an 
offshoot from logic," Whately treats it as the art of "argu-
mentative composition." He considers it under four heads: 
(1) the address to the understanding (= Aristotle's λογικὴ πίασις); 
(2) the address to the will, or persuasion (= Aristotle's ἀθλητικὴ and
In adults the affection of the joints is the most striking feature. The attack is usually ushered in by a feeling of chilliness or malaise, with pain or stiffness in one or more joints, generally those of large or medium size, such as the knees, ankles, wrists or shoulders. At first the pain is confined to one or two joints only, reduced on their being affected, and there is a tendency to symmetry in the order in which they are attacked, the inflammation in one joint being followed by that of the same joint on the opposite side. The affected joints are swollen, hot and excessively tender, and the skin over them is somewhat flushed. The temperature is raised, ranging from about 101° to 103° F., the pulse rapid, full and soft; the face is flushed, the tongue coated with a thick white fur, and there is thirst, loss of appetite, and constipation. The body is bathed in a profuse perspiration, which has a characteristic sour, disagreeable odour. The urine is diminished, acid and loaded with albumen, and the stool contains a large amount of mucus. Rapid, cold, and clammy sweats may be observed. The sleep is disturbed, restless, and shallow, and when attempted the patient is awakened by a sharp pain in the affected parts.

Treatment.

The patient should be placed in bed between blankets, and should wear a light flannel or woollen shirt. The affected joints should be kept at rest as far as possible, and enveloped in cotton-wool. Salicylate of soda or salicin, first suggested by Dr Maclagan in 1876, appear to exercise a specific influence in acute rheumatism. They have a powerful effect not only in reducing the temperature, but in relieving the pain and cutting short the attack. Frequent and fairly large doses of salicylate of soda should be administered for the first twenty-four hours: the dose and interval at which it is given should then be gradually reduced till the symptoms subside. In conjunction with this, alkalies such as bicarbonate or citrate of potash should also be administered. The effect of the salicylate should be carefully watched, and the dose reduced if toxic symptoms such as delirium, deafness, and noises in the ears occur. These drugs are of less service in the rheumatism of children than in that of adults, as they do not appear to exercise any specific influence in arresting the cardiac inflammation to which children are specially liable, though they have a marked effect on the joint affections. Aspirin has
RHEUMATOID ARTHRITIS

recently come into use as a substitute for salicylates, and may succeed when salicylates fail.

Subacute rheumatism.—This term is sometimes applied to attacks of the disease of a less severe type in which the symptoms, though milder in character, are usually of longer duration and more intractable than in the acute form. It is difficult, however, to draw a hard-and-fast line between the two, but the term may perhaps be most appropriately applied to the repeated and protracted attacks of cardiac rheumatism in children.

Chronic rheumatism.—This term has been somewhat loosely applied to various chronic joint affections, sometimes of gouty origin or the result of rheumatoid arthritis. Strictly speaking, it may be applied to cases in which the joint lesions persist after an attack of rheumatism, and chronic inflammatory thickening of the tissues takes place, so that they become stiff and deformed. It is also appropriate to certain joint affections occurring in later life in rheumatic subjects, who are liable to repeated attacks of pain and stiffness in the joints, usually induced by exposure to cold and wet. This form of rheumatism is less migratory than the acute, and is commonly limited to one or two of the larger joints. After repeated attacks the affected joints may become permanently stiff and painful, and crackling or crepitation may occur on movement. There is seldom any constant local disturbance, and the heart is not liable to be affected.

Muscular rheumatism.—By this is understood a painful affection of certain groups of muscles attributable to inflammation of their fibrous and tendinous attachments. It is commonly brought on by exposure to cold and wet, and especially by a chill after violent exercise and free perspiration when the clothes are not changed. Any movement of the affected muscles gives rise to severe and sharp pain which may induce a certain degree of spasm and rigidity at the time. The pain usually subsides and passes off rapidly while the patient is at rest, but occurs on the slightest movement of the affected muscles.

The chief varieties of muscular rheumatism are:

1. Lumbago, in which the muscles of the lower part of the back are affected so that stooping, particularly the attempt to rise again to the erect position, induces severe pain.
2. Intercostal rheumatism, affecting the muscles between the ribs, so that taking a deep breath and certain movements of the arms give rise to pain.
3. Torticollis or stiff neck, affecting the muscles of one side of the neck.

Treatment.—Salicylates, which are of service in acute rheumatism, are not so reliable in the chronic varieties, but are sometimes of service. Aspirin, salicyl, quinine and iodide of potassium may be more successful, but other active treatment is usually required. The application of heat in the form of poultices or fomentations, counter irritation by mustard leaves or blisters, are indicated in some cases. In others massage, hot douches, or electricity may be required. Mineral waters and baths of various health resorts are of great benefit; in obstinate cases, such as those of Buxton, Bath, Harrogate, Woodhall Spa, &c., in England, or of Aix-les-Bains, Wiesbaden, Wildbad, &c., and many others on the continent of Europe. Wintering abroad in warm, dry and sunny climates may be advisable in some cases when this is practicable.

(J. F. H. B.)

RHEUMATOID ARTHRITIS (OSTEO-ARTHRITIS, ARTHRITIS DEFORMANS), terms employed to designate a disease or group of diseases characterized by destructive changes in the joints. Though it is only in comparatively recent times that the disease was definitely recognized as separate clinically from either rheumatism or gout, it is certain that it prevailed in ancient times. Characteristic changes in the bones have been found in remains in tombs in Egypt attributed by Petrie to 1300 B.C., and ancient Roman as well as British graves have held bones showing distinct traces of the diseases. Of early medical writers, Paulus Aegineta observed the lesions and seemed to consider them distinctive. Landré Beauvais in 1830 published a description of the disease under the title of Goutte asthénique primitif. The first endeavour, however, to separate rheumatoid arthritis as a distinct disease was made by William Heberden in 1803; while in 1805 John Haygarth recognized the difference between it and rheumatism, and suggested the term "nodosity of the joints." A wide divergence of opinion during the 19th century as to its relation to rheumatism and to gout gave rise to the unfortunate term "rheumatic gout." The name arthritis deformans was suggested by Virchow in 1859. Various causes, such as nervous origin, inherited arthritic diathesis, a relationship to rheumatism or gout, and reflex irritation, have been put forward as giving rise to the disease, but in the present state of medical knowledge two are most favoured. The first ascribes the disease to an infective process arising from micro-organisms. Several observers have found bacteria in the synovial fluid and membranes of affected joints,—Max Schiller finding both bacilli and cocci, while in 1866 Gilbert Bannatyne, Wohlmann and Blaxall isolated a micro-organism, a bacillus with a bipolar staining, which they stated to be almost constantly present in the joints of patients with true rheumatoid arthritis. The second view is that the disease is the result of a chronic toxæmia produced by absorption of toxins from the intestine, with perhaps some error in metabolism. In the latter case there seems to be a direct connection of a local infection, injury being the determining factor, and some families seem to have joints which are specially liable to degeneration. The disease may begin at any age, for there is no doubt that persistent cases have been met with in quite young children; but it usually begins in early middle-age, and statistics seem to confirm the impression of the greater liability of females. Conditions which tend to lower the general health seem to act as a predisposing cause to rheumatoid arthritis, e.g. mental worry, uterine disorders and various lowering diseases, prominent among which are influenza and tonsillitis. In a number of cases in women the onset occurs about the time of the menopause.

The method of onset varies according to the form. There are four well-marked types,—(1) the peri-articular form, in which the most marked changes are in the synovial membrane and peri-articular tissues, and the cartilage may be involved to a lesser degree. In this variety is found every grade of severity. The onset may be acute, resembling an attack of rheumatic fever, for which it may be mistaken; the joints, one or more, are swollen, tender and painful to the touch; the temperature elevated to 100°; 101°; but unlike rheumatic fever, sweating and hyperpyrexia are uncommon. The acute stage may then subside, a slight thickening remaining in the capsule of the joint, and the contours of the limb scarcely regaining the normal; or the attack may gradually develop into the chronic form. The pain varies greatly, and is not necessarily in ratio to the amount of arthritis present. Various joints may be involved, the spinal vertebrae not infrequently sharing in an arthritis; the most usual joints to be attacked, however, are the knee and shoulder. When the knee is attacked there is commonly effusion into the joint. Muscular atrophy is usually present, but varies greatly in its extent. In most cases it is present to some extent, but in the majority of cases there is no apparent destruction of the muscles. The skin has in these cases a curious glossy appearance, and pigmentation may be noticed. In chronic forms the onset is gradual, one joint becoming painful and swelling, and then the others successively; in these slow forms the outlook for the recovery of the joint is not so good as in the acute, and some cases may proceed to extreme deformity with little or no pain. Gradually the shape of the joint is altered; this is in a great measure due to synovial thickening, and partly to the presence of osteophytes in the joint. When the affected joint is moved a distinct crepitation can be felt. The muscles about the joint atrophy often to an extreme degree, and contractures supervene, flexing the leg upon the thigh if the knees should be affected, and the thigh upon the abdomen should the hip be affected. In extreme degrees the patient may become a complete cripple. Later, in many cases a quiescent stage of the
disease is reached, the patients cease to suffer pain, and are inconvenient only by the deformities in the limbs, in which a considerable degree of motion may be retained. Remarkable deformities are seen in hands in which a considerable amount of usefulness still remains. Dyspepsia and anaemia are frequently associated with arthritis. Monarticular arthritis more particularly affects the aged; and when it affects the hip is known as morbus coxae senilis.

(2) The atrophic form of arthritis is not very common. The chief anatomical change is due to atrophy in the bone and cartilage. The disease occurs at an earlier period in life than the peri-articular form, from which the initial symptoms do not markedly differ; but the disorganization in the joint is greater, dislocations frequently occur, and ankylosis of the joints follows. This is the modified form of arthritis.

(3) In the hypertrophic form the anatomical changes include the formation of new bone as well as changes in the cartilage. This new-bone formation may lead to progressive ankylosis in the joints. Should the vertebral column be affected a rigid condition of the spine known as spondylitis deformans ("poker back") may ensue. What are termed "Heberden's nodes" are small hard knobs about the size of a pea frequently found upon the fingers near the terminal phalangeal joints; they rarely give rise to symptoms. Popularly ascribed to gout, these nodes are in reality a manifestation of arthritis.

(4) A variety of arthritis occurring in children is known as Still's disease; swelling of the joints is associated with swelling of the lymph glands and of the spleen. The onset is often acute, with fever and rigor; sweating is profuse and the joints are enlarged and painful. There may be much muscular wasting and limitation of movement in the joints, and anaemia is associated with the disease. The treatment of rheumatoid arthritis is rarely curative, once the disease has been permanently established; and it is therefore important to begin treatment before destructive changes have taken place in the joints. In the acute febrile form, which is frequently taken for rheumatism, the essential treatment is rest to the affected joints, with the application of oil of wintergreen; the joint should not be fixed but supported. In the more chronic forms medicinal treatments are usually of little value. Potassium iodide is useful in some cases by promoting absorption of the hypertrophied fibrous tissue, and guaiacol if administered for a sufficiently long time is said to be capable of arresting the disease, diminishing the size of the joint and helping movement. Where anaemia accompanies the disease iron and arsenic are of value. The general health of a patient suffering from rheumatoid arthritis must be maintained, and he should live upon a dry soil. Visits to Aix-les-Bains, Burton-on-Trent, and Devon, with their baths and shampooings, often prove useful, particularly when combined with gentle massage. It is a mistake to keep the joints entirely at rest in the chronic forms, as this tends to the formation of contractures and ankylosis. Moderate exercise without undue fatigue is desirable. Patients should go early to bed and have plenty of rest, sunshine and fresh air. It is important that the diet should be nourishing and plentiful, and should there be intestinal putrefaction fermented milk is useful. As regards the local treatment, it will be well in the majority of cases to determine by the X-rays the exact state of the affected joints. Radiant heat, vibration and hot-air baths are among the best treatments. The active hyperaemia induced by hot air favours restoration of movement and alleviates pain, but where there is pronounced destruction of bone and cartilage full restoration of a joint cannot take place. Systematic exercises of the joints tend to prevent the atrophy of the adjacent muscles, and Bier's passive hyperaemia induced by the temporary use of an elastic bandage has the same results. Should an X-ray photograph reveal the presence of spurs or loose bodies in the joints interfering with free movement their removal is called for. Sometimes the breaking down of adhesions under an anaesthetic is necessary, and gentle passive and later active movements of the joints should follow if freedom of use is to be gained. Recently treatment by radium has taken a definite place in the therapeutics of chronic arthritis, its analgesic properties seeming of great benefit.

RHEYDT, a town of Germany, in the Prussian Rhine province, situated on the Niemels, 10 m. W. of Düsseldorf, on the main line of railway to Aix-In-Chapelpe, and on the junction of lines to Crefeld and Stolberg. Pop. (1905) 40,140. It has two Roman Catholic and two Evangelical churches, a handsome new town hall (1803), a gymnasmum, and several technical schools. The principal products of its numerous factories are silk, cotton, woolen and mixed fabrics, velvet, iron goods, machinery, shoes, clothes, soap and cigars. Dyeing and finishing, brewing and distilling, are also carried on. Rheydt is an ancient place, but its industrial importance is of very recent growth, and it only received municipal rights in 1856.

RHIANUS, Greek poet and grammarian, a native of Crete, friend and contemporary of Eratosthenes (275-195 B.C.). Suda says he was at first a slave and overseer of a palaestra, but obtained a good education later in life, and devoted himself to grammatical studies, probably in Alexandria. He prepared a new recension of the Iliad and Odyssey, characterized by sound judgment and poetical taste. His bold metaphors are frequently mentioned in the scholia. He also wrote epigrams, eleven of which, preserved in the Greek anthology and Athenaeus, show elegance and vivacity. But he was chiefly known as a writer of epics (mythological and ethnographical), the most celebrated of which was the Messenica in six books, dealing with the second Messenian war and the exploits of its central figure Aristomenes, and used by Pausanias in his fourth book as a trustworthy authority. Other similar poems were the Achaika, Eliaca, and Thessalica. The Heracleia was a long mythological epic, probably an imitation of the poem, of the same name by Fanny, and containing the same number of books (fourteen).

Fragments in A. Meinecke, Analecta Alexandrina (1843); for Rhianus's work in connexion with Homer, see C. Mayhoff, De Rhianii Studiis Homericis (Dresden, 1870); also W. Christ, Geschichte der griechischen Literatur (1898).

RHIGAS, CONSTANTINE, known as Rhigas of Velestinos (Pherec), or Rhigas Phereis (1760-1768), Greek patriot and poet, was born at Velestinos, and was educated at Zagora and at Constantinople, where he became secretary to Alexander Ypsilanti. In 1786 he entered the service of Nicholas Mavrog- negen, hospodar of Wallachia, at Bucharest, and when war broke out between Turkey and Russia in 1787 he was charged with the inspection of the troops at Craiova. Here he entered into close and friendly relations with a Turkish officer named Osman Pasaev-Djou (1758-1877), afterwards the famous governor of Widin, whose life he saved from the vengeance of Mavrogeven. After the death of his patron Rhigas returned to Bucharest to serve for some time as interpreter at the French Consulate. At this time he wrote the famous Greek version of the Marseillaise, well known in Byron's paraphrase as "sons of the Greeks, arise." He was the founder of the Hetaireia, a society formed to organize Greek patriotic sentiment and to provide the Greeks with arms and money. Believing that the influence of the French Revolution would spread to the Near East, he betook himself to Vienna to organize the movement among the exiled Greeks and their foreign supporters in 1793, or possibly earlier. He published in Vienna many Greek translations of foreign works, and presently found a Greek press there, but his chief glory was the collection of national songs which, passed from hand to hand in MS., roused patriotic enthusiasm throughout Greece. They were only printed posthumously at Jassy in 1814. While at Vienna Rhigas entered into communication with Bonaparte, to whom he sent a snuff-box made of the root of a laurel tree taken from the temple of Apollo, and eventually he set out with a view to meeting the general of the army of Italy in Venice. But before leaving Vienna he forwarded papers, amongst which is said to have been his correspondence
with Bonaparte, to a compatriot at Istria. The papers were betrayed by Demetrios Okonomitis, Kozanites into the hands of the Austrian government, and Rhigas was arrested at Trieste and handed over with his accomplices to the Turkish authorities at Belgrade. Immediately on arrest he attempted suicide. His Turkish friend, Passvan-Oglou, sought to secure his escape, and the government apparently consented to release him on the payment of a ransom of about £6,000; but meanwhile the Turkish pasha commanding at Belgrade had taken the law into his own hands. Rhigas's five companions were secretly drowned, but he himself offered so violent a resistance that he was shot by two Turkish soldiers. His last words are reported as being: "I have sown a rich seed; the harvest is coming when my country will rise up to its glorious fruits." Rhigas left to his friend in the Rhine dialect instead of the classical Greek, aroused the patriotic fervour of his contemporaries and his poems were a serious factor in the awakening of modern Greece.

See Rizos Nérollos, Histoire de la révolution grecque (Paris, 1889); I. C. Bolanachi, Hommes illustres de la Grèce moderne (Paris, 1875); and Mrs. E. M. Edmonds, Rhigias Pheranos (London, 1890).

RHINE (Lat. Rhenus, Ger. Rhein, Fr. Rhin, Dutch Rijn, or Rijn), the chief river of Germany and one of the most important in Europe. It is about 830 m. in length and drains an area of 75,000 sq. m. The distance in a direct line between its source in the Alps and its mouth in the German Ocean is 460 m. Its general course is north-north-west, but it makes numerous deflections and at one point is found running in a diametrically opposite direction. The name Rhine, which is apparently of Celtic origin, is of uncertain etymology, the most favoured derivations being either from der Rhinnen (the flowing), or from Rein (the clear), the latter being now the more generally accepted.

1. The Swiss Section.—The Rhine rises in the mountains of the Swiss canton of the Grisons, and flows for 283 m. In Swiss territory, within which its drainage basin includes about 14,469 sq. m., and every canton save Geneva. The two main branches of the Rhine, the Hinter Rhine and the Vorder Rhine, unite at Reichenau, 6 m. S.W. of Coire. (1) The principal stream is considered to be that of the Hinter Rhine, which issues (7271 ft.) from the glaciers of the Rheinwaldhorn group, and then flows first N.E. through the Rheinwald valley, and next N. through the Schaum valley, which communicates by the well-known gorge of the Via Mala with the Tomlesch valley at Thusis, whence the stream continues its course to Reichenau; total length 333 m., total fall 3711 ft. It receives a number of mountain torrents during its course, the most important being that from the Averler glen, and the Albula, a tributary of the Rhine, on the right, which is itself formed by many mountain streams. (2) The Vorder Rhine rises in the small Toma lake (7691 ft.), S. of the Oberalp Pass, not far from the St. Gotthard Pass, and then flows N.E. past Disentis and Ianz, which claims the honour of being the "first town on the Rhine," to Reichenau; total length 42 m., total fall 3492½ ft. Its chief affluents are the stream dignified by the name of Medels Rhine, that rises in the Cadillo glen, W. of the Lukmanier Pass, and, after flowing through the Medels glen, joins the Vorder Rhine at Disentis, and the Glener, flowing from the Lugen glen, both on the Right. From Disentis to its united streams flowing to Coire, the capital of the canton of the Grisons, and then turn towards the N., past Ragatz, the valley broadening out, and the river being joined on the right by the Landquart and the Ill, before it expands into the Lake of Constance. Extensive "corrections" of the river bed, especially the canal of Diepoldswa, have been carried out in the lower bit of this part of the valley, while from a little north of Ragatz the right bank belongs first to Liechtenstein and then to the Austrian province of the Vorarlberg. On issuing from the Lake of Constance at St. Cassan, the Rhine flows nearly due west to Basel, where it leaves Switzerland, and turns south-westerly. On its passage through the Aargau district the river being entirely Swiss, save the town of Constance, but the north shore belongs to Baden, save in the case of the Swiss town of Stein-am-Rhein and the Swiss canton of Schaffhausen. The chief towns on its banks are Constance (S.), Schaffhausen (N.), Waldshut (N.), Laufenburg (S.), Säckingen (N.), Rheinfelden (S.), and Basel (both banks). About 14 m. below Schaffhausen the river forms the famous Falls of the Rhine, or Falls of Schaffhausen (60 ft. high), while at Coblenz, opposite Waldshut, it receives its chief affluent, the Aar, recently swollen by the Reuss and the Limmat, and of greater volume than the river in which it loses its identity.

(W. A. B. C.)

2. The German and Dutch Portion.—After Basel, when the Rhine turns to the north and enters Germany, its breadth is between 550 and 600 ft., while its surface now lies not more than 800 ft. above the sea, showing that the river has made a descent of 6900 ft. by the time it has traversed a third of its course. About 240 m. below Basel, the Rhine flows through a wide, shallow valley, bordered on the east and west by the parallel ranges of the Black Forest and the Vosges. Its banks are low and flat, and numerous islands occur. The tendency to divide into parallel branches has been curbed in the interests of navigation, and many windings have been cut off by leading the water into straight and regular channels. At Mannheim the river is nearly 1500 ft. in width, and at Mainz, where it is diverted to the west by the barrier of the Taunus, it is still wider. It follows the new direction for about 20 m., but at Bingen it again turns to the north and begins a completely new stage of its career, entering a narrow valley in which the enclosing rocky hills abut so closely on the river as often barely to leave room for the road and railway on either bank; during this portion of its course the speed of the current at a normal state of the water exceeds 6 m. an hour. This is the most beautiful part of the whole course of the river, abounding in ruined castles, romantic crags and sunny vineyards. At Coblenz the valley widens and the river is 1200 ft. broad, but the hills close in again at Andernach, and this ravine-like part of its course cannot be considered as ending till below the Siebungebirge (Seven Mountains), where the river once more expands to a width of 1300-1600 ft. Beyond Bonn and Cologne the banks are again flat and the valley wide, though the hills on the right bank do not completely disappear till the neighbourhood of Düsseldorf. Farther on the country traversed by the Rhine is perfectly level, and the current becomes more and more sluggish. On entering Holland, which it does below Emmerich, its course is again deflected to the west. Within Holland the banks are so low as to require at places to be protected by embankments against inundations. Almost immediately after entering Holland the stream divides into two arms, the larger of which, carrying off about two-thirds of the water, diverges to the west, and joins the Waal, and soon the Waal, and the Waal, and soon the Maas. The smaller branch to the right retains the name of Rhine and sends off another arm, called the Yssel, to the Zuider Zee. The Rhine now pursues a westerly course almost parallel with that of the Waal. At Wijk another bifurcation takes place, the broad Lek diverging on the left to join the Maas, while the "Kromme Rijn" to the right is comparatively insignificant. Beyond Utrecht, where it is again diminished by the divergence of the Vecht to the Zuider Zee, the river under the name of the "Oude Rijn," or Old Rhine, degenerates into a sluggish and almost stagnant stream, which requires the artificial aid of a canal devised by Spaendonck, to find its way across the polders. The Rhine at this part of its course seems to have been a full and flowing river, but by the 9th century it had lost itself in the sands of Katwijk, and it was not until the beginning of the 10th century that its way to the sea was re-opened. Though the name Rhine thus at last attaches to a very insignificant stream, the entire district between the Waal on one side and the Yssel on the other, the Insula Batavorum of Caesar, in reality belongs to the delta of the famous river. Tributaries.—The Rhine is said to receive, directly or indirectly, the waters of upwards of 20,000 tributaries of all sizes. Leaving out account the immemorial glacier streams that swell its volume above the Lake of Constance, the most important affluents to its upper course are the Wutach, the Alb and the Wiese, descending on the right from the Black Forest, and the Aar, draining several Swiss cantons on the left. In the upper Rhinian basin, between
RHINE

241

Basel and Mainz, the tributaries, though numerous, are mostly short and unimportant. The Ill and the Nahe on the left and the Neckar and the Main on the right are, however, notable exceptions. Before joining the Rhine the Ill runs almost parallel with it and at no great distance, for upwards of 50 m. In the stretches parallel the valley, between Bingen and Cologne, the Rhine receives the waters of the Lahm and the Sieg on the right, and those of the Mosel, bringing with it the Saar, and the Ahr on the left. Still lower, on the right, the Dindelsee and on the left the Ruhr and the Lippe on the right, and the Erft on the left. The numerous arms into which the Rhine branches in Holland have all but disappeared.

Physical Geography.—The Rhine connects the highest Alps with the mud banks of Holland, and touches in its course the most varied geological periods; but the river valley itself is, geologically speaking, comparatively recent. Near the source, in the ancient grey-gees of the St Gotthard, the Rhine finds its way down to the Lake of Constance between layers of Triassic and Jurassic formation; and between that lake and Basel it penetrates the chalk barrier of the Jura. The upper Rhinen valley is evidently the bed of an ancient lake, the shores of which were formed by the gneiss and granite of the Black Forest on the one side and the granite and sandstone of the Vosges on the other. Within the valley all the alluvial deposits are recent. Between Bingen and Bonn the Rhine forces its way through ailly and rocky district belonging to the Devonian formation. The contorted strata of sandstone, slate, and gneiss must have been folded and more or less altered anterior to that in which the lake of the upper valley managed to force an outlet through the enclosing barriers. Probably this section may be looked upon as the oldest portion of the river course proper. Some distance below Bingen the river starts its journey through a highly gravelly district. Below the town of作者所有

or Mainz, Borbetomagus or Worms); but at the beginning of the historical period we find the Celts everywhere in retreat before the advancing Teutons. Probably the Teutonic pressure began as early as the 4th century before Christ, and the history of the next few hundred years may be summed up as the gradual substitution of a Germanic for a Celtic population along the banks of the Rhine. Its second historical period begins with the advent of the Romans, who stemmed the advancing Teutonic tide. Augustus and his successors took good care to fortify the Rhine carefully, and a large proportion of the Roman legions were constantly in garrison here. For two hundred years the Rhine formed the boundary between the Roman Empire and Germany's Teutonic enemy. During that period the left or Roman bank made prodigious strides in civilization and culture. The wonderful Roman remains at Trier and elsewhere, the Roman roads, bridges and aqueducts, are convincing proofs of what the Rhine gained from Roman domination. This Roman civilization was, however, destined to be swamped by the current of Teutonic immigration, which finally broke down the barriers of the Roman empire and overwhelmed the whole of the Rhennish district. Under Charlemagne, whose principal residence was in Aix-la-Chapelle, the culture of the Rhine valley again began to flourish, its results being so lasting that it was at least partly in connection to the important architectural remains of this period. At the partition of the domains of Charlemagne in A.D. 843 the Rhine formed the boundary between Germany and the middle kingdom of Lotharingia; but by 870 it lay wholly within the former empire. For nearly eight hundred years it continued in this position, the frontier of the German empire coinciding more or less with the line of the Rhine. During the early middle ages the bank of the Rhine formed the most cultured part of Germany, basing its civilization on its Roman past. The Thirty Years' War exercised a most prejudicial effect upon the district of the Rhine; and when the imperialists gave France a footing on the left bank of the hitherto exclusively German river by the acquisition of Alsace. The violent seizure of Strassburg by France in 1681 was ratified by the peace of Rysswick in 1697, which recognized the Rhine as the boundary between Germany and France from Basel to about Germersheim. It was an easy inference for the French mind that the Rhine should be the boundary throughout and the Gaul of Caesar restored. This ideal was realized in 1801, when the whole of the left bank of the Rhine was formally ceded to France. The congress of Vienna (1815) restored the lower part of the Rhennish valley to Germany, but it was not till the war of 1870–71 that the recovery of Alsace and Lorraine made the Rhine a German river, not Germany's frontier. In the military history of all these centuries constant allusion is made to the Rhine, its passages and its fortresses. Every general who has fought in its neighbourhood has at one time or another had to provide for a crossing of the Rhine, from Julius Caesar, who crossed it twice, down to our own time. The wars carried on here by Louis XIV. are still remembered in the Rhine district, where the devastations of his generals were of the most appalling description; and scarcely a village or town but has a tale to tell of the murder and rapine of this period.

The Rhine in Literature.—The Rhine has always exercised a peculiar sort of fascination over the German mind, in a measure and in a manner not easily paralleled by the case of any other river. "Father Rhine" is the centre of the German's patriotism and the symbol of his country. In his literature it has played a prominent part from the Nibelungenlied to the present day; and its weird and romantic legends have been alternately the awe and the delight of his children. The Rhine was the classic river of the middle ages; and probably the Tiber alone is of equal historical interest among European rivers. But of late years the beauties of the Rhine have become sadly marred; the banks in places, especially between Coblenz and Bonn, disfigured by quarrying, the air made dense with the smoke of cement factories and steam-tugs, commanding spots falling a prey to the speculative builder and villages growing into towns.

Jahrhundert; Horn, Der Rhein, Geschichte und Sagen seiner Burgen (Stuttgart, 1893); Trutlein, Die neuen Deutschen Reichs- strömstudien und ihre Ergebnisse (in Ausland, 1893); A. Chambal, Die Stromveränderungen des Niederreins seit der vorromischen Zeit (Cologne, 1892), and handbooks of Baederker, Meyer and Woel. (J. F. M.; P. A. A.)

RHINE PROVINCE, or RHINELAND, the most westerly province of the kingdom of Prussia, bounded on the N. by Holland, on the E. by the Prussian provinces of Westphalia and the Rhine, and the grand duchy of Hesse-Darmstadt, on the S.E. by the Bavarian Palatinate, on the S. and S.W. by Lorraine, and on the W. by Luxembourg, Belgium and Holland. The small district of Wetzlar in the midst of the province of Hesse also belongs to the Rhine Province, which, on the other hand, surrounds the Oldenburg principality of Birkenfeld. The extent of the province is 10,433 sq. m.; its extreme length, from north to south, is nearly 200 m., and its greatest breadth is just under 90 m. It includes about 200 m. of the course of the Rhine, which forms the eastern frontier of the province from Bingen to Coblenz, and then flows through it in a north-western direction.

The southern and larger part of the Rhine province, belonging geologically to the Devonian formations of the lower Rhine, is hilly. On the left bank are the elevated plateaus of the Hunsrück and the Eifel, separated from each other by the deep valley of the Mosel, while on the right bank are the spurs of the Westerwald and the Sauerland, the former reaching the river in the picturesque group known as the Seven Mountains (Siebengebirge). The highest hill in the province is the Waldersberg (1670 ft.) in the Hochwald, and there are several other summits above 2000 ft. on the left bank, while on the right there are few which attain a height of 1500 ft. Most of the plateau is covered with vegetation, and the Eifel is a barren and bleak plateau. To the north of a line drawn from Aix-la-Chapelle to Bonn the province is flat, and marshy districts occur near the Dutch frontier. The climate varies considerably with the configuration of the surface. That of the northern lowlands and of the sheltered valleys is the mildest and most equable in Prussia, with a mean annual temperature of 50° Fahr., while on the hills of the Eifel the mean does not exceed 44°. The annual rainfall varies in the different districts from 18 to 32 inches. Almost the whole province belongs to the basin of the Rhine, but a small district in the north-west is supplied by the rivers of the Moselle and Sieg system. The river, besides the Eifel, is in the hands of small proprietors, and this is alleged to have had the effect of somewhat retarding the progress of scientific agriculture. The usual cereal crops are, however, all grown with success, and tobacco, hops, flax, rape, hemp and beetroot (for sugar) are cultivated for commercial purposes. Large quantities of fruit are also produced. The vine-culture occupies a space of about 30,000 acres, about half of which are in the valley of the Mosel, a third in that of the Rhine itself, and the rest mainly on the Nahe and the Ahr. The choicest varieties of Rhine wine, however, such as Johanniserger and Steinberger, are produced higher up the river, beyond the limits of the Rhine Province. In the hilly districts more than half the surface is sometimes occupied by forests, and large plantations of oak are formed for the use of the bark in tanning. Considerable herds of cattle are reared on the rich pastures of the lower Rhine, but the
number of sheep in the province is comparatively small, and is, indeed, not greatly in excess of that of the goats. The wooded hills are well stocked with deer, and a stray wolf occasionally finds its way from the forests of the Ardennes into those of the Hunrück. The salmon fishery of the Rhine is very productive, and trout abound in the mountain streams.

The great mineral wealth of the Rhine province probably furnishes its most substantial claim to the title of the "richest jewel in the crown of Prussia." Besides parts of the carboniferous measures of the Saar and the Ruhr, it also contains important deposits of coal near Aix-la-Chapelle. Iron ore is found in abundance near Coblenz, the Eifel and in the Eifel possesses an apparently inexhaustible supply of lead, and zinc is found near Cologne and Aix-la-Chapelle. The mineral products of the district also include lignite, copper, manganese, vitriol, lime, gypsum, volcanic stones (used for millstones) and slates. By far the most important item is coal. Of the numerous mineral springs the best known are those of Aix-la-Chapelle and Kreuznach.

The mineral resources of the Prussian Rhine province, coupled with its favourable situation and the facilities of transit afforded by its great waterway, have made it the most important manufacturing district in Germany. The industries are concentrated in two chief centres, Aix-la-Chapelle and Düsseldorf (with the valley of the Wupper), while there are naturally few manufactures in the hilly districts of the south or the marshy flats of the north. The largest iron and steel works are at Essen, Oberhausen, Duisburg, Düsseldorf and Cologne, while cutlery and other small metallic wares are extensively made at Solingen, Remscheid and Aix-la-Chapelle. The cloth of Aix-la-Chapelle and the silk of Crefeld form important articles of export. The chief industries of Eibergfeld, Barmen and the valley of the Wupper are cotton-weaving, calcio-printing and the manufacture of turkey red and other dyes. Linen is largely made at Gladbach, leather at Malmedy, glass in the Saar district and beetroot sugar near Cologne.

Though the Rhineland is par excellence the country of the vine, beer is largely produced; distilleries are also numerous, and large quantities of sparkling Moselle are made at Coblenz, chiefly for exportation to England. Commerce is greatly aided by the navigable rivers, a very extensive network of railways, and the excellent roads constructed during the French régime. The imports consist mainly of raw material for working up in the factories of the district, while the principal exports are coal, fruit, wine, dyes, cloth, silk and other manufactured articles of various descriptions.

The population of the Rhine province in 1905 was 6,435,778, including 4,472,958 Roman Catholics, 1,877,582 Protestants and 55,408 Jews. The Roman Catholics must strongest on the left bank, while on the right bank about half the population is Protestant. The great bulk of the population is of Teutonic stock, and about a quarter of a million are of Flemish blood. On the north-west frontier reside about 10,000 Walloons, who speak French or Walloon as their native tongue. The Rhine province is the most thickly populated part of Prussia, the general average being 617 persons per sq. m. The province contains a greater number of large towns than any other province in Prussia. Upwards of half the population are supported by industrial and commercial pursuits, and barely a quarter by agriculture. There is a university at Bonn, and elementary education is especially successful. For purposes of administration the province is divided into the five districts of Coblenz, Düsseldorf, Cologne, Aix-la-Chapelle and Trier. Coblenz is the official capital, though Cologne is the largest and most important town. Being a frontier province the Rhineland is strongly garrisoned, and the Rhine is guarded by the three strong fortresses of Cologne with Deutz, Coblenz with Ehrenbreitstein, and Wesel. The province sends 35 members to the German Reichstag and 62 to the Prussian house of representatives.

History.—The present Prussian Rhine province was formed in 1815 out of the ducholes of Cleves, Berg, Gelderland and Jülich, the ecclesiastical principalities of Trier and Cologne, and nearly a hundred small lordships and abbeys. At the earliest historical period we find the line of the Ardennes and the Rhine occupied by the Treviri, the Eburones and other Celtic tribes, who, however, were all more or less modified and influenced by their Teutonic neighbours. On the right bank of the Rhine, between the Main and the Lahn, were the separated lands of the Germanic Chatti, while farther to the north were the Usipetes and Tencteri. Julius Caesar conquered the tribes on the left bank, and Augustus established numerous fortified posts on the Rhine, and maintained a line of garrisons for two centuries near the Rhine at the right bank. As the power of the Roman empire declined the Franks pushed forward along both banks of the Rhine, and by the end of the 5th century had regained all the lands that had formerly been in Roman hands. The title of Germanic sovereigns at Cologne (d. 476) and the designation of the Rhine under the Frankish empire, however, remained relatively small and the territories of the provinces they subdued, and all traces of Roman civilization were submerged in a new flood of paganism. By the 6th century the Frankish dominion was firmly established in central Germany and northern Gaul. On the division of the Carolingian realm the part of the province to the east of the river fell to the share of Germany, while that to the west remained with the evanescent kingdom of Lotharingia. By the time of Otto 1. (d. 973) both banks of the Rhine had become German, and the Rheinisch territory was divided between the duchies of Upper and Lower Lorraine, the one on the left bank and the other on the right. The title of German sovereign became weakened, the Rhineland followed the general tendency and split up into numerous small principalities. The principalities of the Rhineland were often on the point of annexation to some of the larger states. The French and the English made several attempts to acquire: the province on the continent as a means of checking the German states. The French were twice driven to leave them in undisturbed possession of the liberal institutions they had become accustomed to under the republican rule of the French.

RHINOCEROS, the designation for such perissodactyle (odd-toed) ungulate mammals as carry one or more horns on the head, and their extinct relatives (see PERISSODACTYLA). Rhinoceroses are of large size and massive build, but have little intelligence, and are generally timid in disposition, though ferocious when wounded or brought to bay. The African species use the nasal horns as weapons, while the African and the Asian species use theirs as protecting organs. The rhinoceroses exhibit their sharp lower tusks much as does a boar. Rhinoceroses are dull of sight, but their hearing and scent are remarkably acute. They feed on herbage, shrubs and leaves of trees, and, like so many other large animals which inhabit hot countries, sleep the greater part of the day, and are most active in the cool of the evening or even during the night. Some are found in more or less open plains, while others inhabit swampy districts. Members of the group have existed in both east and west hemispheres since the beginning of the Miocene period, but in America they all became extinct before the end of the Pliocene period, and in the Old World their distribution has become greatly restricted. They are, for instance, no longer found in Europe and North Asia, but only in Africa and in portions of the Indian and Indo-Malayan regions. Living rhinoceroses may be arranged in three groups: (1) With a single nasal horn, and very thick skin, which is raised into strong, definitely arranged ridges or folds. In this group there are two well-marked species. The Indian rhinoceros (Rhinoceros unicornis), the largest of the Asiatic forms, is the most widely known, from its being exhibited in zoological gardens. A famous rhinoceros presented to the Zoological Society of London in July 1864 lived till December 1866. It was a male, 12 feet 2 inches long end of the shoulder and was blackish grey in colour; the horn rarely exceeds a foot in length, but one in the British Museum measures 9 in. This species is now met with in a wild
state in the Assam plain, though it formerly had a wider range.

The first rhinoceros seen alive in Europe since the time when these animals, in common with nearly all the large remarkable beasts of both Africa and Asia, were exhibited in the Roman shows, was of this species. It was sent from India to Emmanuel, king of Portugal, in 1513; and from a sketch taken in Lisbon, Albert Dürer composed his celebrated but fanciful engraving, which was reproduced in so many old books on natural history. This species chiefly frequents swampy grass jungle and is fond of a mud-bath. According to General A. H. Kinloch, it is hunted by "tracking the animal on a single elephant until he is at last found in his lair, or perhaps standing quite unconscious of danger; or by beating him out of the jungle with a line of elephants, the guns being stationed at the points where he is most likely to break cover. In the latter case it is necessary to have reliable men with the beaters, who can exercise authority and keep them in order, for both mahouts and elephants have the greatest dread of the huge brute, who appears to be much more formidable than he really is." The Javan rhinoceros (Rhinoceros sondaicus) is distinguished by its smaller size, and a different arrangement of the skin-folds (as may be seen by comparing figs. 1 and 2). The horn in the female is little developed, if not altogether absent. This species has a more extensive geographical range than the last, being found in the Bengal Sundarbans near Calcutta, Burma, the Malay Peninsula, Java, Sumatra and Borneo. The colour is uniform dusky grey. A female obtained in the Sundarbans stood 5 ft. 6 in. high. This species is more an inhabitant of tree-forest than of grass jungle, and its usual habitat appears to be in hilly countries.

In the second section there is a well-developed nasals, and a small frontal horn separated by an interval. The skin is thrown into folds, but these are not strongly marked, and lower tusks are present. This group or genus is represented at the present day only by the Sumatran rhinoceros, Rhinoceros (Diceros bicornis) sumatrensis, with its sub-species. It is the smallest of all the species, and its geographical range is nearly the same as that of the Javan species, though not extending into Java; it has been found in Assam, Chittagong, Burma, the Malay Peninsula, Sumatra and Borneo. The colour varies from earthy brown to blackish, and the greater part of the body is thinly covered with hair, and the ears and tail are fringed. The average height of adults is from 4 ft. to 4 ft. 6 in. This species inhabits forests, and ascends hills to considerable elevations; it is shy and timid, but easily tamed even when adult. A specimen from Chittagong acquired in 1872 by the Zoological Society of London was named R. lastotis, as it differed from the typical form by its larger size, paler and browner colour, smoother skin, longer, finer and redder hair, and the long fringe of hair on the ears. It is now recognized as a local race.

RHINOCEROS

To the third group or genus (Diceros) belong the two African rhinoceroses, which have two horns, the skin without definite folds, and no lower tusks. The black rhinoceros (Rhinoceros (Diceros) bicornis) is the smaller of the two, and has a pointed prehensile upper lip. It ranges through the wooded and watered districts of Africa, from Abyssinia in the north to the Cape Colony, but its numbers are yearly diminishing, owing to the opening up of the country. It feeds exclusively on leaves and branches of bushes and small trees, and chiefly frequents the sides of wood-clad rugged hills. Specimens in which the posterior horn has attained a length as great as or greater than the anterior have been separated under the name of R. keitloa, but the characters of these appendages are too variable for specific distinctions. The black rhinoceros is more rarely seen in menageries in Europe than either of the Asiatic species, but one lived in the gardens of the London Zoological Society from 1868–1891.

Lastly we have the white—Burchell’s, or square-mouthed—rhinoceros (Rhinoceros (Diceros) simus), the largest of the five, and differing from the other species in having a square truncated upper lip. In conformity with the structure of the mouth, this species lives entirely by browsing on grass, and is therefore more partial to open countries or districts where there are broad grassy valleys between the tracts of bush. In its old haunts in

RHINTHON—RHIZOPODA

the reserve it is practically extinct; but ten were reported from a reserve in Zululand in 1902. A detached colony exists, however, near Lado, on the Upper Nile. No specimen of this species has ever been brought alive to Europe. Mr F. C. Selous gives the following description of its habits:—

"The square-mouthed rhinoceros is a huge, ungainly looking beast with a disarrangement lurkling a large male weighing 6 ft. 6 in. at the shoulder. Like elephants and buffaloes they lie asleep during the heat of the day, and feed during the night and in the cool hours of early morning and evening. Their sight is very bad, but they have a keen sense of hearing; and the scent is very keen; they are, too, often accompanied by rhinoceros birds, which, by running about their heads, flapping their wings, and screeching at the same time, frequently give them notice of the approach of danger. When thus disturbed they go off at a swift trot, which soon leaves all pursuit from a man on foot far behind; but if chased by a horseman they break into a gallop, which they can keep up for some distance. Although they run very swiftly, when their size and heavy build is considered, they are not match for an average good horse. They are, as a rule, very easy to shoot on horseback, as, if one gallops a little in front of and on one side of them, they will hold their course, and come sailing past, offering a magnificent broadside shot, while under similar circumstances a preensile-lipped rhinoceros will usually swerve away in such a manner as only to present his hind-quarters for a shot. When either running or walking, the square-mouthed rhinoceros still holds its head very low, its nose nearly touching the ground. When a small calf accompanies its mother, it always runs in front, and she appears to guide it by holding some sort of horn up in front of the animal's mouth; but it is perfectly wonderful to note how in all sudden changes of pace, from a trot to a gallop, or vice versa, the same position is always exactly maintained. During the autumn and winter, when the rhinoceroses from March to May wander about the search of branches, the rhinoceros is usually very fat; and its meat is then most excellent, being something like beef, but yet having a peculiar flavour of its own. The part in greatest favour among hunters is the hump, which, if cut off whole and roasted just as it is in the skin, in a hole dug in the ground, would, I think, be difficult to match either for juiciness or flavour."

(W. H. F.; R. L.)*

RHINTHON (c. 323–285 B.C.), Greek dramatist, son of a potter. He was probably a native of Syracuse and afterwards settled at Tarentum. He invented the kilourtragodia, a burlesque of tragic subjects. Such travesties were also called phylages ("fooleries") and their writers phylacographi. He was the author of thirty-eight plays, of which only a few titles (Amphitryon, Heracles, Orestes) and lines have been preserved, chiefly by the grammarians, as illustrating dialectic Tarentine forms. The metre is iambic, in which the greatest licence is allowed. The Amphithrco of Plautus, although probably imitated from a different writer (Archippus of the Middle Comedy), may be taken as a specimen of the manner in which such subjects were treated. There is no doubt that the hilarotragodia exercised considerable influence on Latin comedy, the Rhinthonica (i.e. fabula) being mentioned by various authorities amongst other kinds of drama known to the Romans. Scenes from these travesties are probably represented in certain vase paintings from Lower Italy, for which see H. Heydemann, "Die Phylakendarstellungen auf bemalten Vasen," in Jahrbuch des archäologischen Instituts, i. (1886).

Fragmenta in monograph by E. Völker (Leipzig, 1887); see also E. Sommerbrodt, De Phylacographia Graecorum (Breslau, 1875); W. Christ, Geschichte der griechischen Litteratur (1898).

RHIZOPODA, the name given by Dujardin (pro parte, 1838) to a group of Sarcodeina Protozoa. They are distinguished by their pseudopods, simple or branched, passing by wide bases into the general surface, never fine radial nor fusing into complex networks; skeleton absent or a simple shell ("test," "theca"), never (?) a calcareous shell, nor represented by a siliceous network; nor spicules. Reproduction by binary fission; by division or abstriction of buds after the body has become multiform; or by division of the body into two or four by the broad uniloculate zoospores (amoebule or flagellule) which may conjugate as gametes; plasmodium formation unknown; encystment (in "resting cysts" or "hypnecysts") common. Without a knowledge of the history it is impossible to distinguish a naked Lobose from the Amoebula (pseudopodispor) of a Myxomycete or Proteomyxan. As to the name, Dujardin included the thecate Loboss, the Filosa, and the Reticuloria or Foraminifera (q.e.t.). The latter had already received the name Foraminifera (for their shells) from d'Orbigny; and as it is impossible to separate naked from thecate Lobosa we have merged his Amoebina (Ambiens) in the larger group. The Filosa were removed by Lang from the Reticularia; in habit and test they are inseparable from the Lobosa; and though their cytoplasm approaches that of Reticularia, their ectosarc is much less granular, though not free from granules as stated by Lang.

The majority of Rhizopoda are fresh-water forms, some occurring in the film of water on mosses, among Sphagnum, or about the bases of grass-haulms; many, however, are exclusively marine. The aquatic forms generally may lurk among Coniferae or higher weeds, or lie in the bottom of decomposing or excrementitious matter in still or slow-flowing waters. Of these some may become temporarily pelagic, floating up by the formation of gas vacuoles (containing probably CO₂) in the cytoplasm. It is easy to verify this by placing Arcella (fig. 1, 7) in a drop of water on a glass cover and inverting this over a glass ring; the Arcella sink to the free convex surface of the drop and escape from this most unnatural position by secreting gas-vacuoles; when they float up to contact with the glass cover, so as to touch it by the convex back of the shell, they put forth long pseudopoda which attach themselves to the glass and by their contraction turn the animal over, so that it can crawl over (i.e. under) the glass. Amoeba (Entamoeba) histolytica, Schaudinn, is the cause of tropical dysentery and hepatic abscess in man. Pelomyxa (fig. 1, 5–6) is remarkable for containing symbiotic bacteria. Zoanthellae (symbiotic green cells—Algae or Flagellates) occur in several species; and Paulinella contains two sausage-shaped blue-green bodies, "chromatophores," which are probably symbiotic Cyanophyceae. The shell, even when not a simple membrane, has always a continuous inner membrane of a complex nitrogenous substance containing sulphur, allied to keratin and termed pseudochitin. The outer layer when present is composed of little hollow prisms (Arcella, fig. 1, 7), sand, or inorganic matter first swallowed by the animal (Difflugia, Pseudodifflugia), sometimes partially digested (Lecquereuxia), or else of plates secreted as "reserve plates" within the cytoplasm of the animal Cyphoderia (fig. 6, B), Quadrula, Nebelia, Euglypha (figs. 4, 6, A), &c. In Quadrula irregularis alone are the plates said to be calcareous; elsewhere they are always silicose and simply refractive, so that the silica is probably hydrated (opal). The cement is possibly of silicised pseudochitin. This material is often permeated by a ferric oxide or hydrate, even when it is not coloured rusty brown. Shell formation of the membranous test is by simple surface-excretion; under budding we describe its accomplishment in the aggregated shells.

The "pylome," or aperture for the protrusion of the proto- plank, is usually single. There are two pylomes at opposite poles in several Filosa (Ditremus), hence united by some authors into a distinct family (figs. 7, 1, 5, 11), and in the gelatinous theca of Trichiophyrum (fig. 5) are numerous permanent pylomic pores. The nucleus is variable in form and character. In Amoebo binucleata two nuclei are always present; and some genera are permanently binucleate (Pelomyxa, Arcella, fig. 1, 7). It often gives forth fragments into the cytoplasm, the "chromidia" of R. Hertwig, which, as in Foraminifera (q.e.t.), may play an important part in reproductive processes. The contractile vacuole (there are two in Arcella, fig. 1, 7) in actively progressing Rhizopods always discharges at the hinder end. Absent or sluggish in marine forms, it is of constant occurrence in all fresh-water Rhizopods except Pelomyxa. In Ameoba propea (fig. 1, 4) they are mere promontory-like extensions of the body; in A. radiosa (fig. 1, 1–3) and Trichiophyrum (fig. 5) they are distinct slender processes, tapering, and either blunt or finely pointed at the apex; in Pelomyxa (fig. 1, 5, 6) as in A. Lithamo e discus (fig. 2) they are "eruptive," hemispherical, formed apparently by the rupture of the ectoplasm, and the outpouring of the endoplasm which at once differentiates a clear outer layer as a new ectoplasm; in Amoeba limax during
progression the body is roughly oval with the apex truncated posteriorly and the wide anterior end forming a single anterior pseudopod. Progression chiefly takes place by a rolling over of the anterior end (fig. 3—see also Amoeba); but it may take place by the extension of a pseudopod, its attachment at the tip, followed by its contraction to pull up the rest of the animal; this is well shown in the thecate species. Another mode is that of A. radosa (fig. 1, 1-3), which can roll over on the tips of its stiff pseudopods. The pseudopods of the Filosa (figs. 6, 7) are branched, but less rich in granules, and less viscid than those of Foraminifera; they rarely anastomose, and never congregate to form perforated plates.

A process whose relations to reproduction are not fully made out is that of "plastogamy," where two or more individuals unite completely by their cytoplasm, the nuclei remaining distinct; it may be temporary or permanent: in the latter case

determining, of course, a much more rapid increase of size than that due to growth. Thanks to the labours of F. Schaudinn, we now know the full life cycles of at least half a dozen species; previously we only knew with certainty of two modes of fission—equal constriction (Amoeba—fig. 1, 1-3) and bud-fission (Difflugia). As in other Sarcodina, chromidia, or fragments of nuclear substance budded off from the nucleus into the endoplasm, play an important part in many reproductive processes. Equal binary fission is common. In the thecate forms, e.g. Difflugia, Euglypha (fig. 4), this is replaced by bud-fission; half the cytoplasm passes out through the pylome, and becomes invested with its covering there; the enclosed "reserve" skeletal elements pass to the surface in order, so that the pylome of the new shell faces that of the old; the original nucleus divides. in situ and one daughter nucleus passes into what we may call the bud-cytoplasm; the two daughters of the original cell, which we may call the "bud-sister" and the "stock-sister" respectively, now separate. In the plurinucleate forms a true bud-formation takes place, nucleate masses of cytoplasm being constricted off at the surface. A simultaneous resolution into uniclinal cells may affect the multinucleate species (or the multinucleate state of habitually uninucleate species); this is termed schizogony.

In Trichosphaerium (fig. 5) it occurs at the close of two.

---

**Fig. 1.**—1-3. Amoeba radosa (Dactylosphaerium polydomum), M. Schultze, in three stages of equal binary fission during fifteen minutes: a, nucleus; b, contractile vacuole (after M. Schultze). 4. Amoeba princeps, Ehr.; a, nucleus; b, c, vacuoles; food vacuoles shaded (after Auerbach). 5, 6, Pelomyxa palustris: 5, a small example; a in. in diameter, moderately extended; 6, a portion more highly magnified; a, ectosor; b, vacuoles; c, d, pseudopods formed by eruption and containing endosor; e, vesicles containing a solution of glycogen; f, nucleus; the numerous little pods are symbiotic bacteria. 7, Arcella vulgaris: a, shell; b, cytoplasm; e, lobose pseudopods; d, d, d, 3 nuclei; e, one of the contractile vacuoles; the dark shaded circles represent bubbles or gas vacuoles. 8, Cochlospodium pellucidum: a, "vesicular" nucleus, with dense central mass or "karyosome." (a frequent type of Protistic nucleus). (From Lankester.)

**Fig. 2.**—Amoeba (Lithamoeba) discus (after Lankester). A, quiescent; B, putting forth eruptive pseudopods. c, v, contractile vacuole through which the richly vacuolated cytoplasm is seen; f, food particles; conc., concretions, insoluble in dilute HCl and KH\textsubscript{2}O, soluble in strong HCl; n, nucleus.

**Fig. 3.**—1, ideal perspective view of left half of a crawling Amoeba; 2, diagram showing successive position of marked points on anterior end; 3, diagrammatic section, the arrows showing directions of absolute motion—the rate being indicated by the length of the shaft.

From Jenning's Contributions to the Study of the Behavior of Lower Organisms, by permission of the Carnegie Institution of Washington, D.C.
distinct periods in the life cycle which we may call A and B; the individuals of the A period being distinguished by the presence of radiating spicules of MgCO₃ in the gelatinous theca; the resolution of period A is simple (fig. 5, 3) and the uninucleate brood-cells are amoebulae (pseudopodiospores) (fig. 5, 4) which grow into the multinucleate B type, with a nonspiculate theca (fig. 5, 5). The resolution of the B type is preceded by rapid multiplication of the nuclei by mitosis (fig. 5, 7), and the uninucleate cells are 2-flagellate zoospores (fig. 5, 9). These pair with zoospores of a different brood to their own (fig. 5, 10) (i.e. they are exogamous gametes); and the fusion cell (fig. 5, 11) so formed is the starting-point of the A type (fig. 5, 12). Brood formation by resolution of a multinucleate individual has been observed or conjectured in Amoeba, &c.

A formation of numerous pseudopodiospores within Pelomyxa has been repeatedly described, and these have been seen to conjugate equally, the zygote becoming multinuclear. But the possibility of the alleged reproductive cells being parasites has not yet been fully excluded.

Chlamyphrys stercorea is a small Filose, occurring in the faeces of several mammals, but only forming its characteristic shell outside the body; plastogamic monstrositias are frequent. The nucleus degenerates, and is expelled with some plasm. The chromidia remain inside the shell, and differentiate or aggregate into about eight nuclei; the cell is then resolved into as many 2-flagellate swarvers, which escape as isogamous exogametes. The zygote becomes surrounded by a brown cyst. When
swallowed by a mammal it develops, and the ordinary form is found in the excreta.

_Centropyxis aculeata_ is closely allied to _Diffugia_. It divides by fission and also at the end of a cycle by schizogyony, the offspring being amoebulae. In some of these acquire a shell directly; in others a second brood division into four takes place, and it is only then that shells are formed. The latter conjugate as males with the former as females; and the fusion cell encysts within the approximated shells; it emerges as a naked amoeba after a period of rest, forms a shell and assumes the type of the species. Other types of reproduction are known, _Amoeba coli_, an inhabitant of the gut of man, showing an endogamous pairing of closely related nuclei similar to that of _Actinopharynx_ (see _HELIOZOA_).

**Classification**

Lobosa.—W. B. Carpenter. Cytoplasm with a clear ectosarc, not wetted by the medium; pseudopods never finely branching, usually rounded at the apex; nucleus single or multiple; shell ("test," "theca") absent, gelatinous, membranous or of cemented granules of ingested sand, &c., or plates secreted in the endosarc.

Selected genera: § 1. Naked Amoeba (q.v. "Amibe," Bory), with the subgenera Dactylopharynx, Hertwig and Lesser (fig. 1, 1–3), with slender, pointed pseudopods; _Lithamoenia_, Lankester, always containing inorganic grains (fig. 2). _Polymyxna_, (fig. 5, 6), with blunt, eruptive pseudopods and numerous nuclei, in or more in diameter when contracted. _Arcuatirhix_, Claparède and Lachmann, with one or more slender, very mobile, flagelliform pseudopods as well as the loose ones.

§ 2. Test gelatinous, perforated by pseudopods: _Amphiodinia_, Greelf; _Trichospharynx_, Schneider (fig. 5).

§ 3. Test membranous: _Cocklodiapodium_, Hertwig and Lesser (fig. 8).

§ 4. Test "chitinous," shagreened: _Arcella_, Stein (fig. 1, 7).

§ 5. Test of ingested particles: _Diffigia_, Leclerc; _Centropyxis_, Stein; _Lacustrina_, Schlumberger (shell material of diatomaceous tests fused into sausage-shaped masses).

§ 6. Test of secreted siliceous or chitinous plates: _Quadrala_, F. E. Schultze. (In _Q. irregularis_ the plates are said to be calcareous.)

Filosa.—A. Lang. Cytoplasm without definite ectosarc; pseudopods branching, tapering to fine tips, somewhat granular; test present in all known species and varying as in the Lobosa.

Selected genera: § 1. Test membranous: _Goniocystis_, Dujardin (pro parte); _Mikrogonia_, Hertwig; _Diptolyphax_, Barker (fig. 7, 1); _Ditrematia_, Archer; _Amphithria_, Archer (fig. 7, 11); the last three have a mouth-like aperture (pylema) at either end of the test.

§ 2. Test of ingested or incrusted particles: _Pseudodiphylla_, Schlumberger; _Diaphorodactylos_ (figs. 4, 6, A); _Pseudodiphylla_, Lauterborn.

systems, causing the formation of numerous lakes and of the waterfalls which determined the situation of many of the manufacturing cities of the state.

In the N.W. is Durfee Hill, which attains an elevation of 805 ft., and is the highest point within Rhode Island. The mean elevation for the entire state is 200 ft. The coast-line, including the shores of the bays and islands, is extensive; its western portion is only slightly indented, but its eastern portion is deeply indented by Narragansett Bay, a body of water varying in width from 3 to 12 m., and extending inland for about 28 m. The land surface E. of this bay is very gently rolling, but to the W. it consists of a somewhat more rugged upland which slopes gradually southward. Over the whole state there is a layer of drift deposited by the glaciers which once covered this region. This glacial material is in the form of a till or boulder clay, but in the lowlands, and especially along Narragansett Bay, it is generally overlaid by stratified drift deposited by glacial streams. Within Narragansett Bay are the numerous islands characteristic of an area which has suffered comparatively recent depression, the largest being Rhode Island (or Aquidneck), Conanicut Island and Prudence Island. Of these the most important is Rhode Island, 15 m. long and 3 m. wide, which has given the state its name. Lying about 10 m. off the coast and S. of the central part of the state is Block Island, a sandy tract 6 m. long and from 1 to 4 m. wide, with a rolling surface.

The rivers of the state are short and of no great volume, but they flow swiftly and are useful in supplying power for manufactory. The Providence river is really an arm of Narragansett Bay, into which flow the waters of the Pawtuxet and the Blackstone rivers. The latter stream at Pawtucket has a fall of about 50 ft., and the Pawtuxet river also has a number of falls along its course. Mount Hope Bay and the eastern arm of Narragansett Bay, and is also the estuary of the Taunton river. The Sakonnet river is a long bay separating Aquidneck or Rhode Island from the mainland on the S. The Pawtuxet river is the largest stream in the western half of the state, and as it flows from its source, on the course it forms the boundary between Rhode Island and Connecticut.

Fauna and Flora.—The fauna of the state does not differ from that of southern Connecticut and eastern Massachusetts. The marine fauna is of economic importance. The woodland area of the state has been estimated at about 400 sq. m., or about 37% of the land area, but the trees are generally too small for timber. The most common varieties of trees are the oak, walnut and chestnut. There are a few stretches of pine forest, and in the S. the swamps are sometimes overgrown with cedar.

Climate.—Rhode Island has a most moderate climate than that of the northern sections of New England. There are no great extremes of either heat or cold, and a number of the towns and cities, especially Newport and Narragansett Pier, have become noted summer resorts. Narragansett Pier has a mean annual temperature of 49°, a mean summer temperature (for June, July and August) of 69°, and a mean winter temperature (for December, January and February) of 29°. The mean annual temperature at Providence is 50°; the means for the summer 72°, and for the winter 30°; while the highest and lowest temperatures ever recorded are respectively 102° and -5°. The mean annual rainfall is about 50 in., ranging from 47 4 in. at Narragansett Pier to 53 2 in. at Kingston.

Soils.—The Boulder clay or "hard pan" of which most of the surface lands are composed, forms a very indifferent support for vegetation, and consequently the state is not well adapted for the growing of crops.

Agriculture.—The acreage of improved farm land in Rhode Island decreased from 356,487 in 1850 to 137,354 in 1900, but the value of farm property (including land with improvements, implements, machinery and live stock) increased in the same period from $69,100,640 to $269,989,189. The number of farms remained about the same—535 in 1850 and 549 in 1900; but the average area diminished from 102-9 acres to 82-9 acres. The value of farm products increased from $3,670,135 in 1879 to $6,333,864 in 1905. The average value of farms increased from $5547 in 1850 to $4909 in 1900. The number of persons engaged in agricultural pursuits in 1885 was 10,986, and in 1900, 10,957.

The total acreage of cereals (barley, buckwheat, Indian corn, oats, rye and wheat) decreased from 19,575 acres in 1857 to 10,552 acres in 1899, and the total product of these crops decreased from 801,111 bu. in 1849 to 352,110 bu. in 1899.

The number of small cattle on farms decreased from 36,262 in 1850 to 36,966 in 1900, but the number of dairy cows increased from 16,968 to 23,660.

Fisheries.—Whaling was an established industry in Rhode Island as early as 1723, and in 1731 the colonial assembly provided for the survey and marking of whaling grounds in the open ocean. In 1846 about 50 whaling vessels sailed from Rhode Island ports; but by the close of the century the industry had become practically extinct. In 1905 the number of persons employed in the general fisheries industry (fishing, etc.) was 1,536,658, the largest items being: lobsters, 64,358; squeteague (weakfish), 86,478; scup, 128,030; and oysters (for market), 471,322.

Minerals.—Rhode Island's mineral wealth is relatively slight. The total value 1 of all the mineral products of the state in 1907 was $937,384, and in 1908, $705,694, and of these totals granite

---

RHODE ISLAND

was valued in 1908 at $56,774. The value of the clay products, lime and salt, decreased from $245,378 in 1907 to $112,815 in 1908. In 1908, 191,162 (or 52.7%) were employed in manufacturing.

Manufactures.—Rhode Island is essentially a manufacturing state; of the 191,023 persons in the state, engaged in gainful occupation in 1908, 189,024 (or 98.9%) were employed in manufacturing and mechanical pursuits. By the middle of the 17th century, boat-building had become an established industry, and large vessels were built at Newport. In 1777, the state offered a large premium for every pound of steel, similar to German steel, made within its boundaries; and in 1789 a rolling and slitting mill was built near Providence. Cotton was first imported to Providence from Spain in 1785; a company to carry on cotton-spinning, formed at Providence in 1786, established there in the following year a factory containing a spinning Jenny of 28 spindles (the first machine of the kind to be used in the United States), and also a carding machine, and a spinning frame with which was manufactured a kind of jean having a linen warp and a cotton filling. The fly shuttle was also apparently first introduced at Providence in 1788. The first calico printed in the United States was made at East Greenwich about 1794. The Providence Association of Mechanics and Manufacturers, incorporated in 1789, organized industrial development. The prohibition of the exportation from England of machinery, models or drawings retarded mechanical improvement, but in 1790 an industrial company was formed at Providence to carry on cotton spinning, and in December of that year there was established at Pawtucket a factory equipped with Arkwright machines constructed by Samuel Slater. This machinery was operated by water-power, then first used in the United States for the spinning of cotton thread; and from this may be dated the beginning of the factory system in Rhode Island. These machines were soon adapted to the spinning of wool, and in 1804 a woollen factory was built at Peacedale, South Kingstown. The first power-loom used in the United States was invented about 1812, and was set up at Peacedale, in 1814, for the manufacture of woollen saddlery and other webbing. The first power-loom for cotton manufacture was set up in North Providence in 1817. Textile manufactures, which were of enormous importance, was hardly established in Rhode Island before 1825. The manufacture of jewelry, which was established in Providence in 1784, was greatly promoted ten years later by Nehemiah Dodge's invention of the process of "gold-filling," still further improved in 1846 by Thomas H. Lowe. The manufacture of silverware was begun in Providence soon after the close of the War of Independence.

Rhode Island’s water powers have been its only natural resources which have aided in the development of its manufactures, and its transportation facilities have always been inadequate, because of shallow water at Providence and scanty railway communication; but the state’s manufacturing enterprises are of great importance.

In 1900 Rhode Island ranked 17th among the states in the value of its manufactured products, but led all of the states in the value per capita ($430). The total number of establishments in 1890 was 864; in 1890, 337, and in 1900, 419. In 1900 there were 1678 factories, and in 1905, 1617 factories. The total capital invested in manufacturing in 1890 was $135,067; in 1890, $126,483,401, and in 1900, $183,748,587, of which $176,901,606 was in factories; in 1905 the capital invested in factories was $215,000,000. The amount invested in manufacture was $22,117,688; in 1900, $142,500,625, and in 1900, $184,074,378, of which $165,520,382 was the value of factory products; in 1905 the value of factory products was $202,109,583. The average number of employees in 1890 was 20,867; in 1900, 51,111; and in 1905, 68,813, of whom 88,197 were factory employees; in 1905 there were 97,318 factory employees.

1 The 1905 census of manufactures gives statistics only for establishments under the factory system, excluding the hand trades, and gives factory statistics for 1905 and for 1906. The statistics given above for 1900 in comparison with 1905 are for factory products.

1900, 98,813, of whom 88,197 were factory employees; in 1905 there were 97,318 factory employees.

In 1900 Rhode Island ranked first in 1900 ($13,229,313) and in 1905 ($14,317,756) among the states of the United States in the value of jewelry, which was fourth in the value of the state’s manufactures; second in value of machinery ($3,341,320; 1905, $3,101,672) which were first in value in the state’s manufactures; and third in dyeing and finishing textiles (1900, $5,848,878; 1905, $9,981,457), which ranked fifth among the state’s manufactures. The value of metal products (second in rank in the state) fell from the fourth rank in 1900 ($82,065,175) to fifth rank in 1905 ($30,628,843), when the value of Rhode Island’s product was less than that of Georgia. Other important manufactures were cotton textiles (not including flax, hemp and jute products) in 1900, $77,996,396; in 1905, $103,906,311; foundry and machine shop products in 1900, $15,250,986; in 1905, $16,338,522; woolen goods in 1900, $5,330,580; in 1905, $8,163,167; rubber boots and shoes in 1900, $8,934,445; in 1905, $3,334,655; cotton and silk manufactures in 1900, $11,132,922; in 1905, $5,435,474; silversmithing and silversware in 1890, $5,149,356; in 1900, $3,236,264; gold and silver, reducing and refining (not from ore) in 1900, $3,449,454; in 1905, $4,260,068; cotton small wares in 1900, $2,379,500; in 1905, $3,044,607; hosiery and knit goods in 1900, $2,713,850; in 1905, $3,344,655; silk and silk goods in 1900, $1,314,333; in 1905, $2,555,986. In 1905, 116 establishments reported power, as against 1350 in 1900—a decrease of 15.7%, but the total horsepower increased from 155,545 to 190,777, or 22.7%.

Transportation.—Steam railway mileage in Rhode Island increased from 68 m. in 1850 to 248 m. in 1900. The Providence and Pawtucket Railway, incorporated in 1850, was the first railroad (or interurban) completed in 1856. The state has a natural water outlet in the Providence river and Narragansett Bay, but there is barely sufficient depth of water for ocean traffic. The ports of entry are Providence (by far the largest, with imports valued at $1,893,551, and exports valued at $1,527,417 in 1900), Newport and Bristol.

Population.—The total population of Rhode Island in 1880 was 276,531; in 1900, 345,566; in 1900, 428,556; and in 1910, 542,674.2 The increase from 1880 to 1890 was 24.9% from 1890 to 1900 24%, and from 1900 to 1910, 26.6%. Of the total population in 1900, 285,278 were native whites, 134,510 were foreign-born, 9992 were negroes, 366 were Chinese, 35 were Indians and 13 were Japanese. Of the foreign-born, 35,501 were Irish, 31,533 were French-Canadians and 22,832 were English. Of the total population, 275,143 were of foreign parentage, i.e., either one or both parents were foreign-born—chiefly of Irish, English, and French parentage. The religious affiliation of the island is varied, and the people represent a great number of religious denominations. In 1900, 115,340 were Roman Catholics. Second in importance were the Baptists, who founded the colony; in 1906 they numbered 5,149,878, of whom 14,304 were of the Northern Convention. There were 14,443 Protestant Episcopalians, 5278 Congregationalists, 7982 Methodists. The Friends, whose influence was so strong in the early history of Providence, numbered in 1900 only 648 in the whole state.

Administration.—The state is governed under the constitution of 1842, with amendments adopted in 1854, 1856, 1862, 1864, 1869, 1880, 1892, 1894, and 1907. All male citizens of the United States are naturalized citizens of the United States residing in Rhode Island. The population of the state was 275,143 in 1880, 345,566 in 1900, and 542,674 in 1910. The population of the cities were: Providence, 212,367; Pawtucket, 50,622; Woonsocket, 26,204; Newport, 22,034; and Central Falls, 27,754.
Rhode Island are citizens of the state. Under an act of 1724, the suffrage was restricted to adult males who possessed a freehold of the value of $134 (see History). So far as state and national elections are concerned, the general franchise of Rhode Island, as fixed by the constitution of 1842, to naturalized foreigners who had served in the Civil War by an amendment of the 7th of April 1866, and to all adult male citizens by the amendment of the 4th of April 1888. A curious survival of the old system exists in the provision that only those who pay taxes on $134 worth of property may vote for members of city councils or on propositions to levy taxes or to expend public money. The working men are thus almost entirely excluded from participating in the government of the large factory towns.

Amendments to the constitution must be passed by both houses of the General Assembly at two consecutive sessions, and must then be ratified by three-fifths of the electors of the state present and voting thereon in town and ward meetings. Fifteen amendments have thus been added to the constitution of 1842. An amendment of the 7th of April 1886 forbade the manufacture and sale of intoxicating beverages, but it was badly enforced and was repealed by a subsequent amendment of the 20th of June 1899.

The powers of the governor are unusually small. Until 1809, when a constitutional amendment was adopted, he had no power of veto, and his very limited nominal powers of appointment and removal are largely made up by the General Assembly. The other executive officers are a secretary of state, an attorney-general, an auditor, a treasurer, a commissioner of public schools, a railroad commissioner, and a factory inspector, and various boards and commissions, such as the board of agriculture, the board of health, and the commissioners of inland fisheries, commissioners of harbours and commissioners of pilots.

The legislative power is vested in the General Assembly, which consists of a senate and a house of representatives, both of whom are elected by the people. Each house is subdivided, with final revision and appellate jurisdiction upon all questions of law and equity. Below this are the twelve district courts, the town councils, probate courts in the larger towns, and justice of the peace courts. The several district courts and the district judges are elected by the General Assembly, the former during good behaviour, the latter for terms of three years. The town (or township) is the unit of local government, the county being merely the largest unit of the state and the district a subdivision of that unit. There are in the entire state 251 towns, with about 1,000 villages and 20,000 incorporated towns and cities.

Finance.—The chief sources of revenue in the order named are the general property tax, the tax on savings banks, the tax on securities of the federal and state governments, and the corporation franchise tax. The total receipts from all sources for the year 1899 were $2,317,512, the expenditures $2,345,359. The public debt, which originated in 1732, amounted to $70,000 sterling in 1764, to $4,000 in 1882, and to $6,768,216 in 1900. Part of the public debt was paid in depreciated paper, part was assumed by the United States government, part was paid at various rates of depreciation ranging from 13 1/2 to 71 1/2 per cent. The total debt in 1847. Other obligations had accumulated in the meantime, however, so that the debt in 1848 amounted to $18,000,000. This was gradually reduced until the Civil War, when it was increased to about $50,000,000. The total debt in 1869 was $43,971,000, and in 1874, $44,000,000. It was again increased to $44,500,000 in 1875, and the entire sum was extinguished by the 1st of August 1894. The issue of bonds for the construction of the new capitol building and other purposes has led, however, to a new debt, which at the beginning of 1900 amounted to $4,000,000. There was at the same time a sinking fund of $654,099. Before the adoption of the Federal constitution Rhode Island was badly afflicted with the paper money hoax. $500 were printed in 1790, $1,000 in 1791, and $5,000 in 1793. These notes were subsequently extinguished.

History.—Rhode Island was founded by refugees from Massachusetts, who went there in search of religious and political freedom. The first settlements were made at Providence by Roger Williams (q.v.) in June 1636, and at Portsmouth on the island of Aquidneck by the Antinomians, William Coddington (1601-1678), John Clarke (1600-1676), and Anne Hutchinson (1391-1643), in March April 1636.
RHODE ISLAND

Becoming dissatisfied with conditions at Portsmouth, Codding-
ington and Clarke removed a few miles farther south on the 29th of April 1639, and established a settlement at New-
port. In a similar manner Warwick was founded in 1643 by secders from Providence under the head of Samuel
Gorton. The union of Portsmouth and Newport, March 12, 1649, was followed by the consolidation of all four settlements,
May 19, 1647, under a patent of March 14, 1644, issued by
the parliamentary board of commissioners for plantations.
The particularistic sentiment was still very strong, however,
and in 1651 the union split into two confederations, one in-
cluding the mainland towns, Providence and Warwick; the
other, the island towns, Portsmouth and Newport. A re-
union was effected in 1654 through the influence of Roger
Williams, and a charter was secured from Charles II. on the
8th of July 1663. In the patent of 1664 the entire colony
was made Providence Plantations. On the 13th of March
1644 the Portsmouth-Newport General Court changed the
name of the island from Aquidneck to the Isle of Rhoses or
Rhode Island. The official designation for the province
as a whole in the charter of 1663, therefore, was Rhode Island
and Providence Plantations. The charter was suspended
at the beginning of the Andros regime in 1686, but was re-
stored again after the Revolution of 1689. The closing years
of the 17th century were characterized by a gradual transition
from the agricultural to the commercial stage of civiliza-
tion. Newport became the centre of an extensive business in piracy,
privateering, smuggling and legitimate trade. Copper,ROOTAE,
manufactured from West Indian sugar and molasses,
were exported to Africa and exchanged for slaves to be sold
in the southern colonies and the West Indies. The passage of
the Sugar Act of April 5, 1764, and the steps taken by
the British government to enforce the Navigation Acts seriously
affected this trade. The people of Rhode Island played
a prominent part in the struggle for independence. On the
9th of June 1772 the "Gaspee," a British vessel which had
been sent over to enforce the acts of trade and navigation,
ran aground in Narragansett Bay and was burned to the
water's edge by a party of men from Providence. Nathanael
Greene, a native of Rhode Island, was made commander of
the Rhode Island militia in May 1775, and a major-general
in the Continental army in August 1776, and in the latter
capacity he served with ability until the close of the war.
In the year 1776, General Howe sent a detachment of his
army under General Henry Clinton to seize Newport as a
base of operations for reducing New England, and the city
was occupied by the British on the 8th of December 1776.
To capture this British garrison, later increased to 6000 men,
the co-operation of about 10,000 men (mostly New England
militia) under Major-General John Sullivan, and a French
fleet carrying 4000 French regulars under Count D'Eastaing,
was planned in the summer of 1778. On the 9th of August
Sullivan crossed to the north end of the island of Rhode Island,
but as the Frenchmen were disembarking on Conanicut Island,
Lord Howe arrived with the British fleet. Count D'Eastaing
hastily re-embarked his troops and sailed out to meet Howe.
For two days the hostile fleets manoeuvred for positions,
and then they were dispersed by a severe storm. On the
20th, D'Eastaing returned to the port with his fleet badly
crippled, and only to announce that he should sail to Boston
to refit. The American officers protested but in vain, and
on the 28th they decided to retreat to the north end of the
island. The British pursued, and the next day there was
a severe engagement in which the Americans were driven
from Turkey and Quaker Hills. On the 30th the Americans,
learning of the approach of Lord Howe's fleet with 5000
troops under Clinton, decided to abandon the island. The
British evacuated Newport the 25th of October 1779, and the
French fleet was stationed here from July 1780 to 1781.

The influence of Roger Williams's ideas and the peculiar
conditions under which the first settlements were established
have tended to differentiate the history of Rhode Island from

that of the other New England states. In 1640 the General
Court of Massachusetts declared that the representatives of
Aquadneck were "...not to be capitulated withal either for them-
sew, or for the people of the isle where they inhabit," and in
1643 again and in 1648 the application of the Narragansett
settlers for admission to the New England Confederacy was
refused except on condition that they should pass under the
jurisdiction of either Massachusetts or Plymouth. Rhode
Island was one of the first communities in the world to advo-
cate religious freedom and political individualism.
The individualistic principle was shown in the jealousy of
the towns toward the central government, and in the establish-
ment of legislative supremacy over the executive and the
judiciary. The legislature migrated from county to county up
to 1824, and there continued to be two centres of govern-
ment until 1900. The dependence of the judiciary upon the
legislature was maintained until 1860, and the governor is still
shorn of certain powers which are customary in other states
(see Administration). In the main the rural towns have
adhered most strongly to the old individualistic sentiment,
whereas the cities have kept more in touch with the modern
nationalistic trend of thought. This was shown, for example,
in the struggle for the ratification of the Federal constitution.
Under the Articles of Confederation it was principally Rhode
Island that defeated the proposal to authorize Congress to
levy an impost duty of 5% mainly as a means of meeting the
deficit of the Central government. When the constitui-
tional convention met in Philadelphia in 1787 to frame a con-
stitution for a stronger Federal government, the agriculturists
of Rhode Island were afraid that the movement would result
in an interference with their local privileges, and especially
with their favourite device of issuing paper money, and the
state refused to send delegates, and not until the Senate had
passed a bill for severing commercial relations between the
United States and Rhode Island, did the latter, in May 1790,
ratify the Federal constitution, and then only by a majority
of two votes. Rhode Island, like the rest of New England,
was opposed to the War of 1812 and the Mexican War.
During the Civil War it sent 23,457 men into the service of
the Union.

The economic transition of the later 17th century from the
agricultural to the commercial régime was followed by a further
transition to the manufacturing régime during the closing years
of the 18th and the early years of the 19th centuries. Com-
mercial interests have been almost entirely destroyed, partly
because of the abolition of the slave trade and partly because
of the embargo and the war of 1812, but mainly because the
cities of the state are unfavourably situated to be the termini
of interstate railway systems. Providence, owing to its superior
water-power facilities, has therefore become one of the leading
manufacturing centres of New England, whereas Newport
is now known only as a fashionable summer resort. The move-
ment as a whole was of exactly the same nature as the
industrial revolution in England, and it led to the same result,
"a struggle for electoral reform. The system of apportionment
and the franchise qualifications were worked out to meet the
needs of a group of agricultural communities. The charter of
1603 and the franchise law of 1724 established substantial
equality of representation among the towns, and restricted the
suffrage to freeholders. In the course of time, therefore,
the small towns came to be better represented proportionally
than the large cities, and the growing class of artisans was entirely
disfranchised. The city of Providence issued a call for a
constitutional convention in 1796, and similar efforts were made
in 1799, 1817, 1821, 1832 and 1824, but nothing was accom-
plished. About 1835 Thomas W. Dorr (1805-1854), a young
lawyer of Providence, began a systematic campaign for an
extension of the suffrage, a reapportionment of representation
and the establishment of an independent judiciary. The
struggle, which lasted for several years, and in fact is not yet
totally over, was one between the cities and the country,
between the manufacturers and the agriculturists. It was
also complicated by racial and religious prejudices, a large proportion of the factory operatives being foreigners and Roman Catholics, and most of the country people native Protestants. The former were in general associated with the Democratic party, the latter with the Whigs. A convention summoned without any authority from the legislature, and elected on the principle of universal manhood suffrage, met at Providence, October 18, 1841, and drafted a frame of government which came to be known as the People's Constitution. A second convention met on the call of the legislature in February 1842 and adopted the so-called Freeman's Constitution. On being submitted to popular vote the former was ratified by a large majority (December 27, 28, 29, 1841), while the latter was rejected by a majority of 676 (March 21, 22, 23, 1842). At an election held on the 18th of April 1842 Dorr was chosen governor. The supreme court of the state and the president of the United States (Tyler) both refused to recognize the validity of the People's Constitution, whereupon Dorr and a few of his more zealous adherents decided to organize a rebellion. They were easily repulsed in an attack upon the Providence town arsenal, and Dorr, after a brief period of exile in Connecticut, was convicted of high treason on the 26th of April 1844, and was sentenced to imprisonment for life. He was released by act of the Assembly in June 1845, and was restored to the full rights of citizenship in May 1851. The Freeman's Constitution, modified by another convention, which held its session at Newport and East Greenwich, September 12—November 5, 1842, was finally adopted by popular vote on November 21—23, 1842. Only a partial concession was made to the demand for reform. The suffrage was extended to non-freeholders, but only to those of American birth. Representation in the lower house of the legislature was apportioned according to population, but only on condition that no city or town should ever elect more than one-sixth of the total number of members. Each city and town without regard to population was to elect one senator. In order to perpetuate this system the method of amending the constitution was made extremely difficult (see Administration). Since the adoption of the constitution the conditions have become worse owing to the extensive immigration of foreigners into the large cities and the gradual decay of the rural towns. From about 1845 to 1886 most of the immigrants were Irish, but since 1880 the French-Canadians have constituted the chief element. In 1890 about 30% of the population of the state was foreign-born. A constitutional amendment of 1888 extended to them the right of suffrage in state and national elections, and an amendment of 1900 partially remedied the evils in the system of apportionment. When the last Federal census was taken in 1910, Providence, Pawtucket, Woonsocket, and Newport, with a combined population of 341,222, had four senators, whereas the remainder of the state, with a population of 201,452, had thirty-four. Providence, with a population of 224,326 out of a total of 549,674, had one member in a Senate of thirty-eight and twenty-five members in a House of Representatives of one hundred. The Republican machine finds it easy with the support of the millionaire summer colony at Newport and the street railway corporations to corrupt the French-Canadians and a portion of the native element in the rural towns and maintain absolute control of the state government. The majority has occasionally protested by electing a Democratic governor, but he has not been able to accomplish a great deal, because until 1900 he did not have veto power nor effectual means to induce the Senate to ratify his appointments. Bonds were issued on the 8th of November 1892 for the construction of a new state house at Providence, the corner stone was laid in October 1896, and the building was thrown open to use on the 1st of January 1901. A constitutional amendment of 1900 dispensed with the session of the legislature at Newport.

In presidential campaigns the state has been Federalist, 1792—1800; Democratic Republican, 1804; Federalist, 1808—1812; Democratic Republican, 1816—1820; Adams (Republican), 1824—1828; National Republican, 1832; Democratic, 1836; Whig, 1840—1848; Democratic, 1852; and Republican since 1856.

BIBLIOGRAPHY.—For general physical description see C. T. Jackson, Report on the Geological and Agricultural Survey of Rhode Island and Providence Plantation (1856-1863); N. S. Schaler, J. B. Woodworth, and A. F. Foerester, Geology of the Narragansett Basin (Washington, 1899); and T. Nelson Dale, The Chief Commercial Granites of Massachusetts, New Hampshire and Rhode Island (Ibid., 1908), being Bulletin 354 of the U.S. Geological Survey. Administration—The charters of 1644 and 1663 and the constitution of 1842 are all given in F. N. Thorpe, Constitutions, Charters, and Organic Laws (Washington, 1909), vol. vi. See also the annual reports of the treasurer, the auditor general of the state, the board of education, and the board of state charities and corrections; W. H. Tolman, History of Higher Education in Rhode Island (Washington, 1894); Henry Phillips, Jr., Historical Sketches of the Paper Currency of the American Colonies, 1661-1866, (Ibid., 1880); Thomas Durfee, Gleanings from the Judicial History of Rhode Island (Providence, 1883); and the works of Field, Richman and Mowry (see History, Bibliography).

History.—For many years the standard authority on the period before the ratification of the Constitution was S. G. Arnold, History of Rhode Island, 1636-1790 (2 vols., New York, 1839-40, 4th ed., Providence, 1890). His work has, however, been partially superseded by T. B. Richman, Rhode Island: Its Making and Meaning, 1636-1683 (2 vols., 1902), and Rhode Island: A Study in Separatism (Boston and New York, 1905). Edward Field (Editor), State of Rhode Island and Providence Plantation at the end of the Century: A History (3 vols., Boston, 1902), is valuable for the more recent history of the state. See also Adelos Gorton, The Life and Times of Samuel Gorton (Philadelphia, 1898); W. B. Weedon, Early Rhode Island: The Social History of the People (New York, 1910); F. G. Bates, Rhode Island and the Formation of the Union (New York, 1898); A. M. Mowry, The Dorr War; or the Constitutional Struggle for Rhode Island (Providence, 1901); Records of the Colony of Rhode Island and Providence Plantation, 1636-1792 (6 vols., Providence, 1856-65); Rhode Island Historical Society, Collections (10 vols., to be continued, Providence, 1852-1902); Proceedings of the Governor and the General Assembly (1807-1912); Rhode Island Historical Tracts, Series 1., 20 vols. (Providence, 1877-1884); Series II., 5 vols. (Providence, 1889-96). For genealogy see Brown, J. R., Barlett, Bibliography of Rhode Island (Providence, 1864); C. R. Brigham, in Field, III., pp. 661-81; and Richman, in A Study in Separatism, pp. 353-58.

1 Jackson was a Liberation Whig—favouring the liberation of Dorr from prison—but he was elected on the Democratic ticket.

2 Sprague was elected over the radical Republican candidate through a coalition of Democrats and conservative Republicans.

RHODES, CECIL JOHN (1853-1902), British colonial and Imperial statesman, was born on the 9th of July 1853, at Bishop Stortford, in Hertfordshire. His father was a clergyman, but he claimed descent from yeoman stock. Cecil John Rhodes was the fifth son in a large family of sons and daughters. At the time of his birth his father held the living of Bishop Stortford. The boy was educated at Bishop Stortford grammar school with the intention of preparing for the Church; but at the age of sixteen his health broke down, and in the latter part of 1870 he was sent to join an elder brother, then engaged in farming in Natal. In that year diamonds were discovered in the Kimberley fields. By the end of 1871 Mr Rhodes and his brother were among the successful diggers. The dry air of the interior restored Mr Rhodes's health, and before he was nineteen he found himself financially independent, physically strong and free to devote his life to any object which commended itself to his choice.

Rhodes has left behind him an interesting record of the manner in which he was affected by the situation. He determined to return to England, and to complete his education by reading for a degree at Oxford; but before doing so, he spent eight months in a solitary journey through the then little known parts of the country lying to the north of the Orange and Vaal rivers. He went through Bechuanaland to Mafeking, thence to Pretoria, Murchison, Middelburg and back through the Transvaal to Kimberley. The journey, made in an ox-wagon at a rate of progression of some 15 to 20 miles a day, represented a walking tour of eight months through the vast spaces of rolling veld which at that time filled those regions of Southern Africa. He saw one of the healthiest countries in the world barely occupied. He knew the agricultural possibilities of Natal. He knew its mineral wealth. The effect of the combined influences on his mind, in the circumstances in which he found himself, was profound. The idea took passionate possession of him that the fine country through which he moved ought to be secured for occupation by the British race, and that no power but Great Britain should be allowed to dominate in the administration of South Africa. When he brought his self-imposed pilgrimage to an end, he had found an object to which he proposed to devote his life. It was nothing less than the governance of the world by the British race. A will exists written in Mr Rhodes's own handwriting a couple of years later, when he was still only twenty-two, in which he states his reasons for accepting the aggrandizement and service of the British empire as his highest ideal of practical achievement. It ends with a single bequest of everything of which he might die possessed, for the furtherance of this great purpose. Five-and-twenty years later his final will carried out, with some difference of detail, the same intention.

The share which he allotted to himself in the general scheme was the extension of the area of British settlement in Africa, but he did not attempt to address himself immediately to public work. He returned, in accordance with his first resolve, to Oxford, where he matriculated at Oriel. In 1873 his health again failed, and he was sent back to South Africa under what was practically a death sentence. Years afterwards he saw the entry of his own case in the diary of the eminent physician whom he consulted, with a note, "Not six months to live." South Africa again restored him to health. Three years later he was back at Oxford, and from 1876 to 1878 he kept his terms. During this period he spent the Long Vacation each year in South Africa, where his large financial interests were daily increasing in importance. He was a member of the Cape Colony Legislative Assembly, and in 1879 he lost his seat and took his degree. He did not read hard at Oxford, and was more than once remonstrated with in the earlier terms for non-attendance at lectures. But he passed his examinations and though he was never a student in the university sense of the term, he was to the end of his life a keen devourer of books. He kept always a special liking for certain classic authors. Aristotle was the guide whom as a lad he followed in seeking the "highest object", on which to exercise the
“highest activity of the soul,” Marcus Aurelius was his constant companion. There exists at Grote Schuur a copy of the Meditations deeply scored with Mr Rhodes's marks.

During this Oxford time, and on to 1881, Mr Rhodes was occupied with the amalgamation of the larger number of the diamond mines of Kimberley with the De Beers Company, an operation which established his position as a practical financier and gave him an important connection and following in the business world. To many admirers who shared his ideals on public questions his connexion with the financial world and his practical success were a stumbling-block. It was often wished for him that he had “kept himself clear of all that.” But this was not his own view. His ideals were political and practical. To him the making of money was a necessary preliminary to their realization, and he was proud of his practical ability in this direction. He was personally a man of most simple tastes. His immense fortune was spent in the execution of his ideals, and it has been justly said of him that he taught the world a new chapter of the romance of wealth.

In 1881 Mr Rhodes entered upon the public life as a member of the Cape assembly. It was the year of the Majuba settlement. South Africa was convulsed with questions which had arisen between the British and the Dutch, and leaders of Dutch opinion at the Cape ventured to speak openly of the formation of a United States of South Africa under its own flag. The British party needed a rallying-ground, and Mr Rhodes took his stand on a policy of local union combined with the consolidation and expansion of Imperial interests. He offered to Dutch and British alike the idea of a South African Federation governing itself within the empire, and extending, by its gradual absorption of native territories, the range of Imperial administration. Local self-government was, in his opinion, the only enduring basis on which the unity of the empire could be built, and throughout his life he was as keen a defender of local rights as he was of Imperial unity. There was a period somewhat later in his career when this attitude on his part gave rise to a good deal of misapprehension, and his advocacy of the elimination of direct Imperial interference in local affairs caused him to be viewed in certain quarters with suspicion as a Separatist and Independent. Those who were inclined to take this view were greatly strengthened in their suspicions by the fact that at a critical moment in the struggle for Home Rule in Ireland Mr Rhodes contributed £4,000 to the funds of the Separatist party. The subsequent publication of his correspondence on the subject with Mr Parnell, who was at that time leading the Home Rule party, demonstrated, however, the essential fact that, whatever might have been the secret intentions of the extreme Irish Home Rulers, Mr Rhodes’s contribution was made strictly subject to the retention of the Irish members at Westminster. He remained of the opinion that the Home Rule movement, wisely treated, would have had a consolidating and not a disruptive effect upon the organization of the empire.

In South Africa the influence which he acquired over the local inhabitants and the Dutch vote was subsequently an important factor in enabling him to carry out the scheme of northern expansion which he had at heart, and which he had fully developed in his own mind at Oxford in 1878. In 1881 the Bechuanaland territory was a sort of no man’s land through which ran the trade routes to the north. It was evident that any power which commanded the trade routes would command the unknown northern territory beyond. The Pretoria Convention of 1881 limited the westward extension of the Transvaal to a line east of the trade routes. Nevertheless, the reconstituted republic showed itself anxious to encroach by irregular overrol into native territories, and Mr Rhodes feared that the Cape would lose its key position of the British colonist permanently seized by Dutch occupation. One of his first acts as a member of the Cape assembly was to urge the appointment of a delimitation commission. He served in person on the commission, and obtained from the chief Mankoroane, who claimed about half of Bechuanaland, a formal cession of his territories to the British government of the Cape. The Cape government refused to accept the offer. In February 1884 a second convention signed in London again defined the western frontier of the Transvaal, Bechuanaland being left outside the republic. With the consent of Great Britain, Germany had occupied, almost at the same time, the territory on the Atlantic coast now known as German South-West Africa. In August 1884 Mr Rhodes was appointed resident deputy commissioner in Bechuanaland, where, notwithstanding the conventions to the contrary, Bechuanaland was retained from the considerable areas and set up the so-called republics of Griqualand and Stellaland. An old Dutchman who knew the value of the position said privately to Mr Rhodes, “This is the key of South Africa.” The question at issue was whether Great Britain or the Transvaal was to hold the key. It was a question about which at that time the British public knew nothing and cared nothing. Mr Rhodes made it his business to enlighten them. President Kruger, speaking for the government of the Transvaal, professed to regard the Dutch commandoes as freebooters, and to be unable to control them. It devolved upon Great Britain to oblige them to evacuate the territory. Largely as the result of Mr Rhodes’s exertions the necessary step was taken. The Warren expedition of 1884–85 was sent out. In the presence of British troops upon the frontier President Kruger recovered his controlling power over the Transvaal burghers, and without any fighting the commandoes were withdrawn. Thereupon southern Bechuanaland was declared to be British territory, while a British protectorate was declared over the northern regions up to the 22nd parallel (September 1885).

It was the first round in the long duel fought on the field of South Africa between Mr Rhodes, as the representative of British interests, and President Kruger, as the head of the militant Dutch party. The score on this occasion was to Mr Rhodes, and the entrance to the interior was secured. But the 22nd parallel was far short of the limits to which Mr Rhodes hoped to see British influence extend, and he feared lest Germany and the Transvaal might yet join hands in the native territory beyond, and bar his farther progress towards the north. The discovery of gold on the Witwatersrand in 1886, by adding to the wealth and importance of the Transvaal, gave substance to this fear.

The territory to the north of the 22nd parallel was at that time under the domination of Lobengula, chief of the Matabele, a native potentate celebrated alike for his ability and for the despotic character of his rule. There were rumours of Dutch and German emissaries at the kraal of Lobengula, engaged in persuading that chief to cede certain portions of his territory. Portugal also was putting forward shadowy claims to the country. It was in these circumstances that Mr Rhodes conceived the idea of forming a British Chartered Company, which should occupy the territory for trading and mining purposes as far as the Zambezi, and bring the whole under the protection of Great Britain. The idea took shape in 1887, in which year Mr Rhodes’s first emissaries were sent out. The charter of the British South Africa Company was granted in October 1889. Between the two dates his conception of the possibilities to be achieved by the Company had expanded. Mr Rhodes no longer limited the sphere of his operations to the Zambezi, but, crossing the river at the back of the Portuguese settlements at its mouth, he obtained permission to extend the territories of the Chartered Company to the southern end of Lake Tanganyika, including within the sphere of its operations the British settlements already made in Nyassaland. He hoped to go farther still, and to create a connected chain of British possessions through the continent which might eventually justify the description “Africa British.”

The treaty negotiated between Great Britain and Germany in 1890 extended the German sphere of influence from the East Coast to the frontier of the Congo Free State, and defeated this hope. But Mr Rhodes did not wholly renounce the idea. In 1892, when the question of the retention or abandonment of Uganda hung in the balance at home, he threw all the weight of his influence into the scale of retention, and undertook at his own personal expense to connect
RHODES, C. J.

that territory by telegraph with British possessions in the south. In the following year, 1893, it was found inevitable to fight the Matabele, and a war, prosecuted with a success that is perhaps unique of its kind, placed the country entirely in British hands. The territory thus added to the British empire, which was of enormous extent and of immense value, of which large portions consist of healthy uplands suitable for white colonization. The pioneer party who constructed the first road and founded the first British stations in the country received their orders to cross the frontier in the end of 1898. By the end of 1899, before the outbreak of the South African War, though the country had passed through the trial of a war, two native rebellions, and the scourge of rinderpest, it had become, under the name of Rhodesia, a well-settled province of the British empire, with a white population of some 12,000 to 15,000 persons.

The six years which followed the granting of the charter may be regarded as the most successful of a singularly successful life. In 1890, not many months after the granting of the charter, Mr Rhodes accepted the position of prime minister of the Cape. He was maintained in power very largely by the Dutch vote, which he spared no pains to conciliate; and having the confidence of both political sections of the colony, he found himself practically in a position to play the part of benevolent despot in South Africa. He used the position well so far as the public was concerned. While his scheme of northern expansion was making the rapid progress which has been indicated, he did much to elevate and to enlarge the field of local politics. He frankly declared and worked for the policy of uniting British and Dutch interests in South Africa; he took a keen interest in local education. He also during this period carried through some important reforms in native policy. He had the courage to restrict the franchise, introducing an educational test and limiting the exercise of voting power to men enjoying an income equal to a labourer's wage—thus abolishing, without making any distinction of colour, the abuses of what was known as the "blanket" vote.

But his native policy was far from being one of simple restriction. He liked the natives; he employed them by thousands in the mining industry, he kept native servants habitually about his person. He seemed to understand their peculiarities and was singularly successful in dealing with them. The first canon of his native policy was that liquor should be kept from them; the second, that they should be encouraged to labour, and guaranteed the full possession of their earnings; the third, that they should be educated in the practical arts of peace. He appreciated the full importance of raising their territorial condition from one of tribal to individual tenure; and while he protested against the absurdity of permitting the uncivilized Kaffir to vote on questions of highly civilized white policy, he believed in applying to the native for his own native affairs the principle of self-government. Of these views some received practical embodiment in the much-disputed act known as the Glen Grey Act of 1894. In this connexion it may also be noted that he was one of the warmest and most convinced supporters of Lovedale, the very successful missionary institution for the education of natives in South Africa.

The position of benevolent despot has obvious drawbacks. In Mr Rhodes's case the dependence which the populations of Cape Colony were led to place on him had its reaction on the public in a demoralizing loss of self-reliance, and for himself it must be admitted that the effect on the character of a man already much disposed to habits of absolutism in thought and action was the reverse of beneficial. Mr Rhodes felt himself to be far stronger than any man in his own surroundings; he knew he had the support of all the great invested interests of the trust, and he felt that he was one of the warmest and most convinced supporters of Lovedale, the very successful missionary institution for the education of natives in South Africa.

The position of benevolent despot has obvious drawbacks. In Mr Rhodes's case the dependence which the populations of Cape Colony were led to place on him had its reaction on the public in a demoralizing loss of self-reliance, and for himself it must be admitted that the effect on the character of a man already much disposed to habits of absolutism in thought and action was the reverse of beneficial. Mr Rhodes felt himself to be far stronger than any man in his own surroundings; he knew he had the support of all the great invested interests of the trust, and he felt that he was one of the warmest and most convinced supporters of Lovedale, the very successful missionary institution for the education of natives in South Africa.

He displayed, in the circumstances, characteristic qualities of pluck and candour. He made no concealment of his own share in the catastrophe; he took full responsibility for what had been done in his name by subordinates, and he accepted all the consequences which ensued. He resigned his premiership of the Cape (January 1896); and, recognizing that his presence was no longer useful in the colony, he turned his attention to Rhodesia. His design was to live in that country, and to give all the stimulus of his own presence and encouragement to the development of its resources. The Matabele rebellion of March 1896 intervened to prevent the immediate realization of his plans. In June Imperial troops were sent up, and by the end of July the result of the military operations had driven the natives to the Matopo Hills, where they held a position which was impregnable. The prospects of a pacification continued war, with a result of a costly campaign, in the following year. Mr Rhodes conceived the idea that he might effect single-handed the pacification which military skill had failed to compel. To succeed, it was essential that he should trust and be trusted. He accordingly moved his tent away from the troops to the base of the Matopo Hills. He lay there quietly for six weeks, in the power of the enemy if they had chosen to attack. Word was circulated among the natives to which his own best efforts were directed. To work with him was practically impossible for those who were not willing to accept without demur the yoke of dogmatic authority. He had a few devoted personal friends, who appreciated his arms and were inspired by his example; but he was feeling in regard for individuals, and a great part of his daily life was spent in the company of satellites and instruments, whom he used with cynical unconcern for the furtherance of his ends.

In 1896 the brilliant period of his premiership was brought to an end by the incident which became famous under the name of the Jameson Raid. The circumstances which led to the Raid belong properly to the history of the Transvaal. It is enough to say briefly here that the large alien population which had been attracted to the Transvaal by the phenomenal wealth of the Johannesburg goldfields, conceiving themselves to have reason to revolt against the authority of the Transvaal government, resolved towards the end of 1895 to have recourse to arms in order to obtain certain reforms. Mr Rhodes, as a large mine-owner, was theoretically a member of the mining population. In this capacity he was asked to give his countenance to the movement. But as prime minister of a British colony he was evidently placed in a false position from the moment in which he became cognizant of a secret attempt to overturn a neighbouring government by force of arms. He did more than become cognizant. The subsequent finding of a Cape committee, which he accepted as accurate, was to the effect that "in his capacity as controller of the three great joint-stock companies, the British South Africa Company, the De Beers Consolidated Mines, and the Gold Fields of South Africa, he directed and controlled the combination which rendered such a proceeding as the Jameson Raid possible." He gave money, arms and influence to the movement; and as the time fixed for the outbreak of the revolution approached, he allowed Dr Jameson, who was then administrator of the British South Africa Company in Rhodesia, to move an armed force of some 500 men upon the frontier. Here Mr Rhodes's participation in the movement came to an end. It became abundantly clear from subsequent inquiry that he was not personally responsible for what followed. A cipher correspondence, seized and published by the Boers, left the civilized world in no doubt as to Mr Rhodes's share in the previous preparation, and he was for a time believed to be responsible for the Raid itself. Subsequent inquiries held by committees of the Cape parliament and of the British House of Commons acquitted him entirely of responsibility for Dr Jameson's final movement, but both committees found that he had acted in a manner which was inconsistent with his duty as prime minister of the Cape and managing director of the British South Africa Company.

He displayed, in the circumstances, characteristic qualities of pluck and candour. He made no concealment of his own share in the catastrophe; he took full responsibility for what had been done in his name by subordinates, and he accepted all the consequences which ensued. He resigned his premiership of the Cape (January 1896); and, recognizing that his presence was no longer useful in the colony, he turned his attention to Rhodesia. His design was to live in that country, and to give all the stimulus of his own presence and encouragement to the development of its resources. The Matabele rebellion of March 1896 intervened to prevent the immediate realization of his plans. In June Imperial troops were sent up, and by the end of July the result of the military operations had driven the natives to the Matopo Hills, where they held a position which was impregnable. The prospects of a pacification continued war, with a result of a costly campaign, in the following year. Mr Rhodes conceived the idea that he might effect single-handed the pacification which military skill had failed to compel. To succeed, it was essential that he should trust and be trusted. He accordingly moved his tent away from the troops to the base of the Matopo Hills. He lay there quietly for six weeks, in the power of the enemy if they had chosen to attack. Word was circulated among the natives
that he had come alone and undeterred to hear their side of the case. A council was held by them in the very depths of the hills, where he sat down to write the whole book. He was invited to attend it. It was a case of staking his life on trust. He displayed no hesitation, but mounted and rode unarmed with the messenger. Three friends rode with him. The confidence was justified. They met the assembled chiefs at the place appointed. The native grievances were laid before Mr Rhodes. At the end of a long discussion Mr Rhodes, having made and exacted such concessions as he thought fit, asked the question, "Now, for the future is it peace or is it war?" And the chiefs, laying down their sticks as a symbol of surrendered arms, declared, "We give you one word: it is peace!" The scene, as described by one of the eye-witnesses, was very striking. Rhodes, rising up, characterized it simply as "one of the scenes which make life worth living."

His life was drawing towards its end. He had still a few years, which he devoted with success to the development of the country which bore his name. The railway was brought to Bulawayo, and arrangements were made for carrying the line on in sections as far as the south end of Lake Tanganikya, a construction which was part of his pet scheme for connecting the Cape by a British line of communication with Cairo. He also concluded arrangements for carrying a telegraphic land line, through to Egypt, and had the satisfaction of seeing the mineral development of the country fairly started. But the federal union of South Africa, to which he had always worked as the surest basis of the extension of British rule in the southern half of the continent, was not for him to see. The South African War broke out in 1899. Mr Rhodes took his part at Kimberley in sustaining the hardships of a siege; but his health was broken, and though he lived to see victory practically assured to British arms, peace had not been concluded when, on the 26th of March 1902, he died at Muizenberg, near Cape Town.

His life's work did not end actually with his death. He left behind him a will in which he dedicated his fortunes, as he had dedicated himself, exclusively to the public good. He left the bulk of his vast wealth for the purpose of founding scholarships at Oxford of the value each of £300 a year, to be held by students from every important British colony, and from every state and Territory of the United States of America. The sum so bequeathed was very large; but it was not for the munificence of the legacy that the will was received with acclamation throughout the civilized world: it was for the striking manifestation of faith which it embodied in the principles that make for the enlightenment and peace and union of mankind, and for the fine constancy of Mr Rhodes's conviction that the unity of the British Empire, which he had been proud to serve, was among the greatest of organized forces unifying the universal good. The will was drawn up some years before his death. A codicil, signed during the last days of his life, gave evidence of some enlargement of his views as to the association of races necessary in order to secure the peace of the world, and added to the original scheme a certain number of scholarships to be held at the disposal of German students.

The publication of the will silenced Mr Rhodes's detractors and converted many of his critics. It set a seal which could not be mistaken upon his completed life. The revulsion of sentiment towards him was complete, and his name passed at once in the public estimation to the place which it is probably destined to take in history, as one which his countrymen are proud to count among the great makers of the British Empire.

(F. L. L.)

The Rhodes Scholarships.—The scholarship system founded by the will of Cecil Rhodes provides in perpetuity for the support at Oxford, for a term of three years each, of about 175 selected scholars. Each scholar from the colonies and the United States has an allowance of £300 per annum during the continuance of his scholarship; those from Germany, as being nearer to Oxford, an allowance of £250 each. In each province of Canada, with the exception of the Red River Province, the Minto University College of Western Canada, the University College of the Cape of Good Hope, the University of Stellenbosch, and the University of the Cape of Good Hope, a scholar is elected each year. Each college or university, as a rule, sends its representative tope of these scholarships; and the University of the Cape of Good Hope, in the dominion of the Transvaal, and the universities of Natal, South Africa, and St Andrew's College, Grahamstown, are the institutions which send their representatives to Oxford. In each college or university there is a committee of scholars, representing the different nationalities of the student body, to choose the candidates. Each college or university sends its representative to the selection committee, which meets annually at Oxford. On the selection committee are appointed representatives of the United States, of the colonies, and of any other colony or country in which it is found desirable to have a representative. In the case of the United States, the committee is composed of the president of the American Board of Trustees of American Universities in Oxford, the rector of Harvard University, a representative of the educational committees of the British colonies, and a representative of the Canadian government, or other person of high public officials. These committees all candidates who have passed the qualifying tests submit their claims. The committee are entrusted with the power of selection, but are expected to exercise that power, as closely as circumstances permit, in accordance with the suggestions made by Rhodes. The trust arranges for the distribution of elected scholars among the colleges of Oxford, each of which has agreed to receive a limited number of approved candidates.

(R. G. P.)

RHODES, JAMES FORD (1845- ), American historian, was born in Cleveland, Ohio, on the 1st of May 1845. He
entered the university of New York as a special student in 1865, studied at the university of Chicago in 1866-67, and at the Collège de France in 1867-68, and in 1868 served as occasional Paris correspondent to the Chicago Times. He then took a course in metallurgy in the School of Mines, at Berlin; subsequently inspected iron and steel works in western Germany and in Great Britain; and in 1870 joined his father in the iron, steel and coal business in Cleveland, becoming a member of the firm in 1874. He retired from business with an ample fortune in 1885, and after two years devoted to general reading and travel he began his History of the United States from the Compromise of 1850, which, closing the narrative with the year 1877, was published in seven volumes in 1893-1906. In recognition of the merit of his work he received honorary degrees from various American universities, was elected president of the American Historical Association in 1899, and received the Loubet prize of the Berlin Academy of Sciences in 1901. In 1909 he published a volume of Historical Essays.

RHODES, the most easterly of the islands of the Aegean Sea, about 10 m. S. of Cape Alyko in Asia Minor. It forms, with the islands of Syme, Casos, Carpathos, Castelorizo, Telos and Charki, one of the four sanjaks into which the Archipelago vilayet of Turkey is divided. The governor-general of the vilayet resides at the town of Rhodes. The length of the island is about 45 m. from N.E. to S.W., its greatest breadth 22 m., and its area nearly 424 sq. m. The population of the island comprises 7000 Moslems, 21,000 Christians, and 2000 Jews.

The island is diversified in its surface, and is traversed from north to south by an elevated mountain range, the highest point of which is called Atairo (anc. Atabyris or Atabyrium) (4560 ft.). It commands a view of the elevated coast of Asia Minor towards the north, and of the Archipelago, studded with its numerous islands, on the north-west; while on the south-west is seen Mount Ida in Crete, often veiled in clouds, and on the south and south-east the vast expanse of waters which wash the African shore. The rest of the island is occupied in great part by ranges of moderately elevated hills, on which are found extensive woods of ancient pines, planted by the hand of nature. These forests were formerly very thick, but they are now greatly thinned by the Turks, who cut them down and take no care to plant others in their place. Beneath these hills the surface of the island falls lower, and several hills in the form of amphitheatres extend their bases as far as the sea.

Rhodes was famed in ancient times for its delightful climate, and it still maintains its former reputation. The winds are liable to little variation; they blow from the west, often with great violence, for nine months in the year, and at other times from the north; and they moderate the summer heats, which are chiefly felt during the months of July and August, when the hot winds blow from the coast of Anatolia.

Rhodes, in addition to its fine climate, is blessed with a fertile soil, and produces a variety of the finest fruits and vegetables. Around the villages are extensive cultivated fields and orchards, containing fig, pomegranate and orange trees. On the sloping hills carob trees, and others both useful and agreeable, still grow abundantly; the vine also holds its place, and produces a species of wine which was highly valued by the ancients, though it seems to have degenerated greatly in modern times. The valleys afford rich pastures, and the plans cultivated species of grain.

The commerce of the island has been of late years increasing at a rapid rate. Many British manufacturers are imported by indirect routes, through Smyrna, Constantinople, Beyrout and other places. Cotton stuffs, calicoes and grey linen are among the goods most in demand; they are exported to the neighbouring coast of Anatolia, between Budrum and Adalia, and thence conveyed into the interior. The expansion of the trade has been very much owing to the establishment of steam navigation direct to the island, which is now visited regularly by French and Austrian steamers, as well as by some from England to Smyrna.

The only town of any importance in the island is the capital, Rhodes, which stands at the north-east extremity. It rises in an imposing manner from the sea, on a gentle slope in the form of an amphitheatre. It is surrounded with walls and towers, and defended by a large moated castle of great strength. These fortifications are all the work of the Knights of St John. The houses in the old town are generally narrow, and the well interior of the city does not correspond to its outward appearance. No trace exists of the splendour of the ancient city, with its regular streets, well-ordered plan and numerous public buildings. The modern city of Rhodes is in general the work of the Knights of St John, and has altogether a medieval aspect. The picturesque fortifications also by which the city is surrounded remain almost unaltered as they were in the 15th century. The principal buildings which remain are the church of St John, which is become the principal mosque; the hospital, which has been transformed into public granaries; the palace of the grand master, now the residence of the pasha; and the senate-house, which still contains some marbles and ancient columns. Of the streets, the best and widest is a long street which is still called the Street of the Knights. It is perfectly straight, and formed of old houses, on which remain the armorial bearings of the members of the order. On some of these buildings are still seen the arms of the popes and of some of the royal and noble houses of Europe.

The only relics of classical antiquity are the numerous inscribed altars and bases of statues, as well as architectural fragments, which are found scattered in the courtyards and gardens of the houses in the extensive suburbs which now surround the town, the whole of which were comprised within the limits of the ancient city. The foundations also of the moles that separate the harbours are of Hellenic work, though the existing moles were erected by the Knights of St John.

Rhodes has two harbours. The lesser of these lies towards the east, and its entrance is obstructed by a barrier of rocks, so as to admit the entrance of but one ship at a time. It is sufficiently sheltered, but by the negligence of the Turks the sand has been suffered to accumulate until it has been gradually almost choked up. The other harbour is larger, and also in a bad condition; here small ships may anchor, and are sheltered from the west winds, though they are exposed to the north and north-east winds. The two harbours are separated by a mole which runs obliquely into the sea. At the eastern entrance is the fort of St Elmo, with a lighthouse.

History.—It is as yet difficult to determine the part which Rhodes played in prehistoric days during the naval predominance of the neighbouring island of Crete; but archaeological remains dating from the later Minoan age prove that the early Aegean culture maintained itself there comparatively unimpaired until the historic period. A similar conclusion may be drawn from the legend which people primitive Rhodes with a population of skilful workers in metal, the "Telchines." Whatever the racial affinities of the early inhabitants may have been, it is certain that in historic times Rhodes was occupied by a Dorian population, reputed to have emigrated mainly from Argos subsequently to the "Dorian invasion" of Greece. The three cities founded by these settlers—Lindus, Ialysus and Camiros—belonged to the "League of Six Cities," by which the Dorian colonists in Asia Minor sought to protect themselves against the barbarians of the neighbouring mainland. The early history of these towns is a record of brisk commercial expansion and political enterprise. The position of Rhodes as a distributing centre of Levantine produce, especially of wines, is well attested by archaeological finds. Its colonies extended not only eastward along the southern coast of Asia Minor, but also linked up the island with the westernmost parts of the Greek world. Among such settlements may be mentioned Phaselis in Lycia, perhaps also Soli in Cilicia, Salapia on the east Italian coast, Gela in Sicily, the Lipari islands, and Rhoda in north-east Spain. In home waters the Rhodians exercised political control over Carpathos and other islands.
RHODESIA

The history of Rhodes during the Persian wars is quite obscure. In the 5th century the three cities were enrolled in the Dellan League, and democracies became prevalent. In 412 the island revolted from Athens and became the headquarters of the Peloponnesian fleet. Four years later the inhabitants of Rhodes, under the command of Chares of Rhodes, fled to Athens and took refuge in the city. This expedition was followed by a series of campaigns against the Persians, and in 399 B.C. the island was again enrolled in the Dellan League. In 395 B.C. the Rhodians were again forced to yield to Athens, and in 386 B.C. they were again enrolled in the Dellan League. In 381 B.C. the Rhodians were again forced to yield to Athens, and in 377 B.C. they were again enrolled in the Dellan League. In 360 B.C. the Rhodians were again forced to yield to Athens, and in 356 B.C. they were again enrolled in the Dellan League. In 350 B.C. the Rhodians were again forced to yield to Athens, and in 346 B.C. they were again enrolled in the Dellan League. In 340 B.C. the Rhodians were again forced to yield to Athens, and in 336 B.C. they were again enrolled in the Dellan League. In 330 B.C. the Rhodians were again forced to yield to Athens, and in 326 B.C. they were again enrolled in the Dellan League. In 320 B.C. the Rhodians were again forced to yield to Athens, and in 312 B.C. they were again enrolled in the Dellan League. In 308 B.C. the Rhodians were again forced to yield to Athens, and in 299 B.C. they were again enrolled in the Dellan League. In 290 B.C. the Rhodians were again forced to yield to Athens, and in 282 B.C. they were again enrolled in the Dellan League. In 278 B.C. the Rhodians were again forced to yield to Athens, and in 271 B.C. they were again enrolled in the Dellan League. In 262 B.C. the Rhodians were again forced to yield to Athens, and in 253 B.C. they were again enrolled in the Dellan League. In 248 B.C. the Rhodians were again forced to yield to Athens, and in 244 B.C. they were again enrolled in the Dellan League. In 240 B.C. the Rhodians were again forced to yield to Athens, and in 234 B.C. they were again enrolled in the Dellan League. In 224 B.C. the Rhodians were again forced to yield to Athens, and in 220 B.C. they were again enrolled in the Dellan League. In 214 B.C. the Rhodians were again forced to yield to Athens, and in 210 B.C. they were again enrolled in the Dellan League. In 206 B.C. the Rhodians were again forced to yield to Athens, and in 202 B.C. they were again enrolled in the Dellan League. In 197 B.C. the Rhodians were again forced to yield to Athens, and in 192 B.C. they were again enrolled in the Dellan League. In 187 B.C. the Rhodians were again forced to yield to Athens, and in 182 B.C. they were again enrolled in the Dellan League. In 178 B.C. the Rhodians were again forced to yield to Athens, and in 173 B.C. they were again enrolled in the Dellan League. In 168 B.C. the Rhodians were again forced to yield to Athens, and in 164 B.C. they were again enrolled in the Dellan League. In 159 B.C. the Rhodians were again forced to yield to Athens, and in 154 B.C. they were again enrolled in the Dellan League. In 149 B.C. the Rhodians were again forced to yield to Athens, and in 144 B.C. they were again enrolled in the Dellan League. In 139 B.C. the Rhodians were again forced to yield to Athens, and in 134 B.C. they were again enrolled in the Dellan League. In 129 B.C. the Rhodians were again forced to yield to Athens, and in 124 B.C. they were again enrolled in the Dellan League. In 119 B.C. the Rhodians were again forced to yield to Athens, and in 114 B.C. they were again enrolled in the Dellan League. In 109 B.C. the Rhodians were again forced to yield to Athens, and in 104 B.C. they were again enrolled in the Dellan League. In 99 B.C. the Rhodians were again forced to yield to Athens, and in 94 B.C. they were again enrolled in the Dellan League. In 89 B.C. the Rhodians were again forced to yield to Athens, and in 84 B.C. they were again enrolled in the Dellan League. In 79 B.C. the Rhodians were again forced to yield to Athens, and in 74 B.C. they were again enrolled in the Dellan League. In 69 B.C. the Rhodians were again forced to yield to Athens, and in 64 B.C. they were again enrolled in the Dellan League. In 59 B.C. the Rhodians were again forced to yield to Athens, and in 54 B.C. they were again enrolled in the Dellan League. In 49 B.C. the Rhodians were again forced to yield to Athens, and in 44 B.C. they were again enrolled in the Dellan League. In 39 B.C. the Rhodians were again forced to yield to Athens, and in 34 B.C. they were again enrolled in the Dellan League. In 29 B.C. the Rhodians were again forced to yield to Athens, and in 24 B.C. they were again enrolled in the Dellan League. In 19 B.C. the Rhodians were again forced to yield to Athens, and in 14 B.C. they were again enrolled in the Dellan League. In 9 B.C. the Rhodians were again forced to yield to Athens, and in 4 B.C. they were again enrolled in the Dellan League. In A.D. 1 B.C. the Rhodians were again forced to yield to Athens, and in A.D. 1 they were again enrolled in the Dellan League.

RHODESIA (so named after Cecil Rhodes), an inland country and British possession in South Central Africa, bounded S. and S.W. by the Transvaal, the Bechuanaland Protectorate and German South-West Africa, N. by Portuguese East Africa, W. by Nyasaland, and E. by the British Nyasaland Protectorate and Portuguese East Africa. It covers an area of about 450,000 sq. m., being larger than France, Germany and the Low Countries combined. It is divided into two parts of unequal size by the middle course of the Zambezi.

Southern Rhodesia, with an area of 148,573 sq. m., consists of Matabeleland and Mashonaland, the western and eastern provinces, while the trans-Zambezi regions are divided into North-Western Rhodesia (or Barotseland) and North-Eastern Rhodesia.

Physical Features.—Rhodesia forms part of the high tableland which constitutes the interior of Africa south of the Congo basin. Hydrographically the greater part of the country belongs to the basin of the Zambezi (q.v.), but in the N.E. it includes the eastern headstreams of the Congo, and in the S. and S.E. it is drained by the tributaries of the Limpopo, the Sabi and the Pungwe. The Limpopo forms the boundary between Southern Rhodesia and the Transvaal. The north-western regions, drained by the upper Zambezi and its affluents, are described under Barotseland, and North-Eastern Rhodesia, bounded with the adjacent Nyasaland Protectorate, under British Central Africa. The eastern portion of the tableland of Southern Rhodesia runs from the S.W. to the N.E., and forms a broad watershed between the tributaries of the Zambezi—flowing south and the rivers flowing south and east. It is along this high plateau that the railway runs from Bulawayo to Salisbury and onwards to Portuguese East Africa. The elevation of the railway varies from 4500 ft. to 5500 ft. There is a gradual sloping away of the plateau to the N.W. and S.E., so
that only a small portion of Southern Rhodesia is under 3000 ft. The eastern boundary, along Portuguese East Africa, forms the edge of the tableland; the height of the edge is accentuated by a series of ridges, so that the country here assumes a mountainous appearance, the grass-clad heights being reminiscent of the Cheviot Hills of Scotland or the lower Alps of Switzerland.

**Geology.**—The geology of this region is very imperfectly known. Metamorphic rocks extend over immense areas, but these and the other formations are to a great extent hidden beneath superficial deposits. Conglomerates and banded ironstone rocks are found in the metamorphic areas around Bulawayo and the borders of Katanga; but to what extent these represent the different formations older than the Karroo and newer than the Swaziland shales (see **Transvaal**) has not been satisfactorily determined. Certain gold-bearing conglomerates are regarded as the equivalents of the Witwatersrand series, but the main sources of gold are the veins of quartz and igneous rocks developed in the metamorphic series. The Karroo formation is well represented, and covers extensive areas in the Zambezi basin. The Dwyka conglomerate appears to be developed in the Tuli district. The coal-bearing strata of Tuli and Wankies are certainly of Karroo age. They have yielded the fossil remains of fishes **Acroelepis molyneuxi**, the freshwater molluscs **P還是mamutus**, a few reptilian bones, and species of **Glossoperis** among plants.

The age of a widely distributed series of red-white sandstones, named by Molyneux the Forest Sandstone, remains uncertain. Molyneux considers them Tertiary, but it is improbable that these rocks of various ages from Karroo to those of Recent date are represented. They contain numerous interbedded sheets of basalt, but it is doubtful if any of these are of so recent a date as Tertiary. Rocks of Karroo age occur round Lake Bangweulu, and contain numerous fossil plants and a few small shells. The age of the wide, thick sheet of basalt, through which the Zambezi has cut the Hatoke gorge between the Victoria Falls and Wankies, remains uncertain.1

**Climate.**—As Southern Rhodesia extends between 16° S. and 22° S., and is thus within the tropics, it might be expected that the climate would be trying for Europeans, but owing to the elevation of the country the temperature is rarely too high for comfort. Another factor that tends to moderate the climate is the rainy season coincides with the summer months, and the winter months are dry. The nights are always cool, so that the climate approximates to the ideal. On the high tableland which forms the great proportion of the area so recently reaches 100° and there is just sufficient frost in the winter to be useful to farmers. The winter months are June, July and August, and the hottest months of September, October and November, just before the Tuli Pluvial. The temperature of 110° is sometimes reached in the low-lying district of Tuli (elevation 1890 ft.) and in the Zambezi valley. There is a striking difference between the temperature of the plains and those registered 4 ft. from the ground. The latter rarely reach freezing-point, but the ground temperature is sometimes as low as 24°. Hoar frost is most noticeable in the veld and low-lying areas.

**Fauna.**—Rhodesia is rich in the larger granivorous animals, especially in antelope, which number about twenty-five varieties, including kudu, eland, hartebeest, roan, sable, wildebeest and impala. The most common are the duiker, the stembok and the rietbok. Other horned animals in the country are the buffalo, giraffe, zebra, elephant, hippopotamus, rhinoceros (black and white), warthog, and various baboons and monkeys. The buffalo is now rare, having been almost exterminated by the rinderpest in 1896. The carnivora include the lion, leopard, cheetah, and various wild cats, foxes, wolves, jackals and dogs. There are at least five varieties of the mongoose. Amongst the rodents are squirrels, dormice, rats (eleven kinds), the porcupine, the Cape hare and the rock hare. Of insects the antelopes, the hedgehog and various shrews may be mentioned. Bats number eleven varieties. Snakes are numerous, the most important being the python, the puff-adder and the cobra. Many lizards are found in most of the rivers, and chameleons and lizards are very common. Rhodesia abounds in beetles, butterflies and moths, and new varieties are found with each season. The period known as the cobra season extends from September to March, but the greatest amount falls in the last three months of that period. The mean annual rainfall for various stations in the eastern half of Rhodesia ranges from 24 to 44 in., the greatest amount being along the eastern border. For the western half the mean rainfall is from 19 to 27 in., but in the south-west corner it is much drier, the rainfall there has never reached 1 ft. In the hot season there is a sufficiency of rain for all summer crops, but winter crops, such as wheat, must be assisted by irrigation. Malnutrition is prevalent in certain districts during the wet season, but this is now preventable and the country is very healthy, children, especially in towns and on the high veld, growing sturdily. The death rate amongst Europeans is only about 15 per 1000.

**Plants.**—Rhodesia is quite rich in the larger granivorous varieties, especially in antelope, which number about twenty-five varieties, including kudu, eland, hartebeest, roan, sable, wildebeest and impala. The most common are the duiker, the stembok and the rietbok. Other horned animals in the country are the buffalo, giraffe, zebra, elephant, hippopotamus, rhinoceros (black and white), warthog, and various baboons and monkeys. The buffalo is now rare, having been almost exterminated by the rinderpest in 1896. The carnivora include the lion, leopard, cheetah, and various wild cats, foxes, wolves, jackals and dogs. There are at least five varieties of the mongoose. Amongst the rodents are squirrels, dormice, rats (eleven kinds), the porcupine, the Cape hare and the rock hare. breeding season, when they are on guard over their harems of from ten to fifteen wives—the sunbirds, with their long curved beaks that enable them to pick up the hair of flowers, and the honeyguides, with their agitated "chuck, chuck," lead the wayfarer to bees' nests with expectation of joining in the plunder. The small birds of Rhodesia are usually very brilliantly coloured, the most distinguishing feature is known as the blue jay, with its bright, iridescent, light blue plumage.

**Flora.**—The vegetation of the territory is luxurious and mainly subtropical, as the lower valleys the flora assumes a tropical aspect. The country is well-watered in this respect, owing to the high tablelands farther south. The trees as a rule attain no greater height than about 20 ft., but in some districts, such as Southern Rhodesia, Better and Wankles, there are remains of forests of large timber. The small growth of the trees is said to be due to the annual veld fires, and it is noticeable that native trees that are protected attain a much greater height. As a rule the wood is either very hard or very soft, so that timber for building has still to be imported, although the existing timber is useful for mining purposes. One of the hardest woods is the so-called Rhodesian teak (native Ilexus), which is about 90% harder than real teak (Tectona grandis). The trees most commonly met with are mapane, used for poles; umkamba, resembling mahogany; m'lanje cedar, chiefly found along the eastern border; umususa, used for firewood; impachla, the native wisteria. Among other trees are the baobab with enormous very soft trunk, the fruit being a large nut containing citrate of magnesia, which natives use to make a cooling drink; the umvagaz—blood-wood—which issues a blood-coloured juice when injured; the umbyangana, or blood-flower, which has been much incised. The bark of the umusasa, the umhondo, and the umugo are much used by natives for binding fibres in making huts and are also used for tanning. The bark of the babob yields a dye which is sold for the decorative cloth and calico. A wide range of useful plants are found, many of which are used in medicinal purposes.

The period of the year when flowers begin to bloom is rather remarkable. After the long spell of dry weather, lasting from five to six months, the rains begin in February, and the veld turns green over the veld. Most of such flowers are those of bulbous plants or plants with large roots that have been stored with nourishment during the previous growing wet season. The flowers are sustained by this stock food until the rains appear again to re-enrich the roots. Even grass sprouts green over the earth before the rains appear, and the hard-baked veld is pierced by the shoots of the gladiosus, the orchid, the asparagus, the solanum, the convolvulus and many other curious flowers. When the rains are far advanced, the annuals shoot rapidly and make a second show of bloom. A peculiarity of the early spring shoots on trees and shrubs is that the new blossoms are the flowers of the older regions, but are all shades of brown and orange and red and yellow.

One of the chief features of Rhodesia is the vast stretches of grass-covered veld, the grasses varying from a few inches to 15 ft. in height. Looming above the veld are the thickets of fowls, which rivers are to be found palms, tree ferns, bananas, dracaenias and other hot climate plants. Rubber, indigo and cotton are indigenous and there are groves of lemon trees, but these were most probably introduced by early settlers. Tobacco, which grows luxuriantly, may also have been introduced.

**Inhabitants.**—In Southern Rhodesia about half the European population, which in 1900 was approximately 16,300, is British born or of British parentage, and about one-third is South Africans. The remaining one-fifth are of African parentage and the population is equally divided between the urban and rural areas. In rural areas the chief occupations are mining and agriculture. Industrial pursuits, including mining, engage about 25% of the population, 8% are employed in agriculture, and 15% in commerce. Mashonaland has 7,500 white inhabitants, and Matabeleland 9,000. There are about 20,000 Asiatics in Southern Rhodesia.

The **Natives** of Rhodesia belong to the Bantu-Negro stock and are roughly divisible into two groups; those long settled in the country, and the Amazulu, who during the 19th century left Zululand and, passing through the more southern regions, eventually settled in Mashonaland. The Barotse (q.s.) are mainly settled in Northern Rhodesia, and the tribes of Rhodesia, in spite of incursions from Portuguese territory and from the north, the natives can be still clearly divided into Mashona and Matabele, living in the eastern and western pro-

vinces respectively. The name Mashona is not used by the natives but is useful as distinguishing the allied tribes of the eastern division from the Matabele in the west. The languages of the Mashona tribes are allied and are distinct from that of the Matabele (or Zulu), but it is uncertain whether these Mashona tongues should be regarded merely as different dialects, or languages as different as those of the various nations of Europe (but see **Bantu Languages**). The tribes round Salisbury and extending as far as Marondera in the east and about 100 m. north are clearly branches of the Vasezuru people, that is, the people from "higher up," the "higher up" being a region in the south-east. Their history can be traced from about the beginning of the 18th century; but there is a great lack of tradition amongst this class of native, which is distinctly inferior in type to the Matabele in the west.

Farther north there are the Makorikori and the Mabuduja or Mabusha. It would appear that the country in which these people now dwell was formerly in the possession of the Barotse, and some of the present chiefs obtained their positions by permission of the Barotse. Previously, according to Portuguese documents of the 16th and 17th centuries, the Matabele or Makalanga now located in the south round about Victoria had possession of the country as far north as the Zambezi. Their language is allied to that of the present inhabitants, but in many respects is widely different and of late has become more so owing to intercourse with the Matabele. Along the eastern border two more tribes can be differentiated, namely, Umsasa's people in the north and those speaking the Chindawo language in the south. Their languages are merely variants of the language spoken in the Salisbury and Mzoe districts.

All the tribes in the eastern province have very similar habits and customs. Their huts are circular with a wall a foot or two high, made of poles and dagga (mud) surmounted by a conical thatched roof. They differ thus from the bee-hive huts of the Zulus. They are built indiscriminately together and are not surrounded by stockades. The whole family dwells in the same hut along with dogs, goats and fowls, and sometimes even with cattle, though there are usually separate kraals for their cattle. The kraals are as a rule filthy, but the inside of the hut is kept clean. There is a special place for a fire, and a raised portion of the mud floor on which to sleep, but no furniture. Their drinking water comes from a distance from the place of abode, but their tobacco gardens are near the camping place. The main object in life seems to be to grow sufficient grain for food and beer. The grain they store in granaries, resembling small huts, placed on rocks or on stakes, out of the reach of white ants and secure from the depredations of animals. They amuse themselves occasionally by making earthenware pots which are very soft and easily broken, or by engaging in iron-work or brass-wire work for ornamentation. In the south they are quite clever in making water-tight baskets from rushes grown by the Sabi river. In their religious beliefs spirits play a great part. Above all there is a vague idea of a Supreme Being whom they call a spirit, and to whom they pay reverence and fear. After the death of a person the belief in the spirits of their ancestors, the spirits of the witch-doctors, the spirits of the Matabele, the spirits of old women, the spirits of the foolish, the spirits of baboons, &c. Every occurrence is attributed to the influence of a spirit, and if the occurrence is an evil one a feast and dance of propitiation are held. Feasts of thanksgiving are also held on such occasions as the gathering of the first-fruits, the harvest festival, or on the return from a long and dangerous journey. Of the tribes already mentioned the most advanced are Umsasa's people and the Makaranga. The probable connexion of the tribes now inhabiting Mashonaland with the architects of the ancient stone buildings which are scattered over the country is discussed in the section **Archaeology**. Of these ruins the most extensive are situated near Victoria and are known as Zimbabwe (q.s.).

In the western province the Matabele, or rather Amandabele, are the descendants of the Zulus who trekked under the
leadership of the famous Moslikatze up through the Transvaal, whence they were driven by the Boers. Moslikatze died in 1868, and his son L. Moslikatze, after a brother, assumed sway in 1870. His people were divided into three main sections: the Abenezi (who were the aristocrats), the Abenhla and the Amakhola. The Amakhola or Holi were the inhabitants of the land at the time of the invasion and thereafter were practically in the position of bondsmen and rarely allowed to possess cattle. The great spirit of the Holis was the Mlimo, who was practically the spirit of the nation. Among the Holi tribes are the Abashangwe, the Abanyai, the Batoroke (near the Zambesi), the Abanganwa of the Wankie district, the Ababiro of the Tuli district, and the Abashungwe, a group subsisting on game. There is a small tribe in the Beletingwe district called the Abahlemba, which would appear to have been in touch with the Arabs in early times. Their customs include circumcision and the rejection of pork as food.

The natives in Southern Rhodesia number about 700,000, and of these 10,000 work on the mines and 20,000 are engaged in farm, railway and household work under Europeans.

Chief Towns.—Salisbury, which lies 4880 ft. above the sea, is the capital of Southern Rhodesia, being the seat of government, and is situated in the southern plateau (the Mashonaland). The town is complete, with Government house, hospital, schools, banks, post office and numerous hotels. There is a considerable number of government offices, and the administrator and resident commissioner live here. The only industries are a brewery and a tobacco factory for grading and packaging the tobaccos of the local growers.

Bulawayo (q.v.), situated 4460 ft. above the sea, is the largest town and is in the western province, Matabeleland. It is 301 m. by rail S. of Salisbury, and 1362 m. N.W. of Cape Town. The population is some 4000 Europeans and about the same number of natives. It has the advantage of a good pipe water supply and a sewerage system of excellent work. It was the ancient capital of the Matabele king, Lobengula. There is a Government house, with an administration occupied, and was the residence of Cecil Rhodes. It is from Bulawayo that the World’s View, the burial-place of Rhodes in the Matopo Hills, is usually visited.

The other towns are Umtali, on the eastern border, pop. 800 whites, railway works, centre for numerous large and small gold mines; Gwelo, the central town, about midway between Salisbury and Bulawayo; Victoria Falls; and Maseru in the south, centres of farming districts. Victoria, near which are the famous Zimbabwe ruins, is reached by mail cart (80 m.) from Selukwe, and Melsetter by mail cart (95 m.) from Umtali. There are also smaller towns, such as Shonga, Zvishavane, Mutare, and Zvishavane, through the Bulawayo and Salisbury are managed by town councils, the other towns have sanitary boards.

The Rhodesian railway system connects the chief towns and mining centres with one another and all the important South African countries. The main line is a continuation of the railway from Cape Town through Kimberley and Mafeking. It runs from Mafeking in a general N.E. direction to Bulawayo, whence it goes N.W. to the Zambezi, which is crossed a little below the Victoria Falls. The bridging of the river was completed in April 1905. Thence the railway is continued N.E. (92 m.) to Kalomo, Barotseland, and onward to the Katanga district of Belgian Congo. The section from Kalomo to Broken Hill (261 m.) was completed in 1907, and the extension to the frontier of Belgian Congo (126 m.) in 1909. This main line forms the southern link in the Cape to Cairo railway. The line branches off the main line at Bulawayo (treble line) N.E. by Gwelo to Salisbury and thence S.E. to the Portuguese port of Beira. From Bulawayo another line (120 m. long) runs S.E. to the Nkombo Hills. This is the line from Gwelo a railway (40 m.) goes S.E. to Yankee Doodle, and from this thence branches a line (50 m. long) in an easterly direction to Blinkwater. From Salisbury a line runs N.W. to Lomagundi (84 m.). The last-named has a 2 ft. gauge. The line from Mafeking to Kimberley is the line of the standard gauge of South Africa—3 ft. 6 in. The distances from Bulawayo to the following places are:—Gwelo, 113 m.; Salisbury, 301 m.; Umtali, 471 m.; Beira, 675 m.; Mafeking, 490 m.; Kimberley, 713 m.; Cape Town, 1362 m.; Port Elizabeth, 1060 m.; East London, 800 m.; Johannesburg, 931 m.; Pretoria, 977 m.; Lourenco Marques, 1307 m.; Durban, 1328 m. (the last four places all via Fort Victoria, a branch line via Foss Flats, a junction 48 m. N. of Kimberley), and Victoria Falls, 112 m.

About 4000 m. of roads have been built and are maintained by government. The telegraph and telephone system is very complete, being there for the whole of Rhodesia about 8000 m. of wires. This territory includes the telephone wires within the African Transcontinental system and is served by about ninety telegraph offices. A Post office savings bank was brought into operation on the 1st of January 1905. Over 2,500,000 letters, post-cards and parcels are despatched annually.

Agriculture.—The country is well adapted for agriculture. Chief attention has been paid by farmers to the growing of maize, the annual produce being about half a million bushels. It is a very good cereal. The land is such a fertile country as Rhodesia, and is extensively grown by natives, but the improved methods of the whites easily secure a yield of from twice to eight times that of the native. The average yield by European farmers is about eight hundred and twenty bushels per acre, which is a very good yield. Wheat, barley and oats are grown with some success under irrigation in the winter time, but the moisture with attendant rust is too excessive for these crops in summer. Tobacco promises to be a great source of wealth to the territory about the Turkeen and Virginia. Virginian tobaccos have been raised and cured and put on the market, where they were easily disposed of. They are of better quality than those grown elsewhere in South Africa. In 1908 only about 500 acres were under cultivation, but there are large tracts of land suitable for this industry.

Fruits of very extensive variety thrive in Rhodesia; they include plums, peaches, nectarines, peaches, apricots, figs, loquats, pineapples, Cape gooseberries, mulberries, tree tomatoes, rosella, granadillas, all kinds of citrus fruits. The most flourishing are the citrus fruits and the Japanese plums, but in the higher altitudes pears and apples are also very productive. Vegetables, as well as all kinds can be grown, especially potatoes, tomatoes, asparagus and sweet potatoes, yams, &c. Coffee produces as much as 4 lb. of beans to the shrub in certain parts of the country. There are two securing Rhodesia, and stock-raising promises to be the chief agricultural industry of the future. During the early period of European occupation rinderpest and at a later date East African fever decimated the country, but the prevention of these diseases is now thoroughly understood, and in consequence of 1896 swept away large herds, cattle have been increasing rapidly in number. There is hardly any portion of the territory which is not suitable for cattle, and the rapid natural increase indicates a speedy prosperity in cattle ranching. Cattle and woolsheds give a number about 800,000 in the territory. Donkeys and mules thrive, but horses are very liable to horse-sickness towards the end of the rainy season.

Mining.—When Rhodesia was first opened up to European occupation, attention was immediately called to the large number of gold workings made by unknown former inhabitants of the country. These workings have been carried on to a limited extent, being stopped probably by the presence of water and the lack of suitable machinery. European enterprise has resulted in the mining of gold, silver, copper, nickel and other minerals. The chief mines are at Mafeking, the Wanderer in the Gwelo district; the Giant in the Hartley district; the Jumbo in the Mazoe district; the Ayrshire district; the Magumondi district, the Penhalonga and the Rezende in the Umtali district, while there are smaller mines in the Njove, in the Umtali and the Gwanda, Insiza, Gwelo, Hartley and Umtali districts. The output of gold increased in value from £368,000 in 1900 to £2,623,000 in 1909. In another one-third of the gold output there is being extracted the ore indicated by ancient workings, it is probable that many gold reefs still await discovery, and includes silver, of which 262,000 oz. were produced in 1909; coal, 170,000 tons (1909), and lead, 965 tons. Extensive discoveries of chrome iron have been made in the Selukwe region. There is a steady export of this metal, of which the output in 1909 was over 25,000 tons. Besides these, small quantities of copper, wolframite and diamonds have been exported, while scheelite and asbestos have been discovered, but no payable quantities.

Commerce.—Taking the returns for a series of years ending 1908, the total imports amounted to about £1,475,000 per annum, 55% of which were manufactured articles, including £250,000 worth of imports of packing machinery. Imports of food and drink amounted to £30,000. In 1900 the total imports amounted to £2,214,000, the chief items being food and drink (432,000), machinery, animals and cotton goods. Exports of tobacco and tea amounted to £213,000 in 1908. The exports of tobacco and tea amounted to £1,780,000. Included in the total is £342,000 goods exported and re-exported.

Administration.—The administration of Rhodesia is carried on by the British South Africa Company under an order in council of 1898, amended by orders in council of 1903 and 1905. The company is called upon to appoint for Southern Rhodesia an administrator or administrators. The company also appoints an executive council of not fewer than four members to advise the administrator upon all matters of importance in administration. An order in council of 1903 provided for a
RHODESIA

legislative council consisting of the administrator, who presides, seven nominees of the company approved by the secretary of state, and seven members elected by registered voters (the number was 5 in 1898 and 5 in 1901). In 1907 it was agreed to reduce the company’s nominees by one, so that the elected members should form the majority of the council. The secretary of state appoints a resident commissioner, who sits on both executive and legislative councils without vote. The duty of the resident commissioner is to report to the high commissioner upon all matters of importance. Ordinances passed by the legislative council are submitted to the high commissioner for consent or otherwise, but may be disallowed by the secretary of state.
