and, it may be said, un-English type. A seated statue in stone roughly hewn with characteristic breadth by the Danish sculptor, Louis Hesselriis, has for some years been placed in the apse of the Castle of Kronborg, in which, according to the Danish tradition, Shakspeare is said to have resided as a youth with his master, the Lord of Denmark. America possesses some well-known statues. That by J. Q. A. Ward is in Central Park, New York (1872). In 1886 William Ordway Edwards made a marble statue of the bard and placed it in the Lincoln Park, Chicago; and later, Frederic MacMonnies produced his very original statue for the Library of Congress, Washington, D.C. This is in some measure based on the 'Droeshout engraving.' William R. Bruce, in 1864, cast a bronze portrait bust of 'Shakspeare' at the instigation of the Wisconsin Historical Society, and the bust was purchased from him by the Library of Congress. Great consideration is given by some to the bust made by William Page of New York in preparation for a picture of the poet he was about to paint. He founded it with pathetic faith and care and ambition, but it was never completed (1870); it is described as 'a little resembles; as he was no sculptor the bust is no more successful than the picture. The bust by R. S. Greenough, already mentioned as based in part on the 'Boston Zuccaro' portrait, must be included here, as well as the romantic, dreamy, marble bust by Augusto Possagno of Florence (presented to the Garrick Club by Salvinii in 1876); the imaginative work by Altni (Duke of Northumberland, Albick Castle); and the busts by F. M. Miller, E. G. Puller, Albert Toft, J. E. Carew (Mr Muspratt, Liverpool) and P. J. Char digny of Paris. The last named was a study made in 1850, for a proposed statue, 100 ft. high, which the sculptor hoped to be commissioned to produce. A cast of one of any of those busts and the statue and statuettes have also been produced. Some attention has been accorded for several years past to the great pottery bust attributed to John Dwight's Fulham Pottery (c. 1675). The present writer, however, has been informed that it is by Lippombe, in the latter portion of the 19th century.

The wood carvings are numerous. The most interesting among them are the series of famous men carved from walnut and mulberry-tree; and those which are the most attractive are the arcadia carvings by Selb (1761). One statuette of a primitive order of art was sold in 1900 in London for a fantastic sum; it was absurdly claimed to be the original of Scheekensha's statue, but without the slightest attempt at proof or justification.

The Medals and Coins of Shakespeare offer material for a separate number of the series, but they are by no means numerous. The best of them are as follows: Jean Dassier (Swiss; in the "Series of Famous Men," c. 1730); J. J. Barre (French; in the "Series numismatica universalis," 1818); Westwood (Garrick Jubilee, 1766); J. G. Hamond's fine short-lived series, reprinted in the Hogarth, and inset in the back of the "Shakespeare chair" presented by the artist to David Garrick (in the possession of Mr W. Burdett-Coutts). The statuettes alluded to be carved from the wood of the mulberry-tree by artist W. H. Pyne, and there is a medallion of Shakespeare executed, which is the most attractive are the arcadia carvings by Selb (1761). One statuette of a primitive order of art was sold in 1900 in London for a fantastic sum; it was absurdly claimed to be the original of Scheekensha's statue, but without the slightest attempt at proof or justification.

The 18th-century tradesmen's Tokens, which passed current as money during the period, are of great utility for the collector, needs, constitute another branch for collectors. About thirty-of these, including variations, bear the head of Shakespeare. With one exception (a farthing, 1719), issued much later than the bust of Shakespeare, these are all minted in London. There are the "Warwickshire" series, the "London and Middlesex," and the "Stratford Promissory" series. Many of these have edge with a word or a tail piece on the special places in which they are payable. In addition to these may be mentioned the 24 "imitation regal" tokens which bear Shakespeare's name, around (except in one or two cases) the head of the king. They belong to the last quarter of the 18th century.

The many more important kilns have produced portraits of Shakespeare in porcelain and pottery, in statuettes, busts, in low relief, and as plates and medallions. Thomas Seigneur, of Berkeley, Derby; Chedsey-Derby; old Staffordshire (salt-glaze), frequently reproducing, as often as not with fantastic archaism, Scheekensha statue; and on flat surfaces by transfer of printed designs—both 18th- and 19th-century productions; also French-Dresden and Wedgwood. In the last-named ware is the fine bust, half-life-size, in black basalt, as well as several "cameos" in various sizes, in blue and white jasper, or yellow ground, and in black basalt. The busts were also produced in different sizes. Worcester produced the well-known "Benjamin Webster" service, with the portrait, Chandos type, en cameleaf, as well as the mag in "jet enamel," which was the fifth of the set of thirteen. Several of the portraits have also been produced commercially in biscuit china.

Gems with intaglio portraits of Shakespeare have been copiously produced since the middle of the 19th century, nearly all of them based upon earlier portraits of Shakespeare who were masters of their still-living craft. The principal of these latter are as follows: Edward Burch, A.R.A., exhibited in 1765; Nathaniel Marchant, R.A., exhibited 1773 (Garrick turning to a bust of Shakespeare); Thomas W. Read (1776); and James E. Stirling and W. Wyon (the Elder: Shakespeare and Garrick); W. B. Wray (a beautiful drawing for this in the Print Room of the British Museum); and Yeo. In the same class may be reckoned the Cameos, variously sardonyx, chalcedony, and shell, some excellent examples of which have been executed, and the Ivories, both in the round and in relief. The Waxes form a class by themselves; in the latter portion of the 18th century a few small busts and reliefs were put forth, very good of their kind. These have been imitated within recent years and attempts made to pass them off as originals, but only the novice is deceived by them. Similarly the old Shakespeare brass pipe-stoppers have latterly been widely reproduced, and the modern specimens are not inferior to those produced from the original. So voracious is the public appetite for portraits of the poet that the old embroi deries in hair and more recently in woven silk found in black silver, bronze, iron, and lead are eagerly snapped up, and postage stamps with Shakespeare's head have been issued with success. The acquisitiveness of the collector paralyses his powers of selection. The vast number of objects serves daily use by bearing the portrait of Shakespeare call for no notice here.

(M. H. S.)

**BIBLIOGRAPHY**

The following is an attempt to supply the want of a select classified bibliography of the literature connected with Shakespeare (hereafter called M. H. S., arranged chronologically under each heading in order to give the literary history of the special subject. Articles in periodicals not issued separately, and modern critical editions of single plays, are not included; and only those of the plays usually contained in the collective editions are noticed.

SHALLOT, *Allium ascalonicum*, a hardy bulbous perennial, which has not been certainly found wild and is regarded by A. de Candolle as probably a modification of *A. Cepa*, dating from about the beginning of the Christian era (Origin of Cultivated Plants, p. 71). It is extensively cultivated and is much used in cookery, besides which it is excellent when pickled. It is propagated by being planted in March or October, but the principal crop should not be got in earlier than February or the beginning of March. In planting, the tops of the bulbs should be kept a little above ground, and it is a commendable plan to draw away the soil surrounding the bulbs when they have got root-hold. They should not be planted on ground recently manured. They come to maturity about July or August. There are two sorts—the common, and the Jersey or Russian, the latter being much larger and less pungent.

SHALMANESER [Ass. Šulmanu-yašar, "the god Sulman (Solomon) is chief"], the name of three Assyrian princes. Shalmaneser I., son of Hadad-nirari I., succeeded his father as king of Assyria about 1310 B.C. He carried on a series of campaigns against the Aramaeans in northern Mesopotamia, annexed a portion of Cilicia to the Assyrian empire, and established Assyrian colonies on the borders of Cappadocia. According to his annals, discovered at Assur, in his first year he conquered eight countries in the north-west and destroyed the fortress of Arinu, the dust of which he brought to Assur. In his second year he defeated Sattuwa, king of Malatia, and his Hitrite allies, and conquered the whole country as far south as Carchemish. He built palaces at Assur and Nineveh, restored "the world-temple" at Assur, and founded the city of Calah.

Shalmaneser II. succeeded his father Assur-nazir-pal III. 858 B.C. His long reign was a constant series of campaigns against the eastern tribes, the Babylonians, the nations of Mesopotamia and Syria, as well as Cilicia and Ararat. His armies penetrated to Lake Van and Tarsus, the Hitrites of Carchemish were compelled to pay tribute, and Hamath (Hamah) and Damascus were subdued. In 854 B.C. a league formed by Hamath, Arvad, Ammon, "Ahab of Israel" and other neighbouring princes, under the leadership of Damascus, fought an indecisive battle against him at Karkar (Qarqar), and other battles followed in 849 and 846 (see JESUS §10). In 842 Hazael was compelled to take refuge within the walls of his capital. The territory of Damascus was devastated, and Jehu of Samaria (whose ambassadors are represented on the Black Obelisk now in the British Museum) sent tribute along with the Phoenician cities. Babylonia had already been conquered as far as the marshes of the Chaldeanans in the south, and the Babylonian king put to death. In 836 Shalmaneser made an expedition against the Tibareni (Tabal) which was followed by one against Cappadocia, and in 832 came the campaign in Cilicia. In the following year the old king found it needful to hand over the command of his armies to the Tartan (commander-in-chief), and six years later Nineveh and other cities revolted against him under his rebel son Assur-dan-in-pal. Civil war continued for two years; but the rebellion was at last crushed by Samas-Rimmon or Samsi-Hadad, another son of Shalmaneser. Shalmaneser died soon afterwards in 823 B.C. He had built a palace at Calah, and the annals of his reign are engraved on an obelisk of black marble which he erected there.

See V. Scheil in Records of the Past, new series, iv. 36-79.

Shalmaneser III. (or IV.) appears as governor of Zimrirra in Phoenicia in the reign of Tiglath-pileser IV. (or III.) and is summoned by Habiru, who are often planted in September. At all events, on the death of Tiglath-pileser, he succeeded to the throne the 25th of Tebet 728 B.C., and changed his original name of Ululu to that of Shalmaneser. The revolt of Samaria took place during his reign (see JEWES §15), and while he was besieging the rebel city he died on the 12th of Tebet 722 B.C. and the crown was seized by Sargon.

For all these rulers see BABYLONIA AND ASSYRIA, Sections V. and VIII., and works quoted.

(A. H. S.)

SHAMANISM, the name commonly given to the religion of the Ural-Altaic peoples. Properly speaking, however, there is nothing to distinguish Shamanism from the religions of other peoples in a similar stage of culture. On the other hand, the shaman or priest (Tungus saman, Altan Turk kama, cf. Russian domovoe) performs the embodiment of the idea of justice. Several of those of the ordinary magician; one of his main functions is to protect individuals from hostile supernatural influence. He deals both with good and bad spirits; he also performs sacrifices and procures oracles. The drum (tungur) is an important instrument in his ceremonies; it may be assumed that in many cases the effect of the preliminary performances is to induce autohypnotic phenomena. The shaman's office is held to be hereditary and his chief assistants are ancestral spirits.

SHAMASH, or Šamaš, the common name of the sun-god in Babylonia and Assyria. The name signifies perhaps "servitor," and would thus point to a secondary position occupied at one time by this deity. Both in early and in late inscriptions Shamash is designated as the "offspring of Nannar," i.e. of the moon-god, and since, in an enumeration of the pantheon, Sin generally takes precedence of Shamash, it is in relationship, presumably to the sun-god that the sun-god appears as the "chief" god. Such a supposition would accord with the prominence acquired by the moon in the calendar and in astrological calculations, as well as with the fact pointed out (see SITS) that the moon-cult belongs to the nomadic and therefore earlier, stage of civilization, whereas the sun-god rises to full importance only after the agricultural stage has been reached. The two chief centres of sun-worship in Babylonia were Sippara (Sippar), represented by the mounds at Abu Habba, and Larsa, represented by the modern Senkerah. At both places the chief temple bore the name E-barra (or E-balbara) "the shining house"—a direct allusion to the brilliancy of the sun-god. Of the two temples, that at Sippara was the more famous, but temples to Shamash were erected in all large centres—as Babylon, Ur, Nippur and Nineveh.

The attribute most commonly associated with Shamash is justice. Just as the sun disperses darkness, so Shamash brings wrong and injustice to light. Khammurabi attributes to Shamash the inspiration that led him to gather the existing laws and legal procedures into a code, and in the design accompanying the code the king represents himself in an attitude of adoration before Shamash as the sun-god. In the middle centuries before Khammurabi, Ur-Engur of the Ur dynasty (c. 2600 B.C.) declared that he rendered decisions "according to the just laws of Shamash." It was a logical consequence of this conception of the sun-god that he was regarded also as the one who released the sufferer from the grasp of the demons. The sick man, therefore, appeals to Shamash as the god who can be depended upon to help those who are suffering unjustly. This aspect of the sun-god is vividly brought out in the hymns addressed to him, which are, therefore, among the finest produc- tions of the entire realm of Babylonian literature.

It is evident from the material at our disposal that the Shamash cults at Sippara and Larsa so overshadowed local sun-deities elsewhere as to lead to an absorption of the minor deities by the predominating one. In the systematized pantheon these minor sun-gods become attendants that do his service. Such are Bunene, spoken of as his chariot driver, whose consort is Atgimakh, Kettu ("justice") and Mesharu ("right"), who are introduced as servitors of Shamash. Other sun-deities, as Ninib (Gr.) and Nergal (Gr.), the patron deities of important centres, retained their independent existence as certain phases of the sun, Ninib becoming the sun-god of the morning and of the spring time, and Nergal the sun-god of the noon and of the summer solstice, while Shamash was viewed as the sun-god in general.

Together with Sin and Ishtar, Shamash forms a second triad
SHAMBLES—SHANGHAI

by the side of Anu, Bel and Ea. The three powers, Sin, Shamash and Ishtar (q.v.), symbolized the three great forces of nature, the sun, the moon and the life-giving force of the earth. At times, instead of Ishtar, we find Adad (q.v.), the storm-god, associated with Sin and Shamash, and it may be that these two sets of triads represent the doctrines of two different schools of theological thought in Babylonia which were subsequently harmonized by the recognition of a group consisting of all four deities.

The consort of Shamash was known as A. She, however, is rarely mentioned in the inscriptions except in combination with Shamash.

(M. Ja.)

SHAMBLES, a slaughter-house, a place where butchers kill animals for domestic food, an "abattoir." The word in the singular means properly a bench or stall, which butchers display their meat for sale in a market, and appears in O. Eng. fiô-scœmœl, foot-stool. It represents the L. scœmulum, diminutive of scœmum, step, bench; the root is seen in Gr. σκέπτε. to prop, cf. " sceptre." The distinct word "shambles," meaning to walk awkwardly, is to be traced to the O. Du. schampelen, to stumble, an adaptation of O. Fr. escamper, to decamp (Lat. ex, out of, and campus, field). The same French word has given the English "scamp," a worthless rascal, a rogue, vagabond.

SHAMMAI, a Jewish scribe of the time of King Herod, whom tradition almost invariably couples with Hillel (q.v.), with whom he was possibly associated in a rich library. Shammai took part in decisions and discussions, but also in character and temperament. His motto (Aboth i. 15) reads: "Make thy study of the Thora a firmly established duty; say little and do much; and receive every man with friendly countenance." The last advertisement is characteristic, as Shammai was choleric and brusque. The opposition between Shammai and Hillel was perpetuated by their respective schools, till, under Gamaliel II., the strife was decided at Jabneh in favour of the school of Hillel. (W. B.)

SHAMOKIN, a borough of Northumberland county, Pennsylvania, on the Sunbury Creek, W. of River, E. N. of E. of Harrisburg. Pop. (1890) 18,322, of whom 2793 were foreign-born; (1910 U.S. census) 19,588. Shamokin is served by the Philadelphia & Reading, the Northern Central, and two interurban railways. There are two parks. The mining and shipping of anthracite coal and the manufacture of silk goods and of hosiers and knit goods are the borough's principal industries, but it has, also, foundries and machine shops, and manufactory of powder, powder-kgs., shirts, overalls, hooks and eyes, brick, flour and dressed lumber. The total value of its factory product in 1905 was $1,443,915. The borough was named in honor of the Creek (aca) Shamokin, the name of a Delaware Indian word meaning "full of eels." The Indian village named Shamokin was on the site of the present Sunbury, Pa. Shamokin was formed in 1852 by the union of two villages, Groveville and Mary Ann. It was incorporated as a borough in 1864.

SHAMPOO, a word now principally used as a hair-dresser's term for washing the head and hair with soap and water or some special preparation. It is properly the Hindustani word (champia, to thrust, press; imperative champ) for the kneading and rubbing of the body, &c., which is 45 cm. (the principal features of the various forms of hot bath as practised in the East.

SHAMYL (c. 1797–1871), the leader of the tribes of the Caucasus in the war against Russia. He was born about 1797, and educated by the Mullah Djemaleddin, soon took a leading part in preaching a holy war against the Russians. He was both the spiritual and military leader of the tribes, who maintained the struggle for twenty-five years (1834–1859). This perpetual guerrilla was a severe strain upon the resources of the great power, and Shamyli's romantic fight for independence, making his home in the north of Russia, and his main headquarters on the Caspian Sea, and being occasionally seen, the summer months are excessively hot. Cholera occurs in the native city every summer, malarial fever exists and dysentery is apt to become chronic in spring and autumn, on account of the sudden changes of temperature—a fall from 20° to 5° in a few hours—and the moisture-laden atmosphere. Smallpox is endemic in the Chinese city during the autumn and winter. All the opium smokers of the city, in the European and native settlements, owing to sanitary enactments, cholera is rare, and Europeans who adopt ordinary precautions "have nothing to fear from the climate of Shanhsai." (China Sea Directory, vol. iii., col. 133.)

At first merchants appeared disinclined to take advantage of the opportunities offered them at Shanghai. "At the end of the first year of its history as an open port Shanghai could count only 23 foreign residents and families, 1 consular flag, 11 merchants' houses, and 2 Protestant missionaries. Only
forty-four foreign vessels had arrived during the same period."

By degrees, however, the manifold advantages as a port of trade possessed by Shanghai attracted merchants of all nationalities; and from the banks of the Hwang-pu arose handsome dwellings-houses, which have converted a reed-covered swamp into one of the greatest cities in the East.

The number of foreigners, other than British, who took up their abode in the British settlement at Shanghai made it soon necessary to adopt some more catholic form of government than that supplied by a British consul who had control only over British subjects, and by common agreement a committee of residents, consisting of a chairman and six members, was elected by the renters of land for the purposes of general municipal administration. It was expected when the council was formed that the three settlements—the British, French and American—would have been incorporated into one municipality, but international jealousy prevented the fulfilment of the scheme, and it was not until 1863 that the Americans threw in their lot with the British.

In 1834 the prosperity of the settlements received a severe check in consequence of the capture of the native city by the T'ai-p'ing rebels, who held possession of the walls from September in that year to February 1835. This incident, though in many ways disastrous, was the cause of the establishment of the foreign customs service, which has proved of such inestimable advantage to the Chinese government. The confusion into which the customs system was thrown by the city being held by the rebels induced the Chinese authorities to request the consuls of Great Britain, France and the United States to nominate three officers to superintend the collection of the revenue. This arrangement was found to work so well that on the reoccupation of the city the native authorities proposed that it should be made permanent, and H. N. Lay, of the British consular service, was in consequence appointed inspector of the Shanghai customs. The results of Mr Lay's administration proved so successful that when arranging the terms of the treaty of 1858 the Chinese willingly assented to the continuance of the arrangement.

The treaty of 1858 had also secured to the British a place in the treaty ports, and Mr Lay was thereupon appointed inspector-general of maritime customs. On the retirement of Mr Lay in 1862 Sir Robert Hart was appointed to the post.

From 1856 to 1864 the trade of Shanghai vastly increased, and its prosperity culminated between 1860 and 1864, when the influx of Chinese into the foreign settlement in consequence of the advance of the T’ai-p’ing rebels added enormously to the value of land. But the period was brought to a close by the withdrawal of the British, who were driven back by the British troops and volunteers, aided by the naval forces of England and France. It was in consequence of this occupation of the city that the British and American army, which under his direction gave a reality to the boastful title of "ever-victorious army" it had assumed under the two American adventurers Ward and Burgevin, to Shanghai the successful occupation of which was the reward of temporary residence. With the disappearance of the T’ai-p’ings the refugees returned to their homes, leaving whole quarters deserted. The loss thus inflicted on the municipality was considerable, and was intensified by a commercial crisis in cotton and ten, in both of which there had been a great deal of over-speculation. But, though the abnormal prosperity was thus suddenly brought to an end, the genuine trade of the port has steadily advanced, subject of course to occasional fluctuations. For example, in 1880 the value of trade was £8,223,017, and in 1908 it was £40,000,000. The total burden of foreign steamers which entered and cleared at Shanghai during 1884 was 5,145,242 tons, while in 1898 it was over 10,000,000 tons. The principal items of import are cotton yarns, metals, sugar, petroleum, and coal; of export, silk, representing in value 34% of the total exports, cotton, tea, rice, hides and skins, wool, wheat and beans. Great Britain and the British colonies supply nearly 31% of the imports, Japan 12%, and the United States 12%; and of the exports Great Britain and the British colonies take 18%, the United States 4% and Japan 3%. The supplanting of China by other countries in the foreign trade, but is rapidly becoming a large manufacturing and industrial centre. In this category the first place must be given to cotton manufactures; though not very numerous, give promise of considerable development. The demand in China for foreign cotton is chiefly the produce of the Bombay mills, has been steadily on the increase. On the other hand, China produces raw cotton in infinite quantity, and is the largest source of supply for the Japanese mills. Cloth weaving has been tried in two or three places, but abandoned in favour of spinning. Next in importance is the reeling of silk cocoons by machinery. This is gradually supplanting the hand-winding; it is, however, a more laborious process, and consequently more valuable article. Shanghai also contains three large establishments for docking, repairing and building ships. Among minor industries are match factories, rice and paper mills, ice, cigarette, piano, carriage and furniture factories, wood carving, &c.

The vastness of British interests in China and the large British population in Shanghai (1864) were sufficient to induce the British supreme court for China at Shanghai, Sir Edmund Hornby, then judge of the British court at Constantinople, being the first judge appointed to the new office. Now, by virtue of extra-terri- torial powers given by the treaty of 1858, in all cases in which the British, because of their possession of the British subjects, are exempted from the jurisdiction of the Chinese authorities, and made justiciable only before their own officials. As there are now fourteen treaty powers represented at Shanghai, there are consequently fourteen courts, each administering the law of its own nationality. In addition, there is also a Chinese court, commonly called the Mixed Court, though it is no more mixed than any of the others in an international sense, except that a foreign assistor sits with the Chinese judge in cases where any of his own nationality are interested as plaintiffs. At first sight this arrangement seems somewhat complicated, but the proper simple enough, viz., that a defendant must always be sued in the court of his own nationality. In criminal cases there is, of course, no difficulty. For the British, English law alone prevails, and they can only be tried and punished in the British court; and so on in other nationalities. In the case of suits in which the parties of the same nationality, there is also no difficulty, e.g., for British subjects the British court is the forum, for German subjects it is the German court. In cases, however, in which a British subject is sued by an American, the court is a tribunal between an Englishman and a German, if the German constitutes himself plaintiff he must sue his opponent before the British court, and vice versa. The greatest anomaly, however, in respect of the courts of Shanghai, is that of the Chinese, who, although their own laws are exercised by the foreign community as a whole without regard to nationality, and is a share of the power which properly belonged to the Chinese local authorities, but which by convention of usage they have allowed to fall into foreign hands. It is extended only within the area termed the foreign settlements, which were originally nothing more than the "area set apart for the residence of foreign merchants. Of these, three—the British, acquired in 1845, the French, acquired in 1850, and the American, acquired in 1862. At an early date, as a foreign town began to spring up, the necessity of having some authority to look after the public welfare, to make provision for the comfort, benefit, became evident, and as the Chinese authorities shirked the work and expense, the foreigners resolved to tax themselves voluntarily, and appointed a committee of works to see the money properly laid out. In 1854 the consuls of Great Britain, France, and the United States drew up a joint code of regulations applicable to both the then settlements, British and French, which being ratified by all the powers, gave a law to the foreigners resident in their respective subjects. The two areas thus became an international settlement, and the subjects of all three—nationalities—the only powers then interested—acquired the same privileges and became liable to the same obligations. This, however, was not without some difficulty; the Chinese authorities and by other nationalities as they came in, and it conferred on the foreign community local self-government, practically free from official control of any description. In 1863 the area covered by these regulations was extended to the American settlement, which meanwhile had been obtained by that government from the Chinese. But about the same time, 1862, the French decided to withdraw from the joint arrangement, and pro-

† The Treaty Ports of China and Japan, by W. F. Mayer.
SHANHAI-KWAN—SULLIVAN

The executive is entrusted to a municipal council of nine, elected annually from among the general body of foreign residents. The council alone has the power to appoint and remove the mayor and to make law, as the French legislation by all ratepayers possessing a certain pecuniary qualification in public meeting assembled. Proxies for absentee landlords are allowed. One date each public meeting must be held annually to pass the budget and fix the taxation for the year. No official sanction is required, and no veto is allowed for such money votes. Special meetings may be held at any time for special purposes. New York, in the kind method, the city may be governed by treaty powers in order to be binding on their several nationalities, but within certain limits the ratepayers can pass by-laws which do not require such sanction. The French municipal council works on similar lines, except that every vote and every disbursement of money is subject to the approval of the French consul-general. The executive council consists of eight members, four of whom must be native born and four may be foreigners. The French consul-general is chairman ex officio, so that the control in any case is French and practically official.

Both settlements were originally intended for the residence of foreign merchants only, but as the advantages of living under foreign protection became evident by reason of the security it gave from arbitrary taxation and arrest, Chinese began to flock in. This movement has continued, and is now particularly noticeable in the cases of retired officials, many of whom have made Shanghai their home. The total native population in the settlement was by the census of 1895 was 286,753, and the estimated population of the tow of Shanghai, including the suburbs, was 411,753. The census of the foreign population in 1905 showed 3713 British, 2157 Japanese, 1329 Portuguese, 991 Americans, 785 Germans and 568 Indians, out of a total of 11,407. The magnitude of the foreign community in Shanghai may be gathered from the following rough summary: Assessed value of land in settlements registered as foreign-owned £5,500,000; docks, wharves and warehouses £1,500,000; public concessions £2,500,000; private property estimated £1,500,000 — total £19,250,000. This is exclusive of banks, shipping and insurance companies, and other institutions which draw profits from other places besides Shanghai.

SHANHAI-KWAN, a garrison town in the extreme east of the province of Chih-li, China. Pop. about 30,000. It is situated at the point where the ranges of hills carrying the Great Wall of China dips to the sea, leaving a kau or pass of limited extent between China proper and Manchuria. It is thus an important military station, and the thoroughfare of trade between Manchuria and the great plain of China. The Imperial Northern railway from Tientsin and Taku, 174 m. from the former, runs through the pass, and skirts the shore of the Gulf of Liao-tung as far as the treaty port of Niu-chwang, where it connects with the railways leading from Port Arthur to the Siberian main line.

The pass formed the southern limit of the Russian sphere of influence as defined in the convention between Great Britain and Russia of the 28th of April 1858.

SHANKARSET (1800-1862), the recognized leader of the Hindu community of Bombay for more than forty years, was born in 1800 into a family of goldsmiths of the Daividnya caste. Unlike his forefathers, he engaged in commerce, and soon acquired what was in those days a large fortune, a great part of which he devoted to the good of the public. So high was his credit that Arabs, Afghans and other foreign merchants chose to place their treasures in his custody rather than with the banks. Foreseeing the need of better methods of education, he became one of the founders of the School Society and the Native School of Bombay, the first of its kind in Western India. He established the Indian Council of Education, and again in 1840 into the Board of Education which preceded the Elphinestone Educational Institution founded in 1856. When the Students' Literary and Scientific Society first opened their girls' schools, in spite of strong opposition of the Hindu community, he set the good example of providing another girls' school entirely at his private cost. His zeal for progress was also shown in his starting the English School, the Sanskrit Seminary and the Sanskrit Library, all in Girgaum. To Jagannath Shankarsett and his public-spirited friends, Sir George Birdwood and Dr Bhau Daji, Bombay is also indebted for the contraction which, beginning in 1857, gradually changed a close network of lanes and streets into a spacious and airy city, adorned with fine avenues and splendid buildings. He was the first Indian to be nominated to the legislative council of Bombay under the Act of 1861. While his influence was used by Sir John Malcolm to induce the Hindus to acquiesce in the suppression of suttee or widow-burning, his own community remember gratefully that to him they owe the cremation ground at Sonapur. He died at Bombay on the 3rd of July 1865, regretted by all classes of society, who, about a year before his death, in a public meeting assembled at the Town Hall, voted a marble statue to perpetuate his memory.

SHANKLIN, a watering-place in the Isle of Wight, England, 8½ m. S. of Ryde by rail. Pop. of urban district (1901) 4533. It is beautifully situated on the cliffs bordering the S.E. coast, and is sheltered W. by high-lying downs. The church of St John the Baptist is Perpendicular. There are several modern churches and chapels, numerous villas, a pier and a link connecting the town with the esplanade beneath the cliff. The picturesque winding chasm of Shanklin Chine breaches the cliffs S. of the town.

SHANNON, CHARLES HAZELWOOD (1865— ), English artist, was born at Sleaford in Lincolnshire, the son of the Rev. Frederic Shannon. He attended the Lambeth school of art, and was subsequently considerably influenced by his friend Charles Ricketts and by the example of the great Venetians. In his early work he was addicted to a heavy low tone, which he abandoned subsequently for clearer and more transparent colour. He achieved great success with his portraits and his Giorgionesque figure compositions, which are marked by a classic sense of style, and often interests invested in Shanghai may be gathered from the following rough summary: Assessed value of land in settlements registered as foreign-owned £5,500,000; docks, wharves and warehouses £1,500,000; public concessions £2,500,000; private property estimated £1,500,000 — total £19,250,000. This is exclusive of banks, shipping and insurance companies, and other institutions which draw profits from other places besides Shanghai.

SHANNON, CHARLES JEBUSA (1862— ), Anglo-American artist, was born at Auburn, New York, in 1862, and at the age of eight was taken by his parents to Canada. When he was sixteen, he went to England, where he studied at South Kensington, and after three years won the gold medal for figure painting. His portrait of the Hon. Horatia Stopford, one of the queen's maids of honour, attracted attention at the Royal Academy in 1881, and in 1887 his portrait of Henry Vigne in hunting costume was one of the successes of the exhibition, subsequently securing several medals for the artist at Paris, Berlin and Vienna. He soon became one of the leaders of the new school of portrait painters in London. He was one of the first members of the New English Art Club, and in 1897 was elected an associate of the Royal Academy, and R.A. in 1909. His picture, "The Flower Girl," was bought in 1901 for the National Gallery of British Art.

SHANNON, the principal river of Ireland. It flows with a bow-shaped course from N. to S. and S.W., from the N.W. part of the island to its mouth in the Atlantic on the S.W. coast, with a length of about 240 m. and a drainage area of 4544 sq. m. Rising in county Cavan in some small pools at the foot of Cullaghas Loughs and in county Sligo near the town of Lettermore, traversing the first of a series of large lakes, Lough Allen (9 m. in length). It then separates county Roscommon on the right (W.) bank from counties Leitrim, Longford, Westmeath and King's County on the left. In this part of its course it forms Loughs Boderg (7 m. long), Forbes (3 m.) and Ree (8 m.), and receives from W. the river Boyle and from E. the Inny, while in county Longford it is joined by the Royal Canal. It now separates county Galway on the right from King's County and county Tipperary; receiving the Suck from W. and the Brosna from E., and forming Lough Derg (23 m.). Dividing county Clare from counties Tipperary and Limerick, the Shannon reaches the city of Limerick as a broad and noble river, and debouches upon an estuary 60 m. in length with a direction nearly E. and W. This divides county Clare on the right from counties Limerick and Kerry on the left.

XXIV. 26
A wide branch estuary, that of the Fergus, joins from N., and the rivers Mulkear, Maigue and Deel enter from S. From Lough Allen to Limerick, where the Shannon becomes tidal, its falls is 144 ft. With the assistance of short canals the river is navigable for light vessels to Lough Allen, and for small steamers to Athlone; while Limerick is accessible for large vessels. The salmon-fishing is famous; trout are also abundant. On the banks are found, Athlone, Killaloe, and Castleconnel are favourite stations for sportsmen. The scenery is generally pleasant, and on the loughs, with their deeply indented shores and numerous islands, often very beautiful. These islands are in several cases sites of early religious settlements, while on those on the river-banks the most noteworthy is that of the seven churches of Clonmacnoise.

SHANS, a collective name, probably from Chinese Shan-tse, Shan-ye (Shan = mountain )), “highlanders,” given by the Burmese to all the tribes of Thai stock subject to the former kingdom of Burma (see SHAN STATES below). The Shans call themselves Tai or Pauang; while the Chinese call them Pai or P’ai-ya. Among them exist the purest types of the Thai race. They are found all over the province of Yunnan and in the borderland between China and Burma. Politically, where not under the direct control of Chinese magistrates, the tribes are organized under their own chiefs, who are recognized by the Chinese government and endowed with official rank and title. In Burmese such native chiefs are termed Shan-si, or Shan-si, in French, Thaïs. See also LAOS, MIANZEE, LOLLOS. Also A. R. Colquhoun, Amongst the Shans (1885); E. Aymonier, “Les Thaïes,” in Revue de l’histoire des religions for 1891.

SHAN-SI, a northern province of China, bounded N. by Mongolia, E. by Chihli, S. by Ho-nan, and W. by Shen-si. Estimates of its area vary from 66,000 to 81,000 sq. m. and it has its capital, Tai-yuen Fu (pop. 230,000), eight prefectural cities. The population is returned as 12,700,000. It includes, in the northern districts, about 500,000 Mongoils. The configuration of Shan-si is noteworthy, forming, from its southern frontier as far north as Ning-wu Fu—an area of about 30,000 sq. m.—a plateau 2600 to 6600 ft. above the level of the sea, the whole of which is one vast coal-field. North and west the plateau is bounded by high mountain ranges trending south-west and north-east. Down the central line of the province from north to south lies a series of deep depressions, all of which are ancient lake basins. But though forming a series these lakes were not formerly connected with each other, some being separated from those adjoining by high ridges, and being drained by different rivers and in different directions. The Fén-ho, the longest river in Shan-si, with a general S.W. direction, and the Chin-ho, also a considerable stream, are both tributaries of the Yangtze.

Shan-si is one of the most remarkable coal and iron regions in the world, a veritable second Pennsylvania, and Baron von Richthofen gave it as his opinion that the world, at the present rate of consumption of coal, could be supplied for thousands of years from Shan-si alone. In the south the neighbourhood of Tsé-chow Fu abounds in both coal and iron, and has probably, partly through being within reach of the populous plain of Hwai-kang Fu, of the yellow river, of T’ai-kow Chin and Sew-wu Hien (the shipping places for Tientsin and the Grand Canal) and of Ho-nan Fu, furnished more iron to the Chinese than any other of the provinces. A further extent in the empire, the coal is of great purity and easily fusible, while iron, of good quality and for moulds, &c., and a superior anthracite coal, lie ready to hand. The coal is of two kinds, bituminous and anthracite, the line of demarcation between the two is taken by the long tributary of the Hsing-ho. The continuation of the Shan-han range, the fields of bituminous coal being west of these hills, and those of anthracite east. In the neighbourhood of P’ing-t’ing Chow the extent of the coalfield is large and it is also abundant, and even in that part of the country explored by the explorers of the U.S. Geographical Society, Mr. Downie and Mr. Hothofer says: “These extraordinary conditions, for which I know no parallel on the globe, will eventually give rise to some curious features in mineralogy, which I have not predicted that if a coalfield of such extent could ever be built from the plain to this region, branches of it will be constructed within the body of one or other of these beds of anthracite, which are among the thickest and most valuable known among the various beds of coal of the world. The famous anthracite districts of the present coal-belt of P’ing-t’ing Chow. Such a tunnel would allow of putting the produce of the various coal-beds immediately on rail-road carts destined for distant places.” These mines are worked by the Peking Syndicate, which has gained a valuable railway line to connect the lines of the Fén-ho and Han trunk line, which traverses the east of the province.

Salt is produced in the prefecture of P’ing-yang in the south of the province, both from a salt lake and from the alluvial soil in the neighbourhood of the Fén-ho. Shan-si produces cereals, tobacco, cotton and sometimes rice, but in agricultural products the province is poor and the transport is ruinously and insufficient. The people of Shan-si are great traders, and nearly all the commerce of southern Mongolia is in their hands. A railway connecting the capital with Pekin was opened in 1906. The only wagon road leading into and through Shan-si is the great highway from Peking to Si-gan Fu, which enters Shan-si west of Chéng-t’ing Fu, and leaves the province at Tung-kwan at the great bend of the Hwang-ho. Transport is chiefly on the backs of camels, mules and asses. The province suffered from a terrible famine in 1875-1879, about which time Protestant missionaries began work in the capital. In the north, beyond the Great Wall, is the city of Kwei-hwa-Cheng (pop. about 200,000), formerly the residence of the grand Lama of Mongolia; it has many Lama monasteries.

Shan-si university, one of the best equipped in China, owes its existence to the Boxer rising. Certain Protestant missionary bodies in the province refused to accept the compensation awarded them for damage to their property, and at their request the money was devoted to the foundation of a university, the missionaries being guaranteed for ten years the control of the work. By the 30th of June, 1902, the six states were under the governor of the S. Shan States, and 37 under the superintendent and political officer of the S. Shan States. In addition, two states are under the commissioner of the Mandalay division, namely, Hkamti Long on the N. of Myitkyina district and Mông Mit which is temporarily administered as a subdivision of the Ruby Mines district; and two states, Sinkalng Hkamti and Hsawng Haup, near Manipur, are under the supervision of the commissioner of the Sagaing division. There are besides a number of Shan States beyond the border of Burma, under Chinese and Thai control.

SHAN STATES, a collection of semi-independent states on the E. frontier of Upper Burma inhabited by the Shan or Thai race. The Shan States have a total area of 57,915 sq. m. and a total population (1902) of 1,387,444. There are six states under the direct control of the S. Shan States, and 37 under the superintendent and political officer of the S. Shan States. In addition, two states are under the commissioner of the Mandalay division, namely, Hkamti Long on the N. of Myitkyina district and Mông Mit which is temporarily administered as a subdivision of the Ruby Mines district; and two states, Sinkalng Hkamti and Hsawng Haup, near Manipur, are under the supervision of the commissioner of the Sagaing division. There are besides a number of Shan States beyond the border of Burma, under Chinese and Thai control.

Physical Features.—The shape of the Shan States is roughly that of a triangle, with its base on the plains of Burma and its apex on the Mekong river. The Shan plateau is properly only the country between the Salween and Irrawaddy rivers. On the W. it is abruptly marked by the long line of hills, which bend down to the Mekong and run S. till they sink into the plains of Lower Burma. On the E. it is no less sharply defined by the deep and narrow rift of the Salween. The average height of the plateau is between 2000 and 3000 ft., but it is seamed and ribbed by mountain ranges, which split up and run into one another. On the N. the Shan States are barred across by the E. and W. ranges which follow the line of the Namtu. The huge mass of Loi Limg, 9000 ft., projects S. from this, and on either side of the ranges is the foot of the ranges, which extend down to Mong Nai. The highest peaks are in the N. and the S. Loi Limg is the highest point W. of the Salween, and in Kongkang there is a peak of 8100 ft. There are many peaks above 7000 ft. The majority of the intermediate parallel ranges have an average of between 4000 and 5000 ft. with peaks rising to over 6000. The country beyond the Salween is a mass of broken hills, ranging in height from 3000 to 4000 ft. In the range of the Wa tribes towards the Wa states they average from 5000 to 7000. Several peaks rise to 8000 ft. such as Loi Maw (8102). The climate varies
Shan-Tung—Shapira

considerably. From December to March it is cool everywhere, and 10° to 18° F. on the coast. The average temperature is 80° to 90°, rising to 100° in the Salween valley. The rains begin about the end of April, but are not continual till August, which is usually the wettest month. They last until the end of October, and from the middle of May to the end of July the temperature varies from 60 in. in the broader valleys to 100 on the higher mountains.

Race and Language.—According to the census of 1901 there were 18,787,035 Chinese (see above) in Burma. The Thai or Tai, as they call themselves, were first known to the Burmese as Taroks or Tarets. The original home of the Thai race was S.W. China, or rather that was the geographical center from which the various branches spread out as a people. It is probable that their first settlement in Burma proper was in the Shweil valley, and that from this centre they radiated at a comparatively recent date N., W. and S.E. through Upper Burma, Lower Burma, and the Shan districts. They are represented by tribes of various races across the whole breadth of Indo-China, from the Brahmaputra as far as the gulf of Siam and Tonking; that is among those peoples not only the Shan proper, the Lao of the Mekong, the Hakas of S. China, and the Li, the inhabitants of the interior of the far eastern island of Hainan in the Chinese seas. But no exhaustive survey of the Thai has yet been accomplished for the S. Burmese of Burma they may be divided into the N.W., the N.E., the E. and the S. Shan. The Siamese and the Laos are the principal representatives of the S. division. Siamese are found in considerable numbers in the Peninsular Burmese and the Lao in the northern division. The total at the time of the census of 1901 was 31,800, while that of the Laos was 1647. The country of the E. Shan lies between S.E. Kachin between the Meghna and the Irrawaddy, roughly between the N. and S. by the 22nd and 20th parallels of latitude. It includes the S. Shan States and comprises the country of the Lü and the Hkün of the states of Kengtung and Kuki. The country of the Yemai is divided into the kind in the Akyaung described in the Shan dominion acknowledged the suzerainty of the Sawbwa of Mogun. The N.E. Shan are the Chinese-Shan who are found near Upper Burma and the N. Shan states border on China.

The language may be divided into sub-groups, the N. and the S. The S. includes Siamese, Lao, Lü and Hkün; the N. the three forms of Shan, namely N., Burmese-Shan, S., Burmese Shan and Chinese-Shan with Hkamti and Ahom. The vernacular of the people who are directly known in Burma as Shan is the Burmese of Shan. This language is isolating and polytonic. It possesses five tones, a mastery of which is a sine quod non if the language is to be properly pronounced. It is the language of the Shan dominion acknowledged the suzerainty of the Sawbwa of Mogun. The Burmese of Shan are a peaceable race, fond of trading. During the past decade the trade with Burma has increased very largely, and with the construction of the railway to Lashio a still further increase is expected. In the Shan districts the cultivation of rice and potatoes in the S. states promise wealth also when a railway furnishes them means of getting the produce out of the country. Since 1893 the peace of the Shan States has been practically restored.

See N. Elias, Introductory Sketch of the History of the Shan, S. Burmese Shan, and Chinese-Shan with Hkamti and Ahom, the vernacular of the people who are directly known in Burma as Shan, 1878; Cushing, Shan Dictionary (Introduction); Bock, Traité d'Ethnographie de l'A. Phayre, History of Burma; A. R. Colquhoun, Across Chryse (London, 1883), and Amongst the Shan (1885); Duguet, Étude de la langue Thai (Paris, 1896).

Shan-Tung ("East of the Mountains"), a maritime province of China, bounded N. by the province of Chih-li and the Gulf of Chih-lí, E. by the Yellow Sea, S. by Kiangsu and the Yellow Sea, W. by Hopeh, separating it from Manchuria (estimated) 37,500,000. It is the most densely inhabited part of China, and is celebrated as the native province both of Confucius and Mencius. It is divided into ten prefectures, with as many prefectural cities, of which Chi-nan Fu (q.v.), the provincial capital, is the chief.

The physical features of the province are very plainly marked. The centre and eastern are occupied by mountain ranges running N.W. and S.E. The principal mountain range is the T'ai-shan, which lies parallel with the coast, while the western, southern and western portions form part of the great deltaic plain of the north of China. The mountainous region projects seaward beyond the normal coast line forming a large peninsula. The shores of which are deeply indented and abound in good harbours, such as that of Kiao-chow. The most considerable range of mountains occupies the centre of the province, the highest peak being the T'ai-shan (5050 ft.), a mountain famous in Chinese history for more than 4000 years, and to which hundreds of pilgrims annually resort. The Lao-shan, east of Kiao-chow, fringes the eastern coast for about 18 m. With the exception of the Hwang-ho, which traverses the province in a north-easterly direction to the sea, there are no large rivers in Shan-Tung. The most considerable are the Wei, which flows into the Gulf of Chih-li; the Ta-sui and the Ta-yan, which unite to form the Ta-wen, which rises at the southern foot of the I-shan Mountains and terminates in the Grand Canal. The canal traverses the provinces S. to N. east of the mountain region. There are several lakes notably the Tse-shan Hu, which borders on the Grand Canal and lies in the south-west. The fauna includes wild boars, wolves, foxes, badgers, partridges, quails and snipe. Cotton, silk, coal, grain, &c. are produced in the province. The value of the exports is of the same order as the value of the imports. Not being a low-elevation region, the mountains are unproductive, and yield only brushwood and grass, while the plain to the north is so impregnated with salt that it is almost valueless, especially near the coast. Shan-Tung is divided into two distinct parts, the border between the mountains and the plain to the south-west are, however, extremely rich and fertile.

The chief wealth of Shan-Tung consists in its minerals, the principal of which is coal. Several coal-fields are worked; the most considerable lies in the valley of the Lao-fu river in the centre of the province. Another large field lies on the plain a little to the south of I-chow Fu in the south. A third field is in the district of Wei Hien to the north; and a fourth in the neighbourhood of I-Hien in the southern part. Iron ore, ironstone, gold, galena, lead and copper are also found in considerable quantities in many districts.

The staple products of Shan-Tung are rice, sugarcane, hemp, rice, corn, pulse, arrowroot and many varieties of fruits and vegetables. Rice is grown in the extreme south of the province. Amongst trees, stunted pines, dwarf oaks, poplars, willows and the cypresses are fairly plentiful. Thousand acres of fine plains, and such rice as is grown near the river, is often green in the neighbourhood of Lai-yang in the east, giving rise to a considerable trade in the rice produced by the wild insects. Unlike the wheat of the Shan-Tung breed and become productive in the same districts. They are placed upon the trees in the spring, and at the close of the summer they void a peculiar substance which when melted forms wax. In the autumn they are taken off the trees, and are preserved within doors until the following spring. Sericulture is an important industry. The worms are fed in the west on mulberry leaves, in the east on those of the dwarf oak, the material made from the silk produced from these worms being known as great or Chinese silk. The silk itself, after the cocoon has been used, is eaten and is esteemed a delicacy.

Besides Chin-nan Fu, the provincial capital, other inland cities are Tiao-Chow Fu (pop. 150,000) on the Grand Canal (an industrial centre) and Wei-hsien (100,000), a commercial centre. The ports of Shan-tung include Chifu, Wei-hai-wei and Kiao-chow (Tsing-tao), all separately noticed.

As part of compensation for the murder of two German missionaries in 1897 in this province—Protestant mission work has been restricted to the southern part of the province—the Germans took possession on lease of the port of Kiao-chow, 30° 30' N., a lease run by a British company, and which were associated many railway and mining rights in the district. In fulfilment of these rights a railway has been constructed connecting Kiao-chow with Chin-fu, the capital; there it connects with another railway crossing the province north to south and forming part of the Tientsin-Chin-kang line. In consequence of this acquisition of territory by Germany and the subsequent seizure of Port Arthur by Russia, Great Britain accepted the lease of Wei-hai-wei on the same terms. The convention confirming this arrangement was signed on the 1st of July 1898. It was in Shan-Tung that the Boxer movement was first put down against foreigners (see China, § History).

Shapira, M. W. (c. 1830-1884), Polish vendor of spurious antiquities, was of Jewish birth, but appears to have become a Christian early in life. He opened a shop for the sale of antiquities in Palestine, and after the discovery of the Moabite Stone in 1872 was successful in selling to the Russian government for 20,000 thaler a number of alleged pieces of Moabite pottery. These were shown by Clermont-Ganneau and others (cf. Kautzsch and A. Soci, Archiv der moabitisches Alterthümer, 1876) to be forgeries produced by Shapira’s client Selim al-Kari. Undeterred by this exposure, Shapira continued to do a considerable trade especially in Hebrew MSS. from Yemen, but
ultimately ruined himself by a fraud perpetrated upon the British Museum. In 1883 he offered, for the price, it is said, of $1,000,000, a number of leather strips containing speeches of Moses varying in many particulars from, though similar in matter to, those in Deuteronomy, and written in archaic Hebrew characters. It proved, however, that he had obtained them from a British Museum cupboard and discovered them in a Moabite cave. The fragments were submitted to C. D. Ginsburg, who published translations in The Times of Aug. 4, 17, 22, 1883. The French government, however, sent over Clermont-Ganneau to investigate, and, though the British Museum authorities declined to give him permission to make a complete study, he satisfied himself from a few strips which were publicly exhibited that the whole collection must be a forgery (The Times, Aug. 15). This view was confirmed by Ginsburg's report to the Museum. Shapira, who was never known to have been the actual forger, committed suicide in Rotterdam on the 11th of March 1884.

For the fragments see Guthrie, Fragmenta einer Lederhandschrift (Leipzig, 1884); see also Clermont-Ganneau, Les Fragments archéologiques (Paris, 1885), iii., iv.

**SHAPUR**

(Pahlavi, Shakh pervr, "son of the king"); Greek *Sapor*, commonly *Sapor*, the name of three Sassanian kings.

1. **SHAPUR I.** (a. d. 241-272), son of Ardashir I. The Persian legend which makes him the son of an Arsacid princess is not historical. Ardashir I. had towards the end of his reign renewed the war against the Romans. Shapour conquered the Mesopotamian fortresses Nisibis and Carrhae and advanced into Syria; but he was driven back by C. Furius Timesitheus,1 father-in-law of the young emperor, Gordianus III., and beaten at Resena (243). Shortly afterwards Timesitheus died, and Gordianus (q.v.) was murdered by Philip the Arabian, who concluded an ignominious peace with the Persians (244). When the invasion of the Goths and the continuous elevation of new emperors after the death of Decius (251) brought the Roman empire to utter dissolution, Shapour resumed his attacks. He conquered Armenia, invaded Egypt, plundered the treasure of the Church of Ægyptos, and, after the death of Vahran, the marching against him, but suffered near Edessa the fate of Crassus (260). Shapour advanced into Asia Minor, but was beaten by Ballista; and now Odaenathus (Odainath), prince of Palmyra, rose in his rear, defeated the Persian army, reconquered Carrhae and Nisibis, captured the royal harem, and twice invested Ctesiphon (263-265). Shapour was unable to resume the offensive; he even lost Armenia again. But according to Persian and Arabic traditions, which appear to be trustworthy, he conquered the great fortress of Hatra in the Mesopotamian desert; and the great glory of his reign was that a Roman emperor was by him kept prisoner to the day of his death. In the valley of Istakhr (near Persepolis), under the tombs of the Achaemenids at Nakshi Rustam, Shapour is represented on horseback, in the royal armour, with the crown on his head; before him kneels Valerian, in Roman dress, asking for grace. The same scene is represented on the rocks near the ruins of the towns Darabjird and Shapour in Persia. Shapour left other relics and rock inscriptions; one, at Nakshi-Rajab near Persepolis, is accompanied by a Greek translation; here he calls himself "the Mazdazianan (worshipper of Ahuramazda), the god Sapor, king of kings of the Aryans (Iranians) and non-Aryans, of divine descent, son of the Mazdazianan, the god Artaxares, king of kings of the Aryans, grandson of the god-king Papak." Another long inscription at Hajjibad (Istakhr) mentions the king's exploits in archery in the presence of his nobles.

From his titles we learn that Shapur I. claimed the sovereignty over the whole earth, although in reality his domain extended

1. Timesitheus is the generally accepted variant for the Misithiun ("God-Hater") of Capitolinus; Zosimus, i. 16, 17, preferred Timesiologiae. In a paper read before a meeting of the British School of Archaeology in Rome on the 30th of January, 1900, Mr. A. S. Yamey endeavoured to show that Timesitheus is the general commemoration of a bust in the Sala delle Colonne of the Capitoline Museum; this bust is a portrait of Sanguvus in the Museo delle Terme, representing a battle between Romans and barbarians, where the forehead in each case is a non-Christian incised cross of unknown significance.

SHAPUR—SHARE

little farther than that of Ardashir I. Shapour built the great town Gundev-Shapour near the old Achaemenian capital Susa, and increased the fertility of this rich district by a barrage through the Karun river near Shushtar, which was built for his grandson, the emperor Khosrau I., and the mole of the Canopus. Under the reign of the prophet Mani, the founder of Manichaeism (q.v.) began his preaching in Persia, and the king himself seems to have favoured his ideas.

For the monuments and inscriptions cf. Sir R. Ker Porter, Travels; Flandin and Coste, Voyage en Perse; Stolze, Persiopolis; Thomas, Journal R. Asiast. Soc., new series, iii., 1868; West in Grundrisse der Iranischen Philologie, ii. 76; Dittenberger, Orientis Graeci inscr. i., No. 434. A gem with the portrait of the king is in the museum of Goa, cf. Pertsch, Zeitsch. d. deutschen morgenl. Ges. xxii. 280.

2. **SHAPUR II.** (310-379). When King Hormizd II. (302-310) died, the Persian magnates killed his eldest son, blinded the second, and imprisoned the third (Hormizd, who afterwards escaped to the Romans); the throne was reserved for the unborn child of one of the wives of Hormizd. This child, named Shapur, was therefore born king; the government was conducted by his mother and the magnates. But when Shapur came of age, he turned out to be one of the greatest monarchs of the dynasty. Under his reign the collection of the *Avesta* was completed, heresy and apostasy punished, and the Christians persecuted. This was the natural oriental reaction against the weakness of his predecessors, and the union of the Roman and Sassanian empires was completed.

In 337, just before the death of Constantine, Shapour broke the peace concluded in 297 between Nares and Diocletian, which had been observed for forty years, and a war of twenty-six years (337-363) began. Shapour attempted with varying success to conquer the great fortresses of Roman Mesopotamia, Singara, Nisibis (which he invested three times in vain), Amida (Diarbekr). The emperor Constantius II. was always beaten in the field. Nevertheless Shapour made scarcely any progress; the military power of his kingdom was not sufficient for a lasting occupation of the conquered districts. At the same time he was attacked in the E. by nomad tribes, among whom the Chionites are named. After a prolonged struggle they were forced to conclude a peace, and their king, Grumbates, accompanied Shapour in the war against the Romans. Shapour now conquered Amida after a siege of seventy-three days (359), and took Singara and some other fortresses in the next year. In 363 the emperor Julian, at the head of a strong army, advanced to Ctesiphon, but was killed. His successor Jovian was defeated and made an ignominious peace, by which the districts on the Tigris and Euphrates were ceded to the Persians, and the Romans promised to interfere no more in Armenia. In the rock-sculptures near the town Shapur in Persia (Stolze, *Persopolis*, pl. 141) the great success is represented; under the hoofs of the king's horse lies the body of an enemy, probably Julian, and a suppliant Roman, the emperor Jovian, asks for peace.

- Shapur now invaded Armenia, took king Arsaces III. (of the Arsacid race), the faithful ally of the Romans, prisoner by treachery and forced him to commit suicide. He then attempted to introduce Zoroastrian orthodoxy into Armenia. But the Armenian nobles resisted him successfully, secretly supported by the Romans, who sent King Pap, the son of Arsaces III. into Armenia. The war with Rome threatened to break out again; but Valens sacrificed Pap and caused his assassination in Tarsus, where he had taken refuge (374). Shapour had conducted great hosts of captives from the Roman territory into his dominions, most of whom were settled in Susiana. Here he rebuilt Susa, after having killed her rebellious inhabitants, and founded some other towns. He was successful in the east, and the great town Nishapur in Khorasan (E. Parthia) was founded by him.

3. **SHAPUR III.** (383-389), son of Shapur II., elevated to the throne by the magnates against his uncle, Ardashir II., and killed by them after a reign of five years. He concluded a treaty with Theodosius the Great.

(Ed. M.)

**SHARE** (O. Eng. scær or, chiefly in compounds, e.g. land-scær, a share of land, from scærn to cut; cf. "shear"), something cut off, a portion, a definite part of anything distributed among a
number of persons. The word is particularly applied to the fixed and equal amounts into which the capital of a limited company is divided (see STOCKS AND SHARES; COMPANY; and DEBENTURES). From the same O.Eng. verb sceran is derived "share" (O.Eng. sear), the cutting blade of a plough (q.v.).

SHARI, an important river of North-Central Africa, carrying the drainage of a large area into Lake Chad (q.v.). Its headstreams rise on the watersheds between the Lake Chad basin and those of the Nile and Congo. The principal headstream, known variously as the Wahme, Wa, Wam or Wom, rises, in about 6°N., 10°E., in the middle of the grassy plains that divide between the Chad system and the basin of the Sanga affluent of the Congo.

The Wam flows east and then north and in about 7°20' N., 18°20' E. is joined by the Fafa, a considerable stream rising east of the Wam. The upper course of the Wam is much obstructed by rapids, but from a little above the Fafa confluence it becomes navigable. Below the confluence the river, now known as the Bahr Sara, receives three tributaries from the west. In about 9°20' N., 21°05'E., it is joined by the Bamingi, which is formed by the junction of the eastern headstreams of the Shari. The Bamingi, before the exploration of the Wam, was thought to be the true upper course of the Shari. One of its branches, the Kukuru, rises in about 7°21' N., 21°30'E. and its source the Bamingi becomes navigable, being 12 ft. deep and flowing with a gentle current. In 8°42'N. it receives on the west bank the Gribingi, a river rising in about 6°20' N. It is narrow and tortuous with rocky banks and often obstructed by navigation. A little below this point it flows in great part through a forest-clad country. A few miles above its confluence with the Bahr Sara the Bamingi receives on the right the Mambere, a large river, which joins the Bahr Sara in about 7°45' N. and 22° E. in a range of hills which separates the countries of Dar Runga and Dar Bands, and, like the Bamingi, flows through open or bush-covered plains with isolated granite ridges.

Below the junction of the Bahr Sara and the Bamingi the Shari becomes, as it is now called, becomes a large river, reaching, in places, a width of over 4 m. in the rains; while its valley, bordered by elevated tree-clad banks, contains many temporary lakes and backwaters. Its waters abound with hippopotami and crocodiles, and the country on either side with game of all kinds. In 9°46' N. it receives the Bahr Salamat (Awash Aouk) from the east, known in its upper course as the Aukadebe. This, like the Bahr es Salamat, which enters the Shari in 9°28' N. traverses a wide extent of arid country in southern Wadai, and brings no large amount of water to the Shari. In 10°12' a divergent branch, the Ereggi, leaves the main stream, only to rejoin it in 11°30'.

In 12°15' N. and 15° E. the Shari receives on the west bank its largest tributary, the Logone, the upper branches of which rise far to the south between 6° and 7° N. The principal headstreams are the Pende and the Mambere. The Pende rises some 30 m. N. by E. of the source of the Wam. It flows northwards through a fertile valley, enriched by its affluents, the Mambere, which rises in the hills of Adamawa, and flows in a course roughly parallel to the Pende. Below the junction of the Pende and Mambere the Logone is a broad and deep river. Its system is connected with that of the Tope (Sarki) by the Gulf of Guinea. The Logone, flowing northward, a channel joining the Logone in about 10°30' N. Below the Logone confluence, the Shari, here a noble stream, soon splits up into various arms, forming an alluvial delta, filled at high water, before entering Lake Chad. From the source of the Wam to the mouth of the river is a distance, following the windings of the stream, of fully 1400 m.

The existence of the Shari was made known by Oudney, Denham and Clapperton, the first Europeans to reach Lake Chad (1823). In 1852 Heinrich Barth spent some time in the region of the lower Shari and Logone, and in 1872-1873 Gustav Nachtigal studied their hydrographical system and explored the Gribingi, which he called the Bahar el Ardhe. It was not, however, until the partition of the Chad basin between Great Britain, France and Germany (1885-1890) that the systematic exploration of the Shari and its affluents was undertaken. The most prominent explorers have been Frenchmen. In 1865 Emile Gentil reached the Bamingi and in a small steamer passed down the river to its mouth. The existence of the Bahar Sara had been made known by C. Malteste in 1892, and in 1894 F. J. Clozel discovered the Wam. In 1900 A. Bernard demonstrated the identity of these two streams. In 1897 an expedition under Captain E. Lenfant undertook to follow the Shari from its source to the confluence with the Bamingi and showed it to be the true upper course of the Shari. The same expedition also discovered the Pende tributary of the Logone. Captain Lenfant had previously demonstrated (1903) the connexion between the Benue and Logone. From the mouth of the Shari in Lake Chad there is a current towards the Bahr-el-Ghazal channel at the south-eastern end of that lake. This channel has been supposed to be a dried-up affluent of the lake (see CHAD). Investigations by the French scientists E. F. Gautier and R. Chudeau led Chudeau to the conclusion that the Shari did not end in Lake Chad, but, by way of the Bahr-el-Ghazal, passed between Tibesti and Ennedi and ended in some salt in the Libyan desert. That the Shari may have reached the Nile is an hypothesis not absolutely rejected. (See Missions au Sahara, tome ii. (Paris, 1909), and for theories as to the Niger-Nile connexion see NIGER.)

From the spot where it is intersected by 10°40' N. to Lake Chad the Shari forms the boundary between the German colony of Cameroons and French Congo. The best route from the Congo to Lake Chad is via the Sanga affluent of the Congo to the station of Carnot, and thence across the watershed to the Pende.

See the works of Barth, Nachtigal and other travellers, especially Lenfant's La Decouverte des grandes sources du centre de l'Afrique (Paris, 1909).

SHARK, a Selachian fish (see SELACHIANS), belonging to the order Plagiostomi, suborder Squali.

Sharks are almost exclusively inhabitants of the sea, but some species enter the mouths of large rivers, and one species (Car-chorias gangeticus) occurs frequently high up in the large rivers of India. C. nigerognathus of the lake of Nicaragua and the Rio San Juan appears to have taken up its residence permanently in that water. In the tropics there are numerous between the tropics, a few only reaching the Arctic circle; it is not known how far they advance S. in the Antarctic region. Altogether some hundred and fifty different species have been described.

With regard to their habits many are litoral species, the majority pelagic, and a few are known to belong to the deep-sea fauna, having hitherto been obtained down to a depth of nearly 1000 fathoms.

Littoral Sharks. —The littoral forms are of small size, and generally known under the name of "dog-fishes," "hounds," &c. Some pelagic sharks of larger size also live near the shore on certain parts of a coast, but they are attracted to it by the abundance of food, and are as frequently found in the open sea, which is their birthplace; therefore we shall refer to them when we speak of the pelagic kinds.

The majority of the littoral species live on the bottom, sometimes close inshore, and feed on small marine animals or on any animal substance. The following are deserving of special notice.

The tope (Galeus) is common on the coasts not only of England, Ireland and of S. Europe, but also of S. Africa, California, Tasmania and New Zealand. Its teeth are equal in both jaws, of rather small size, flat, triangular, with the point directed towards the one side, and with a notch and denticulations on the shorter side (fig. 1). It is of a uniform slaty-grey colour, and attains to a length of 6 ft. The female brings forth some thirty living young at one birth in May. It becomes troublesome at times to fishermen by taking their bait and driving away other fish they desire to catch. The fins of G. sephurus of the Californian coast are much esteemed for culinarm use by the Chinese.

The hounds proper (Mustelus) possess a very different dentition, the teeth being small, obtuse, numerous, arranged in several rows like pavement (fig. 2). Five or six species are known from the shores of the various temperate and subtropical seas, one (M. vulgaris) being common on the coasts of Great Britain and the United States, on the Pacific as well as the Atlantic side. It is of a uniform grey colour or sparingly spotted with white, and attains to a length of 3 or
SHARK

4 ft. The young, about twelve in number, are brought forth alive in November. It is comparatively harmless and feeds on shells, crustaceans and decomposing animal substances.

The dogfishes proper (Scylium, Chiloscyllium, &c.) are spread over nearly all the temperate and tropical seas. Their teeth are small, in several series, with a longer pointed cusp in the middle, and generally one or two smaller ones on each side (figs. 3 and 5). They are all oviparous, their oblong egg-shells being produced at each corner into a long thread by which the egg is fastened to some fixed object. Some of the tropical species are ornamented with a pretty pattern of coloration. The two British species, the lesser and the larger spotted dogfish (Sc. canicula and Sc. catulus), belong to the most common fishes of the coast and are often confounded with each other. But the former is finely dotted with brown above, the latter having the same parts covered with larger rounded brown spots, some of which are nearly as large as the eye. As regards size, the latter exceeds somewhat the other species, attaining to a length of 4 ft. Dogfishes may become extremely troublesome by the large numbers in which they congregate at fishing stations; they are rarely used as food, except in the Mediterranean countries, in China and Japan, and in the Orkneys, where they are dried for home consumption. The black-mouthed dogfish (Pristiurus melanostomus) is rarely caught on the British coasts, and is recognized by a series of small, flat spines with which each side of the upper edge of the caudal fin is armed.

The tiger-shark (Stegostoma tigrinum) is one of the commonest and handsomest sharks in the Indian Ocean. The ground colour is a brownish-yellow, ornamented with black or brown transverse bands or rounded spots. It is a littoral species, but adult specimens, which are from 10 to 15 ft. long, are met far from land. It is easily recognized by its enormously long bladelike tail, which is half as long as the whole fish. The teeth are small, trilobed, in many series. The fourth and fifth gill-openings are close together.

The genus Crossorhinus, of which three species are known from the coasts of Australia and Japan, is remarkable as the only instance in this group of fishes in which the integuments give a "protective" resemblance to their surroundings. Skinny frond-like appendages are developed near the angle of the mouth, or form a wreath round the side of the head, and the whole body closely assimilates that of a rock covered with short vegetable and coralline growth. The species of Crossorhinus grow to a length of 10 ft.

The so-called Port Jackson shark (Heterodontus Cestracion) is likewise a littoral form. Besides the common species (H. philippus), three other closely allied kinds from the Indo-Pacific are known. This genus, which is the only existing type of a separate family, is one of special interest, as similar forms occur in Primary and Secondary strata. The jaws are armed with small obtuse teeth in front, which in young individuals are pointed, and provided with from three to five cusps. The lateral teeth are larger, pad-like, twice as broad as long and arranged in oblique series (fig. 7). The fossil forms far exceeded in size the living, which scarcely attain to a length of 5 ft. The shells of their eggs are found thrown ashore like those of our dogfishes. The shell is pyriform, with two broad lamellar ridges each wound edgewise five times round it (fig. 8).

The spiny or piked dogfish (Acanthias) inhabits the temperate seas of both the N. and S. hemispheres. For some part of the year it lives in deeper water than the sharks already noticed, but at uncertain irregular times it appears at the surface and close inshore in almost incredible numbers. Couch says that he has heard of 20,000 having been taken in a seine at one time; and in March 1858 the newspapers reported a prodigious shoal reaching W. to Uig, whence it extended from 20 to 30 m. seaward, and in an unbroken phalanx E. to Moray, Banff and Aberdeen. These fishes are distinguished by each of the two dorsal fins being armed in front by an acute spine. They do not possess an anal fin. Their teeth are rather small, placed in a single series, with the point so much turned aside that the inner margin of the tooth forms the cutting edge (fig. 9). The spiny dogfish are of a greyish colour, with some whitish spots in young specimens, and attain to a length of 2 or 3 ft. They are viviparous, the young being produced throughout the summer months.

Finally, we have to notice among the littoral sharks the "angel-fish" or "monk-fish" (Rhino squatinus), which, by its broad flat head and expanded pectoral fins, approaches in general appearance the rays. It occurs in the temperate seas of the S. as well as the N. hemisphere, and is not uncommon on sandy parts of the coast of England and Ireland. It does not seem to exceed a length of 5 ft. and is too rare to do much injury to other fish. It is said to produce about twenty young at a birth.
Pelagic Sharks.—All these are of large size, and some are surpassed in bulk and length only by the larger kinds of cetaceans.

Those armed with powerful cutting teeth are dangerous to man, whilst others, which are provided with numerous but very small teeth, feed on small fishes only or marine invertebrates, and are of a timid disposition, which causes them to retire into the solitudes of the open sea. On this account we know very little of their life. All pelagic sharks have a wide geographical range, and nearly all seem to be viviparous.

Of the more remarkable forms which we propose to notice here the genus most abundantly represented in species and individuals is *Carcharias*, now split up by many authors into several separate genera. Perhaps nine-tenths of the sharks of which we read in books of travel belong to this genus. Between thirty and forty species have been distinguished, all of which are found in tropical seas. They are the sharks which so readily attach themselves to sailing vessels, following them for weeks. Others affect more the neighbourhood of land. One of the most common species is the blue shark (*Carcharias glaucus*), of which specimens (4 to 6 ft. long) are frequently caught on the S. coasts of England and Ireland. Other species of *Carcharias* attain a length of 30 ft. The mouth of all is armed with a series of large flat triangular teeth, which have a sharp, smooth or serrated edge (fig. 10).

*Galeocerdo* is likewise a large shark very dangerous to man, differing from the preceding chiefly by having the outer side of its teeth deeply notched. It has long been known to occur in the N. Atlantic, close to the Arctic Ocean (*G. arcticus*), but its existence in other parts has been ascertained within a recent period; in fact, it seems to be one of the most common and dangerous sharks of the Indo-Pacific, the British Museum having obtained specimens from Mauritius, Kurrajbee, Madras and the W. coast of Australia.

Hammerheaded sharks (*Sphyraena* *Zygana*) are sharks in which the anterior portion of the head is produced into a Lower Tooth of *Lamna* lobe on each side, the extremity of which is occupied by the eye. The relation of this unique configuration of the head to the economy of the fish is unknown. Otherwise these sharks resemble *Carcharias*, and are equally formidable, but seem to be more stationary in their habits. They occur in all tropical and subtropical seas, even in the Mediterranean, where *S. Zygana* is by no means rare. In the Indian Ocean it is common, and Cantor states that specimens may be often seen ascending from the clear blue depths of the ocean like a great cloud.

The porbeagles (*Lamna*) differ from the preceding sharks in their dentition and are not dangerous to man; at least there is no instance known of a person having been attacked by the species common on the British coast (*L. cornubia*). This is referred to in the works of older British authors as "*Beaumaris* shark." The short and stout form of its body contrasts strikingly with its much attenuated tail, which, however, is strengthened by a keel on each side and terminates in a large and powerful caudal fin. The snout is pointed, and the jaws are armed with strong lanceolate teeth, each of which bears a small cusp on each side of the base (see fig. 11). The teeth are not adapted for cutting, like the flat triangular teeth of man-eating sharks, but rather for seizing and holding the prey, which consists chiefly of various kinds of fishes and cephalopods. In the upper jaw there are from thirteen to sixteen teeth on each side, the third being remarkable for its small size; in the lower jaw from twelve to fourteen. The gill-openings are very wide. The porbeagle attains to a length of 10 or 12 ft., and is a pelagic fish, not rare in the N. Atlantic and Mediterranean, and frequently wandering to the British and more rarely to the American shores. This species is widely distributed over the N. of the Atlantic and Pacific Oceans. Other closely allied species (*L. spallanzanii*, *L. glauca*) are known to occur in the S. Atlantic, from the Mediterranean to the Cape of Good Hope.

To the genus *Carcharodon* particular interest is attached, because the single still existing species is the most formidable of all sharks, as were those which preceded it in Tertiary times. The existing species (*C. rodesti*) occurs in almost all tropical and subtropical seas, but seems to be verging towards extinction. It is known to attain to a length of 40 ft. The tooth figured...
hereof the natural size (fig. 12) is taken from a jaw much shrunk in drying, but still 20 in. wide in its transverse diameter, and taken from a specimen 36 ft. long. The extinct species must have been still more gigantic in bulk, probably reaching a length of 90 ft., as we may judge from teeth which are found in the crag or which were dredged up from the Pacific Ocean by the "Challenger" expedition, and which are 4 in. wide at the base and 5 in. long measured along their lateral margin. In some Tertiary strata these teeth are extremely abundant, so much so that—for instance, in Florida—the strata in which they occur are quarried to obtain the fossil remains for export to England, where they are converted into artificial manure.

The shark or thresher (Alopecias vulpes), of which every year specimens are captured on the British coast, but which is common in the N. and S. hemispheres, is readily recognized by its extremely slender tail, the length of which exceeds that of the remainder of the body. Its teeth are small, flat, triangular and without serration. It follows the shoals of herrings, pilchards and sprats in their migrations, destroying incredible numbers and frequently injuring the nets. When feeding it uses the long tail in splashing the surface of the water, whilst it swims in gradually decreasing circles round a shoal of fishes which are thus kept crowded together. Sometimes two threshers may be seen working together. Statements that it has been seen to attack whales and other large cetaceans rest upon erroneous observations; its dentition is much too weak to bite through their skin. The thresher attains to a length of 15 ft., the tail included.

The basking shark (Cetorhinus maximus), sometimes erroneously called "sunfish," is the largest fish of the N. Atlantic, growing to a length of more than 30 ft. Though best known from the N. of the Atlantic or Pacific oceans, this species has also been recorded from the Australian seas. The mouth is of an extraordinary width, and, like the gill-cavity, capable of great expansion, so as to enable the fish to take at one gulp an enormous quantity of the small fish and other marine creatures on which it subsists. Also the gill-slits are of great width, and the internal opening of each is guarded by a kind of strainer, formed by the enormously elongated gill-riders, which serves to prevent the food organisms from passing out through the slits. The teeth are very small, numerous, arranged in several series, conical and probably without use in feeding. This shark is therefore quite harmless if not attacked. Off the W. coast of Ireland it was at one time hunted for the sake of the oil from the liver, one fish yielding from a ton to a ton and a half. Its capture is not unattended with danger, as one blow from the tail is sufficient to stave in the sides of a large boat. The basking shark is gregarious, and may be seen in calm weather lying with the upper part of the back raised above the surface of the water, a habit which it has in common with the true sunfish (Orthagoriscus), and from which it has derived its name.

A shark similar in many points to the basking shark, and an inhabitant of the Indo-Pacific Ocean, is Rhinodon typicus. So far as our present knowledge goes, it is the largest of all sharks, as it is known to exceed a length of 50 ft., but it is stated to attain that of 70. The captures of only a few specimens are on record, at the Cape of Good Hope and near the Seychelles, where it is known as the "chagrin." The snout is extremely short, broad and flat, with the mouth and nostrils placed at its extremity; the gill-openings very wide, and the eye very small. The teeth are extremely small and numerous, conical in shape. No opportunity should be lost of obtaining exact information.

**Fig. 13.—Basking Shark.**

**Fig. 14.—Greenland Shark (Lamarche borealis).**

**Fig. 15.—Dentition of Greenland Shark.**

On this shark. The same applies to the allied Microstomus punctatus recorded from off the W. coast of America.

The Greenland shark (Lamarche borealis) belongs to the same family as the spiked dogfish, but grows to a much larger size, specimens 26 ft. long having been met with. The two dorsal fins are small and destitute of spines. The teeth (fig. 15) in the upper jaw are small, narrow, conical in shape; those of the lower flat, arranged in several series, one on the top of the other, so that only the uppermost forms the sharp dental edge of the jaw. The points of these lower teeth are so much turned aside that the inner margin only enters the dental edge.

The Greenland shark is an inhabitant of the Arctic regions, sometimes straying to the latitudes of Great Britain and of Cape Cod in the W. Atlantic; it is one of the greatest enemies of the whale, which is often found with large pieces bitten out of the tail by this shark. Its voracity is so great that, as Scoresby tells us, whilst engaged in feeding on the carcass of a whale it will allow itself to be stabbed with a lance or knife without being driven away. The spiny shark (Echinarhynchus spinosus) is readily recognized by the short bulky form of its body, its short tail, and the large round bony tubercles which are scattered all over its body, each of which is raised in the middle into a pointed conical spine. While most frequently recorded from the E. Atlantic, specimens have also been obtained from the coasts of N. America and of New Zealand. It always lives on the bottom, and probably descends to some depth. It does not seem to exceed a length of 10 ft.

**Bathybiel Sharks.**—Sharks do not appear to have yet reached the greatest depths of the ocean; and so far as we know at present we have to fix the limit of their vertical distribution at 1000 fathoms. Those which we find to have reached or to pass
the 100 fathoms line belong to generic types which, if they include littoral species, are ground-sharks—as we generally find the bottom-feeders of our littoral fauna much more strongly represented in the deep sea than the surface swimmers. All belong to two families only, the Scylliidae and Spinacidae, the littoral members of which live for the greater part habitually on the bottom and probably frequently reach to the 100 fathoms line. Distinctly bathyal species are two dogfishes—

**Spinax granulatus** from 120 fathoms, and

**Scyllium canescens** from 400 fathoms, both on the S. W. coast of S. America; also *Centroscyllium granulatum* from 340 fathoms in the S. Ocean, whose congener from the coast of Greenland probably descends to a similar depth. The shark which reaches the greatest depth recorded hitherto appears to be *Scyliorhinus indicaus* obtained by the Valdivia expedition from a depth of nearly 1000 fathoms in the W. Indian Ocean. It belongs to the genus *Centrophorus*, of which some ten species are known, all from deep water in the N. Atlantic, Mediterranean, the Molucca and Japanese seas. The Japanese species were discovered by the naturalists of the

**Notidaniidae** are the Chlamydoselachidae or frilled sharks, represented so far as is known by a single living species, *C. anguineus* Garman (fig. 16), which occurs frequently in deep water off the coast of Japan and as isolated specimens off the coasts of New South Wales, Madeira and Norway. A fossil species has been described from the Pliocene of N. Italy. It resembles a conger in shape, and differs from the *Notidani* proper by its elongated body; wide nearly terminal mouth, extremely wide gill-openings and peculiarly formed teeth. The teeth are similar in both jaws, each composed of three slender curved cusps separated by a pair of minute intermediate points, and with a broad base directed backwards.

A few words may be added with reference to the economic uses of this group of fishes. As mentioned above, some of the smaller dogfishes are eaten at certain seasons by the cappers, and by Japanese fishermen for the covers of which the population. An interior kind of oil, chiefly used for the adulteration of cod-liver oil, is extracted on some of the N. fishing stations from the liver of the spiked dogfishes, and occasionally of the larger sharks. Cabinet-makers make extensive use of shark's skin under the name of "shagreen" for smoothing or polishing wood. This shagreen is obtained from species (such as our dogfishes) whose skin is covered with small, pointed, closely-set, calcified papillae, whilst very rough skins, in which the papillae are large or blunt, are useless for this purpose. The dried fins of sharks (and as rays) form in India and China the Chinese preparing gelatin from them, and using the better sort for culinary purposes. They are assorted in two kinds, viz."white" and "black." The former consists exclusively of the dorsal fins, which alone are cut in this way, the pectoral, ventral and anal fins constitute the "black" sort; the caudal are not used.

(A. C. G.: J. G. K.)

**SHARON**, a borough of Mercer county, Pennsylvania, U.S.A., on the Shenango river, about 70 m. by rail N. N. W. of Pittsburg. Pop. (1900) 8916, of whom 1805 were foreign-born and 113 were negroes; (1910 U.S. census) 15,270. Sharon is served by the Erie, the Lake Shore & Michigan Southern, and the Pennsylvania (Erie and Pittsburg divisions) rail ways. Sharon has an excellent public school system, and the F. H. Buhl Club (1905) is a social and educational institution, which has added much to the comfort of the borough. Sharon is an iron manufacturer of the borough. The borough has blast furnaces and rolling-mills; and iron and steel products, tinplate and terne-plate are its principal manufactures. The total value of factory products in 1905 was $4,776,914, being 26.9% more than in 1900. Sharon and South Sharon (pop. by U.S. census in 1910, 10,100), which was separately incorporated as a borough in 1901, form what is virtually a single industrial community. Sharon was first settled in 1795, but was only a small village when a movement for developing the coal-mines in the vicinity was begun in 1836. It was incorporated as a borough in 1841.

**SHARP, GRANVILLE** (1735-1813), English philanthropist, was the ninth of the fourteen children of Thomas Sharp (1693-1758), a prolific theological writer and biographer of his father, John Sharp, archbishop of York. Granville, who was born at Durham in 1735, was educated at the grammar school there, and apprenticed to a London draper, but obtained employment in the government ordnance department in 1758. Sharp's tastes were scholarly; he managed to acquire knowledge of Greek and Hebrew, and before 1779 he had published more and educational institution, which has added much to the comfort of the borough. Sharon is an iron manufacturer of the borough. The borough has blast furnaces and rolling-mills; and iron and steel products, tinplate and terne-plate are its principal manufactures. The total value of factory products in 1905 was $4,776,914, being 26.9% more than in 1900. Sharon and South Sharon (pop. by U.S. census in 1910, 10,100), which was separately incorporated as a borough in 1901, form what is virtually a single industrial community. Sharon was first settled in 1795, but was only a small village when a movement for developing the coal-mines in the vicinity was begun in 1836. It was incorporated as a borough in 1841.

**Challenger** on the Hyalonema ground off Inosima in 345 fathoms. Dr E. P. Wright found *C. coelolepis* at a still greater depth on the coast of Portugal. The fishermen of Setúbal fish for these sharks in 400 or 500 fathoms, with a line of some 600 fathoms in length. "The sharks caught were from 3 to 4 ft. long, and when they were hauled into the boat fell down into the like so many dead pigs"; in fact, on being rapidly withdrawn from the great pressure under which they lived they were killed, like other deep-sea fishes in similar circumstances. It is noteworthy that the organization of none of these deep-sea sharks has undergone such a modification as would lead us to infer that they are inhabitants of great depths.

One of the most interesting types of the division of sharks is the small family of *Notidaniidae*, which is externally distinguished by the presence of a single dorsal fin only, without spine and opposite to the anal, and by having six or seven wide branchial openings. They represent an ancient type, the presence of which in Jurassic formations is shown by teeth extremely similar to those of the living species. Their skeleton is notochordal. Only four species are known, of which one (*Notidanus griseus*) has now and then strayed N. to the English coast. Allied to

emancipated slaves at Sierra Leone. Granville Sharp was also one of the founders of the British and Foreign Bible Society, and of the Society for the Conversion of the Jews. One of his tracts, entitled Remarks on the Uses of the definitive article in the Greek text of the New Testament, published in 1798, propounded the rule known as "Granville Sharp's canon," which on account of its important bearing on Unitarianism has since been confuted by numerous writers. In the controversy leading divines took part, including Christopher Wordsworth. This rule was to the effect that "when two personal nouns of the same case are connected by the copulate ον, if the former has the definite article and the latter has not, they both belong to the same person." Sharp died on the 6th of July 1813, and a memorial of him was erected in Westminster Abbey.

SHARP, JAMES (1618–1679), Scottish divine, the son of William Sharp, sheriff-clerk of Banffshire, and Isabel Leslie or Lesley, daughter of Leslie of Kinininvie, of the family of Halyburtons of Pitcur in Angus, was born in Banff Castle on the 4th of May 1618. In 1633 he went to King's College, Aberdeen, and graduated in 1637. He there studied divinity for one or two years, Aberdeen being at that time the home of Episcopal sentiment. Through the outbreak of civil war in 1644 and 1645 he shared the experiences of the Covenanters, meeting with Cromwell in London and visited Oxford and perhaps Cambridge, becoming acquainted with the principal English divines. Upon his return he was chosen in 1643, through the influence of Lord Rothes, to be one of the "regents" of philosophy in St Leonard's College, St Andrews. In December 1647 he went through his ordinary trials for the ministerial office before the presbytery of St Andrews, and was appointed minister of Crall in Fife, on the presentation of the earl of Crawford, in January 1648. In the great schism of Resolutioners and Protestors, he, with the large majority of educated men, took active part with the former. As early as March 1651 he was recognized as one of the leading men of the party, and was taken prisoner by Cromwell's forces. For eight months he was kept in the Tower of London, and liberated on parole. His first public employment was in 1656, when he went to London to endeavour to counteract with the Protector the influence of Archibald Johnston, Lord Wariston, who was acting for the Protestors. He displayed all his undoubted talents for small diplomacy, and considerable subtlety in argument, while on this service, and his mission was doubtless successful. He returned to Scotland in 1659, but upon Monk's march to London was appointed to meet the Resolutioners to watch over their interests in London, where he arrived on the 13th of February. He was most favourably received by Monk, to whom it was of great importance to remain on good terms with the dominant party in Scotland. His letters to Douglas and others during this period, if they may be trusted, are useful towards following the intrigues of the time day by day. In the beginning of May he was despatched by Monk to the king at Breda. His letters on this occasion to Douglas show that he regarded himself equally as the emissary of the Scottish bishops, who appointed him to this office, as he was the bearer of a secret letter from Lauderdale to the king. There can be little doubt that while on this mission he was finally corrupted by Charles and Clarendon, not indeed so far as to make up his mind to betray the kirk, but at any rate to decide in no way to imperil his own chances by too firm an integrity. The first thing that aroused the jealousy of his brethren was his writing from Holland in commendation of Clarendon. This jealousy was increased on his return to London (May 26) by his plausible endeavours to stop all coming of Presbyterian missionaries from Scotland and Ireland, though he professed to desire the presence of Douglas and Dickson, by his urgent advice that the Scots should not interfere in the restoration of Episcopacy in England, and by his endeavours to frustrate the proposed union of Resolutioners and Protestors. He informed them that Presbyterianism was a lost cause in England, but as late as August 11 he intimated that, though there had been great danger for the Scottish kirk as well, this danger had been constantly and successfully warded off by his efforts. He returned to Scotland in this month, and busied himself in endeavouring to remove all suspicions of his loyalty to the kirk, but at the same time in 1663, he still supported all petitions from Scottish ministers to king, parliament or council. His letters to Drummond, a Presbyterian minister in London, and to Lauderdale, without absolutely committing him, show clearly that he was certain that Episcopacy was about to be set up. How far he was actively a traitor in the matter had always been disputed until the question was set at rest by the discovery of his letter, dated May 21, from London, whither he went in April 1661, to Middleton, the high commissioner, whose chaplain he now was, showing that he was in unlimited communication with Clarendon and the English bishops, that he was earnestly co-operating in the restoration of Episcopacy in Scotland, that he had before leaving Scotland held frequent conferences with Middleton on the subject (a fact which he had vehemently denied) and was aware that Middleton had all along intended it, and that he drew up the quibbling proclamation of June 10, the sole purpose of which was "the disposing of minds to acquiesce in the king's pleasure." The original of this letter (which is printed in the Lauderdale Papers and in the Scottish Review) is preserved in the Museum of the Society of Antiquaries, and shows that Sharp was determined on the 13th of May, on the eve of starting on his mission to court with Rothes and Glencarne, he declared to Baillie that no change in the kirk was intended. The mask was at length dropped in August, when Episcopacy was restored, and Sharp was appointed archbishop of St Andrews. He and Leighton, Fairfoul and Hamilton were dubbed, first preaching deacons, then presbyters, and then consecrated bishops in one day, by Dr Sheldon and a few others." On April 8th the new prelates entered Scotland, and on the 20th of April 1662 Sharp preached his first sermon at St Andrews.

Sharp had carefully kept on good terms with Lauderdale, and when the Billeting Plot was concocted in September 1662 against the latter by Middleton, he managed to avoid acting against him; indeed it is probable that, after being appointed under an oath of secrecy to be one of the scrutineers of the billets, he, in violation of the oath, was the cause of Lauderdale receiving timely information of the decision against him; and yet he shortly went up to London to explain the whole affair in Middleton's interest. When Lauderdale's supremacy was established he readily co-operated in passing the National Convention on the 13th of May, in the first step in the intended subjection of the church to the crown. In 1664 he was again in London, returning in April, having secured the grant of a new church commission. So oppressive was his conduct and that of other bishops that it called forth a written protest from Gilbert Burnet. Sharp at once summoned him before the bishops and endeavoured to obtain a sentence of deprivation and excommunication against him, but was overruled by his brethren. On the death of Glencarne, the chancellor's greatest efforts were made to secure the vacant office for Sharp, and he failed in his object, his lay interest; the place was given, however, filled up until 1667, and then by the appointment of Rothes. He was in strict alliance with Rothes, Hamilton and Dalyell, and the other leaders of oppression, and now placed himself in opposition to the influence of Lauderdale, attacking his friends, and especially the earl of Kincardine. In 1665 he was again in London, where, through his own folly and mendacity, he suffered a complete humiliation at the hands of Lauderdale, well described by the historian Burnet. The result of their system of violence and extortion was the rising of the Covenanters, during which, being in temporary charge during the National's absence, he showed, according to Bellenden, the utmost fear, equalled only by his cruelty to the prisoners after the rout of Pentland. When the convention of estates met in January 1665 Hamilton was substituted for him as president. He now
wrote letters of the most whining contrition to Lauderdale, who extended him a careless reconciliation. For a time he made himself actively useful, and helped to restrain his brethren from writing to London to complain of the conciliatory policy which for a while Lauderdale carried out. On July 10, 1668 an attempt was made upon his life by James Mitchell, who fired a pistol at him while driving through the streets of Edinburgh. The shot, however, missed Sharp, though his companion, the bishop of Orkney, was wounded by it, and Mitchell for the time being fell. When Sharp went up to London, returning in December, and with his assistance Tweeddale's tolerant proposals for filling the vacant parishes with some of the "outed" ministers were carried out. In the debates on the Supremacy Act, by which Lauderdale destroyed the autonomy of the church, Sharp at first showed reluctance to put in motion the desired policy, but gave way upon the first pressure. When, however, Leighton, as archbishop of Glasgow, endeavoured to carry out a comprehensive scheme, Sharp actively opposed him, and expressed his joy at the failure of the attempt. From this time he was completely subservient to Lauderdale, who had now finally determined upon a career of oppression, and in 1674 he was again in London to support this policy. In this year also Mitchell, who had shot at him six years before, was arrested, and, upon Sharp's promise to obtain a pardon, privately made a full confession. When Mitchell later claimed this promise, Sharp denied that any such promise had been given. His falsehood was proved by the entry of the act in the records of the court. Mitchell was finally condemned, but a reprieve would have been granted had not Sharp himself insisted on his death. This was speedily avenged. On the 3rd of May 1679, as he was driving with his daughter Isabel to St Andrews, he was set upon by nine men, and, in spite of the appeals of his daughter, was cruelly murdered. The place of the murder, on Magus Muir, now covered with fir trees, is marked by a monument erected by Dean Stanley, with a Latin inscription recording the deed.

Unless otherwise mentioned, the proofs of the statements in this article are to be found in vols. i. and ii. of the Lauderdale Papers (Cambden Society) and in two articles in the Scottish Review, July 1884 and January 1885.

SHARP, JOHN (1645-1714), English divine, archbishop of York, was born at Bradford on the 16th of February 1645, and was educated at Christ's College, Cambridge. He was ordained deacon and priest on August 12th 1667, and until 1676 was chaplain and curate in the family of Sir Heneage Finch at Kensington House. Meanwhile he became archdeacon of Berkshire (1673), prebendary of Norwich, rector of St Giles's-in-the-Fields, and in 1681 dean of Norwich. In 1686, when chaplain to James II., he was suspended for ten months on a charge of having made some reflections on the king, and in 1688 was cited for refusing to read the declaration of indulgence. Under William and Mary he succeeded Tillottson as dean of Canterbury in 1689, and (after declining a choice of sees vacated by non-jurors who were his personal friends) followed Thomas Lumplugh as archbishop of York in 1691. He made a thorough investigation of the affairs of his see, and regulated the disordered chapter of Southwell. He preached at the coronation of Queen Anne and became her almoner and confidential adviser in matters of church and state. He welcomed the Armenian bishops who came to England in 1713, and corresponded with the Prussian court on the possibility of the Anglican liturgy as a means of reconciliation between Lutherans and Calvinists. He died at Bath on the 2nd of February 1714.

SHARP, RICHARD (1759-1835), known as "Conversation Sharp," was born in Newfoundland in 1750, the son of a British officer in garrison there. He was for many years in business in London, and amassed a large fortune. He was the host of leading literary and political men at his houses in Park Lane and near Dorking. Johnson, Burke, Rogers, Hallam, Grattan, Sydney Smith, James Mill, Wordsworth and Coleridge were among his many friends. From 1806 to 1812 he was M.P. for Castle Rising, and subsequently he represented Portarlington and Ilchester. He was the author of a volume of Letters and Essays in Prose and Verse (1834), which the Quarterly Review declared to be remarkable for "wisdom, wit, knowledge of the world and sound criticism." Sharp died at Dorchester on the 30th of March 1835.

SHARP, WILLIAM (1745-1824), English line-engraver, was born at London on the 29th of January 1749. He was originally apprenticed to what is called a bright engraver, and practised as a writing engraver, but gradually became inspired by the higher branches of the engraver's art. Among his earlier plates are some illustrations, after Stothard, for the *Nemesis* Magazine. He engraved the "Doctors Disputing on the Immaculateness of the Virgin" and the "Ecce Homo" of Guido Reni, the "St Cecilia," of Domenichino, the "Virgin and Child" of Dolci, and the portrait of John Hunter of Sir Joshua Reynolds. His style of engraving is thoroughly masterly and original, excellent in its play of line and rendering of half-tints and of "colour." He died at Chiswick on the 25th of July 1824. In his youth, owing to his hotly expressed adherence to the politics of Paine and Horne Tooke, he was examined by the privy council on a charge of treason. Mesmer and Brothers found, in Sharp a staunch believer; and for long he maintained Joanna Southcott at his own expense as an engraver he achieved a European reputation, and at the time of his death he enjoyed the honour of being a member of the Imperial Academy of Vienna and of the Royal Academy of Munich.

SHARP, WILLIAM (1856-1905), Scottish poet and man of letters, was born at Paisley on the 12th of September 1856. His was a double personality, for during his lifetime he was known solely by a series of poetical and critical works of great, but not of outstanding merit, while from 1894 onwards he published, with elaborate precautions of secrecy, under the name of "Fiona Macleod," a series of stories and sketches in poetical prose which made him perhaps the most conspicuous Scottish writer of the modern Gaelic renaissance. His early life was spent chiefly in the W. highlands of Scotland, and after leaving Glasgow University he went to Australia in 1877 in search of health. After a cruise in the Pacific he settled for some time in London as clerk to a bank, became an intimate of the Rossettis, and began to contribute to the *Pall Mall Gazette* and other journals. In 1885 he became art critic to the *Glasgow Herald*. He spent much of his life in Rome and travelled extensively in America and the Near East. He had a number of cousins, one of whom was John Macleod, a writer of *Athenaeum* stating that she wrote under the name of "Fiona Macleod." He wrote biographies of Dante Gabriel Rossetti (1882), of Shelley (1887), of Heinrich Heine (1888), of Robert Browning (1890), and edited the memoirs of Joseph Severn (1892). The most notable of his novels was *Silence Farm* (1890). During the later years of his life he was obliged for reasons of health to spend all his winters abroad. The secret of his authorship of the "Fiona Macleod" books was faithfully kept until his death, which took place at the Castello di Manlace, Sicily, on the 13th of December 1905.

of dreams (1890); The Divine Adventure: Isaacs and other Studies in Spiritual History (1900), and Winged Destiny (1904).

SHARPE, DANIEL (1860–1850), English geologist, was born in Marylebone, London, on the 6th of April 1866. His mother was a sister of Samuel Rogers, the poet. At the age of 10 he entered the counting-house of a Portuguese merchant in London, and at the age of 25, after spending a year in Portugal, he joined his elder brother as a partner in a Portuguese mercantile business. As a geologist he first became known by his researches (1832–1840) on the geological structure of the neighbourhood of Lisbon. He studied the Silurian rocks of the Lake District and North Wales (1842–1844), and afterwards investigated the structure of the Alps (1854–1859). He was elected F.R.S. in 1850. He published several essays on cleavage (1847–1852), and showed from the evidence of distortion of organic remains that the direction of the pressure producing concretions in the rocks was perpendicular to the planes of cleavage. Most of his papers were published in the Quarterly Journal of the Geological Society, but one ‘On the Arrangement of the Foliation and Cleavage of the Rocks of the North of Scotland,’ was printed in the Phil. Trans. 1852. He was also author of a Monograph on the Cephalopoda of the Chalk, published by the Palaeontographical Society (1853–1857). In 1856 he was elected president of the Geological Society, but he died in London, from the effects of an accident, on the 23rd of May that year.

SHARPSBURG (1806–1856), a borough in Allegheny county, Pennsylvania, U.S.A., on the Allegheny river, opposite the N.E. part of Pittsburg. Pop. (1900) 6842 (1280 foreign-born); (1910) 8153. Sharpsburg is served by the Pennsylvania and the Baltimore & Ohio railways. Coal is mined in the vicinity. Among the manufactories are iron pipes, truck and bar iron, wire, stove, paint and lubricating oil. Sharpsburg was settled in 1826, was named in honour of James Sharp, the original proprietor, and was incorporated in 1841.

SHASHI, the chief of the province of Hu-pch, China, on the left bank of the river Yangtsze, about 83 m. below Ich'ang. Pop. about 80,000. It was opened to foreign trade under the Japanese treaty of 1895. The town lies below the summer level of the Yangtsze, from which it is protected by a strong embankment. Formerly Shashi was a great distributing centre, but the opening of Ich'ang to foreign trade diverted much of the traffic to the last-named port. It is the terminus of an extensive network of canals which run through the low country lying on the north bank of the Yangtsze as far down as Hankow. Native boats, as a rule, prefer the canal route to the turbulent waters of the Yangtsze, their cargoes being transferred at Shashi across the embankment into river boats. Foreign residents are few, and the trade passing through the maritime customs is comparatively insignificant. The place is still, however, a large distributing centre for native trade, and is the seat of an extensive manufacture of native cotton cloth. The British consulate was withdrawn in January 1899, British interests being placed under the care of the consul at Ich'ang.

SHAW, GEORGE BERNARD (1856– ), British dramatist and publicist, was born in Dublin on the 26th of July 1856. His father, George Carr Shaw, was a retired civil servant, the younger son of Bernard Shaw, high sheriff of Kilkenny. His mother, Lucinda Elizabeth Gurlty, was a good musician, who eventually became a teacher of singing in London. G. B. Shaw went to school in Dublin, and began to earn his living when he was fifteen. He was for five years a clerk in the office of an Irish land-agent, but came to London with his family in 1876, and in 1879 was, according to his own account in the preface to The Irrational Knot, in the offices of the Edison telephone company. He had begun to write novels, which did not immediately find their market. The Irrational Knot, written in 1879, and Love among the Artists (written in 1881) first appeared as serials in Our Corner, a monthly edited by Mrs Annie Besant; Cashel Byron's Profession (reprinted in 1901 in the series of "Novels of his Nonage") and An Unsocial Socialist first appeared in a Socialist magazine To-day, which no longer exists. Shaw joined the Fabian Society in 1884, a year after its formation, and was active in socialist propaganda, both as a street orator and as a pamphleteer. In 1889 he edited the Fabian Essays, to which he contributed "The Economic Basis of Socialism" and "The Transition to Social Democracy." He began journalism, through the influence of William Archer, on the reviewing staff of What's New in 1887, and in London in 1890 as musical critic, writing from 1888 to 1890 for the Star, where his articles were signed "Corno di Bassetto," and then in 1890 to 1894 for the World. In 1895 to 1898 he was dramatic critic to the Saturday Review, his articles being collected in 1907 as Dramatic Opinions and Essays. He was an early champion of Richard Wagner and of Henrik Ibsen, and indicated his aesthetic point of view in the pamphlets, The Quintessence of Ibsenism (1891) and The Perfect Wagnerite (1898). His first play, Widowers' Houses, two acts of which had been written in 1895 in collaboration with Mr William Archer, was but fees by the Independent Theatre under the management of Mr J. T. Grein at the Royalty in 1892. This found few admirers outside Socialist circles, and was hoisted by the ordinary playgoer. In 1893 he wrote The Philanderer, a topical comedy on Ibsenism and the "new woman," for the same theatre, but the piece proved technically unsuitable for Mr Grein's company. To replace it Mr Shaw wrote Mrs Warren's Profession, a powerful but disagreeable play, which was rejected by the censor and not presented until the 5th of January 1893, when it was privately given by the Society at the Theatre Royal Haymarket. The play was printed in New York by Mr Arnold Daly's company in 1905 the actors were prosecuted. These three plays were classed by the author as "unpleasant plays" in the printed version. Arms and the Man was produced at the Avenue Theatre (21st of April 1894) by Miss Florence Farr, who was experimenting on the lines of the Independent Theatre, and by Mr Richard Mansfield at the Herald Square Theatre, New York (the 17th of Sept. 1894). The scene was laid in Bulgaria, the piece being a satire on romanticism, a destructive criticism on military "glory." The original was written in 1894 for Mr Mansfield, who did not produce it until December 1895, but it was played in Aberdeen in July 1897 by the Independent Theatre Company. This defence of the poetic point of view against brute force and common sense was admirably constructed and it proved one of the most popular of his plays. The pieces which followed are: The Man of Destiny (written in 1895, played at Croydon in 1897 by Mr Murray Carson), a Napoleonic drama, which was revived at New York by Arnold Daly in 1904; You Never Can Tell (written in 1896, produced at the Strand Theatre in 1906), a farce, and a comedy, The Devil's Disciple (produced at New York by Richard Mansfield in 1899), a play with the scene of which is laid in the War of American Independence, Caesar and Cleopatra (1898) and Captain Brassbound's Conversion (1898)—printed as Three Plays for Puritans (1900); The Adorable Bashville (Stage Society, Imperial Theatre, 1903), a dramatization of Cashel Byron's Profession. He had found no regular English audience when he published Plays Pleasant and Unpleasant (2 vols.) in 1898, and his pieces first became well known to the ordinary playgoer by the performances given at the Royal Court Theatre under the manage- ment of Mr Harley Granville Barker. The oldest play of all is Superman (published in 1903) was produced there on the 23rd of May 1903, in a necessarily abridged form, with Granville Barker in the part of John Tanner, the author of the "Revolutionists' Handbook and Pocket Companion," printed as an appendix to the play. Mr Shaw asserted that the piece originated in a suggestion from Mr A. B. Walkley that he should write a Don Juan play, which he proceeded to do in a characteristic topsy-turvy fashion. John Tanner (Juan Tenor) is a voluble exponent of Schopenhauer and Nietzsche, who finally falls a victim to the life force in Aryan Major Bards (Court Theatre, Nov. 1905), a "discussion in three acts," placed the Salvation Army on the stage. The Vedrenne-Barker management also revived Candida (April 1904), You Never Can Tell (May 1905), Captain Brassbound's Conversion (March 1906) and John Bull's other Island (November 1904), a statement of the Irish land
question, which had been produced at the Camden Theatre in 1903, and later by the Stage Society. At the same theatre was produced (20th of November 1906) The Doctor's Dilemma, a satire on the medical profession, and How He Lied to Her Husband (Feb. 1905), which had been previously played in New York. Later plays were: Getting Married (1908), The School for Scandal by (1812) and The Women (1893).

Among Mr. Shaw's later writings on economics are: Socialism for Millionaires (1901), The Common Sense of Municipal Trading (1904), and Fabianism and the Fiscal Question (1904). Although an energetic member of the South Sth Pancras borough council, he failed to secure election to the London County Council when he stood as a candidate in 1904. Mr. Shaw married in 1898 Miss Charlotte Frances Payne-Townshend.

In his work H. L. Mencken (Boston and London, 1905), by E. E. Hale (Dramatists of To-Day London, 1906), &c.; "The Plays of Mr. Bernard Shaw," in the Edinburgh Review (April 1905); Mr. Bernard Shaw's Counterfeit Presentment of Women, in the Fortnightly Review (March 1906); "Bernard Shaw as Critic," in the Fortnightly Review (June 1907); and an appreciation by Holbrook Jackson, Bernard Shaw (1907).

SHAW, HENRY WHEELER (1818-1885), American humorist, known by the pen-name of "Josh Billings," was born of Puritan stock at Lanesborough, Massachusetts, on the 21st of April 1818. His father, Edward Walter Shaw, was a representative in Congress in 1817-1821. The son left Hamilton College to go West. In 1858 he settled in Poughkeepsie, N.Y., as a land-agent and auctioneer, and began writing newspaper articles, especially for the Poughkeepsie Daily Press. His "Essa on the Muel bi Josh Billings" (1860) in a New York paper was followed by many similar articles, chiefly in the New York Weekly and the New York Sunday Paper, and by several popular volumes, among which are Josh Billings: His Sayings (1860), Josh Billings on Ice (1868), Everybody's Friend (1870), Josh Billings: His Works, Complete (1876), Trump Card's (1879), Old Probabilities (1879), Josh Billings' Spice-Box (1881), and Josh Billings' Farmers' Almanax, burlesquing the Old Farmers' Almanac, issued annually between 1870 and 1880, and collected into a volume in 1902 under the title Josh Billings' Old Farmers' Almanax.

He died in Monterey, California, on the 14th of October 1885. His platform lectures, such as "Milk," "Hobby Horse," "The Pensive Cockroach," and "What I Know about Hotels," his mannerisms and apparently unstudied witticisms made him conspicuous.

See Life and Adventures of Josh Billings (New York, 1883), by Francis S. Smith.

SHAW, LEMUEL (1781-1861), American jurist, was born at Barnstable, Massachusetts, son of the minister of the West Parish there, on the 9th of January 1781. He graduated from Harvard College in 1800, and was admitted to the bar (of New Hampshire and of Massachusetts) in 1804. In 1805 he began to practice law in Boston. He was a vigorous Federalist and was a member of the Massachusetts House of Representatives in 1811-1814, in 1826, and in 1832, and of the state Senate in 1821-1822, a delegate to the state constitutional convention of 1820-1821, and chief justice of the Supreme Court of the state from 1830 to 1860. He died in Boston on the 30th of March 1861.

As chief justice Shaw maintained the high standard of excellence set by Theophilus Parsons. He presided over the trial in 1850 of Professor John White Webster (1792-1839) for the murder of Dr George Parkman. His work in extending the equity, jurisdiction, and powers of the court was especially notable. He was also largely instrumental in defeating an attempt (1843) to make a reduction of salary apply to judges already in office, and an attempt (1852) to abolish the life term of judges. His opinion in Cary v. Daniels (8 Metcalfe) is the basis of the present law in Massachusetts as to the regulation of water power rights of riparian proprietors.

See the address by B. F. Thomas in Proceedings of the Massa- chusetts Historical Society (1851) for a sketch of his life; and through his son, Henry, in his Life and Works (by F. L. Tracy, 1883) by Samuel S. Shaw and P. Emary Aldrich in vol. iv, pp. 240-247, of Memorial Biographies of the New England Historic Genealogical Society (Boston, 1885).

SHAW, RICHARD NORMAN (1831-1912), British architect, was born in Edinburgh on the 7th of May 1831. At the age of sixteen he went to London and became a pupil of William Burn. In Burn's office he formed that friendship with William Eden Nesfield which so profoundly influenced the careers of both, and was thoroughly grounded in the science of planning and in the classical vernacular of the period. He also attended the architectural schools of the Royal Academy, and devoted himself with industry to study and practice.

In 1854, having finished his term of apprenticeship, with Burn, he gained the gold medal and travelling studentship of the Royal Academy, and until 1856 travelled on the continent, studying and drawing old work. On his return in 1856 he was requested by the Council of the Royal Academy to publish his drawings. This work, entitled Architectural Sketches from the Continent, was issued in 1858. In the meantime Nesfield was continuing his studies with Anthony Salvin; Mr. Shaw also entered his office, and remained there until 1857, when he widened his experience by working for three years under George Edmund Street. In 1862, after sixteen years of severe training, he began to practise. For a short time he and Nesfield joined forces, but their lines soon diverged. Mr. Shaw's first work of importance was Leyes Wood, in Surrey, a building of much originality, followed shortly afterwards by Cragside, for Lord Armstrong, which was begun in 1880. From that time until he retired from active practice his works followed one another in quick succession. In 1872 Mr. Shaw was elected an Associate of the Royal Academy, and a full member in 1877; he joined the "club" list at the end of 1887.

Other characteristic examples of his work are: Freemen's, Shropshire; New Zealand Chambers, Leadenhall Street; Pierscourt, Wispers, and Merrist Wood, in Surrey; Lower Lodge, Kensington; Adcote, in Shropshire; his houses at Kensington, Oxford, and Cambridge, and his house at Henley near Oxford; Lodge, Berkshire; Dawpool, in Cheshire; Bryanstone, in Dorset- shaftire; Chesters, Northumberland; New Scotland Yard, on the Embankment. Besides several fine works in Liverpool and the neighbourhood, he has drawn the plan and portions of the best known of which are St John's Church, Leeds; St Margaret's, Deal, and All Saints', Leek. His early buildings were most frequently the "half timber" and "hung" effect, and only at the current work of time. The use of "half timber" and hanging tiles, the projecting gables and massive chimneys, and the cunningly contrived bays and recessed fireplaces, together with the complete freedom from the conventions and trammels of "style," not only appealed to the artist, but gained at once a place in public estimation. Judged in the light of his later work, some of those early buildings appear almost too full of feature and design; they show, however, very clearly that Shaw was discarding one of the "academic" styles, and inventing a style appropriate to the age and environment.

His work throughout is especially distinguished by treatment of scheme. There is nothing tentative or hesitating. His planning is invariably fine and full of ingenuity. Adcote (a beautiful drawing of which hangs in the Diploma Gallery at Burlington House) is, perhaps the best example of the series of his country houses built between 1870 and 1880. The elements are few but perfectly proportioned and combined, and the scale throughout is consistent. The Great Hall is the keynote of the plan, and is properly but not unduly emphasized. The grouping of the rooms round the Hall is very ably managed—each room is in its right position, and has its appropriate character and aspect. Chanctonbury (another work of about the same period (1870-1880)), is a valuable example of Mr Shaw's versatility. Here he employed a completely different method of expression from any of his preceding works, and there is a certain boldness in the planning which, in one of those of 1870-1880), is a valuable example of Mr Shaw's versatility. Here he employed a completely different method of expression from any of his preceding works, and there is a certain boldness in the planning which, in his design, and in the best contemporary style. The Hall is divided into two stories, and a large cell of brickwork between the two stories, divided by piers of brickwork into three equal spaces, filled by shaped bays rich with moulded plaster; above, defining the whole composition together, is a finely enriched plaster cove. An attic storey, roofed with three gables, completes the building, which is the antithesis of the accepted type of city offices; it is yet perfectly adapted to modern uses. New Scotland Yard is another masterpiece of Mr Shaw's, so also is Lowther Lodge. The granite base is not only subtly suggestive of the purposes of the building, but by dividing the height with a strongly marked line gives a greater apparent width to the structure; it suggests also a division into compartments. Above, in the attic story, the walls dwelled on the necessary irregularity of the lower windows, which are not only different in character from those of the upper storeys, but more numerous and quite irregularly spaced. The projecting
angle turrets are most happily conceived, and besides giving emphasis to the corners, form the main point of interest in the composition of the river front. The chimneys are not allowed to cut the sky; indeed the whole line of them is kept continuous and full. The variety of the time, however, blocks, and contribute much to the general air of dignity and strength for which this building is remarkable. Simple roofs of ample span complete, a composition conspicuous for its breadth and unity.

Mr. Shaw's influence on his generation can only be adequately gauged by a comparison of current work with that which was, in 1950 when he began his career. The works of Pugin, Scott, and other names of the time, and most of the thoughts both of architects and the public towards a "revived Gothic." Before he entered the field, this teaching had hardened into a creed. Mr. Shaw was not content with this line of work, and with characteristic courage threw over these artificial barriers and struck out a line of his own. The rapidity with which he conceived and created new types, and as it were set a new fashion in building, compelled admiration for his genius, and won the ranks of his adherents. It is largely owing to him that there is now a distinct tendency to approach architecture as the art of Building rather than as the art of Designing, and the study of old work as one of methods and expressions which are for all time, rather than as a means of learning a language of forms proper only to their period.

SHAW-KENNEDY, SIR JAMES (1788–1865), British soldier and military writer, was the son of Captain John Shaw, of Dalton, Kirkcudbrightshire. Joining the 43rd (Monmouthshire) Light Infantry in 1805, he first saw service in the Copenhagen Expedition of 1807 as a lieutenant, and under Sir David Baird took part in the Corunna Campaign of 1807–8. In the retreat Shaw contracted a fever, from the effects of which he never fully recovered. The 43rd was again engaged in the Dourou and Talavera Campaigns, and Shaw maintained his instant and unflinching reputation in the battle of Talavera. As Robert Craufurd's aide-de-camp he was on the staff of the Light Division at the Costa and the Aguade, and with another officer prepared and edited the "Standing Orders of the Light Division" (printed in Home's Précis of Modern Tactics, pp. 257–277), which serve as a model to this day. He was wounded at Almeida in 1810, but rejoined Craufurd at the end of 1811 and was with his chief at the siege of Ciudad Rodrigo in January 1812. At the great assault of January 19th Shaw carried his general, mortally wounded, from the glaci, and at Badajoz, now once more with the 43rd, he displayed, at the lesser breach, a gallantry which furnished his brother officer William Napier with the theme of one of his most glorious descriptive passages (Peninsular War, bk. xvi. ch. v.). At the siege and the battle of Salamanca, in the retreat from Burgos, Shaw, still a subaltern, distinguished himself again and again, but he had to return to England at the end of the year, broken in health. Once more in active service in 1815, as one of Charles Alten's staff officers, Captain Shaw, by his reconnoitring skill and tactical judgment was of the greatest importance, and was primarily responsible for bringing him brevet-major in July, and brevet lieutenant-colonel in 1819. During the occupation of France by the allied army Shaw was commandant of Calais, and on his return to England was employed as a staff officer in the North. In this capacity he was called upon to deal with the Manchester riots of 1819, and his memorandum on the methods to be adopted in dealing with civil disorders embodied principles which have been recognized to the present day. In 1820 he married, and in 1824, on succeeding, in right of his wife, to have been distinguished by Kirkcham, near Wetherby, W. Yorks, he returned to his old regiment and was promoted to colonel in 1842, and in 1852 commanding the 57th, and became colonel commandant of the 43rd; he was also ADC. to the Duke of Wellington, and his name is associated with the organization of the Royal Irish Constabulary, which he raised and trained according to his own ideas. He remained inspector-general of the R.I.C. for two years, after which for ten years he led a retired country life. In 1848, during the Chartist movements, he was suddenly called upon to command at Liverpool, and soon afterwards was offered successively a command in Ireland and the governorship of Mauritius. Ill-health compelled him to decline these, as also the offer to command a little later, and for the rest of his life he was practically an invalid. He became full General in 1862 and was made K.C.B. a year later. In 1859, at the time of the Orsini case, he published a remarkable essay on The Defence of Great Britain and Ireland, and in 1865 appeared his famous Notes on Waterloo, appended to which is a Plan for the defence of Canada. He died the same year.

See the autobiographical notice in Notes on Waterloo, also the regimental history of the 43rd, and Napier, passim.

SHAWL, a square or oblong article of dress worn in various ways dependent from the shoulders. The term is, of Persian origin (šād), and the article itself is most characteristic of the natives of N.W. India and Central Asia; but in various forms, and under different names, the same piece of clothing is found in most parts of the world. The shawls made in Kashmir occupy a pre-eminent place among textile products; and it is to them and to their imitations from Western looms that specific importance attaches. The Kashmir shawl is characterized by the elaboration of its decoration; and especially those in which the "cone" pattern is a prominent feature, and by the glowing harmony, brilliance, depth, and enduring qualities of its colours. The basis of these excellences is found in the very fine, soft, short, fleshy under-wool, called pashm, found on the shawl-goat, a variety of Capra hircus inhabiting the elevated regions of Tibet. There are several varieties of pashm, but the finest is a strict monopoly of the maharaja of Kashmir. Inferior pashm and Kirman wool—fine soft Persian sheep's wool—are used for shawl weaving at Amritsar and other places in the Punjab, where colonies of Kashmir shawlers are established. From these, and from Kashmir, there are only two principal classes: (1) loom-woven shawls called tilla-wool, till-šād or kān-šād—sometimes woven in one piece, but more often in small segments which are sewn together with such precision that the sewing is quite imperceptible; and (2) embroidered shawls-amālik-šād, in which over a ground of plain pashmina is worked by needle a minute and elaborate pattern.

SHAW, SHALM (Fr. chalumeau, chalumele, haubois; Ger. Schalmei, Schalme; It. Piffer cernavole; Lat. calamus; ibid; Gr. αἷμα), the medieval forerunner of the oboe, the trembler member of the large family of reed instruments known in Germany as the Pommern (q.v.), Bombart or Scholme family. Michael Praetorius, at the beginning of the 17th century, enumerates the members of this family (see Oboe); the two of highest pitch are Schalmeys, the first or little Schalme being in B (third line) or A, the second, also called cantus or discantus, in E or D below. The shawl or Schalme had a compass of two octaves, the second diatonic octave being obtained by overblowing each of the notes of the first octave an octave higher. To the chalumeau, or Schalme, and shalmeys, are assigned the notes of the palate; the holes by cross-fingering. In some instances the reed mouthpiece was half enclosed in a pirouette, a small case having a slit through which that part of the reed which is taken into the mouth of the player was alone exposed, the edges of the slit thus forming a rest for his lips.

In the miniatures of the illuminated MSS. of all countries, more especially from the 14th century, and in early printed books, Schalmeys and Pommern are represented in every conceivable phase of social life in which music takes a part.

SHAWNEE or SHAWNO (said to mean "southerner"), a tribe of North American Indians of Algonquian stock. They are said to have been first found in Wisconsin. Under the name Sacannas towards the end of the 17th century they had their headquarters in South Carolina on the upper Savannah. Moving eastward they came in contact with the Iroquois, by whom they were driven S. again into Tennessee. Thence they crossed the mountains into South Carolina and again spread northward as far as New York state and southward to Florida. Subsequently they recrossed the Alleghany mountains, once more in contact with the Iroquois and were driven into Ohio. They joined in Pontiac's conspiracy. They fought on the English side in the War of Independence and again in 1812 under Tecumseh. They are now on a reservation in Oklahoma.

SHAWNEE, a city of Pottawatomie county, Oklahoma, U.S.A., on the North Fork of the Canadian river, about 38 m. E.S.E. of Oklahoma city. Pop. (1907) 10,955, including 274 negroes and 20 Indians; (1910) 12,474. Shawnee is served by the Atchison, Topeka & Santa Fé, the Chicago, Rock Island & Pacific, and the Missouri, Kansas & Texas railways and by interurban electric.
lines. The city has two large public parks and a Carnegie library, and is the seat of the Curtice Industrial School. Shawnee is situated in a fine agricultural region, is a shipping-point for allia, cotton and potatoes, is an important market for mules, and has large railway repair shops, and cotton-gins and cotton compresses; among its manufactures are cotton-seed oil, cotton goods, lumber, bricks and flour. Shawnee was first settled in 1805 and was chartered as a city in 1806.

SHAYS, DANIEL (1747–1825), American soldier, the leader of Shays's Insurrection in W. Massachusetts in 1786–1787 (see MASSACHUSETTS: History), was born in Hopkinton, Massachusetts, in 1747. In the War of Independence he served as second lieutenant in a Massachusetts regiment from May to December 1775, became captain in the 5th Massachusetts regiment in January 1777, and resigned his commission in October 1780. After the collapse of Shays's Insurrection he escaped to Vermont. He was pardoned in June 1788, and died at Sparta, New York, on the 20th of September 1825.

SHEarer, THomas, English 18th-century furniture designer and cabinet-maker. The solitary biographical fact we possess relating to this distinguished craftsman is that he was the author of most of the plates in The Cabinet Maker's London Book of Prices and Designs of Cabinet Work, issued in 1788 "For the London Society of Cabinet Makers." The majority of these plates were republished separately as Designs for Household Furniture. They exhibit their author as a man with an eye at once for simplicity of design and delicacy of proportion. Indeed some of his pieces possess a dainty and slender elegance which has been rarely seen in the history of English furniture.

There can be little doubt that Shearer exercised considerable influence over Hepplewhite, with whom there is reason to suppose that he was closely associated, while Sheraton has recorded his admiration for work which has often been attributed to others. Shearer, in his turn, owes something to the brothers Adam, and something no doubt, to the stock designs of his predecessors. There is every reason to suppose that he worked at his craft with his own hands and that he was literally a cabinet-maker—so far as we know, he never made chairs. Much of the elegance of Shearer's work is due to his graceful and reticent employment of inlays of saithwood and other foreign woods. But he was as successful in form as in decoration, and no man ever used the curve to better purpose. In Shearer's time the sideboard was in process of evolution; previously it had been a table with drawers, the pedestals and cabinet-boxes being separate pieces. He would seem to have been first to combine them into the familiar and often beautiful form they took at the end of the 18th century. The combination may have been made before, but his plate is, in point of time, the first published document to show it.

Shearer, like many of his contemporaries, was much given to devising "harlequin" furniture. He was a designer of high merit and real originality, and occupies a distinguished place among the little band of men, often, like himself, ill-educated and obscure of origin, who raised the English cabinet-making of the second half of the 18th century to an illustrous place in artistic history.

SHEARS, an implement for cutting or clipping. The O. Eng. shears, to clip, cut, represents one branch of a very large number of words in Indo-European languages which are to be referred to the root shars, to cut, and of which may be mentioned Gr. 

For cutting cloth "shears" take the form of a large, heavy pair of scissors with two crossed flat blades pivoted together, each with a looped handle for the insertion of the fingers; for clipping or "shearing" the sheep the usual form is a single piece of steel bent round, the ends being shaped into the cutting blades, and the bend or "bow" forming a spring which opens the blades when the pressure used in cutting is released. Another form of the same word, "sheers," is used of an apparatus for hoisting heavy weights, generally known as "sheer-legs." These consist of two or more uprights meeting at the top, where the hoisting tackle is placed, and set wide apart at the bottom. The mastings of ships was formerly carried out from another vessel, a dismasted hulk, hence a "sheer-hulk," on which the "sheer-legs" were placed (see CRANE). From this word must be distinguished "sheer," straight, precipitous, also absolute, downright; this is to be connected with Dan. skjær, clear, bright; Ger. schier, free, clear; the root is also seen in O. Eng. scianen, to shine. The nautical phrase "to sheer off," to deviate from a course, is due to the similar Dutch use of scheren, to cut, shear, to cut off a course abruptly.

SHEARWATER, the name of a bird, first published in F. Willughby's Ornithologia (p. 232), as made known to him by Sir T. Browne, who sent a picture of it with an account that is given more fully in J. Ray's translation of that paper (p. 334), stating that it is "a Sea-fowl, which fishermen observe to resort to their vessels in some numbers, swimming..." to and fro, backward, forward and about them, and doth as it were radere aquam, shear the water, from whence perhaps it had its name. Ray's mistaking young birds of the Isle of Man for the young of the couterneb, now usually called "Puffin," has already been mentioned under that heading; and not only has his name Puffinus anguorum hence become attached to this species, commonly described in English books as the Manx puffin or Manx shearwater, but the barbarous word Puffinus has come into use for all birds thereto allied, forming a well-marked group of the family Procellariidae (see PETREL), distinguished chiefly by their elongated bill, and numbering some twenty species, if not more—the discrimination is that Puffinus has fixed the ingenuity of Ornithologists. Shearwaters are found in nearly all the seas and oceans of the world generally within no great distance from the land, though rarely resorting thereto, except in the breeding season. But they also penetrate to waters which may be termed inland, as the Bosphorus, where they are known to the French-speaking part of the population as âmes damnées, it being held by the Turks that they are animated by condemned human souls. Four species of Puffinus are recorded as visiting the coasts of the United Kingdom; but the Manx shearwater is the only one that at all commonly breeds in the British Islands. It is a very plain-looking bird, black above and white beneath, and about the size of a pigeon. Some other species are larger, and almost whole-coloured, being of a sooty or dark cinereous hue both above and below. All over the world shearwaters seem to have precisely the same habits, laying their single purely white egg in a hole under ground. The young are thickly clothed with long down, and are extremely fat. In this condition they are thought to be good eating, and enormous numbers are caught for this purpose in some localities, especially of a species, the P. brevicaudus of Gould, which frequents the islands off the coast of Australia, where it is known as the "Mutton-bird." (A. N. T. 1.)

SHEATHBILL, a bird so-called by T. Pennant in his Gen. Birds, ed. 2, p. 43) from the horny case which ensheaths the basalt part of its bill. It was first made known from having been met with on New-Year Island, off the coast of Staten Land, where Cook anchored on New Year's eve 1774. A few days

³ Meaning, no doubt, skimming or "hovering." the latter word was used by Browne in his Account of Birds found in Norfolk (Mus. Brit. Mus. MS. Sloane, No. 422, p. 193) and also by Edwards (Gleanings, lii. 315) speaks of comparing his own drawing "with Brown's old draught of it, still preserved in the British Museum." This seems to be the latter's "shearwater " with the "puffin of the Isle of Man."

⁴ Tyrie appears to be the most common local name for this bird in Orkney and Shetland; but Scrab and Scraeb are also used in Scotland. These are from the Scandinavian Skraæ or Skraa, and considering Skraa's remarks (Etym. Dictionary) as to the alliance between the words shear and scraee it may be that Browne's hesitation as to the derivation of "shearwater" had more ground than at first appears.

⁵ The chief exception would seem to be the Bay of Bengal and thence throughout the W. of the Malay Archipelago, where, though they occur, they are very uncommon.

⁶ A strange fallacy arose that this case or sheath was movable. It is absolutely fixed.

⁷ Doubtless some of the earlier voyagers had encountered it, as Forster suggests (Deter. animalium, p. 330) and Lesson asserts.
later he discovered the islands that now bear the name of South Georgia, and there the bird was again found—in both localities frequented the rocky shores. On his third voyage, while seeking some land reported to have been found by Kerguelen, Cook in December 1768, probably an atoll lying to the E. of Cook's Islands, the species was generally known by the name of the French explorer, and here, among many other kinds of birds, was a Sheathbill, which for a long while no one suspected to be otherwise than specifically identical with that of the western Antarctic Ocean; but, as will be seen, its distinctness has been subsequently admitted. The Sheathbill, so soon as it was brought to the notice of naturalists, was recognized as belonging to a genus different from the one now and J. R. Forster in 1778 (Enchiridion, p. 37) conferred upon it, from its snowy plumage, the name Chionis, which has most properly received general acceptance, though in the same year the compiler Comte de Buffon (Histoire Naturelle, v. 6, p. 631) arranged it under the generic name of his own country, as Anthus, under the English name, and the species alba. It has thus become the Chionis alba of ornithology. It is about the size of and has much the aspect of a Penguin; its plumage is pure white, its bill somewhat yellow at the base, passing into pale pink towards the tip. Round the eyes the skin is bare, and beset with cream-coloured papillae, while the legs are bluish-grey. The second or eastern species, first discriminated by G. Hartlaub (Rei. zoologique, 1841, p. 5; 1842, p. 402, pl. 2) as A. minor, is smaller in size, with plumage just as white, but having the bill and bare skin of the face black and the legs much darker. The former of the two species is a much finer bird; the latter is quite different, for in C. alba it is almost level throughout, while in A. minor it rises in front like the pommel of a saddle. The western and larger species gathers its food, consisting chiefly of sea-weeds and shell-fish, on or near the shore; but it is more especially fond of eating birds' eggs. As to the flavour of its flesh, some assert that it is wholly unattractive, and others that it is palatable. Though most abundant as a shore-bird, it is frequently met with far out at sea, and has once been shot in Ireland. It is found on Auckland Island and the Crozetts, is smaller, with pinkish feet. The eggs of both species, though of peculiar appearance, bear an unmistakable likeness to those of oyster-catchers, while occasionally exhibiting a resemblance to those of the tropic-birds. The systematic position of the sheathbills has been the subject of some discussion. The name Chionis was first employed in a generic sense by R. Forster (Gen. Chioniae, amongst Charadriiformes, asiaticae, vol. ii. p. 192), and has been maintained by J. Forster (in his account of the Xizincormes and Attagis, which are peculiar to certain localities in S. America and its islands). SHEBOYGAN, a city and the county seat of Sheboygan county, Wisconsin, U.S.A., on the W. shore of Lake Michigan at the mouth of the Sheboygan river, about 52 m. N. of Milwaukee. Pop. (1910 census) 26,398. The population is largely of German descent, and two German newspapers are published; many Greeks settled here after 1855. Sheboygan is served by the Chicago and Northwestern railway, by interurban electric lines and by a steam-boat line to Green Bay and Oswego. The city N. of the river and the southern half of the peninsula of the river are built on a plateau 20-40 ft. above the lake level. Along the river is the factory district. The principal public buildings are a fine Federal building in which are housed the post-office and the office of the internal revenue; a Carnegie library, the Sheboygan County Court House, an opera house, St Nicholas Hospital and a county insane asylum. Included in the public school system is a school for deaf children, partly supported by the state. The city is a good harbour and is an important distributing point for fruit and salt. A rich agricultural region, (Man. d'ornithologie, ii. 343); but for all practical purposes we certainly owe its discovery to the naturalist's second volumes of New Zealand. By some error, probably of transcription, New Zealand, instead of New-York Island, appears in many works as the place of its discovery, while not a few writers have added thereto New Holland. Hitherto there is no real evidence of the occurrence of a Sheathbill in the waters of Australia or New Zealand. The Kelp-Pigeon is called the "Kelp-Pigeon," and by some of the earlier French navigators the "Phoebus plane a bras." The cognate species of Kerguelen Land is named by the sealers "Bore-eye Pigeon," from its prominent fleshly orbits, as well as "Pied-Diable." It is distinguished from its white plumage calling to mind that of some of the smaller Egrets. In the same region, and not suspecting it to be distinct, Whitehead (loc. cit.) has been led to reconcile the discrepancies of the latter's description with that given of the other species by earlier authors

SHEBOYGAN—SHECHEM
devoted largely to dairying, extends to the N., S. and W., and large quantities of cheese are exported. Among the city's other manufactures are furniture, particularly chairs (for which the city is noted), toys, machinery, bee-hives, gloves, knit goods, brick, carriages, wagon parts of the Hebrews, wicker-work, enamel ware, canned vegetables (especially peas), beer, flour, pianos and plumbing supplies. The total value of the factory product in 1905 was $10,856,609, 38.1% representing furniture; and 56.7% of the whole number of factory wage-earners were employed in the furniture factories. A trading post at the mouth of the Sheboygan river was established about 1820 and was maintained for about fourteen years; in 1834 a saw-mill was built at the first rapids of the river, about 2 m. from its mouth, and during the next three years many settlers came and a great city was platted on paper. Sheboygan was incorporated as a village in 1846, and was first chartered as a city in 1857. Several miles from Sheboygan Falls (pop. in 1905, 1411), a village about 5 m. W. of Sheboygan and S.W. of Plymouth (pop. in 1905, 2764), the Spring Farms Association, a Fourierite community of ten families, farmed successfully thirty acres of land from 1845 until 1848, when lack of interest in the experiment brought about a dissolution by mutual agreement.

SHECHEM (mod. Nablus), an ancient town of Palestine, S.E. of Samaria, which first appears in history as the place where Jacob built his family's second altar (Gen. xxxiii. 19; cf. John iv. 12). It was occupied then by Hivites and a tragedy took place in connexion with the chieftain's violation of Jacob's daughter Dinah. It was set apart as a city of refuge (Jos. xx. 7) and was occupied by the Kohathite Levites in the tribe of Ephraim (xxii. 21). Here, between Ebal and Gerizim, Joshua made his last speech to the elders of the Israelites (Jos. xxiv. 1). The mother of Abimelech the son of Gideon was a Shechemite, and Shechem was the centre of his short-lived kingdom (Jud. viii. 31, x.). Here Rehoboam made the foolish wager, and John the Baptist sought the revolting of the N. kingdom (1 Kings xii. 1), after which it was for a time the headquarters of Jeroboam (1 Kings xii. 25). Shechem was evidently a holy place in remote antiquity. The "oak" under which Jacob hid his teraphim (Gen. xxxiv. 4) was doubtless a sacred tree, as there the images (which it was not so easily to bring on a pilgrimage to Beth-el) would be safe. The god of the Canaanite city was Baal-Berith; his temple was destroyed when Abimelech quelled the rising of his fickle subjects (Jud. ix. 4, 46). A great standing stone under an oak-tree here was specially associated with Joshua's last speech (Jos. xxiv. 26). During the last two centuries the name Shechem has been a thing of history; nothing of Shechem, no doubt on account of the commanding importance of the neighbouring city of Samaria. It no doubt owed its subsequent development to the destruction of Samaria and the rise in the district surrounding the Samaritan nation founded on the colonists settled by Sargon and Assur-bani-pal. To Josephus it was the "new city" by the inhabitants called Mabotha (B. J., iv. viii. 1), but the official name Neapolis or Flavia Neapolis, so called to commemorate its restoration by Titus Flavius Vespasianus, soon became universal; and is still preserved in the modern name Nablus—a signal exception to the general rule that the place-names of Palestine, whenever disturbed by foreign influence, usually revert in time to the old Semitic nomenclature.

There was a bishopric at Neapolis during the Byzantine period, and an attack made by the Samaritans on the bishop (Pentecost, a.d. 474) was punished by the emperor Zeno, who gave Gerizim to the Christians. It was captured by the crusaders under Tancred soon after the conquest of Jerusalem (1099); they held it till 1184, when they lost it to Saladin. The principal mosque of the town is a church settled for a while (1185) by the headquarters of the turbulent sheik Kasim el-Ahmad. In 1834 the soldiers of Ibrahim Pasha pillaged it.

Nablus is now the chief town of a subdivision of the province of Beirut. It lies in the valley between Ebal and Gerizim, on the main caravan route from Jerusalem northward. The situation
is famous for its beauty. There are about 24,000 inhabitants—
all Moslems except about 150 Samaritans and perhaps 700
Christians. The inhabitants are notorious for fanaticism and
lawlessness, and Europeans are usually greeted with vile epithets.
There are missions, both Protestant and Roman Catholic; and
an important hospital under the auspices of the Church Missionary
Society. There is a flourishing trade in soap, which is here
manufactured, and a considerable commerce in wool and cotton
with the regions E. of the Jordan.

In the neighbourhood of Nablus are shown: (1) a modern building
which covers the traditional site of the tomb of Joseph, as accepted
by Jews, Samaritans and Christians. The authority for the burial
of Joseph was a very especial one (Acts xii. 16), though
Josephus places the sepulchre at Hebron (Ant. ii. 22). Moslem
tradition also regards Shechem as the burial-place of Joseph; but
it appears as though the actual site, as shown, has not been always
in one unvarying spot. (2) The well of Jacob; about a mile and
a half from Nablus on the way to Jerusalem, which is an excavation
of great depth. The tradition fixing this hallowed place seems to have
been common throughout the whole of the Christian centuries, and
it is one of the very few "holy places" shown to travellers and
pilgrims in Palestine, the authenticity of which deserves considera-
tion. It is one of the small number of sites mentioned by the
Bordeaux pilgrim (A.D. 353).

The site of the sacred oak has been sought at two places: one
called El-'Amud, "the column"—where is "Joseph's tomb"; and
the other at Balata (a name containing the consonants of the
Semitic word "shech") near Jacob's Well. (3) The House of
Shed. (1) A small hut, shelter or outhouse, especially one
with a "shed roof" or "lean-to," a roof with only one set of
rafters, falling from a higher to a lower wall, like an aisle roof.
"Shed" is also the term applied to a large roofed shelter open at
the sides for the storage of goods, rolling-stock, locomotives, &c.,
on a railway or dock-wharf. According to Skeat, the word is a
Ger. Schatten; the ultimate origin is the root ska-, to cover,
seen in Gr. σκια, shadow, ωμοχων, tent, shelter, stage, whence
Eng. scene. The Eng. "sky-barn" comes from a closely allied root, ska-, to cover, as in Lat. salubraria, "a shelter" (2) To separate, to cast off; originally the word seems to have meant to part,
to divide, a use only surviving in "watershed." The O. Eng. verb
was seedan, in Mid. Eng. sheden, to divide, separate. "Shed"
"in the sense of to spill has, however, by some etymologists been
taken to be a separate word from that meaning to part; it would
in that case appear to be connected with O. Fris. scheda, to shake,
the root of which is found in "shudder."
undulating districts, rather than the precipitous heights to which goats are partial. It may be added that the long tails of most tame breeds are, like wool, in all probability the results of domestication.

The Pamir plateau, on the confines of Turkestan, at an elevation of 16,000 ft. above the sea-level, is the home of the magnificent Ovis poli, named after the celebrated Venetian traveller Marco Polo, who met with it in the 13th century. It is remarkable for the great size of the horns of the old rams and the wide open sweep of their curve, so that the points stand boldly out on each side, far away from the animal's head, instead of curling round nearly in the same plane, as in most of the allied species. A variety inhabiting the Thian Shan is known as O. poli carelini.

An even larger animal is the argali, O. ammon, typically from the Altai, but represented by one race in Ladak and Tibet (O. ammon hodgsoni), and by a second in Mongolia. Although its horns are less extended laterally than those of O. poli, they are grander and more massive. In their short summer coats the old rams of both species are nearly white. Ovis sairensis from the Sair mountains and O. litedalei from Kulja are allied species. In the Stanovoi mountains and neighbouring districts of E. Siberia and in Karachatka occur two sheep which have been respectively named O. borealis and O. mincola. They are, however, so closely allied to the so-called bighorn sheep of N. America, that they can scarcely be regarded as more than local races of O. canadensis, or O. cervina, as some naturalists prefer to call the species. These bighorns are characterized by the absence of face-glands, and the comparatively smooth front surface of the horns of the old rams, which are thus very unlike the strongly wrinkled horns of the argali group. The typical bighorn is the khaki-coloured and white-rumped Rocky Mountain animal; but on the Stickin river there is a nearly black race, with the usual white areas (O. canadensis stewarti), which was introduced in Alaska by the nearly pure white O. c. dalli; the grey sheep of the Yukon (O. c. fannini) being perhaps not a distinct form. Returning to Asia, we find in Ladak, Astor, Afghanistan and the Punjab ranges, a sheep whose local races are variously known as urial, urial and shapo, and whose technical name is O. vigui. It is a smaller animal than the members of the argali group, and approximates to the Armenian and the Sardinian wild sheep or mouflon (Ovis orientalis and O. musimon) (see MOUFLON). We have in Tibet the bhural or blue sheep, Ovis (Pseudois) bhural, and in N. Africa the udad or aoudad, O. (Ammotragus) lervia, both of which have no face-glands and in this and their smooth horns approximate to goats (see BHARAL and AOUDAD).

The sheep was domesticated in Asia and Europe before the dawn of history, though unknown in this state in the New World until after the Spanish conquest. It has now been introduced by man into almost all parts of the world where agricultural operations are carried on, but flourishes especially in the temperate regions of both hemispheres. Whether this well-known and useful animal is derived from any one of the existing wild species, or from the crossing of several, or from some now extinct species, are matters of conjecture. The variations of external characters seen in the different breeds are very great. They are chiefly manifested in the form and number of the horns, which may be increased from the normal two to four or even eight, or may be altogether absent in the female alone or in both sexes; in the shape and length of the ears, which often hang pendent by the side of the head; in the peculiar elevation or arching of the nasal bones in some eastern races; in the length of the tail, and the development of great masses of fat at each side of its root or in the tail itself; and in the colour and quality of the fleece.

On the W. coast of Africa two distinct breeds of hairy sheep are indigenous, the one characterized by its large size, long limbs and smooth coat, and the other by its inferior stature, lower build and heavily maned neck and throat. Both breeds, which have short tails and small horns (present only in the rams), were regarded by the German naturalist Fitzinger as specifically distinct, and he named them Ovis hugiana and Ovis vittata. For the first type he proposed the name O. longipes and for the second O. jubata. Although such distinctions may be doubtful (the two African breeds are almost certainly descended from one ancestral form), the retention of such names may be convenient as a provisional measure.

The long-legged hairy sheep, which stands a good deal taller than a Southdown, ranges, with a certain amount of local variation, from Lower Guinea to the Cape. In addition to its long limbs, it is characterized by its Roman nose, large (but not dropping) ears, and the presence of a dewlap on the throat (Fig. 15). The ewes are hornless, but in Africa the rams have very short, thick and somewhat goatlike horns. On the other hand, in the W. Indian breed, which has probably been introduced from Africa, both sexes are devoid of horns. The colour is variable. In the majority of cases it appears to be pied, showing large blotches of black or brown on a white ground; the head being generally white with large black patches on the sides, most of the neck and the fore-part of the body black, and the hind-quarters white with large coloured blotches. On the other hand, these sheep may be uniformly yellowish white, reddish brown, greyish brown or even black. The uniformly reddish or chestnut-brown specimens approach most nearly to the wild mouflon or urial in colour, but the chestnut extends over the whole of the underparts and flanks; domestication having probably led to the elimination of the white belly and dark flank band, which are doubtless protective characters. The feeble development of the horns is probably also a feature due to domestication.

In Angola occurs a breed of this sheep which has probably been crossed with the fat-tailed Malagasy breed; while in Guinea there is a breed with lappets, or wattles, on the throat, which is probably the result of a cross with the long-eared sheep of the same district. The Guinea long-eared breed, it may be mentioned, is believed to inherit its drooping ears and throat wattles from an infusion of the blood of the Roman-nosed hornless Theban goat (see GoAT). Hairy long-legged sheep are also met with in Persia, but are not pure-bred, being apparently the result of a cross between the long-legged Guinea breed and the fat-tailed Persian sheep.

The maned hairy sheep (Ovis jubata), which appears to be confined to the W. coast of Africa, takes its name from a mane of longish hair on the throat and neck; the hair of the body being also longer than in the ordinary long-legged sheep. This breed is frequently black or brown and white; but in a small sub-breed from the Cameroons the general colour is chestnut or foxy red, with the face, ears, buttocks, lower surface of tail and under-parts black. The most remarkable thing about this Cameroonian sheep is, however, its extremely diminutive size, a full-grown ram standing only 19 in. at the withers.

In point of size this pigmy Cameroon breed comes very close to an exceedingly small sheep of which the limb-bones have been
SHEEP

BRITISH BREEDS OF SHEEP, from photographs by F. Babbage. The comparative sizes of the animals are indicated by the scale of reproduction.

found in certain ancient deposits in the S. of England; and the question arises whether the two breeds may not have been nearly related. Although there are no means of ascertaining whether the extinct pigmy British sheep was clothed with hair or with wool, it is practically certain that some of the early European sheep retained hair like that of their wild ancestor; and the reason why the breed in question should not have been hairy. On the other hand, since the so-called pecat-sheep of the prehistoric Swiss lake-dwellers appears to be represented by the existing Graubünden (Grisons) breed, which is woolly and coloured something like a Southdown, it may be argued that the former was probably also woolly, and hence that the survival of a hairy breed in a neighbouring part of Europe would be unlikely. The latter part of the argument is not very convincing, and it is legitimate to surmise that in the small extinct sheep of the S. of England we may have a possible relative of the pigmy hairy sheep of W. Africa.

Fat-rumped sheep, *Ovis steatopyga*, are common to Africa and Asia, and are piebald with rudimentary horns, and a short hairy coat, being bred entirely for their milk and flesh. In fat-tailed sheep, on the other hand, which have much the same distribution, the coat is woolly and generally piebald. Four-horned sheep are common in Iceland and the Hebrides; the small half-wild breed of Sos often showing this reduplication. There is another four-horned breed, distinguished by its black (in place of brown) horns, whose home is probably S. Africa. In the unicorn shire of Nepal or Tibet the two horns of the rams are completely welded together. In the Himalayan and Indian hump sheep, the rams of which are specially trained for fighting, and have highly convex foreheads, the tail is short at birth. Most remarkable of all is the so-called Wallachian sheep, or Zackelschaf (*Ovis strepsiceros*), represented by several more or less distinct breeds in F. Europe, in which the long upright horns are spirally twisted like those of the mazzkhor wild goat.

**Modern Breeds of Sheep.**—The sheep native to the British Isles may be classified as the lowland and the mountain breeds, and subdivided into longwools and shortwools—the latter including the Down breeds, sometimes termed black-faced. The *longwool* breeds are the Leicester, Border Leicester, Cotswold, Lincoln, Kent, Devon Longwool, South Devon, Wensleydale, and Roscommon. The *shortwool* breeds are the Oxford Down, Southdown, Shropshire, Hampshire Down, Suffolk, Ryeland, Dorset, and Somerset Horn, Kerry Hill, Radnor, and Clun Forest. The mountain breeds include the Cheviot, Scotch Black-face, Long, Rough Swaaledale, Derbyshire Gritstone, Penistone, limestone, Herdwick, Dartmoor, Exmoor, and Welsh Mountain. These breeds are all English, except the Border Leicester, Cheviot and Scotch Black-face, which belong to Scotland; the Welsh Mountain, which belongs to Wales; and the Roscommon, which is Irish. The majority of the true mountain breeds are horned, the males only in the cases of Cheviot, Herdwick, Penistone and Welsh, though most Cheviot and many Herdwick rams are hornless. Of Derbyshire Gritstone neither sex has horns. In the other horned breeds, the Dorset and Somerset, Limestone, Exmoor, Old Norfolk, and Western or Old Wiltshire, both sexes have horns. The remaining breeds are hornless. The white-faced breeds include the Leicester, Border Leicester, Lincoln, Kentish, Cheviot, Ryeland, Devon Longwool, South Devon, Dorset, and Somerset Horn, Limestone, Penistone, Exmoor, and Roscommon.

The Leicester, though now not numerous, is of high interest. It was the breed which Robert Bakewell took in hand in the 18th century, and greatly improved by the exercise of his skill and judgment. Bakewell lived at Dishley Grange, Leicestershire, and in France the Leicester sheep are still called Dishleys. In past centuries considerable wool was extensively employed in the improvement or establishment of other long-wool breeds, but the Leicester, as seen now, has a white wedge-shaped face, the forehead covered with wool; thin mobile ears; neck full towards the trunk, short and level with the back; width over the shoulders and through the heart; a full broad breast; fine clean legs standing well apart; deep round barrel and great depth of carcass; firm flesh, springy pelt, and pink skin, covered with fine, curly, lustrous wool. The breed is maintained pure upon the richer pastures of Leicestershire, E. and N. Yorkshire, Cheshire, Cumberland and Durham, but its chief value is for question, when it is found to promote maturity and to improve the fattening propensity.

The Border Leicester originated after the death in 1795 of Bakewell, when the Leicester breed, as it then existed, diverged into two branches. The one is represented by the breed still known in England as the Leicester. The other, bred on the Scottish Borders, with an early admixture of Cheviot blood, acquired the name of Border Leicester. The distinguishing characteristics of the latter are that it is an upstanding animal of gay appearance with light offal; and has a long though strong neck carrying a long, lean, clean head covered with white, hard, but not wiry hair, free from wool, long highset ears and a black muzzle; back broad and muscular, belly well covered with wool; legs clean, and a fleece of long white woolly, arranged in characteristic locks or pilres.

The Blue-faced Wensleydales take their name from the Yorkshire dale of which Thirsk is the centre. They are longwool sheep, derived from the old Teeswater breed by crossing with Lincoln rams. They have a tuft of wool on the forehead. The skin of the body is sometimes smooth, whilst the wool has a bright lustre, is curled in small distinct pirs, and is of uniform staple. The rams are in much favour in Scotland and the N. of England for crossing with ewes of the various black-faced horned mountain breeds to produce mutton of superior quality and to use the cross-ewes to breed to a pure longwool or sometimes a Down ram.

The Cotswold is an old-established breed of the Gloucestershire hills, extending thence into Oxfordshire. It was but slightly crossed for improvement by the Dishley Leicesters and has retained its characteristic type for generations. They are big, handsome sheep, with finely-arched necks and graceful carriage. With their broad, straight backs, curved ribs, and capacious quarters, they carry a great weight of carcass upon strong, wide-standing legs. The fine white fleece of long wavy wool gives the Cotswold an attractive appearance, which is enhanced by its topknot or forelock. The mutton of the Cotswolds is not of high quality except at an early age, but the sheep are useful for crossing purposes to impart size, and because they are exceptionally hardy.

The Lincolns are descended from the old native breed of Lincolnshire, improved by the use of Leicester blood. They are hardy and prolific, but do not quite equal the Cotswold in size. They have larger, bolder heads than the Leicesters. Breeders of Lincoln rams like best a darkish face, with a few black spots on the ears; and white legs. The wool has a broad staple, and is denser and longer, and the fleece heavier, than in any other British breed. For this reason it has been the best breed in favour with breeders in all parts of the world for mating with Merino ewes and their crosses. The progeny is a good general-purpose sheep, giving a large fleece of wool but only a medium quality of mutton. With a greater proportion of Lincoln blood in the mixed flocks of the world there is a growing tendency to produce a better mutton by using Down rams, but, for the sacrifice of part of the yield of wool. In 1906 Henry Dudding, of Riby Grove, Lincolnshire, obtained at auction the sum of £1,450 guineas for a Lincoln ram bred by him,—the highest price paid for a sheep in the United Kingdom. In the same year Robert and William Wright, of Nocton Heath, Lincoln, sold their flock of 950 animals to Señor Manuel Cobo, Buenos Aires, for £30,000.

The Devon *Longwool* is a breed locally developed in the valleys of W. Somerset, N. and E. Devon, and parts of Cornwall. It originated in a strong infusion of Leicester blood amongst the old Bampton stock of Devonshire. The Devon Longwool is not a large sheep, but has a well constituted carcase. It is white-faced, with a lock of wool on the forehead.

The South Devon or South Down are, like the cattle of that
name, a strictly local breed, which likewise exemplify the good results of crossing with the Leicester. The South Devons have a fairly fine silky fleece of long staple, heavier than that of the Devon Longwool, which it also excels in size.

The Roscommon—the one breed of modern sheep native to Ireland—is indebted for its good qualities largely to the use of Leicester blood. It is a big-bodied, high-standing sheep, carrying a long, wavy, silky fleece. It ranges mainly from the middle of Ireland westwards, but its numbers have declined considerably in competition with the Shropshire.

The Kent or Romney Marsh is native to the rich tract of grazing land of that name, county of Kent. They are hardy, white-faced sheep with a close-coated longwool fleece. They were gradually, like the Cotswolds, improved from the original type of slow-maturity sheep by selection in preference to the use of rams of the Improved Leicester breed. With the exception of the Lincoln, no breed has received greater distinction in New Zealand, where it is in high repute for its hardiness and general usefulness. When difficulties relating to the quantity and quality of food arise the Romney is a better sheep to meet them than the Lincoln or other longwools.

The Oxford Down is a modern breed which owes its origin to crossing between Cotswolds and Hampshire Downs and Southdowns. Although it has inherited the forelock from its longwool ancestors, it approximates more nearly to the shortwool type, and is accordingly classified as such. An Oxford Down ram has a bold masculine head; the poll well covered with wool and the forehead adorned by a topknot; ears self-coloured, upright, and of fair length; face of uniform dark brown colour; legs short, dark, and free from spots; back level and chest wide; and the fleece heavy and thick. The breed is popular in Oxford and other midland counties. Its most notable success in recent years is on the Scottish and English borders, where, at the annual sales at Kelso, a greater number of rams is auctioned of this than of any other breed, to cross with flocks of Leicester-Cheviot ewes especially, but also with Border Leicesters and three-parts-bred ewes. It is supplanting the Border Leicester as a sire of mutton sheep; for, although its progeny is slower in reaching maturity, legs can be fed to greater weights in spring—65 to 68 lb per carcass—without becoming too fat to be classed as finest quality.

The Southdown, from the short close pastures upon the chalky soils of the South Downs in Sussex, was formerly known as the Sussex Down. In past times it did for the improvement of the shortwool breeds of sheep very much the same kind of work that the Leicester performed in the case of the longwool breeds. A pure-bred Southdown sheep has a small head, with a light brown or brownish grey (often mouse-coloured) face, fine bone, and a symmetrical, well-leshed body. The legs are short and neat, the animal being of small size compared with the other Down sheep. The fleece of is fine, close, short wool, and the mutton is excellent. “Underhill” flocks that have been kept for generations in East Anglia, on the Weald, and on flat meadow land in other parts of the country, have assumed a heavier type than the original “Upperdown” sheep. It was at one time thought not to be a rent-paying breed, but modern market requirements have brought it well within that category.

The Shropshire is descended from the old native sheep of the Salopian hills, improved by the use of Southdown blood. Though heavier in fleece and a bulkier animal, the Shropshire resembles an enlarged Southdown. As distinguished from the latter, however, the Shropshire has a darker face, blackish brown as a rule, with very near ears, whilst its head is more massive, and is better covered with wool on the top and at the sides. This breed has made rapid strides in recent years, and it has acquired favour in Ireland as well as abroad. It is an early-maturity breed, and no other Down produces a better back to handle for condition—the frame is so thickly covered with flesh and fat.

The Hampshire Down is another breed which owes much of its improved character to an infusion of Southdown blood. Early in the 19th century the old Wiltshire white-faced horned sheep, with a scanty coat of hairy wool, and the Berkshire Knott, roamed over the downs of their native counties. Only a remnant of the former under the name of the Western sheep survives in a pure state, but their cross descendants are seen in the modern Hampshire Down, which originated by blending them with the Southdown. Early maturity and great size have been the objects aimed at and attained, this breed, more perhaps than any other, being identified with early maturity. One reason for this is the early date at which the ewes take the ram. Whilst heavier than the Shropshire, the Hampshire Down sheep is less symmetrical. It has a black face and legs, a big head with Roman nose, darkish ears set well back, and a broad level back (especially over the shoulders) nicely filled in with lean flesh.

The Dorset Down or West Country Down, “a middle type of Down sheep pre-eminently suited to Dorsetshire,” is a local variety of the Hampshire Down breed, separated by the formation of a Dorset Down sheep society in 1904, about eighty years after the type of the breed had been established.

The Suffolk is another Down, which took its origin about 1790 in the crossing of improved Southdown rams with ewes of the old black-face Horned Norfolk, a breed still represented by a limited number of animals. The characteristics of the latter are seen in the black face and legs of the Suffolk, but the horns have been bred out. The fleece is moderately short, the wool being of close, fine, lustrous fibre, without any tendency to mat. The limbs, woolled to the knees and hocks, are clean below. The breed is distinguished by having the smoothest and blackest face and legs of all the Down breeds and no wool on the head. Although it handles hard on the back when fat, no breed except the old Horned Norfolk equals it in producing a saddle cut of mutton with such an abundance of lean red meat in proportion to fat. It carried off the highest honours in the dressed carcass competition at Chicago in 1903, and the championship in the “block test” at Smithfield Club Show was won for the five years 1902-1906 by Suffolks or Suffolk cross lambs from big-framed Cheviot ewes. In 1907, the championship went to a Cheviot wether, but in the two pure, short-woolled classes all the ten awards were secured by Suffolks, and in the two cross-bred wether classes nine of the ten awards went to a Suffolk cross. The mutton of all the Down breeds is of superior quality, but that of the Suffolk is pre-eminently so.

The Cheviot takes its name from the range of hills stretching along the boundary between England and Scotland, on both sides of which the breed now extends, though larger types are produced in East Lothian and in Sutherlandshire. The Cheviot is a hardy sheep with straight wool, of moderate length and very close-set, whilst wiry white hair covers the face and legs. Put to the Border Leicester ram the Cheviot ewe produces the Half-bred, which as a breeding ewe is unsurpassed as a rent-paying, arable-land sheep.

The Scotch Black-face breed is chiefly reared in Scotland, but it is of N. of England origin. Their greater hardness, as compared with the Cheviots, has brought them into favour upon the higher grounds of the N. of England and of Scotland, where they thrive upon heather hills and coarse and exposed grazing lands. The colour of face and legs is well-defined black and white, the black predominating. The spiral horns are low at the crown, with a clear space between the roots, and sweep in a wide curve, sloping slightly backwards, and clear of the cheek. The fashionable fleece is down to the ground, hairy and strong, and of uniform quality throughout.

The Lowk has its home amongst the moorlands of N. Lancashire and the W. Riding of Yorkshire, and it is the largest of the mountain breeds of the N. of England and Scotland. It bears most resemblance to the Scotch Black-face, but carries a finer, heavier fleece, and is larger in head. Its face and legs are mottled black and white, and its horns are strong. The tail is long and rough. The Herdwick is the hardiest of all the breeds thriving upon the poor mountain land in Cumberland and Westmorland. The rams sometimes have small, curved, wide horns like those of the Cheviot ram. The colour of the fleece is white, with a few darkish spots here and there; the faces and legs are dark in the lambs, gradually becoming white or light grey in a few years.
The wood is strong, standing up to the shoulders and down the breast like a mane. The forehead has a topknot, and the tail is well covered.

The **Limestone** is a breed of which little is heard. It is almost restricted to the fells of Westmorland, and is probably nearly related to the Scotch Black-face. The breed does not thrive off its own geological formation, and the ewes seek the ram early in the season. The so-called "Limestones" of the Derbyshire hills are really Leicesters.

The **Welsh Mountain** is a small, active, soft-wooled, white-faced breed of hardy character. The legs are often yellowish, and this colour may extend to the face. The mutton is of excellent quality. The ewes, although difficult to confine by ordinary fences, are in high favour in lowland districts for breeding fattening lambs to Down and other early maturity rams.

The **Clun Forest** is a local breed in W. Shropshire and the adjacent part of Wales. It is descended from the old Tan-faced sheep. It is now three parts Shropshire, having been much crossed with that breed, but its wool is rather coarser.

The **Radnor** is short-limbed and low-set with speckled face and legs. It is related to the Clun Forest and the **Kerry Hill** sheep. The draft ewes of all three breeds are in high demand for breeding to Down and longwool rams in the English midlands.

The **Ryeland** breed is so named from the Ryelands, a poor upland district in Herefordshire. It is a very old breed, against which the Shropshire has made substantial headway. Its superior qualities in wool and mutton production have been fully demonstrated, and a demand for rams is springing up in S. as well as N. America. The Ryeland sheep are small, hornless, have white faces and legs, and remarkably fine short wool, with a topknot on the forehead.

The **Dartmoor**, a hardy locally Devonshire breed, is a large hornless, longwool, white-faced sheep, with a long mottled face. It has been attracting attention in recent years.

The **Exmoor** is a horned breed of Devonshire moorland, one of the few remaining remnants of direct descent from the old forest breeds of England. They have white legs and faces and black nostrils. The hooves are more closely to the head than in the Dorset and Somerset Horn breed. The Exmoors have a close, fine fleece of short wool. They are very hardy, and yield mutton of choice flavour.

The **Dorset and Somerset Horn** is an old west-country breed of sheep. The fleece is fine in quality, of close texture, and the wool is intermediate between long and short, whilst the head carries a forelock. Both sexes have horns, very much coiled in the ram. The muzzle, legs and hoofs are white; the nostrils pink. This is a hardy breed, in size somewhat exceeding the Southdowns.

The special characteristic of the breed is that the ewes take the ram at an unusually early period of the year, and cast ewes are in demand for breeding house lamb for Christmas. Two crops of lambs in a year are sometimes obtained from the ewes, although it does not pay to keep such rapid breeding up regularly.

The **Merino** is the most widely distributed sheep in the world.

**From a photo in Professor Robert Walpole’s *Farm Life* Stock of Great Britain (4th edition).**

It has been the foundation stock of the flocks of all the great sheep countries. A few have existed in Britain for more than a hundred years. They thrive well there, as they do everywhere, but they are wool-sheep which produce slowly a secondary quality of mutton—thin and blue in appearance. The Merino resemble the Dorset Horn breed. The rams possess large coiling horns which the ewes do not carry. The wool is generally thick and is flesh-coloured and the face covered with wool. The wool, densely set on a wrinkled skin, is white and generally fine, although it is classified into long, short, fine and strong. Merino cross with early-maturity longwool, Down, or other close-wooled rams, are good butchers' sheep, and most of the frozen mutton imported into the United Kingdom has had more or less of a merino origin.

(W. Fr.; R. W.)

**Lowland Sheep-breeding and Feeding.**—A Shropshire flock of about two hundred breeding ewes is here taken as a typical example of the sheep-system. They are predominantly Westmorland longwool and an early maturity ram. The flock is managed on a part-time basis between the family farms of Swedes and Swedes and Swedes. The ewes are generally kept in good condition through the winter, and are mated in February. The lambs are weaned in May and are turned out to the hills in June. The lambs are marketed at the age of six months, and are then turned out to the hills in January to the end of February. The lambs have the shelter of a lambing shed for a few days. When drafted to an adjoining field they run in front of their mothers and get a little crushed oats and linseed cake meal, the ewes receiving kail or roots and hay to develop milk. The sheep are given place to mangolds, rye and clover before the end of May. In the autumn, pasture is left for the sheep to eat 

**Dr.**
Sheepshanks.

North America. It is said to attain to a length of 30 in. and a weight of 15 lb. Its food consists of shellfish, which it detaches with its incisors from the base to which they are fixed, crushing them with its powerful molars. It may be distinguished from other allied species by seven or eight dark cross-bands traversing the body, by a recumbent spine in the dorsal fin, by twelve spines and as many rays of the dorsal and ten rays of the anal fin, and by forty-six scales along the lateral line. The term "sheephead" is also given in some parts of North America to a freshwater sciaenoid, *Cortina obscura*, which is much less esteemed for the table.

Sheerness, a garrison town and naval seaport in the Faversham parliamentary division of Kent, England, in the Isle of Sheppey, on the right bank of the Medway estuary at its junction with the Thames, 53 m. E. of London by the South-Eastern & Chatham railway. Pop. of urban district (1901) 18,179. Blue Town, the older part of the town, with the dockyard, is defended by strong modern-built fortifications, especially the forts of Garrison Point and Barton's Point, commanding the entrance of both the Thames and the Medway. The dockyard, chiefly used for naval repairs, covers about 60 acres, and consists of three basins and large docks, the depth of water in the basins ranging down to 26 ft. Within the yard there are extensive naval stores and barracks. Outside the dockyard are the residences of the admiral of the home fleet and other officers, and barracks. The harbour is spacious, sheltered, and deep even at low water. Sheerness has some trade in corn and seed, and there is steamboat connexion with Port Victoria, on the opposite side of the Medway; with Southend, on the opposite side of the Thames; and with Chatham and London, and the town is in some favour as a seaside resort. A small fort was built at Sheerness by Charles II., which, on the 10th of July 1667, was taken by the Dutch fleet under De Ruyter.

Sheet, an expanse or surface, flat and thin, of various materials; a rope attached to a sail. These two apparently widely separated meanings are to be explained by the generally received etymology. In O. Eng. there are three words, all from the root seen in "shoo," to dart, let fly, thrust forward; *scate* or *scicle*, a sheet of cloth, *scot* or *corner* or fold of a garment, projecting angles, region (e.g. *sæs scæl*, portion of the sea, gulf, bay), and *scetla*, foot of a sail, *pes veli* (Wright, *Glass*). The original meaning, according to Skeat, is "projection," or that which shoots out, then a corner, especially of a garment or of a cloth; after which it was extended to mean a whole cloth or "sheet." In Icelandic, the cognate word *skóull* has much the same meanings, including that of a rope attached to a sail. Other cognate forms in Teutonic languages are Ger. *Schoss*, lap, bosom, properly fold of a garment, Dutch *schoot*, Icel. *skaut*, &c. In current English usage, "sheet" is commonly applied to any flat, thin surface, such as a sheet of paper, a sheet of metal, or, in a transferred application, to an expanse of water, ice, fire, &c. More specifically it is used of a rectangular piece of linen or cotton used as that part of the usual bed cloth which lies next the body. In nautical usage the term "sheet" is applied to a rope or chain attached to the lower corners of a sail for the purpose of extension or change of direction (see Rigging). The connexion in derivation with "shoot" is clearly seen in "sheet-anchor," earlier "shoot-anchor"—one that is kept in reserve, to be "shot" in case of emergency (see Anchors).

Sheffield, John Baker Holroyd, 1st Earl of (1735–1821), English politician, came of a Yorkshire family, a branch of which had settled in Ireland. He inherited considerable wealth, and in 1760 bought Sheffield Place in Sussex from Lord de la Warr. Having served in the army, he entered the House of Commons in 1768, and in that year was prominent against Lord George Gordon and the rioters. In 1783 he was created an Irish peer as Baron Sheffield of Roscommon, a barony of the United Kingdom (Sheffield of Sheffield, Yorks) being added in 1802. In 1816 he was created Viscount Pevensey and earl of Sheffield. He was a great authority on farming, and in 1803 he was made president of the Board of Agriculture; but he is chiefly remembered as the friend of Gibbon (q.v.), whose works he afterwards edited. His son and grandson succeeded him, and the latter (1812–1890) being a well-known patron of cricket, at whose death the earldom became extinct. The Irish barony, however, under a special remainder, passed to the 4th baron Stanley of Alderley, who thus became Baron Sheffield of Roscommon.

Sheffield, a city, and municipal, county and parliamen- tary borough in the West Riding of Yorkshire, England, 158 m. N.N.W. from London. Pop. (1901) 409,070. It is served by the Midland, Great Central and Great Northern railways, and has direct connexion with all the principal lines in the north of England. The principal streets are (St. John's Central) and Midland. Sheffield is situated on hilly ground in the extreme south of the county, and at the junction of several streams with the river Don, the principal of which are the Sheaf, the Porter, the Rivellin and the Loxley. The manufacturing quarter lies mainly in the Don valley, while the chief residential suburbs extend up the picturesque hills to the south. The centre of the city, with the majority of the public buildings, lies on the slope south of the Don, and here are several handsome thorough- fares. The older portions were somewhat irregular and over- crowded, but a great number of improvements were effected under an act of 1875, and have been steadily continued. There is an extensive system of tramways, serving the outlying townships. The parish church of St Peter is a cruciform building, mainly Perpendicular. The original Norman building is supposed
to have been burned during the wars of Edward III. with the barons, and the most ancient existing part is the tower, dating from the 14th century. A restoration in 1886, when transepts and a W. front were added, improved the church by detaching it from the Shrewsbury University buildings. There are a number of interesting mural monuments; and the Shrewsbury chapel contains a fine tomb of the 4th earl of Shrewsbury, who founded it in the 16th century. Of the principal public buildings, the town hall was opened by Queen Victoria in 1897. It is a fine building in the style of the Renaissance, surmounted by a lofty tower, which is crowned by an emblematic statue in bronze. The Cutlers' hall was built in 1832 and enlarged in 1857 by the addition of a magnificent banqueting hall. The handsomë corn exchange, in Tudor style, and the market hall were acquired from the duke of Norfolk by the corporation. Among several theatres the Theatre Royal was originally erected in 1793. Others are the Alexandra, Lyceum and Alhambra. There are extensive barracks. Literary and social institutions include the Athenaeum (1847), with news-room and library; the literary and philosophical society (1822), the Sheffield club (1862), the Sheffield library, founded in 1777, and the free library (1856), with several branches. The public museum and the Mappin art gallery are situated in Weston Park; and in Meersbrook Hall is the fine Ruskin museum, containing Ruskin's art, mineralogical, natural history, and botanical collections, and some original drawings and valuable books. These are in the custody of the corporation. Beyond St Peter's church relics of antiquity are few, but there remains a part of the manor-house of Hallam, dating from the 16th century. In the S. of the city is Broom Hall, a fine ancient half-timbered building.

The educational establishments are important. University College, constituted by that title in 1897, was founded in 1879 as the Firth College by Mark Firth (1819-1880), an eminent steel-manufacturer. This institution was enlarged in 1897, and comprises both the college and the Technical college (1882), occupying the buildings of the former grammar school, and equipped with metallurgical laboratories, steel works, iron foundry, a machine and fitting shop, &c.; and a medical school, together with a school of pharmacy. In 1903 the foundation was laid of a building, at Western Bank, to contain the departments of medicine, arts, pure science, commerce, &c. When the college became dissociated in 1904 from the Victoria University, Manchester, of which it had formed a constituent, the necessary financial and other preparations were taken in hand to enable the corporation to form a separate and self-sustained institution, which was opened as such by King Edward VII. Other educational institutions are the free writing school (1715, rebuilt in 1827), the boys' charity school (founded 1760), the girls' charity school (1780), the Church of England educational institute, the Roman Catholic reformatory (1861), the Wesley College, associated with London University, Ranmoor College of the Methodist New Connexion, the mechanics' institute, and the school of art.

Among numerous medical or benevolent institutions may be mentioned the general infirmary, opened in 1797; the public hospital, erected in 1858 in connexion with the Sheffield medical school established in 1792; the school and manufactory for the blind, 1879, and the South Yorkshire lunatic asylum, 1872. Among many charities founded by citizens the most noteworthy is the Shrewsbury hospital for twenty men and twenty women, originally founded by the 7th earl of Shrewsbury (d. 1616), but greatly enlarged by successive benefactions.

Among public monuments are the statue of Queen Victoria before the town hall; the statue to James Montgomery the poet (1771-1854), chiefly erected by the Sunday school teachers of Sheffield; the monument in Weston Park to Ebenesor Elliot (1781-1849), known as the Corn Law rhymr; the column to Godfrey Sykes the artist (1852-1866); the monument to those who died during an outbreak of cholera in 1832; and the monument to the natives of Sheffield who fell in the Crimean War. Sir Francis Chantry, the eminent sculptor, was born (1781) and died (1842) near Norton in Derbyshire, in the neighbourhood of Sheffield, which was the scene of his earlier work.

Sheffield is well supplied with parks and public grounds. In the western suburbs is Weston Park, occupying the grounds of Weston Hall purchased by the corporation in 1873. The Firth Park, of 36 acres, on the N.E. of the city, was opened in 1874 by Mark Firth, and was opened in 1875 by King Edward VII. and Queen Alexandra when prince and princess of Wales. There are botanical gardens of 18 acres in the western suburbs. A park and other recreation grounds have been presented by the duke of Norfolk as lord of the manor. To the N.W., towards Penistone, is Wharncliff, retaining much of the characteristics of an ancient forest, and overlooking the valley of the Don from bold rocky terraces and ridges. The Bramall Lane cricket ground in Sheffield is used for the great annual match by the three county cricket matches. The prosperity of Sheffield is chiefly dependent on the manufacture of steel. The smelting of iron in the district is supposed to date from Roman times, and there is distinct proof carrying it back as far as the Norman Conquest. The town had become famed for its cutlery by the 14th century, as is shown by allusions in Chaucer. There was an important trade carried on in knives in the reign of Elizabeth, and the Cutlers' Company was incorporated in 1624. Sheffield steel was introduced for the first time (1740) by Benjamin Huntsman of Handsworth, introduced the manufacture of cast steel, and Sheffield retains its supremacy in steel manufacture, besides being the chief centre of the manufacture of surgical instruments, &c. The manufacture of steel is still made in Sheffield. The heavy branch of the steel manufacture includes armour plates, rails, tyres, axles, large castings for engines, steel shot, and steel for rifles. The cutlery trade embraces almost every variety of instrument and tool—sawing and springing knives, razors, scissors, surgical instruments, mathematical instruments, edge tools, files, saws, scythes, sickles, spades, shovels, engineering tools, hammers, vices, &c. The manufacture of engines and machinery is also largely carried on, as well as that of stoves and grates. The art of silver plating was introduced by Thomas Bolsover in 1742, and specimens of early Sheffield plate are highly prized. Among the other industries of the town are tan-netting, confectionery, cabinet-making, bicycle-making, iron and brass founding, silver refining, the manufacture of brushes, combs, optical instruments, horse-hair cloth, and railway fittings, and testing. The Cutlers' Company (1624) exercises, by acts of 1883-1888, jurisdiction in all matters relating to the registration of trade marks, over all goods composed in whole or in part of any metal, wrought or unwrought, as also over all marks of Metal or steel personal to the Corporation, and within 6 m. thereof. There are numerous collieries in the neighbourhood.

Sheffield is the seat of a suffragan bishop in the diocese of York. The town trust for the administration of property belonging to the town's estates, and composed of the town council and a number of aldermen, was by an act of 1832 confirmed and further regulated. The manner of election of the "town trustees" was definitely settled by a decree of the Court of Chancery. Additional powers were conferred by an act of 1883, by which the committee of the first returned members to parliament in 1832. In 1885 the representation was increased from two to five members, the parliamentary divisions being Attercliffe, Brightside, Central, Ecclesall and Hallam. The county borough was created in 1888, and in 1893 the town became a city. The corporation consists of a lord mayor (the title was conferred on the chief magistrate in 1897), 16 aldermen, and 48 councillors. Area, 23,662 acres.

At the time of the Domesday Survey the four manors of Grimesthorpe, Hallam, Attercliffe and Sheffield (Escafele) made up the township of the same name. Of the four manors, Hallam was the most important, being the place where Earl Walthere, the Saxon lord of the manors, had his court. After the Conquest the earl was allowed to retain his possessions, and when he was executed for treason they passed to his widow Judith, niece of William the Conqueror, of whom Roger de Busli was holding Hallam with the three less important manors at the time of the Domesday Survey. From him the manors passed to the family of de Lovetot, but in the reign of Henry II., William de Lovetot, the 2nd lord, died without male issue, and his property passed to the monks of Exeter, who held it until the Dissolution. By the end of the 14th century Sheffield had become more important than Hallam, partly no doubt on account of the castle which one of the Furnivals had built here. Thomas de Furnival, great-grandson of Gerard and Maud, in 1296 obtained a grant of a market every Tuesday and a fair every year on the
SHEFFIELD PLATE—SHEIKH

eve, day and morrow of Holy Trinity, and in the following year he gave the inhabitants a charter granting them the privileges of holding the town at a fee-farm rent of £5, 8s. 9d. yearly, of having a court baron held every three weeks, and of freedom from toll throughout the whole of Hallamshire. From the Furnivals the manor passed by marriage to John Talbot, after wards earl of Shrewsbury, whose descendant the 6th earl was entrusted with the care of the magnificent portraits which hang in the town hall in Sheffield. In the reign of Edward VI. the property belonging to the town which had been amalgamated with other land left to the burgesses in trust for certain charitable uses was forfeited to the crown under the act for the suppression of colleges and chantries, but on their petition it was restored in 1554 by Queen Mary, who at the same time incorporated the town under the government of twelve capital burgesses.

See Victoria County History, Yorkshire: Joseph Hunter, Hallamshire: the history and topography of the parish of Sheffield (1860).

SHEFFIELD PLATE, the name applied to a variety of articles of domestic use or ornament, made of copper coated with silver by a special and now abandoned process. Many of them were actually manufactured in Birmingham, but as the secret of producing the material was discovered and brought to perfection in Sheffield, the name of that town was naturally connected with it, and thence transferred to articles constructed from it.

In 1742 a workman named Thomas Bolsover was mending the handle of a knife made of silver and copper, when, accidentally overheating it, he caused the metals to fuse and find that as a consequence the silver adhered to the copper as a thin coating. Being an intelligent man, he perceived the commercial value of this chance discovery, and began the manufacture of articles which, with all the appearance of silver, were both cheaper and stronger than those made of the pure metal.

He apparently, however, confined himself to applying the silver direct to the surface of the copper after the latter had been given the shape destined to it, and was thus limited to the production of small articles such as snuff-boxes, knife handles, toilet articles, &c. It was reserved to Joseph Hancock to realize that by making the plate first and working it into the desired form afterwards he could almost indefinitely extend the possibilities of the material. The process in its final and highest development was as follows. The groundwork was a mixture of copper and brass, either metal alone having serious defects. This was cast into an oblong ingot, 1 to 1½ in. in thickness, 2½ in. in breadth, and of a length regulated by the size of the plate desired. The surface of this was brought by planing, grinding and other means to the highest possible pitch of smoothness and evenness. A sheet of silver of a finer quality than standard, ranging in thickness from ¼ in. to nearly 1 in. according to the quality aimed at, and of the same superficial extent as the copper bar, was levelled and polished in the same way and accurately fitted to it, neither surface at any time being soiled by contact with the workman’s fingers. A sheet of copper, rather smaller than the other two and ¼ in. thick was laid upon the silver, and on the top of all was added a piece of iron, ¼ in. thick, 1 in. wide, and a little shorter than the three others, to protect them from the direct contact of the strong iron wire which was to be used to roll them. The finished compound was put into the furnace and the edges of the silver and copper-blend was treated with a flux of borax and the whole was submitted to the heat of a furnace until the silver was seen to be melting, when it was instantaneously removed, care being taken to avoid pressing upon the upper or lower surfaces, as the liquid silver in that case would have been squeezed out from between the two enclosing plates and the operation ruined. It was then left to cool, and after being thoroughly cleansed presented the appearance of a copper ingot with one silver side. This was passed again and again between gradually approximated rollers, with occasional annealing, until the desired thickness had been attained. The great extension of surface thus produced had the drawback of exaggerating any small defect in the union of the two metals, increasing it to a blister of an inch or more in diameter. It was, however, fortunately found easy to remedy this. The blister if unbroken was heated, pricked, and then rubbed level with a burnisher; if, as sometimes happened, the silver had flaked away it was replaced by coatings of pure leaf silver rubbed in with a burnisher. The plate when passed as flawless was cut into the desired form and moulded as far as possible into shape, the edges where necessary being soldered. At first only one surface of the copper was plated with silver, and thus its usefulness was necessarily restricted, but it was a simple matter to apply the silver to both sides and thenceforward whatever was made in solid metal could be reproduced in plate, and firm after firm went into the business, ever and anon introducing further improvements. The possibility of embossing the metal beyond a certain point without fracturing the coating of silver was got over by casting or stamping the raised ornament in silver, filling the hollows with a form of pewter and soldering the result to the appropriate part of the general design. Another difficulty, the concealment of the inner core of copper which was seen as a thinned line when a cut edge was exposed, was met about 1784 by George Cadman, who adopted the practice of soldering on an edging, generally ornamented, of solid silver so as to cover the junction, and the presence of this is one of the trustworthy tests by which genuine Sheffield plate may be recognized.

The labour of rolling the metal by hand was done away with about 1760, by the firm of Tudor, Leader & Sherburn, who first employed horse-power, and for more than half a century the trade both in Sheffield and Birmingham continued to flourish. In 1736 there were under 10,000 inhabitants in the former city; in 1760 when Horace Walpole passed through rapidly for the purpose of examining the plate of local origin, he thought it “quite pretty,” and pronouncing it to be “one of the foulest towns in England,” there were two-and-twenty thousand who remitted eleven thousand pounds a week to London. It would be impossible, were it desirable, to enumerate all the varieties of the articles turned out, or to overpraise the beauty and elegance of most of them. The designs were identical with those in favour with the gold- and silver-smiths of the period, which was happily one when exceptionally good taste prevailed. The appreciation of light and well-proportioned curves and the skillful employment of well-contrived pierced work are conspicuous features.

The success was, however, doomed to be short lived and to come to an end as swiftly as it had grown up. In the year 1800 W. Cruikshank was already experimenting with a process of electro-plating, and in 1837 Mr Spencer in England, and in 1838 Professor M. H. Jacobi (1801-1874) in Russia, working independently, succeeded in contriving methods which could be made commercially profitable. Two years later Messrs Elkington in London and M. de Ruolz of Paris started in business on those lines, and the Sheffield plate rapidly fell into disuse, and the costly manufacture at Sheffield and Birmingham was thus utterly died out.

Of recent years old Sheffield plate after long neglect has come into fashion again, and genuine articles in good condition have greatly gone up in value, often exceeding in cost those of more modern date in sterling silver. Concurrently fraudulent imitation has regrettably increased. In some cases the whole object is a modern reproduction in electro-plate, but more often really old articles from which the original plating has been worn off in course of time have been replaced, both equally being in the eyes of the connoisseur, unworthy of serious attention and comparatively valueless. The difference after a little experience is not difficult to detect, though inexplicable in words. The pressure to which the Sheffield plate was submitted produces a definite colour and texture which is absent from the surface produced by the deposit of silver in a liquid medium by electrical means, and the coat of silver is spread by the latter uniformly over the whole surface without a break, while in the former the junction between the embossed ornaments and the silver strips covering the cut edges may often be detected on careful examination.

See Sheffield Plate by Bertie Wyllie; H. N. Veitch, Sheffield Plate: its history, manufacture and application (M. Be.)

SHEIKH, or SHAikh, an Arabic title of respect. Strictly it means a venerable man, of more than fifty years of age. It is specially borne by heads of religious orders, chiefs of
tribes and headmen of villages. Every village, however small, every separate quarter of a town, has a sheikh in whom is lodged the executive power of government—a power loosely defined, and of more or less extent according to the personal character and means of the individual who wields it. A village sheikh is a sort of head magistrate and chief of police. The Koran, the sole authentic authority in all matters, legal or civil, never accurately distinguished between the sheikh and the cadî (q.v.), and its phrases, besides, are vague and capable of admitting different and even opposite interpretations. (For the Sheikh al-Islam see MURR.)

RICHARD LEIL LALOR (1791-1821), Irish politician and writer, was born at Drumdowney, Tipperary, on the 17th of August 1791. His father, Edward Shell, had acquired considerable wealth in Spain, and owned an estate in Tipperary. The son was taught French and Latin by the Abbé de Grimau, a French refugee. He was then sent to a school in Kensington, London, presided over by another émigré, M. de Broglie. In October 1804 he was removed to Stonyhurst college, Lancashire, and in November 1807 entered Trinity College, Dublin, where he specially distinguished himself in the debates of the Historical Society. After taking his degree in 1811 he entered Lincoln's Inn, and was admitted to the Irish bar in 1814. His play of _Adelaie, or the Emigrants_, was played at the Crow Street theatre, Dublin, on the 19th of February 1824, with complete success, and on the 23rd of May 1816 it was performed at Covent Garden. The _Apology_, produced at the latter theatre on the 3rd of May 1817, firmly established his reputation as a dramatist. His principal other plays are _Ballamira_ (written in 1818), _Exodane_ (1810), _Huguenot_, produced in 1822, and _Montini_ (1820). In 1822 he began, along with W. H. Curran, to contribute to the _New Monthly Magazine_ a series of graphic and racy papers entitled _Sketches of the Irish flora_. These were edited by M. W. Savage in 1855 in two volumes, under the title of _Sketches Legal and Political_. Shell was one of the principal founders of the Catholic Association in 1823 and drew up the petition for inquiry into the mode of administering the laws in Ireland, which was presented in that year to both Houses of Parliament. In 1825 Shell accompanied O'Connell to London to protest against the suppression of the Catholic Association. The protest was unsuccessful, but, although nominally dissolved, the association continued its propaganda after the defeat of the Catholic Relief Bill in 1825; and Shell was one of O'Connell's leading supporters in the agitation persistently carried on till Catholic emancipation was granted in 1829. In the same year he was returned to Parliament for Milborne Port, and in 1831 for Louth. He took a prominent part in all the debates relating to Ireland, and although he was greater as a platform orator than as a debater, he gradually won the somewhat reluctant admiration of the House. In August 1839 he became vice-president of the board of trade in Lord Melbourne's ministry. After the accession of Lord John Russell to power in 1846 he was appointed master of the mint, and in 1850 he was appointed minister at the court of Tuscany. He died at Florence on the 23rd of May 1854.

See Memoirs of Richard Lalor Shell, by W. Torrens M'Cullagh (2 vols., 1855). His _Speeches_ were edited in 1845 by Thomas McNevin.

SHEKEL (from Heb. _shakol_, to weigh), originally a Jewish unit of weight (₁₉ of a mina, and ₁₃ of a talent) and afterwards a coin of the same weight. The Biblical references to shekels must refer to uncoined ingots. In the time of Josephus it seems that the _light_ shekel weighed from 210 to 210.55 grains; the _heavy_ shekel was twice that amount, which is practically identical with the Phoenician weight (224.4 grains). It corresponded to 1 s. 3d. and 2s. 9d. respectively in English silver. Jewish shekels were first coined by Simon the Hasmonaeus, probably in 139-138 B.C. These bear inscriptions in the archaic Hebrew and various emblems, such as the cup or chalice, the lily branch with three flowers, the candlestick, the citron and palm branch and so forth. They never bear the portraits of rulers or figures of animals. A later series of shekels, belonging to the Roman period, are tetradrachms, "which came from the mints of Caesarea and Antioch and were used as blanks on which to impress Jewish types." Hence in Matt. xvi. 24 the temple tax of half a shekel is called a dirachm (2 drams). In 2 Samuel xiv. 26 we read of "shekels after the King's weight." The royal norm was heavier than the common norm. The Hebrews divided the shekel into 20 parts, each of which was called a _gerah_. (See also NUMISMATICS.)

_SHEKINAH_, a Hebrew word meaning "that which dwells" or "the dwelling." It is one of the expressions used in the Targums in place of "God." In the Targums.—The word "Shekinah" is of constant occurrence in the Targums or Aramaic paraphrases of the Biblical lections that were read in the synagogue-service to the people. Great care was taken by the scribes in these renderings to mitigate the anthropomorphic expressions applied to God in the Scriptures, and by paraphrase, the use of abstract terms and indirect phraseology, to prevent such expressions from giving rise to the idea of God's "personal" majesty. Indeed, the popular mind. Whenever, e.g., any indication of local limitation or action was implied or expressed, in the Hebrew text, of God the Targumists were careful to substitute some expression involving the use of "Shekinah." In these connections "Shekinah" thus becomes the equivalent of "God" or its synonyms. One or two examples will make the Targum-usage clear. Thus Ex. xxix. 45 ("and I will dwell among the children of Israel and will be their God") is rendered in the Targum (Onkelos): "And I will cause my Shekinah to dwell in the midst of the children of Israel, and I will be their God." All expressions implying God's "local" presence are similarly rendered: thus e.g. Habak. ii. 20 ("Jehovah is in his holy temple") is rendered "Jehovah was pleased to cause His Shekinah to dwell," etc. To see "God" is similarly paraphrased. Thus Is. xxxii. 17 ("thine eyes shall see the King in His beauty") is rendered (Targum of Jonathan): "Thine eyes shall see the Shekinah of the king of the worlds in His beauty." So too "hiding the face" when used of God is regularly paraphrased "remove His Shekinah" (Is. lvii. 17, viii. 17, lxx. 2; Jer. xxxiii. 5; cf. Is. i. 15, &c.).

Closely connected with the idea of the Shekinah, but distinct from it, is "the glory of the Lord," "the Shekinah," "the apparel," etc. In this connexion it was conceived of as a property of the Shekinah (as, in fact, it is of God for whom "Shekinah" is the equivalent). For the divine "glory" as a property of the Shekinah, cf. e.g. Is. vi. 5 ("mine eyes have seen the King, the Lord of hosts"). which is rendered in the Targum: "mine eyes have seen the glory of the Shekinah of the King of the worlds the Lord of hosts." In the New Testament.—In the New Testament both the term and the idea are referred to in various ways. The close association of the divine "glory" with the visible Shekinah has already been referred to. This Shekinah-glory is several times designated in the New Testament by δόξα. The most notable passage is Rom. i. 4 where St Paul, enumerating the list of Israel's privileges, says: "whose is the adoption, and the glory" (i.e. the Shekinah-glory, the visible presence of God among His people), &c. cf. Luke ii. 9. There is also an obvious allusion to the Shekinah in the description of the theophanic cloud of the transfiguration narrative (St. Matt. xvii. 5: "a bright cloud overshadowed them, and behold a voice out of the cloud, saying" &c.; cf. St Mark ix. 7; St Luke ix. 34), the same verb being used as in the LXX. of Exod. xi. 34, 35, of the cloud which rested on the tabernacle when it was filled with the glory. Indeed.

There can be no doubt, too, that the word rendered "tabernacle" (σκηνή) with the corresponding verb "to tabernacle" (σκηνοθείμαι) has been chosen for use in St John i. 14 and Rev. xii. 3, from its likeness both in sound and meaning to the term "Shekinah." The passage in Revelation runs: "Behold the tabernacle (σκηνή) of God is with men, and He will tabernacle (σκηνοθείμαι) with them." In St John i. 14 there is an allusion to the Word (=memra) of the Targums, the Shekinah, and the Shekinah-glory,
all of which the writer declares became incarnate in Jesus. Cf. also Heb. i. 3 ("effulgence of the [Shekinah] glory").

In Talmud and Midrash.—It is remarkable that the memra (=Logos or "Word") of the Targums almost entirely disappears in the Midrashic literature and the Talmud, its place being taken by Shekinah. The Rabbis apparently dreaded the possibility of such terms being assimilated into personal entities distinct from God. Against this they emphasized the Shekinah-idea. It is safe to say that wherever Shekinah is mentioned in Rabbinc literature it is God’s direct action or activity that is thought of. Independent personality is never imputed to it.1 It is probable that the use of the term was often in Rabbinc writings polemical (against Jewish Christians or gnostic sects).

SHELBY, ISAAC (1750-1826), American soldier and pioneer, was born at North Mountain, near Hagerstown, Maryland, on the 11th of December 1750. With his father, Evan Shelby (1720-1794), an emigrant from Wales, he removed to what is now Bristol, Tennessee, in 1771, and in 1774 took a conspicuous part in the battle of Point Pleasant.2 He was a surveyor in Kentucky for the Transylvania Company in 1775; became a captain of Virginia minute-men in 1776, and in 1777 became commissary with supervision over transportation of supplies from Staunton, Virginia, to the frontier. In 1779 he was elected to the House of Delegates, but by the Age of Eippey. Until 1813 he commanded twelve Kentucky regiments at the battle of the Thames, and for his services received the thanks of Congress and a gold medal. In 1818 he was a commissioner with Andrew Jackson to the Chickasaws. He died on his estate in Lincoln county, Kentucky, on the 18th of July 1826.

SHELBVILLA, a city and the county-seat of Shelby county, Indiana, U.S.A., about 27 m. S.E. of Indianapolis, on the Big Blue river. Pop. (1890) 5451; (1900) 7160, including 326 foreign-born; (1890) 16,643. There are many industries: linen, cotton, and woolen mills; boat yards; wool and flour mills; a large railway station; and a large market. The city also has a public library, a hospital, and a children’s home. The city is a trading centre for the surrounding farming region; among its manufactures furniture is the most important. Shelbyville, named in honour of General Isaac Shelby of Kentucky, was platted in 1822, incorporated as a town in 1850, and chartered as a city in 1860.

SHELDRAKE, or, as commonly spelled in its contracted form, Sheldrake, a word whose derivation1 has been much discussed, one of the most conspicuous birds of the duck tribe, Anatidae, called, however, in many parts of England the "Burrow-Duck" and in some districts by the almost obsolete name of "Bergander" (Du. Berg-ende, Ger. Bergente), a word used by Turner in 1544.

The sheldrake is the Anas tadorina4 of Linnaeus, and the Tagomodora of modern ornithology, a bird somewhat larger and of more upright stature than an ordinary duck, having its bill, with a basal fleshy protuberance (whence the specific term cornuta), pale red, the head and upper neck very dark glossy green, and beneath that a broad white collar, succeeded by a still broader belt of bright bay extending from the upper back across the upper breast. The outer scapulars, the primaries, a median abdominal stripe, which dilates at the vent, and a bar at the tip of the middle tail-quills are black; the inner secondaries and the lower tail-coverts are grey; and the speculum or wing-spot is rich bronzed-green. The rest of the plumage is pure white, and the legs are flesh-coloured. There is little external difference between the sexes, the female being only somewhat smaller and less brightly coloured. The sheldrake frequents the sandy coasts of nearly the whole of Europe and North Africa, extending across Asia to India, China and Japan, generally keeping in pairs and sometimes penetrating to favourable inland localities. The nest is always made under cover, usually in a rabbit-hole among sandhills, and in the Frisian Islands the people supply this bird with artificial burrows, taking large toll of it in eggs and ducks.

T. radjah of Australia, Papuasia and the Moluccas almost equals the true sheldrake in its brightly contrasted plumage, but the head is white in both sexes. Barbary, southern-Europe, and Central Asia are inhabited by an allied species of more inland range and very different coloration, the T. casarea or Casarea rutula of ornithologists, the ruddy sheldrake of English authors—for it has several times strayed to the British Islands—and the "Brahminy Duck" of Anglo-Indians, who find it resorting in winter, whether by pairs or by thousands, to their inland waters. This species is of an almost uniform bay colour all over, except the quill-feathers of the wings and tail, and (in the male) a ring round the neck, which are black, while the wing-coverts are white and the speculum shines with green and purple; the bill and legs are dark-coloured.4 A species closely resembling the last, but with a grey head, C. cana, inhabits South Africa. In Australia occurs another species of more sombre colours, the C. tadoronoides; and New Zealand is the home of another species, C. variegata, still less distinguished by bright hues. In the last two the plumage of the sexes differs not inconceivably.

The males will, if attention be paid to their wants, breed freely in captivity, crossing if opportunity be given them with other species, and an incident therewith connected possesses an importance hardly to be overrated by the philosophical naturalist. In the Zoological Society’s gardens in London in the spring of 1859 a male of T. cornuta mated with a female of C. cana, and, as will have been inferred from what has been before stated, these two species differ greatly in the colouring of their plumage.

The young of their union, however, presented an appearance wholly unlike that of either parent, and an appearance which can hardly be said, as has been said (P.Z.S., 1859, p. 442), to be "a mixture of both parents." Both sexes of this hybrid have been admirably portrayed by J. Wolf; and, strange to say, when these figures are compared with equally faithful portraits by the same master of the Australian and New Zealand species, C. tadoronoides and C. variegata, it will at once be seen that the hybrids present an appearance almost midway between that of the parents.5

4 Jordon (B. India, iii. 793) tells of a Hindu belief that once upon a time two lovers were transformed into birds of this species, and that they or their descendants are condemned to pass the night on the opposite banks of a river, whence they unceasingly call to one another: "Chakwa, shall I come?" "No, Chakwi." "Chakwi, shall I come?" "No, Chakwa." As to how, in these circumstances, the race is perpetuated the legend is silent.
between the two species last named—species which certainly had nothing to do with their production.1

The genera Todorna and Casarca, as shown by the tracheal characters and coloration, are most nearly related to Chenolepis, containing the third so well known as the Egyptian goose, C. aegyptiaca, and an allied species, C. jubata, from South America. For the same reason the genus Plectropterus, composed of the spur-winged geese of Africa, and perhaps the Australian Anseranas and the Indian and Ethiopian Sarcidionus, also appear to belong to the same group, which should be reckoned rather to the Anatine than to the Anserine section of the Anatidae. (A. N.)

SHELLEY, CHARLES MONROE (1857— ), American Congregational clergyman, was born in Wellsville, New York, on the 26th of February 1857. Graduating at Brown University in 1885 and at Andover Theological Seminary in 1886, he was pastor at Wellington, Massachusetts, in 1886-1888, and in 1889 became pastor of the Central Congregational Church of Topeka, Kansas. He is well known as the author of a number of widely read books of fiction, which at the same time inculcate an uncompromising obedience to the precepts of the Gospel in everyday life. Of these, In His Steps (1890), though not the earliest, is perhaps the best, and it is this one which first brought him into prominence.

SHELLEY, GILBERT (1566—1677), archbishop of Canterbury, was born at Stanstede in the parish of Ellastone, Staffordshire, and educated at Oxford. He was ordained in 1622 and was appointed chaplain to Thomas Lord Coventry (1578—1649). Four years later he was elected warden of All Souls' College, Oxford. During the years 1632—1639 he received the livings of Hackney (1635); Oddington, Oxfordshire; Ickford, Buckinghamshire (1636); and Newington, Oxfordshire; besides being a prebendary of Gloucester from 1632. In 1638 he was on a commission appointed to visit Merton College, Oxford. He was intimate with the Royalist leaders, participated in the negotiations for the surrender of Oxford, and collected funds for the King. In 1643 he was appointed chaplain of Felbridge, in order of parliament, and imprisoned for some months, but he regained the wardenship in 1659. In 1660 he became bishop of London and master of the Savoy, and the Savoy Conference was held at his lodgings. He was consecrated archbishop of Canterbury in 1663. He was greatly interested in the welfare of Oxford University, of which he became chancellor in 1667, succeeding Clarendon (1600—1674). The Sheldonian theatre at Oxford was built and endowed at his expense.

SHELF (O. Eng. shell, shield, cf. D. schel, shell, Goth. skæls, tile; the word was used for thin flake, cf. Swed. skal, to peel off; it is allied to “sable” and “skill,” from a root meaning to cleave, divide, separate), the hard outside natural covering of anything, as of some fruits and seeds; more particularly, the conch (q.v.) or integument which acts as a defence for the bodies of various animals (see Mollusca, Gastropoda, Malacostraca, &c.), the test, crust or carapace; also the outer covering of an egg. The word is also used of many objects resembling the natural shell in use or shape, and especially of a hollow projectile filled with explosives (see Ammunition, § Shell, and Ordinance).

See also Shell-heaps, Shell-money.

SHELLEY, MARY WOLLSTONECRAFT (1759—1815), English writer, only daughter of William Godwin and his wife Mary Wollstonecraft, and second wife of the poet Percy Bysshe Shelley, was born in London on the 30th of August 1759. For the history of her girlhood and of her married life see Godwin, William, and Shelley, P.B. When she was in Switzerland with Shelley and Byron in 1816 a proposal was made that various members of the party should write a romance or tale dealing with the supernatural. The result of this project was that Mrs Shelley wrote Frankenstein, Byron the beginning of a narrative about a vampyre, and Dr Poldiory, Byron’s physician, a tale named The Vampyre, the authorship of which used frequently

in past years to be attributed to Byron himself. Frankenstein, published in 1818, when Mrs Shelley was at the utmost twenty-one years old, is a very remarkable performance for so young and inexperienced a writer; its main idea is that of the combination of vital and life-giving principle in the recesses of nature, of an adult man, who, entering the world thus under unnatural conditions, becomes the terror of his species, a half-involuntary criminal, and finally an outcast whose sole resource is self-immolation. This romance was followed by others: Valperga, or the Life and Adventures of Castruccio, Prince of Luna (1823), an historical tale written with a good deal of spirit, and readable enough even now; The Last Man (1829), a fiction of the final agonies of human society owing to the universal spread of a pestilence—this is written in a very stilted style, but possesses a particular interest because Adrian is a portrait of Shelley; The Fortunes of Perkin Warbeck (1830); Lodore (1835), also bearing partly upon Shelley’s biography, and Falkner (1837). Besides these novels there was the Journal of a Weeks’ Tour (the tour of 1814 mentioned below), which is published in conjunction with Shelley’s prose-writings; and Rambles in Germany and Italy in 1840—1842—1843 (which shows an observant spirit, capable of making some true forecasts of the future), and various miscellaneous writings. After the death of Shelley, for whom she had a deep and even enthusiastic affection, marred at times by defects of temper, Mrs Shelley in the autumn of 1823 returned to London. Shortly afterwards she married for the last time, and the only son of her second marriage. Mrs Shelley died on the 29th of November 1851.

SHELLEY, PERCY BYSSHE (1792—1822), English poet, was born on the 4th of August 1792 at Field Place, near Horsham, Sussex. He was the eldest child of Timothy Shelley (1753—1844), M.P. for Shoreham, by his wife Elizabeth, daughter of Charles Pilkford, of Effingham, Surrey. His father was the son and heir of Sir Bysshe Shelley, Bart. (d. 1815), whose baronetcy (1806) was a reward from the Whig party for political services. Sir Bysshe’s father Timothy had emigrated to America, and he himself had been born in Newark, New Jersey; but he had gone to England in 1640 and was an invaluable lessee of the Manor of Worminghurst.

The branch of the Shelley family to which the poet Percy Bysshe belonged traces its pedigree to Henry Shelley, of Worminghurst, Sussex, who died in 1623. These Worminghurste or Castle Goring Shelleys are of the same stock as the Michelgrove Shelleys, who trace up to Sir William Shelley, judge of the common pleas under Henry VII., thence to a member of parliament in 1451, and to the reign of Edward I., or even to the epoch of the Norman Conquest. The Worminghurst branch was a family of credit, but not of special distinction, until its fortunes culminated under the above-named Sir Bysshe Shelley.

In the character of Percy Bysshe Shelley three qualities became early manifest, and may be regarded as innate: impressionableness or extreme susceptibility to external and internal impulses of feeling; a lively imagination or erratic fancy, blurring a sound estimate of solid facts; and a resolute repudiation
of outer authority or the despoticm of custom. These qualities were highly developed in his earliest manhood, were active in his boyhood, and no doubt made some show even on the borderland between childhood and infancy. At the age of six he was sent to a day school at Warnham, kept by the Rev. Mr Edwards; at ten to Sion House School, Brentford, of which the principal was Dr Greenlaw, while the pupils were mostly sons of local tradesmen; at twelve (or immediately before that age, on the 29th of July 1804) to Eton. The headmaster of Eton, up to nearly the close of Shelley's sojourn in the school, was Dr Goodall, a mild disciplinarian; it is therefore a mistake to suppose that Percy (unless during his very brief stay in the lower school) was frequently flagellated by the formidable Dr Keate, who only became headmaster after Goodall. Shelley was a shy, sensitive, mopish sort of boy from one point of view—from another a very unruly one, having his own notions of justice, independence and mental freedom; by nature gentle, kindly and retiring—under provocation dangerously violent. He resisted the odious fagging system, exerted himself little in the routine of school-learning, and was known both as "Mad Shelley" and as "Shelley the Atheist." Some writers try to show that an Eton boy would be termed atheist without exhibiting any propensity to atheism, but solely on the ground of his being mutinous. However, as Shelley was a declared atheist a good while before attaining his majority, a shrewd suspicion arises that, if Etonians dubbed him atheist, they had some relevant reason for doing so.

Shelley entered University College, Oxford, in April 1810, returned thence to Eton, and finally quitted the school at mid-summer, and commenced residence in Oxford in October. Here he met a young Durham man, Thomas Jefferson Hogg, who had preceded him in the university by a couple of months; the two youths at once struck up a warm and intimate friendship. Shelley had at this time a love for chemical experiment, as well as for poetry, philosophy, and classical study, and was in all his tastes and bearing an enthusiast. Hogg was not in the least an enthusiast, rather a cynic, but he also was a steady and well-read classical student. In religious matters both were sceptics, or indeed decided anti-Christians; whether Hogg, as the senior and more informed disputant, pioneered Shelley into strict atheism, or whether Shelley, as the more impassioned and unflinching speculator, outran the easy-going jeering Hogg, is a moot point; we incline to the latter opinion. Certain it is that each egged on the other by perpetual disquisition on abstruse subjects, conducted partly for the sake of truth and partly for that of mental exertion, without on either side any disposition to bow to authority or stop short of extreme conclusions. The upshot of this habit was that Shelley and Hogg, at the close of some five months of happy and carefree college life, got expelled from the university. Shelley—for he alone figures as the writer of the "little syllabus," although there can be no doubt that Hogg was his confidant and coadjoctor throughout—published anonymously a pamphlet or fly-sheets entitled The Necessity of Atheism, which he sent round to bishops and all sorts of people as an invitation or challenge to discussion. It amounted to saying that neither reason nor testimony is adequate to establish the existence of a deity, and that nothing short of a philosophical and logical proof that the deity would be sufficient. The college authorities heard of the pamphlet, and accordingly, as its author, and summoned him before them—"our master, and two or three of the fellows." The pamphlet was produced, and Shelley was required to say whether he had written it or not. The youth declined to answer the question, and was expelled by a written sentence, ready drawn up. Hogg was next summoned, with a result practically the same. The precise details of this transaction have been much controverted; the best evidence is that which appears on the college records, showing that both Hogg and Shelley (Hogg is there named first) were expelled for "contumaciously refusing to answer questions," and for "repeatedly declining to disavow" the authorship. Thus they were dismissed as being mutineers against academic authority, in a case pregnant with the suspicion—not the proof—of atheism; but how the authorities could know beforehand that the two undergraduates would be contumaciously and stiff against disavowal, so as to give warrant for written sentences ready drawn up, is nowhere explained. Possibly the sentences were worded without ground assigned, and would only have been produced in terraeum had the young men proved more reasonable. The date of this incident was the 6th of March 1811.

Shelley and Hogg came up to London, where Shelley was soon left alone, as his friend went to York to study convivancying. Percy and his incensed father did not at once come to terms, and for a while he had no resource beyond pocket-money saved up by his sisters (four in number altogether) and sent round to him, sometimes by the hand of a singularly pretty school-fellow, Miss Harriet Westbrook, daughter of a retired and moderately rich hotel-keeper. Shelley, in early youth, had a somewhat "griggish turn for moralizing and argumentation, and a decided mania for proselytizing; his school-girl sisters, and their little Methodist friend Miss Westbrook, aged between fifteen and sixteen, must all be enlightened and converted to anti-Christianity. He therefore cultivated the society of Harriet, calling at the house of her father, and being encouraged in his assiduity by her much older sister Eliza. Harriet not unnaturally fell in love with him; and he, though not it would seem at any time ardently in love with her, dallied along the flowery pathway which leads to sentiment and a definite courtship. This was not his first love-affair; for he had but a very few months before been courting his cousin Miss Harriet Grove, who, alarmed at his last disgust with school, and at his proposal to have her family and himself brought to the country, of which he was sojourn for a month or so.) Shelley had gone away, had by that time all suffered grief and perturbation at the time. It is averred, and seemingly with truth, that Shelley never indulged in any sensual or dissipated amour; and, as he advances in life, it becomes apparent that, though capable of the passion of love, and unusually prone to regard with much effusion of sentiment women who interested his mind and heart, the mere attraction of a pretty face or an alluring figure left him unenthralled. After a while Percy was reconciled to his father, revisited his family in Sussex, and then stayed with a cousin in Wales. Hence he was recalled to London by Miss Harriet Westbrook, who wrote complaining of her father's resolve to send her back to her school, in which she was now regarded with repulsion as having become too apt a pupil of the atheist Shelley. He replied counselling resistance. "She wrote to say" (these are the words of Shelley in a letter to Hogg, dating towards the end of July 1811) "that resistance was useless, but that she would fly with me, and threw herself upon my protection." Shelley, therefore, returned to London, where he found Harriet agitated and waverings; finally they agreed to elope, travelled in haste to Edinburgh, and there, on the 28th of August, were married with the rites of the Scottish Church. Shelley, she would understand, had by this time his griefs and perturbations had been relieved, not only by the open and openly broken, not only with the dogmas and conventions of Christian religion, but with many of the institutions of Christian polity, and in especial with such as enforce and regulate marriage; he—who with William Godwin and some other theorists—that marriage ought to be simply a voluntary relation between a man and a woman, to be assumed at joint option and terminated at the after-option of either party. If, therefore, he had acted upon his personal conviction of the right, he would never have wedsed Harriet, whether by Scotch, English or any other law; and, if such was his decision, he could understand that in such an experiment the woman's stake, and the disadvantages accruing to her, are out of all comparison with the man's. His conduct, therefore, was so far entirely honourable; and, if it derogated from a principle of his own (a principle which, however contrary to the morality of other people, was and always remained matter of genuine conviction on his individual part), this was only in deference to a higher and more imperious standard of right.

Harriet Shelley was not only beautiful; she was amiable, accommodating, adequately well educated and well bred. She liked reading, and, in fact, broke off with Hogg in a strictly frivolous. But she could not (as Shelley said at a later date) "feel poetry and understand philosophy." Her attractions were all on the surface;
there was (to use a common phrase) "nothing particular in her.""

For nearly three years Shelley and she led a shifting sort of life upon an income of £400 a year, one-half of which was allowed (after his first severance in January at the mutual estrangement was past) by Mr. Timothy Shelley, and the other half by Mr. Westbrooke. The couple left Edinburgh for York and the society of Hogg; broke with him upon a charge made by Harriet, and evidently fully believed by Shelley at the time, that, during a temporary absence of his upon business in Sussex, Hogg had tried to seduce her (this quarrel was entirely made up at the end of about a year); moved off to Keswick in Cumberland, where they received kind attentions from Southey, and some hospitality from the duke of Norfolk, who, as chief magistrate in the Shoreham region of Sussex, was at pains to reconcile the father and his too unfilial heir; sailed thence to Dublin, where Shelley was wages and in some degree romanced, in the good cause of Catholic emancipation, conjoined with repeal of the union; crossed to Wales, and lived at Nant-Gwili, near Rhayader, then at Lymmouth in Devonshire, then at Tanyrallt in Carnarvonshire. All this was between September 1811 and February 1813. At Lymmouth an Irish servant of Shelley's was sentenced to six months' imprisonment for distributing and posting up printed papers, bearing no printer's name, of an inflammatory or seditious tendency—being a Declaration of Rights composed by the youthful reformer, and some verses of his named The Devil's Walk, at Tanyrallt, named Robin Pant Evan, being irritated by some well-meant acts of Shelley in terminating the lives of dying or diseased sheep, did really combine with two other shepherds to drive the Tanyrallt Evan was the person who made out the part of "asylum." He himself avowed as much to members of a family, Greaves, who were living at Tanyrallt between 1847 and 1865. This was the break-up of the residence of the Shelleys at Tanyrallt; they revisited Ireland, and then settled for a while in London. Here, in June 1813, Harriet gave birth to her daughter Ianthe Eliza (she married a Mr. Esdaile, and died in 1876). Here also Shelley brought out his first poem of any importance, Queen Mab; it was privately printed, as its exceedingly aggressive tone in matters of religion and morals would not allow of publication. In July the Shelleys took a house at Broad Street, Watling Forest, where they had congenial neighbours, Mrs. Boinville and her family.

The speculative sage whom Shelley especially reverenced was William Godwin, the author of Political Justice and of the romance Caleb Williams; in 1796 he had married Mary Wollstonecraft, authoress of The Rights of Woman, who died shortly after giving birth, on the 30th of August 1797, to a daughter Mary. With Godwin Shelley had opened a volunteered correspondence late in 1811, and he had known him personally since the winter which closed 1812. Godwin was then a bookseller, living with his second wife, who had been a Mrs. Claremont; there were four other inmates of the household, two of whom, call for some mention here—Fanny Wollstonecraft, the daughter of the authoresses and Mr. Imlay, and Claire (Clara Mary Jane), the daughter of Mrs. Claremont. Fanny committed suicide in October 1816, being, according to some accounts which remain unverified, hopelessly in love with Shelley; Claire was closely associated with all his subsequent career. It was towards May 1814 that Shelley first saw Mary Wollstonecraft Godwin as a grown-up girl (she was well on towards seventeen); he instantly fell in love with her, and she with him. Just before this, on the 24th of March, Shelley had remarried Harriet in London, apparently with a view to strengthening his position in his relations with his father as to the family property; but, on becoming enamoured of Mary, he seems to have rapidly made up his mind that Harriet should not stand in the way. She was at Bath while he was in London. They had, however, met again in London and come to some sort of understanding before the final crisis arrived—Harriet remonstrating and indifferent, but incapable of effective resistance—Shelley sick of courtship, and bent upon gratifying his own wishes, which as we have already seen he must at odds with his avowed principles of conduct. For some months past there had been bickerings and misunderstandings between him and Harriet, aggravated by the now detested presence of Miss Westbrook in the house; more than this cannot be said, and it seems dubious whether more will be hereafter known. Shelley, and not he alone, alleged grave misdoing on Harriet's part—perhaps mistakenly. The upshot came on the 28th of July, when Shelley aided Mary to elope from her father's house, Claire Claremont deciding to accompany them. They crossed to Calais, and proceeded across France to Switzerland. Godwin and his wife were greatly incensed. Though he and Mary Wollstonecraft had entertained and avowed bold opinions regarding the marriage-bond, similar to Shelley's own, and had in their time acted upon these opinions, it is not clearly made out that Mary Godwin had ever been encouraged by paternal influence to think or do the like. Shelley and she chose to act upon their own likings and responsibility—he disregarding any claim which Harriet had upon him, and Mary setting at nought her father's authority. Both were prepared to ignore the claims of the laws, and to run the risks of love.

The three young people returned to London in September. In the following January 1815 Sir Bysahe Shelley died, and Percy, who had lately been in great money-straits, became the immediate heir to the entailed property inherited by his father Sir Timothy. This entailed property seems to have been worth £4000 per annum, or little less. There was another very much larger property which Percy might shortly before have secured to himself, contingently upon his father's death, if he would have consented to put it upon the same footing of entail; but this he resolutely refused to do, on the professed ground of his becoming a peer, and proceeded upon the system of entail. Godwin, on his grandfather's death the larger property passed wholly away from any interest which Percy might have had in it, in use or in expectancy. He now came to an understanding with his father as to the remaining entailed property; and, giving up certain future advantages, he received henceforth a regular income of £1000 a year. Out of this he assigned £200 a year to Harriet, who had given birth in November to a son, Charles Bysahe (he died in 1826). Shelley, and Mary as well, were on moderately good terms with Harriet, seeing her from time to time. His peculiar views as to the relations of the sexes appear markedly again in his having (so it is alleged) invited Harriet to return to his and Mary's house as a domicile; a curious arrangement which of course did not take effect. He had, undoubtedly, while previously abroad with Mary, invited Harriet to stay in their immediate neighbourhood. Shelley and Mary (who was naturally always called Mrs. Shelley) now settled at Bishopgate, near Windsor Forest; here he produced his first excellent poem, Alastor, or the Spirit of Solitude, which was published soon afterwards with a few others. Thomas Love Peacock was one of his principal associates at Bishopgate.

In May 1816 the pair left England for Switzerland, together with Miss Claremont, and their own infant son William. They went straight to Sécheron, near Geneva; Byron, whose separation from his wife had just then taken place, arrived there immediately afterwards. A great deal of controversy has arisen as to the
motives and incidents of this foreign sojourn. The clear fact is that Miss Clairmont, who had a fine voice and some inclination for the stage, had seen Byron, as connected with the management of Drury Lane theatre, early in the year, and an amorous intrigue had begun between them in London. Prima facie it seems quite reasonable to suppose that she had explained the facts to Shelley or to Mary, or to both, and had induced them to convey her to the society of Byron abroad; were this finally established as the fact, it would show no inconsistency of conduct, or breach of his own code of sexual morals, on Shelley's part. On the other hand, documentary evidence exists showing that Mary was totally ignorant of the amour shortly before they went abroad. Whether or not they knew of it while they and Claire were in Drury Lane theatre, is not known. Byron, by him on the shore of the Lake of Geneva, may be left unargued. The three returned to London in September 1816, Byron remaining abroad; and in January 1817 Miss Clairmont gave birth to her daughter named Allegra.

The return of the Shelles was closely followed by two suicides —first that of Fanny Wollstonecraft (already referred to), and second that of Harriet Shelley, who on the 9th of November drowned herself in the Serpentine. The body was not found until the 10th of December. The latest stages of the lovely and ill-starred Harriet's career have never been very exactly recorded. It seems that she formed a connexion with some gentleman from whom circumstances or desertion separated her, that her habits became intemperate, and that she was treated with contumelious harshness by her sister during an illness of their father. She had always had a propensity (often laughed at in earlier and happier days) to the idea of suicide, and she now carried it out in act—possibly without anything which could be regarded as an extremely cogent predisposing motive, although the total weight of her distresses, accumulating within the past two years and a half, was beyond question heavy to bear. Shelley, then at Bath, hurried up to London when he heard of Harriet's death, giving manifest signs of the shock which so terrible a catastrophe had produced on him. Some self-reproach must no doubt have mingled with his affliction and dismay; yet he does not appear to have considered himself gravely in the wrong at any stage in the transaction, and it is established that in the train of quite recent events which immediately led up to Harriet's suicide he had borne no part.

This was the time when Shelley began to see a great deal of Leigh Hunt. Hunt, the poet and artist (author of the Dreamer), they were close friends, and Hunt did something to uphold the reputation of Shelley as a poet—which, we may here say once for all, scarcely obtained any public acceptance or solidity during his brief lifetime. The death of Harriet having removed the only obstacle to a marriage with Mary Godwin, the wedding ensued on the 30th of December 1816, and the married couple settled down at Great Marlow in Buckinghamshire. Their tranquillity was shortly disturbed by a Chancery suit set in motion by Mr Westbrook, who asked for the custody of his two grand-children, on the ground that Shelley had deserted his wife and intended to bring up his offspring in his own atheistic and anti-social opinions. Lord Chancellor Eldon delivered judgment on the 27th of March 1817. He held that Shelley, having avowed condemnable principles of conduct, and having fashioned his own conduct to correspond, and being likely to inculcate the same principles upon his children, was unfit to have the charge of them. He appointed as their curator Dr Hume, an orthodox army-physician, who was Shelley's own nominee. The poet had to pay for the maintenance of the children a sum which stood eventually at £1000 a year. He was asked at the divorce of Claire, that was no more than what he had previously allowed to Harriet. This is the last incident of marked importance in the perturbed career of Shelley; the rest relates to the history of his mind, the poems which he produced and published, and his changes of locality in travelling. The first ensuing poem was The Revolt of Islam, referred to near the close of this article.

In March 1818, after an illness which he regarded (rightly or wrongly) as a dangerous pulmonary attack, Shelley, with his wife, their two infants William and Clara, and Miss Clairmont and her baby Allegra, went off to Italy, where the short remainder of his life was passed. Allegra was born in March; to Venetia, to her father, who, ever since parting from Miss Clairmont in Switzerland, showed a callous and unfelling determination to see and know no more about her. In 1818 the Shelles—always nearly with Miss Clairmont in their company—were in Milan, Leghorn, the Bagni di Lucca, Venice and its neighbourhood, Rome, and Naples; in 1819 in Rome, the vicinity of Leghorn, and Florence (both their infants were now dead, but a third was born late in 1819, Percy Florence Shelley, who in 1844 inherited the baronetcy); in 1820 in Pisa the Bagdi di Pisa (or di San Giuliano), and Leghorn; in Pisa and Leghorn; in Venice, Genoa, Leghorn; and on the Bay of Spezia, between Lerici and Tenerizzo. The incidents of this period are but few, and of no great importance apart from their bearing upon the poet's writings. In Leghorn he knew Mr and Mrs Gisborne, the latter a once intimate friend of Godwin; she taught Shelley Spanish, and he was eager to promote a project for a steamer to be built by her son for a brother marriage, the engineer Henry Reveley; it would have been the first steamer to navigate the Gulf of Lyons. In Pisa he formed a sentimental intimacy with the Countess Emilia Viviani, a gifted woman, pining in a convent pending her father's divorce, who was a hotelier, and of both of whom he was very fondly attached—which soon came to an end, as Emilia's character developed less favourably in the eyes of her Platonic adorer—produced the transcendental love-poem of Epipsychidion in 1821. In Ravenna the scheme of the quarterly magazine the Liberal was concerted by Byron and Shelley, the latter being principally interested in it with a view to benefiting Leigh Hunt by such an association with Byron. In Pisa Byron and Shelley were—very constantly together, having in their company at one time or another Shelley's cousin and schoolfellow Captain Thomas Melmoth (1788—1849), Lieutenant Edward Ellicker Williams (1793—1822) and his wife, to both of whom the poet was very warmly attached, and Captain Edward John Trelawny, the adventurous and romantic-natured seaman, who has left important and interesting reminiscences of this period.

Byron admired very highly the generous, unworlily and enthusiastic character of Shelley, and set some value on his writings; Shelley half-worshipped Byron as a poet, and was anxious, but in some conjunctures by no means able, to respect him as a man. In Pisa he knew also Prince Alexander Mavrocordato, one of the pioneers of Greek national feeling, Captain Thomas Melmoth (1788—1849), Lieutenant Edward Ellicker Williams (1793—1822) and his wife, to both of whom the poet was very warmly attached, and Captain Edward John Trelawny, the adventurous and romantic-natured seaman, who has left important and interesting reminiscences of this period. Byron admired very highly the generous, unworlily and enthusiastic character of Shelley, and set some value on his writings; Shelley half-worshipped Byron as a poet, and was anxious, but in some conjunctures by no means able, to respect him as a man. In Pisa he knew also Prince Alexander Mavrocordato, one of the pioneers of Greek national feeling, Captain Thomas Melmoth (1788—1849), Lieutenant Edward Ellicker Williams (1793—1822) and his wife, to both of whom the poet was very warmly attached, and Captain Edward John Trelawny, the adventurous and romantic-natured seaman, who has left important and interesting reminiscences of this period.
exists that an aged Italian seaman on his deathbed confessed that he had been one of the crew of the fatal felucca, and that the collision was intentional, as the men had plotted to steal a sum of money supposed to be on the "Don Juan," in charge of Lord Byron. In fact there was a moderate sum there, but Byron had neither embarked nor intended to embark. This may perhaps be the true account of the tragedy; at any rate Trelawny, the best possible authority on the subject, accepted it as true. He it was who laboriously tracked out the shore-washed corpses of Williams and Shelley, and who undertook the burning of them, after the ancient Greek fashion, on the shore near Via Reggio, on the 15th and 16th of August. The great poet's ashes were then collected, and buried in the new Protestant cemetery in Rome. His height, within a month of completing the thirty-third year of his age—a surprising example of rich poetic achievement for so young a man.

The character of Shelley can be considered according to two different standards of estimation. We can estimate the original motive forces in his character; or we can form an opinion of his actions, and thence put a certain construction upon his personal qualities. We will first try the latter method. It cannot be denied by his admirers and eulogists, and is abundantly clear to his censors, that his actions were in some considerable degree abnormal, and not to be called handsome. His height was nearly 5 ft. 11; he was slim, agile, and strong, with something of a stoop; his complexion brilliant, his hair abundant and wavy, dark brown but early beginning to grizzle; the eyes, deep blue 'in tint, have been termed "stag-eyes"—large, fixed and beaming. His voice was wanting in richness and suavity—high-pitched, and tending to the screechy; his general aspect, though extremely variable according as his mood of mind and his expression shifted, was on the whole uncommonly juvenile. The only portrait of Shelley, from which some idea of his looks used to be formed, is that painted by an amateur, Miss Curran, in 1817; Mrs Shelley, later, pronounced it to be "in many things very like." This is now in the National Portrait Gallery, together with a quasi-duplicate of it painted by Clint, chiefly from Miss Curran's likeness, and partly from a water colour (now lost) by Lieutenant Williams. In 1905 (Century Magazine) another portrait was brought forward: a pencil sketch taken in the last month of the poet's life by an American artist, William E. West, followed by an oil-painting founded on that sketch. The two works differ very considerably, and neither of them resembles Miss Curran's portrait; yet I cannot incline to believe that the sketch was really taken from Shelley.

If we except Goethe (and leave out of count any living writers, whose ultimate value cannot at present be assessed), we must consider Shelley to be the supreme poet of the new era which, beginning with the French Revolution, remains continuous into our own day. Victor Hugo comes nearest to him in poetic stature, and might for certain reasons be even preferred to him; Byron and Wordsworth also have their numerous champions not to speak of Tennyson or Browning. The grounds, however, on which Shelley may be set highest of all are mainly three. He excels all his competitors in idealism, he excels them in music, and he excels them in importance. By importance we here mean the direct import of the work performed, its controlling power over the reader's thought and feeling, the tangential fire of its white-hot intellectual passion, and the long reverberation of its appeal. Shelley is emphatically the poet of the future. In his own day an alien in the world of mind and invention, and in our day but partially a denizen of it, he appears destined to become, in the long vista of years, an innermost shrine of human thought. Shelley appeared at the time when the sublime frenzy into which the French revolutionary movement had exhausted the elasticity of men's thought—at least in England—and had left them flaccid and stolid; but that movement prepared another in which revolution was to assume the milder guise of reform, conquering and to conquer. Shelley was its prophet. As an iconoclast and an idealist he took the only position in which a poet could advantageously work as a reformer. To outrage his contemporaries was the condition of leading his successors to triumph and of personally triumphing in their victories. Shelley had the temperament of an innermost shrine of human thought, in which wondrously poetical he united speculative keenness and humanitarian zeal in a degree for which we might vainly seek his precursor. We have already named idealism as one of his leading excellences. This Shelleyan quality combines, as its constituents, sublimity, beauty and the abstract passion for good. It should be acknowledged that, while this great quality forms the chief and most admirable factor in Shelley's poetry, the defects which go along with it mar his work too often—producing at times vagueness, unreality and a pomp of glittering indistinctness, in which excesses of sentiment welled up and exceeded words. This blinism affects the long poems much more than the pure lyrics; in the latter the rapture, the music and the emotion are in exquisite balance, and the work has often as much of delicate simplicity as of fragile and flower-like perfection.

Some of Shelley's principal writings have already been mentioned above; we must now give a brief account of others. Of his early work prior to Queen Mab—such romances as Zastrozzi and Si Iryne, such verse as the Poems by Victor and Cazire, and the Fragments of Margaret Nicholson—we can only here refer. In 1816 Shelley wrote The Necessity of Nature, a short essay on the grounds of science and art and the possible existence of God. In 1817 Shelley's first work of importance was contributed to the Cazire, or The House of Dante; it is a translation of Dante's Inferno with a commentary and an introduction. Of the first of the later fragments, the The Revolt of Islam, a poem of no common importance, in the Spenserian stanza, preaching bloodless revolution; it was written in a sort of friendly competition with Keats (who produced Endymion) and is amazingly fine in parts, but as a whole somewhat long-drawn and exhausting. This transcendent epic (for such it may be termed) was at first named Lamo and Cythna, or The Revolution of the Golden City, and the lovers of the story were then brother and sister as well as lovers—an experiment upon British endurance which the publishers would not connive at. The year 1818 produced Rosalind and Helen, a comparatively weak poem, begun in England and finished in Italy, and Julian and Maddalena, a very strong one, written in the neighbourhood of Venice—demonstrating in Shelley a singular power of seeing ordinary things with directness, and at once figuring them as reality and transfiguring them into poetry. In each of these two poems Shelley gives a quasi-portraiture of himself. The next year, 1819, was his culmination, producing as it did the grand tragedy of The Cenci and the sublime ideal drama Promethus Unbound, composed partly on the ruins of the Baths of Carculla in Rome. This last we have no hesitation in calling his masterpiece. In forms of surpassing imagination and beauty; and in an intellect and most daring conceptions. Prometheus, the human mind and will, has invested with the powers proper to himself Jupiter, the god of heaven, who thereupon chains and torments Prometheus and oppresses mankind; in other words, the anthropomorphic god of religion is a creation of the human mind, and both the
mind of man and man himself are enslaved as long as this god exercises his delegated but now absolute power. Prometheus, who is from old wedded to Asia, or Nature, protests against and anathematizes the usurper enthroned by himself. At last the anathema (although Prometheus has revok'd it by an act of self-confess) takes effect: Eternity, Demogorgon, dismisses Jupiter to unending pursuits, for Prometheus is at once bound and free; he is reunited to his spouse Nature, and the world of man passes from thraldom and its degradation into limitless progression, or (as the phrase goes) perfectibility, moral and material. This we regard as in brief the argument of Prometheus Unbound. It is closely analogous to the argument of the juvenile poem Queen Mab, but so raised in form and creative touch that, whereas to write Queen Mab was only to be an ambitious and ebullient tiro, to invent Prometheus Unbound was to be the poet of the future. The Witch of Atlas (1820) is the most perfect work among all Shelley's longer poems, though it is neither the deepest nor the most interesting. It may be rated as a pure exercise of rousing imagination—guided, however, by an intense sense of beauty, and by its author's exceeding fineness of nature. The poem has often been decried as practically meaningless; we do not subscribe to this opinion. The "witch" of this subtle and magical invention seems to represent that faculty which we term the "fancy"; using this assumption as a clue, we find plenty of meaning in the poem, but necessarily it is fanciful or volatil meaning. The action is a spirit and the arena of poetry, yet without being distorted out of its own essence—is to be found in the English language.

The chief original authorities for the life of Shelley (apart from his own writings, which contain a good deal of autobiography, if heedfully sifted and collated) are—(1) the notices by Mrs Shelley interpolated in her edition of the Poems; (2) Hogg's amusing, discerning and authentic, although in some respects exaggerated, book; (3) Trelawny's Records; (4) the Life by Medwin; and (5) the articles written by Peacock. Some other writers, especially Leigh Hunt, might be mentioned, but they come less close to the facts. Among biographical books produced since Shelley's death, by authors who did not know him personally, the leading work is the Life by John Addington Symonds, in 2 vols. (1886), which was the work of the English poet while in residence, by the Shelley family. The Real Shelley, by J. C. Jeaffreson (1885), is controversial in method and decidedly hostile in tendency, and tries a man of genius by tests far from well adapted (in our opinion) to bring out a right result; it contains, however, an ample share of solid information and sharp disquisition. The memoir by W. M. Rosetti, prefixed to an edition of Shelley's Poems in two volumes (1875), is an attempt to formulate in brief space, out of the then confused and conflicting accounts, an accurate account of Shelley—admiring, but not uncandidly one-sided. There is valuable material in Lady Shelley's Shelley Memorials, and in the Thomas Love Peacock's life of Shelley, which was published in 1831 by his widow. The Life of Shelley, in the English Men of Letters series, is characteristic of the writer. The most complete edition of Shelley's poems is now the Oxford edition, edited by Thomas Hutchinson (Clarendon Press, 1905), which contains the original pieces of all the other editions, as well as the emendations, &c., published by Mr C.D. Locock (1903) from examination of the MSS. in the Bodleian Library. Mr Buxton Forman's earlier and excellent edition includes the writings in prose as well as in verse. (W. M. R.)

SHELLEY'S CASE, RULE IN, an important decision in the law of real property. The litigation was brought about by the settlement made by Sir William Shelley (c. 1450–1549), a judge of the Court of King's Bench, pleads, on an estate of shell-sized shells of the common degradation of Sion Monastery. After prolonged argument the celebrated rule was laid down by Lord Chancellor Sir Thomas Bromley, who presided over an assembly of all the judges to hear the case in Easter term 1580–1581. The rule may be stated as follows: when an ancestor by any gift or conveyance takes an estate of freehold and in the same gift or conveyance an estate is limited, either mediatly or immediately, to his heirs or the heirs of his body, in such a case the word "heirs" is a word of limitation and not of purchase; that is to say, the estate of the ancestor is not a life or other freehold estate with its power to the heirs or heirs of the body, but an estate in fee or an estate tail according to circumstances. The rule is a highly technical one, and has led to much litigation, and in many cases without doubt to the defeat of a testator's intentions. It is said to have had its origin in the wish of the law to preserve to the lords their right of wardship, which would have been ousted by the heir taking as purchaser and not as successor. The rule is reported by Lord Coke in 1 Reports 93 b. (see also Von Grafton v. Foswell, 1897, A.C. 629). In the United States the rule in Shelley's case was not followed in a case in which a life estate was disposed of, on one condition of purchasing the common law, but it has been repealed by statute in most states. SHELL-HEAPS, or KITCHEN-MIDDEN (Dan. Kjøbken-mødding), prehistoric refuse heaps or mounds found in all quarters of the globe, which consist chiefly of the shells of edible molluscs mixed with fragments of animal bones, and implements of stone, bone and horn. They may sometimes, as in the Straits of Magellan, be seen in process of formation. Many having a prehistoric origin have been examined, notably on the eastern coast of Denmark. These were at first thought to be raised beaches, and other examples, not in process of formation, were thought to be artificial construction. Further investigation by archaeologists proved these shell-heaps to belong to a very ancient period, probably the early part of the Neolithic age, "when the art of polishing flint implements was known, but before it had reached its greatest development" (Lord Avebury, Prehistoric Times, 6th ed. p. 235). They contained the remains of quadrupeds, birds and fish, which served as the food of the prehistoric inhabitants. Among the bones were those of the wild bull or aurochs, beaver, seal and great auk, all now extinct or rare in this region. Moreover, a striking proof of the antiquity of these shell-heaps is that the bones of the shell-heaps, which are mixed with oyster, which cannot live at present in the brackish waters of the Baltic except near its entrance, the inference being that the shores where the oyster at that time flourished were open to the salt sea. Thus also the eatabile cockle, mussel and periwinkle abounding in the kitchen-middens are of full ocean size, whereas those now living in the adjoining waters are dwarfed to a third of their natural size by the want of saltiness. It thus appears that the connexion between the ocean and the Baltic has notably changed since the days of these rude stone-age peoples. The middens of debris were in some places ten to twelve feet thick and stretched a thousand feet. It does not appear that the men of the kitchen-middens had any knowledge of agriculture, nor traces of grain of any sort being found. The only vegetable remains were burnt pieces of wood and some charred substance, possibly a sea-plant used in the production of salt. Flat stones blackened with fire, forming hearths, were also found. That periods of scarcity must have been frequent in the absence of cereals is indicated by the discovery of bones of the fox, wolf and other carnivora, which would hardly have been eaten from choice. The kitchen-middens of Denmark were not mere summer-quarters: the ancient fishermen appear to have stayed in the neighbourhood for two-thirds, if not the whole, of the year. This is suggested by an examination of the bones of the wild animals, from which it is often possible to tell the time of year when they were killed. Thus the remains of the wild swan (Cygnus musica),
a winter visitor, leaving the Danish coast in March and returning in November, are found in abundance. Additional proof is afforded among the mammalian remains by two periodical phenomena, the shedding of the stag's antlers and the birth and growth of the young. The flint implements found include flake, axes, awls, slinging-stones or net-weights, and rude lanceheads. A fragment of one polished axe was found at Havelse which had been worked up into a scraper. Small pieces of coarse pottery are also met with. The Danish kitchen-midden men were not cannibals. In physique they seem to have resembled the Lapps, a race of small men with heavy-hanging brows and round heads. The excavation of the Danish shell-heaps was followed by the investigation of others in other countries. At Omori (Japan), in the Aulean Islands, in British Columbia, Oregon and California shell-mounds were explored, always with the result of proving that the present populations had been preceded by ruder tribes of great antiquity. On the Atlantic coast of Brazil shell-heaps, which must have taken thousands of years to accumulate, are now overgrown with dense forests.

SHELL-MONEY, a medium of exchange common to many primitive races, consisting of sea shells or pieces of them worked into beads or artificially shaped. Shell-money has not been restricted to one quarter of the globe, but in some form or other appears to have been almost universal. It has been found in America, Asia, Africa and Australia. The shell used by the Indians of Alaska and California was the Dentalium pretiosum, a species of tusk-shell found along the north-west coast. It received its name from its tusk-like appearance, and was valued by length and not by the number of shells. The usual method of measuring was by the finger-joints, and the iga, the highest denomination of their coinage, consisted of twenty-five shells strung together, which from end to end made a total measurement of a fathom (6 ft.) or thereabouts, equalling in English coinage about £50. Farther south on the shore of California the Indians used the Saxidomus gracilis or Tapa gracilis, while in the islands close to the littoral the Lhoboria obesa was in common use.

But the shell most used by primitive peoples has always been the Cypraea Moneta, or money shell (COWRY). It is not abundant in the Indian Ocean, and is collected more particularly in the Maldivie Islands, in Ceylon, along the Malabar coast, in Borneo and other East Indian islands, and in various parts of the African coast from Ras Hafun to Mozambique. It was formerly in familiar use in Bengal, where, though it required 3840 to make a rupee, the annual importation was valued at about £30,000. In western Africa it was, until past the middle of the 19th century, the usual tender, and before the abolition of the slave trade there were large shipments of cowry shells to some of the English ports for reshipment to the slave coast of Africa. The value of the cowry was very much greater in West Africa than in the regions from which the supply was obtained, the trade was extremely lucrative, and in some cases the gains are said to have been 500%. The use of the cowry currency gradually spread inland in Africa, and about 1850 Heinrich Barth found it fairly recognized in Kano, Kuka, Gando, and even Timbuktu. Barth relates that in Muniyoma, one of the ancient divisions of Bornu, the king's revenue was estimated at 30,000,000 shells, every full-grown man being required to pay annually 1000 shells for himself, 1000 for every pack-ox, and 2000 for every slave in his possession. In the countries of Mozambique and south-western Africa the cowry is most commonly found in strings of 50 or 100 each, so that fifty or twenty strings represented a dollar; but in the interior they were laboriously counted one by one, or, if the trader were expert, five by five. The districts mentioned above received their supply of kurti, as they were called, from the west coast; but the regions to the north of Unyamwezi, where they were in use under the name of simbi, were dependent on the Moslem traders from Zanzibar. The shells are still used in the remnant parts of Africa, but the yearly tendency to give way to ordinary currency. The shell of the land-snail, Achatina monetaaria, cut into circles with an open centre has been long used as coin in Benguella, Portuguese West Africa. In parts of Asia Cypraea annulus, the ring cowry, so-called from the bright orange-coloured ring on the back or upper side of the shell, was commonly used. Many specimens were found by Sir Henry Layard in his excavations at Nimrud in 1845-1851.

In north Australia different shells were used, one tribe's shell being often absolutely valueless in the eyes of another. In parts of the islands north of New Guinea the shells are broken into flakes. Holes are bored through these flakes, which are then valued by length, as in the case of the American tusk-shell, the measuring, however, being done between the nipples of the breasts instead of by the finger-joints. Two shells are used by these Pacific islanders, one a cowry found on the New Guinea coast, and the other the common pearl shell broken into flakes. As late as 1882 local trade in the Solomon Islands was carried on by means of a coinage of shell beads, small shells laboriously ground down to the required size by the women. No more than were actually needed were made, and as the process was remunerative the value of these islands increased greatly. The custom of breaking or flaking shells was common among some of the American Indian tribes, but the shells so manipulated were of the ponderous Pachyderma crassatellodes species, while in the south Pacific Islands the Oliva canoel was used.

SHELTON, THOMAS (fl. 1612-1620), English translator of Don Quixote. In the dedication of The delightfull history of the witte knight, Don Quixote (1612) he explains to his patron, Lord Howard de Walden, afterwards 2nd Earl of Suffolk, that he had translated Don Quixote from Spanish into English some five or six years previously in the period of forty days for a very dear friend who was unable to understand the original. Shelton did not use the original editions published in Brussels in 1605. On the appearance of the Brussels imprint of the second part of Don Quixote in 1616, he translated that also into English, completing his task in 1620, and printing at the same time a revised edition of the first part. His performance has become a classic among English translations for its racry, spirited rendering of the original. Light was thrown on Thomas Shelton's personal history by the researches of Mr. Alexander T. Wright in a paper published in October 1868. Among the kinsfolk of the earl of Suffolk were three persons bearing the name Thomas Shelton, and though all died before 1620 it is probable that one of the members of the same family. It seems safe to identify him with the Thomas Shelton who wrote a sonnet prefixed to the Restitution of Decayed Intelligence (1605) of Richard Verstegan, who was most likely the friend referred to in Shelton's preface, for there is reason to believe that both of them were then employed in a matter of doubtful loyalty, the intrigues of the Roman Catholics in England. He was acquainted with the "cries of the wild Irish," and seems to have been honestly employed in carrying letters to persons in England from Lord Deputy Fitzwilliam at Dublin Castle. But in 1599 he apparently acted as agent for Florence McCarthy to offer his services to the king of Spain, especially fitted him. Soon afterwards an official précis of the facts was drawn up, in which Shelton was implicated.
by name. A second version of this document in 1617 is actually signed by him, but all reference to his share in the matter is omitted. Lady Suffolk, the wife of his patron, received yearly £1000 in secret service money from the Spanish king, and Shelton may have been her accomplice. If the "many affairs" of his preface were official he would not wish to call attention to his antecedents by owning friendship with Verstegan.

The 1612 edition is available in Mr Fitzmaurice Kelly's reprint for the Tudor Translations (1892); that of 1620 is reproduced in Macmillan's "Library of English Classics" with an introduction by Mr A. W. Pollard, who incorporates the suggestions made by Mr A. T. Wright in his Thomas Shelton, Translator. This gives "name only" "(posteriori)", the Bible, the eldest of the three sons of Noah, whose superiority over Canaan is reflected in the tradition that Noah pronounced a curse upon the latter (Gen. ix. 20-27). In the genealogies (x. 21 sqq.), Semitic numbers among his descendants Assyrian, Arabian, Aramaean and Hebrew populations, whence the ethnic Semitic (strictly speaking, Semitic) has been coined as a convenient term for these peoples. It is not altogether scientific, since the Lydians (Lud) and Elamites are included among Sem's or Noah's sons, apparently on account of their geographical position rather than their immediate kinship to Assyrian culture. On the traditions of Sem, see E. Meyer, Israeliten u. Nachbarstämme (Halle, 1906), pp. 219 sqq.

**Shemakia**, a town of Russian Transcaucasia, in the government of Baku, 70 m. W. of the town of Baku, and in 41° 38' N. and 48° 40' E. It has some 20,000 inhabitants, consisting of Tatars (75%), Armenians and Russians. Shemakia was the capital of the khanate of Shirvan, and was known to the Roman geographer Ptolemy as Kamachia. About the middle of the 16th century it was the seat of an English commercial factory, under the traveller Jenkinson, afterwards envoy extraordinary of the khan of Shirvan to Ivan the Terrible of Russia. In 1743 Shemakia was taken and destroyed by Nadir Shah of Persia, who, to punish the inhabitants for their creed (Sunnite Mahomedanism), built a new town under the same name about 16 m. to the W., at the foot of the main chain of the Caucasus. The new Shemakia was at different times a residence of the khan of Shirvan, but it was finally abandoned, and the old town rebuilt. The Russians first entered Shirvan in 1723, but soon retired. In 1795 they captured Shemakia as well as Baku; but the old town once more declined, and Shemakia was not finally annexed to Russia until 1805.

**Shenandoah**, a borough of Schuykill county, Pennsylvania, U.S.A., about 40 m. N.N.W. of Reading. Pop. (1910, census), 25,774. Among the foreign-born the Lithuanians and Poles predominate—in 1910 a Lithuanian and a Polish paper were published here. Shenandoah is served by the Pennsylvania, the Lehigh Valley and the Philadelphia & Reading railways. The borough has a public library. The United Greek Catholic Church (Ruthenian Rite) here is said to be the first of this sect in the United States; it was organized as St Michael's Parish in 1885, the first building was erected in 1888, and a new building was completed in 1909. Shenandoah is situated in the eastern part of the middle basin of the great anthracite coal region of Pennsylvania, and the mining and shipping of coal are its chief industries. A log house was built on the site of the present Shenandoah as early as 1835, but there was no further development until 1862, when the first colliery was opened. The borough was incorporated in 1866.

**Shenandoah Valley Campaigns.** During the American Civil War the Shenandoah Valley was frequently the scene of military operations. The town was at one time or another in the war these operations rose to the height of separate campaigns possessing great significance in the general development of the war. From a military point of view the Shenandoah Valley was valuable to the army which controlled it as a requisitioning area, for in this fertile region crops and cattle were plentiful. There were, moreover, numerous mills and factories. For the Confederates the Valley was also a recruiting area. A macadamized road from Lexington via Staunton and Winchester to Martinsburg gave them access to Maryland and enabled them to cover Lynchburg from the north. By a system of railways which united Gordonsville and Charlottesville troops from Richmond and Lynchburg were detainted within easy distance of five good passes over Blue Ridge, and as Strasburg in the valley lies almost due west of Washington it was believed in the North that a Confederate army therabouts menaced a city the protection of which was a constant factor in the Federal plan of campaign. The Valley was 60 m. wide at Martinsburg and had been cleared of timber, so that the movements of troops were not restricted to the roads: the creeks and rivers were fordable at most places and the Shenandoah Valley was consequently valuable to the Confederates as a territory specially suited for mounted troops. The existence of the parallel obstacle between Strasburg and Newmarket, the two forks of the Shenandoah river enclosing the Massanutten range, afforded opportunities for strategic manœuvres.

In the spring of 1862 the immense army organized by General McClellan advanced and threatened to sweep all before it. The Confederates, based on Richmond, were compelled to show a front westward to the Alleghanies, northward to the Potomac and eastwards to the Atlantic. The main armies were engaged at Yorktown, but the Shenandoah Valley operations were secondary. Yet in one instance a Confederate detachment that varied in strength between 5000 and 17,000 contrived to make some stir in the world and won renown for its commander. General Thomas J. Jackson with small means achieved great results, if we look at the importance which politics played in the affairs of the belligerents; and even in a military sense he was admirable for skilfully utilizing his experiences, so that his discomfitures of the winter of 1861, when Rosecrans and Lander and Kelley were opposed to him, taught him how to deal with such Federal leaders as Shields and Banks, Milroy and Frémont, and to the Yorktown operations he was a marked success.

In the Valley operations in 1862 began by a retrograde movement on the part of the Confederates, for Jackson on the 12th of March retired from Winchester, and Banks at the head of 20,000 men took possession. Banks pushed a strong detachment under General Shields on to Strasburg a week later, and Jackson then withdrew his small division (5000) to Mount Jackson, so yielding the Shenandoah Valley for 40 m. south of Winchester. He was now acting under instructions to employ the invaders in the Valley and prevent any large body being sent eastward to reinforce the main army, and he had a number of operations here to the danger of defeat. He was to keep near the enemy, but not so near as to be compelled to fight Banks's superior forces. Such instructions, however, were difficult to carry out. When, on the 21st of March, Banks recalled Shields in accordance with orders from Washington, Jackson conceived that he was bound to follow Shields, and, when Shields stood at bay at Kernstown on the 23rd of March with 7000 men, Jackson at the head of 3500 attacked and was badly beaten.

For such excess of zeal two years later Sigel was removed from his command. But in 1862 apparently such audacity was true wisdom, for the road thus afforded by Jackson of his inability to contend with Shields seems to have been regarded by the Federal authorities as an excuse for reversing their plans: Shields was reinforced by Williams's division, and with this force Banks undertook to drive Jackson from the Valley. A week after the battle of Kernstown, Banks moved to Strasburg with 16,000 men, and a month later (April 26) is found at Newmarket, after much skirmishing with Jackson's rear-guard which burnt the bridges in retiring. Meanwhile Jackson had taken refuge in the passes of Blue Ridge, where he too was reinforced. Ewell's division joined him at Swift Run Gap, and at the beginning of May he decided to watch Banks with Ewell (who was not to, and to proceed himself with the remainder of his command to join Edward Johnson's division, then beset by General Milroy west of Staunton. Secretly moving by rail through Rockfish Gap, Jackson united with Johnson and in a few days located Milroy at the village of McDowell. After reconnaissance Jackson concentrated his forces on Settlington Hill and proposed to attack on the morrow (May 8th), but on this occasion the Federals (Milroy having just been joined by Schenck) took the initiative, and after a four
hours' battle Jackson was able to claim his first victory. The Confederates lost 500 of 6000 men and the Federals 250 out of 2500 men. Jackson's pursuit of Milroy and Schenck was fruitless, and he returned to his camp at McDowell on the 14th of May. Meanwhile General Banks had been ordered by President Lincoln to fall back from Newmarket, to send Shields's division to reinforce General McDowell at Fredericksburg, to garrison Front Royal, and to entrench there was of brief duration, for McDowell was moving westward from Fredericksburg and Frémont eastward from Franklin under instructions from Washington to intercept him. On the 31st of May Frémont had reached Cedar Creek, McDowell was at Front Royal and Jackson had retired to Strasburg, where he was compelled to wait for a detachment to come in. This rejoined on the evening of the 1st of June. Ewell's division held Frémont back until Jackson was on his way to Newmarket.

Jackson's opportunity had come to destroy Banks's force completely. The Confederates numbered 16,000, the Federals only 6000 men. Jackson availed himself of the Luray Valley route to intercept Banks after capturing the post at Front Royal. He captured the post, but failed to intercept Banks, who escaped northwards by the turnpike road and covered his retreat across the Potomac by a rear-guard action at Winchester on the 25th of May. Jackson followed and reached Halltown a few days later. But his stay

McDowell had sent Shields up the Valley by the Luray route. But Jackson gained Newmarket in safety and destroyed the bridge by which Shields could emerge from the Luray Valley to join Frémont, who was left to cope with Jackson single-handed. Jackson's rearguard destroyed the bridges and otherwise impeded Frémont's advance, but a week later (June 7th) Frémont at Harrisonburg located his enemy at Cross Keys and next day he attacked with 10,500 men. Shields was still at Luray. Jackson held Frémont with Ewell's division (5000) and with the remainder proceeded to the left bank
of the Shenandoah near Port Republic to await developments, for Shields had pushed forward a strong advanced guard under General Tyler, whose vanguard (two squadrons) crossed the river while Frémont was engaged with Ewell. Tyler’s cavalry was driven back with heavy loss. Jackson retained possession of the bridge by which Tyler and Frémont could unite, and next day he crossed the river to attack Tyler’s two brigades. The engagement of the 9th of June is called the battle of Port Republic. Jackson with 13,000 men attacked Tyler with 5000 men, and Tyler, after stoutly resisting in the vain hope that the main body under Shields would come up from Conrad’s Store or that Frémont would cross the river and fall upon Jackson, retired with a loss of some 800 men, leaving as many Confederates hors de combat. Tyler’s brave efforts were in vain, for Shields had once more received orders from Washington which appeared to him to justify leaving his detachment to its fate, and Frémont could not reach the river in time to save the bridge, which Ewell’s rear-guard burnt after Jackson had concentrated his forces against Tyler on the right bank. A few days later Jackson received orders to quit the Valley and join the main army before Richmond, and President Lincoln simultaneously discovered that he could not afford to keep the divisions of Frémont, Banks and McDowell engaged in operations against Jackson: so the Valley was at peace for a time.

In strict connection with the operations of the main armies in Virginia, the Confederates brought off two great coups in the Valley—Jackson’s capture of Harper’s Ferry and Martinsburg in the autumn of 1862 and Ewell’s expulsion of Milroy from Martinsburg and Winchester in June 1863. The concentration of the Federal forces in N. Virginia in May 1864 for the campaign which ultimately took Grant and Lee south of the James involved a fresh series of operations in the Valley. At first a Union containing force was placed there under Sigel; this general, however, took the offensive and unwisely divided his army and was defeated at Newmarket. Next Hunter, who superseded Sigel in command in West Virginia and the Valley, was to co-operate with the Army of the Potomac by a movement on Staunton and thence to Gordonsville and Lynchburg, with the object of destroying the railways and canal north of the James river by which troops and supplies reached the Confederates from the West. Sigel meanwhile was to cover the Ohio railroad at Martinsburg. Hunter encountered Jones’s division at Piedmont (Mount Crawford) on the 5th of June and caused General Lee to detach from his main army a division under Breckinridge and Jones. Grant then detached Sheridan to join Hunter at Charlottesville, but Lee sent Hampton’s cavalry by a shorter route to intercept Sheridan, and a battle at Trevilian Station compelled Sheridan to return and leave Hunter to his fate. The losses in this cavalry combat exceeded 1000, for the dense woods, the use of barricades and the armament of the mounted troops caused both sides to fight on foot until lack of ammunition brought the action to an end. Sheridan during his three months’ command of the Federal cavalry had steadily adhered to the principle of always fighting the enemy’s cavalry, and, though now compelled to return to the Pamunkey, he contrived to draw Hampton’s force after him in that direction.

Meanwhile on the 13th of June General Early had moved from Cold Harbor to add his command to the Confederate forces in the Valley. Early succeeded ininterposing between Hunter and Lynchburg, and within a week drove Hunter out of Virginia by the Kanawha river route. Early then moved down the Valley turnpike unchallenged. Expelling Sigel from Martinsburg on the 4th of July and crossing the Potomac opposite Sharpsburg, he marched to a position between Winchester and the Rappahannock, and, with the aid of Lee’s and Ewell’s divisions and the newly arrived force under Lew Wallace on the Monocacy. Grant then detached Wright’s corps (VI.) from Petersburg and called Emory’s corps (XIX.) from the West to oppose Early, who after creating serious alarm retired, on the 13th of July, by Leesburg and Snicker’s Gap into the Valley at Winchester. Hunter had meanwhile gained Harper’s Ferry via the Baltimore and Ohio Railroad, and, when Early withdrew towards Strasburg, General Crook collected the forces of Hunter and Sigel to follow

the Confederates, but Early turned upon Crook and drove him back to the Potomac. Early then sent a detachment into Maryland to burn the town of Chambersburg. The alarm in the North for the safety of Washington was only quieted by the appointment of General Sheridan to command in the Valley.

He arrived on the scene early in August. His mission was to drive Early up the Valley or, if the Confederates crossed into Maryland, to intercept their return, and in any case he was to destroy all supplies in the country which could not be consumed by his own army. Sheridan made Harper’s Ferry his headquarters and concentrated at Hailtown. Early retained his position about Bunker’s Hill, on the Orange and Alexandria Railroad, and held the main road up the Valley until Sheridan moved out in force on the 10th of August. Early then retreated up the Valley to Fisher’s Hill (Strasburg), where he expected to be joined by Anderson’s corps from Richmond. Sheridan had followed Early, but hearing of this reinforcement to the enemy, he decided to take up a defensive line at Hailtown—the only point in the Valley which did not favour flanking operations—and await reinforcements. Sheridan’s retrograde movement from Cedar Creek on the 17th of August was, however, regarded in the North as a sign of indecision, and the few days he held at the end of August, Sheridan meanwhile had moved out between the Shenandoah and the Opequon to seize all routes towards Washington, from Martinsburg on Early’s left as far up as the Winchester-Berryville turnpike by which his own reinforcements reached the Valley through Snicker’s Gap. Sheridan also held the Smithfield crossing of the Opequon in Early’s front. Each commander, however, hesitated to bring on a battle, Sheridan because the result of the Presidential election would be seriously affected by his defeat at this moment, and Early because with his inferior forces he was content to keep the field for the more powerful forces than Sheridan’s flank effectively covered the Valley. But Sheridan, being a veteran of a formidable army that had ever invaded this region. It consisted of three small army corps under Wright (VI.), Emory (XIX.) and Crook (VIII.) and Torbert’s cavalry (6000) in three divisions under Averell, Merritt and Wilson, the whole numbering 30,000 infantry, 6000 cavalry and 27 batteries. Early continued to hold Winchester with four divisions under Rodes, Gordon, Breckinridge and Rameur and two cavalry divisions under Fitz Lee and Lomax. He had soon been deprived of Anderson’s corps which was sorely needed at Richmond, a fact which Sheridan discovered through his spies in Winchester, and indeed Sheridan had been waiting a fortnight for this movement by which Early’s command was to be reduced. For a month the two armies had manoeuvred between Hailtown and Strasburg, each commander hoping for such an increase to his own or decrease of his enemy’s numbers as would justify attack. The Valley operations were aided indirectly by assaults and sorties about Petersburgh. Grant aimed at preventing Lee sending reinforcements to Early until Sheridan’s plans had been carried out. Meanwhile Early had been gathering up the harvests in the northern Valley, but on the 9th of August Sheridan was able to report “I have destroyed everything that was valuable south of Winchester, and they will have to haul supplies from well up to Staunton.” Sheridan in September could put 25,000 infantry and 8000 cavalry into action, and at this moment he was visited by Grant, who encouraged his subordinate to seize an opportunity to attack the enemy.

The first encounter of Sheridan and Early took place on the
19th of September about 2 m. east of Winchester. Sheridan had crossed the Opequon and found the enemy in position astride the Winchester-Berryville road. Early was out-numbered and outfought, but he attributed his defeat to the enemy’s “immense superiority in cavalry,” and in fact Sheridan deployed Mansfield’s division (Longstreet’s corps), or pistol in hand and literally riding down a hostile battery, taking 1200 prisoners and 5 guns. The Federal victory, however, cost Sheridan 4500 casualties and he had hoped for greater success, since Early had divided his forces. Sheridan’s plan was to overwhelm Ramsay before he could be supported by Rodes and Gordon, but Early contrived to bring these divisions up and counter-attack while Sheridan was engaged with Ramsay. Early had confided his left to Fitz Lee’s cavalry and taken Breckinridge to strengthen his right. But Merritt’s horsemen rode cavalry the Confederate cavalry, who fled, communicating their panic to the infantry of the left wing, and the day was lost. Early retreated through Newtown and Strasburg, but at Fisher’s Hill behind Tumbling Run, where the Valley was entrenched on a front of 3 m. between the Shenandoah river and Little North Mountain, Early rallied his forces and again detailed his cavalry to protect his left from a turning movement. But Sheridan repeated his manoeuvre, and again on the 22nd of September Early was attacked and routed, General Crook’s column having outflanked him by a détour on the western or Back road. Early now retreated, and Kozeny’s division (Longstreet’s corps) at Tumbling Run, and, evading all Sheridan’s efforts to bring him again to battle, reached Port Republic on the 25th of September. On learning of this disaster, and the distress of his troops, General Lee promised to send him boots, arms and ammunition, but under pressure of Grant’s army, he could not spare any troops. Lee had estimated Sheridan’s force at 12,000 effective infantry, and Early’s report as to his being outnumbered by three or four to one was not credited. Yet Early had much to do to avoid destruction, for Sheridan had planned to cut off Early by moving his cavalry up the Laurel Valley. As the Valley was formed in the front, the infantry held him at Fisher’s Hill; but Torbert with the cavalry blundered. Sheridan made Harrisonburg his headquarters on the 25th of September, where he relieved Averell of his command for having failed to pursue after the battle of Fisher’s Hill. In the first week of October Sheridan held a line across the Valley from Port Republic along North river to the Back road, and his cavalry had advanced to Waynesboro to destroy the railroad bridge there, to drive off cattle, and burn the mills and all forage and breadstuffs. Early had taken refuge in Blue Ridge at Rockfish Gap, where he awaited Ross’s cavalry, and Kershaw’s division (Longstreet’s corps), for Lee had resolved upon once again reinforcing the Valley command, and upon their arrival Early advanced to Mount Crawford and thence to Newmarket. The Federals retired before him, but his cavalry was soon to suffer another repulse, for Rosser and Lomax having followed up Sheridan closely on the 9th of October with five brigades, the Federal cavalry under Torbert turned upon this body when it reached Tom’s Brook (Fisher’s Hill) and routed it. Sheridan burnt the bridges behind him as he retired on Winchester, and apparently trusted that Early would trouble him no more and then he would rejoin Grant at Petersburg. But Early determined to go north again, though he had to rely upon Augusta county, south of Harrisonburg, for supplies, for he had resisted Rockingham and Shenandoah counties in accordance with Grant’s order. The Union commander-in-chief, contemplating a longer struggle between the main armies than he had at first reckoned on, had determined that the devastation of the Valley should be thorough and lasting in its effect.

Sheridan at Winchester was now free to detach troops to aid Grant, or remain quiescent covering the Ohio railroad, or move east of Blue Ridge. He had resisted the demand of the government, which Grant had endorsed, that Early should be rejoined through the Blue Ridge back on Richmond. Sheridan pointed out that guerrilla forces were always in his rear, that he would need to reopen the Alexandria railroad as a line of supply, that he must detach forces to hold the Valley and protect the railroads, and that on nearing Richmond he might be attacked by a column sent out by Lee to aid Early. Yet in fact Sheridan carried out the government programme at the beginning of 1865, and a defensive line along the north bank of the Ohio river from the end of November, Early again advanced to reconnoitre at Cedar Creek, but was driven back to Newmarket. At the beginning
of December the weather threatened to interfere with movement, and both sides began to send back their troops to Petersburg. During the winter the extremely caravans and guerilla warfare and in February 1865 the remaining on each side was less than a strong division. Sheridan seized the opportunity to advance with 10,000 cavalry. Early delayed this advance with his cavalry, while he evacuated Staunton; he called up a brigade to defend Lynchburg and proceeded to Wayneboro to await developments. Sheridan feared to advance on Lynchburg leaving Early on his flank and decided to attack Early at Wayneboro; and on the 2nd of March the Federal commander was warned by despatch, capturing 1,000 and his cannon and artillery. Early himself escaped and Rosser's cavalry dispersed to their homes in the Valley, but with Early's third defeat all organized resistance in the Shenandoah Valley came to an end. Sheridan moved over Blue Ridge to Charlottesville and began his work of destruction south and east. Lynchburg was too strongly held to be captured, but from Amherst Court House the railway to Charlottesville and the canal to Richmond were destroyed, and thus Lee's army was deprived of these arteries of supply. On the 16th of March at Columbia, on the James River Railroad to Petersburg, a division of cavalry, sent to reward Grant of his success, and on the 19th of March he rejoined the main army in Eastern Virginia, receiving Grant's warm commendation for having "voluntarily deprived himself of independence." (G. W. R.)

SHENDI, a town in the Anglo-Egyptian Sudan in the madiria (province) of Berber, on the right bank of the Nile in 18° 1' N., 33° 59' E., and 104 m. N.N.W. of Khartum by rail. Shendi possesses small manufactories of leather, iron and cotton; extensive railway workshops and a government experimental farm. It is the headquarters of the cavalry of the Egyptian army stationed in the Sudan. Shendi lies within the "Island of Meroë" and is a town of great antiquity. Thirty miles north are the pyramids of Meroë. On the opposite (west) bank of the Nile is the village of Mettemma, whence there is a caravan route across the Bayuda Desert to the Merawi (Merowe) by Jebel Barkal; this was the route followed by the desert column under Sir Herbert Stewart in 1884 in the Gordon relief expedition. In 1772 James Bruce stayed some time at Shendi—then governed by a woman—on his way to Egypt after visiting the source of the Blue Nile. When the Egyptians invaded the Sudan in 1820, Shendi, then a place of considerable size, submitted to Ismail Pasha, son of Mehmet Ali, the pasha of Egypt. In 1822, however, Ismail and his chief followers were treacherously burnt to death at Shendi by order of the mek (ruler) of the town, in revenge for the cruelties committed by the Egyptians. Later in the same year an Egyptian army from Kordofan raged the town to the ground, most of the inhabitants being massacred. From that period until the establishment of Anglo-Egyptian rule in 1898 Shendi was but a poor village. Its subsequent growth has been comparatively rapid. There is a considerable area of fertile land on either side of the Nile in the neighbourhood.

SHENG-KING, SHEN-KING, or LIAO-TUNG, a province of the Chinese empire, in southern Manchuria. It occupies an area of 50,000 sq. m. and contains a population of 4,000,000. Its capital is Mukden, or, as it is otherwise known, Sheng-kung, "the Flourishing Capital." The province includes the Liao- tung peninsula, the most southern part of which, including Port Arthur, is leased to Japan.

Sheng-kung is a lofty mountainous. A line drawn from King-chow Fu (41° 12' N., 121° 10' E.) N.E. to Mukden, and then south by west through Lénoi-yang and Hai-ch'eng to Kai-ping and the sea, would define the level country. A large portion of the province is fertile, but in the neighbourhood of the sea the saline exudation common in the north of China renders futile all attempts at cultivation. North and east of this district run numerous mountain ranges, for the most part in a north-and-south direction. The climate of Sheng-kung is marked by extremes of heat and cold. In summer the temperature varies from 70° to 90° F., and in winter from 50° above to 10° below zero. The mountain scenery is extremely picturesque, and the trees and shrubs are such as are common in England, the mountain ash being the only common tree which is there conspicuous by its absence. The most important rivers are the Liao-ho and the Yalu. The former takes its rise in Mongolia, and after running an easterly course for about 400 m., turns S.W., and empties into the Gulf of Liao-tung, in the neighbourhood of Ying-tsze, up to which town, 20 m. from the bar, the river is navigable for large junks. The Yalu rises in the contain- tains to the south of the plain, and empties into the Yellow Sea.

The chief cities, Mukden, Liao-yang, Niu-chwang, Port Arthur and Tairen (Dalny) are separately noticed. Niu-chwang is the chief port of the province. Sheng-kung is well supplied with railways, Mukden being in direct railway connexion with Peking, Niu-chwang, Port Arthur and Tairen as well as with the Korean railways, and with European and Vladivostock by the trans-Siberian line. The Mukden-Peking railway for another route to the interior has been begun (Dairen) which passes through the Great Wall at Shan-kai-wan and along the shores of the Gulf of Chih-li, and after leaving Mukden divides into three branches—one going eastward to Korea, another going by Kirin and A-she-ho to San-sing, while a third diverges N. by W. to Faku; thence through Mongolia to Pe-tu-na, and then to T'ai-tai-har, Mengen, and the Amur. Another road leads east from Niu-chwang to Fung-hwang-chung, now a station on the Mukden-Korea railway. The chief agricultural products are wheat, barley, millet, oats, maize, cotton, indigo and tobacco. Coal, iron and gold are also found in considerable quantities in the district. (See also Manchuria and China.)

SHEN-SI, a northern province of China, bounded N. by the Great Wall, W. by the province of Kan-su, S. by the province of Sze-ch'uen, and E. by Shan-si, from which it is separated by the Hwang-ho. Area about 75,000 sq. m.; pop. about 8,300,000. Si-gan Fu (q.v.), or Sian Fu, is the provincial capital; there are six other prefectural cities. Shen-si is divided into two parts by a barrier of mountains, consisting of the Fu-niu Shan and the Tsing-ling Shan, which attain elevations of over 11,000 ft., and run across the southern portion of the province. The great rivers of the west divide into the basins of the Wei-ho and of several other tributaries to the Hwang-ho. The name Shen-si, "west of the pass," refers to the Tungkwan pass, near the confluence of the Wei and the Hwang-ho. The valley of the Wei, situated between high tableland (the Ordis plateau) on the north and rugged mountains to the south, forms the great channel of communication between Eastern China and Central Asia. Were it in the hands of an enemy the Chinese colonies in Central Asia would be completely severed from the mother country, hence the eagerness evinced by the government through- out the Han-kiang and the Tien-shan, the district are the sites of cities used as capitals of China in remote antiquity. Si-gan Fu, founded in the 3rd century B.C., was usually the capital until the time of the Kin dynasty (A.D. 1127), and it was chosen by the dowager empress as the temporary capital during the stress of the Boxer outbreak (1900-1901). It is noted also as containing the celebrated Nestorian tablet, erected A.D. 781, on which is engraved an edict according to Moslem to the Nestorian missionaries. Modern Christian (Protestant) mission work in the city dates from 1896. The walls of Si-gan enclose a square space of 6 m. each way, and, unlike most Chinese cities, its fortifications are kept in perfect repair. During the Mahomedan rebellion it was closely invested for two years (1868-1870) by the rebels, who, however, failed to capture it. During a great famine which occurred in 1902 about 2,500,000 persons in the province died of starvation.

From Si-gan Fu radiate a number of roads going east, south and west. The east road is the great Tung-kwan road, which forms the main principle of communication between Peking and the north-eastern provinces of the empire, and Sze-ch'uen, Yunnan and Tibet. To the south, one road crosses the mountains to Shang-chow, and is connected with the Tsaidam and the Tsaidam river. Another to the east leads to the Yangtze-kiang, and another to the Yangtze-shan. This road was followed by the Nestorians and by the T'ang-shan nann-lu. It was along these roads that the fame of China first reached Europe, and it was by the T'ang-shan nann-lu that Marco Polo entered the empire. To defend this line of communication the Great Wall...
SHENSTONE—SHEPPY

was extended beyond Su-chow, and the Kia-yu gate, “the door of the empire,” was built. During the reign of Hia-wu Ti of the Han dynasty, Chinese colonies and high roads lined with fortified cities were established along this route, and though at times the government have lost possession of the line beyond the Great Wall, it has always succeeded in re-establishing its supremacy over it. Occupying a position, then, at the confluence of the roads which connect north-east China with the west and south, and although the city of Peking is in the north and the city of Hu-tu in the south, it was a city of great commercial importance. It has few manufactures, but does an extensive trade principally in the importation of silk from Cheh-chiang and Sze-ch‘en, tea from Hu-peh and Hu-tu, and manufactured goods from the north and the south. It is the present home of many of the other articles (such as skins and furs) to Kan-suh, Russia and Central Asia.

Shen-si is purely an agricultural province. Its principal products are Poem, cotton and opium—the anti-opium decrees of 1906 had little effect on the province up to 1910—and these it exchanges with the neighbouring provinces for coal, iron, salt, &c., Kao-liao, pulse, millet, maize, groundnut, barley, beans, peas, luceerne, and rye are also produced. In addition to these crops, Si-gan evergreen trees or shrubs are to be met with within the province. Shen-si is specially noted for the varnish tree. Wolves are numerous in the mountains; the heron, ibis, wild goose and snipe in the valleys.

SHENSTONE, JOHN [Jack] (1714-1765), English poet, son of Thomas Shenstone and Anne, daughter of Willem Penn of Harborough Hall, Hagley, was born at the Leasowes, a property in the parish of Halesowen, now in Worcestershire, but then included in the county of Shropshire. At school he began a life-long friendship with Richard Jago, and at Pembroke College, Oxford, where he matriculated in 1732, he made another firm friend in Richard Graves, the author of The Spiritual Quixote. He took no degree, but, while still at Oxford, he published for private circulation Poems on various occasions, written for the entertainment of the author (1737). This edition, containing the first draft of "The Schoolmistress," Shenstone tried hard to suppress, but in 1742 he published anonymously a revivified form of The Schoolmistress, a Poem in imitation of Spenser.

The original was Sarah Lloyd, teacher of the village school where Shenstone received his first education. Isaac D’Israeli pointed out that it should not be classed, as it was by Robert Dodson, as a moral poem, but that it was intended as a burlesque, to which Shenstone appended in the first instance a "ludicrous index." In 1741 he published The Judgment of Hercules. He inherited the Leasowes estate, and retired there in 1745 to undertake what proved the chief work of his life, the beautifying of his property. He embarked on elaborate schemes of land drainage which gave the Leasowes a wide celebrity, but sadly impoverished the owner. Shenstone was not a contented recluse. He desired constant admiration of his gardens, and he never ceased to lament his lack of fame as a poet.

Shenstone’s poems of nature were written in praise of her most artificial aspects, but the emotions they express were obviously genuine. His Schoolmistress was admired by Goldsmith, with whom Shenstone had much in common, and his "Elegies" written at various times and to some extent biographical in character won the praise of Robert Brooke, in the preface to Poems, chiefly in the Scottish Dialect (1786), called "the most celebrated poet whose divine elegies do honour to our language, our nation and our species." This was the best pure example of his skills in the management of the anaepaestic trimer in his "Pastoral Ballad in Four Parts" (written in 1743), but first printed in Dodson’s Collection of Poems (vol. iv., 1755). Shenstone died unmarried on the 11th of February 1765.

His works were first published by his friend Robert Dodson (3 vols., 1773), but the most complete edition is that of R. A. Dodsley, containing the Poetical Works and Correspondence of the Leasowes. The last, consisting of correspondence with Graves, Jago and others, appeared after Dodson’s death. Other letters of Shenstone’s are included in Select Letters (ed. Thomas Hill 1728). The letters of Lady Luxborough (née Henrietta St John to Shenstone were printed by T.Dodside in 1775; much additional correspondence is preserved in the British Museum—letters to Lady Luxborough are in the MS. 28959, and correspondence between Shenstone and Bishop Percy from 1737 to 1763—the last being of especial interest to Shenstone was due to the original suggestion of Percy’s Reliques, a celebrated collection of poetry which would attract attention. Shenstone’s work has been a monument of the romantic movement in English literature. See also Richard Graves, Recollections of some particulars in the Life of the Late William Shenstone, 1770; H. Sydney Grazebrook, The Family of Shenstone the Poet (1800); Lenear Morison, “Shenstone" in the Gentleman’s Magazine (vol. 289, 1900, pp. 196-205); A. Chalmers, English Poets (1810, vol. xii), with "Life" by Samuel Johnson; his Poetical Works (1778), and, in the Modern Library of the British Classics (ed. G. Grimaldi; T. D’Oyly), "The Domestic Life of a Poet—Shenstone vindicated," in Curiosities of Literature; and "Burns and Shenstone," in Field in Field (1894), by "Hugh Halliburton" (J. L. Robertson.

SHEPPY, JOHN [Jack] (1702-1724), English criminal, was born at Stepney, near London, 11 December 1702. His father, who, like his grandfather and great-grandfather, was a carpenter, died the following year, and Jack Sheppard was brought up in the Bishopsgate workhouse. One of his father’s old employers apprenticed him to the family trade, but young Sheppard fell into bad company at a neighbouring Drury Lane tavern. Here he met Elizabeth Lyon, known as "Edgeworth Bess," a woman of loose character with whom he lived, and to gratify whose tastes he committed many of his crimes. At the end of 1723 he was arrested as a runaway apprentice, and then escapes. In 1724, "he was heard of almost every one that stood in my way," Joseph Blake, known as "Blueskin," being a frequent confederate. In the first six months of 1724 he twice escaped from gaol, and towards the end of that period he was responsible for an almost daily robbery in or near London. Eventually, however, his independent attitude provoked the bitter enmity of Jonathan Wild, who procured his capture at the end of July. Sheppard was tried at the Old Bailey and condemned to death, but, largely thanks to "Edgeworth Bess," he managed to escape from the condemned cell, and was soon back in his old haunts. In September he was re-arrested and imprisoned in the strongest cell of Newgate, being actually chained to the floor of his cell, but by a combination of strength and skill he escaped through the chimney to the roof of the prison, whence he lowered himself into the adjoining house. After a few days' concealment he was roused enough to reappear in the Drury Lane quarter. He was captured, hopelessly drunk, in a Clare Market tavern and reimprisoned, his cell being now watched night and day. On 16th of November 1724 he was hanged at Tyburn. He was then not quite twenty-two.

Sheppard has been made the unworthy hero of much romance, of which Harrison Ainsworth’s novel, Jack Sheppard (1839), is the most notable instance. In truth he was merely a vulgar scoundrel, who did not hesitate to rob his only real friend.

See A Narrative of all the Robberies, Escapes, &c., of John Sheppard, attributed to Daniel Defoe (London, 1724); Newgate Calendar, ed. Knapp and Baldwin; Grifiths, Chronicles of Newgate; British Journal (August, October 1724); Weekly Journal (August, September, November 1724); Celebrated Trials.

SHEPPY, an island off the Kentish coast of England, included in the north-eastern parliamentary division of Kent. It is the largest of the several low islands which are separated from the mainland by the ramifying creeks about the mouth of the river Medway. The strait isolating Sheppy is called the Swale; it is about 3 m. broad at its eastern end, but narrows to some 300 yds. at the west, where it is crossed on a bridge by a branch of the South-Eastern & Chatham railway, and by a road. There is a ferry here, but at low water the straggers are low-lying, with one small elevation slightly exceeding 200 ft. near the north coast, which presents slight cliffs towards the shallow sea. These are frequently encroached upon by the sea, while the flat shore on the south is protected by embankments. Sheppy is 10¾ m. in extreme length from E. to W., while the greatest breadth is about 5 m. On the south, narrow branches of the Swale, formerly wider, divide the isles of Harty and Elmley from the main island, of which, however, they now practically form part. Sheppy is for the most part treeless but very fertile,
bears much grain and fruit; its name, meaning the "island of sheep," is still appropriate, as great flocks are bred. On the west are the port of Queenborough and the naval station of Sheerness. From here the Sheppey light railway runs east through the island, serving Sheppey, Lowen, and Lovelady, which are in some favour as seaside resorts. The London clay, of which the island is composed, abounds in fossils.

SHEPSTONE, SIR THEOPHILUS (1817–1893), British South African statesman, was born at Westbury near Bristol, England, on the 8th of January 1817. When he was three years old his father, the Rev. William Shepstone, emigrated to Cape Colony. Young Shepstone was educated at the native mission stations at which his father worked, and the lad acquired great proficiency in the Kaffir languages, a circumstance which determined his career. In the Kaffir War of 1835 he served as headquarters interpreter on the staff of the governor, Sir Benjamin D'Urban, and at the end of the campaign remained on the frontier as clerk to the agent for the native tribes. In 1838 he was one of the party sent from Cape Colony to occupy Port Natal on behalf of Great Britain. This force was recalled in 1839, when Shepstone was appointed British resident among the Fingo and other tribes in Kafraria. Here he remained until the definite establishment of British rule in Natal and its organization as an administrative entity, when Shepstone was made (1843) agent for and captain-general of the native tribes. In 1848 he became captain-general of the native levies; in 1855 judicial assessor in native causes; and, in 1856, on the remodelling of the Natal government, secretary for native affairs and a member of the executive and legislative councils. This position he held until 1877. Thus for over thirty years he was the director of native policy in Natal. A man of strong will and pronounced views he gained a great influence over the natives, by whom he was called "father, and, in acknowledgment of his hunting exploits, "Somsete." The main line of his policy was to maintain tribal customs as far as consistent with principles of British law and not to attempt to force civilization. The result of his policy is still traceable in the condition and status of the Natal natives. While he remained in charge there was but one serious revolt of the natives—that of Langalilebele in 1873—against white control.

Shepstone's influence with the Zulus was made use of by the Natal government; in 1861 he visited Zululand and obtained from Panda a public recognition of Cetywayo as his successor. Twelve years later Shepstone attended the proclamation of Cetywayo as king, the Zulu chieftain, and shepherded Cetywayo to live at peace with his neighbours. In 1874 and again in 1876 Shepstone was in London on South African affairs, and to his absence from Natal Cetywayo's failure to keep his promises is, in part, attributed. When in London in 1876 Shepstone was entrusted by the 4th Earl of Carnarvon, then secretary of state for the colonies, with a special commission to confer with the Transvaal executive on the question of the federation of the South African states, and given power, should he deem it necessary, to annex the country, subject to the confirmation of the British government. Shepstone went to Pretoria in January 1877, and on the 12th of April issued a proclamation announcing the establishment of British authority over the Transvaal. Shepstone's force consisted of twenty-five mounted policemen only, but no overt opposition was made to the annexation; the republic at the time was in a condition bordering on anarchy. "Nothing but annexation," wrote Sir Theophilus to the Colonial Office, "will or can save the state, and nothing else can save South Africa from the direst consequences. All the thinking and intelligent people know this, and will be thankful to be delivered from the thrall of petty factions which, if they are perpetually kept in a state of excitement and unrest, because the government and everything connected with it is a thorough sham" (Martineau's Life of Sir Bartle Frere, ch. 18). Shepstone's action has been condemned as premature. He had, however, reason to believe that if Great Britain remained inactive, Germany would be induced to undertake the protection of the Transvaal.

Moreover, had the policy of self-government for the Boers which he outlined in his annexation proclamation been carried out, the revolt of 1880–81 might not have occurred. The British policy also probably of the 19th century, and a science of native expeditions, as assistant-commissary of Zululand, in the South African War, 1899-1902, and became in 1909 secretary for native affairs (Natal) and secretary of the Natal native trust. A younger brother of Sir Theophilus, John Wesley Shepstone (b. 1827), filled between 1846 and 1866 various offices in Natal in connexion with the administration of native affairs.

SHEPSTONE MALLET, a market town in the eastern parliamentary division of Somersetshire, England, 22 m. S.W. of Bath, on the Somerset & Dorset and the Great Western railways. Pop. of urban district (1911), 5,258. The old town extends in a narrow line along the river Sheppey, while the modern town has for its main street a viaduct across the river valley. The church of St Peter and St Paul is especially noteworthy. Consisting of a chancel, clerestoried nave, and aisles, it is Early English and Perpendicular in style, and contains a beautiful 13th-century oak roof of 350 panels, each with a different design; a 15th-century pulpit of carved stone; and some interesting old monuments of the Strode, Mallet and Gournay families. The market cross, over 50 ft. high, and one of the finest in Somerset, was erected by Walter and Agnes Buckland in 1500. Shepstone possesses a grammar school, a training college, and an agricultural and art school. The once flourishing cloth and woollen trades have declined, but there are large breweries, roperies, potteries, and, in the neighbourhood, marble, granite, asphalt and lime works.

Shepton, before the conquest called Sepetom, was in the possession of the abbots of Glastonbury for four hundred years, and then passed to a Norman, Roger de Courcelle. Afterwards it came into the possession of the Norman barons Mallet or Mallet, one of whom was fined for rebellion in the reign of King John. From the Mallets it went to the Gournays, but in 1556 it reverted to the crown, and it is now included in the duky of Cornwall. The town received the grant of a market from Edward II. Monmouth and the rebel army passed through Shepton twice in 1685, and twelve of the rebels were hanged here by Judge Jeffreys.

SHERANI, or SHRANI, a Pathan tribe on the Dera Ismail Khan border of the North-west Frontier Province of India. The Sherani Agency occupies an area of 1,500 sq. m. and had a population in 1901 of 12,371. The Sherani occupy the principal part of the mountainous tract known as the Tskhi-i-Sulman and the country thence eastward down to the border of Dera Ismail Khan district. They are bounded on the north by the Gomal Pass, and beyond that by the Mahaud Wahziris; on the south by the Ustaranas and Zmarais; and on the west by the Haripals, Kakars and Mandu Khels. Between the Sherani country and the British border lie several small mountain ridges, across which the three chief passes are the Zarakni or Shidkhi Haidar.

1 Freer to J. M. Maclean, 22nd of April 1881: Life of Sir Bartle Frere, vol. ii. p. 183.)
the Drabant and the Chandwan. The Sheranis are generally of middling stature, thin, but handy and active. They have bold features, high cheek-bones, and their general appearance is wild and manly. Their dress consists of a coarse black blanket tied round the waist, and another thrown over the shoulders. Their chief occupation is agriculture, but they carry on an extensive trade in furs, and it is said that the jaffa men of the Dera jacket district. The Sherani tribe and country are divided into two well-defined branches called Bargha and Largha, or the Highlands and the Lowlands, the inhabitants being called respectively Barghawals and Larghawals. The Highlands are on the side of Zhub, the Lowlands on the side of the Dera jacket, and the dividing line being generally the watershed and higher peaks of the Takhti-Sultan range of mountains. The physical configuration of the country makes the separation so complete that the two tribal divisions act independently of each other. After the Zhub expedition of 1890 the question of boundaries between the Punjab and Baluchistan came up for settlement, and the government decided that Bargha should remain with Baluchistan and Largha with the Punjab. The Gomal river from Kundar-Domandi to Kajuri-Kach is the boundary between Baluchistan and Waziristan, as well as between the respective provinces. In 1901 these frontier districts were transferred from the Punjab to the North-west Frontier Province.

SHERATON, THOMAS (c. 1735-1806), next to Chippendale, the most famous English furniture-designer and cabinet-maker, was born in humble circumstances as the Stockton-on-Tees. His education was rudimentary, but he picked up drawing and geometry. He appears to have been apprenticed to a cabinet-maker, but he was ever a strange blend of mechanic, inventor, artist, mystic and religious controversialist. Indeed, it is as a writer on theological subjects that we first hear of him. Although his parents were church people he was a Baptist, and in 1782 he published at Stockton A Scriptural Illustration of the Doctrine of Regeneration, to which was added A Letter on the Subject of Baptism, describing himself on the title page as a "mechanic, one who never had the advantage of a collegiate or academical education." Of his career as a meister and designer of furniture nothing is known until he is first heard of in London in 1790, when he was nearly forty. The date of his migration is uncertain, but it probably took place while he was still a young man. In London he did work which, although it has made him illustrious to posterity, never raised him above an almost sordid poverty. Biographical particulars are exceedingly scanty, and we do not know to what extent, if at all, he worked with his own hands, or whether he confined himself to evolving new designs, or modifying and adapting, and occasionally partly copying, those of other men of his time. It was not until after he began to write, and we know that some part of his scanty income was derived from giving drawing lessons. Even the remarkable series of volumes of designs for furniture which he published during the last sixteen years of his life, and upon which his fame depended, were not a commercial success. He was a great artistic genius who lived in chronic poverty. The only trustworthy information we possess regarding his circumstances is found in the Memoirs of Adam Black, who when he first arrived in London lodged a week in his house, only two years before Sheraton's death. "Sheraton," he says, "lived in a poor street, in London, his house half shop, half dwelling-house, and himself looked like a worn-out Methodist minister, with threadbare black coat. I took tea with them one afternoon. There was a cup and saucer for the host, and another for his wife, and a little porringer for their daughter. The wife's cup and saucer were given to me, and she had to put up with another little porringer. My host seemed a good man, with some talent. He had been a cabinet-maker, and was now author, publisher, and teacher of drawing, and, I believe, occasional preacher. Black shrewdly put his finger upon the very quickness of Sheraton's failure. He was a worn-out encyclopaedist and preacher is an interesting character. . . . He is a man of talent and, I believe, of genuine piety. He understands the cabinet business—I believe he bred to it. He is a scholar, writes well, and, in my opinion, draws masterfully—

is an author, bookseller, stationer and teacher. . . . I believe his abilities and resources are his ruin in this respect—by attempting to do everything he does nothing. There is, however, little indication that Sheraton chafed under the tyranny of those twin jailors of the daring heart, low birth and iron form as it was, 'I cannot help the reader,' he writes in one of his books, 'though I am thus employed in raking my invention to design fine and pleasing cabinet-work, I can be well content to sit upon a wooden-bottom chair, provided I can but have common food and raiment wherewith to pass through life in peace.' His first book on furniture was published in 1791 with the title of The Cabinet-Maker and Upholsterer's Drawing Book. It was issued in parts by T. Bensley, of Bolt Court, Fleet Street; there was a second edition in 1793 and a third in 1802, each with improvements. In the first edition it was stated that copies could be obtained from the author at 41 Davies Street, Grosvenor Square; in the second, that he was living at 106 Wardour Street; the last address we have is 8 Broad Street, Golden Square. There was also an 'Accompaniment' and an "Appendix." In this book, which contained 111 copper-plate engravings, Sheraton gives abundant evidence of the arrogance and conceit which marred all his publications. He dismissions Chippendale's designs in a patronizing way as "now wholly antiquated and laid aside, though possessed of great merit according to the times in which they were executed." His lack of practical common sense is suggested by the fact that most of the book is taken up with a treatise on perspective, needless then and unreadable now. He falls foul of every volume on furniture which had been published before his time, and is abundantly satisfied of the merit of his own work. The designs in the book are exceedingly varied and unequal, ranging from pieces of perfect proportion and the most pleasing simplicity to efforts ruined by too abundant ornament. Some of the chair-backs are delightful in their grace and delicacy, but in them, as in other of his drawings, it is easy to trace the influence of Hepplewhite and Adam—his mentor. In 1802 he published a book, the authorship of which is generally ascribed to Adam. Sheraton, indeed, like his predecessors, made extensive use not so much perhaps of the works of other men as of the artistic ideas underlying them which were more or less common to the taste of the time. He was sometimes original, sometimes adaptive—what Alexandre Dumas père called a "conqueror"—sometimes a copyist. His "conquest" of Hepplewhite was especially unmerciful, for he abused as well as pillaged him. But his slender forms and sweeping curves were his own inspiration, and his extensive use of sashwood differentiated his furniture from that of his contemporaries. It must be remembered that Sheraton's books, like those of the other great cabinet-makers of the second half of the 18th century, were intended not for the "general reader" but for the practical use of the trade, which, no doubt, copied their designs extensively, although it is reasonable to suppose that he himself obtained orders by the publication of his books and employed other cabinet-makers to manufacture the work. It seems certain, however, that he himself never possessed anything more than a small shop. Of his own actual manufacture only one piece is known with certainty—a glass-fronted book-case, of somewhat frigid charm, stamped "T.S." on the inside of one of the drawers. It lacks the agreeable swan-necked pediment so closely associated with his style. The Drawing Book, of which a German translation appeared at Leipzig in 1794, was followed in 1802 and 1803 by The Cabinet Dictionary, containing an Explanation of all the Terms used in the Cabinet, Chair and Upholstery branches, containing a display of useful articles of furniture, illustrated with eighty-eight copperplate engravings. The text is in alphabetical form, and, in addition to a supplement with articles on drawing and painting, the book contained a list of "most of the master-cabinet-makers, upholsterers, and chair makers,"" 252 in number, then living in and around London. Sheraton told his readers that he had hitherto derived no profit from his publications on account of the cost of producing them.
SHERBET—SHERBORNE

Some of the designs in this volume show the earlier stages of the tendency to the tortured and the bizarre which disfigured so much of Sheraton's later work. This debased taste reached its culmination in The Cabinet Maker, Upholsterer and General Artists' Encyclopedia, the publication of which began in 1804. It was to consist of 125 numbers, but when the author died two years later only a few had been issued. The plates are in colour. The scope of this work was much wider than the title suggests. It dealt not only with furniture and decoration, but with history, geography, biography, astronomy, botany and other sciences. The method of illustration was the engraving of "material things that Sheraton loved in his style, once so graceful and so delicate, by an over-anxious following of the pseudo-classical taste which in France marked the period of the Consulate and the Empire. The harmonious marquetry, the dainty painting of flowers in wreaths and festoons, the lightness and finish were replaced by pieces of furniture which at the best were clumsy and at the worst were hideous. Some of the chairs especially which he designed in this last period are amazingly grotesque, their backs formed of fabulous animals, their "knees and legs and heads of animals." Sheraton was a very changing little work-tables bear Sheraton's attribution, even if these graceful trifles in his later forms lose their delicacy and become squat and heavy. He designed many beautiful sideboards and bookcases, but he finished by drawing pieces that were ruined by insistence upon the characteristics, and often the worst characteristics, of the Empire manner. Sheraton's inventive ingenuity had led him to devise many of the ingenious pieces of combination or "harlequin" furniture which the latter part of the 18th century loved. Thus a library table would conceal a step-ladder for reaching the top shelves of bookcases, a dressing table would be also a wash-stand and an escritoire—but this he admitted that he did not introduce—looking-glasses would enclose dressing-cases, writing-tables or work-tables. But his most astonishing fancy was an ottoman with "heating urns" beneath, "that the seat may be kept in a proper temperature in cold weather." How far he was responsible for the introduction of the hideous hall chair, made of mahogany, with the owner's crest painted on the back, which was common for three-quarters of a century after he died, is not clear; but he describes and illustrates it.

That Sheraton can have been personally popular is incredible. His books make it evident that his character was tart, angular and self-assertive, and that he was little disposed to be generous towards the work of predecessors or rivals. Such an attitude towards the world would suffice to explain his lack of substantial success. He appears to have preached occasionally to the end, and even in his furniture books he sometimes falls into improving remarks of a religious character. As we have seen, his first publication was a religious work, and when in 1794 his friend Adam Candler, the landscape painter, wrote a pamphlet entitled Thoughts on the Peaceable and Spiritual Nature of Christ's Kingdom, Sheraton contributed to it an exhortation upon Spiritual Subjection to Civil Government, which was reprinted separately with additions a year later. In 1805 he issued A Discourse on the Character of God as Love. He died on Oct. 22nd, 1806, at No. 8 Broad Street, Golden Square, aged about 55, from, it is said, over-work. An obituary notice of him appeared in the Gentleman's Magazine of the following month, which stated that he had been for many years "a journeyman cabinet-maker, but since 1793 supported a wife and two children by authorship." He was described as "a well-disposed man, of an acute and enterprising disposition." The writer added that he had "left his family, it is feared, in distressed circumstances, and that he had travelled to Ireland to obtain subscribers for the Encyclopedia, of which at the time of his death nearly 1000 copies had been sold. In 1812 there appeared a parallel volume, Designs for Household Furniture exhibiting a Variety of Elegant and Useful Patterns in the Cabinet, Chair and Upholstery Branches on eighty-four Plates. By the late T. Sheraton, Cabinet-maker. This was in the main, if not entirely, a collection of plates from the Cabinet Dictionary and the Encyclopedia.

Thomas Sheraton is unquestionably the most remarkable man in the history of English furniture. His genius was less sane and less balanced than that of Chippendale, but despite his excursions into the Chinese and Louis Quinze manners, Chippendale always produced an impression of English work. Sheraton's greater adaptability, his readiness to receive foreign impressions, his adaptations of Louis Seize ideas, the lightness of his forms and the grace of his conceptions had about them a touch of the exotic which was heightened by his lavish employment of satin-wood and other beautifully grained woods susceptible of a high polish. To this there are no more charming things inside French furniture than some of the creations of Sheraton in his great period. The severe and balanced forms, the delicate inlay, the occasional slight carving in low relief, the painted enrichments, the variety of the backs and legs of his chairs produce an impression of lightness and grace that has never been surpassed; whether he designed a little knife-case or the body of a long clock, harmony, proportion and a delicate fancy were ever present. It is true that he adapted and even copied extensively, but so did every one else, and it is impossible to be sure what he might have done if he had not been adapted to the particular man whose name has become associated with it. Indeed "Sheraton," like "Chippendale," has come to indicate a style rather than a personal attribution. But the volume and the beauty of the designs in his books is such that, when every allowance has been made for adaptation, there remains a mass of beautiful work which cannot be denied to him. In later life his very adaptability was his undoing. The public, always ready to take its mobiliary fashions from France, demanded Empire furniture, and Sheraton may have been, or have have forced himself to be, compelled to give them what they wanted. His extravagant creations in that sphere—far worse than anything that was designed in France—had much to do with the development of a fashion of English Empire which finally ruined British furniture design. He rioted in sphinxes and lions and fabulous beasts, he evolved forms that were dull and cumbrous, and added to their heaviness by brass mounts at once massive and uninspired. After his death the eccentricity may have been less, but the heaviness and dullness were greater, and with the disappearance of Sheraton the brief but splendid outburst of English furniture ended in gloom. It had lasted little more than a half a century, but it was a half-century which only France ever could, or did, rival. It is one of the strangest ironies in the history of art that the last and almost the greatest exponent of the English genius in the sphere of furniture was in fact a visitation from abroad that France ever could, or did, rival. It is one of the strangest ironies in the history of art that the last and almost the greatest exponent of the English genius in the sphere of furniture was in fact a visitation from abroad that France ever could, or did, rival. SHERBROOKE, WESTCOTT

SHERBROOKE, ROBERT LOWE, Viscount (1811–1892), British statesman, was born on the 4th of December 1811 at Bingham, Notts, where his father was the rector. He was educated at Winchester and University College, Oxford, where he took a first class in classics and a second in mathematics, besides taking a leading part in the Union debates. In 1835 he won a fellowship at Magdalen, but vacated it on marrying, in 1836, Miss Georgina Orred (d. 1884). He was for a few years a successful "coach" at Oxford, but in 1838 was bitterly disappointed at not being elected to the professorship of Greek at Glasgow. In 1841 Lowe moved to London, to read for the Bar ("called" 1842); but his eyesight showed signs of serious weakness, and, acting on medical advice, he determined to try his fortune in the colonies rather than in London. He went to Sydney, where he set to work in the law courts. In 1845 he was nominated by Sir George Gipps, the governor, to a seat in the New South Wales Legislative Council; owing to a difference with Gipps he resigned his seat, but was elected shortly afterwards for Sydney. Lowe soon made his mark in the political world by his clever speeches, particularly on finance and education; and besides obtaining a large legal practice, he was one of the principal writers for the Atlas newspaper. In 1850 he went back to England, in order to enter political life there. His previous university reputation and connexions, combined with his colonial experience, stood him in good stead. The Times was glad to employ his ready pen, and as one of its ablest leader-writers he made his influence widely felt. In 1852 he was returned to Parliament for Kidderminster in the Liberal Interest. The House of Commons was not a place for a man of Lowe's size and an agricultural centre. On the separation of the offices of bishop and abbey in 1122, the abbot's see was carved out of the bishop's manor, but did not include the town. Bishop Roger of Caen (1107–1130) built the castle, described by Henry of Huntingdon as scarcely inferior to that of Devizes, "than which there was none greater within the confines of England." Its strength made Stephen force Bishop Roger to surrender it in 1139, but during the civil war in his reign it passed into the hands of the empress Maud. It was later granted to the earls of Salisbury, who seem to have allowed it to fall into disrepair, for in 1315 and in 1319 the abbey of Sherborne was appointed to inquire into its condition. It was recovered by the bishop in 1355, and retained by the see until granted in 1599 to Elizabeth, who gave it to Sir Walter Raleigh. The abbey church was partly burnt in 1437, in a riot due to the monks' refusal to recognize the town's church of St. Peter's. As the parish church, though they had restricted their use of the abbey church for parochial purposes. Signs of this fire are still visible on the walls, which are in part tinged red by the flames. The town, though frequently the centre for medieval assizes and inquisitions, never became a municipal or parliamentary borough, but was governed by two constables, elected in the municipal court. In 1540 Sir John Horsey, who had bought the manor and church at the Dissolution, sold the abbey to the vicar and parishioners. The Reformation made no break in the continuity of the school, which had probably existed in the abbey since the 11th century. Edward VI. by his charter in 1550 made its governors one of the first purely lay educational corporations founded in England. The town suffered severely during the civil wars, the castle being besieged by the parliamentary forces in 1642 and 1645. The fairs now held on the 8th of May, the 26th of July and the first Monday after the 10th of October, have been granted to the town since 1212, 1290 and 1309. After the decline of the medieval trade in cloth, lace and buttons were the only articles manufactured here until the introduction of silk-weaving in 1740. In June 1905, in commemoration of the 1200th anniversary of "the town, the bishopric and the school," an historical pageant, invented and arranged by Louis N. Parker (at one time music-master at the school), was held in the grounds of Sherborne Castle, and set the model for a succession of pageants held subsequently in other historic English towns.

SHERBROOKE, ROBERT LOWE, Viscount (1811–1892), British statesman, was born on the 4th of December 1811 at Bingham, Notts, where his father was the rector. He was educated at Winchester and University College, Oxford, where he took a first class in classics and a second in mathematics, besides taking a leading part in the Union debates. In 1835 he won a fellowship at Magdalen, but vacated it on marrying, in 1836, Miss Georgina Orred (d. 1884). He was for a few years a successful "coach" at Oxford, but in 1838 was bitterly disappointed at not being elected to the professorship of Greek at Glasgow. In 1841 Lowe moved to London, to read for the Bar ("called" 1842); but his eyesight showed signs of serious weakness, and, acting on medical advice, he determined to try his fortune in the colonies rather than in London. He went to Sydney, where he set to work in the law courts. In 1845 he was nominated by Sir George Gipps, the governor, to a seat in the New South Wales Legislative Council; owing to a difference with Gipps he resigned his seat, but was elected shortly afterwards for Sydney. Lowe soon made his mark in the political world by his clever speeches, particularly on finance and education; and besides obtaining a large legal practice, he was one of the principal writers for the Atlas newspaper. In 1850 he went back to England, in order to enter political life there. His previous university reputation and connexions, combined with his colonial experience, stood him in good stead. The Times was glad to employ his ready pen, and as one of its ablest leader-writers he made his influence widely felt. In 1852 he was returned to Parliament for Kidderminster in the Liberal Interest. The House of Commons was not a place for a man of Lowe's size and an agricultural centre. On the separation of the offices of bishop and abbey in 1122, the abbot's see was carved out of the bishop's manor, but did not include the town. Bishop Roger of Caen (1107–1130) built the castle, described by Henry of Huntingdon as scarcely inferior to that of Devizes, "than which there was none greater within the confines of England." Its strength made Stephen force Bishop Roger to surrender it in 1139, but during the civil war in his reign it passed into the hands of the empress Maud. It was later granted to the earls of Salisbury, who seem to have allowed it to fall into disrepair, for in 1315 and in 1319 the abbey of Sherborne was appointed to inquire into its condition. It was recovered by the bishop in 1355, and retained by the see until granted in 1599 to Elizabeth, who gave it to Sir Walter Raleigh. The abbey church was partly burnt in 1437, in a riot due to the monks' refusal to recognize the town's church of St. Peter's. As the parish church, though they had restricted their use of the abbey church for parochial purposes. Signs of this fire are still visible on the walls, which are in part tinged red by the flames. The town, though frequently the centre for medieval assizes and inquisitions, never became a municipal or parliamentary borough, but was governed by two constables, elected in the municipal court. In 1540 Sir John Horsey, who had bought the manor and church at the Dissolution, sold the abbey to the vicar and parishioners. The Reformation made no break in the continuity of the school, which had probably existed in the abbey since the 11th century. Edward VI. by his charter in 1550 made its governors one of the first purely lay educational corporations founded in England. The town suffered severely during the civil wars, the castle being besieged by the parliamentary forces in 1642 and 1645. The fairs now held on the 8th of May, the 26th of July and the first Monday after the 10th of October, have been granted to the town since 1212, 1290 and 1309. After the decline of the medieval trade in cloth, lace and buttons were the only articles manufactured here until the introduction of silk-weaving in 1740. In June 1905, in commemoration of the 1200th anniversary of "the town, the bishopric and the school," an historical pageant, invented and arranged by Louis N. Parker (at one time music-master at the school), was held in the grounds of Sherborne Castle, and set the model for a succession of pageants held subsequently in other historic English towns.

See William Beauchamp Wildman, A Short History of Sherborne from A.D. 705 (1902), and Life of S. Edelheim, first Bishop of Sherborne (Sherborne, 1905).

1 This phrase is always ascribed to Lowe, and has become history in association with him. But what he really said in his address to the Edinburgh Philosophical Institution in 1867 was that it was necessary "to induce our future masters to learn their letters."
SHERIDAN

halfpenny a box on lucifer matches in 1871 (for which he sug-
gested the epigram ex luce lucellum, “out of light a little profit”) rousted a storm of opposition, and had to be dropped. In 1873 he was transferred to the Home Office, but in 1874 the govern-
ment resigned. When the Liberals returned to power in 1880 he was raised to the peerage as Viscount Sherbrooke, but from 1875 till his death at Watlingham, Surrey, on the 27th of July 1892, his health was constantly failing, and by degrees he figured less and less in public life.

Bobby Lowe, as he was popularly known, was one of the most remarkable personalities of his day, with his tall, striking figure, albinic complexion, and hair, and faculty for epigram and irony. During the ’seventies the following epitaph was suggested for him by one of the wits of his day:—

“Here lies poor old Robert Lowe;
Where he’s gone I don’t know;
If to the realms of peace and love,
Farewell to happiness above:
If, haply, to some lower level,
We can’t congratulate the devil.”

Lowe was delighted with this, and promptly translated it into Latin, as follows:—

“Centinuntur hac in fossa
Humilis Roberti ossa;
Sic ad coelum evolabit,
Pax in coele aut non restabit;
Sin in inferis jacebit,
Diabolum ejus poenitet.”

His literary talent, though mainly employed in journalism, was also shown in a little volume of verses, Poems of A Life (1884). He married a second time, in 1885, but left no children.

See Life and Letters by A. Patchett Martin (London, 1902) (H. Ct.)

SHERBROOKE, a city and port of entry of Quebec, Canada, and capital of Sherbrooke county, 101 m. E. of Montreal, at the confluence of the rivers Magog and St Francis, and on the Grand Trunk, Canadian Pacific, Quebec Central and Boston & Maine railways. Pop. (1901) 11,765. It is the seat of a Roman Catholic bishopric and of the district courts, and contains manufactories of woolens and cotton goods and machinery, also saw and gist mills. It derives its name from Sir John Coape Sherbrooke (1764-1830), who from 1816 to 1818 was governor-general of Canada.

SHERE ALI KHAN (1825-1879), Amir of Afghanistan, was born in 1825, one of the younger sons of the amir Dost Mahommed, whom he succeeded in 1863. For some time after his succession Afghanistan was in a state of anarchy, and his rebellious half-brothers overran the country while he remained at Kandahar mourning the loss of a favourite son. At length, however, the capture of Kabul in 1866 roused him to action, but in spite of his own bravery he suffered general defeat until 1868, when he regained Kabul. Supported by the viceroys of India, Lord Lawrence and Lord Mayo, Shere Ali remained on good terms with the British government for some years; but after the rebellion of his son Yakub Khan, 1870-74, he leaned towards Russia, and welcomed a Russian agent at Kabul in 1878, and at the same time refused to receive a British mission. This led to long negotiations, and ultimately to war, when the British forced the Khyber Pass in November 1878, and defeated the Amir’s forces on every occasion. Shere Ali fled from his capital and, taking refuge in Turkestan, died at Mazar-i-Sharif on the 21st of February 1879.

SHERIDAN, the name of an Anglo-Irish family, made illustri-
sous by the dramatist Richard Brinsely (No. 4 below), but prominently connected with literature in more than one genera-
tion before and after his.

1. THOMAS SHERIDAN (1687-1738), grandfather of the drama-
tist, was born at Cavan in 1687, and was educated at Trinity College, Dublin, taking his B.A. degree in 1711 and that of M.A. in 1714; he married in 1716. By a marriage with Elizabeth, heiress of Charles MacFadden, he restored to the Sheridan family Quilcagh House, which they had forfeited by their Jacobite sympathies. Thomas Sheridan is chiefly known as the favourite companion and confidant of Swift during his later residence in Ireland. His correspondence with Swift and his whimsical treatise on the “Art of Punning”1 make perfectly clear from whom his grandson derived his high spirits and delight in practical joking. The “Art of Punning” might have been written by the author of The Critic. Swift had a high opinion of his scholarship, and that it was not con-
temptible is attested by a translation of the Sappho he prepared in Dublin in 1726. He also translated the Satires of Juvenal and the Philoctetes of Sophocles. When Swift came to Dublin as dean of St Patrick’s, Sheridan was established there as a schoolmaster of very high repute, and the two men were soon close friends. Sheridan was his confidant in the affair of

Draper’s Letters; and it was at Quilcagh House that Gulliver’s Travels was prepared for the press. Through Swift’s influence he obtained a living near Cork, but damaged his prospects of further preferment by a feat of unlucky absence of mind. Having to preach at Cork on the anniversary of Queen Anne’s death he hurriedly chose a sermon with the text, “Sufficient unto the day is the evil thereof,” and was at once struck off the list of chaplains to the lord-lieutenant and forbidden the castle. In spite of this mishap, for which the archdeacon of Cork made amends by the present of a lease worth £250 per annum, “I still remained,” said the earl of Orrery (Remarks on the Life and Writings of Jonathan Swift, 1751), “a punster, a quibbler, a fiddler and a wit,” the only person in whose genial presence Swift relaxed his habitual gloom. His latter days were not prosperous, probably owing to his having “a better knowledge of Covent Garden of a man in the way of commerce” than Swift by fulfilling an old promise to tell the dean if he ever saw signs of avarice in him, and the friends parted in anger. He died in poverty on the 10th of October 1738.

The original source of information about Dr Sheridan is his son’s Life of Swift (vol. i. pp. 369-395), where his scholarship is dwelt upon as much as his improvident conviviality and simple kindness of nature.

2. THOMAS SHERIDAN (1719-1788), son of the above, was born in Dublin in 1719. His father sent him to an English school (Westminster); but he was forced by stress of circumstances to return to Dublin and complete his education at Trinity College, where he took his B.A. degree in 1739. Then he went on the stage, and at once made a local reputation. He even wrote a play, Captain O’Blunder, or the Brave Irishman, which became a stock piece, though it was never printed. There is a tradition that on his first appearance in London he was set up as a rival to Garrick, and Moore counterfeited the idea that Garrick remained jealous of him to the end. For this tradition there is little foundation. Sheridan’s first appearance in London was at the Theatre Royal, Drury Lane, on March 4, 1741, when, heralded in advance as the brilliant Irish comedian, he played for three weeks in a succession of leading parts, Hamlet being the first. In October he appeared at Drury Lane, playing Horatio in Rowe’s Fair Penitent, and subsequently as Pierre in Otway’s Venice Preserved, and in Hamlet and other parts. On his return to Dublin he became manager of the Theatre Royal, and married Frances Chamber-
laine. He was driven from Dublin as a result of his unpopular efforts to reform the theatre. A young man named Kelly had insulted the actresses, and when Sheridan interfered threatened him with the police. Shere Ali fled from his capital and, taking refuge in Turkestan, died at Mazar-i-Sharif on the 21st of February 1879.

SHERIDAN, the name of an Anglo-Irish family, made illustri-
sous by the dramatist Richard Brinsley (No. 4 below), but prominently connected with literature in more than one genera-
tion before and after his.

1 Published in Nichols’s Supplement to the works of Swift (1779).
Sheridan's the in his most failure Drury scheme was but success was of his children hitherto, and that they would exercise the school-master in the quality of patience, for two such impenetrable plumes as "for" and "had never," humorously described was Richard Brinsley, then aged seven. At the age of eleven he was sent to Harrow school. Sheridan was extremely popular at school, winning somehow, Dr Parr confessed, "the esteem and even admiration of all his schoolfellows"; and he acquired, according to the same authority, more learning than he is usually given credit for. He left Harrow at the age of seventeen, and was placed under the care of a tutor. He was also trained by his father daily in elocution, and put through a course of English reading. He had fencing and riding lessons at Drury Lane.

After leaving Harrow he kept up a correspondence with a school friend who had gone to Oxford. With this youth, N. B. Halhed, he concocted various literary plans, and between them they actually executed and published (1771) metrical translations of Aristaenetus. In conjunction with Halhed he wrote a farce entitled Jupiter, which was refused by both Garrick and Foote and remained in MS., but is of interest as containing the same device of a rehearsal which was afterwards worked out with such brilliant effect in The Critic. Some of the dialogue is very much in Sheridan's mature manner. Extracts given from papers written in the seven years between his leaving Harrow and the appearance of The Rivals—sketches of unfinished plays, poems, political letters and pamphlets—show that he was far from idle. The removal of the family to Bath in 1770-1771 led to an acquaintance with the daughters of the composer Thomas Linley. The eldest daughter, Elizabeth Ann (b. 1754), a girl of sixteen, the prima donna of her father's concerts, was exceedingly beautiful, and had many suitors, among them Sheridan, N. B. Halhed and a certain Major Mathews. To protect her from this man's persecutions, Sheridan, who seems to have acted at the time rather as a friend, than as a protector, drew up a plan of escorting Miss Linley, in March 1772, to a nunnery in France. Sheridan returned and fought two duels with Mathews, which made a considerable sensation at the time. The pair had gone through the ceremony of marriage in the course of their flight, but Sheridan kept the marriage secret, and was sternly denied access to Miss Linley by her father, who did not consider him an eligible suitor. Sheridan was sent to Waltham Abbey, in Essex, to continue his studies, especially in mathematics. He was entered at the Middle Temple on the 6th of April 1773, and a week later he was openly married to Miss Linley.

His daring start in life after this happy marriage showed a confidence in his genius which was justified by its success. Although he had no income, and no capital beyond a few thousand pounds brought by his wife, he took a house in Orchard Street, Portman Square, furnished it "in the most costly style," and proceeded to return on something like an equal footing the hospitalities of the fashionable world. His first comedy, The Rivals, was produced at Covent Garden on the 17th January 1775. It is said to have been not so favourably received on its first night, owing to its length and to the bad playing of the part of Sir Lucius O'Trigger. But the defects were remedied before the second performance, which was deferred to the 28th of the month, and the piece at once took that place on the stage which it has never lost. His second piece, St Patrick's Day, or, The Scheuning Lieutenant, a lively farce, was written for the benefit of the artist's work, hangs at Knole, Sevenoaks, Kent.
SHERIDAN

performance (2nd of May 1779) of Lawrence Clinic, who had succeeded as Sir Lucius. In November 1775, with the assistance of his father-in-law, he produced the comic opera of The Duenna, which was played 75 times at Covent Garden during that season. Sheridan now began to negotiate with Garrick for the purchase of his share of Drury Lane, and the bargain was completed in June 1776. The sum paid by Sheridan and his partners, Thomas Linley and Dr Ford, for the half-share was £33,000; of this Sheridan contributed £10,000. The money was raised on mortgage, Sheridan contributing only £5,000 in cash.1 Two years afterward Sheridan and his friends bought the other half of the property for £55,000.

From the first the direction of the theatre would seem to have been mainly in the hands of Sheridan, who derived very material assistance from his father. In February 1777 he produced his version of Vanbrugh's Relapse, under the title of A Trip to Scarborough. This is printed among Sheridan's works, but he has no more title to the authorship than Colley Cibber to that of Richard III. His chief task was to remove inconsistencies he added very little to the dialogue. The School for Scandal was produced on the 8th of May 1777. Mrs Abington, who had played Miss Hoyden in the Trip, played Lady Teazle, who may be regarded as a Miss Hoyden developed by six months' experience of marriage and town life. The lord chamberlain refused to license the play, and was only persuaded on grounds of personal friendship with Sheridan to alter his decision. There are tales of the haste with which the conclusion of The School for Scandal was written, of a stratagem by which the last act was got out of him by the anxious company, and of the fervent "Amen" written on the last page of the copy by the prompter, in response to the author's "Finished at last, thank God!"

But, although the conception was thus hurriedly completed, we know from Sheridan's sister that the idea of a "scandalous college" had occurred to him five years before in connexion with his own experiences at Bath. His difficulty was to find a story sufficiently dramatic in its incidents to form a subject for the machinations of the character-slayers. He seems to have tried more than one plot, and in the end to have desperately forced two separate conceptions together. The dialogue is so brilliant throughout, and the action scene and the screen scene so effective, that the construction of the comedy meets with little criticism. The School for Scandal, though it has not the unity of The Rivals, nor the same wealth of broadly humorous incident, is universally regarded as Sheridan's masterpiece. He might have settled the doubts and worries of authorship with Puff's reflection: "What is the use of a good plot except to bring in good things?"

Sheridan's farce, The Critic, was produced on the 29th of October 1779, The School for Scandal meantime continuing to draw larger houses than any other play every time it was put on the stage. In The Critic the laughable instruments of all classes connected with the stage—authors, actors, patrons and audience—are touched off with the lightest of hands; the fun is directed, not at individuals, but at absurdities that grow out of the circumstances of the stage as naturally and inevitably as weeds in a garden. It seems that he had accumulated notes for another comedy to be called Affection, but his only dramatic composition during the remaining thirty-six years of his life was Pizarro, produced in 1790—a tragedy in which he made liberal use of some of the arts ridiculed in the person of Mr Puff. He also revised for the stage Benjamin Thompson's pantomime, The Stranger, of Kotzebue's Menschenkass und Reue.

He entered parliament for Stafford in 1780, as the friend and ally of Charles James Fox. Apparently he owed his election for Stafford to substantial arguments. He is said to have paid the burgesses five guineas each for the honour of representing them, beside gifts in dinners and ale to the non-voting part of the community, for their interest and applause. His first speech in parliament was to defend himself against the charge of bribery, and was well received. He spoke little for a time and chiefly on financial questions, but soon took a place among the best speakers in the House. Congress recognized his services in opposing the war in America by offering him a gift of £20,000 which, however, he refused. Under the wing of Fox he filled subordinate offices in the short-lived ministries of 1782 and 1783. He was under-secretary for foreign affairs in the Rockingham ministry, and a secretary of the treasury in the Coalition ministry. One of the diatribes he has published is for Sir G. C. (Sheridan's) antagonist's argument, and the happy art of putting them in an irresistibly ludicrous light without losing his good temper or his presence of mind. In those heated days of parliamentary strife he was almost the only man of mark that was never called out, and yet he had no match in the weapon of ridicule.

Sheridan found his great opportunity in the impeachment of Warren Hastings. His speeches in that proceeding were by the unanimous acknowledgment of his contemporaries among the greatest delivered in that generation of great orators. The House denounced Hastings July 1787, on the charges brought against Hastings with regard to the beggars or princesses of Oude. Sheridan spoke for more than five hours, and the effect of his oratory was such that it was unanimously agreed to adjourn and postpone the final decision till the House should be in a calmer mood. Of this, and of his last great speech on the subject in 1794, only brief abstractions have been preserved; but with the second, the four days' speech delivered in his capacity of manager of the trial, in Westminster Hall, on the occasion so brilliantly described by Macaulay, posterity has been more fortunate. Gurney's verbatim reports of the speeches on both occasions, published by Sir G. C., were more successful in instigation 1839, and from them we are able to form an idea of Sheridan's power as an orator. There are passages here and there of gaudy rhetoric, loose ornament and declamatory hyperbole; but the strong common sense, close argumentative force and masterly presentation of telling facts enable us to understand the impression produced by the speech at the time.

From the time of the break-up of the Whig party on the succession of Burke he was more or less an "independent member," and his isolation was complete after the death of Fox. When the Whig denunciation of the French Revolution, Sheridan joined with Fox in vindicating the principles of non-intervention. He maintained that the French people should be allowed to settle their constitution and manage their affairs in their own way. But when the republic was succeeded by the empire, and it became apparent that France under Napoleon would interfere with the affairs of its neighbours, he employed his eloquence in denouncing Napoleon and urging the prosecution of the war. One of his most celebrated speeches was delivered in support of strong measures against the mutineers at the Nore. He was one of the few members who actively opposed the union of the English and Irish parliaments. When the Whigs came into power in 1806 Sheridan was appointed treasurer of the navy, and became a member of the Privy Council. After Fox's death he succeeded his chief in the representation of Westminster, and aspired to succeed him as leader of the party, but this claim was not allowed, and thenceforward Sheridan fought for his own hand. When the prince became regent in 1811 Sheridan's private influence with him helped to exclude the Whigs from power. Throughout his parliamentary career Sheridan was one of the boon companions of the prince, and his champion in parliament in some dubious matters of payment of debts. He always resented any imputation that he was not prince's confidential adviser or mouthpiece. A certain proud and sensitive independence was one of the most marked features in Sheridan's parliamentary career. After a coolness arose between him and his Whig allies he refused a place for his son from the government, lest there should be any suspicion in the public mind that his support had been bought.

His last years were harassed by debt and disappointment. He sat in parliament for Westminster in 1806-1807. At the general election of 1807 he stood again for Westminster and was defeated, but was returned as member for Ilchester, at

---

1 For the elucidation of these transactions, see Brander Matthews's edition (1885) of Sheridan's Comedies (pp. 29-31).
the expense apparently of the prince of Wales. In 1812 he failed to secure a seat at Stafford. He could not raise money enough to buy the seat. He had quarrelled with the Prince Regent, and seems to have had none but obscure friends to stand by him. As a member of parliament he had been safe against arrest for debt, but now that this protection was lost his creditors closed on him, and the history of his life from this time till his death in 1816 is one of the most painful in the biographie of great men. It may be regarded as certain, however, that the description of the utter destitution and misery of the last weeks of his life given in the Croker Papers (i.e. pp. 288-312, ed. L. J. Jennings) is untrue. In any attempt to judge of Sheridan as he was apart from his works, it is necessary to make considerable deductions from the mass of floating anecdotes that have gathered round his name. It was not without reason that his grand-daughter Mrs Norton denounced the unfairness of judging of the real man from unauthenticated stories. The real Sheridan was not a pattern of decorous respectability, but we may fairly believe that he was very far from being the Sheridan of vulgar legend. Against the stories about his reckless management of his affairs we must set the broad facts that he had no source of income but Drury Lane theatre, that he bore from it for thirty years all the expenses of a fashionable life, and that the theatre was twice rebuilt during his proprietorship, the first time (1791) on account of its having been pronounced unsafe, and the second (1809) after a disastrous fire. Enough was lost in this way to account ten times over for all his debts. The records of his wild bets in the betting books of the Club, which he frequented, give a wide notion of his first wife, to whom he was devotedly attached. He married again in 1795, his second wife being Esther Jane, daughter of Newton Ogle, dean of Winchester. The reminiscences of his son's tutor, Mr Smyth, show amusing and fidgety family habits, curiously at variance with the accepted tradition of his imperturbable recklessness. He died on the 7th of July 1816, and was buried with great pomp in Westminster Abbey.

Sheridan's only son by his first marriage, THOMAS SHERIDAN (1775-1817), was a poet of some merit. He became colonial treasurer at the Cape of Good Hope. His wife, Caroline Henrietta, née Calander (1779-1851), wrote three novels, which had some success at the time. She received, after her husband's death, quarters at Hampton Court, and is described by Fanny Kemble as more beautiful than anybody 'but her daughters. The eldest child, HELEN SELINA (1807-1867), married Commander Price Blackwood, afterwards Baron Dufferin. Her husband died in 1841, and in 1862 she consented to a ceremony of marriage with George Hay, Earl of Gifford, who died a month later. Her Songs, Poems and Verses (1854) were published, with a memoir, by her son, the famous Second Countess of Dufferin and Ava. Her husband, Mr. Dufferin, married Mrs Norton (q.v.). The youngest, JANE, GEORGINA, married Edward Adolphus Seymour, afterwards 12th Duke of Somerset.

BIBLIOGRAPHY.—Memoirs of the . . . Life of . . . R. B. Sheridan, with a Particular Account of his Family and Connections (1817), by John Watkins ("who deals," said Byron, "in the life and libel line"), was an altogether inadequate piece of work, and made many false statements. The Memoirs, &c. (1823), compiled by Thomas Moore did not contain the information of the Watkins suite. In 1840, in the family, William Smyth (Memoir of Mr Sheridan, 1840), who had been a tutor in Sheridan's house, was responsible for many of the scandals and sombre details of the latter's career. Smith's material is sometimes made use of by the dramatist's parents and of his grandfather are given by Alicia Lefanu in her Memoirs of the Life and Writings of Mrs Frances Sheridan, &c. (1854). There are numerous references to Sheridan in the Letters and Journals of Byron, and several anecdotes (see especially vol. v. p. 411 seq., ed. Prothero, 1901). Popular works on the Sheridans are Mrs Oliphant's Sheridan (1853) in the "English Men of Letters" series; Mr Percy Fitzgerald's Life of the Sheridan (2 vols., London, 1880) by R. B. Sheridan's son, the Rev. H. B. L. R. C. Sanders in the "Great Writers" series. An attractive sketch of Sheridan's political career is given in Wilkes, Sheridan, Fox: the Opium War (1799) by Mr W. B. Croker. From a careful re-construction of Sheridan's biography from the original sources and vindicating his reputation from the misstatements of earlier writers, in Sheridan: a Biography (2 vols., 1896), which has an introduction by the marquess of Dufferin and Ava, the great-grandson of the dramatist. The Life of R. B. Sheridan by Walter Sickel (1909) is, however, the best account now available.

Severalnumerous works of Sheridan's plays, of which only The Rivals was published by the dramatist himself, may be mentioned: Sheridan's Plays now printed as he wrote them (1902), edited by W. Fraser Rae, who quotes at length the criticisms in the contemporary press; Plays of J. B. Stepney (1900), edited by Mr A. W. Pollard; and Sheridan's Comedies (Boston, U.S.A., 1885), with a valuable introduction by Mr Brander Matthews. For further details see the exhaustive bibliography by Mr J. P. Anderson in the Life by Lloyd C. Sanders.

SHERIDAN, PHILIP HENRY (1832-1888), American general, was born at Albany, N.Y., on the 6th of March 1831. His early life was spent in a country district in Perry county, Ohio, and he proceeded to West Point in 1848, graduating in 1853. He was assigned to the infantry and served on the frontier and on the Pacific coast, gaining some experience of war in operations against the Indians. At the outbreak of the Civil War in 1861 he had just become first lieutenant, and soon afterwards he was promoted captain and entrusted with administrative duties in the western theatre of war. Early in 1862 he was commissioned colonel of the 2nd Michigan cavalry, with which he served in Halleck's army on the Tennessee. In June he was placed in command of a cavalry brigade, and a month later he won promotion to the rank of brigadier-general U.S.V. by his skilful conduct of the fight of Booneville on the 1st of July. He took part in General Buell's campaign against Bragg, and led the 11th division of the Army of the Ohio at the hard-fought battle of Perryville (October 8). Sheridan distinguished himself still more at the sanguinary battle of Murfreesboro (Stone river), and on (June 7-28), in view of co-operation with the army of General David Hunter in the Valley. In the course of this was fought the battle of Yellow Tavern, where the Confederate general J. E. B. Stuart was killed. After rejoining the army Sheridan fought another well-contested action at Hawes' Shop and took and held Cold Harbor. After the battle at that place Sheridan undertook another raid, this time towards Charlottes- ville. Sheridan's corps took part in the battles of the Wilderness and Spottsylvania Court House (see the article Wilderness), incidents of which led to a bitter quarrel between Sheridan and Meade and to Sheridan's being despatched by General Grant on a far-reaching cavalry raid towards Richmond. In the course of this was fought the battle of Trevilian's Station (June 11). A little later came General Sheridan's greatest opportunity for distinction. He was appointed to command a new "Army of the Shenandoah" to oppose the forces of General Early, and conducted the brilliant and decisive campaign which crushed the Confederate army and finally put an end to the war in Northern Virginia (see AMERICAN CIVIL WAR AND SHENANDOAH VALLEY CAMPAIGNS). The victories of the Opequon, or Winchester (September 19), Fisher's Hill (September 21) and Cedar Creek (October 9) produced great elevation on the North and corresponded with depression in the Confederacy, and Sheridan was made successively brigadier-general U.S.A. for Fisher's Hill and major-general U.S.A. for Cedar Creek. "Sheridan's Ride" of 20 m. from Winchester to Cedar Creek to take command of the hard-pressed Union troops is a celebrated incident of the war. His capacity for accepting the gravest responsibilities was shown, not less than by his handling of an army in battle, by his ruthless devastation of the Valley—a severe measure felt to be necessary both by Sheridan himself and by Grant. From the Valley the cavalry rode through the enemy's country to join Grant before Petersburg, fighting the action of Waynesboro', destroying
SHERIFF

communications and material of war, and finally reporting to the general-in-chief on the 25th of March 1865. A few days later the indefatigable Sheridan won the last great victory of the war at Five Forks. The operations were conducted entirely by him and were brilliantly successful, leading to the retreat of Lee from the lines of Petersburg and the final catastrophe of Appomattox Court House. In the course of the battle of Five Forks Sheridan once more displayed his utter fearlessness of criticism by summarily dismissing from his command General G. K. Warren, an officer of the highest repute, whose corps was only temporarily under Sheridan's orders. The part played by the cavalry corps in the pursuit of Lee was most conspicuous, and Sheridan himself commanded the large forces of infantry and cavalry which cut off Lee's retreat and compelled the surrender of the famous Army of Northern Virginia (see AMERICAN CIVIL WAR and PETERSBURG).

Soon after the close of the war, Sheridan, who by these services had gained his reputation as one of the greatest soldiers of the time, was sent to exercise the military command in the southwest, where a corps of observation, on the Mexican frontier, watched the struggle between Maximilian and the Liberals (see MEXICO: Hidalgo). General Sheridan was stated to be responsible that material assistance was afforded to the Liberals out of the U.S. arsenals, and the moral effect of his presence on the frontier certainly influenced the course of the struggle to a very great extent. Later, in the Reconstruction period, he commanded the Fifth Military District (Louisiana and Texas) at New Orleans, where his administration of the conquered states was most stormy, his differences with President Johnson culminating in his recall in September 1867. He was then placed in charge of the Department of the Missouri, which he commanded for sixteen years, and in 1869, on Grant's election to the presidency and Sherman's consequent promotion to the full rank of general, he was made lieutenant-general. In 1868-1869 he conducted a winter campaign against the Indians, which resulted in their defeat and surrender. During the Franco-German War of 1870 General Sheridan accompanied the great headquarters of the German armies as the guest of the king of Prussia. In 1873, at the time of the "Virginius" incident (see CUBA), when an invasion of Spain was projected, Sheridan was designated to command the United States field army. In 1875 he was sent to New Orleans to deal with grave civil disorder, a duty which he carried out with the same uncompromising severity that he had previously shown in 1867. In 1883 he succeeded Sherman in the chief command of the United States army, which he held until his death at Norquitt, Mass., on the 5th of August 1888. A few months previously he had been raised to the full rank of general. As a soldier, Sheridan combined brilliant courage and pains-taking skill. As a fighting general he was unsurpassed. Few of the leaders of either side could have stemmed the tide of defeat as he did at Stone river and turned a mere rally into a great victory as he did at Cedar Creek, by the pure force of personal magnetism. His restless energy was that of a Charles XII., to whom in this respect he has justly been compared, while, unlike the king of Sweden, he was as careful and vigilant as the most methodical strategist. He was a devout Roman Catholic, and in his private life he had the esteem and admiration of all who knew him well. General Sheridan was president of the Society of the Army of the Potomac and of the Society of the Army of the Cumberland, the latter for fourteen years. In 1875 he married Irlene, daughter of General D. H. Rucker, U.S.A.

His Personal Memoirs (2 vols.) were published soon after his death.

SHERIFF, or SHIRE-REEVE (O. Eng. scir-reve or scirman, 1 Latin, vice-come), often called "high sheriff," the English and Irish executive authority in a county, or other place, often called his "bailliwick." The office also exists in about twenty ancient cities and boroughs, among which may be named London, Norwich, York, Bristol, Oxford, Lincoln, Chester and Cheshire, and Dublin, Cork, Limerick, and other places in Ireland. In most of these the office is of an honorary 1 nature. The office is at present an annual one, though this has not been always the case. Three names are put on the list by the chancellor of the exchequer and the judges of king's bench division on the morrow of St Martin (24th of November), and the first name is usually picked by the king in council in the February or March following. City and borough sheriffs are usually appointed by the corporations for by the act of 1887, s. 33, and the sheriffs of the counties of Cornwall and Lancaster are separately appointed, the act not applying to them. The sheriff was at one time a far more important office than it is at present. "The whole story of English justice and police," says Maitland (Justice and Police, 69), "might be brought under this rubric, the decline and fall of the sheriff." That the sheriff sometimes abused his power is obvious from the grievances stated in the Inquest of Sheriffs of 1170. But he was necessary to protect the interests of the crown and the people against the powerful local baronage. Besides executing the king's writs, he called out the posse comitatus on any emergency needing an armed force. He had the form of the shire (the rent he paid being called "sheriff-geld") and presided at the quarterly Sessions of the Peace and assizes. He was until the 17th century an officer of judicial purposes he held as the king's deputy the sheriff's town, where his jurisdiction had not been ousted by franchise. He might be a peer or a judge, Bracton being an instance of the latter. The appointment seems to have been originally by popular election, a right confirmed by 28 Edw. I. c. 8, but ultimately vested in the crown unless where certain powerful landowners had contrived to make the office hereditary. The hereditary shrievalty of Wearmouth was not abolished until 1850 by 13 & 14 Vict. c. 36. The tendency of the hereditary office to become obsolete was no doubt helped by the creation of Viscount Beaumont as an hereditary peer under the new dignity of vice-comes in 1440. At one time contributions to the expense of the office were made by the magnates and others of the county. "Sheriff-tooth" was a tenure on condition of supplying entertainment to the sheriff at the county court. Up to the 19th century "riding with the sheriff" was an incident of the assizes, the riders being some of the principal men of the shire who brought with them wine and victuals in order to assist the sheriff in showing hospitality to the judges.

At the present day the expensive duties of the sheriff depend on numerous statutes beginning with 2 Edw. III. c. 3 (1358). The most important is the Sheriffs Act 1887, mainly a consolidating act applying to England only. The person nominated is usually a magistrate for the county, but anyone is eligible provided that he have land in the county sufficient to answer the 5. Exempt are peers, clergy, officers in active service, practising barristers and solicitors and others. Poverty is also a ground of exemption. The sheriff appoints his undersheriff. The duties of the office at the present day are both administrative and judicial. Among the former the most important is attendance on the judges at assizes and election petitions. A certain amount of stately ceremony is required, and any lack of it is punishable by fine either by the judge of assize or by the High Court. Other administrative duties are execution of writs 4 and of the sentence of death, acting as returning officer at parliamentary elections, preparing the panel of jurors for assizes, the keeping prisoners in safe custody, he being liable for their escape, and the—now nominal—duty of summoning the posse comitatus. His judicial duties consist in himself or his deputy sitting to assess damages under the Lands Clauses Act 1845, and in cases set down for trial where the defendant has made default in appearance and the issue resolves itself into one of damages. The expenses of the office are partly met by the 4 The form is abolished by the act of 1887, s. 19.

1 Abolished by s. 18 of the same act.

4 Repealed and re-enacted by the act of 1887, s. 31.

6 Where a question arises as to the ownership of goods seized in execution the sheriff may have to undergo the process known as sheriff's interpleader
Treasury in accordance with the Treasury order of the 2nd of August 1898. The order lays down with somewhat grim humour that the sheriff is not limited to the allowances, but may spend more if he likes. A sheriff cannot during his year of office act as a magistrate for the county of which he is sheriff.

See the works on the history of law by Stubbs, Pollock and Maitland and Holdsworth. Also W. S. McKeehan's The Law of Sheriff's & Justices' Accounts (1683); Greenwood, Baudetueren (1685); The Compleat Sheriff (1696); Impye (1766); Atkinson (1785); Churchill and Bruce (1862); and MacKie, Discount (1903).

Scotland.—As far as is known the sheriff did not exist in Scotland before the beginning of the Norman period. In the feudal system he became as in England the centre of the local administration of justice, the representative of the crown in executive as well as judicial business, and was always a royal officer appointed by and directly responsible to the king. The earliest sheriffs on record belong to the reigns of Alexander I. and David I., and the office was common before the death of Alexander II. In many cases it had become hereditary, instances of which are those of De Sinton in Selkirk and Alistair Galloway. The ordinance of Edward I. in 1305 rejected the hereditary character of the office, but an act of James II. shows that the office had again become hereditary.

One of the consequences was that sheriffs ignorant of law required deputies to discharge their judicial duties. In the course of succeeding reigns, down to that of James VI., the jurisdiction of the sheriffs was made extremely extensive by grants of baronies and regalities which gave the grantees the right to hold both civil and criminal courts of less or greater jurisdiction to the exclusion of the sheriff.

The civil jurisdiction of the sheriff was originally of very wide extent, and was deemed specially applicable to questions relating to the land within the shire, but after the institution of the court of session in 1532 it became restricted, and all causes relating to property in land, as well as those requiring the action called declarator for establishing ultimate right, and most of those requiring equitable remedies, were withdrawn from it. Nor did it possess any consistorial jurisdiction. Practically, therefore, the civil jurisdiction of the sheriff fell under the head of actions concluding for payment of money and actions to regulate the possession of land. The criminal jurisdiction of the sheriff was in like manner in its origin of almost universal extent. But this was first limited to cases where the offenders were caught in or shortly after the act, afterwards to cases in which the trial could be held within forty days, and subsequently further restricted as the business of the justiciary court became more organized. The punishment of death, having by long custom come to be held beyond the power of the sheriff, and the statutory punishments of transportation or penal servitude never having been entrusted to him, his jurisdiction as regards crimes was usually said to be limited to those punishable arbitrarily, that is, by imprisonment, fine or admonition.

As a consequence of the suppression of the Jacobite rising of 1745, after the 1st of March 1748 all heritable sheriffships were extinguished by 20 Geo. II. c. 43. The act declared that there should be but one sheriff-depute or steward-depute in every shire or stewartry, who was to be an advocate of three years' standing, appointed by the crown. Since 1769 the sheriff-depute has held his office ad vitam aut culpam. Power was given to him by 20 Geo. II. c. 43 to appoint one or more sheriffs-substitute. In 1787 the sheriff-substitute was placed on the civil establishment and paid by the crown; in 1824 a qualification of three years' standing (now five years by the Sheriff Courts (Scotland) Act 1877) as an advocate or procurator before a sheriff court was required (6 Geo. IV. c. 23); in 1838 he was made removable by the sheriff-depute only with the consent of the lord president and lord justice clerk, and it was made compulsory that he should reside in the sheriffdom, the provision of 20 Geo. II. c. 43, which required the sheriff-depute so to reside for four months of each year, being repealed (1 & 2 Vict. c. 119).

In 1877 the right of appointment of the substitutes was transferred from the sheriff-depute to the crown by the act of 1877.

While the sheriff-depute has still power to hear cases in the first instance, and is required to hold a certain number of sittings in each place where the sheriff-substitute holds courts, and also once a year a small-debt court in every place where a circuit small-debt court is appointed to be held, the ordinary course of civil procedure is that the sheriff-substitute acts as judge of first instance, with an appeal under certain restrictions from his decision to the sheriff-depute, and from him to the court of session in all cases exceeding £5 in value. An appeal direct from the sheriff-substitute to the court of session is competent, but is not often resorted to. By the Interpretation Act 1880, s. 28, the word "sheriff" in any act relating to Scotland is to include a sheriff-substitute.

As regards criminal proceedings, summary trials are usually conducted by the sheriff-substitute; trials with a jury either by him or, in important cases, by the sheriff-depute. The sheriff-substitute also has charge of the preliminary investigation into crime, the evidence in which, called a preognition, is laid before him, and if necessary taken before him on oath at the instance of his procurator-fiscal, the local crown prosecutor.

The duties of the sheriff-deputes are now divided into ministerial and administrative. The ministerial are the supervision of the accounts of the inferior officers of the sheriffdom; the superintendence of the parliamentary elections; the qualification and election of the sheriff-substitutes of the courts for registration of electors; the preparation of the list of persons liable to serve both on criminal and civil juries; the appointment of sheriff officers and supervision of the execution of judicial orders by them; and all occasionals connected with the task of attending to the duties of justices of the peace for the counties or the county of which his jurisdiction extends.

The administrative duties of the sheriff-depute are, as regards crimes, the trial of all causes remitted by the counsel of the crown for the trial by sheriff and jury, as well as summary trials if he chooses to take them. This now means for which a maximum of two years imprisonment (or, in cases where a sentence of more than eighteen months is the longest sentence imposed) is deemed sufficient, and which are not by statute reserved for the justiciary court. His civil jurisdiction is regulated by several statutes too technical for detail, but may be said generally comprise the conduct of all matters which can only be determined by the court of session, and thus the sheriff-depute is required to hold the courts at which appeals can be heard.

The courts which the sheriff holds are (1) the criminal court; (2) the ordinary civil court; (3) the small-debt court for cases under £12 in value (6 Geo. IV. c. 48); (4) the debts recovery court for cases above £12 and under £50 in value (Debts Recovery [Scotland] Act 1895). It is subject to appeal. The court of session, as stated, is subject to review by the court of justiciary, and in the ordinary civil court and the debts recovery court by the court of session. As in the case of the small-debt court, an appeal lies to the next circuit court of justiciary. The sheriff-substitute may competently exercise all the judicial jurisdiction of the sheriff, subject to appeal in civil cases other than small debt cases. As regards his administrative functions he assists the sheriff generally, and may act for him in the registration and taxing courts, and he superintends the preliminary stage of criminal inquiries, consulting with the sheriff if necessary; but the other administrative duties of the office are conducted by the sheriff-depute in person.

The executive functions of the sheriff are performed by messengers-at-arms. The civil jurisdiction depends on numerous statutes known as the Sheriff Courts Act 1854. The salaries of sheriff-deputes vary from £2000 to £5000 a year, those of sheriff-substitutes from £400 to £500. There is a principal sheriff-clerk appointed by the crown for each county, who has depute clerks under him in the principal courts. In England an important position is occupied by the sheriff, and a procurator-fiscal for the conduct of criminal prosecutions for each county and district of a county, who is appointed by the sheriff with the sanction of the home secretary.

Ireland.—The sheriff has much the same duties as in England. His position is defined by numerous statutes, beginning with 53 Geo. III. c. 68 (1817). There is no consolidating act such as that of 1887 in England.

United States.—The office of sheriff is generally elective.
SHERIFFMUIR—SHERMAN, J.

The sheriff has administrative and limited judicial authority. He sometimes serves for combined counties, as in England for Cambridge and Huntingdon.

SHERIFFMUIR, a battlefield situated on the verge of the extreme north-western flank of the Ochils, Porthshire, Scotland, watered by Wharry Burn, an affluent of the Allan. It lies within the bounds of the parish of Dunblane, 2 1/2 m. E. by N. of the town. It was the site of an indecisive battle (13th of November 1715) between the Jacobites, about 12,000 strong, under John Erskine, 6th or 11th Earl of Mar, and 4000 Royalists under Archibald Campbell, afterwards 3rd duke of Argyll. Both sides, each of which lost 500 men, claimed the victory, although the in fact Mar deemed it prudent to retreat. The "battle stone" enclosed by a railing marks the scene of the encounter.

SHERIF PASHA (1818-1887), Egyptian statesman, was a Circassian who filled numerous administrative posts under Said and Ismail pashas. He was of better education than most of his contemporaries, and had married a daughter of Colonel Séves, the French non-commissioned officer who became Soliman Pasha under Mehemet Ali. As minister of foreign affairs he was useful to Ismail, who used Sheriff's bluff boshkoumie to veil many of his most insidious proposals. Of singularly 'veiled' disposition, he yet possessed considerable tact—he was in fact an Egyptian Lord Melbourne, whose policy was to leave everything alone. His favourite argument against any reform was to appeal to the Pyramids as an immutable proof of the solidity of Egypt financially and politically. His fatal optimism rendered him largely responsible for the collapse of Egyptian credit which brought about the fall of Ismail. Upon the military suspension of September 1881, Sheriff was summoned by the khedive Tewfik to form a new ministry. The impossibility of reconciling the financial requirements of the national party with the objectives of the British and French controllers of the public debt, compelled him to resign in the following February. After the suppression of the Arabi rebellion he was again installed in office (September 1882) by Tewfik, but in January 1884 he resigned rather than sanction the evacuation of the Sudan. As to the strength of the mahdist movement he had then no conception. When urged by Sir Evelyn Baring (Lord Cromer) early in 1883 to abandon some of the more distant parts of the Sudan, he replied with characteristic light-heartedness: "Nous en causerons plus tard; d'abord nous allons donner une bonne râclée à ces mousseurs" (i.e., the mahdists). Hicks Pasha's expedition was at the time preparing to march on El Obeid. (Vide Egypt No. 1 (1907), p. 115). Sheriff died at Gratz, on the 20th of April 1887.

SHERLOCK, THOMAS (1678-1716), English divine, the son of William Sherlock (q.v.), was born at London in 1678. He was educated at Eton and at St Catharine's Hall, Cambridge, and in 1704 succeeded his father as master of the Temple, where he was very popular. In 1714 he became master of his old college at Cambridge and vice-chancellor of the university, whose privileges he defended against Richard Bentley. In 1715 he was appointed dean of Chichester. He took a prominent part in the Bangorian controversy against Benjamin Hoadly, whom he succeeded as bishop of Bangor in 1728; he was afterwards translated to Salisbury in 1734, and to London in 1748. Sherlock was a capable administrator, and cultivated friendly relations with dissenters. In parliament he was of good service to his old schoolfellow Robert Walpole. He published against Anthony Collins's deistic Grounds of the Christian Religion a volume of sermons entitled The Use and Interest of Prophecy in the Several Ages of the World (1725); and in reply to Thomas Woolston's Discourses on the Miracles he wrote a volume entitled The Tryal of the Witnesses of the Resurrection of Jesus (1729), which soon ran through fourteen editions. His Pastoral Letter (1750) on "the late earthquakes" had a circulation of many thousands, and four or five volumes of Sermons which he published in his later years (1754-1758) were also at one time highly esteemed. He died in July 1761.

A collected edition of his works, with a memoir, in 5 vols. 8vo, by J. S. Hughes, appeared in 1830.

SHERLOCK, WILLIAM (c. 1641-1707), English divine, was born at Southwark about 1641, and was educated at Eton and at Peterhouse College, Cambridge. In 1669 he became rector of St George's, Botoilp Lane, London, and in 1681 he was appointed a prebendary of St Paul's. In 1674 he showed his controversial bent by an attack on the puritan John Owen, in The Knowledge of Jesus Christ and Union with Him. In 1684 he published The Case of Resistance of the Supreme Powers stated and resolved according to the Doctrine of the Holy Scriptures, an ably written treatise, in which he drew the distinction between active and passive obedience which was at that time generally accepted by the high church clergy; in the same year he was made master of his college, and involved him in a warm controversy with Robert South and others. In 1691 he became dean of St Paul's in 1691, and died at Hampstead in June 1707. His sermons were collected in 2 vols. 8vo (4th ed., 1755).

SHERMAN, JOHN (1829-1900), American financier and statesman, a younger brother of General W. T. Sherman, was born at Lancaster, Ohio, on the 10th of May 1829. He began the study of law at Mansfield, Ohio, and was admitted to the bar in 1844. For ten years he practised his profession with success, and with only an occasional interest in politics. His associations and predilections were with the Whigs, and he was a delegate to the National Convention that nominated General Zachary Taylor in 1848. Upon the repeal of the Missouri Compromise by the Kansas-Nebraska Bill in 1854, he joined the great popular movement in Ohio against the policy represented by this bill, and was elected to Congress in the autumn of that year as an "Anti-Nebraska" man. In the summer of the next year he took an active part in the formal organization of the Republican party in the state, and at the opening of Congress in December began a long career of public service. As a member of the House (1855-1861), he quietly manifested the qualities which characterized his whole political life. Though a thorough and avowed partisan, he was within the party the counsellor of moderate rather than extreme measures, and thus gained on the whole a position of great influence. He was a member of the committee sent by the House in 1856 to investigate the troubles in Kansas, and drafted the report of the majority. In 1859 he was the Republican candidate for Speaker of the House, but was defeated, after a contest that lasted two months, to withdraw, largely because of the recommendation he had inadvertently given to an anti-slavery book, The Impending Crisis of the South (1857), by Hinton Rowan Helper (1829-1909). He became, however, chairman of the Committee on Ways and Means, and was instrumental in the enactment of the Morrill Tariff Act of 1860. In March 1861 he took his seat in the Senate, to which he had been elected to succeed Salmon P. Chase, when the latter became secretary of the treasury. As senator he sat continuously until he became secretary of the treasury in 1877. His interest and efficiency in financial legislation in the House led to his appointment on the Senate Committee of Finance, and after 1876 he was chairman of that body and influential committee. He thus became associated with the enactment of all the great fiscal laws through which the strain of war and of reconstruction was sustained. He gave earnest support to the Legal Tender Act, and the substitution of the national for the state banking system. When after the end of the war the question of financial readjustment came up, he vigorously opposed Secretary Hugh McCulloch's policy of retiring the legal tenders, and urged a different plan for effecting the resumption of specie payments. On the questions relating to political reconstruction and the
SHERMAN, R.—SHERMAN, W. T.

851

policy of President Johnson, he supported his party, though opposed to its Radical leaders. He warmly advocated the insertion in the Reconstruction Acts of a provision ensuring the early termination of military government; and he opposed the impeachment of President Johnson, though he voted for conviction on the trial. During the administrations of Presidents Polk and Taylor, his leadership in shaping financial policy became generally recognized. The Resumption Act of 1875, which provided for the return of specie payments four years later, was largely his work both in inception and in formulation, and his appointment to the head of the Treasury Department by President Hayes in 1877 enabled him to carry the policy embodied in the law to successful execution. His administration of the department, in circumstances of great difficulty arising out of the "greenback" agitation and the adverse political complexion of Congress, won him high distinction as a financier.

At the end of the Hayes administration he was again elected to the Senate from Ohio and held his seat until 1897. During this period he was largely concerned in the enactment of the Anti-Trust Law of 1890, and of the so-called Sherman Act of the same year, providing for the purchase of silver and the issuing of Treasury notes based upon it. This latter Act he approved only as a means of escaping the free coinage of silver, and he supported its repeal in 1893. In 1880 and 1888 he aspiringly to the Republican nomination for the presidency, but failed to obtain the requisite support in the Convention. During the whole of the last year of the presidency of the Senate Committee on Foreign Affairs. Upon the accession of President McKinley in 1897, he resigned from the Senate and became secretary of state; but under the tension of the war with Spain the duties of the office became too exacting for his strength at his age, and in April 1898 he resigned and withdrew into private life. Infirmities multiplied upon him, until his death at Washington on the 22nd of October 1900.

W. A. D.

SHERMAN, ROGER (1721-1793), American political leader, a signer of the Declaration of Independence, was born at Newton, Massachusetts, on the 19th of April 1721 (O.S.). He removed with his parents to Stoughton in 1723, attended the country school there, and at an early age learned the cobbler's trade in his father's shop. Removing to New Milford, Connecticut, in 1743, he worked as county surveyor, engaged in mercantile pursuits, studied law, and in 1754, was admitted to the bar. He represented New Milford in the Connecticut Assembly in 1755-1756 and again in 1758-1761. From 1761 until his death New Haven was his home. He was once more a member of the Connecticut Assembly in 1764-1766, was one of the governor's assistants in 1766-1785, a judge of the Connecticut superior court in 1766-1789, treasurer of Yale College in 1765-1776, a delegate to the Continental Congress in 1774-1781 and again in 1783-1784, a member of the Connecticut Committee of Safety in 1777-1779 and in 1781, mayor of New Haven in 1784-1793, a delegate to the Continental and Federal Conventions of 1787, and to the Connecticut Ratification Convention of the same year, and a member of the Federal House of Representatives in 1789-1791 and of the United States Senate in 1791-1793. He was on the committee which drafted the Declaration of Independence, and also on that which drafted the Articles of Confederation. His greatest public service, however, was performed in the Federal Constitutional Convention. In the bitter conflict between the large state party and the small state party he and his colleagues, Oliver Ellsworth and William Samuel Johnson, acted as pacemakers. Their share in bringing about the final settlement, which provided for equal representation in the house and proportional representation in the other, was so important that the settlement itself has come to be called the "Connecticut Compromise." He helped to defeat the proposal to give Congress a veto on state legislation, showing that it was illogical to confer such a power, since the constitution itself is the law of the land and no state act contravening it is legal. In the Federal Congress (1789-1793) he favoured the assumption of the state debts, the establishment of a national bank and the adoption of a protective tariff policy. Although strongly opposed to slavery, he refused to support the Parker resolution of 1789 providing for a duty of ten dollars per head on negroes brought from Africa, on the ground that it emphasized the property element in slavery. He died in New Haven on the 23rd of July 1793. Sherman was not a deep and original thinker like James Wilson, nor was he a brilliant leader like Alexander Hamilton; but owing to his conservative temperament, his sound judgment and his wide experience he was well qualified to lead the compromise cause in the convention of 1787.

Two of Sherman's grandsons, William M. Evarts and George F. Hoar, were prominent in the later history of the country. Lewis H. Boutell's Life of Roger Sherman (Chicago, 1866), based on material collected by Senator Hoar, is a careful and accurate work.
brigadier-general of volunteers, Sherman was in August sent to Kentucky to serve under General Robert Anderson. In October he succeeded to the command of the department. On the 26th of October he reported that 200,000 men would be required for the Kentucky campaign. He was relieved of his post soon afterwards in consequence, but the event justified Sherman’s view. He was soon re-employed in a minor position, and, at the head of a division of new troops, accompanied Grant’s army to Pittsburg Landing. At the battle of Shiloh Sherman’s supply column was almost the only one to remain intact. His appreciation of Grant, and his sympathy with the chaplain he suffered after this battle, cemented the friendship between the two. He took part in Halleck’s advance on Corinth, Mississippi, and at the close of 1862 led the Mississippi column in the first Vicksburg campaign. He suffered defeat at Chickasaw Bayou, but the capture of Port Hindman, near Arkansas Post, compensated to some extent for the Vicksburg failure. In Grant’s final Vicksburg campaign Sherman commanded the XV. corps and the right of the investing line, and after the surrender he was sent to oppose General Johnston in the country about Jackson, Miss. In July he was made a brigadier-general in the regular army. When, after Rosecrans’s defeat at Chickamauga, Grant was placed in supreme command in the west, Sherman succeeded to the command of the Army of the Tennessee, with which he took part in the great battle of Chattanooga (q.v.). He had already prepared for a further advance by making an expedition into the heart of Mississippi as far as Meridian, destroying railways and making impracticable, for a season, the transfer of military operations to that region; and he was transferred becoming general-in-chief (March 1864) he was made commander of the military division of the Mississippi, including his Army of the Tennessee, now under McPherson, the Army of the Cumberland, under Thomas, and the Army of the Ohio, under Schofield. Making detachments for garrisons and minor operations in a theatre of war over 500 m. wide, he assembled, near Chattanooga, his three armies, aggregating 100,000 men, and began (May 1864) the invasion of Georgia. After a brilliant and famous campaign of careful manoeuvre and heavy combats (see American Civil War), Sherman finally wrested Atlanta (q.v.) from the Confederates on the 1st of September. His able opponent Johnston had been removed from his command, and Hood, Johnston’s successor, began early in October a vigorous movement designed to carry the war back into Tennessee. After a devious chase of a month Hood moved across Alabama to northern Mississippi. Sherman thereupon, leaving behind Thomas and Schofield to deal with Hood, made the celebrated “March to the Sea” from Atlanta to Savannah with 60,000 picked men. After a march of 300 m. Savannah was reached in December. Railways were cut and many stores were captured, the country cleared of supplies, and the Confederate government, severed from its western states. In January 1865 Sherman marched northwards again, once more abandoning his base, towards Petersburg, where Grant and Lee were waging a war of giants. Every mile of his march northwards through the Carolinas diminished the supply region of the enemy, and desperate efforts were made to stop his advance. General Johnston was recalled to active service, and showed his usual skill, but his forces were inadequate. Sherman defeated him and reached Raleigh, the capital of North Carolina, on the 13th of April, having marched nearly 500 m. from Savannah. Lee’s position in Virginia was now desperate. Hood had been utterly defeated by Thomas and Schofield, and Schofield (moved 2000 m. by land and sea) rejoined Sherman in North Carolina. With 90,000 men Sherman drove Johnston before him, and when Lee surrendered to Grant Johnston also gave up the struggle. There was much friction between Sherman and the war secretary, Stanton, before the terms were ratified, but with their signature the Civil War came to an end.

Sherman had the good fortune to learn the art of command by degrees. At Bull Run his brigade was wasted in isolated and disconnected regimental attacks, at Shiloh his division was completely surprised owing to want of precaution; but his bravery and energy were beyond question, and these qualities carried him gradually to the front at the same time as he acquired skill and experience. When therefore he was entrusted with an independent command he was in every way fitted to do himself justice. At the head of a hundred thousand men he showed, besides the large grasp of strategy which planned the Carolinas march, besides the patient skill in manoeuvre which gained ground day by day towards Atlanta, the strength of will which sent his men to the hopeless assault of Kennesaw to teach them the

---

SHERMAN—‘S HERTOGENBOSCH

In 1866 Sherman was promoted lieutenant-general, and in 1869, when Grant became president, he succeeded to the full rank. General Sherman retired, after being commanding general of the army for fifteen years, in 1884, and he died at New York on the 14th of January 1891. An equestrian statue, by Saint Gaudens, was unveiled at New York in 1903, and another at Washington in the same year.

Sherman’s Memoirs were published in 1875 (New York). See also Rachel Sherman Thornblæke, The Sherman Letters (New York, 1894); Home Letters of Gen. Sherman (1903), edited by M. A. De Wolfe Howe; Sherman—A Memoir of His Life and Services (New York, 1892); Brownson Memorial (New York, 1892); Sherman: A Military Biography (New York, 1865); W. Fletcher Johnson, Life of William Tecumseh Sherman (Philadelphia, 1891); Manning F. Force, General Sherman (Great Commanders’ series) (New York, 1899).

SHERMAN, a city and the county-seat of Grayson county, Texas, U.S.A., 64 m. by rail N. by E. of Dallas and 9 m. S. of Denison. Pop. (1890) 737; (1900) 10,243, of whom 133 were negroes; (1910 census) 12,412. Sherman is served by the St Louis & San Francisco (Frisco System), which has car shops here, the St Louis & South-Western, the Gulf, Colorado & Santa Fé, the Missouri, Kansas & Texas, the Texas & Pacific, and the Houston & Texas Central railways, and by electric lines connecting with Denison and Dallas. In the city are Austin College (Presbyterian, 1830; removed from Austin to Sherman in 1876) for men, Carr-Burndette College (Christian, 1894) for girls, North Texas Female College and Conservatory (Methodist Episcopal, 1877) and Saint Joseph’s Academy (Roman Catholic) for girls. Sherman is situated on a ridge 270 ft. above sea-level between the Red river and the Trinity river, near a fertile part of the Red River Valley, in which the principal industries are the growing of cotton, Indian corn, wheat, oats, potatoes and alfalfa, and stock raising. The city contains cotton gins and compresses, and has various manufactures; in 1905 the value of factory products was $2,841,066 (94.4% more than in 1900). The municipality owns and operates the waterworks and the electric lighting plant. Sherman was settled in 1848 and was chartered as a city in 1865.

SHERRY, originally the name of a wine coming from Xeres (Jerez de la Frontera), near Cadiz, Spain, and now the general name of the strong white wines, the lower grades excepted, which are made in the south of Spain (see Wine). The early form of the word in English was “sherris” (abbreviated from “sherris-wine” or “sherris-sack”), which was taken to a plural, and “sherry” was formed as a singular by mistake.

‘S HERTOGENBOSCH (’s Bosch, or den Bosch, French Bois-le-Duc), the capital of the province of North Brabant, Holland, at the confluence of the Rivers Smeeren and As, which unite before forming the Dieze, and a junction station 29½ m. S.S.E. of Utrecht and 27½ m. W.S.W. of Nijmegen by rail. It is connected by steam tramway with Helmond (21 m. S. by E.) and by the Zuid-Willem’s canal with Maastricht (60 m. S. by E.). Pop. (1900) 32,345. ’s Hertogenbosch is a well-built city and contains several churches. The Roman Catholic cathedral of St John, the Janskerk, with its interior in a state of preservation rare in Holland, is one of the finest architecturally in the country. Occupying the site of a much earlier building, of which there are remains, the present church was begun in the middle of the 15th century. The 15th-century font, the pulpit (1570), the organ (1617), and the early Gothic Lady
chapels containing a much venerated 13th-century image of the Virgin, which was annually carried in procession through the town, are all noticeable. The choir-screen was sold to the South Kensington Museum, but the figure of the Virgin, this sum being devoted to the work of modern restoration. The town hall contains an interesting series of decorative panels by a modern artist, A. Derkinderen, describing the founding of the city. It also includes a museum of local antiquities. In the Provincial museum are interesting Roman, German and Frankish antiquities. The principal other buildings are the court house, government buildings (formerly a Jesuit monastery), episcopal palace, grammar school (once attended by Erasmus), a prison, hospitals, arsenal and barracks. 'S Hertogenbosch is the market of the fertile Meify district, and carries on a commerce in trade, chiefly by water, with Dortrecht and Rotterdam, Nijmegen, Amhem, Maastricht and Liége. The chief industries include distilleries, breweries, glass works, cigar factories and the ancient linen and cutlery manufactures.

SHERWIN, JOHN KYESE (1751-1790), English engraver and history-painter, was born in 1751 at East Deane in Sussex. His father was a wood-cutter employed in shaping bolts for shipbuilders, and the son followed the same occupation till his seventeenth year, when, having shown an aptitude for art by copying engravings and drawings, he was instructed with exceptional accuracy; he was befriended by William Mitford, upon whose advice the elder Sherwin worked, and was sent to study in London, first under John Astley, and then for three years under Bartolozzi—for whom he is believed to have executed a large portion of the plate of Cytie, after Annibal Caracci, published as the work of his master. He was entered as a student of the Royal Academy, and gained a silver medal, and in 1772 a gold medal for his painting of "Coriolanus taking Leave of his Family." From 1774 till 1780 he was an exhibitor of chalk drawings and of engravings in the Royal Academy. Establishing himself in St James's Street, he painted and engraved portraits with considerable success, and obtained great popularity and began to mix in fashionable society. His drawing of the "Finding of Moses," a work of but slight artistic merit, which introduced portraits of the princess royal of England and other leading ladies of the aristocracy, hit the public taste, and, as reproduced by his burin, sold largely. In 1785 he succeeded Woollett as engraver to the king, and he also held the appointment of engraver to the prince of Wales. His professional income rose to about £12,000 a year; but he was constantly in pecuniary difficulties, for he was shiftless, indolent, and unaccountable. He was assisted in his pecuniary difficulties—and prodigal, too, in less reputable directions, for he became a reckless gambler, and habits of intemperance grew upon him. He died in extreme penury on the 24th of September 1790—according to Steevens, the editor of Shakespeare, at "The Hog in the Pound," an obscure alehouse in Swallow Street, or, as stated by his pupil J. T. Smith, in the house of Robert Wilkinson, a printseller in Cornhill.

It is as an engraver that Sherwin is most esteemed; and it may be noted that he was an ambidexterous, working indifferently with either hand upon his plates. His drawing is correct, his line excellent and his textures are varied and intelligent in expression. Such of his plates as the "Holy Family" after Nicholas Poussin, "The Sower" after Vermeer, "The Mill," after the marquis of Buckingham after Gainsborough and that of Pict. occur and hold a place among the productions of the English school of line-engravers. He also worked after Pincio, Dance and Kauffman.

SHERWOOD, MARY MARTHA (1775-1851), English author, was born at Stanford, Worcestershire, on the 6th of May 1775; the daughter of the Rev. George Butt, D.D., then rector of Stanford. In 1803 she married her cousin, Captain Henry Sherwood, an officer in the British army, and subsequently accompanied him to India, where she devoted herself to charitable work and to writing. Her Indian story, Little Henry and his Bear, was translated into many languages. Her best-known work, however, is The History of the Fairchild Family, written after her return to England, of which the first part appeared in 1818, and the second and third parts in 1842 and 1847 respectively. The sub-title of this tale is The Child's Manual, being a series of stories calculated to show the importance and effects of a religious education. The book had a very large sale among the English middle-classes. Mrs Sherwood wrote nearly a hundred stories of a religious type and tracts, mainly for the young. She died on the 22nd of September, 1850.

See The Life and Times of Mrs Sherwood, from the Diaries of Captain and Mrs Sherwood, edited by F. J. H. Darton (1910).

SHERWOOD FOREST, one of the ancient English forests, in Nottinghamshire. It extended from Nottingham northward to Worksop, being over 20 m. long and from 5 to 9 m. broad. The soil is sandy and poor, and although a considerable portion has been brought under cultivation, the district preserves many acres of ancient character, especially as a great part of it is covered by the dome of ancient trees. The Sherwood Dukeries (q.v.). Sherwood was a crown forest from the time of Henry II. and a favourite hunting-ground of several kings; the land was divided between various lords of the manor, and its disafforestation was carried out at various times. The forest is traditionally noted as the retreat of Robin Hood, whose cave is seen at Papplewick near Newstead.

SHELTON, or ZETLAND, a group of islands constituting a county of Scotland, and the most northerly British possession in Europe. It consists of an archipelago of islands and islets, with the number of the islets. Its most important ancient character, especially as a great part of it is covered by the dome of ancient trees. The Sherwood Dukeries (q.v.). Sherwood was a crown forest from the time of Henry II. and a favourite hunting-ground of several kings; the land was divided between various lords of the manor, and its disafforestation was carried out at various times. The forest is traditionally noted as the retreat of Robin Hood, whose cave is seen at Papplewick near Newstead.

The islands occupy an area of 352,889 acres or 551-4 sq. m. Besides Mainland, the principal member of the group, the more important are Yell, Unst and Fetlar in the north, Whalsay and Bressay in the east, Trondra, East and West Burra, Papa Stour, Fair Isle and the north-west in the south. The islands present an irregular surface, frequently rising into hills of considerable elevation (an extreme of 1475 ft. is found in the north-west of Mainland). Most of the inland scenery is bleak and dreary, consisting of treeless and barren tracts of peat and boulders. The coast scenery, especially on the west, is always picturesque and often grand, the cliffs, sheer precipices of brilliant colouring, reaching a height of over 1000 ft. at some places. The shores are so extensively indented with voes, or firths—the result partly of denudation and partly caused by glacial action—that no part of Zetland is more than 3 m. from the sea. There are sheets of fresh water in the larger islands of Orkney, and the most important being Strom Loch (2 m. long), Girlsta (3½ m. long) and Spiggie (1½ m.) in Mainland, and Loch of Cliff (2 m.) in Unst, and numerous short streams. The principal capes are Sumburgh Head, the most southerly point of Mainland, a bold promontory 300 ft. high; Fitful Head, on the south-west of the same island, a magnificent headland, 2 m. in length and nearly 1000 ft. high, where Norna, the prophetess of Sir Walter Scott’s Pirate, was supposed to have her abode and which the Norsemen called the White Mountain, in allusion to the colour of the clay slate composing it; and the Noup and Herma Ness, two of the most northerly points in Unst.

Geology.—The geological character of this group of islands resembles that of the northern part of Scotland. Old Red Sandstone, red grits, sandstones and marls and conglomerate occur in a narrow belt on the east side of Mainland from Sumburgh Head to Rova Head, north of Lerwick; they also form the island of Bressay. In the western portion of Mainland, in Northmavine, there is a considerable tract of rocks of this age which are formed largely of intrusive diabase-porphyrhy; similar volcanic rocks occur in Papa Stour. These are penetrated by intrusions of granitic and felsitic character; one of these masses in Papa Stour is a handsome pink porphyry, which locally all the river beds are filled up by metamorphic schists and gneissses which occur in great variety and with which are associated numerous dikes and masses of intrusive igneous rock. The southern part of Mainland, from Laxfirth Voe to Old Noup Head, is a series of gneissses mixed with granite and with intercalated schists and schistose gneissses, and the rocks are divided into two formations, the other being a series of mixed igneous beds of limestone, which may be followed across the island in a northerly direction to Yell Sound, and to Dales Voe in Delting.
Gabbaro occurs in the peninsula of Fethland; diorite in North-
mavine between Rinas Voe and Mavis Grind; and epidote-syenite in
Dunrossness. Yell is formed of coarse gneiss and granitic rocks.
In Yell is the west wall of a large chambered tomb, which was
followed eastward by schists of various kinds, then by a belt of
serpentine, 2 m. to a quarter of a mile in breadth, which crosses
the island from S.W. to N.E.; this is succeeded by a belt of gabbro, and
finally by the northern edge of a large mass of siliceous schists.
Similar rocks occur in Fetlar. Whalsay is built of coarse
gneisses and schists. During the height of the glacial period the ice
must have reached the islands, or at any rate the main centres of
population. According to Dr. Jakobsen, the largest inhabited island,
belonging to the eastern side are found as boulders scattered over
the western districts. Important formations of chronicle are found
at Hagrid and the Heig Hills; staitite occurs at Kleber Geo, and
many schists are found in the boulder clay cover. Climate and
Population.—The average annual rainfall amounts to 46 in.,
and the mean temperature for the year is 46° F., for March
39° F. and for July 54° F. The climate is very cold in winter,
lasting from November to March; spring begins in April, but it is
the middle of June before warmth becomes general, and by the end
of August summer is gone. The summer is almost nightless, print being
legible at midnight, but in winter the days are only 4 hours long,
though the nights are frequently illuminated with brilliant displays
of the aurora borealis. The well-known Shetland breed of shaggy
ponies are in steady demand for undergound work in coal fields.
The pollen of wills about 1850. The most valuable commercial
feature is the raising of barley, fleecy, furnish beef of remarkable tenderness and flavour; while the
cows, when well fed, yield a plentiful supply of rich milk. The native
sheep is a shaggy and thickly-furred breed, which has a
beauty, as well as
rams generally have short horns, and the wool is long and very fine.
White, black, speckled grey and a peculiar russet brown, called
mooral, are the prevailing colours. It is customary to pluck the wool
by hand, and the dainty fleece is then washed, reared to twice its
second crop. Black-faced and Cheviots are also found in some
places. Large numbers of geese and poultry are kept. The lochs
and tarns are well stocked with brown trout, and the voes and
gills, or narrow inlets off the sea, are well supplied with fish. The
fish are captured in the bays and sounds; the grampus, dolphin and porpoise,
bount the coasts, and seals occasionally bask on the more
outlying islets. Besides the commoner kinds of fishes, sharks, the torsk, ophid and
dolphins inhabit the waters. The waterfowl are very plentiful; the
dpapharole, fulmar petrel, kitiwake, Manx shearwater,
black guillemot, whimbrel, puffin and white-tailed eagle.
Croatling agriculture is conducted on primitive methods, spade
tillage being almost universal, and seaweed the principal manure.
The cottages are generally grouped in small hamlets called "towns.
There are numerous grazing lands, which are generally
owned under 5 acres, but the average holding runs from 5 to 20 acres. At
one time the land was held on the "runrig" system—that is, different
tenants had different tracts of land—whereas for the present the rule of
farming is separate. About one-sixth of the total area is under cultivation,
and barley being the chief grain, and potatoes (introduced in 1730)
and turnips (1807) the chief green crops. Cabbage, said to have been
introduced by a detachment of Cromwellian soldiers, is also raised,
and among fruits black and red currants riper in sheltered situations.
In spite of somewhat adverse climatic conditions, live stock is reared
with success.

The distinctive manufacture is knit goods. The finest work is
said to come from Unst, though each parish has its own speciality.
The making of gloves was introduced about 1800, of shawls about
1850. The art has been improved, and the women do most of the farm work and spend their spare time in
knitting. Fishing is the occupation of the men, and the real
mainstay of the inhabited. Formerly the fishery was not important
in the Dutch, whose supremacy was destroyed, however, by the imposition
of the salt tax in 1712. So complete was their control that they are
estimated to have derived from it more than 200 million sterling
sterlings a year. At present, however, the fishery is not what it was, but
in some measure it is improved, and the fishermen are
forever at war. Meanwhile the fishermen have been content to use the
"skerries," or six-armed fishing boats, till the last quarter of the 19th century, when boats of modern type were introduced.

The Orkney and Shetland fishery districts is the most important north of
Aberdeen, and the Shetland fishery district is the most important north of
the Orkney.

The haaf or deep-sea catch principally consists of cod,
lings, etc. In the north, communication with the islands is maintained
by steamers from Lerwick to Orkney, the Shetland capital, and to Scalloway, the former capital, and other points
once (once a week). Population.—In 1891 the population amounted to 28,711 and in 1901 it was 28,166 or 51 persons to the sq. m. The females
numbered 15,753, or 127 to every 100 males, considerably the
largest proportion to any county in Scotland. In 1901 there
were 55 persons speaking Gaelic and English, none who spoke
Gaelic only, and 92 foreigners (almost all Scandinavians).

In the inhabited islands, proceeding from south to north; but it will be understood
that they do not lie in a direct line, that several are practically
on the same latitude, that the bulk are situated off the east
and west coast of Mainland, and that two of them are distinctly
outlying members of the group. The figures within brackets
include all islands, populated or not. The number of inhabitants
is 10,448. The inhabited islands, proceeding from south to north:
the

S.W. of Sumburgh Head, and is 3 m. long by about 2 m. broad.
The name is derived from the Norse faar, a sheep (a derivation better seen in the Faroe Islands). It is a hilly island, with rocky
cliffs; North Haven, on the east coast, being almost the only place
where landing can be safely effected. From the survivors of
a vessel of the Spanish Armada that went ashore in 1588 the
natives are said to have acquired the art of knitting the coloured
hosiery for which they are noted. The shipwrecked sailors
taught the people how to prepare dyes from the plants and
seaweeds, and the craft has been carried on ever since.

The Inhabited Islands.—The following is a list of the inhabited
islands, proceeding from south to north; but it will be understood
that they do not lie in a direct line, that several are practically
on the same latitude, that the bulk are situated off the east
and west coast of Mainland, and that two of them are distinctly
outlying members of the group. The figures within brackets
include all islands, populated or not. The number of inhabitants
is 10,448. The inhabited islands, proceeding from south to north:
the
(25) lies off the west coast of Mainland, south of the two Burrs. East Burra (203), about 1 m. long by 1 m. broad, is separated from Mainland by Cliff Sound, a narrow arm of the sea, 8 m. long. West Burra (612), 6 m. long by 1 m. broad, with a very irregular coast-line, lies alongside of East Burra and contains a church. It is said to be the Burgh Westra of Sir Walter Scott's *Pirate*. Burra is a contraction of *Borgar-øy*, meaning "Broch island." Trondra (151), "Trond's island," Trond being an old Norse personal name, in the mouth of Scalloway Bay. Oxna (36) lies about 4 m. S.W. of Scalloway, and Papa (priest's isle, 10), to the E. of Oxna. Bressay (676) lies 1 m. E. of Lerwick, from which it is separated by the Sound of Bressay, in which Haakonson, by his will, left it to his widow. Here it removed to fit with Shetland north of the head of a small bay, lies Haroldswick, where Harold Haafager is believed to have landed in 892, when he annexed the Orkney and Shetland Islands to Norway. Burra Firth, in the north of Unst, is flanked on both sides by magnificent cliffs, including the Noup of Unst, the hill of Saxavord (934 ft.), the Gord and Herma Ness. Muckle Flugga (3), about 1 m. N. of Unst, is the most northerly point of Shetland, and the site of a lighthouse.

Administrative. — Shetland unites with Orkney to return a member to parliament. The island is divided into Mainland district (comprising the parishes of Northmavine, Delling, East Burra, Scalloway, Northmavine, and Dunrossness) and North Isles district (the parishes of Unst, Fetlar and Yell). It forms a sherriffdom with Orkney and Caithness, and there is a resident sheriff-substitute at Lerwick, the county town. There are parish poorhouses in Dunrossness and Unst, besides the Shetland combination poorhouse at Lerwick. The county is under school board jurisdiction and Lerwick has a secondary school, and a few of the other schools earn grants for higher education. The "residue" grant is expended on navigation and swimming classes.

Shetland and Orkney, the South-west, is divided into a number of districts, each with a "parish council," which has a seat in the House of Keys, the "Legislative Assembly." This body consists of the members of the group of Otter Skerries, about 4 m. N.E. of Whalsay. There is a lighthouse on Bound, and the rest are fishing stations. Yell (2483), separated from the north-east coast of Mainland by Yell Sound, is the second largest island of the group, having a length of 17 m., and an extreme width of 6½ m., though towards the middle the veso of Mid Yell and Whale Firth almost divide it into two. It contains several brochs and ruined chapels and is an important fishing station. Fetlar (347) lies off the east coast of Yell, from which it is divided by Colgrave Sound and the isle of Hascosay and is 5 m. long by 6½ m. broad. It ranks with the most picturesque and most fertile members of the group and contains a breed of ponies, a cross between the native pony and the horse. Uyea, "the isle," from the Old Norse øy (3), to the south of Unst, from which it is divided by the narrow sounds of Uyea and Skuda, yields a beautiful green serpentine. Unst (1940), to the N.E. of Yell and separated from it by Blue-mull Sound, is 12 m. long and 6 m. wide. It has been called the "garden of Shetland," and often inducements to sportmen in its trout and game. The male inhabitants of the islands engaged in the fisheries and the women are the expert knitters of hosiersy in the islands. Unst contains several places of historic interest. Near the south-eastern promontory stands Muness Castle, now in ruins, built in 1598 — according to an inscription on a tablet above the door — by Laurence Bruce, natural brother to Lord Robert Stewart, 1st earl of Orkney. Buess, near Balta Sound, was the house of Dr Laurence Edmonston (1795—1879), the naturalist. Near Ballasta are the remains of three stone circles. It is supposed the Ting, or old Assembly, met at one of these. Later it removed to Dinwall Firth north of the head of a small bay, lies Haroldswick, where Harold Haafager is believed to have landed in 892, when he annexed the Orkney and Shetland Islands to Norway. Burra Firth, in the north of Unst, is flanked on both sides by magnificent cliffs, including the Noup of Unst, the hill of Saxavord (934 ft.), the Gord and Herma Ness. Muckle Flugga (3), about 1 m. N. of Unst, is the most northerly point of Shetland, and the site of a lighthouse.
SHIBARGHAN, a town and khanate of Afghan Turkestan. The town lies some 60 m. W. of Balkh, and contains 12,000 infantry and about 2,000 Uzbek garrison troops, with a detachment of Persians and Parsees. It has a citadel, but is not otherwise fortified, and is surrounded by good gardens and excellent cultivation. The khanate is one of the "four domains," which were long in dispute between Bokhara and Kabul, but were allotted to the Afghans by the Anglo-Russian boundary agreement of 1873.

SHIBBOLETH, a Hebrew word, meaning an ear of corn or a stream or river, from shibal, to grow, increase, flow, used by Jephthah, probably in the second sense with reference to the river Jordan, as a word to distinguish the Ephraimites, who were unable to pronounce the sh, from the men of Gilead (see Judges xii. 6) at the passage of the Jordan. The word ciceri was similarly used at the time of the massacre of the French known as the Sicilian Vespers, for they betrayed their nationality by their inability to pronounce it. The term has also come generally to mean a watchword, catch-phrase or cry, to which the members of a party adhere after any significance or meaning which it may have imported has disappeared.

See ALPHABET, i. 725, for a discussion of the sibilant difficulty involved in the test of Judges xii. 6.

SHIEL, LOCH, a lake near the Atlantic seaboard of Scotland, lying between the district of Moidart in Inverness-shire and the districts of Ardgour and Sunart in Argyllshire. The boundary line between the two counties is drawn lengthwise down the centre of the lake and is continued down the river Shiel to the sea. The loch is 173 m. long and varies in width from 200 yds. to 1 m., and is only 11 ft. above the sea. The maximum depth is 430 ft. with a mean depth of 83 ft. The lake has an area of 484 acres on 73 sq. m., and drains directly a basin of 745 sq. m., and with an outflow from Loch Dillate, or Dollake, of 85 ft. sq. m. Loch Dillate lies 1½ m. E. of Loch Shiel, into which it flows by the Polloch. It is 13 ft. long at its maximum, with a maximum depth of 55 ft., and covers an area of 142 acres. For fully three-fourths of its length Loch Shiel has a south-westery direction, but at Eilean Fhianain (Finnan's Island) it strikes towards the west. It receives the Finnan and other small streams and discharges by the Shiel to the salt-water Loch Moidart. On the north-west and south-east it is skirted by lofty hills (Sgor Cholma (3164), Sgor nau Coireachan (3153) and others of over 2000 ft.), but the land at the western extremity in Ardmarnoch is low-lying.

SHIELD, WILLIAM (1748–1829), English musical composer, was born at Swalwell, near Newcastle, in 1748. His father began to teach him singing before he had completed his sixth year, but died three years later, leaving him in charge of guardians, who made no provision whatever for continuing his musical education, for which he was therefore dependent entirely upon his own aptitude for learning, aided by a few lessons in thoroughbass which he received from Charles Avison. Notwithstanding the difficulties inseparable from this imperfect training, he obtained admission in 1772 to the orchestra at the Italian Opera in London, at first as a second violin, and afterwards as principal viola, and this engagement he retained for eighteen years. In the meantime he turned his serious attention to composition, and in 1778 produced his first English comic opera, The Fitch of Bacon, at the Little Theatre in the Haymarket, with so great a success that he was immediately engaged as composer to Covent Garden Theatre, for which he continued to produce English and other dramatic pieces in quick succession until 1797, when he resigned his office, and devoted himself to compositions of a different class, producing a great number of very beautiful glees, some instrumental chamber music, and other miscellaneous compositions. In 1817 he was made master of the royal music. He died in London on the 25th of January 1829, and was buried in the south cloister at Westminster Abbey.

Shield's most successful dramatic compositions were Rosina, The Tie and the Blood, The Lock and Key and The Castle of Andalusia. As a composer of songs he was in no degree inferior to his great contemporary Charles Dibdin. Indeed, The Arthure, The Heaving of the Lead and The Post Captain are as little likely to be forgotten as Dibdin's Tom Bowling or Saturday Night at Sea. His vein of melody was inexpressible, thoroughly English in character and always conceived in the purest and most delicate taste, and hence it is that many of his airs are still sung at concerts, though the operas for which they were written have long been banished from the stage. His Introduction to Harmony (1794 and 1800) contains a great deal of valuable information; and he also published a useful treatise, The Rudiments of Thoroughbass.

SHIELD (O. Eng. scild, cf. Du. and Ger. Schild, Dan. Skjold; the origin is doubtful, but may be referred to the root seen in "shell" or "scale"); another suggestion connects it with iccl. skjallo, to clasp, and skjeld, a skene, in skjeldbrae (as seen in Gr. axiros, eioro Lat. culis, skin, scutum, shield, O. Eng. skid, hide, and in "sky"), a piece of defensive armour borne upon the left arm or carried in the left hand as a protection against missiles. Varying in shape and form, it was the principal piece of defensive armour from the Bronze and Iron Age to the introduction of fire-arms, and is still borne by savage warriors throughout the world (see ARMS AND ARMOUR, and for the heraldic shield HERALDY).

In modern times the principle of the shield has been applied to guns of all calibres from 1 in 6 to 1 in 20, and to calibres from 3 to 15 inches. When the turreted, the elongated, and other heavy-armoured structures are intended to be proof against the heaviest projectiles, the shield is usually only designed to resist rife and shrapnel bullets or very light shells. For the application of shields to field artillery, &c., see the articles Artillery and Ordnance.

SHIELDS, JAMES (1810–1879), American soldier, was born in Dungannon, county Tyrone, Ireland, in 1810. He emigrated to the United States in 1826, and in 1832 began to practice law in Kaskaskia, Illinois. He was prominent in Democratic politics at that time. He was a member of the Illinois House of Representatives in 1836–1838, was state auditor in 1841–1843, was judge of the supreme court of the state in 1843–1845, and was commissioner of the U.S. General Land Office in 1845–1847. In the Mexican War he served as a brigadier-general of volunteers under General Zachary Taylor on the Rio Grande, under General John E. Wool in Chihuahua, and under General Winfield Scott in the southern campaign; he was brevetted major-general for gallantry at Cerro Gordo, where he was severely wounded, and he was again wounded at Chapultepec. In 1849–1855 he was a United States senator from Illinois; and in 1856–1859 was a senator from Minnesota. In 1860 he returned to California. In August 1861, soon after the outbreak of the Civil War, he was commissioned brigadier-general of volunteers; in March 1862 he succeeded to the command of General Frederick W. Lander's division; he was in command on the Federal side at Winchester (23 March 1862) and at Port Republic (9 June); and in March 1863 he resigned his commission. He then settled in Carrollton, Missouri, and in 1875 was a member of the State House of Representatives; in 1879 he was United States senator from Missouri for six weeks to fill an unexpired term. He died at Ottumwa, Iowa, on the 3rd of June 1879.

SHIFNAL, or Shiffnal, a market town in the Newport (N.) parliamentary division of Shropshire, England, 154 m. N.W. from London on the Wolverhampton-Shrewbury line of the Great Western railway. Pop. (1901) 3321. The church of St Andrew is cruciform and full of fine details of late Norman, Early English and Decorated work. Trade is mainly agricultural, and cattle-fairs are held. There are large iron-works. The name of the town was Idsal in the Domesday Book in 1086. The town did not come under the Great Seal until the reign of Edward I. It lies on the Severn.

Within 6 m. E. of Shifnal are Tong, Boscoed and the nunnery of White Ladies. Tong Castle shares with the castle of the same name in Kent the legend of the dealings of the Saxon Hengist with the British chieftain Vortigern. The medieval building was demolished late in the 18th century, and the present castle erected in mingled Gothic and Moorish styles. Tong church, of fine early Perpendicular work, contains a remarkable series of ornate tombs, mainly of the 15th and 16th centuries, to members of the Vernon and Stanley families, former owners of the castle.
The Golden Chapel on the south side is rich late Perpendicular, with a roof of fan-tracery, showing signs of the original decoration in colours. The mansion of Boscobel is famous as the house in which Charles II. was concealed in 1652 after an adventurous journey from Worcester, where his arms had failed before those of Cromwell. The secret chamber which hid him is preserved, but he also found refuge in a tree of the forest which then surrounded Boscobel. A tree close to the house still bears the name of Charles's oak, but tradition goes no further than to assert that it grew from an acorn of the original tree. White Ladies was a Cistercian nunnery; and the slight remains are Norman. The pleasant wooded district was formerly part of Brewood Forest, which extended into Staffordshire.

SHIATSÉ, one of the largest towns in Tibet, next in importance to Lhasa, the capital. The town, which is at the confluence of the Nyang chu with the Tsangpo, contains about 9000 inhabitants (exclusive of priests), and is about ½ m. long by a ¼ m. broad. About 1 m. to the north-east is a monastery called Konkaling, whilst to the south-west is the far-famed Tashilhunpo monastery, the residence of the Dalai Lama of Lhasa. Between the Tashilhunpo monastery and the city is the Thom or open market, where all the business of the place is daily transacted. A wall about 1 m. in circumference surrounds the Tashilhunpo monastery, within which are numerous temples and houses, four of the larger temples being decorated with gilded spires. A great wealth of jewels and precious metal is said to enrich the numerous idols of Tashilhunpo. The monastery maintains 3300 priests. The city is protected by a fort which stands on a low hill to the north-west, and the fortifications are strengthened here. The municipal government is in the hands of two dépen assisted by resident Jongpons. The soil around Shigatse is rich and productive, the elevation being between 11,000 and 12,000 ft. Shigatse lay to the west of the British route of advance on Lhasa in 1894, but it was visited by Captain Rawling on his way to open the market at Gartok.

SHIGNAN and ROUSHAN, two small hill states E. of the Badakshan province of Afghanistan. They extend eastwards from the Panj-e, where it forms the eastern boundary of Badakshan to the Pamirs. The native rulers of Roshan and Shigan claim descent from Alexander the Great, and it is given to some extent that the Buddhists are still current in the country about the upper Oxus. The two states were conquered by Abdur Rahman in 1882, but were assigned to Russia by the Durand agreement of 1863. Since that agreement Russia has retired from all districts previously occupied by her on the left bank of the Panj, or upper Oxus.

SHÍ'ITES (from Arab. shi'a, a party, and then a sect), the name of one of the two great religious divisions of Islam. The Shiites hold that the imamate and caliphate belong to the house of Mahomet (Muhammad) alone, and so to 'Ali, Mahomet's son-in-law, and his successors. After the arbitration on the claims of 'Ali and Moawiyah to the caliphate (A.D. 658), two great parties emerged from the strife of feeling caused in the East by the deposition of 'Ali. Those who were known as the Kharijites, being mainly country Arabs, were democratic, and claimed that the office of caliph was elective, and that the caliph might be chosen from any Arab Moslem family. In strong opposition to these stood the party afterwards called the Shiites, who regarded 'Ali and his descendants as the only rightful caliphs. For them the caliphate was a God-given office, and not one to be given by human appointment. Belief in this was an article of faith, and an article of the faith. He who did not accept it as such was an unbeliever. Moreover, the party consisted largely of Persians who on their conversion to Islam brought with them many of the doctrines of their old faith, religious and political. Among these was the belief in the divinity of the sovereign and the duty of worshipping him. Gnostic elements, which may have come from the old religion of Babylonia, were also introduced. The idea of an absolute personal and hereditary monarchy was thus developed among the subjects of 'Ali. But in Islam there is no separation between politics and theology. The theological position of the Shiites was that the superhuman power of Mahomet descended to the members of his house ('Ali and his children), so that they could interpret the will of God and tell future events. The imam was infallible and a mahdi or guide for life. What the imam gained the Koran lost, and many of the Shiites held the Mu'tazilite or rationalistic opinion of the created nature of the sacred book.

The growth of the Shiites was fostered by the great discontent of the eastern half of the caliphate, with Omeyyad rule (see CALIPHATE, and PERSIA: History). Before long an active propaganda was started, and leaders (often adventurers) arose who formed parties and founded sects of their own in the ranks of the Shiites. One of the earliest of these was 'Abdallah ibn Sabah (founder of the Shab'tiyya), who in the caliphate of Othman had preached the return of Mahomet (founded on Koran xxvii. 84), had been concerned in the assassination of Othman, and had proclaimed the divinity of 'Ali, but had been disowned and punished by him. On 'Ali's death he declared the thunder to the Mahomet, and the lightning the scourge of the translated caliph, and announced that his divine power had passed to his successors, the imams.

Another sect, the Kaisanlyya, followed Kaisan, a freedman of 'Ali, in believing in the superhuman knowledge of Mahomed ibn Hanafiyya, a son of 'Ali but not by Fatima. Religion for these was obedience not to law but to a person. When the doctrine of a hidden imam arose, they differed from the Sabahyya in expecting his return from his place of concealment on earth, not from heaven. Among them an adventurer Mohktar (Mukht- tar) ibn 'Ali claimed to be the house of the Sabahyya was converted to the imam of both the knowledge and of the will of God—a development of Mahomet's own teaching. He claimed to fight to avenge the death of Hosain (see HASAN AND HOSAIN) and to serve Mahomed ibn Hanafiyya, who, however, disowned him. He was killed in 687. Some of the Shiite leaders, as Abu Moslim, when renounced by the members of the house of 'Ali, transferred their allegiance to the house of 'Abbas (see KAWDEN). The success of the Abbasids in supplanting the Omeyyads was largely due to the help of the Shiites, and the early Abbasid caliphs, to the time of Moawawillik, were half-Shiites of a lax order. Shahristani (q.v.) in his Book, and the Sects (Khitab Mid-lavan, Nâqî, ed. Curzon, pp. 109 ff; Haarbrücker's translation, vol. I. pp. 164 fo.) divides the Shiites into five main divisions: the Kaisanlyya, the Zaidlyya, the Imamiyya, the Ghâlîyya and the Isma'ilîyya. Of these the Ghâlîyya are represented by the followers of Ibn Sabah (see above), and the Kaisanlyya have been already described. These parties as such have now ceased to exist, the others still remain. The Zaidites or Zaidlyya are the followers of Zaid, a grandson of Hosain, and are the most moderate of the Shiites, for though holding that the imamate belongs only to the descendants of 'Ali by Fatima, and that any of the four channels might be imam (even though two or three should be in existence at the same time), they allow that circumstances might justify the appointment of another caliph for the time. Thus they acknowledge the imamate of Abu Bekr and Omar, though 'Ali was more entitled to the office. One branch of the Zaidites held Tawbaristan from 864 until overrun by the Samanids in 928; another branch, arising about 803 in Yemen, has remained there until the present day. The Isma'ilites or Isma'ilîyya are the followers of Isma'il, the elder son of Ja'far us-Sadiq, the sixth imam (see table below). He was rejected as successor by his father for drinking wine, and eventually he died in 803. Nevertheless, he was revered as imam for the adventurous sceptic 'Abdallah ibn Maimun (for his propaganda see CARMATHIANS). Owing to the success of this man the Isma'ilites have given rise to the Carmathians (q.v.), the Fātimites (q.v.), the Assassins (q.v.) and the Druses (q.v.).

At the present time the Isma'ilîyya still exist in small numbers, chiefly about Surat and Bombay. The Imamiyya believe that each imam has been definitely named by his predecessor. This party broke up into numerous divisions, and imams manifest or hidden secured each his own following. The most important of these parties is that of the Twelve (the Ithna 'ashariyya), who accept and follow the twelve descendants of 'Ali numbered in the accompanying table.
The twelfth imām Maḥommed is said to have vanished and to be in hiding, but will be restored by God to his people, when it pleases Him. The creed of this pantheon of traditions was handed down, when the Safawids conquered the country, and still remains its official creed. The shāh is thus only the temporary substitute for the hidden imām; and authoritative decisions in religious matters are pronounced by Muftis, i.e. theologians who can form their own opinions and require obedience to their decisions.

Other points in which Shi'ites differ from Sunnites depend on their legitimist opinions, or are accommodations of the rites of Islam to the Persian nationality, or else are petty matters affecting ceremonial. The rejection of all the Sunnite books of tradition goes with the repudiation of the caliphs under whose protection these were handed down. The Shi'ites, however, have their own collections of traditions. An allegorical and mystical interpretation reconcile the words of the Koran with the inordinate respect paid to 'Alī; the Sunnite doctrine of the uncreated Koran is denied. To the Mahommedan confession "There is no god but God and Mahomet is His ambassador" they add "and 'Alī is the viceregent of God" (wali, properly "confidant"). There are some modifications in detail as to the four main religious duties of Islam—the precepts of ritual purity, in particular, being made the main duty of the faithful. The prayers are almost exactly the same, and the Shi'ites allow the prayer of the congregation. Pilgrimage to Mecca may be performed by a hired substitute, or its place can be taken by a visit to the tombs of Shi'ite saints, e.g. that of 'Ali at Najef, of Ḥosain at Kerbelā, of Reşā at Meshed, or of the "unstained Fāţima" at Kūm (Fāţima-i-ma‘āṣım, daughter of Mūsā, the seventh imām). The Shi'ites are much the most zealous of Moslems in the worship of saints (real or supposed descendents of 'Ali) and in pilgrimages to their graves, and they have a characteristic eagerness to be buried in those holy places. The Persians have an hereditary love for processions and festivities, and so the Shi'ites have devised many religious feasts. Of these the great sacrificial feast (id-i- Qurbān; Turkish Qurbān Bārām) is also Sunnite; the first ten days of the month Muharram are dedicated to the mourning for the death of Ḥosain at Kerbelā (q.v.), which is celebrated by passion-plays (ta’sayy), while the universal joy of the Nauroz, or the New Year of the Old Persian calendar, receives a Mahommedan sanction by the tradition that on this day the prophet conferred the caliphate on 'Alī.

While they naturally reject the four Sunnite schools of jurisprudence, the Shi'ites also derive all law from the Koran, and their trained clergy (muftis) are the only class that can give legitimate legal responses. The training of the muftis resembles that of the Sunnite 'ālim. The course at the madrasa (medresse) embraces grammar, with some rhetoric and proseody, logic, dogmatic Koran exegesis, tradition and jurisprudence, and finally some arithmetical and algebra. The best madrasa is at Kerbelā. The scholar discharged from his studies becomes first a simple mollah, i.e. local judge and notary. A small place has one such judge, larger towns a college of judges. He is called the shāh, or imām-āl-Islām. The place of the Sunnite muftis is filled by certain of the imām-jum'-a, i.e. presidents of the chief mosques in the leading towns, who in respect of this function bear the title of imām mujtahid. This is a dignity conferred by the tacit consent of people and clergy, and is held at one time only by a very few distinguished men. In Persia, the cadi (kāfi) is an inferior judge who acts for the sheikh u'l-Islām in special cases, and a mufti is a solicitor acting under the judge to prepare cases for court.

Under the Safawids, when the clergy had great influence, they had at their head the podūr 'l-sodrār, who administered all pious foundations and was the highest judicial authority. But so great a power was found dangerous; 'Abbas the Great (1586–1628) abstained from filling up a vacancy which occurred in it, and, though Shāh Saffī (1628–1651) restored the office, he placed it in commission. Nādir Shāh abolished it in his attempt to get rid of the Shiite hierarchy (1736), and since then it has not been restored. Yet the imām-jum'-a of Isfahān, the old Safawi capital, is tacitly regarded as representative of the invisible imām of the house of 'Alī, who is the true head of the church. Few of the ceremonies introduced by the Shīites have been a success in Persia; they are not sanctioned by the clergy, and outside the great shrines of the sect, they are a matter of more religious than civil ceremonies. To the Khoja, or shari'ah, which are used in the courts of the sect, and the mullahs adjust the contract and share the women’s profits. There is still a little life and virgo among the Shi'ites, as appears among the sects, which, allowance being made for "taqyia," play no inconsiderable part. The Akhāhrār (traditionalists), who adopt a semi philosophical way of explaining away the plainest doctrines (such as the resurrection of the flesh) on the authority of false traditions of 'Ali, are not so much a sect as a school of theology within the same pale as the orthodox Shīa or Mu'tahīds. A real dissenting sect, however, is the Sheikhs who are of the Shi'ite shari'ah, and whose doctrines we have but imperfectly correctly. The representation of the Sheikhs, which claim that 'Ali was a divine incarnation, are found all over Persia in the "Ali-Ishāh" or "Ali-Allāh" sect ("Ali defiers"). Finally, in the 19th century arose the remarkable attempt at reform known as Bāshīl (q.v.).

Dory, Essai sur l’histoire de l’islamisme (Leiden and Paris, 1879); G. van Vrooren, Recherches sur la domination arabe, le chhtisme, etc. (Amsterdam, 1894); various works of A. von Kremer and I. Goldzheber; J. E. Polak, Persien. Das Land und seine Bewohner (2 vols., Leipzig, 1865); E. G. Browne, A Year among the Persians (London, 1841).

SHIKARPUR, a town of British India, in the Sukkur district of Sind, Bombay. It is situated about 18 m. from the right bank of the Indus, with a station on the North-Western railway, 23 m. N.W. of Sukkur. Pop. (1901) 49,491. Shikarpur has always been a place of importance, this being the trade route through the Bolan Pass, and its merchants have dealings with many towns in Central Asia. It has a large market and manufactures of carpets, cotton cloth and pottery. Shikarpur was formerly the headquarters of a district of the same name. In 1901 two subdivisions of this district were detached to form the new district of Larkana, and the two other subdivisions were then constituted the district of Sukkur.
SHILLOD, a town market in the Bishop Auckland parliamentary division of Durham, England, 9 m. N.W. from Darlington by a branch of the North Eastern railway. Pop. of urban district of Shildon and East Thockley (1901) 11,759. At New Shildon or East Thockley are extensive railway engine and wagon works belonging to the railway company. A large coal traffic is handled here, as there are collieries and foundries in the vicinity.

SHILLETO, RICHARD (1809-1876), English classical scholar, was born at Ulleskelf in Yorkshire on the 25th of November 1809. He was educated at the Clifton Grammar School and Wesleyan College, Cambridge, and in 1867 was elected a fellow of Peterhouse. His whole life was spent in Cambridge, where he died on the 24th of September 1876. Shilleto was one of the greatest Greek scholars that England has produced; in addition, he had an intimate acquaintance with the Latin and English languages and literature. He published little, being obliged to devote the best years of his life to private tuition. He was the most famous classical "coach" of his day, and almost all the best men passed through his hands. His edition of the De falsa legatione of Demosthenes will always remain in high quarters. His pamphlet Thucydidès or Great? excited a considerable amount of feeling. While it undoubtedly damaged Grote's reputation as a scholar, it was felt that it showed a want of appreciation of the special greatness of the historian. Shilleto's powers as a translator from English into Greek (especially prose) and Latin were unrivalled; a selection of his versions was published in 1901.

SHILLING, an English silver coin of the value of twelve pence. The term is derived from a French word.

There was an Anglo-Saxon coin termed scilling or scyulling, worth about fivepence, which is said to be derived from a Teutonic root, skil, to divide, + iling on the analogy of farthing (q.v.). The silver shilling was first struck in 1504, in the reign of Henry VII. In Charles II.'s reign shillings were first issued with milled edges. In George IV.'s reign they were issued so-called "lion shillings," bearing the royal crest, a crowned lion on a crown, a design reverted to in the coinage of Edward VII. A shilling is token money of a type, it is nominally in value the one-twentieth of a pound, but one pound of sliver is coined into sixty-six shillings, the standard weight of each shilling being 87-27 grains.

SHILLONG, a town of British India, in the Khasi Hills district of Eastern Bengal and Assam. It is situated in 25° 24' N. and 91° 53' E., on a plateau 4978 ft. above the sea, 63 m. by cart-road S. of Saultali, on the Brahmaputra. Pop. (1901) 8384. Shillong practically dates from 1864, when the district headquarters were transferred from Cherrapunji. It was chosen as the seat of government in 1874, when the province of Assam was constituted. Every one of the public buildings and houses that quickly grew up was levelled to the ground by the great earthquake of the 12th of June 1897, but they have since been rebuilt. Cantuorns are still in the form of a wall of Gurkhas with two guns, and Shillong is the headquarters of the Assam brigade of the 8th division of the Northern army. There are a government high school and a training school for masters. The Welsh Presbyterian mission is active in promoting education. Since 1895, when Dacca became the capital of the new province of Eastern Bengal and Assam, Shillong has declined in importance; but it is still the summer residence of the government and the headquarters of the district.

SHILLUH, or Sooery ("ingabonds"), the name given by the Arabized Moors to the Berber peoples of southern Morocco. They occupy chiefly the province of Sus. The name is said to be a corruption of ashkhil (pl. iskhali), a camel-hair tent. They are of fine physique, strong and wiry, and true Berbers in features and fairness. They are as a rule shorter than the Berbers of Algeria (see BERBERS and MOROCCO).

SHILLUK, a Negro race of the upper Nile valley, occupying the lands west of the White Nile from the Sobat northward for about 360 m., and stretching westward to the territory of the Baggar tribes. They are the most numerous of the Negro tribes of the Anglo-Egyptian Sudan, and form one great family with the Alur and Acholi (q.v.) and others in the south. Formerly extending as far north as Khartum and constituting a powerful Negro kingdom, they are now decadent. They are the only race on the upper Nile recognizing one chief as ruler of all the tribes, the chieftainship passing invariably to the sister's child or some other relative on the female side. The Shilluk towns on the Nile bank are usually placed near to one another. They own large herds of cattle. In physique the Shilluks are typically Negroes and jet black. The men used to wear nothing from the waist upward but a calico attached to their girdle, but with the establishment of Anglo-Egyptian control, c. 1900, they gradually adopted clothes. The poorer people smear themselves with ashes. They ornament the hair with grass and feathers in fantastic forms such as a halo, helmet, or even a broad-brimmed hat. When they saw Schweinfurth wearing a broad felt hat they thought him one of them, and were amazed when he took it off. They are skilful as hunters, and especially as fishermen, spearing fish while wading or from amblesh rafts. Their arms are spears, shields and clubs. Their religion is a kind of ancestor worship and nature worship.

SHILOH, BATTLE OF. This, the second great battle in the American Civil War, also called the battle of Pittsburg Landing, was fought on the 6th-7th of April 1862 between the Union forces under Grant and Buell and the Confederates under A. S. Johnston and Beauregard. In view of operations against Corinth, Mississippi, Grant's army had ascended the Tennessee to Pittsburg Landing and there disembarked, while the co-operating army under Buell was passing through the Cumberland valley. The Confederates concentrated about 40,000 men at Corinth and advanced on Pittsburg Landing with a view to beating Grant before Buell's arrival, but their concentration had left them only a narrow margin of time, and the advance was further delayed by the wretched condition of the roads. Beauregard advised Johnston to give up the enterprise, but on account of the bad effect a retreat would have on his raw troops Johnston resolved to continue his advance. Grant meantime had disposed his divisions in camps around the Landing rather with a view to the Confederate army making a direct advance. The Confederates sniped towards the Landing, astonishing Johnston and leading him to cut off and force surrender. Another division had its commander, W. H. L. Wallace, killed. But on the other side the disorder became greater and greater, many regiments were used up, and Johnston himself killed in vainly attacking on a point of Wallace's line called the Hornets' Nest. The day passed in confused and savage scuffles between the raw enthusiasts of either side, but by 5.30 P.M. Grant had formed a last (and now a connected) line of defence with Buell's leading division (Nelson's) and all of his own infantry that he could rally. This line was
hardly 600 yds. from the Landing, but it was in a naturally strong position, and Beauregard suspended the attack at sunset. There was a last fruitless assault, delivered by some of the Confederate brigades on the right that had not received Beauregard's order against Nelson's intact troops, who were supported by the fire of the gunboats on the Tennessee. During the night Grant's detached division (Lew Wallace's) and Buell's army came up, totalling 25,000 fresh troops, and at 5 A.M. on the 7th Grant took the offensive. Beauregard thereupon decided to extricate his sorely-tried troops from the misadventure, and retired fighting on Corinth. About Shiloh Church, a strong rearguard under Bragg repulsed the attacks of Grant and Buell for six hours before withdrawing, and all that Grant and Buell achieved was the withdrawal of the able-bodied troops, who had sustained a federate failure, but not a Union victory, and, each side being weakened by about 10,000 men, neither made any movements for the next three weeks.

**SHILOH**, a town of Ephraim, where the sanctuary of the ark was, under the priesthood of the house of Eli. According to 1 Sam. iii. 3, 15, this sanctuary was not a tabernacle but a temple, with doors. But the priestly narrator of Jos. xviii. 1 has it that the tabernacle was set up there by Joshua after the conquest. In Judges xx. 19 seq. the yearly feast at Shiloh appears as of much importance, in the choice of the champion. The sanctuary of Shiloh having been destroyed, probably by the Philistines after the battle of Ebenezer; cf. Jeremiah vii. 12 seq. The position described in Judges, loc. cit., gives certainty to the identification with the modern Sellun lying some 2 m. E.S. of Khan Labban (Lebanon), on the road from Bethel to Shechem. Here there is a ruined village, on an elevation protected by lofty hills on three sides, and open only towards the south, offering a strong position, which suggests that the place was a stronghold as well as a sanctuary. Fertile land surrounds the hill. The name Sellun corresponds to "Σαλεύον in Joseph. LXX, iam biu. The forms given in the Hebrew Bible (נֶשֶלֶג, נֶשֶלֶג) have dropped the final consonant, which reappears in the adjective נֶשֶלֶג.

**SHIMÔGA, or SHEEMOGA**, a town and district in the state of Mysore, southern India. The town is situated on the Tunga river, and is the terminus of a branch railway. Pop. (1901) 6240. The area of the district is 4025 sq. m. Its river system is twofold; in the east the Tunga, Bhadra and Varada unite to form the Tungabhadra, which ultimately falls into the Kistna and so into the Bay of Bengal, while in the west a few minor streams empty themselves into the Sharavatti, which near the north-western frontier bays through the Western Ghats by the celebrated Falls of Gersoppa (q.v.).

The western half of the district is mountainous and covered with magnificent forest, and is known as the Malnad or hill country, some of its peaks being 4000 ft. above sea-level. The general elevation of Shimoga is about 2000 ft.; and towards the east it opens out into the Maidan or plain country, which forms part of the general plateau of Mysore. The Malnad region is very picturesque, its scenery abounding with every charm of tropical forests and mountain wilds: on the other hand, the features of the Maidan country are for the most part comparatively tame. The mineral products of the district include iron-ore and laterite. The soil is loose and sandy in the valleys of the Malnad, and in the north-east the black cotton soil prevails. Bisons are common in the taluk of Saugar, where also wild elephants are occasionally seen; while tigers, leopards, bears, wild dogs and other wild animals are numerous in the wooded tracts of the west. Shimoga presents much variety of climate. The south-west monsoon is felt in full force for about 25 m. from June to September, bringing an annual rainfall of more than 150 in., but the rainfall gradually diminishes to 21 in. at Shimoga station and to 25 in. or less at Chennagi. The population in 1901 was 53,173. Rice is the staple crop; next in importance is sugar-cane; among the vegetables, temperance of course, include vegetables, fruits and pepper. The chief manufactures are coarse cotton cloths, rough country blankets, iron implements, brass and copper wares, pottery and jaggery. The district is noted for its beautiful teakwood carving.

During the Mahomedan usurpation of Mysore from 1761 to 1799, unceasing warfare kept the whole country in constant turmoil. Although the Hindu emperor Shimoga became the scene of disturbances caused by the mal-administration of the Deshast Brahmans, who had seized upon every office and made themselves obnoxious. These disturbances culminated in the

**SHINGLE.** (1) A Middle English corruption of schindel, from Lat. *scindula* or *scandula*, a wooden tile, from *scandere*, to cut—"a kind of wooden tile, generally of oak, used in places where timber is plentiful, for covering roofs, spires, &c. In England they are generally plain, but on the continent of Europe the ends are sometimes rounded, pointed or cut into ornamental form.

(2) Water-worn detritus, of larger and coarser form than gravel, chiefly used of the pebbly detritus of a sea-beach. This word is of Norwegian origin, from *singl* or *singling*, coarse gravel. It is apparently derived from *singla*, to make a ringing sound, a form *singl* (Lebonah) with alluvial "singling," which is pebbles dropped when walking over shingle.

(3) The word "shingles" the common name of *herpes* *soster*, a particular form of the inflammatory eruption of the skin known as herpes (*q.v.*), is the plural of an obsolete word for a girdle, *sengle*, taken through O. Fr. *cesnelle* from Lat. *cinguluni*, *cingere*, to gird.

**SHINWARI**, a Durani Afghan tribe occupying the northern slopes of the Safed Kob below Jalalabad. One clan, the Ali Sher Khel, fall within the British sphere in the North-West Frontier Province of India. They live on the Loagai border of Peshawar district and numerous fighting men. The remaining three clans are Afghan subjects.

**SHIO-GHI**, the Japanese game of chess. Like Go-bang, the game of the middle classes, and Sugorochu (double-six), that of the common people, it was introduced from China many centuries ago and is still popular with the educated classes. It is played on a board divided into 81 squares, nine on a side, with 20 pieces on each side, arranged on the three outer rows. The pieces, which are flat and pent-shaped with the smaller end towards the front, represent, by means of different inscriptions, the O, or Shio, King-General, with whose checkmate the game ends, his two white sides, the Kii and Ghiu, Gold and Silver Generals (two of each), Ko-Ma, horse or knight (two), Yari, spearman (two), Hisho, or flying chariot (rook), one Kaku (bishop), and nine Hio or Fu, soldiers or pawns. All these pieces, like those in chess, possess different functions. The chief difference between chess and Shio-gi is that in the Japanese game a piece does not cease to be a factor in the game when it is captured by the opponent, but may be returned by him to the board at any time as a reserve; and, secondly, all pieces, except the King and Gold General, are promoted to higher powers upon entering the last three rows of the enemies territory. This possibility of utilizing captured forces against their former masters and the altering values of the different men render shio-gi a very difficult and complicated game.

**SHIP**, the generic name (O. Eng. *scip*, Ger. *Schiff*, Gr. *σκάφος*, from the root *skap*, cf. "scoop") for the invention by which man has contrived to convey himself and his goods upon water. The derivation of the word points to the fundamental conception by which, when realized, a means of flotation was obtained superior to the raft, which we may consider the earliest and most elementary form of vessel. The trunk of a tree hollowed out, whether by fire, or by such primitive tools as are fashioned and used with singular patience and dexterity by savage races, represents the first effort to obtain flotation depending on something other than the mere buoyancy of the material. The poets, with characteristic insight, have fastened upon these points. Homer's hero Ulysses is instructed to make a raft with a raised platform upon it, and selects trees "withered of old, exceeding dry, that might float lightly for him" (Od. v. 240). Virgil, glorifying the dawn and early progress of the arts, tells us, "Rivers then first the hallowed alders felt" (Georg. i. 136, ii. 451). Alder is a heavy wood and not fit for rafts. But to make for the first time a dug-out canoe of alder, and so to secure its flotation, would be a triumph of primitive art, and thus the poet's expression represents a great step in the history of the invention of the ship.

Primitive efforts in this direction may be classified in the
following order: (1) rafts—floating logs, or bundles of brushwood or reeds or rushes tied together; (2) dug-outs—hollowed trees; (3) canoes of bark, or of skin stretched on framework or inflated skins (balsas); (4) canoes or boats of pieces of wood stitched or fastened together with sinews or thongs or fibres of vegetable growth; (5) vessels of planks, stitched or bolted together with inserted ribs and decks or half decks; (6) vessels of which the framework is first set up, and the planking of the hull nailed on to them subsequently. All these in their primitive forms have survived, in various parts of the world, with different modifications marking progress in civilization. Climatic influences and racial peculiarities have imparted to them their specific characteristics, and, combined with the available choice of materials, have determined the particular type in use in each locality. Thus on the north-west coast of Australia is found the single log of buoyant wood, not hollowed out but pointed at the ends. Rafts of reeds are also found on the Australian coast. In New Guinea catamarans of three or more logs lashed together with thongs are common, and similar forms appear on the Madras coast and throughout the Asiatic islands. On the coast of Peru rafts made of a very buoyant wood are in use, some of them as much as 70 ft. long and 20 ft. broad; these are navigated with a sail, and, by an ingenious system of centre boards, let down either fore or aft between the lines of the timbers, can be made to tack. The sea-going raft is often fitted with a platform so as to protect the goods and persons carried from the wash of the sea. Upright timbers fixed upon the logs forming the raft support a kind of deck, which in turn is itself fenced in. The result is a vessel completely open to the horizon; the method of side planking to raise the freight above the level of the water and to save it from getting wet, are among the earliest typical expedients which have found their development in the progress of the art of shipbuilding.

I. HISTORY TO THE INVENTION OF STEAMSHIPS

Whether the observation of shells floating on the water, or of split reeds, or, as some have fancied, the nautilus, first suggested the idea of hollowing out the trunk of a tree, the practice ascends to a very remote antiquity in the history of man. Dug-out canoes of a single tree have been found associated with objects of the Stone Age among the ancient Swiss lake dwellings; nor are specimens of the same class wanting from the bogs of Ireland and the estuaries of England and Scotland, some obtained from the depth of 25 ft. below the surface of the soil. The hollowed trunk itself may have suggested the use of the bark as a means of flotation. But, whatever may have been the origin of the bark canoe, its construction is a step onwards in the art of shipbuilding. For the lightness and pliability of the material necessitated the invention of some internal framework, so as to keep the sides apart, and to give the stiffness required both for purposes of propulsion and the carrying of its freight. Similarly, in countries where suitable timber was not to be found, the use of skins or other water-tight material, such as felt or canvas, covered with pitch, giving flotation, demanded also a framework to keep them distended and to bear the weight they had to carry. In the framework we have the rudimentary ship, with longitudinal bottom timbers, and ribs, and cross-pieces, imparting the requisite stiffness to the covering material. Bark canoes are found in Australia, but the American continent is their true home. In northern regions skin or woven material made water-tight supplies the place of work. They are built up of pieces fitted together with ridges on their inner sides, through which the fastenings are passed. These canoes have the advantage of elasticity, which gives them ease in a seaway, and a comparative immunity where ordinary boats would not hold together. In these cases the body of the canoe is constructed first and built to the shape intended, the ribs being inserted afterwards, and attached to the sides, and having for their main function the uniting of the deck and cross-pieces, with the body of the canoe. Vessels thus stitched together, and with an inserted framework, have from a very early time been constructed in the Eastern seas far exceeding in size anything that would be called a canoe, and in some cases attaining to 200 tons burden.

From the stitched form the next step onwards is to fasten the materials out of which the hull is built up by pegs or treenails; and of this system early types appear among the Polynesian islands and in the Nile boats described by Herodotus (ii. 96), the prototype of the modern "nugger." The raft of Ulysses described by Homer presents the same detail of construction. It is remarkable that some of the early types of boats belonging to the North Sea present an intermediate method, in which the planks are fastened together with pins or treenails, but are attached to the ribs by cords passing through holes in the ribs and corresponding holes bored through ledges cut on the inner side of each plank.

We thus arrive, in tracing primitive efforts in the art of ship construction, at a stage from which the transition to the practice of setting up the framework of ribs fastened to a timber keel laid lengthwise, and subsequently attaching the planking of the sides, is not far off. The earliest type of modern vessel may be said to have its prototype in the single log which was the parent of the dug-out. The side planking of the vessel, which has an earlier parentage than the ribs, may be traced to the attempt to fence in the platforms upon the sea-going rafts, and to the planks fastened on to the sides of dug-out canoes so as to give them a raised gunwale. The ribs of the modern vessel are the development of the framework originally inserted after the completion of the hull of the canoe or built-up boat, but with the difference that they are now prior in the order of fabrication. In a word, the skeleton of the hull is now first joined together, with the ribs, &c., as a framework, before the covering is put upon it. This method is the one universally adopted in modern practice.

It is noticeable that the invention of the outrigger and weather platform, the use of which is at the present time distributed from the Andaman Islands eastward throughout the whole of the South Pacific, has never made its way into the Western seas. It is strange that Egyptian enterprise, which seems at a very early period to have penetrated eastward down the Red Sea and round the coasts of Arabia towards India, should not have brought it to the Nile, and that the Phoenicians, who, if the legend of their great migration from the shores of the Persian Gulf to the coast of Canaan is accepted, would in all probability, in their maritime expeditions, have had opportunities of seeing it, did not introduce it to the Mediterranean. That they did not do so, if they saw it at all, would tend to prove that even in that remote antiquity both nations possessed the art of constructing vessels of a type superior to the outrigger canoes, both in speed and in carrying power.

The earliest representations that we have as yet of Egyptian vessels carry us back, according to the best authorities, to a period little short of 3000 years before Christ. Some of these are of considerable size, as is shown by the number of rowers, and by the cargo consisting in many cases of cattle. The earliest of all presents us with the peculiar mast of two pieces, stepped apart but joined at the top. In some the masts are shown lowered

3 See Captain Cook's account of the Friendly Islands, La Pérouse on Easter Island, and Williams on the Fiji Islands.

4 Compare the planks upon the Egyptian war galley, added so as to protect the rowers from the missiles of the enemy.

5 It is curious that these two methods should still survive, and be in use in the construction of modern vessels. Some of these are built ribs first, and skin laid on afterwards; others, skin laid on moulds and framework first, and ribs inserted in the shell when turned over.
SHIP

and laid along a high spar-deck. The larger vessels show on one side as many as twenty-one or twenty-two and in one case twenty-six oars, besides four or five steering. They show considerable camber, the two ends rising in a curved line which in some instances ends in a point, and in others is curved back and over at the stern and terminates in an ornamentation, very frequently of the familiar lotus pattern. At the bow the stem is sometimes seen to rise perpendicularly, forming a kind of forecastle, sometimes to curve backward and then forward again like a neck, which is often finished into a figure-head representing some bird or beast or Egyptian god. On the war galleys there is frequently shown a projecting bow with a metal head attached. In the Phoenician, and the navigation have given place to the single mast furnished with bars or rollers at the upper part, for the purpose apparently of raising or lowering the yard according to the amount of sail required. The sail in some of the galleys is shown with a bottom as well as a top yard. In the war galleys during action it is shown rolled up like a curtain with loops to the upper yard. The steering was effected by paddles, sometimes four or five in number, but generally one or two fastened either at the end of the stern or at the side, and above attached to an upright post in such a way as to allow the paddle to be worked by a tiller.

There are many remarkable details to be observed in the Egyptian vessels figured in Duemichen's Flet of an Egyptian Queen, and in Lepsius's Denkmäler. The Egyptian ship, as represented from time to time in the period between 3000 and 1000 B.C., presents to us a ship proper as distinct from a large canoe or boat. It is the earliest ship of which we have cognizance. But there is a noticeable fact in connexion with Egypt which we gather from the tomb paintings to which we owe our knowledge of the Egyptian ship. It is evident from these records that there were at that same early period, inhabiting the littoral of the Mediterranean, nations who were possessed of sea-going vessels which visited the coasts of Egypt for plunder as well as for commerce, and that sea-fights were even then not uncommon. Occasionally the combination of these peoples for the purpose of attack assumed serious proportions, and we find the Pharaohs recording naval victories over combined Dardanians, Teucrians and Myrians, and, if we accept the explanations of Egyptologists, over Pelasgians, Daunians, Oscans and Sicilians. The Greeks, as they became familiar with the sea, followed in the same track. The legend of Helen in Egypt, as well as the numerous references in the Odyssey, point not only to the attraction that Egypt had for the maritime peoples, but also to long-established habits of navigation and the possession of an art of shipbuilding equal to the construction of sea-going craft capable of carrying a large number of men and a considerable cargo besides.

But the development of the ship and of the art of navigation clearly belongs to the Phoenicians. It is tantalizing to find that the earliest and almost the only evidence that we have of this development is to be gathered from Assyrian representations. The Assyrians were an inland people, and the navigation which they were familiar was that of the two great rivers, Tigris and Euphrates. After the conquest of Phoenicia, they had knowledge of Phoenician naval enterprise, and accordingly we find the war galley of the Phoenicians represented on the walls of the palaces unearthed by Layard and his followers in Assyrian discovery. But the date does not carry us to an earlier period than 700 B.C. The vessel represented is a bireme war galley which is "aphract," that is to say, has the upper tier of rowers unprotected and exposed to view. The apertures for the lower oars are of the same character as those which appear on Egyptian ships of a much earlier date, but without oars.

The artist has shown the characteristic details, though somewhat conventionally. The fish-like snout of the bow, the line of the parodius or outside gangway, the wickerwork cancelli, the shields ranged in order along the side of the bulwark, and the heads of a typical crew on deck (the πρωτες looking out in front in the forecastle, an ἐκβάτας, two chiefs by the mast, and, aft, the κελευτής and κυρευμένης). The supporting timbers of the deck are just indicated. The mast and yard and fore and back stays with the short ratline indicated. But although there can be little doubt that the Phoenicians, after the Egyptians, led the way in the development of the shipwright's art, yet the information that we can gather concerning them is so meagre that we must go to other sources for the description of the ancient ship. The Phoenicians at an early date constructed merchant vessels capable of carrying large cargoes, and of traversing the length and breadth of the Mediterranean, perhaps even of trading to the far Cassiterides and of circumnavigating Africa. They in all probability (if not the Egyptians) invented the bireme and trireme, solving the problem by the use of increased oar-power and consequently speed could be obtained without any great increase in the length of the vessel.

It is, however, to the Greeks that we must turn for any detailed account of these inventions. The Homeric vessels were aphract and not even decked throughout their entire length. They carried crews averaging from fifty to a hundred and twenty men, who, as we are expressly told by Thucydides, all took part in the labour of rowing, except perhaps the chiefs. The galleys do not appear to have been armed as yet with the bow, though later poets attribute this feature to the Homeric vessel. But they had great pikes used in fighting, and the term employed to describe these (ναύβαμαξαί) implies a knowledge of naval warfare. The general characteristics are indicated by the epithets in use throughout the Iliad and the Odyssey. The Homeric ship is sharp (θηόδ) and swift (ϊώκεια); it is hollow (κολύς, γλαυκόμφι, μεγακτης), black, vermilion-cheeked (μιλστάγγαρος), dark-drowed (κολανθραόρος), curved (κορωσόμ, ἀμφελλος), well-timbered (ἐθνελομος), with many thwarts (σαλαςγους, καλαςγους). The stems and sterns are high, upright, and resemble the horns of oxen (οθημωσαμα). They present in the history of the shipping of the Mediterranean a type parallel with that of the Vikings' vessels of the North Sea.

On the vases, the earliest of which may date between 700 and 600 B.C., we find the bireme with the bows finished off into a beak shaped as the head of some sea monster, and an elevated forecastle with a bulwark evidently as a means of defence. The craft portrayed in some instances are evidently piracy vessels, and exhibit a striking contrast to the trader, the broad ship of burden (φορτις ελεχα), which they are imitating. The trireme, which was developed from the bireme and became the Greek ship of war (the long ship, ποσ μακρα, πολει λογα, παρ εξελλενς), dates, so far as Greek use is concerned, from about 700 B.C. according to Thucydides, having been first built at Corinth. The earliest sea-fight that the same author knew of he places at a somewhat later date—664 B.C., more than ten centuries later than some of those portrayed in the Egyptian tomb paintings.

The trireme was the war ship of Athens during her prime, and, though succeeded and in a measure superseded by the larger rates,—quadrireme, quinquereme, and so on, up to vessels of sixteen banks of oars (inhabilis prope magnitudinis)—yet, as containing in itself the principle of which the larger rates merely exhibited an expansion, a difference in degree and not in kind, has, ever since the revival of letters, concentrated upon itself the attention of the learned who were interested in such matters. The literature connected with the question of ancient ships, if collected, would fill a small library, and the greater part of it turns upon the construction of the trireme and the disposition of the rowers therein.

1 See Rawlinson, Ancient Monarchies, vol. ii. p. 176.
During the 17th century a fresh light was thrown upon the subject by the discovery (1634) at the Peiraean by some records of the shipwrights dealing with several years between 373–324 B.C. These were published and admirably elucidated by Boeckh. Further researches were carried out by his pupil Dr Graser. Since the publication of Graser's notable work, De re navali veterum, the subject has been copiously treated by A. Cartault, Breusing, C. Torr and others. The references to ancient writers, and the illustrations from vases, coins, &,c., have been multiplied, and, though the vexed question of the seating of the rowers cannot be regarded as settled, yet, notwithstanding some objections raised, it seems probable that some form of the 'trippe' or 'tribune' was generally used. The two-class system, however, still holds the field, especially as practical experiment has shown the possibility of a set of men, seated very nearly according to his system, using their oars with effect, and without any interference of one bank with another.

On one point it is necessary to insist, because upon it depends the right understanding of the problem. The ancients did not employ more than one man to an oar. The method employed on medieval galleys was alien to the ancient system. A. Jal, Admiral Finetti, Admiral Torr, and others, have all acknowledged that the subject, some as recently as 1906, have led to advocate erroneous, if ingenious, solutions of the problem, by neglect of, and in contradiction with, the facts. The foundation on which it is built, consequently, which overwhelmingly establishes as an axiom of the ancient marine the principle of "one oar, one man." The distinction between 'apbrach' and 'cataphract' which marks the first attempt to classify the ancient vessels. The words, meaning 'infenced' and 'fenced,' refer to the bulwarks which covered the upper tier of rowers from attack. In the apbrach vessels these side planking were continuous and the upper tier of oars was exposed to view from the side. Both classes of vessels had upper and lower decks, but the apbrach class carried their decks on a lower level than the cataphract. The system of side planking with a view to giving additional strength to the vessel is probably a Greek invention, and may be seen in some of the Egyptian representations, but among the Greeks it does not seem to have been adopted till long after the Hellenic period. The Thasians are credited with the introduction of the system.

In our account of the trireme, both as regards the disposition of the rowers and the construction of the vessel, we have mainly, though not entirely, followed Graser. Any such scheme must at the best be hypothetical, based upon inference from the ancient texts, or upon necessities of construction, and in every case plenty of room will be left for the critic, along with the Horatian invitation, "si quid novisti rectius sitis, Candidus imperit." In the ancient vessels the object of arranging the oars in banks was to economize horizontal space, and to obtain an increase in the number of oars without having to lengthen the vessel. It has been reckoned that the difference between the 'hippodrome,' or 'scapeceum,' or space horizontally measured from oar to oar, was 2 cubits. This is exactly borne out by the proportions of an Attic trireme preserved upon a richly coloured Attic vase in the British Museum. The rowers in all classes of banked vessels sat in the same vertical plane, and seats ascending in a line obliquely towards the stern of the vessel. Thus in a trireme the triariste, or oarsman of the hightest in itself conjugal (We may of the things of which to which he belonged. Next behind him and somewhat below him sat his zygiste, or oarsman of the second bank; and next below and behind the zygiste sat the thalamite, or oarsman of the lowest bank. The vertical distance between these seats was probably 2 ft., the horizontal distance about 1 ft. The horizontal distance, it is well to repeat, between each seat in the same bank was 5 ft. (the seat itself about 9 in. broad). Each man had a resting place for his feet, sometimes one seat apart, fixed to the bench of the man on the row next below and in front of him. In rowing, the upper hand, as is shown in most of the representations which remain, was held with the palm turned inwards towards the body. This is accounted for as the difference between the ['hippodrome'] or space horizontally measured from oar to oar, was 2 cubits. This is exactly borne out by the proportions of an Attic trireme preserved upon a richly coloured Attic vase in the British Museum. The rowers in all classes of banked vessels sat in the same vertical plane, and seats ascending in a line obliquely towards the stern of the vessel. Thus in a trireme the triariste, or oarsman of the hightest in itself conjugal (We may of the things of which to which he belonged. Next behind him and somewhat below him sat his zygiste, or oarsman of the second bank; and next below and behind the zygiste sat the thalamite, or oarsman of the lowest bank. The vertical distance between these seats was probably 2 ft., the horizontal distance about 1 ft. The horizontal distance, it is well to repeat, between each seat in the same bank was 5 ft. (the seat itself about 9 in. broad). Each man had a resting place for his feet, sometimes one seat apart, fixed to the bench of the man on the row next below and in front of him. In rowing, the upper hand, as is shown in most of the representations which remain, was held with the palm turned inwards towards the body. This is accounted for as the difference between the outer vole, or side oar, and the inner oar, the latter being the one used as the steersman. Each outer-oar was protected by an ascoma or leather bag, which fitted over the rower, closing the aperture against the wash of the sea without impeding the action of the oar. The oar was attached by a1
bolted to them under either extremity and both within and without, and presented a side of length and breadth equal to the whole of the vessel. The timbers were wedged and let into the box so as to give the vessel, generally painted red, and in the upper part of these the eyes (δεδομένοι) answering to our hawse holes, through which ran the cables for the anchors. On either side of the stern-post about 22 ft. below the deck two projecting pieces into the prow (φυράδως) resting on the ribs of the vessel. This projection was of about 18 to 24 in., which gave a space, increased to about 3 ft., in which was placed the rowing curule or hawse of the vessel. It was held by the upper flanges or strengthening plates. This part of the vessel was provided with supports for the deck, for a passage on either side of the vessel. This gangway was placed in the outer side so as to afford protection to the seamen and marines, who could pass along its whole length under the deck, the crew being divided into two parts. The rowers were posted as light-armed troops, and when needed could use the long supernumerary oars (πτερύγια) mentioned above. The ribs, prolonged upwards upon an inward curve, supported on their upper sides (θέμα) the main deck, and were ditto on the stern-post, which was divided into six sections, and was fastened to the vessel in sections. At various levels on the stern the decks (πρώπια) rose in two or three gradations, upon which was a kind of deck-house for the captain and a seat for the steersman, but none for the rowers of the vessel. The stern was fixed in the upper part of the paddles, which, in later times at least, ran over wheels (πρόκλητα), giving him the power of changing his vessel's course with great rapidity. Behind the deck-house rose the flagstaff, on which was hoisted the pennant, as signals from the stern were given in the case of an admiral's ship. On either side of the decks ran a balustrade (σαλοίστρον), which was covered for protection against attack. The vessel was also provided with a strong and large lower girdle (σαλόνιστρον), as a protection against grappling irons and missiles of all kinds. In Roman vessel towers were carried up fore and aft from which darts could be showered on the enemy's deck; the heavy corvus or boarding bridge swung suspended by a chain near the bows; and the ponderous δολία hung at the ends of the yards ready to fall on a vessel that came near enough alongside. But these were later inventions; the larger ships of the Attic trireme was built for speed and for ramming purposes. The dimensions of some dry docks discovered at Mynychus and Zante, and the measurements of the ancients called them, afford some indications as to the dimensions of the later Athenian vessels. It is likely that the Athenians, who used them. The measurements indicate for these houses about 150 ft. in length and 20 ft. in breadth. We may infer, therefore, that the size of the vessel was not exactly in proportion to her length. Fortresses necessarily have been some space in the dock houses, on either side and at both ends. Allowing 2 ft. on either side for passage room, and 10 ft. at either end, we should have room for a vessel of about 130 ft. in length including the beam, and of about 16 ft. beam. If the 2 cubic "intercalium," the rowing space in the trireme (31 by 3) for the upper tier would equal 93 ft. Allowing 6 ft. for bows and 15 for stern, and 10 for beam, we have 130 ft. as the aggregate length of the war vessels of three banks of oars. This, of course, is conjectural, but we submit that it is a reasonable conjecture fom the evidence which we possess. There was indeed very reasonable evidence that these vessels were used as ramming ships, of course consistent with their necessary requirements, and it is to be remembered that it was constantly being hauled up on shore for the night and launched again in the morning. Again, as to "intercalium," it does not appear to exist in older treatises, yet it certainly appears in later Athenian writing. In the Egyptian dragon boats, which are 73 ft. long and under 5 ft. beam, and have each 54 rowers or paddlers, it does not exceed 2 ft. 6 in. An oarsman whose feet rest on a level below that of his seat, is not likely that the ancient oarsman, who, according to Polybius, rarely rose to the top of the man-of-war's cutter. All the Attic triremes appear to have been built on the same model, and their gear was interchangeable. The Athenians had a peculiar system of girding the ships with long cables (μυμπάλαι), the lower ends of which reached to the stern-post, ran all round the vessel lengthwise immediately under the waling-pieces. They were fastened at the stern and tightened up with levers. These cables, by shrinking as soon as they were wet, tightened the whole fabric of the vessel, and in action, in all probability, relieved the hull from the weight of the oars; the whole of which was done by the waling-pieces convergent in the beaks. These rope-girdles are not to be confused with the process of undergirding or frapping, such as is narrated of the vessel in which St Paul was being carried to Italy. The trireme appears to have had two masts. The Greeks did not use sails, and everything that could be lowered was stowed below. The mainmasts and larger sails were often left ashore if they were not necessary. The crew of the Attic trireme consisted of from 200 to 225 men. In all of these were rowers—54 on the lower bank (θαλαμίται), 54 on the middle bank (γυγίται), and 62 on the upper bank (θριαντίται), giving the upper oars more numbers because of the contraction of the space available for the lower tiers near the bow and stern. Besides the rowers were about 10 marines (ετεράδες) and 20 seamen. The officers were the triarch and next to him the helmsman (κυλιόμενος). The vessel was about 120 ft. short of the trireme of the period of the Peloponnesian War. It was such that, Cicero remarks, there was not room for one man more. The improvement made in the build of their vessels by the Corinthian and Syracusean ships, with which the rowers were so much strengthened that they were able to meet the Athenian attack stem on (προφεδἀθρος), caused a change of tactics, and gave an impetus to the building of larger vessels—quadriremes and quinqueremes—in which increased oar-power was available for the propulsion of the heavier weights. The improvement was only of the trireme, so far as the disposition of the rowers was concerned, but the speed could not have increased in proportion to the weight, and hence arose the variety of contrivances which superseded the long voting or the days of Phormio. In the century that succeeded the close of the Peloponnesian War victory of building big vessels became prevalent. We hear of various numbers of banks of oars up to sixty (εθέαρηχιάς)—the big vessel of Demetrius Poliorcetes. The famous tesseraconters or forty-banked vessel of Ptolemy Philopator, if it ever existed except in the imagination of Callixenus, was in reality nothing more than a costly and ingenious toy, and never of any practical use. The story, however, of its construction indicates the perfection to which the shipwright's art had been carried among the ancients. The Romans, who developed their naval power during the First Punic War, though it is clear from the treaty with Carthage, 509 B.C., that they had had some maritime interests and adventures before that great struggle began, were deficient in the art of naval construction. A Carthaginian quinquereme, which had drifted ashore, served them for a model, and with crews taught to row in a framework set up on dry land they manned a fleet which was launched in sixty days from the time that the trees were felled. Their first attempt was, as might have been expected, a failure. But they persevered, and the invention of the corvus, by means of which boarding were opposed to ramming tactics, gave them under Darius (200 B.C.) victory at Mylæ, and eventually the command of the sea. From that time onwards they continued to build ships of many banks, and seem to have maintained their predilection for fighting at close quarters. The larger vessels with their "turrets," or castles, fore and aft, deserved Horace's description as "alta navium propugnaculum." The "corvus" and the "dolphin" were ready in action to fall on the enemy's decks, and in Caesar's battle with the Veneti off the coast of Gaul the "falces," great spars with which the steel heads like a sickle, moved through the rigging and let down the sails on which alone the foe depended for movement. But the fashion of building big ships received a severe shock at the battle of Actium (31 B.C.), when the light Liburnian "biremes," eluding the heavy missiles of the larger vessels, swept away their banks of oars, leaving them crippled and unable to move, till one by one they were burnt down to the water's edge and sank. After this experience the Romans adopted the Liburnians as their principal model, and though the building of vessels with many banks continued for some centuries, yet the Liburnian type was so far dominant that...
SHIP

the name was used generically, just as the name of trireme had been used before, to signify a man-of-war, without reference to the size of vessel or the number of banks of oars.

Meanwhile, with the peace of the Mediterranean ensured, for piracy was kept in check by the imperial power, and with increased commercial activity, the building of large merchant vessels naturally followed. These were propelled by sails and not by oars, which, however, continued to furnish the principal motive power for the ship of war until the necessity for increasing its carrying power began to make it too unwieldy for propulsion by rowing.

The great corn ships, which brought supplies from Egypt to the capital, were, if we may take the vessel described by Lucian as a typical instance, 120 cubits long by 30 broad and 20 deep. The ship in which St. Paul and his companions were wrecked carried 276 souls besides cargo. Even larger vessels than these were constructed by the Romans for the transport of marbles and great obelisks to Italy. These huge vessels carried three masts, with square sails, and on the main mast a topsail, which the corn ships from Alexandria alone were allowed to keep set when coming into the Italian port. All other merchant vessels were compelled to strike the supparum.

But while the construction of large vessels for commercial purposes was thus developed, the policy of keeping the war-vessel light and handy for maneuvering purposes prevailed, and, therefore, vessels of three, four or even five banks were still built, the great majority did not rise above two banks. In the war with the Vandals (A.D. 440-470) we hear of ships of a single bank, with decks above the rowers. These, we are told, were of the type which at a later date were called Dromons (δρόμους) in allusion to their speedy qualities, a name which generally superseded the Liburnian, as indicating a man-of-war. During the following centuries the Mediterranean was the scene of constant naval activity. The rise of the Musulman power, which by A.D. 825 had mastered Crete and Sicily, made the Mediterranean the stage for the rivalry of the Western and Southern emperors of the East, and as the Arab invasion became more threatening, and piracy more rife, so the necessity of improving their galleys as regards speed and armament became more and more pressing. It was during this period, and that very largely by the Arabs, that a great advance was made in the employment of what we should call artillery. The use of Greek fire and of other detonating and combustible mixtures, launched by siphons or in the form of bombs thrown by hand or machinery, led to various devices by way of protective armour, such as leather or felt caisng, or woollen stuffs soaked in vinegar, and all such contrivances were put to use to alter the character as well as the equipment of the war vessel.

During the same period the rise and growth of the Venetian republic mark the entrance on the scene of a new seafaring and shipbuilding power.

Meanwhile, the northern seas were breeding a new terror. In the 5th century the Roman fleet which guarded the narrow entrance into the British Channel had disappeared. The Frankish power gradually established itself in Gaul. But behind the Franks still fiercer races, born to the use of oar and sail, were rising for the invasion of the west and south. For a while it seemed as if the empire consolidated by Charlemagne would be able to withstand their inroads. Yet even in the year of his coronation (A.D. 800) the piratical Northmen had carried their ravages as far as Aquitaine. Charlemagne organized a naval force at Boulogne and at Ghent. But, though in alliance with the kings of Mercia and Wessex, he had not that control of the Channel which the possession of both shores had given to the Romans. The ships of the Vikings, propelled by oar and sail, were seagoing vessels of an excellent type. They were of various sizes, ranging from the shado of about 50 oars to ask or skid with 64 oars and a crew of 240, and to the still larger dreki or dragon boats, and the famous snekkur or serpent, said to be represented on the Bayeux tapestry. Of these vessels we have fortunately, though of the smaller class, a typical instance in the well-known Viking ship discovered in 1880 in a tomb-mound at Gokstad near Christiania, of which the dimensions are given as: length 78 ft., beam 16 ft. 7 in., depth 5 ft. 9 in., with high stem and stern; clinker-built of oak throughout, with 16 oars on either side. Of this type were vessels large and small which had by the 9th century or even earlier found their way into the Mediterranean. Such were the fleets which continually infested the northern and western coasts of Gaul, carrying swarms of the fierce Northmen who eventually came to stay, and gave their name to the portion of Neustria which they had wrested from the Frankish king (p.12).

If, as is probable, the Danes who invaded England used the same class of vessel, Alfred the Great must, according to the Saxon Chronicle, be credited with improvements in construction, which enabled him to defeat them at sea (869). He built, we are told, vessels twice as long as those of the Danes, swifter, steadier and higher, some of them for 60 oars, and after his own design, not following either the Danish or Frisian types.

While the northern seas were thus full of activity and conflict, there was little repose in the Mediterranean. The emperors of the West do not seem to have maintained their fleets or naval stations as they had been of old. Ravenna and Misenum were born of their ancient glories. But in the East things were different. There, as we have said, it was fully perceived that the maintenance of the empire depended upon sea power. The Tactics of the Emperor Leo (886-911), followed by Constantine Porphyrogenitus (915-99), give us full details as to the composition of a Byzantine fleet and its units. Dromons of two sizes and of two banks of oars are described, and, besides these, smaller Dromons of great speed are referred to as "galleys or single-banked ships." In all these the rule was still "one oar, one man," but the way was being prepared for improvements by which the medieval galley, still preserving a comparatively low freeboard, was enabled to equal or to surpass the many-banked vessel in speed, while it was gradually adapted to carry greater weight and more powerful means of offence.

The "man-of-war" (μαχητης), the first vessel of war properly so called, in which the merchant vessel (μυκοφορος), but the use of longer oars or sweeps took the place of the smaller paddling oars of the ancient vessel, and altered greatly the angle at which the oars reached the water. It was the increase in the length and weight of the oar, requiring for its efficiency greater power than that of one man, which led to the employment of more than one man to an oar. With the longer oar the necessity arose of placing the weight at a greater distance from the power applying the lever. This was gained by the invention of the apotis, which was practically a framework standing out on each side of the hull and running parallel to a strong external timber, in which the thowls, again when the oars were rowed, were set. By this means it became possible not only to arrange the oars horizontally, in sets of three or more of different lengths (αλλα σεμελη), instead of in banks one above the other obliquely, but still further to make an innovation, unknown to the ancients, which, while greatly increasing the length and substance of the oar, and its leverage, applied the strength of three or four men (or even up to seven with the larger galleys and gallasses) for the motive power of each blade. As time went on oars of from 30 to 50 ft. came into vogue, the inboard portion of which was about one-third of the length, and furnished with handles (manettes) attached to the boom, while the men for each oar were arranged in steps (αλλα σαλοειει). It must not be imagined that these developments took place all at once, or that any improvements in building, or in the method of propulsion, were generally adopted but by slow degrees. Moreover, as commerce increased and merchant vessels gained in size, the necessity of being able to defend themselves against piratical attacks became more and more cogent, a necessity which ultimately led the way to the supersession of the galley by the sailing vessel. Yet the galley for centuries, especially in the Mediterranean, maintained its place as the ship of war par excellence, even when mixed fleets of galleys and sailing vessels were not uncommon. In the Atlantic and northern seas it was less en evidence, though even with the Spanish Armada some galleys and galasses were included in the invading fleet.
The period of the Crusades was one of great activity in shipbuilding, in which the Venetians and the Genoese were the leaders in the Mediterranean, but the enterprise of England under Richard Coeur de Lion (1189-1190) shows that in the northern seas great efforts were being made in the same direction, with the undoubted result that the English vessels built for the purpose were more familiarized with the sea, and more eager for maritime adventure. Richard's fleet which sailed from Dartmouth consisted of 110 vessels, and its total in the Mediterranean after reinforcement amounted to 230 vessels. Among these were Busses, or Dromons of large size, with masts and sails, ships of burden and triremes. Nor were the Saracens without great vessels, if the story of Richard's destruction of a three-masted vessel, carrying reinforcements to Acre, on board of which there were no less than 1500 men, be true. The attack of a swarm of galleys upon the great ship as she lay becalmed was exactly like the attack of a swarm of torpedoes upon a disabled battleship to-day.

The whole period of the Crusades was, as regards naval matters, one of mixed fleets, in which the sailing vessels were mostly merchant vessels armed for fighting purposes. The effect of the Crusades upon the seafaring races of northern Europe was that the revelation of the East and its traffic quickened their desire for adventure in that and other directions. Hence rivalries between them and the Mediterranean sea powers, and consequent improvement in sea-going vessels and in seamen-ship. The steering side-paddle gradually disappeared, and the rudder became the usual means of directing the vessel's course. The merchant vessels when prepared for war have fore-castles and stern-castles (compare the Roman *turrest*) erected on them, of which the one survives in name, and the other in the quarter-deck of modern times. But a change was at hand which was destined to affect all classes, from the galley with its low freeboard to the *alta poppugnaculum* of the great sailing vessels.

The invention of gunpowder, and the consequent use of cannon on board ship, was the cause of many new departures in building and armaments. In the galleys we find guns mounted in the bows, and broadside on the upper deck, *en barbette*, firing over the bulwarks. Soon, however, the need of cover suggested portholes cut for the guns, just as in the ancient galleys they had been cut for the oars. The desire to carry many guns led to many alterations in build, such as the tumble-home of the sides, and the desire for speed to many improvements in rig, as well as to an increase in the number of masts and consequently larger spread of sail. About 1370-1380 French, Venetians and Spaniards are using the new artillery in action, and the policy of maintaining a navy composed of sailing vessels, particularly built for the purposes of war, and not merely of armed merchant ships impressed for the emergency, soon began to take effect.

In England Henry V. (1413) built large vessels for his fleet, "great ships, cogs, carracks, ships, barges and ballingers," some of which were of nearly 1000 tons, but the generality from 420 to 520 tons. In the list of his fleet no galleys seem to be included. Meanwhile in the south the type of vessel called "caravel" was being developed, in which Portuguese and Spaniards dared the Atlantic and made their great discoveries. It was a vessel which ranks kind the stern became the usual means of steering, and which was able to reach the Indies by a western route.1 She was but little over 230 tons when fully laden. Her forecastle overhung the stern by nearly 12 ft. Aft she had a half deck and a quarter deck. Her total length was 128 ft., her beam nearly 26 ft. She had three masts and a bowsprit. Her fore and main masts were square-rigged, but the mizen had a lateen sail. The vessels in which Vasco da Gama first doubled the Cape of Good Hope (1497) were of the same type but larger. The ship of John Cabot (1497) in which he discovered Newfoundland must have been much smaller, as he had a crew of only eighteen men.

Among the results of these world-famous voyages and discoveries was naturally a great increase in maritime adventure.

1 See Sir G. V. Holmes, *Ancient and Modern Ships*, i: 87, to which the writer is indebted for many of the details concerning modern vessels.

In England during the Tudor times a great advance in shipbuilding is observable. Henry VII. with his new ships, the "Regent" and the "Sovereign," and Henry VIII. with his "Henry Grace à Dieu," or "Great Harry," both came abreast of their times, but it is worthy of notice that the French then, as well as at an earlier date, were providing the best models for naval architecture. These big ships were armed at first with "serpentines," and later with cannon and culverins. The representations of them show several tiers of guns, four or even five masts, and enormous structures by way of forecastles and deck-houses aft. As regards merchant vessels, the Genoese and the Venetians during the 15th and 16th centuries carried out great improvements. The "carracks" of the 16th century often reached as much as 1600 tons burden. There is a record of a Portuguese carrack captured by the English, of which the dimensions reached 165 ft. in length. She carried 32 pieces of brass ordnance and between 600 and 700 passengers. The Spanish Armada (1588) was composed of 132 vessels, of which the largest was about 1300 tons and 30 under 100 tons. Four galleys and four gallasses accompanied the fleet. The opposing fleet consisted of 197 vessels of which only 34 belonged to the royal navy. Of these the largest was the "Triumph" of about 1000 tons. The "Ark," the flagship of the English admiral, was of 800 tons, carrying 35 guns. Among the armed merchant vessels employed with the fleet was the "United" consisting of 230 tons. The English vessels were built of oak, and were 230 tons. In the men-of-war the lower tier of guns, which, as in the galleys, had been carried dangerously near the water-line, began to be raised. This improvement, however, does not seem to have been adopted in the English ships till after the Restoration. Meanwhile, in the Mediterranean the galley was still in vogue, being only partially superseded by the great galleasses, six of which are recorded to have taken part in the battle of Lepanto (1571), in which the Venetians and their allies employed no less than 208 galleys with single banks and long sweeping oars. The contrast between the galleasses of the Mediterannian and the large English voyaging vessels and those engaged in the case of the Spanish Armada is interesting and instructive as typical of the different development of naval power in the inland and the open seas.

During the 17th century the expansion of trade and the increase of mercantile enterprise were incessant. The East India Company organized its fleet of armed vessels of about 600 tons, and fought its way through Portuguese obstruction to the Indian coast. The Dutch were also competing for the trade of the East and the West, and formed similar companies with this object in view. The struggle between the French, the English, the Dutch, the Venetians and the Genoese was incessant, and international jealousies were inevitable. Hence in the British navy the construction of large vessels such as the "Prince Royal" and the "Sovereign of the Seas" (see RIGGINS) which may be considered as among the earliest types of the modern wooden men-of-war. English oak afforded the best timber for shipbuilding, and skillful naval architects, such as Phineas Pett, succeeded in constructing the kind of sea-going war vessel which eventually gave England the superiority in its struggle with other naval powers in this and the following century. This, however, was by no means equally gained. The Dutch and the French were not slack in the building of merchant vessels and men-of-war. The capture of vessels from time to time on either side served to enlarge the area of improvement and to assist in the progress of the art of construction. The French navy especially, under the fostering care of Colbert, was greatly strengthened. During
the 18th century it was constantly found that the dimensions of French ships exceeded those of British ships of the same date, and that French vessels were superior in speed. This led from time to time to an increase of the dimensions of British vessels, and so of the class of vessels in the British navy. These were now rated according to the number of guns which they were constructed to carry.

A 90-gun ship of the line at the beginning of the 18th century averaged 164 ft. in length of gun deck, 47 ft. beam, and about 1570 tons, while the frigates now ran to 120 ft. with 34 ft. beam and from 600 to 700 tons. These dimensions, however, were not always maintained, and towards the middle of the century the Admiralty seem to have recognized the consequent inferiority of their vessels. The famous and ill-fated “Royal George” launched at Deptford in 1756, was the result of an effort to improve the line-of-battle ship of the period. She was 178 ft. in length, 52 ft. in beam, was of over 2000 tons, and carried 100 guns and a crew of 750 men. The “Victory,” Nelson’s flagship, was built nearly ten years later. Her dimensions were 186 ft., 52 ft., 2162 tons, and she carried 100 guns. During the same period frigates, which were cruisers carrying their armament on one deck, were built to carry 32 or 36 guns, but in this class also the French cruisers were superior in speed and of larger dimensions. The remainder of the 18th century and the beginning of the 19th witnesses the rigging in proportion to the dimensions of the French and Spanish models being constantly ahead of the British in dimensions and armament. In the American war (1812) the same disparity as regards dimensions became apparent, and the English frigates, and sloops used as cruisers, were generally outclassed, and in some instances captured, by American vessels of their own rate. This as usual led to the construction of larger vessels with greater speed, and though, after the conclusion of the long war, the activity of the royal dockyards slackened, yet the great three-deckers of the last period, before the adoption of steam power, had reached a length of over 260 ft., a beam of 60 ft., and over 3000 tons.

Meanwhile the mercantile navies of the world, but more especially of England, had largely increased. The East Indian, as the armed vessels of the East India Company were called, really performed the functions of merchant vessel, passenger ship, and man-of-war. But, where there was no monopoly, competition soon quickened the development of trading vessels. The Americans with their fast-sailing “clippers” again taught the English builders a lesson, showing that increased length in proportion to beam gave greater speed, while admitting of lighter construction by the adoption of wooden hulls and the adoption of sail. But, as regards the number of men required to work the ship.

The English shipyards were for a long time unequal to the task of producing vessels capable of competing with those of their American rivals, and their trade suffered accordingly. But after the repeal of the Navigation Laws in 1850 things improved, and we find clipper ships from Aberdeen and from the Clyde beginning to hold their own on the long voyages to China and elsewhere.

At this epoch steam power appears in use on the scene, and the period of great wooden vessels closing with iron and steel taking their place in the construction of the hulls, while the sail gives way to the paddle and the screw.

II. History since the Introduction of Steamships

Before steam was applied to the propulsion of ships, the voyage from Great Britain to America lasted for some weeks; at the beginning of the 20th century the time had been reduced to about six days, and in 1910 the fastest vessels could do it in four and a half days. Similarly, the voyage to Australia, which took about thirteen weeks, had been reduced to thirty days or less. The fastest of the sailing tea-clippers required about three months to bring the early teas from China to Great Britain; in 1910 they were brought to London by the ordinary P. & O. service in five weeks. Atlantic liners now run between England and America which maintain speeds of 25 and 26 knots over the whole course, and in approximately three weeks before the introduction of steam. The accommodation in the modern passenger ships is palatial compared with that in the corresponding wooden sailing ships of the middle of the 19th century.

The changes from sail power to steam power for propulsion, and from wood to iron and steel for constructional purposes, proceeded together, though at first very slowly. The marine steam engine was at first a very imperfect motor, and the services upon which steamships could be used to advantage were, in consequence, much restricted. There was, moreover, a national prejudice against the substitution of iron for the wooden Walls of Old England.

It is recorded that an iron boat, intended apparently for passenger service, was built and launched on the river Foss, in Yorkshire, in 1777, and shortly afterwards iron was used for the ship plating of lighters for canal service. One of these, having its shell constructed of plates five-sixteenths of an inch thick, was built near Birmingham in 1787. About the same time parts of wooden ships began to be replaced by iron, the first being beam knees. Early in the 19th century iron “diagonal riders” for providing the longitudinal stiffness, were introduced by Sir Robert Seppings, and from this period dates to the present day iron strengthenings for resisting both transverse and longitudinal strains have been generally used in wooden ships. The introduction of iron as a recognized material for ship construction is often given as dating from 1818, when the lighter “Vulcan” was built on the Monkland canal, near Glasgow.

Among the early objections were: (1) from its weight iron could not be expected to float, and was therefore unsuitable for the construction of a floating body; (2) when a ship constructed of this material grounded and was exposed to bumping on a shore, the bottom would be easily perforated; (3) the bottom could not be preserved from fouling by weeds and barnacles; and (4) the iron affected the compass, making it untrustworthy, if not useless. Gradually, however, the material made its way, and the objections to it proved to be for the most part untenable. Objection (1), although often repeated, was proved to involve a fallacy. With regard to objection (2) it was found that iron ships might ground and be subjected to a great deal of bumping and rough usage without being destroyed, and that, on the whole, they were better off in this respect than wooden ships. On more than one occasion when iron and wooden ships were stranded together on the same shore and in approximately the same circumstances, the iron ships were got off, and, apart from local injury, were found to be little the worse for the grounding, while the wooden ships were either totally wrecked, or, if got off, were strained to such an extent as to be beyond repair. The power of resistance of iron ships to the strains produced by grounding received, in 1846-1847, a remarkable confirmation in connexion with the grounding of the “Great Britain,” the first large screw steamer built entirely of iron. This ship had been initiated by, and built under the supervision of, Mr. J. K. Brunel, who had bestowed much attention upon the details of her construction. In 1846 she ran ashore in Dundrum Bay, in Ireland, and settled on two detached rocks; and although she remained aground for eleven months, including a whole winter, she was subsequently got off and repaired, and afterwards did good service. As regards (3), the fouling of the bottom, this evil, although not preventable,
can be lesened materially by frequent cleaning and repainting, provided, of course, that docks are available. The fourth objection, the effect of iron on the compass, was very serious. After experimenting with the "Rainbow" at Deptford and the "Ironside" at Liverpool, Sir G. B. Airy in 1839 read a paper on the subject before the Royal Society, and the rules which he gave for the correction of the error caused by the iron and steel on board were thus modified. Besides the above, a further objection was raised which applied only to warships, namely, the nature of the damage which would be done to an iron ship by the enemy's shot: this also was found to be less serious, when proper appliances were supplied, than the damage done in the same circumstances to a wooden ship. Thus during the Chinese War in 1854 the "Nemesis," an iron vessel, was able to repair her damage from shot in twenty-four hours at the scene of the fight, while some wooden ships had to go to Bombay, the nearest port at which repairs could be made.

Steel, as a material for shipbuilding, was introduced under modern conditions of manufacture during the years 1820-1875.

It is a homogeneous metal, stronger than iron, and of a more uniform and more trustworthy character.

Its quality is to a considerable extent independent of the skill of those employed in its manufacture, whereas iron is produced by a laborious and unhealthy process, and is largely dependent for its quality on the skill of the workmen.

Among the advantages which have proved iron and steel to possess over wood for the purposes of ship construction are: (1) the weight of the latter is less; (2) it has greater durability; (3) the requisite general and local strengths are much more easily obtained.

The importance of the first of these advantages can scarcely be overstated. The primary object of a particular ship is to carry cargo or passengers, or both, from place to place, at a given speed (in the case of a warship, the armament, ammunition, and crew, of course, are factors), and the maximum draught at which the vessel can properly and safely proceed on her passage the total weight of vessel, cargo, &c., complete, must be a definite quantity, namely, the weight of the water displaced by the ship, it follows that the less the weight required for the structure of the ship, the greater is that available for the cargo, &c.

As to durability, in wooden ships the chief source of deterioration is dry-rot, in iron or steel ships the wasting of the surfaces, especially of such portions of the outer surfaces of the bottom plating as are frequently left bare of paint and exposed to the sea, and of the inner surfaces of the ships' hulls, the inner planking, &c., the life of the wooden ship will be lengthened; so also will the life of the iron or steel ship if the surfaces can be kept covered with paint, to prevent the corrosive action of air and water. With both wood and the metal, however, if the inner planking is once a

and the life of the iron or steel ship if the surfaces can be kept covered with paint, to prevent the corrosive action of air and water. With both wood and the metal, however, if the inner planking is once a

ated and removed, this is usually worth doing when the deterioration is only local. At the end of the 18th century the preservation of wood was not so well understood as it is now; the invariable practice seemed to be to remove all theirable of woods, was, in Great Britain at least, little known. The ships for the Royal Navy as then constructed were only expected to be available for service some fifteen or twenty years. The ships built for the East India Company, made, on an average, four voyages, which occupied eight years. This at one time was considered the vessel's life, so far as the Company's service was concerned; but subsequently, if on examination at the expiration of that time they appeared worth repairing, this was done, and they were allowed to make two more voyages. It was unusual for one of these ships to make more than six voyages; after this they were sold or broken up.

In certain cases, however, ships lasted a considerable length of time; a number of vessels built in the 17th century continued in the service of the Royal Navy until the beginning of the 18th century, though with a reduced number of guns, and specimens of the old wooden battleships which served in the fleet in the earlier part of the last century are still to be found in the naval and other public vessels. Among these is the "Victory" (fig. 1, Plate XIII.). Laid down in 1759, she had been at least 40 years before she took part in the battle of Trafalgar, and to-day she is the only ship of the Royal Navy which is a direct descendant of the old wooden vessel. The examples is Nelson's "Victory,"(1) (fig. 1, Plate XIII.). Laid down in 1759, she had been about 40 years before she took part in the battle of Trafalgar, and to-day she is the only ship of the Royal Navy which is a direct descendant of the old wooden vessel. The examples is Nelson's Nautical Archi

dimensions of the last vessel are: length, 88 ft. 8 in.; breadth, 21 ft. 2 in.; depth of hold, 14 ft. 7 in.; and her gross tonnage, 211. The "Chinese schooner" was a small wooden sailing vessel built in 1723 and still employed in the coasting trade of Denmark. This vessel is 52 ft. 6 in. long, 14 ft. 8 in. breadth, and 9 ft. 2 in. depth. These figures are, however, as given in the "Nautical Almanac."

In the cases of these very old wooden vessels it should be remembered that many portions of the original structures have been replaced by continual repairs. We have less experience concerning steel vessels. That ships of iron or steel have been and still are extremely strong, is well known. Many of these vessels have been condemned and broken up only because they were obsolete; but after twenty or even forty years' service, those parts which by accident remained in a sound condition were found very little the worse for wear. Thus the inner surface of the outside plating of such vessels, coated with cement, have been found to be in as good condition as when the ships were first launched. The hulls of iron and steel vessels still afloat are known to be in excellent condition. The "Himalaya," an iron vessel of 3453 tons and 700 h.p., length 340 ft. 5 in., breadth 46 ft. 2 in., depth 24 ft., built by Mare of Blackwall in 1853 for the F. & O. Steam Packet Co., and purchased by the Admiralty, was actively employed, chiefly as a troop-ship, until 1896, when she was converted into a coal depot, it being found that her plating and framing were still as good as new. Known as "C. 60," she seems to have survived for many years in her new service. The "Warrior"—the first British iron battleship, built in 1861, was converted into a floating workshop forty years later at Portsmouth, where in 1910 she was used as a dry dock. The "Disraeli" and the "Dreadnought" were then practically as sound as when first put together. Experience up to 1910 with vessels built of mild steel indicates that this is more liable to surface corrosion than iron, especially where exposed to the action of brackish water, but mild steel vessels are generally more strong, and consequently little loss of strength, and great local strength can be provided in very little space.

For some purposes, and in some markets, wood is still in favour. In scientific research, for instance, when it is necessary to avoid any disturbance of the compass, this can be ensured by constructing the vessel of wood, with metal fastenings. The "Fram," built in 1892 for Nansen's Arctic expedition, was of wood, her outside planking, in three thicknesses, amounting to the aggregate to from 24 in. up to 28 in.; she was 117 ft. long, rigged as a three-masted schooner, and provided with auxiliary machinery working a water-tight airtight frame. When the expedition reached the North Pole, an old Dundee whaler (the "Esquimaux"), and was reported to be still a "stout" ship with timbers as sound as on the day they were put in twenty-six years before. She is 157 ft. long, 85 ft. beam, and 6 ft. deep. The ship has a nominal horse-power of 100, and she has a lifting screw. In 1901 the "Discovery," a wooden vessel, 172 ft. in length, was built at Dundee for Antarctic exploration, under Captain Robert Scott, R.N., and a vessel specially designed for similar service was constructed in Germany, and in 1910 the "Terra Nova" (Plate I., fig. 2), a wooden Dundee whaler, 187 ft. long, barque-rigged and fitted with auxiliary steam power, which had already served on the Far South, embarked for the Antarctic regions an expedition also led by Captain Scott. Some wooden sailing vessels are still built in the United States and employed in the coasting and other trades. One of these, the "Wyoming," the largest wooden sailing vessel ever built, was launched in December 1909 at Bath. She was a six-masted schooner 350 ft. long, 50 ft. wide and 30 ft. deep. Wood is also in favour for most of the large and palatial river steamers of the Western states of America.

Some progress had been made in the introduction of steam propulsion before the end of the 18th century, but Steamships the advance became much more rapid in the 19th. The early steam vessels paddle-wheels only were used for propulsion.

In 1801-1802 the "Charlotte Dundas," one of the earliest steam vessels, was constructed by Symington in Scotland. She proved her capability for towing purposes on the Forth and Clyde Navigation. Fulton had made his first steam boat in 1807; and after visiting Scotland and witnessing the success of the "Charlotte Dundas," constructed the "Clermont" on the Hudson river in America in 1807. The engines for this vessel were obtained from Boulton & Watt, of Birmingham.

A very complete account of this vessel was given by her designer, Mr. W. E. Smith, C.B., in the Transactions of the Institution of Naval Architects (1905).
SHIP

All the vessels just named were propelled by paddle-wheels. The screw propeller had been advocated as a means of propulsion by many inventors in England, France and America during the latter half of the 18th and the early part of the 19th century; a number of experiments had been made, but these had not been brought to a successful issue, as no suitable steam engine was available for driving the propeller. Benjamin Franklin, in 1775, drew attention to the inefficiency of side paddle wheels as a means of propulsion, and proposed as an alternative to set the steam engine to pump water in at the bow and force it out at the stern, the water passing along a trunk. In 1782 a boat 80 ft. long, fitted with this means of propulsion by James Rumsey, was driven at 4 m. an hour on the river Potomac, and a number of other vessels similarly fitted followed. In 1839 Dr. Ruthven took out a patent for this method of propulsion in which the piston pump was replaced by a centrifugal pump; and in 1865 the “Nautilus,” a vessel of this type, so impressed the British Admiralty of the day that an armed gunboat—the “Waterwitch”—was provided with this system of propulsion. She was built of iron, 162 ft. long, 32 ft. broad, 13 ft. 9 in. deep, was double-ended and fitted with bow and stern rudders, but was otherwise similar to the armed gunboat “Viper” built at the same time and fitted with a screw propeller. Many trials were carried out with the “Waterwitch” and “Viper,” but the system adopted in the former was not repeated for similar reasons, and the great advances made in connexion with the screw propeller.

Many useful experiments appear to have been carried out by Colonel John Stevens in the United States in the early years of the 19th century, but, although some beautiful models of propellers made by him still remain the system was not generally adopted until its commercial possibilities were more successfully demonstrated by Captain John Ericsson—formerly an officer in the Swedish army—and F. P. Smith of England. Smith took out his patent for the propulsion of ships by means of a screw fitted in a recess formed in the deadwood, in May 1836, and in July of the same year Ericsson, then practising as a civil engineer in London, took out his patent. Small vessels were built and fitted by both inventors and both were tested in the Thames. In 1838 Captain Robert F. Stockton, on behalf of the U.S. Navy, ordered two iron boats of Messrs. Lairds of Birkenhead, to be supplied with steam engines and screw propellers of Ericsson’s design. The first boat was named the “Robert F. Stockton,” and arrived at New York under sail early in 1839, with her machinery on board. The machinery was fitted in her at Bordentown, and under the name of “New Jersey” the boat afterwards served a time as a steamer on the Delaware. She was 70 ft. long, 10 ft. broad, and 6 ft. 9 in. draught, and was designed for 130 miles per hour. Ericsson had the satisfaction of seeing his plans very largely adopted in the American Navy, but the mercantile marine adhered with great pertinacity to the paddle-wheel.

Fincham, writing in 1851, says that in English engineers were reluctant to admit the success of the screw propeller, and adds: “A striking instance of prevailing disinclination to the screw propeller was shown on the issue of a new edition of the Encyclopaedia Britannica, in which the article on steam navigation contained no notice whatever of the subject.”

Smith, however, persevered, and with the assistance of some influential people of the day—namely Messrs. Rennie & Co.—formed the Ship Propeller Company, and in 1858 built the “Archimedes,” a vessel of 237 tons burthen, to illustrate the value of the plan. The length of the vessel was 106 ft. 8 in., breadth 21 ft. 10 in., depth in hold 15 ft., draught of water 9 ft. 6 in., h.p. 80 nominal, but only 66 could be developed. A speed of about 7½ knots could usually be maintained, but on one run of 30 m. under very favourable circumstances a speed of 10-9 m. was reported. In 1860 she was placed at the disposal of the Admiralty for experiment, and the trials were favourably reported on. She afterwards passed into the hands of Brunel, who was so satisfied with the results of further trials that he modified the design of the “Great Britain” steamship then
in hand (1843), and fitted her with a screw propeller instead of paddle-wheels as originally intended. The success of this and other vessels was sufficient to largely influence public opinion in favour of the propeller, and the Admiralty took the important step of building the "Rattler," a vessel of 888 tons and 200 H.P., to test the system. She was practically a repeat of the "Alceto," as far as her hull and the power of her machinery were concerned, but she was propelled by a screw propeller, whereas the "Alceto" was propelled by paddle-wheels. These vessels were tested together at sea in March 1845 when the "Rattler" proved the faster vessel; but the great test took place on Thursday, April 18, when the two vessels were secured stern to stern, and it was found that with the engines of both ships working at full power the "Rattler" towed the "Alceto" astern at a speed of 2½ knots. In a few years the screw almost entirely superseded the paddle-wheel for war vessels, and in 1854, during the war with Russia, Great Britain possessed a screw steam fleet, including all classes of ships, built of wood.

The performances of the Great Western and other vessels had demonstrated that ships could be more than doubled, or even trebled, in the work by steam power alone, but great advance had to be made in the marine engine before the ordinary trade could be carried on by its means with economy. In the early marine engines only one cylinder was provided, and various means were employed for transmitting the power to the paddle shaft; later came the oscillating cylinder engine and the diagonal engine, the latter being the type of paddle engine now most frequently adopted in Great Britain. With the introduction of the screw propeller the arrangements became much modified. At first experiments were run at comparatively low speeds, as in paddle-boats, gearing being supplied to give the screw shaft the number of revolutions required, but direct-acting two-cylinder engines gradually replaced the geared engines. The compound engine was first adapted successfully to marine work by John Elder in 1854, and in time direct-acting vertical engines, with one high and one low pressure cylinder, became the common type for all ships. The boiler pressure, moreover, in 1854, had been raised to 42 lb per sq. in.

The further change, accompanying still higher pressures of steam, from compound to triple-expansion engines was, like many other changes, foreseen and in some measure adopted by various workers at the same time, but the first successful application of the principle was due to Dr. A. C. Kirk. In 1854 he fitted a three-crank triple-expansion engine in the Preponitis. The boiler used proved a failure, but in 1882 he fitted a similar set of engines in the Aberdeen, with a boiler pressure of 125 lb, and the result was entirely successful.

Continuous improvements have enabled engineers to produce machinery of less and less weight for the same power, and at the same time to reduce the spaces required for its accommodation, the vibration due to the working of the engines, and the consumption of fuel per horse power. For engines of high power, quadruple expansion has sometimes been adopted, while scientific methods of balancing have been employed, improved qualities of steel and bronze have been introduced, the rate of revolution has been increased, and forced lubrication fitted. In the boilers higher steam pressures have been used, superheating in some cases being resorted to; the rate of combustion has been accelerated by supplying air under pressure in the stokehold or in the furnaces, and in some cases by placing fans in the exhaust to draw the air and products of combustion more rapidly through the fires; the former being known as forced draught and the latter as induced draught. In the Navy, with the view of saving weight, water-tube boilers have been adopted, but boilers of this type have not yet been generally fitted in the mercantile marine. Steam pressures now in common use vary from 100 to 180 lb per sq. in. in cargo ships; from 140 to 220 lb in passenger ships, including the large Atlantic liners; from 210 to 300 lb in large warships where water-tube boilers are used; while in destroyers and other classes of warships in which small tube water-tube boilers are used it varies from 180 to 250 lb per sq. in.

A century ago the reciprocating steam engine was slowly making its way as a means of propulsion as an auxiliary to, or as a substitute for sail power—the steam being obtained by burning wood or coal. In 1815 nine small steam vessels, having an aggregate tonnage of 786 tons, were built and registered in the United Kingdom; in 1825 24 steam vessels were built, having an aggregate of 5003 tons; in 1835 86 vessels were built, having an aggregate of 10,924 tons. In 1910 the reciprocating steam engine was so widely adopted as to comprise the principal form of propulsion, with a degree of perfection and universal adoption, as being large and powerful. While the turbine, coal was being replaced to a considerable extent by oil as a fuel for raising steam, and steam itself was being challenged as a motive agent by the development of the internal combustion engine.

III. STATISTICS

For some years before 1870 the total tonnage of sailing ships built each year in the United Kingdom had been about equal to that of steam ships, but then a great change took place; in 1871 541 sailing vessels, amounting to 123,910 tons, were entered for the register of the United Kingdom, while 433 steam vessels, amounting to 66,572 tons, were entered for the register of steam tonnage thus added being nearly three times that of sailing vessels. A uniform rate of increase of production of steam vessels was on the whole maintained through the year 1882, will be seen by referring to Table I. and fig. 3, considerable fluctuations have occurred, the falling off in steam tonnage being simultaneous with increases of sailing tonnage and vice versa down to 1895. The details are shown in fig. 3, where it will be seen for 50 years of sailing and steam tonnage separately and combined. Roughly speaking, it may be said that from 1860 to 1895 the output of sailing tonnage fell from about 200,000 tons per annum to 100,000 tons; during the later nineties the falling off was more rapid, and between 1900 and 1910 the output varied between 15,000 and 30,000 tons.

The average tonnage of the sailing vessels built in the United Kingdom in 1860 was 206 tons; this increased with a fair degree of regularity to 532 tons in 1890, 749 tons in 1891 and 963 tons in 1892, after which a rapid decrease took place, and by 1896 the average size had fallen to 75 tons; there were fluctuations after this date, but the average never rose above 163 tons; and these vessels are practically restricted to the coasting trade and pleasure purpuses.

The average size of steam vessels has remained almost constant. The figures of the ships built abroad have continued to increase. Under the influence of the shipbuilding depression that prevailed from 1895 and 1902 something like 150 sailing vessels of from 2000 to 3500 tons each were built, but few since. In Germany and in America a few large sailing vessels continue to be built.

The increasing Register tonnage of the "Steam Vessels belonging to England, Scotland and Ireland in the years 1814 to 1899," which shows that in 1839 there were 720 vessels of a total tonnage of 79,426 tons owned in the United Kingdom. Between 1860 and 1866 considerbable numbers of steam ships were built for various services, and the production from 1860 is shown by fig. 3 and Table I. The tonnage added to the Register in 1860 amounted to 93,590 tons, rising over four years to 203,140 tons in 1865; after a gradual decline extending over two years to 100,000 tons it again rose till 1872, when nearly 500,000 tons were added. In 1876 it had fallen to about 200,000 tons; then came the great rising tendency to 1883, when it reached a maximum of 885,495 tons. A rapid decrease followed, and in 1886 it had fallen practically to what it had been ten years before. In another three years it had become again what it had been in 1883; after another period of fluctuating the numbers were again with much smaller fluctuations than previously, great increases were maintained. In 1906 a maximum of 1,458,793 tons was reached, when another rapid fall occurred over two years—the minimum reached being 600,000 tons in 1908.

The fluctuations in output, shown by fig. 3, synchronize approximately with the improvements and depressions in trade. The average tonnage of British steam vessels rose slowly from 890 tons in 1845 to 1870, when it had reached a maximum of 1,515 tons in 1883, and then again it fell slowly till 1889, reaching a maximum of 1,442 tons in 1882. During the next four years it fell gradually to 986 tons, rising again to 1215 tons in 1890, and the average tonnage remained with a small amount of fluctuation, nearly 1500 tons. These figures may be taken as roughly representing the average tonnage of the ships produced throughout the whole of this period. In the years immediately following these vessels are included, the vast increase in the numbers of large-sized vessels which have been built, especially during recent years, is not adequately represented. Of the vessels built in 1890 only 1% exceeded 8000 tons in displacement, whereas the vessels of over 8000

* Excluding Vessels trading on the Caspian Sea, and Wooden Vessels trading on the Great Lakes of North America.
† In the absence of satisfactory information numerous small sailing vessels (belonging chiefly to Greece, Turkey, Southern Russia and the Dutch East Indies) are not included.
‡ Excluding Japanese sailing vessels of under 300 tons net.

**Table II.—Shipping owned in each Country in the World (extracted from Lloyd's Register of British and Foreign Shipping for 1901-1901). Number, Tonnage and Description of all Vessels (exclusive of War Vessels) of 100 Tons and upwards.**
tons built in 1900 made up 12 % of the whole tonnage. In 1890 there were no vessels built whose displacement exceeded 9000 tons; in 1900 such vessels constituted 11 % of the whole, and about 4 % of the whole were over 16,000 tons. The year 1908 was notable for the number of large vessels launched; 10 British and 4 German

vessels were launched whose tonnage averaged about 15,000 tons each, their displacements being about 50 % greater. In 1910 there were almost more than 80 vessels exceeding 12,000 tons, and having an average tonnage of more than 15,500 tons each (see Table XI, page 885). Six of these vessels were over 20,000 tons, and had an average gross tonnage of 25,640 tons each. The tonnage of the largest vessels has almost continuously increased, and vessels with a tonnage of 45,000 tons are now being built, the fully loaded displacement of the vessels being more than 50,000 tons.

Fig. 4 shows the tonnage of wood, composite, iron and steel vessels added to the Register year by year since 1860, and figures for a number of the years are given in Table II. The tonnage of wood and composite vessels added in 1860 was 161,180, increasing to 166,210 tons in 1865 and then falling away at a fairly uniform rate until in 1880 only 19,238 tons were reported, and since that date practically no increase in output of this class of tonnage has taken place. The tonnage of iron ships produced in 1860 was about 63 % of that of wood ships; while wood shipbuilding fell off, iron shipbuilding increased, and in 1870 the tonnage of iron ships was more than five times that of wood and composite ships. The output of iron ships increased until 1883, when a maximum of 866,990 tons was reached. Steel had now come into use, and iron shipbuilding fell away rapidly, amounting only to 50,579 tons in 1888; this figure fell to 10,679 tons in 1895, and since then very few vessels have been built of iron. Steel, which had been used in shipbuilding to a limited extent for special purposes for some eight years, came into use for the hulls of merchant ships in the later 'seventies. In 1880 the tonnage built—38,164 tons—was 41 % of that of iron ships, but by 1885 the ratio was 60 %, and in 1890 the tonnage of steel ships, 913,484 tons, was just 20 times that of iron ships. From that date the statistics of steel shipbuilding are practically those of steam vessels above given.

From Table II, which gives the distribution of ownership of existing merchant vessels and other vessels, excepting warships, it appears that the total tonnage of the world's shipping, excluding vessels under 100 tons and the wood vessels on the Great Lakes of America, is about 42 millions. Of this total, rather less than one-ninth is in sailing vessels, and the remainder in steam vessels. Taking the number of ships instead of their aggregate tonnage, the sailing vessels are 27 % of the whole. Out of the 42 millions, Great Britain and her colonies own about 19 millions, or 45 % of the whole, 18 millions being steamers and 1 million sailing vessels.

Danmark each with about 1.8 %. The leading particulars as to the distribution of ownership of the merchant shipping throughout the world for 1893, 1890 and 1910 respectively are represented graphically in the block diagrams given in Fig. 5, which have been constructed from particulars given in Table II, and similar tables for the other years. The tonnage owned in each of these years, excluding vessels under 100 tons and wood vessels on the Great Lakes of America, is represented by squares drawn to scale, in duplicate, and divided up amongst the principal countries owning shipping in proportion to their ownership. Parts of each holding are shaded in the squares on the right so as to show what portion is sailing tonnage and what steam tonnage, and in the squares on the left so as to show the distribution of the total as regards materials of construction in each country. The total tonnage owned is given for each country, namely, the number of tons, and the percentage of the various countries are tabulated between the pairs of squares.

The tonnage of the shipping of the world has advanced at an increasing rate for many years; the character of this advance may be gathered from the data given in Fig. 5. In 1873 Great Britain and her colonies owned 43.25 %, and in 1890 52.35 %; but although the advance in the shipping of Great Britain and her colonies has continued approximately at the same uniform rate, such has been the increasing rate of the advance of the world's shipping that the percentage owned by the British Empire fell to 40.7 % in 1900 and to 45.4 % in 1910. This is represented in the block diagrams of the tonnage of the world's shipping is shown by Table III. The remarkable rate at which the shipping of the United States and Germany has advanced will also be seen.

Table III.—Rate of Increase of the World's Shipping.

| Table IV, gives the output, for the year 1909, of merchant and other vessels throughout the world, excluding warships, all ships of less than 100 tons and the wood vessels of the Great Lakes of North America. The block diagrams in Fig. 6 are constructed in the same way as the diagrams in Fig. 5, and are arranged to show the output of the principal shipbuilding countries of the world in 1900 and in 1909, the reference square for scale representing one-tenth the amount of that of Fig. 5. The total output for the year 1900 was 5,435,854 tons, of which 1,599,837 tons, or 65 % of the whole, was built in the United Kingdom; 303,339 tons or 13 % was built by the United States of America; 9.4 % by Germany and 5.4 % by France. In 1909 the total output was 5,551,532 tons, of which 971,113 tons or 63 % was built in the United Kingdom; 178,402 or 11.5 % was built in the United States of America; Germany built 8.1 %, France only 3.3 %, the output of Holland and Belgium has risen from 1.38 % in 1900 to 4.34 % in 1909; and Japan appears with 2.08 % instead of about 0.6 % in 1900.

American Shipping.—Under the Registration Laws of the United States, vessels are required to be registered, and those vessels, the tonnage of which is more than 100 tons, are required to be entered. By (a) the using of a British flag, or (b) being enrolled, or (c) licensed. The proportion of vessels coming under these three headings as given by the United States Commissioner of Navigation, 30th June 1909, is shown in Table V.

It will be seen that the Registered Tonnage includes only vessels engaged in the Foreign Trade and in Whaling Fleets, and excludes fishing vessels, which number some in the total to 10,330 vessels. The total registered tonnage is 887,505 tons and include the smallest vessels crossing the St Lawrence equally with ocean liners. Two hundred and twenty-seven of the registered vessels are less than 100 tons, and only nine are over 10,000 tons. Namely, the "Minnesota," "Manchuria," "Mongolia," "Siberia," and "Korea" on the Pacific, and the "St Louis" and "St Paul," "New York" and "Philadelphia" on the Atlantic routes. The Enrolled Tonnage includes vessels engaged in the coasting trade and local fisheries which are over 20 tons; and the Licensed Tonnage vessels similarly engaged, but of a size not exceeding 20 tons. The whole of the tonnage included is officially described as tonnage.

Large numbers of American vessels are not included in the American Returns—such as yachts, boats and lighters employed within the

DOCUMENTED in the United States, and the division is based on the trade on which the vessels are employed, and not as in the United Kingdom on the character of the vessels and their fitness to engage in trade to distant countries or on more local service.

By the United States Navigation Laws all trade between American ports no matter how far they are separated—such as New York to San Francisco, or from either of these ports to Honolulu or Manila—is declared to be coasting trade. None but United States vessels are allowed to engage in this trade, which in recent years has developed so rapidly as to employ the main part of the American Mercantile Marine; it demands large numbers of ocean-going vessels, and many vessels have been transferred from the Foreign Trade to meet the demand.

![Diagram](image-url)
The distribution of the total documented shipping on the coasts of the United States in 1909 is shown by Table VI. The Atlantic Coasts employ 69% of the number and 47% of the tonnage; the Great Lakes 12% of the number and nearly 38% of the tonnage. The total includes a great number of wooden sailing vessels as shown by Table VII, which also shows that the coasting trade employs over 1,000,000 tons of wooden steamers and over 3,000,000 tons of steel steamers (Enrolled and Licensed vessels), while the steamers in the Foreign Trade only reach a total of over 500,000 tons (Registered Vessels).

Though the American Mercantile Marine has greatly varied in the rate of its growth (see Table VIII), very great increases have taken place from time to time, and after 1880 the average rate of increase was very considerable, in thirteen years amounting to 3,300,000 tons or 50%, while in the nine years 1900-1909 the increase was 2,220,000 tons, which is more than 40% of the total in 1900. The increase of the general commerce of the United States in these periods was, however, so vast that, notwithstanding the great increases of tonnage, increasing proportions of the tonnage were absorbed by the home or coastwise trade, and the percentage of United States shipping carrying United States commerce to foreign ports was steadily reduced, as shown in Table IX.

From 1893 to 1908 very great progress was made in the output of ships in the United States; in 1901 a maximum of 483,689 tons was reached; decreases occurred until 1905, when a minimum of 330,316 tons was reported, but a rapid recovery took place; and in 1908 the unprecedented American total of 614,216 tons was made. In 1909 reached 694,429 tons, built and documented during the year ending June 30, 1909.

1 Maximum recorded. 2 Lowest for ten years.

61,000 tons consisted of barges and canal boats, nearly 30,000 tons consisted of sailing vessels, 798 vessels of 47,353 tons are classified as fishing vessels, 17,000 vessels of over 2,000 tons; Great Lakes vessels, and only 6 steam vessels of 16,427 tons were built for ocean trade, while no vessel was registered as built for the foreign trade.

Japanese Shipping.—Recent years have shown a considerable development of shipbuilding in Japan. Several small vessels were built previous to 1895, but in that year the "Hitachi Maru," a steamer of 6000 tons, was built by the Mitsubishi Bishi Works.

Lloyd's Register Reports show that in the five-year period 1895-1899 there were launched 61 ships with a tonnage of 45,661; in 1900-1904, 279 ships (tonnage 138,052); and in 1905-1909, 414 (tonnage 253,512).

IV. Merchant Vessels

Sailing Ships.—Generally speaking, so far as the distribution of sails is concerned, except as regards the abolition of studly-sails, the sailing ships of to-day differ little from those which existed in the middle of the 19th century, and in the main of many types at a much earlier period. The change from wood to iron and steel resulted, of course, in some changes
in rig, to suit the longer and larger vessels; and steel masts, with wire rope standing rigging and various labor-saving appliances, have been introduced. The larger ships also carry steam winches for various purposes, steam windlasses, and steel steering gear, but the general appearance of the vessels has changed very little.

Ships.—Rivers and canals abound with barges of various types, such as the Thames barge, the Tyne wherry or keel, and the Dutch galjoen. Thames barges have been built since the 16th century, and the most characteristic and distinctive vessel of this class, has a length of from 70 to 80 ft., and a carrying capacity of from 100 to 120 tons on about 6 ft. draught. Like the Dutch galjoen, she is provided with lee-boards, and is fore-and-aft rigged. This type of vessel is still largely adopted in the merchant service for small vessels, usually called smackens, of a length, say, from 60 to 90 ft., and a displacement from 150 to 200 tons. These small vessels are square-rigged, with fore-and-aft sails only, and fitted with a running bowsprit; they have no standing jib stay. Such vessels were at one time generally used for coasting passenger traffic. The term "cutter" is also applied to a small sailing boat carried on board ship.

Schooners, Brigs and Brigantines.—A schooner (fig. 7, Plate I.) is usually a two-masted vessel, with yards only on the foremost and foremast. These vessels are generally not fitted with square-rigged sails, but is set flying. In some cases there are no yards at all and the schooner is then called a fore-and-aft schooner, a schooner with yards being sometimes called a square-rigged schooner. Before the days of the large and powerful steamers, schooners were the only ships that survived the introduction of steam as a motive power. They were beautifully modelled craft, and very fast under canvas. A brig is a two-masted vessel having yards on both masts, or square-rigged on both masts. A brigantine is a two-masted vessel having the foremost square-rigged, as in a brig, the main being rigged as in a schooner. Much of the coasting trade of the world is carried on by schooners, brigs and brigantines. These vessels were formerly employed in the Baltic, and to some extent in the West Indies and the Mediterranean. Schooners such as the above are usually from 80 to 100 ft. long, 20 to 25 ft. broad, 10 to 15 ft. deep, and have a gross tonnage of 130 to 200 tons, and may occasionally be as large as 350 tons. If from 90 to 110 ft. long, from 24 to 30 ft. broad, and from 12 to 18 ft. in depth of hold. Brigantines usually occupy, as to size, a position intermediate between schooners and brigs.

Vessels somewhat larger than two-masted schooners and brigs, but of a similar form, are often rigged as three-masted schooners and as the so-called barquentines. The formation of a line in use, many a third or mizen mast added, this being rigged fore and aft, as is the main mast. The latter resembles a brigantine with a third mast added, which is also fore-and-aft rigged. The two rigs thus very nearly resemble each other; both types are square-rigged on the foremost, and fore-and-aft rigged on the main and mizzen; while in the former the foresail is set flying, in the latter it is bent to the yard.

Larger vessels than these are sometimes fitted with four, five, six and even seven masts, as fore-and-aft schooners. A large number of vessels fitted in this manner are much in favour for the coasting trade. The barquentine "Maine," built in 1900 by the Fore River Ship and Engine Co., Quincy, Massachusetts, of steel, 368 ft. long, 50 ft. beam, 34 ft. draft, of 10,000 tons displacement, is a remarkable example of the type. A barquentine has been built for sailing only. She was recently wrecked on the Scilly Isles.

Barques and Ships.—Vessels intended to sail to all quarters of the globe are sometimes rigged as barques; ships; but, as indicated above, these rigs are very far from being universal, as others are very common. A barque is a three-masted vessel, square-rigged on the foremost and main masts, and fore-and-aft rigged on the mizen mast. A ship (a rigging vessel) has three masts, each of which is square-rigged. These were the rigs employed in vessels of new passing away, if indeed they have not already done so. The present day is a time of transition, and need was the quality chiefly aimed at, and carrying power was of secondary importance. For instance, the "Phoenician," built in 1852, had a length of 307 ft., and a displacement of 1900 tons, and the "Taeping," built in 1862, was 217 ft. long and her tonnage 1292. The former made the quickest run on record, up to 1852, from Sydney to London, accomplishing the distance in 83 days; and the latter made a round trip to the China coast in 1863 in only 90 days. Ships of this type were employed on the coast of China, in the United States for the rapid conveyance of early teas from China to London. The American builders had for some years been more successful than their British competitors in the construction of large ships. The formernouned the American ships in speed, and it was, moreover, claimed for her that she delivered her cargo in better condition than the American ships. She was 215 ft. long, and her tonnage was 1290 old measurement, or 938 new measurement. The "Witch of the Wave" on her best voyage made the passage from Whampoa to Dungeness in 90 days, the best day's run being 338 knots in 24 hours, a very remarkable performance. Later, in 1866, the "Lord of the Isles" beat the Whampoa-Plymouth record. The "Armada," a four-masted ship, was built to Great Britain, one of them only by a few minutes; her length was 183 ft., and her tonnage, new measurement, 630. It is noteworthy that such vessels were sometimes fitted with a stem and stern, and sometimes started between British and American ships, was carried on subsequently between British ships alone. In the memorable race of 1866 from Foo-Chow to London, five ships, the "Ariel," "Taeping," "Princess Victoria," "Percy," and "Hampden," each three left Foo-Chow the same day—the "Ariel" first, followed 20 minutes later by the "Taeping" and "Serica" together. The four remaining vessels were due to arrive at the reach of the English Channel, when the "Ariel" and "Taeping" had got abreast, and crossed to the Downs, the former arriving some ten minutes before the latter, the "Serica" reaching the Downs a few hours later. These three vessels took the race, each vessel being responsible for the voyage, and occupied in the above voyages was beaten in 1869 by the "Thermopylae" and "Sir Lanceolot," both British ships and of composite build; the times occupied by the vessels were respectively 90 days from Foo-Chow to Dungeness for the former, and 88 days from Foo-Chow to Deal for the latter, each taking one day more to get into the docks. The dimensions of the "Thermopylae" were 212 ft. by 36 ft. by 21 ft. depth of hold, and of the "Sir Lanceolot" 197 ft. by 331 ft. by 21 ft. The best day's run of the "Sir Lanceolot" was 354 knots in 24 hours. Shortly before the above voyage the "Thermopylae" made the passage from London to Melbourne in an unprecedented time of only 103 days and 4 hours. This ship was built to Fort Philiip harbour. With the opening of the Suez Canal and the general introduction of steam, the demand for exceptionally fast ships for some purposes of service considerably diminished, and, indeed, almost ceased to exist. The type of ship most usually met with to-day is better illustrated by fig. 9 (Plate I.), which represents the "Victoria Regina," built of iron in 1851 at Southampton; she was the largest ship ever designed for the British market.

Ships with four and five masts were employed by several countries during the 19th century. Sometimes, in the case of four-masted ships, these were square-rigged on the fourth or mizen mast, and sometimes fore-and-aftrigged; in the latter case they were called four-masted barques, and fitted out for the sailing of grain, and sometimes for the transport of wool and furs. The American name for the type was "brigantine," and the term was also applied to any type of boat, and the same type of boat, and the same type of vessel, were also called "brigantines," and had a single mast, with yards only on the foremost and foremast, and fore-and-aft rigged on the main and mizen; while in the former the foresail was set flying, in the latter it was bent to the yard.

A five-masted vessel is described in the same number of the "Nautical Chronicle" which was square-rigged on the foremost and fore-and-aft rigged on the main and mizen; while in the former the foresail was set flying, in the latter it was bent to the yard.

A five-masted vessel is described in the same number of the "Nautical Chronicle" which was square-rigged on the foremost and fore-and-aft rigged on the main and mizen; while in the former the foresail was set flying, in the latter it was bent to the yard.

A five-masted vessel is described in the same number of the "Nautical Chronicle" which was square-rigged on the foremost and fore-and-aft rigged on the main and mizen; while in the former the foresail was set flying, in the latter it was bent to the yard.
The full-rigged four-masted ship, 332 ft. long, 451 ft. beam, 26 ft. moulded depth, gross tonnage 3292, and intended to carry 1,500,000 gallons of oil in cases of 10 gallons each from the Union Steamship Company of Shandon, Passages. The vessels consist of hemp, &c. The masts and yards of this vessel, as well as the hull, are of steel. The five-masted German barque "Potosii", built in 1895, which is 366 ft. long, has an 840-ton revenue gross and a deck beam of 40 ft. 6 in. She has a splendid record of quick passages, one reducing the record from Portland Bill to Iquique to 62 days. In 1902 the five-masted ship-rigged vessel "Pfeiffen", of 5864 tons gross, was built of steel, and followed in 1906 by the five-masted barque "R. C. Rickmers" of 5548 tons gross, 441 ft. long over all, 53 ft. 5 in. beam, 30 ft. 5 in. deep, having 487,000 sq. ft. of canvas. Her gross weight is about 10,000 tons, of which 8000 tons are cargo. She carries 50,000 sq. ft. of canvas, and on her first voyage reached a speed of 15 knots for a short time under sail alone, maintaining 13 knots for long periods. Another barque, "Salamanca", of 1856; the "Lizard", 153 days; and the "Triumph" were famous in their day. As a world, "the Lizard", 88 days; "R. C. Rickmers", 71 days; and the "Triumph", 69 days, are the shortest passages, which, together with 88 days, are the results of the steam-sailing ships. As such, the "Salamanca" was a fine performance, and 71 days was the record of the "Triumph"; both vessels being barques.

Although alterations in the rigs of ships have not caused much difference in their appearance over a very long period, a number of changes have been made, mostly for the purpose of saving labour. The mechanical reefing of topsails and top-gallants was introduced about 1858, but only remained in favour for a few years; double topsails, on the other hand, first used in the four-masted American shipentine clipper "Great Republic", have held their own, and double top-gallant sails have since been adopted. Until about 1875 almost all ships carried studding-sails, but since this date they have been gradually discontinued, and at present are usually only to be found in training vessels, and now and again in square-rigged yachts. As already stated, wire rope has been adopted for standing rigging, and deadeyes and lanyards have given place almost universally to rigging screwed in place. The masts of ships have been made of iron for many years, and more recently of steel, and the lower masts and top masts have in a number of cases been made in one length; when constructed in this manner the mast is termed a pole mast. This arrangement is very common in America, where the latest steel sailing ships are so fitted. Most large sailing ships carry a steam boiler or boilers, and engines are provided for all sorts of purposes, for which hand labour used to be commonly employed. The result of this and other labour-saving arrangements has been to effect a very considerable reduction in the number of hands required to man the ship. The change in the character of the crew has taken place, it may be mentioned that whereas a 1000-ton ship of the East India Company in the middle of last century had a crew of 80 all told, a modern four-masted barque of 2500 tons has a total complement of 33 only.

As to the employment of sailing ships, there can at the present day be seen at most large shipping ports a number of sailing ships of various types and sizes. Some of the largest ships are employed in the jute trade of India, the grain trade of California, British Columbia, the nickel ore trade from New Caledonia and the nitrate trade of Chile. From Great Britain herself come a number of vessels, which, however, low freights may be, may in nearly all cases be relied on. Sailing ships are sometimes provided with auxiliary steam propelling machinery of low power to save cost of tugs in getting in and out of harbour, to make headway when becalmed, and to increase the safety of the vessel. In the early days of steam, all sea-going vessels retained their rig, and the machinery fitted was only regarded as auxiliary. In the "Savannah" — the first steam vessel to cross the Atlantic, the paddle-wheel vessel — they were not used long and packed up on board in case of bad weather or when attempting a long voyage, but were replaced and used for getting into port after crossing the Atlantic. The screw propeller was found preferable in such cases, as it offered less obstruction than paddle wheels when the sails were set and the engines stationary; but the resistance offered by the screw when not in use led to various devices for either lifting it completely out of the water, or for "feathering" the blades and fixing them fore and aft, so as to offer less obstruction in going through the water. Auxiliary power is of great advantage to vessels engaged in seal or whale fishing as it enables them to avoid ice floes, and to proceed through open channels in the ice as opportunity offers. In 1902, six such vessels — all barque rigged, and one fitted with a lifting propeller — hailed from Dundee, and a few others hailed from Norway, from Newfoundland and from New Bedford, U.S.A. Several navies have employed vessels fitted with auxiliary steam power for training purposes, such as the Chilean training ship "General Baquendo" built in 1899 of steel, sheathed with teak and coppered; she is 240 ft. long, 452 ft. broad, and of 2500 tons displacement on a mean draught of 16 ft. She has a 500-horsepower screw propeller, and her speed is equal to a speed of 13 knots. In recent years the internal combustion motor has been adopted in some cases in place of the steam engine as a source of auxiliary power, especially in the smaller classes of sailing ships, and in many cases it has made the employment of such vessels remunerative once more. Should the heavy oil engines introduced in 1910 prove sufficiently simple and reliable for auxiliary power in the larger vessels, vessels so fitted might compete successfully with tramp steamers in certain trades.

Steamships — Of merchant steamships, vessels of all sizes are to be met with, from a small launch to the stately Atlantic liner of over 50,000 tons gross and 25 to 26 knots speed, and the huge cargo ship of over 20,000 tons gross and 15 knots speed. They are employed on every service for which sailing ships are used, and upon others for which sailing ships are not employed, and they monopolize nearly the whole of the passenger traffic of the world. The passenger vessel is provided with airy and spacious accommodation for her living freight above water, while the upper part of the cargo vessel is cut down as much as possible consistent with due provision for safe navigation at sea. The passenger ship thus becomes a lofty vessel, especially amidships, while the cargo ship appears long and low lying. Apart from this broad difference, the various sizes of merchant steamships have in general no bold characteristic features like sailing ships; they possess different deck structures and certain differences in form, but, to the ordinary eye, a photograph of a vessel of, say, 1000 tons, apart from details of known size that may serve to fix the scale, may often be taken to represent a vessel of even ten or twenty times the size.

Types of Steamships — A steam vessel may be little more than an open boat with the boiler and engines placed amidships if intended for river use, and may be of any shape necessary to suit local conditions and fulfil the services required. Vessels which proceed to sea must be decked over to prevent them from being "swamped" and built of a suitable form to make them otherwise seaworthy; the height of the forecastle, quarter-deck, or the "beakhead", will be determined by the type of vessel, and the height of the superstructure, or "gallows", and of sufficient height above the upper deck to be serviceable for accommodation forward is called a top gallant forecastle, and aft a poop. It is frequently desirable to build up cabins or other accommodation across the middle of the ship beneath the bridge, forming
what is called a bridge house. Instead of fitting a turtle back or hood aft, a break is sometimes made in the upper deck and the after portion is raised a step higher than the midship portion, the after portion is then called a raised quarter deck. If a poop be extended forward to join the bridge house it is called a long poop. In very many cases when a top gallant forecastle is fitted, the gap which occurs between this forecastle and the bridge house is partly shut in at the sides by the ship's topside plating; the space so formed is then called a well, and the ship a well-decked ship.

Vessels arranged as above described are illustrated by figs. 10, 13, 14, on Plate II.; they include most of the vessels in the coasting trades of Europe, and many of the smaller and medium sized ocean-going cargo vessels. In larger vessels the forecastle, bridge and poop decks are frequently joined to form a light continuous structure. The vessel is then termed a shade-decked vessel—if the ship's sides up to this level are not completely closed in. In still larger ships the sides are completely built in, the thwarts stronger, other decks or deck houses are fitted above it, and the ship is called an awning decked, spar decked, shelter decked or three decked vessel—according to the details of her construction. Above these strong steel decked light promenade decks, sun decks and boat decks are built according to the requirements of the accommodation for passengers, etc.

Barges. The simplest cargo steamer is the steam barge or lighter, often merely a long narrow box of wood or steel made small enough in section to pass through locks and canals, with the ends fashioned more or less abruptly, and spaces allotted aft for the machinery and forward for the crew. For service on rivers and estuaries they are made larger and wider as the circumstances of draught and dock or wharf accommodation permit, the bottoms being generally flat in order that they may ground safely in tidal waters; they are used for transferring cargoes of sea-going vessels to or from warehouses, and are frequently fitted so that they can tow one or more dumb barges.

Many sea-going vessels are built to carry a particular cargo on one voyage and a general cargo on the return voyage. This usually results in their having certain features which adapt them for the special cargo, and do not interfere materially with their carrying a general cargo at remunerative rates. Ordinary cargo ships, or "Ocean Tramps" as they are called, do a very large portion of the world's cargo-carrying. They are mostly built of steel, and their usual speed is from 10 to 11 knots. In the early nineties well-decked vessels formed a large proportion of the total number; but ten years later comparatively few of this type were being built, and these were principally intended for the coal trade, or were comparatively small vessels for coasting purposes. Partial awning-decked steamers, again,

structure. In order to accommodate the maximum cargo possible in vessels of convenient size, the lines of the vessels have been filled out, giving block co-efficients which are frequently over 80 % and in some of the Great Lake freighters have reached 88 %.

Such portions of the ship above the water as do not contribute usefully to carrying cargo, but would be measured for registered tonnage, are cut down to the smallest amount consistent with the provision of sufficient reserve of buoyancy and stability.
3. To provide for a return journey without a cargo, in addition to the double bottom and peak tanks, large water ballast tanks are provided. The excavation is made at the foot of the slope that when ballasted down the metacentric height of the vessel is not excessive. Much of the ballast is carried in side or wing tanks extending to the upper or main deck, or in triangular side ballast tanks, the latter being arranged so that the tanks may be emptied by gravity when practicable.

Hatches have been cleared of obstructions—such as pillars, hold beams and web frames—so that the stowage space for the cargo is unbroken, the necessary strength being given by a heavier system of framing of the ship and by the construction of the side tanks.

5. To facilitate rapid handling of cargo, hatches have been increased in size and number, and special appliances fitted for rapid loading and unloading the vessel—particularly, numbers of derricks or cranes, with convenient steam or electric winches.

Several well-known types of cargo vessels have thus been produced, such as the "Mancunia" built by Messrs W. Gray & Co. at West Hartlepool in 1898, with side-ballast tanks on McGlashan's patent; cantilever-framed vessels by Messrs Rayiton Dixon & Co. on Harrowby and Dixon's patents; trink-deck vessels by Rayner & Co., and trink-deck vessels by Messrs Dows & Co. of Sunderland. Fig. 10 (Plate II.) is a photo of a turret-deck steamer.

Her dimensions: length 439 ft. 8 in., beam 51 ft. 7 in., gross tonnage 3955 and net tonnage 3794. She is of a much superior type of arrangement of being good dead-weight carriers, and the shelf on each side of the central trunking can very conveniently be used for carrying timber and for other purposes.

The "Mancunia" was built by Raynor & Co., and loaded with coal, is an example of a modern cantilever-framed deep-decked vessel. She is 404 ft. long overall, 56 ft. beam, 23-6 ft. moulded depth. On a draught of 23 ft. 9 in. her displacement is about 12,000 tons and dead-weight capacity is 10,000 tons. The machinery is in two engines, which, with a capacity of 3000 h.p., enable her to make 11 knots.
fitted with Diesel motors of 360 H.P. More recently the "Emanuel Nobel" and "Karl Hagelin" have been built for the same firm; they are fitted with Diesel motors of 1200 H.P., are 380 ft. long, combined, and is fitted with one deck, but has two tiers of beams. B (fig. 14, Plate II.) is a vessel with a top-gallant forecastle, bridge-house and poop, and a single deck. C is an awning-decked vessel

and one steamer carrying mails and passengers as well as a large cargo. A is a well-decked vessel (fig. 13, Plate II.), having a top-gallant forecastle with a long raised quarter-deck and bridge-house

The block "coefficients" corresponding to the load conditions are given in Table IV., in order to show the fullness of form commonly adopted in these vessels. The block coefficient is the ratio of the
well-decorated large must considerable, in. Another Details the 8 The These and the called in. Ferry 7 A double-ended, Compound one 330 extends passengers wood-paved loaded 12 (see woodwork, found itself; the MERCHANT 68. The Ferry the numerous vessels extends to a considerable width beyond the body of the hull beneath to give large deck areas; the main deck being about 6 ft. above water and 55 ft. wide. Cart tracks are arranged along the midship portions of the deck with passenger saloons, &c., at the sides. A light shade deck extends forward and aft and carries a pilot house near each end. Water-tube boilers and three cylinder compound engines of 600 H.P. are fitted beneath the deck amidships and drive a propeller at each end of the boat. The "Oakland," "Berkeley" and "Newark" running at San Francisco are much larger than the "Hampton," and have a seating capacity for 2000 people each, with a fine promenade deck above the upper deck. The first two are fitted with beam engines driving side paddle-wheels, while the third has a screw propeller at each end of the vessel driven by vertical triple expansion engines. Each of them burns oil fuel only. River and Sound Steamers.—For service on rivers, harbours and estuaries where the traffic is considerable, paddle-wheel vessels of limited speed are usually preferred, as possessing great maneuvring power, and therefore the capability of being brought alongside the landing-places with rapidity and safety. The paddle-wheel steamer

ment, except in case D in which the machinery and the passenger accommodation absorb much weight. British vessels may not be loaded deeper than a certain mark, known for many years as the Plimsoll mark, which has to be placed on the sides of all merchant vessels. The mode of measuring tonnage is based on the Act of 1894, which embodies preceding legislation and subsequent Acts (see Tonnage).

The numerous varieties of passenger steamers may for convenience be taken in the following order—Ferry; River and Sound; Passenger steamers. Cross Channel; and Ocean Steamers; although it must be understood that in many cases a hard and fast line cannot be drawn between steamers for the several services.

Ferry Steamers.—Ferry steamers ply the rivers and harbours in the United Kingdom; they perform important services in transporting passengers and road traffic across sheltered waters where bridges are not available; and others are built in the United Kingdom for service in all parts of the world. The "Guamuchalan," a double-ended steel vessel built by Messrs Cammell, Laird & Co., for ferry service on Havana Bay, is 140 ft. long overall, breadth moulded 36 ft. depth moulded amidships 18 ft., beam 18 ft., and has a steam output of 1250 I.H.P., and is intended to carry 150 passengers. A number of ferry-boats have been built by Messrs Thornycroft for service in India; they are 105 ft. long overall, of 20 ft. beam, 10 ft. moulded depth and 5 ft. draught;

their machinery of 900 I.H.P. is placed amidships and gives a speed of 12 knots; two saloons are arranged forward and two aft with access to a promenade deck from each, accommodation for 200 passengers with luggage being provided. A light wooden awning extends over all. These vessels are built of steel and divided into eight water-tight compartments; they were built and put together at Southampton, then taken to pieces, packed and shipped abroad, re-erected and completed at Calcutta.

The largest ferry-boats are to be found in America, and an interesting example is the "Hampton" built in 1906 by the New York Shipbuilding Company. She is 168 ft. long overall, 38 ft. beam, 8 ft. 6 in. draught, 625 tons displacement. A feature of this vessel is that all details are arranged with the view to making the vessel practically fireproof, wood fittings being reduced to a minimum. The vessel is double-ended, carries over a thousand passengers and a large number of horses and vehicles on one deck. As in many American river vessels, the upper works extend to a considerable width beyond the body of the hull beneath to give large deck areas; the main deck being about 6 ft. above water and 55 ft. wide. Cart tracks are arranged along the midship portions of the deck with passenger saloons, &c., at the sides. A light shade deck extends forward and aft and carries a pilot house near each end. Water-tube boilers and three cylinder compound engines of 600 H.P. are fitted beneath the deck amidships and drive a propeller at each end of the boat. The "Oakland," "Berkeley" and "Newark" running at San Francisco are much larger than the "Hampton," and have a seating capacity for 2000 people each, with a fine promenade deck above the upper deck. The first two are fitted with beam engines driving side paddle-wheels, while the third has a screw propeller at each end of the vessel driven by vertical triple expansion engines. Each of them burns oil fuel only.

River and Sound Steamers.—For service on rivers, harbours and estuaries where the traffic is considerable, paddle-wheel vessels of limited speed are usually preferred, as possessing great maneuvring power, and therefore the capability of being brought alongside the landing-places with rapidity and safety. The paddle-wheel steamer
Excursion steamers working round the coast are frequently of smaller size than this vessel, but of less length and less extensive open promenade decks. A popular south coast pleasure steamer, built in 1900, is the paddle boat "Bournemouth Queen," shown in fig. 17 (p. 5). She is 227 ft. long, 24 ft. beam, 8 ft. 6 in. moulded depth, tonnage 355 tons gross, 139 tons net; she can carry 610 passengers on a No. 3 certificate and 704 on a No. 4 certificate. Her displacement at 5 ft. 2 in. load draught is 406 tons, and her speed 22 5/8 knots. Her engines, which began to ply on the Clyde in 1901, are 250 ft. long, 30 ft. wide, 10 ft. 6 in. deep to the main deck, and 17 ft. 9 in. to the promenade deck. They are the first passenger and cargo pumping steam turbine. Her speed is 20 knots. A second turbine steamer, the "Queen Alexandra," began to run on the Clyde in 1902; she is generally similar to the "King Edward," but larger and faster. She has an iron hull of the same length, beam and depth. The absence of vibration. They have been followed by others such as the "Kingfisher" on the Thames and the "Atalanta" on the Clyde. The latter being 227 ft. long, 27 ft. beam, depth 10 ft. 6 in., draught 5 ft. 2 in. (p. 5). Her engines, which are compound, but those employed elsewhere are usually built of steel. The "Hendrick Hudson" (fig. 18, Plate III.), built of steel in 1901, one of the most prosperous river boats of America, carries 500 passengers, for whom five decks, which have a breadth of 82 ft.—the full width over the paddle-boxes—are set apart. She is 380 ft. long, 45 ft. breadth moulded, 13 ft. 5 in. moulded depth, draught 8 ft. 6 in., freeboard amidships 5 ft. 2 in., tonnage gross 2817 tons. The old walking-beam type of arrangement of engines, for many years a distinctive feature of American river steamers, is in this vessel replaced by inclined, three-cylinder, compound, direct acting engines; her feathering paddle wheels are 24 ft. in diameter and 16 ft. 6 in. wide, and her speed is 22 knots.

Some of the boats of the Fall River Line are larger than the "Hendrick Hudson"; the "Priscilla," is 422 ft. long, of 7500 tons gross, and 4650 tons gross; the "Priscilla," built in 1904, is very similar to the "Puritan," but is 440 ft. long and 203 ft. depth moulded; her moulded breadth is 281 ft. and her decks extend to an extreme breadth of 28 ft.; the side wheel diameters are 35 ft. in diameter and 14 ft. wide, driven by inclined engines of 8900 I.H.P., and running at about 24 revolutions per minute maintain a speed of about 25 knots on service, still larger vessel of the same type, the "Commonwealth," which is 456 ft. overall, breadth of hull 55 ft., breadth of decks outside guards 96 ft., horse power 11,000. The "Puritan," "Priscilla," and "Commonwealth" run on night service only to Fall River through Long Island Sound, and the accommodation provided is very large; the "Priscilla," for instance, can sleep 1500 persons besides her crew of over 200. In these vessels the freeboard is carried to one deck higher than in the "Hendrick Hudson" and other passenger vessels, considerable care having been bestowed on their passage with safety; and they form a link between the fast river steamer and the fast cross-channel steamer. Similar passenger vessels of a similar type, "The Great Eastern Steam Packet of Cleveland" (fig. 19), built in 1908, of the following dimensions: length overall 404 ft., breadth hull proper 54 ft., width over paddle-boxes 92 ft. 6 in., depth 22 ft.; tonnage 4566 tons gross, 2403 tons net. She is fitted with divisional and fireproofing water-tight compartments and fitted with a cellular double bottom, and has a water chamber of 100 tons capacity to check rolling in a sea way. The engines are compound, three-cylinder, inclined, connected directly to cranks on the paddle-wheel shaft, the diameters of the cylinders being one of 54 in. and two of 82 in., and the stroke 8 ft.; eight single-ended cylindrical boilers fitted with Howden forced draught fans, and a single engine, 28 ft. 8 in. long, of 1250 I.H.P. attained 20 m. or 17-5 knots per hour without difficulty, developing about 6000 I.H.P. at 28 revolutions per minute.

Cross-Channel Steamers.—Cross-channel steamers are of a heavier type than those just described and have a higher freeboard and better sea-keeping qualities to be able to make passages across more exposed waters in all weathers. Over 200 such vessels are employed carrying mails, passengers, luggage, cattle and merchandise between Great Britain and Ireland, the Isle of Man, and continental ports. The mail service between Holyhead and Kingstown has for many years employed a number of splendid vessels of this class. The four paddle boats are: "Mary-i," "Mary-ii," "Mary-iii," and "Mary-naught;" built in 1860, were 337 ft. long, 35 ft. broad and 19 ft. deep; their speed was 18 knots with 6000 I.H.P. A vessel of the same type, but larger, named the "Ireland," was added to the fleet in 1862. In 1875, two more of the same new type were built, and received the same names as the four vessels built in 1860, which they have replaced. Their length is 350 ft., breadth 41 ft. 6 in., draught 14 ft. 6 in., displacement 2230 tons at 14 ft. 6 in. load draught. Their engines are of 9000 I.H.P. and sea-going speed 23 knots, over 24 knots having been reached on trial. They have sleeping-berths for 238 first-class and 124 second-class passengers, and large dining and other public rooms for general accommodation.

In recent years large numbers of very fine vessels of the cross-channel type have been built for other services. In 1903 the "Queen," the first turbine vessel for the Dover-Calais service, was built by Messrs Denny of Dumbarton; she is 310 ft. long and obtained 212 knots. In 1905 the "Invicta" was built of the same dimensions and her first trial by means of her turbines the speed was increased to 23 knots. In the same year the Midland Railway Company ordered three vessels each 330 ft. long, 42 ft. beam and 25 ft. 6 in. moulded depth; and a fourth similar but a foot wider. Two of these vessels, the "Antrim" and "Donegal," were fitted with four-cylinder triple-expansion engines driving twin screws; the third and fourth, the "Londoner I." and "Manxman," were fitted with turbines of 6000 and 8000 I.H.P. respectively. The cylinder and cylinders of the same dimensions. The "Antrim" did better than the "Donegal" and obtained a speed of 21-86 knots with very remarkable economy of turbine. The "Londoner I." built by Messrs Denny, is built by the "Manxman," driven by 23-12 knots, cross proving more economical than the "Antrim" at all speeds above 14 knots.

Other successful vessels of this class are the "St. George" and three sister vessels, 350 ft. long, 2500 tons displacement, 11,000 H.P. and 225 knots speed, built for the Great Western Railway Company for service from Fishguard to Rosslare; and the "Princess Elisabeth," of 24 knots, employed on the Dover-Ostend service. But all these vessels were surpassed by the "Ben-my-Chree," built at Barrow for the Isle of Man Steam Packet Company. She is 375 ft. long, 46 ft. beam, 18 ft. 6 in. moulded depth, carries 2549 passengers on a No. 2 certificate, and displaces 3353 tons at 13 ft. 5 in. draught. In trial she attained 255 knots on the measured mile, and maintained 241 knots for over 6 hours; on service she averages 24 knots at sea and 23 knots between the Liverpool landing stage and Douglas pier. Numbers of cross-channel steamers are owned by continental companies, among which the "Princesse Juliana" (fig. 20, Plate III.) and her two sister vessels, belonging to the Zeeland Steamship Company of Holland, run on the night service between Queenboro' and Barmouth. They are 350 ft. long, 42 ft. 6 in. beam, 16 ft. 4 in. depth, tonnage 2885 tons; they have four-cylinder triple-expansion engines of 10,000 H.P., and attained 224 knots on the mile, and 22 knots on a six hours run; they have excellent accommodation for 520 passengers.

For services on which relatively large cargoes and fewer passengers are carried smaller vessels of less speed are built, such as the "Kowant," built by Messrs D. & W. Henderson & Co. for the Laird Line serving between Glasgow and Dublin. She is 204 ft. long, 38 ft. beam, 17 ft. 6 in. depth moulded, has sleeping accommodation for 200 passengers, triple-expansion engines, and a speed of 16 knots.

In America a number of vessels of the cross-channel type have recently been built. One of these, the "Governor Cobb," 290 ft. long, 54 ft. broad, 20 ft. 6 in. moulded depth, 14 ft. draught loaded, was the first merchant vessel in America to be driven by turbines. She was followed by the "Harvard" and "Yale" of the same type, 407 ft. overall, 65 ft. extreme breadth, 16 ft. draught loaded; they carry 500 passengers and 600 tons freight on a night service between New York and Boston; turbines of 10,000 H.P. give them a speed of 25 knots. "Governor Cobb" is the first of the fast cross-channel vessels on the American coast.

The "Prince Rupert," "Princess Charlotte," &c., recently built for service on the Canadian coast, belong to this section. The first-cruiser (fig. 21, Plate III.) is 306 ft. long, 42 ft. beam, 24 ft. moulded depth. At 15 ft. draught her displacement is 3160 tons, of which 1000 tons is cargo; she is of 3370 tons gross, 6000 H.P. and her speed is 23 knots. The "Prince Rupert" and "Princess Charlotte" has obtained 19-2 knots on trial at 13 ft. 3 in. draught and 2622 tons displacement; both vessels can carry 220 first-class and a

large number of second-class passengers. The "Princess Charlotte" is of 36,000 tons and 20 knots speed.

The table has built and engined five two-channel vessels, which maintain a service between Japan and Korea. They are 335 ft. long, 45 ft. beam, gross tonnage 3200, displacement, at 17 ft. draught, 3880 tons. Parson's turbines of 8,500 H.P., made in Japan, are fitted and give a speed of 20 knots.

OCEAN LINERS.—The article on STEAMSHIP LINES gives an account of the rise of the great shipping companies. The steampships of 12,000 tons and upwards, given in the table on page 873, are shown in Table XI.

TABLE XI.—Vessels of 12,000 Tons and upwards built June 1910.

</table>

The Cunard Company, which was started in 1825, was in control of the Atlantic Transport Company, which was typical of vessels on the Atlantic route carrying a large cargo together with a limited number of passengers. One class of thirty-two first-class passengers, and carried with excellent accommodation. When fully loaded the displacement was over 26,000 tons and the speed 16 knots; the horse-power required being only a sixth of that of the fast Cunarders. To large numbers of passengers the additional period on the voyage is no disadvantage, while the transport of a large cargo at the relatively high speed of 16 knots is a great advantage. **Canadian Liners.**—With the increasing trade between Europe and Canada the direct Canadian liners increased in numbers and in importance, and now bear favourable comparison with the ships running between Europe and the United States. The "Victorian" and "Virginian" of the Allan line, built in 1894 and 1905 and plying between Liverpool and Montreal, were the first ocean liners to be fitted with Parsons' turbines; they are 520 ft. long, 55 ft. beam, 38 ft. moulded depth and 10,629 tons gross; and they can carry 1,500 passengers and a large cargo of a speed at 17 knots. They were ordered in 1893 by the Empress of Britain "and Empire of Ireland," built by the Fairfield Company for the Canadian Pacific Railway Company; they are 570 ft. long over all, 54 ft. between perpendiculars, 56 ft. 6 in. beam, 36 ft. 8 in. depth moulded, tonnage 14,080. The large Canadian lines have been provided with quadruple-expansion engines of 18,000 I.H.P. fitted and a speed of over 20 knots was obtained on trial. Excellent accommodation is provided for 1,850 passengers; and a considerable quantity of meat can be carried in insulated holds provided with refrigerating arrangements, besides a large general cargo, a total of 6,500 tons

FIG. 26.—North German Lloyd Liner Kronprincessin Cecilie.

FIG. 27.—Cunard Liner Mauretania, with Turbinia alongside.
of cargo being carried in addition to the coals, water and stores required for the passage across the Atlantic.

In 1908 the "Laurentic" and "Megantic," were built by Messrs Harland & Wolff. Each holds 41,570 tons dead-weight, 41,475 tons gross, 215 ft. long, 58 ft. 4 in. beam, 36 ft. 7 in. moulded depth, and 12,173 tons of iron. They are fitted with reciprocating engines of 50,000 I.H.P. and 600 ft. long, of 12 cylinders, and 22,900 l.h.p. supplied by 2 sets of Parsons turbines of 7,500 H.P., each, by the Northumberland Shipbuilding Company. They were built in 1908 and are 459 ft. long, breadth 60 ft., depth 38 ft., tonnage 11,150 tons gross, displacement 15,000 tons at 22 ft. 6 in.draught. Parsons turbines of 18,000 H.P. are fitted, driving three screw propellers of 20 ft. 1 in., while 18 ft. has been maintained by the "Royal Edward" from Bristol to Quebec. Accommodation is provided for over 1000 passengers. Still larger and faster vessels were being arranged for in 1910.

**Emigrant Vessels.**—Many vessels on the Atlantic Service are fitted up for carrying emigrants either with or without other passengers; they are known as 'emigrant' or 'emigrant and cargo' ships. Those built for such services include the "Germania," built by the Northumberland Shipbuilding Company in 1909 for Austrian owners. Her length is 415 ft., breadth 58 ft., depth 38 ft., tonnage 18,600 tons. The "Hunter" built in 1908 for the Italian emigrant trade to Canada, is 454 ft. long over all, beam 54 ft., depth 29 ft., she is 7900 tons gross and can carry 8600 tons dead-weight as well as over 1000 emigrants. The "Ancona," built in 1908 by Messrs. Workman, Clark & Co. for the Italian emigrant trade to the United States, is 500 ft. long, 8188 tons gross, 7500 I.H.P.; she can carry 2500 emigrants and a large cargo, and in addition 60 first-class and 150 second-class cabins on a continuous deck. Some of the finest vessels carrying emigrants are the ships of the "Cleveland" type belonging to the Hamburg-American Company. The "Cleveland" is 555 ft. long, 65 ft. breadth moulded, 46 ft. 8 in. depth, 27,000 tons displacement on a draught of 30 ft. 8 in. 13,000 tons dead-weight capacity, about 17,000 tons gross and 10,000 tons net, with machinery of 9300 I.H.P., and 16 knots speed. She can carry 250 first-class, 392 second-class, 494 third-class and 2064 fourth-class or emigrant passengers, making with a crew of 360 a total of 3560 persons, and has cold storage spaces of 10,000 cub. ft. for provisions, and 30,000 cub. ft. for cargo.

**Lines on other Routes.**—Only a few typical vessels engaged on other routes can be mentioned here. The Royal Mail Company’s "Avon," (fig. 33, Plate VIII), trading to the West Indies and round South America to the Pacific coasts, is 520 ft. long, 62 ft. 4 in. beam, 27 ft. 9 in. moulded depth, 18,470 tons displacement at 28 ft. draught, 12,079 tons gross, and obtains 18-76 knots on trial with 13,700 I.H.P. 1150 passengers can be carried as well as some 7000 tons of cargo. The Malaja," which in 1910 was being built for the P. & O. Company, is a larger ship than the "Oriental," 540 ft. long, 62 ft. 4 in. breadth, 12,500 tons gross displacement at 26 ft. draught, 7000 tons dead-weight, and carries 6,000 passengers and 3000 tons of cargo.

**Special Vessels.**—Many vessels are built for special and exceptional purposes, and cannot be classed with either ordinary cargo or passenger vessels. Amongst these may be included dredgers, train-carrying ferry-boats, ice-breakers, surveying vessels, lightships, fishing-vessels, trawlers, and cruisers. The "Eider," of 1490 tons gross, built for the coastguard in 1899, was fitted up with refrigerating machinery, insulated holds and cooling appliances so as to keep the fruit, vegetables or meat at the required temperature, and at the same time maintain a proper degree of humidity of the air. The number and size of vessels engaged in these trades continue to increase, and the enormous volume of the trade may be indicated by the fact that the "Eider" carried 10,000 tons of frozen fish in 1899. The list of vessels fitted for that particular trade.

A typical vessel is the "Highland Laddie," built for the Argentine trade in 1909, 420 ft. long, 56 ft. beam, 37 ft. 6 in. moulded depth to shelter deck, 7907 tons gross displacement at 28 ft. 6 in. draught, 12,500 I.H.P., and carries 1150 passengers in well-fitted and comfortable apartments amidships, and has insulated cargo-holds of 343,000 cub. ft. capacity. To control the temperature of the chilled beef or frozen mutton in these holds she is fitted with powerful refrigerating machinery, and cooled brine is circulated through tubes lining the sides and ceilings of the holds, some 20 miles of pipe being so used. The "Ruahine," built in 1909 for the New Zealand trade, is similarly fitted; she is 480 ft. long, 60 ft. broad, 44 ft. depth moulded, speed on trial 15-9 knots. The "Port Royal" of the Elder Dempster Line has a speed of 15 knots, and is fitted to carry 4000 tons of cargo as well as provisions, besides pineapples, oranges and other tropical and semi-tropical fruits. The fruit is kept at the desired temperature by means of large volumes of cold dry air circulated through the holds, and the air is maintained at 40° Fahrenheit, and the temperature of the fruit is kept below 60°, and the equipment is of the latest design. The "Tortuga," a vessel 390 ft. long, 48 ft. beam, 29 ft. 6 in. depth, 4200 tons gross, built for Messrs. Swan, Hunter & Wigham Richardson, has a storage capacity of 24 of these "Port Royal."
a distance of 16 m. Fig. 36 shows the profile and deck plans of this vessel, for which, with other particulars of the Danish ferries, we are indebted to International Marine Engineering. Particulars of the most important Danish train-carrying vessels are given in Table XIII.

The longest ferry, from Gjøder to Warnemünde, traverses a distance of 48 m. across the lower part of the Baltic Sea, and on this ferry the "Prinsesse Alexandrine" and "Prins Christian", are employed. Two other vessels belonging to the Prussian government also work on this ferry, and the great success of the service led to the Swedish and German governments undertaking a direct ferry service between Sweden and Germany from Trelleborg to Sassnitz, a distance of 65 m. For this service the "Drøtning-Victoria" (fig. 37, Plate IX.) was built by Messrs Swan, Hunter, Wigham Richardson & Co. Her dimensions are: length 370 ft. over all, 350 ft. between perpendiculars, breadth extreme 53 ft. 6 in., 3050 tons gross, displacement 4270 tons dead-weight capacity, 600 tons at a draught of 16 ft. 6 in., 5400 I.H.P. and speed 16½ knots. Two rail tracks are provided, the trains are shipped at the stern and are completely protected from the weather when on board, the bows of the ship being completed as usual for a sea-going vessel; ten full-sized passenger or sleeping carriages can be taken, or eighteen

goods wagons. Ballast tanks are provided, and powerful centrifugal pumps fitted, so that the trim of the vessel can be adjusted as necessary while embarking and disembarking to keep her, as built specially for the purpose, so that she can be driven through ice during the winter months.

In 1883 the "Solano," a large train ferry 406 ft. long, was built by Messrs Harlan & Hollingsworth of Wilmington, Delaware, to run between Bernicia and Porto Costa in connexion with the Central Pacific railway. In 1899 the American railways employed nearly 200 ferries, with an aggregate capacity of over 2000 large wagons, and by the end of the year the capacity of the ferries placed in service had increased to about three times those amounts, on Lake Michigan alone nine such ferries being at work.

Two other interesting examples of train ferries were built on the Tyne by Sir W. G. Armstrong, Whitworth & Co., Ltd., in 1895 and 1896, the former for service on the river Volga, and the latter for service on Lake Baikal in Siberia. The Volga has a rise and fall of no less than 40 ft. between spring and midsummer, and the ice upon it in winter is usually 2 ft., and sometimes 3 ft., thick, thus the problem presented considerable difficulties, which were increased by the fact that the locks of the Marinsky canal system, through which all vessels bound for the Volga must pass, are of such dimensions that it was impossible for vessels of sufficient size to be got through in one piece. It was decided to use two vessels to do the work, the first to act only as an ice-breaker, and the other to act only as a train-carrier. The ice-breaker was built in two pieces, the parts being at the longitudinal middle-line plane of the vessel. This was satisfactorily carried out by means of a double longitudinal middle-line keel, at the whole of the vessel was divided into halves, and the ice at the canal she was divided into halves, and was joined up again after passing through the last of the locks. Her dimensions were: length 147 ft. 6 in., beam 55 ft. 6 in., depth 16 ft. 1 in., fitted with compound engines and twin screws. The ferry steamer itself (fig. 38, Plate IX.) was 252 ft. long, of 55 ft. 6 in. beam, and of 14 ft. 6 in. depth. Four lines of rails were laid upon her deck, sufficient to accommodate eight sets of trucks or carriages, which are shown in position in the figure. The difficulty presented by the great difference in the river level was overcome by an arrangement of hydraulic hoists, placed at the bow, by which two trucks could be lifted at the same time, and the ice broken, and by having lines of rails at the landing-stages at two levels. The vessel was fitted with twin screws and compound engines, which gave her a speed of 9 knots. It was found necessary to divide her into four parts for the passage through the canal locks; the divisions were made at the longitudinal middle-line plane, and the parts were also divided when the parts were aloft.

The Lake Baikal Ferry was built for carrying trains across the lake in connexion with the Siberian railway. For more than half the year the lake is frozen over to a considerable thickness, and in this case the vessel must of necessity be herself a powerful ice-breaker as well as a ferry steamer. Her dimensions are: length 290 ft., beam 57 ft., draught under ordinary conditions 18 ft. 6 in., and displacement 4700 tons. The hull is closely subdivided for additional safety in case of perforation. She has three sets of triple-expansion engines, working three independent screw propellers, two placed fore and one aft in ordinary twin-screw ships, and one placed at the forward extremity for the purpose of disturbing the water under the ice, thus assisting the heavy cast-steel stem and armoured bow to break up the solid field-ice which the vessel has to encounter. The complete structure was: first erected on the Tyne, then taken to pieces and shipped to St. Petersburg; from thence its numerous parts were carried to what was at that time the terminus of the railway on the Volga, thence they were conveyed on sledges, and there the ship was re-erected and launched. The boilers constituted the heaviest individual pieces thus transported, as the weight of each could not be reduced below 20 tons.

An interesting example of a modern river train ferry is the "Fabius," built by Messrs G. Rennie & Co., Greenock, in 1909, for service in southern Nigeria, where the river is 2 m. across. She is similar in form to the Lake Baikal vessels, except that she has a top speed of 6 in., depth 10 ft., draught 5 ft. 6 in., speed 7 knots. She can carry six railway carriages and freight and passengers up to a total of 200 tons.

Ice-Breakers.—Steamboats for breaking a passage through frozen waters date from an early period; one is spoken of as early as 1831. The "Ermack" (fig. 39, Plate IX.), built in 1897, was specially intended for the Arctic regions. Her dimensions are: length 320 ft., breadth 71 ft., depth to the upper deck 42 ft. 6 in., and displacement 8000 tons; her engines develop 8000 I.H.P., giving her a speed of 15 knots.

Her general outline is shown in fig. 40, from which it will be seen that her bow slopes upwards from below, so as to enable her to run up on to the ice and bring her weight to bear in breaking it. The "Ermack" is specially intended for the Arctic regions, and was the first vessel of her class to work in the winter of 1898-1899, when she steamed through the Baltic to Kronstadt, crushing the ice with comparative ease.

In many places round the coast the safe navigation of ships is assisted by vessels called lightships, moored in positions where lighthouses cannot well be built. Around the southern portion of Great Britain these vessels are maintained by the Trinity Corporation (see LIGHTHOUSE).

Fishing Vessels.—It is not many years since a few old paddle tugs were fitted up with fishing appliances. They proved very profitable, and the experiment led to the building and fitting out of steam vessels specially designed for such employment. Screw steam trawlers (see TRAWL) or other fishing-boats are among the vessels most frequently met with round the British coasts.

The "Ermack" was built in 1897 by Messrs Vickers, Sons & Maxim for the Pacific Railway Company as an ice-breaker for the Siberian railway, but her engines were of 8000 I.H.P., giving her a speed of 15 knots. A screw steam vessel laid down in 1895 was the "Siberian Queen," 230 ft. long, 5500 tons, displacement, 71 knots speed, purchased by the Admiralty in 1895, and employed in Eastern waters. The vessels built for the purpose are the "Wong," 145 ft. long, 415 tons displacement, 10 knots speed, built in 1892; and the "Egerton," 155 ft. long, 545 tons displacement, 10 knots speed, built in 1888; both these vessels are propelled by paddle wheels, and both are composite build. The "Dart," a steel yacht 130 ft. long, 500 tons displacement, 71 knots speed, purchased by the Admiralty in 1888, was in 1910 employed by the New South Wales government. The Canadian government has provided vessels such as the "Cartier," a twin-screw steel vessel, built in 1899, 164 ft. long, 29 ft. beam, 648 tons gross and 117 knots speed, for survey work on the coast of British Columbia; the British government had the steel single-screw vessel "Investigator" built by Messrs Vickers, Sons & Maxim for survey of Indian waters; she is 204 ft. long, 33 ft. beam, 15 ft. 3 in. moulded depth, has a displacement of 1700 tons and a speed of 13 knots.

The United States government has provided the screw steam vessel "Carnegie," 128 ft. long, 35 ft. beam, 12 ft. 7 in. draught, 568 tons displacement.

Lightships.—In many places round the coast the safe navigation of ships is assisted by vessels called lightships, moored in positions where lighthouses cannot well be built. Around the southern portion of Great Britain these vessels are maintained by the Trinity Corporation (see LIGHTHOUSE).
SHIP

The coastguard cruisers not only watch the coast but proceed to the fishery grounds to act as international marine police. They are controlled by an admiral, with headquarters at 66 Queen Victoria Street, London, who in 1910 had at his disposal the torpedo gunboats "I," "II," "John Player," "Compagnie des Ponts et Chaussées" "Ringdove," and "Thrush;" the vessels "Colleen," "Jula," and "Fanny," purchased and fitted up for the purpose. The "Fanny" is 28 ft. long by 10 ft. beam, and is specially built for the service. The "Colleen," a wooden vessel built in 1869 and propelled by horizontal trunk engines of 250 I.H.P., is 145 ft. long and 415 tons displacement, and at one time the engines gave a speed of 15 knots. The "Fanny," built by M. and S. White, has a length of 150 ft., beam of 18 ft. 10 in., draught 12 ft., and gross tonnage 230 tons; and the "Norma," built in 1909, is 154 ft. long, 44 ft. 6 in. beam, and 457 tons displacement. In 1908 the Irish Fisheries Board procured the small cruiser "Helga," built by the Dublin Dockyard Co., 155 ft. long, 24 ft. 6 in. beam, 13 ft. 3 in. moulded depth; she obtained a speed of 14.1 knots on trial with a total deadweight of 140 tons carried.

Salvage and Fire Vessels.—Several private companies maintain special vessels which are available for assistance of vessels in distress, salvage work both in and out of port, and work at sea. Some are fitted with derricks and winches for hoisting out cargo and ships fittings, and provided with powerful steam or electrically driven pumps and special hoses for pumping out flooded compartments of vessels. Others are fitted with pumps capable of delivering 5000 gallons a minute for salvage and wreck-raising; others have been built and fitted for salvage and fire-fighting.

A fireboat at Elswick is 45 ft. long, 11 ft. beam and 3 ft. draught; she is fitted with a Merryweather quick-steaming boiler, and engines arranged to drive the boat at 8 knots, or as an alternative to pump out vessels on either side, or to pump from the river for fire purposes and deliver up to 1500 gallons a minute. Many small vessels of this character are provided for harbours, docks and shipbuilding works. One of the most powerful in England is that built for the Manchester Ship Canal. This boat is 90 ft. long, and is fitted with high speed salvage pumps capable of clearing 9000 gallons a minute as well as independent fire service pumps capable of delivering 4000 gallons per minute at a pressure of 150 lb per square inch. Fire and salvage work is of course carried on by the ships of the Pacific Marine of San Francisco, New York and Chicago. Two fireboats of special design were built in 1908 for Chicago. They are 120 ft. long over all, 28 ft. beam, 15 ft. moulded depth, and 9 ft. draught. Powerful turbine pumps are driven by two Curtis steam turbines on the same shafts, which also carry 275-volt 200-kilowatt electric motors for operating the propeller motors. The pumps can be worked so as to deliver 4500 gallons per minute at 300 lb per sq. in., 9000 gallons at 100 lb per sq. in. and 13,000 gallons at 60 lb per sq. in. The speed of the turbines and pumps is 1700 revolutions per minute. Twin screws are fitted and each is driven by a motor arranged to develop 2000 horse-power. In this boat, as well as in the "Ocean," a steam electric light, search-light, and steam steering gear. New York has ten powerful fireboats, several of which can throw over 10,000 gallons of water per minute. The "Beta" of the London Fire Brigade is the only steam fireboat ever fitted with electric signalling equipment. It is 75 ft. long, 27 ft. 4 in. beam, 11 ft. draught, 615 tons displacement, 1400 I.H.P., giving 131 knots with twin screws. The latest paddle tugs of the "Grappler" type are 152 ft. long, 28 ft. beam moulded, 53 ft. by 22 ft. amidships. The power for the 1250 I.H.P. is developed by inclined compound engines fitted with means to work the wheels independently or together as desired. 1250 I.H.P. gives a speed of 12 knots. The "Grappler" is of the following dimensions: length over all 170 ft., beam 27 ft. 6 in., depth of hold 13 ft. 9 in., displacement 576 tons, registered tonnage 334 tons gross, 227 tons net, and Thames moulded depth, and displaces 795 tons at a draught of 12 ft. 41 in.; a single screw driven by triple-expansion engines of 1370 I.H.P. gave a speed of 13 knots on trial. (See LIFEBOAT.)

Coal-Bunkers.—When dry docks and large workshops are often employed for towing, and small tugs are also built for this purpose, but on swift, large rivers the tugs are often of considerable power. The tug "Little John," built by Messrs Yarrow for service on the river Hooghly, is 300 ft. long, 40 ft. beam, and 13 ft. 6 in. moulded depth, and displaces about 160 tons. Two screws are fitted working in tunnels, and this little vessel has towed five barges, weighing with their loads 247 tons, at a speed of 5 knots. A river tug of this kind is the "Shooting Star," 3 bes. 6 ft. 8 in. by 13 ft. 6 in., which works in the waters of the Upper Yangtze, and named the "Shutting," is 150 ft. long, 15 ft. beam, with a depth of 6 ft. 6 in., fitted with compound engines developing about 400 I.H.P., and has a displacement of about 95 tons in tunnels (as the draught of the vessel is very limited) and giving a speed of about 11 knots. After trial at Southampton the tug was taken to pieces, the sections shipped to China, with sections of a large barge, and put together and completed at Kiangan. This was the first steamer to attempt regular passages in these troubled waters, and steamer and consort performed their first voyage with success. The American river tug "Spragge" is 318 ft. long overall, 64 ft. 8 in. width, depth amidships 7 ft., displacement 2200 tons, registered tonnage 1479. She is fitted with a stern wheel 40 ft. in diameter and 40 ft. in width, driven by two screws 24 ft. by 22 ft. 4 in. driving force 600 I.H.P. The "Schuyler" was 280 ft. long, 63 ft. in. diameter; and at 93 revolutions per minute her horse-power is estimated at 1500 I.H.P. In 1907 she towed on one occasion 56 coal boats, each 180 ft. long and 26 ft. wide, loaded with 380 tons each, and average speed was 10 miles an hour. On the American rivers the superiority of the screw propeller is, however, now realized, and shallow-draft tow-boats with two screws are in general use. Such tugs have been built by Messrs Cox & Co. of Falmouth for work in the North-Eastern Railway Docks on the Tyne. Great power in small length was required, and engines of 1000 I.H.P. are installed in vessels 75 ft. long, 26 ft. beam, 12 ft. 6 in. deep, having a displacement of 120 tons; twin screws set widely apart being provided to give manoeuvring power. Tugs in common use in harbour and coasting services are often 90 ft. to 120 ft. in length, 20 to 25 ft. beam, 10 to 12 ft. draught, with 800 to 1200 I.H.P. The "Baird's Buoy" is 100 ft. long, 26 ft. beam, 10 ft. draught, 200 I.H.P., and has some 10,000 tons displacement. The "Baird's Buoy" is a steel tug built by the Bath Iron Works for the American coal trade is 165 ft. over all and 1045 tons displacement, with triple-expansion engines of 900 I.H.P. The "Cornell" is one of the largest America sea-going tugs; when towing she has developed 1300 I.H.P. at 97 revolutions, and when running light 1900 I.H.P. at 135 revolutions and a speed of 15 knots. The "Hearty," built to go out under her own steam to work in the Humber estuary and W. of the Thames, is 182 ft. long, 30 ft. 4 in. beam, 11 ft. draught, 1000 I.H.P., giving 133 knots with twin screws. The latest paddle tugs of the "Grappler" type are 152 ft. long, 28 ft. beam moulded, 53 ft. by 22 ft. amidships. The 1250 I.H.P. is developed by inclined compound engines fitted with means to work the wheels independently or together as desired. 1250 I.H.P. gives a speed of 12 knots. The "Grappler" is of the following dimensions: length over all 170 ft., beam 27 ft. 6 in., depth of hold 13 ft. 9 in. displacement 576 tons, registered tonnage 334 tons gross, 227 tons net, and Thames
Fig. 38.—River Volga Train Ferry.

Fig. 37.—Sea-going Train Ferry Steamer Dröttning Victoria.

Fig. 39.—Ice-breaking Steamer Ermack.
yacht measurement 532 tons; she is rigged as a three-masted schooner; her original sail area, 9200 sq. ft., has recently been reduced to 7950 sq. ft.; her hull is composite, the frames being of iron and the planking of steel. She was built in 1900. Vessels of this class have been built in this country from 1900 to 1943, totalling 2098 tons. Thames Y.M., built in 1910; and 1607 tons gross and 1571 tons Thames, M.Y., built in 1908. These two vessels and many others of similar types are American-owned. The yacht "Emerald," of 750 tons yacht measurement, was built in 1913, had a longer speed, and was fitted with triple-screw propulsers and was built in 1939, and was the first turbine steamer to be classed in any registry. The "Atalanta" (ex Lorenz), of 1398 tons Y.M., built in 1902, was similarly fitted. The "Caribbean", of 888 uniform, was chartered by the U.S. Navy in May 1933, and was the first turbine steamer to be classed in any registry. These two vessels, the "Atalanta" and "Caribbean", were the first to be fitted with turbines and to be completed.

The royal yachts of European sovereigns are the largest yachts yet built. They include the "Empress of Russia" (fig. 2, Plate XII), of 3720 tons and 5600 H.P., built in 1888; the imperial German yacht "Hohenzollern" (fig. 43, Plate XI), of 3773 tons Y.M. and 2950 H.P., built in 1891; the "Impatience," of 1664 tons Y.M., built in 1894; the imperial Russian yacht "Standart," of 4534 tons Y.M. and 11,000 H.P., built in 1895; and the British royal yachts, "Victoria and Albert," of 5005 tons Y.M. and 4900 H.P., built in 1901, and the "Minesty," of 2157 tons Y.M. and 4500 H.P., built in 1907.

Propulsion by Electricity.—In 1888 Messrs Siemens & Co. fitted a launch, 40 ft. 6 in. long, 5 ft. 6 in. beam, and 5 ft. 9 in. deep, with an electric motor capable of giving a speed of eight knots. The "Ravenscroft," of 12 tons, was also driven by the electric motor and operated by a battery of secondary cells, and at a displacement of 5 tons a speed of 9 knots was obtained. A launch 25 ft. long, provided with an electric motor capable of giving a speed of 5 knots, was supplied by Messrs "Victoria and Albert" in 1903. A number of other electric launches similarly fitted have been built chiefly for river service, the batteries being recharged from shore stations from time to time; but the method has not been extensively adopted, except in submarines. In most cases the submarine's secondary battery has been used for propulsion on the surface as well as when submerged, being recharged from shore by being set aside. These small vessels they are used only for propulsion when submerged, the engines fitted for propulsion on the surface being arranged to drive dynamos for recharging the cells. In a number of small vessels and oil-tank steamers electric motors are fitted for driving the propeller and supplied with current from dynamos driven by steam turbines or internal combustion engines.

Propulsion by Naphtha Engines.—In 1888 several launches were being built in the United States which petroleum spirit was used for fuel in place of coal, and also as an expanding agent for driving the propeller machinery in place of steam. A number of these boats were afterward built in England and America as launches for the British and American navies. Further particulars of these boats will be found in a paper read by Mr Yarrow before the Institute of Naval Architects in 1888.

Propulsion by Internal Combustion Engines.—Experiments have been made at various times with machinery in which the fuel is burnt or exploded in the engine itself without having recourse to the transfer of energy by means of an expanding and condensing agent, such as steam or naphtha, and by these experiments the modern internal combustion engine has been slowly evolved and adapted for marine propulsion. In 1680 an engine was patented in which gunpowder was exploded, and the engine was operated by the vacuum produced by the cooling of the gases; in 1794 an engine was patented in which the explosion of turpentine spirit drove the pistons forward, and about 1823 a gas-driven vessel was run on the river Thames. In 1837 Mr. H. Maudslay fitted a gas engine for use in factories, &c., on shore, and petrol engines for driving motor cars, &c., and since the beginning of the present century similar engines have been developed and produced in considerable numbers, especially in the United States, some of the vessels being as large as 800 tons gross. Such vessels may be considered in three groups. (1) High-speed racing boats, pleasure boats of various sizes for service on river and in harbours, fireboats, patrol boats and launches for river work, yachts' tenders and sea-going yachts of light scantlings, in which highly volatile and readily exploded fuels such as gasoline, petrol, paraffin, and illuminating oil are used. (2) Engines in which the weight of the engine is of no great importance, such as barges for use on rivers and canals, ferry-boats, small tug-boats, slow-speed cargo vessels, trawlers, and similar vessels. (3) Engines using kerosene or paraffin, as well as oil fuels of greater specific gravity, and of higher flash-point and requiring a higher temperature for evaporation; in some cases these low-speed vessels have been fitted with engines using gas produced from anthracite coal, prepared charcoal and heavy oil. (3) Vessels in which auxiliary propelling machinery of low power is fitted; they include a large number of fishing vessels, smaller numbers of coastering sloops, lifeboats and a few large vessels; in these both light and heavy oils and gas have been employed. As examples of class (1), there have been mentioned the racing boats "Ursula," built at Cowes in 1908, 49 ft. 6 in. long, 5 tons total weight, fitted with petrol engines of 800 H.P., driving twin screws at about 920 revolutions, and giving a speed of 38½ knots; and "Crescent," built at Cowes in 1909, 45 ft. 6 in. long, 5½ tons displacement, fitted with two petrol engines of 300 H.P., giving 26 ft. long, 65 H.P. and over 30 knots speed; the American yacht "Kalinda," 83 ft. long, 14 ft. 3 in. beam, 3 ft. 9 in. draught; the "Quicksilver," 41 ft. long, 11 ft. beam, 38 tons gross, 5 ft. draught and 160 H.P.; and the "Cleopatra," 41 ft. long, 11 ft. beam, 38 tons gross, 5 ft. draught and 160 H.P., built at Cowes in 1905 and navigated under her own power to St Petersburg.

Examples of class (2) are the double-ended ferry-boat "Miss Virginia," built at New York in 1886, with two engines of 500 H.P., each driving a screw, 9 ft. deep, 9 ft. draught, 150 tons displacement, fitted with two petrol engines each of 75 H.P.; the yacht "Bronzeving" (fig. 45, Plate X), built at Sydney in 1908, 110 ft. long, fitted with thirty 20-h.p. petrol engines, each driving a single screw; the "Modewna" of Glasgow, a barque-rigged sailing yacht of 400 tons, fitted with petrol engines of 200 H.P., giving a speed of 91 knots, the "Cromarty," of 200 tons, fitted with petrol engines of 200 H.P., which is fitted with gas engines of 150 H.P., driving twin screws; and the yacht "Lady Evelyn," of 366 tons Y.M. fitted in 1910 with heavy oil engines of 500 H.P.

The power of individual internal combustion engines completed up to 1910 was somewhat limited, and great difficulties had been encountered in the use of heavy oil fuels; but great advances and improvements had been made which were opening up the way for the more extensive adoption of motors of large power using heavy oil fuels. An ocean-going motor-driven cargo vessel of 9000 tons and 12 knots was speed in 1910 being built in Germany for the Hamburg-Amerika line, and fitted with heavy oil engines of 2000 H.P. driving twin screws; and the engines of 10,000 H.P. were also being manufactured.

V. WAR VESSELS

The adoption of iron and steel as the material for shipbuilding, and the development of the steam engine, have influenced warship construction in the same manner as they have influenced the construction of ships for the mercantile marine; but, in addition, the introduction of armour for the protection of ships, the great advances made in its manufacture, and, above all, the marvellous improvements in the means for converting mechanical energy into propulsive energy, have changed the conditions of naval warfare, and called for corresponding changes in the design of warships. Those who are concerned in such questions may refer with advantage to an interesting comparison between the old "Victory" (fig. 1, Plate XIII), and a modern battleship initiated by Sir Andrew Noble in his address to the Mechanical Science Section of the British Association in 1896. Sir Andrew Noble's remarks in this connexion are the more weighty, coming as they did from the director of the great arsenal of Sir W. G. Armstrong, Whitworth & Co., and from one whose scientific research has included a year's study of the advances in naval armament, and the great improvements of guns and torpedoes, have changed the conditions of naval warfare, and called for corresponding changes in the design of warships.

The most improved battleships of the period just anterior to the Crimean War differed from the type I have just described mainly by the addition of steam power, and for the construction of these engines the country was indebted to the great pioneers of marine engineering, such as J. Penn & Sons, Maudslay, Sons & Field, Ravenhill, Miller & Co., Rennie Bros., &c., not forgetting Messrs Humphreys & Tennant, whose reputation and achievements now stand as a monument to their skill and ingenuity. (2) The "Duke of Wellington," completed in 1853, as the type of a first-rate just before the Crimean War, her length was 240 ft., her breadth 60 ft., her displacement 2580 tons, her indicated horsepower 899, and her speed on the measured mile 9-80 knots. Her armament consisted of 131 guns, of which thirty-six 8-in. and 32-pdr.s were mounted on the lower deck, a similar number on the middle deck, thirty-eight 32-pdr.s on the main deck, and twenty short 32-pdr.s and one 68-pdr. pivot gun on the upper deck. Taking the "Caesar" and the "Hogue" as types of second- and third-rate line-of-battle
ships, the former, which had nearly the displacement of the "Victory," had a length of 207 ft., a breadth of 56 ft., and a mean draught of 21 ft. She had 1420 indicated horse-power, and her speed on the measured mile was 10.3 knots. Her armament consisted of twenty-eight 9-in. guns and sixty-two 32-pdr.s. carried on her lower, main and upper decks. The "Hogue" had a length of 184 ft., a breadth of 48 ft. 4 in., a mean draught of 22 ft. 6 in.; she had 797 indicated horse-power and a speed of 81 knots. Her armament consisted of two 68-pdrs. of 95 cwt., four 12-in. guns, twenty-six 8-in. guns, and twenty-eight 32-pdr.s. of 50 cwt.—sixty guns in all.

"Vessels of lower rates (I refer to the screw steam frigates of the period just anterior to the Crimean War) were, both in construction and armament, so closely analogous to the line-of-battle ships that I will not fatigue you by describing them, and will only allude to one other class, that of the paddle-wheel steam frigate, of which I must make mention of the "Terrible," as a type. This vessel had a length of 226 ft., a breadth of 43 ft., a displacement of about 3000 tons, and an indicated horse-power of 1950. Her armament consisted of seven 68-pdr.s. of 95 cwt., four 10-in. guns, ten 8-in. guns and four light 32-pdr.s."

The warships which existed at the beginning of the latter half of the 19th century were, with the exception of special vessels, divided roughly into three classes—ships of the line, frigates and gun-vessels. For many years the corresponding types of iron and steel vessels were known as battleships, cruisers and gunboats, but recently we have seen the power of the cruiser increased to that of the battleship, and new types have been produced such as the torpedo boat, the torpedo boat destroyer and the scout, the latter developing into the fast cruiser of continually increasing size; while the submarine torpedo boat has become a recognized sea-going vessel rival in speed and endurance in size with the gun-vessel or the small cruiser. It is proposed to refer to these in the order named. (See also NAVY.)

**Battleships.**—The destruction of the Turkish fleet at Sinope (30th November 1853) by the Russian fleet, the latter alone being armed with shell guns, and the combined experience of the British and French fleets before Sevastopol when engaging Fort Constantin, demonstrated conclusively that for ships of the line armour protection had become essential. The French government immediately began to build five armoured-plated vessels, or batteries, as they were called, for service in the Black Sea; and eight similar vessels were begun shortly afterwards by the British government for the same service.1 The British vessels did not arrive in time to take any part in the war; but three of the French batteries did, and were very favourably reported on by Admiral Bruat after an engagement with the Kinburn Forts on the 17th of October 1855. With the exception of these three French batteries, the whole of the fleets employed in the operations were composed of unarmed wooden ships, and a large number of them were sailing line-of-battle ships. As the result of the engagement with the Kinburn Forts, the French began to armourplate sea-going vessels, and the first ship in this class was taken by the celebrated French naval architect M. Dupuy de Lôme, who razed the "Napoleon," a wooden two-decker, and fitted her with a complete belt of 5-in. armour on a backing of 26 in. of wood. This work was completed in 1859, and the ship, renamed "La Gloire," became the first sea-going armour-clad. Two other vessels of the same design, the "Invincible" and "Normandie," were also laid down, and with the "Magenta," "Solférino" and the "Couronne," a few years later, formed the first fleet of French armoured-clads.

In June 1859 the armour-plated iron frigate "Warrior" was commenced by the British government. Others quickly followed, including the "Black Prince," which was a sister ship to the "Warrior," and four other vessels, the "Achilles," the sister ships "Minotaur" and "Agincourt," and the "Northumberland." The distribution of the armour and other features of these vessels are shown in fig. 47. The "Warrior" and "Black Prince" were 380 ft. long and of 8830 tons displacement, had engines of 6000 I.H.P. and a speed of 141 knots; they were designed to carry thirty-six 68-pdr. 100-cwt. guns, but during construction the 7-in. 61-ton gun was introduced into H.M. Service, and the ships when completed for sea carried an armament of 28 of these 7-in. guns. They had a central citadel 213 ft. long, protected with 43-in. iron armour extending from a few feet below the water-line to the height of the upper deck. Their outline was similar to the outline of the wooden frigates of the day, and their rudder-heads and steering-gear were above water and unprotected against injury by shot and shell. In the four vessels which immediately followed, which were from 500 to 1500 tons more displacement, the overhanging bow, as will be seen from fig. 51, was given up, bows adapted for ramming were introduced, and some protection was afforded to the steering-gear by water-line belts of armour which extended the whole length of the vessel. In 1861 the British government began the construction of eleven armour-clads, six of which, including the "Hector" and "Valiant," sister ships of 6750 tons displacement and 3500 I.H.P., were iron vessels, and five, the "Caledonia," "Royal Oak," "Ocean," "Prince Consort," and "Royal Alfred," were wooden vessels of rather over 4000 tons.

The reconstruction of the British fleet was taken in hand in earnest in 1863, when Mr (afterwards Sir) Edward J. Reed was placed at the head of the Construction Department at the Admiralty, with Messrs Barnaby, Barnes, Crossland, Morgan and Wright—the last-named (afterwards Sir James Wright) holding the position of engineer-in-chief—as...

his immediate assistants. Various types of vessels were devised, with arrangements of armour and dispositions of guns, to provide for the new conditions which had been introduced; and, in addition, great advance was made in the structural arrangements of ships, which up to this period had been considerably influenced by the old systems of construction in use in wooden ships. In investigating the qualities of ships, Sir Edward Reed had the good fortune to secure the co-operation and assistance of Mr William Froude, F.R.S., who had been the first to demonstrate the theory upon which the behaviour of ships in a seaway depends. Mr Froude's experimental investigations on the forms of ships and kindred matters, begun in 1870 on behalf of the Admiralty and continued till his death in May 1879, had a most important bearing on the improvement of ships and on the science of naval construction generally. It is not too much to say that nearly the whole of the accurate information as to the best forms of ships and their resistance at various speeds, in the possession of naval architects to-day, is the direct result of Mr Froude's work, and that of his son, Mr R. E. Froude, F.R.S., who continued the work after his father's death.

Among the considerations which Reed had in view in the reconstruction of the navy may be enumerated the following: (1) Steadiness of ship as a gun platform, with ample stability in all conditions of lading to enable her to keep the sea in all weathers, and sufficient stability in a partially loaded condition to enable her to keep the weather in a seaway. (2) Protection by armour of the vital parts of the ship, and of the heavy-gun positions, especially against shell fire. (3) The carrying of guns of power sufficient to penetrate the armour of any possible enemy. (4) Mounting the guns sufficiently high above the water-line to enable them to be fought in bad weather. (5) Simultaneous all-round fire, with concentration of as many guns as possible on any given point of the compass. (6) Speed to overtake or get away from an opponent or an enemy. (7) Proper provision for the berthing of officers and crew. (8) Laid down in June 1866 as a sea-going turret ship. She was launched in May 1868, her dimensions being: length 320 ft., breadth 57 ft. and draught 26 ft.; her I.H.P. was 8000, giving her a speed of about 15 knots, and she was protected by a broadside of 10-in. armour, the thickness of which was 2 inches. The "Hercules," launched in 1866, was a vessel of 7550 tons displacement, 6600 I.H.P., 14 knots speed, and 300 ft. long. Her armament consisted of ten 9-in. 14-ton and five 7-in. 63-ton guns. Her water-line was wholly protected by 6-in. armour, and she was provided with a central battery 98 ft. long, protected with armour of the same thickness. She carried a considerable spread of canvas, and she was fitted with a balanced rudder. The "Hercules," completed in 1866, was a much more important ship, her dimensions being: length 325 ft., breadth 59 ft., draught 26½ ft., displacement 8680 tons. Her engines of 8500 I.H.P. gave her a speed of about 14½ knots. She had two 9-in. guns mounted one forward and one aft on the main deck behind 6-in. armour, and eight 10-in. guns, mounted in a central battery on the main deck. Her water-line was protected by armour 9 in. thick amidships, reduced to 6 in. at her ends, and her highest armament point was 6½-in. armour. The "Sultan," completed in 1871, was in many respects a similar ship but larger, having a displacement of 9300 tons, 2 ft. more beam and 1 ft. more draught; she attained a speed of upwards of 14 knots. Her main-deck battery carried the same guns as the main-deck battery of the "Hercules," but the 9-in. guns at the extremities of the vessel on this deck were dispensed with, and she carried, in addition, an upper-deck battery, placed over the after-end of the main-deck battery, in which four 9-in. guns were carried. Both batteries were protected by 6-in. armour; elsewhere the armour followed that of the "Hercules."

A number of low-freeboard turret vessels of the "Monarch" class, without masts and sails, were built for the British navy at this time, mostly for coast defence. Amongst these, the "Cerberus" for Australia and the "Abyssinia" and "Magdala" for India were completed in 1870. The "Abyssinia" had a displacement of 12,000 tons and a speed of about 9½ knots; her dimensions were: length 225 ft., beam 42 ft., draught 14½ ft., and her armament consisted of four 10-in. 18-ton guns. The other two vessels had the same armament, but were somewhat larger, being of 3400 tons displacement; and the thickness of their side-armour was 8 to 6 in., against 7 to 6 in. in the "Abyssinia." Several vessels of this type were also built for home service, including the single-turret vessels "Glatton" of 4910 tons and "Heispur" of 4010 tons, each carrying two
18-in. 25-ton guns, and the "Cyclope," "Gorgon," "Heate" and "Hydra," each of 3650 tons and provided with two turrets carrying two 10-in. 18-ton guns. They were protected with armour from 8 to 12 in. thick, and their speed was from 10 to 12 knots.

The "Devastation," commissioned in 1869, represented Reed's conventional view of what a turret ship should be. Low sides were adopted, but not in combination with rigging and sails. She was the first sea-going battleship in the British navy which depended wholly on steam power for propulsion. She was 285 ft. long, 62 ft. 3 in. broad, 27 ft. mean draught and 9330 tons displacement. Her sides, which, except right forward, rose only to a height of 4 ft. 6 in. above water, were protected with armour 12 in. thick. Her armament consisted of five aft, four stern, and four bow guns, mounted in pairs in two turrets, one at each end of a raised breastwork or redoubt which extended about 150 ft. along the middle of the upper deck. The guns were thus elevated to the height of some 14 ft. above the surface of the water. The turrets were protected by armour 12 in. and 14 in. thick, and the breastwork or redoubt by armour 10 in. and 12 in. thick. A forecastle extended forward from the fore-end of the breastwork at a height of 9 ft. 3 in. above the water-line; but in wake of this forecastle the side armour dropped to a height of only 4 in. above the surface of the water, at which level there was an armoured deck. She was provided with twin-screw machinery of 7000 I.H.P., which gave her a speed of 14-2 knots, and she carried a large coal supply. After the loss of the "Captain," a special committee, including many of the highest professional and scientific authorities in the United Kingdom, was appointed to examine into the design of such vessels. Of the "Devastation" they reported that "ships of this class have stability amply sufficient to make them safe against the rolling and heaving action of the sea"; they agreed, however, in recommending a plan which the constructors of the Admiralty had proposed, with the view of increasing her range of stability and the accommodation of the crew. This consisted in the addition of side superstructures formed by continuing up the ship's side with light framing and plating as high as the level of the top of the breastwork, and carrying the breastwork deck over to the sides. The structures were continued aft on each side some distance beyond the breastwork, providing two spacious wings, which added largely to the cabin accommodation. A good idea of her general appearance may be obtained from fig. 49 (Plate XII). The "Devastation" was followed by the "Thunderer" of the same dimensions, and the "Dreadnought" of 12,670 tons displacement, 8000 I.H.P. and 14 knots speed; a vessel of higher freeboard, plated with 14 in. of armour and carrying four 12-in. guns; she was the most powerful and best protected vessel of her day. Sir Edward Reed retired from the Admiralty a short time before the "Captain" founderd at sea. During his seven years' term of office some forty iron armour-clads of various sizes and types, besides iron cruisers and numerous other vessels, had been added to the British navy, the adoption of armour for the protection of the vital parts of ships has become established, and especially had the importance of utilizing armour in such a manner as to exclude projectiles from the region of the water-line become recognized. The change from the widely-distributed armament of the first broadside armour-clads to the highly concentrated armament of the turrets, and from the high freeboard ship with sail-power to the low freeboard turret ship without sails, had also been effected; so that when Sir Edward Reed retired in 1879, the latest type of battleship was entirely different from that which existed when he took office; and although the construction of broadside ironclads had not been discontinued, "the wooden walls" had practically ceased to exist. Sir Edward Reed was succeeded by a Council of Construction composed of his immediate assistants, with Mr Barnaby (afterwards Sir Nathaniel Barnaby) as its president; but three years later this council was dissolved, and Sir N. Barnaby was placed at the head of the Construction Department.

The sea-going qualities of the "Devastation" had successfully demonstrated that the battleship of the future might depend wholly on steam propulsion; and although many naval officers and others continued to hold the view that sea-going ironclads must of necessity be rigged ships, in the designs which immediately followed sail power was omitted. In the "Inflexible" (fig. 50, Plate XII), and the sister ships "Ajax" and "Agamemnon," the offensive power was concentrated mainly in two pairs of heavy guns, as it was in the "Devastation" and other turret ships which preceded them; but in them the armour defence also was concentrated over a comparatively small space amidships, the unprotected ends being formed into what was called raft bodies by belts of cork, within which was placed a portion of the ship's coal, &c. Thus the buoyancy was secured by a Citadel amidships which could not be penetrated, and by ends which might be riddled but (it was contended) not be destroyed. The arrangement shown in fig. 51 represents the "Ajax" and "Agamemnon." The "Inflexible" was similar but larger. Sir N. Barnaby described the design of the "Inflexible" in 1874 before the Institution of Naval Architects thus:

"Imagine a floating castle 110 ft. long and 75 ft. wide, rising 10 ft. out of the water, and having above that again two round turrets planted diagonally at its opposite corners. Imagine this castle and its turrets to be heavily plated with armour, and that each turret has within it two guns of about 80 tons each—perhaps in the course of a few years guns of twice 80 tons each. Conceive these guns to be capable of firing, all four together, at an enemy ahead or on either beam, and in pairs towards every point of the compass.

"Attached to this rectangular armoured castle, but completely submerged, every part being 6 ft. to 7 ft. under water, there is a hall of the ordinary form, with a powerful ram bow, with twin screws and a submerged rudder and helm. This compound structure is the fighting part of the ship. Seaworthiness, speed and sharpness in turning would be wanting in such a structure if it had no additions to it; there is therefore an unarmoured structure lying above the submerged ship and connected with it, both before and abaft the armoured castle; and as this structure rises 20 ft. out of the water,
from stem to stern, without depriving the guns of that command of the horizon already described, and as it moreover renders a flying deck unnecessary, it gets over the objections which have been raised against the low freeboard and other features in the "Devastation," "Thunderer" and "Fury." These structures furnish also most luxurious accommodation for officers and seamen. The step in advance has therefore been from 14 in. of armour to 24 in., from 35-ton guns to 80-ton guns, from two guns ahead to four guns ahead, from a height of 10 ft. for working anchors to 20 ft., and this is done without an increase in cost, and with a reduction of nearly 3 ft. in draught of water, &c.

The dimensions of the "Inflexible" were: length 320 ft., beam 75 ft., mean draught 26 ft. 4 in., and displacement 11,880 tons, and her speed was 14 knots. The dimensions of the "Ajax" and "Agamemnon," begun in 1876, were: length 310 ft., beam 66 ft., mean draught 24 ft. 9 in., and displacement 8,660 tons. They carried four 12-in. guns; their citadels were 104 ft. long, protected with 18-in. armour, their turrets being protected by 16-in. armour; and their speed was 12 knots. The "Edinburgh" and "Colossus," begun three years later, were of the same type, but were built of steel and were of 9480 tons displacement. Their citadels were longer, and their speed was 14½ knots. Compound armour, adopted generally appearance is obtained from fig. 53 (Plate XII.), which represents the "Camperdown." The "Victoria" and the "Sans Pareil," built a few years later, were, with the "Benbow," the only ships of the British navy built to carry 110-ton guns, the former having them in pairs in a turret heavily armoured, and the latter singly in barbettes.

Among the last of the battleship designs undertaken by Sir N. Barnaby was that of the "Trafalgar" and "Nile," which was completed by Messrs. F. K. Barnes and H. Morgan after his retirement. These vessels, laid down in January and April 1886, were the largest ships thus built for the British navy. They were 11,940 tons displacement, 345 ft. long, 73 ft. beam, and 28 ft. 10 in. mean draught; had engines of 12,000 I.H.P. and a speed of 16¾ knots. Their armour-protection consisted of a belt 230 ft. long and 20 in. thick, with bulkheads 18 in. and 14 in. thick. Above the belt was an armoured redoubt of 18-in. compound armour which enclosed the turret bases. The turrets themselves had 18-in. armour, and between the turrets was an octagonal battery of 3 in. to 5 in. of steel containing the 4-7-in. Q.F. guns. The thickness of the protective deck was 3 in. The disposition of armament originated in the "Collingwood" was adopted in these vessels, but the heavy guns were placed in turrets instead of in barbettes. The armament

Fig. 52.—The "Collingwood." A, communicating tubes; B, boiler-rooms; D, water-chambers; E, engine-room; M, magazines and shell-rooms; P, patent fuel packing; W, water-ballast tanks.

in these two ships for the first time, gave them a great advantage in defensive power.

The "Collingwood," begun in 1880, was the first of the battleships of a new type known as the "Admiral" class. In these vessels the main armament consisted of four heavy guns mounted in pairs on the middle line of the ship, in fixed heavily protected gun-positions called barbettes, one at each end of the ship; this main armament was supplemented by a secondary armament of lighter and more rapid-firing guns mounted on the broadsides between the barbettes. This arrangement of the armament, which is illustrated in fig. 52, continued, with small modification, to be adopted in the battleships of the British navy down to 1903.

The principal features of the "Collingwood" were: length 325 ft., beam 68 ft., mean draught 27 ft., displacement 9500 tons. She carried 18-in. armour on her sides, 16-in. on bulkheads, 11½-in. on barbettes and 12-in. coating turrets. Her armament consisted of four 12-in. 45-ton guns, six 6-in. guns, and a number of smaller guns. Her speed was 16½ knots, and she carried 900 tons of coal, with capacity for 1200. She was followed two years later by the "Rodney," "Howe," "Benbow," "Camperdown," and "Anson," which were of the same type, but larger. These six ships constitute what is known as the "Admiral" class. A good idea of their

1 The "Fury" was modified and renamed "Dreadnought" before being launched.

2 The "Victoria" was accidentally rammed and sunk by the "Camperdown" during the Mediterranean manoeuvres of 1893.
introduction of compound armour and the adoption of steel instead of iron for the building material, both of which date from his time, allowed of greater armour protection and of other advantages, including increased speed, &c.

Sir Nathaniel Barnaby was succeeded in October 1885 by Mr W. H. White (afterwards Sir W. H. White, F.R.S.). The battleships then building were of four different types and included two of the "Colossus" class, six of the "Admiral" class, two "Trafalgar," and the "Victoria" and "Sans Pareil.". Their completion proceeded very slowly, and no new battleships were laid down till 1889, when the Naval Defence Act resulted in a reconsideration of the subject by the Board of Admiralty.

Before coming to a decision various designs were discussed, and the First Lord convened a meeting, not only of the members of the Board, but of a number of distinguished and experienced naval officers as well as the Director of Naval Ordnance and the Director of Naval Construction. Subsequently the Board issued instructions for the preparation of detailed designs embodying the features which were agreed upon as being most desirable; and on these designs the seven barbette battleships of the "Royal Sovereign" class and the turret ship "Hood" were built.

The general arrangement of guns and armour in the vessels of the "Royal Sovereign" class is shown in fig. 54. They were 380 ft. in length, 75 ft. beam, 27 f. 7 in. draught, 14,150 tons displacement, 13,000 I.H.P., and 17 f. 8 in. speed. The coal bunkers hold 1,450 tons, of which 900 tons is included in the above displacement. For three-fifths of the length amidships the side is protected by an 18-in. belt of armour, a horizontal 3-in. protective deck being worked across the ship at the middle or belt deck; between the belt deck and main deck 4-in. side armour is worked. Before and abaft the belt curved protective decks 2½ in. thick were worked, extending down to the ram forward and covering the steering gear aft. Four 14½-in. B.L. 67-ton guns were fitted in pairs in pear-shaped barbettes forward and aft, protected by 17-in. armoured barbettes extending down to the belt deck; ten 6-in. Q.F. guns were fitted, four being on the main deck in 6-in. armoured casemates, which were adopted in these vessels for the first time; sixteen 6-pdr. and twelve 3-pdr. Q.F. guns were fitted, and seven torpedo tubes. The "Royal Sovereign" was laid down at Portsmouth in September 1889, floated in February 1891, and completed in May 1892. (The six upper-deck 6-in. guns were protected by 5-in. casemates added 1901 to 1903.)

The "Hood" was similar in displacement, armament, armour, horse-power, speed and general dimensions, but was of less freeboard, the heavy guns being fitted in turrets revolving on armoured redoubts of reduced heights.

The "Centaur" and "Barfleur," laid down in 1890, were designed as sheathed second-class battleships for service in distant waters; they were 360 ft. in length, 70 ft. beam, 25 ft. 6 in. mean draught, 10,500 tons displacement, 15,000 I.H.P., and 16½ knots speed. They were armed with four 10½-in. B.L. guns in circular barbettes of 9-in. armour, ten 4½-in. and twenty-two small Q.F. guns, and five torpedo-tubes, four of the 4½-in. guns being on the main deck in amidships and 4 in. thick on the sloping sides above the deck; a broad belt of 9-in. Harveyised armour was fitted, rising to the main deck. The barbettes were protected by 14-in. armour, and all the 6-in. guns were protected by 6-in. casemates. The "Majestic" was laid down at Portsmouth on the 5th of February 1894, floated on the 31st of January 1895, and completed in December 1895.

Nine vessels of the same class were built, the last being the "Hannibal" (fig. 56, Plate XIV.), completed in April 1898. In two of the vessels, "Caesar" and "Illustrated," the barbettes were made circular, central revolving hoists being fitted and the guns arranged to load at any angle of training, a system which was adopted in the heavy gun mountings of all the later British battleships.

The "Formidable" and "London" classes, laid down from 1898 to 1901, differ very slightly from each other, and for all practical purposes may be taken as identical, the main difference being in a rearrangement of the armour protection to the bow in the later ships. The former class consists of the three battleships "Formidable," "Irresistible" and "Implacable," and the latter of the five battleships "London," "Bulwark" (fig. 57, Plate XV.), "Venerable," "Queen," and "Prince of Wales." These classes represent a development of the "Majestic" class, being 400 ft. long, 75 ft. beam, 26 ft. 9 in. draught, and 15,000 tons displacement, the belt being of the same general thickness and extent as in the "Majestic," but of Krupp steel, protection being given to the bow by 2-in. side-plating. In the "Formidable" the protective deck proper was formed as in the "Majestic," but thinner, being 2 in. to 3 in. thick, and a second protective deck, 1 in. thick, was formed at the main deck, giving a flat top to the citadel formed by the side belt and the full bulks. In the "London" class the lower protective deck was thinner and the upper one thicker than in the "Formidable" class, the protection being extended forward by thinner material, tapering to 2 in. at the bow, and the forward transverse armour bulkhead being omitted. The 12-in. guns in both classes were casemates of 5-in. armour; the armour belt was 12 in. thick, the protective decks 2 in., and the side armour between belt and arm, 3 in. thick. They were re-armed and improved in 1902-1903.
longer and heavier than in the ships of the "Majestic" class, and were in barbettes 12 in. thick; in addition, there were twelve 6-in. Q.F. guns—all in casemates—sixteen 12-pdrs. and four torpedo tubes. These eight battleships were each provided with 20 Belleville boilers, developed 15,000 H.P., and had a speed of 18 knots. They carried 900 tons of coal at their normal displacement.

boilers; they had 20 Bellevilles, developed 13,500 H.P., and had a speed of 18 1/2 knots. They carried 1000 tons of coal at normal load, and had bunkers for 2300 tons. The ships of the "Duncan" class were longer and larger than those of the "Canopus" class. They were begun in July 1899, were of 14,000 tons displacement, 405 ft. long, 75 ft. 6 in. beam, 26 ft. 6 in. draught. They had a belt of Krupp steel, 7 in. thick amidships, tapering to 3 in. at bow, and two protective decks, as in the "Canopus"; they had two barbettes, 11 in. thick, for four 12-in. guns, and carried twelve 6-in. Q.F. guns in 6-in. casemates on the main and upper decks; also a number of smaller guns and four submerged torpedo tubes. They were provided with 24 Belleville boilers, would develop 18,000 H.P., and attain a speed of 19 knots. Their normal coal supply was 900 tons, and they had bunker capacity for 2000 tons. Six of these ships were built, one of them, the "Montagu," being lost on Lundy Island in 1906. Vessels of similar type had been built abroad, but there was a tendency to provide in them a more powerful secondary armament. In 1901 France built the "République" with eighteen 6-5-in. guns as her secondary armament; Italy laid down the "Regina Elena," carrying twelve 8-in. guns as her secondary armament; and Germany the "Braunschweig," carrying fourteen 6-7-in. and twelve 3-4-in. guns as her secondary armament. In 1902 the United States followed with the "Georgia," carrying a secondary armament of eight 8-in. and twelve 6-in. guns, while two English vessels, the "Libertad" and "Independencia," laid down for Chile, carried no less than fourteen 7-5-in. guns as their secondary armament.¹ In 1902 the "King Edward VII." (fig. 58, Plate XIV.), the last battleship for which Sir William White was responsible, was laid down, carrying four 12-in. guns, with a secondary armament of four 9-2-in. and ten 6-in. guns. She may be considered as an enlarged "Duncan," with the main-deck guns increased from eight to ten in number and enclosed in a battery having sides and ends protected by 7-in. armour, with the backs of the casemates replaced by splinter bulkheads 1 to 2 in. in thickness, and with the four 6-in. guns in casemates on the upper deck replaced by four 45-calibre 9-2-in. guns, protected by enclosed revolving armour shields. The

¹ These two vessels were afterwards purchased by the British government and became the "Swiftsure" and "Triumph" (fig. 69, Plate X VIII.).

² The gun and armour diagrams and many particulars of modern vessels are taken by permission from Brassey's Naval Annual.
The displacement of the "King Edward VII." was 16,350 tons, the length 432 ft., beam 28 ft., draught 26 ft.; the H.P. 18,000, while the designed speed was 18½ knots. Eight vessels of this class were built, five being ordered in 1902 and three in 1903.

The principal changes to be noted in the development of the battleship type from 1885 to 1902 are:—(1) The successive improvements in armour by the introduction of the Harvey and Krupp processes, which enabled either a saving of weight to be effected for the same degree of protection, or a greater degree of protection to be provided for the same weight. (2) The belt armour was extended longitudinally, shielding a greater portion of the hull and giving increased protection to the stability and to the secondary armament of the vessel. (3) Improvements in guns and explosives, by which more effective gun-fire was obtained with guns of smaller calibre and less weight than those previously in use. (4) The growth in importance of the secondary armament. (5) Improvements in machinery—the adoption of higher steam pressures, lighter and faster-running engines, and of water-tube boilers—which effected great savings in weight for a given power, and enabled increased speed to be obtained in successive ships. Sir William White held office for nearly seventeen years, and during that period a very large number of vessels of various classes were added to the British navy. He retired in February 1902, and was succeeded by Mr. Philip Watts, F.R.S. (b. 1850), who was knighted in 1905.

In 1903 the design of the vessel which afterwards became the "Lord Nelson" was approved, her armament then including four 12-in. and twelve 9·2-in. guns, all of 50 calibre and all mounted in pairs in gun-houses above the upper deck. It was, however, decided to build the three additional "King Edwards" above referred to, in order to complete the squadron of eight vessels of the same type. In the "Lord Nelson," as afterwards laid down in 1905, the conceptions of the early vessels of this class showed to be capable of being developed. In existing docks at Chatham and Devonport led to the reduction of the secondary armament to ten 9·2-in. guns, instead of twelve 9·2-in. guns. Only two vessels of the class were built, the "Lord Nelson" and the "Queen Victoria," by the yards of Brown, Stephen & Co. (XIV.) By Beardsmore & Co. They are 410 ft. long, 79½ ft. beam, 27 ft. draught, 16,500 tons displacement, 17,500 I.H.P. and 18½ knots speed. The general arrangements of the guns and armour are shown in fig. 61; the 12-in. guns are carried in pairs at each end of the ship in gun-houses upon barbettes protected by 12-in. armour, and the ten 9·2-in. guns are carried in gun-houses on the broadside, the midship gun-houses having single and the others pairs of guns instead of each having a pair of guns as originally contemplated. The gun-houses carry 8-in. and 7-in. armour, and the bases of the gun mountings are protected by a Citadel of 8-in. armour rising to the upper deck level. The barbette frames are also twenty-four 12-pdr. anti-torpedo-boat guns carried upon superstructures and a hurricane deck. The water-line is protected by 12-in. armour amidships, tapering to 6 in. forward and 4 in. aft, associated with a side protection of 12-pdr. ammunition. The recommendations were approved in 1903 by the Board and embodied in the designs of the "Dreadnought" type of battleships, and the "Invincible" type of cruiser, as well as in new types of torpedo-boat destroyers.

The principal features of the "Dreadnought" design were as follows (Parl. Paper C. 30 of 1906):—

**Armament.**—Ten 12-in. guns and twenty-four 12-pdr. Q.F. anti-torpedo-boat guns. It is unnecessary to enlarge upon this point. It is obvious that the number of these guns is the result of the limitation of the displacement of the vessel, and not of technical necessities. It is obvious that the close grouping of these guns is the result of the limitation of the displacement of the vessel, and not of technical necessities. It is obvious that the close grouping of these guns is the result of the limitation of the displacement of the vessel, and not of technical necessities.

**Dreadnought Type.**

In arranging for a uniform armament of 12-in. guns it became at once apparent that a limitation to the number of guns that could be usefully carried was imposed by considerations of the blast effect of the shot at ranges of the order of those of those which are effective on the range. It is obvious that it is impossible to place the guns in such relative positions that the blast of any single gun on any permissible training should very seriously hamper the use of one or more of the remaining guns.

"While it is recognized that broadside fire is held to be the most important in a battleship, all-round fire is also considered of great importance, since it lies in the power of an enemy to force an opponent, who is anxious to engage, to fight an end-on action. In the arrangement of armament adopted, six of the guns are mounted in pairs on the broadside, and four or possibly six, 12-in. guns (or 60% of the main armament) can be brought to bear simultaneously to fire broadside. In view of the potentialities of modern torpedo craft, and considering especially the chances of torpedo attack towards the end of a battle, it is considered advisable that the super-structure of the torpedoboat guns as widely as possible from one another, so that the whole of them shall not be disabled by one or two heavy shells. This consideration led the Committee to recommend a number of small torpedo-boat guns arranged in pairs for the purpose of defending the new design and greater power than those hitherto carried for use against torpedo craft.

**Freeboard.**—In order to give the ship good sea-going qualities and to ensure the continued use of the forward gun for fire control is provided giving the ship a freeboard forward of 28 ft.—a higher freeboard than has been given to any modern battleship.

**Machinery.**—The main armament has a maximum thickness of 11 in., tapering to 6 in. at the forward and 4 in. at the after extremity of the vessel; the redoubt armour varies in thickness from 11 in. at 8 in.; the turrets and foreconning tower are 11 in. thick. The after part of the upper deck is 6 in. thick; the protective deck varies from 4½ in. to 24 in. in thickness.

**Special attention has been given to safeguarding the ship from destruction by under-water explosion. All the main transverse bulkheads below the main deck are provided with double parapet lines (which will stop any under-water explosive).**

**Speed.**—Mobility of forces is a prime necessity in war. The greater the mobility the greater the chance of obtaining a strategic advantage. This mobility is represented by speed and fuel endurance. Superior speed also gives the power of choosing the range of fire. To gain this advantage the speed designed for the "Dreadnought" is 21 knots.

**Armour-Machinery.**—The question of the best type of propelling machinery to be fitted was also most thoroughly considered. While recognizing that the steam-turbine system of propulsion has at present some disadvantages, yet it was determined to adopt it for the "Dreadnought," as it seemed to provide a better safety factor for the propulsion machinery, and to be more economical than the orthodox reciprocating type. It was determined that all requirements promise to be fully met by the adoption of suitable, turbine machinery, and that the exposing capabilities of the ship when engaged with a fleet or when working in narrow waters, will be quite satisfactory.

The necessary stopping and astern power will be obtained by astern turbines on each of the four shafts. These astern turbines will be arranged in series, and they will have a low pressure astern turbine on each side of the ship, and in this way the steam will be more economically used when going astern, and a proportionally greater astern power obtained than in the 'Eden' and 'Amethyst.'

**Accommodation.**—Considerable attention has been devoted to the arrangements for the accommodation of the officers and men. In view of the increasing length and greater power of modern ships it became necessary to adopt a super-structure which is the result of the tendencies to increase the length of the ship, and to increase the amount of space thereon, and the amount of space above the water-line. The idea of increasing the amount of space above the water-line is becoming more and more open to objection. Up to the present the principal officers have been bertheted at the farthest possible distance from the engines and machinery, and during the most important duties are performed. It has been decided that in this ship the admiral's and captain's quarters shall be placed on the main deck forward, near the conning tower; also that the officers' messrooms shall be placed on the upper deck, in the fore part of the ship. Ample accommodation is provided above the main deck.

for the remainder of the crew is available on the main and lower decks aft."

The tabulated particulars given in Parl. Paper Cd. 3048 for the designs approved are shown in Table XIV.

It is interesting to note that the distribution of armament finally adopted in the "Dreadnought" was nearly that of a design considered by Sir Nathaniel Barnaby at the Admiralty in 1874, which was a combination of the "Devastation" and "Inflexible" designs. The armament was an all-one-calibre big gun armament of 16-in. 80-ton guns carried in pairs in turrets above the upper deck, one pair being placed at each extremity on the middle line, and two on the broadside en échelon, having training on each broadside as well as ahead and astern, thus giving a fire of six guns ahead, six astern and eight on each broadside. The scheme was considered inadmissible on account of the great displacement involved, 16,000 tons. The arrangement of eight heavy guns then contemplated was actually adopted in the "Invincible" design, but it was not considered that four pairs of 12-in. guns was a sufficiently heavy armament for the battleships of the "Dreadnought" class; a proposal to place a fifth pair of guns on the middle line between the broadside guns and the aftermost pair of guns was finally adopted, the turrets on the broadside being placed abreast of each other instead of en échelon on account of the great increase of length and displacement involved.

The main features in which the "Dreadnought" differed from the "Lord Nelson" are:—(1) The all-one-calibre big gun armament in place of the mixed armament of 12-in. and 9-2-in. guns. (2) The increase of 3 knots in speed. (3) The height of freeboard provided forward to enable the vessel to fight her bow guns at high speed in a sea way. (4) Great increase in manœuvring power due to fitting twin rudders behind propellers.

The weight of the armament of the "Dreadnought" is the same as that of the "Lord Nelson"; it is 30% greater than that of the "King Edward VII." the 1,400 tons increase of displacement (about 8% of the displacement of the "Lord Nelson" and "King Edward VII.") being used in obtaining the increase of 3 knots of speed.

The general arrangements of guns and armour of the "Dreadnought" are shown in fig. 63, and on Plate XIII., fig. 64, a photograph of the vessel is given. She was built and tested as rapidly as possible, her keel was laid on the 2nd of October 1905, she was launched on the 10th of February 1906, King Edward VII. himself performing the christening ceremony and starting the vessel down the ways; and she went to sea, for steam, gunnery and torpedo trials, on the 1st of October 1906, one year after the laying of the keel. The whole of the trials were completed in a short time, and the machinery realized the expectations as to power and smoothness of running, and a speed of 21-6 knots was obtained on the measured mile, with an expenditure of power well within the capacity of the boilers. She left England for a long experimental cruise on the 5th of December 1906.

Immediately after the trials of the "Dreadnought," three other vessels, the "Bellerophon," "Temeraire" and "Superb," of 18,600 tons were begun, the additional 700 tons in displacement being absorbed in additional armour protection and an improved anti-torpedo-boat armament consisting of sixteen 4-in. guns. In 1907 and 1908 the "St. Vincent," "Collingwood" and "Vanguard" of 19,250 tons displacement were begun, in which further additions to the armour protection were made. These were followed by the "Neptune," "Hercules" and "Colossus," of about 20,000 tons displacement, laid down in 1909, the additional 800 tons lengthening the ships and enabling the 12-in. guns on the broadside to be placed en échelon and the second pair of guns from aft to be lifted high enough to fire over the aftermost pairs of guns; the whole of the main armament being thus able to fire on either broadside and eight guns to fire astern. Each of these vessels was completed in two years from the date of laying the keel. See Table XV.

On the 29th of November 1909 the "Orion," the leading vessel of what in 1907 was the most recent group of
"Dreadnoughts," was laid down at Portsmouth, and the following vessels of the group (the "Thunderer," "Monarch" and "Conqueror") were ordered to be built in the private yards of the Thames Iron Works, Sir W. G. Armstrong & Co. on the Tyne, and Beardmore & Co. on the Clyde a few weeks later. In these vessels there is a considerable increase in displacement, amounting to 2500 tons or 123% beyond that reached in the preceding group, their displacement being 22,500 tons on a length of 45 ft. between perpendiculars. The additional displacement has allowed the whole of the turrets to be placed on the middle line, the side armour to be raised to the upper deck, and heavier guns to be carried.

Great Britain thus had in 1910 fourteen "Dreadnoughts" built and building, not including the "Dreadnought" cruisers described later on under cruisers.

In the first seven vessels—Dreadnought, Bellerophon, Temeraire, Superb, St. Vincent, Collingwood and Vanguard—six 12-in. guns could fire directly ahead and six the British navy, elicited some hostile criticism. Its justification lay in the fact that all the world followed the lead. The 22,500 tons of the "Orion" was not acceptable in 1904, but her design was practically that advocated by Lord Fisher when he took office as First Sea Lord in October 1904 after certain modifications had been made as the result of investigations at the Admiralty.

The general growth of the fleets of British and foreign powers is dealt with in the article NAVY. Some details may be given here of foreign battleships.

United States—In 1886 the "Texas," designed by the late Mr. William John, was laid down. On a displacement of 6315 tons she carried an armament of two 12-in. and six 6-in. guns at a speed of 17 knots—the 12-in. guns being mounted in two turrets placed directly astern, and eight could fire on the broadsides. In the next three—Neptune, Colossus and Hercules—six 12-in. guns could fire ahead, eight could fire astern, and the whole ten could fire on either broadside. In the last four—Orion, Thunderer, Monarch and Conqueror—four guns could fire ahead, four astern and the whole ten on either side.

She was launched on the 20th of August 1910.

Fig. 81.—Norwegian Norge.

Fig. 98.—Chilean Chacabuco.
Fig. 66.—U.S.A. Illinois.

Fig. 70.—German Kaiser Frederick III.
The first two American " Dreadnoughts," the " Michigan " and " South Carolina," were laid down in 1906; they are 450 ft. long, 80 ft. 3 in. beam, displacement 16,000 tons and draught 24 ft. 6 in. when carrying 900 tons of coal, increasing to 17,620 tons and 27 ft. draught when fully loaded. Length is increased for 18-5 knots, and the armament consists of eight 12-in. guns mounted in four pairs, two pairs forward and two pairs aft, all on the middle line and arranged so that the guns of the second pair sweep over the turrets of the first and vice versa. Four 8-in. guns are mounted in one turret: an anti-torpedo boat armament of twenty-two 14-prd. guns is provided, but no secondary armament. The sides and barbettes are protected by Krupp steel, and the protective deck is of 2O,000 I.H.P.; on trial the " Delaware " developed 28,578 I.H.P. and recorded a speed of 21-56 knots, while the " North Dakota " reached 31,826 I.H.P. and 22-25 knots. Parsons turbines were adopted for the four battleships laid down. The first two, the " Florida " and " Utah," commenced in 1909, are very similar to the " Delaware," but of 21,825 tons displacement and 28 ft. 6 in. mean draught. The second pair, the " Arkansas " and " Wyoming," begun in 1910, are of much greater displacement, 40,000 tons; 8100 tons greater than the Dreadnoughts and 3500 tons greater than the " Delaware." Both are designed with the main batteries, 12-in., in the central line, and have a beam of 93 ft. and the same mean draught of 28 ft. 6 in. have been accepted. Turbines of 33,000 H.P. are provided for a speed of 20-5 knots, four propellers being as in H.M.S. " Dreadnought." The coal to be carried on trial has been increased to 47,000 tons, and the vessels are to be provided for 10,000 tons in preceding vessels. Twelve 12-in. and twenty-one 5-in. guns are carried on the main deck and in the turrets above, and the forward and after pairs are provided with ten 3-in. guns each. The machinery is of 19,000 I.H.P., provided for a speed of 19 knots, and both were exceeded on the trials of the vessels. They carry 900 tons coal on the trial draught, and when fully loaded with 1900 tons have a draught of 26 ft. This comparatively shallow draught is a distinctive feature of all the early United States battleships, but in later years a notable increase of draught was accepted. Between the "Kearsarge" and the " Georgia " were built in 1869-1898 the " Alabama " and " Illinois " (fig. 66, Plate XVI.), and " Wisconsin," somewhat similar to the " Kearsarge," carrying four 13-in. guns and fourteen 6-in. guns, and in 1890-1901 the second "Maine," the " Missouri " and " Ohio," which more nearly resembled the " Georgia," as they carried 12-in. guns for their main armament. The " Georgia " class was followed by two much larger vessels the "Connecticut " and " Louisiana," laid down in 1901; they were 450 ft. long, 26 ft. 10 in. beam, 17,000 tons displacement and 24 ft. 6 in. draught when loaded with 1000 tons coal, and 26 ft. 9 in. draught when loaded with full complement of ammunition and stores and 2200 tons coal; and they mounted a great advance in fighting power. While retaining four 12-in. guns for the main armament, they carried eight 8-in. and twelve 7-in. guns as a secondary armament, and they were well protected, guns and armour being arranged as in the previous class. They were the last of the "Preussen" class and were started for 19,000 I.H.P., were provided for a speed of 18 knots, and both were considerably exceeded on trial. In these and later American vessels tall towers of open lattice-work, somewhat resembling the Eiffel Tower, were fitted instead of hollow steel masts for supporting signal and fire-control arrangements.

While the vessels of the "Connecticut " class were building in 1904, two other very similar but smaller vessels, the "Idaho " and "Mississippi," were also laid down, of 13,000 tons with reduced armament and armour and less speed.

In 1895 Germany had one first-class battleship, the "König Wilhelm," of 967 tons displacement, and four smaller vessels, the "Baden," "Baden II.," "Sachsen," and "Württemberg," of 7400 tons each. The "Kaiser" and "Deutschland," central-battery ships designed by Sir Edward Reed, and two turret ships, the "Freiheit," and F. der Grosse," followed shortly afterwards. The "Kaiser" and "Deutschland" were laid down for a displacement of 7600 tons, 8000 I.H.P. and 14 knots speed; were armed with eight 22-ton guns and one 18-ton gun, and had side armour of a maximum thickness of 10 in. The vessels of the "Preussen " class were large ships of the "Monarch " type, 308 ft. in length and of 6750 tons displacement and 14 knots speed, with belt armour of a maximum thickness of 91 in. and turret armour 81 in.

In 1891 an advance was made by laying down the "Brandenburg " class of 9901 tons, carrying six 11-in. guns in three barbettes, one forward and one aft, and one on the middle line amidships. They were followed by the five first-class "Preussen " class vessels, the last of which, the "Kaiser Friedrich II. " (fig. 70, Plate XVI.), was finished in 1900. They are of 10,000 tons displacement, length 377 ft., beam 66 ft. 10 in., draught 25 ft. 9 in., 13,500 I.H.P. and 18 knots speed. They have belts of Krupp steel extending from the after
barbette to the stem, with a maximum thickness of 12 in., tapering to 6 in. at the bow; there is no side armour above this belt. The main armament consists of four 5-9-in. guns, placed in pairs in barbettes, one forward and one aft, protected by 10-in. armour. On the main deck they have four 5-9-in. Q.F. guns in 6-in. armoured casemates, two on each side; and on the upper deck they have eight similar guns, protected in like manner, and six others in turrets—three each side; in all, eighteen 5-9-in. guns, besides twelve 3-5-in. and smaller guns. There are five vessels of the "Wittelsbach" class, a development of the "Kaiser Friedrich III."; they have 700 tons more displacement, 15 ft. longer and 11 ft. more beam, but are of shallower draught. They have engines of 15,000 H.P., and a speed of 19 knots, or a knot more than their predecessors. Their armament is the same, but the 9-4-in. guns are better protected. The main armour belt is somewhat longer, but in other respects the thicknesses and general disposition of the protection are similar to the "Kaiser Friedrich III." class.

In the next five vessels, the "Braunschweig" class, laid down in 1901-1902, the 9-4-in. guns were replaced by 11-in. guns for the main armament; and the eighteen 5-9-in. guns were replaced by fourteen 6-7-in. guns for the secondary armament. The displacement was increased to 12,988 tons, the speed of 18 knots was maintained, and the armour protection practically as in the preceding vessel.

**FIG. 67.—Arrangement of Guns and Armour of U.S. "Connecticut."**

The "Nassau," the first of the German "Dreadnoughts" laid down in 1907, was 455 ft. in length and of 18,200 tons displacement, and carried an armament of twelve 11-in., twelve 5-9-in. and sixteen 3-4-in. guns, had an armour belt of Krupp steel 11 in. in thickness, 1.1 H.P. 22,000 for 19 knots and speed on trial 20-7 knots. Fosen (fig. 71, Plate XVII.), "Rhönland" and "Westfalen" of the same type were also laid down in 1907 and were built and completed for sea with extraordinary rapidity. The "Westfalen" attained 20-25 knots on trial with 26,792 H.P.

The next three vessels, "Thüringen," "Helgoland" and "Östfriesland,” laid down in 1908, are provided with twelve 11-in. guns arranged as in H.M.S. "Neptune"; they are of 22,130 tons displacement and 25,000 I.H.P. for 19-5 knots speed (probably at continuous sea speed; a measured-mile speed of 21 knots is expected); they are protected by 12-in. Krupp steel armour; their dimensions are: length 480 ft., beam 98 ft., draught 27 ft. 6 in. These vessels laid down in 1910 were said to be still larger.

**France.**—For many years the French designers favoured the placing of the four heavy guns of their battleships in separate barbettes—a 12-in. gun at each end and a 10-8-in. gun on each side of the vessel amidships, intermediate positions being arranged for the smaller guns. Such vessels as the "Carnot," "Charles Martel," "Jaureguy-Berry," "Masséna," "Bouvet" approximating to 12,000 tons displacement, and built in the nineties, were so arranged. These were followed by a series of vessels in which the 12-in. gun alone was accepted for the main armament, and two pairs were fitted, one forward and one aft as in British vessels; the "Gaulois," "Charlemagne," "St. Louis" and "Suffren" were so arranged. The "Suffren," commenced in 1899 (displacement 12,728 tons, length 410 ft., beam 70 ft. and draught 27 ft. 6 in.), had a complete water-line belt of Harveyized steel armour of 11 in. maximum thickness, and above this, up to the main deck, similar armour, 5 in. thick, extending from the after turret to the bow; she also had a short armoured battery on the main deck which enclosed the funnel and was connected to the main armament by one twin and one single gun, each carrying two 12-in. guns, and six arranged three on each broadside, each carrying a 6-4-in. gun. The armament of the largest turrets was of the same thickness as the armour belt, namely, 11 in., and that of the smaller turret 9-5 in. guns on the superstructure, and also had twenty-two smaller guns and four torpedo tubes, of which two were submerged. She was named the "L'Impératrice." The "République," laid down in 1901, and the "Patrice," laid down in 1902, were superior in speed and armament to any British battleships then building. They had a displacement of 14,856 tons, and were of 439 ft. length, 79 ft. 6 in. beam, and 29 ft. 9 in. draught. They had three screws, and a nominal I.H.P. of 17,500 for a speed of 18 knots; but on trial these were considerably exceeded. The "Patrice" reporting 19,000 I.H.P. and 19-47 knots. They carried four 12-in. B.L. guns in pairs on the midship line, as in the British ships, twelve 6-4-in. Q.F. guns in pairs in turrets on the upper deck, six additional 6-4-in. Q.F. guns in casemates on the main deck, twenty-six 3-pdr., three above-water and two submerged torpedo tubes. There was a complete water-line belt of a maximum thickness of 12 in., the bow was protected by 4-in. armour and there was a partial 4-in. belt above the 12-in. belt. The protective deck was 4 in. thick on the slopes, and the armour of the main turrets 12 in., the whole armour being of Harvey quality. Four later vessels of the class, "Justice," "Démocratie," "Liberté," and "Vérité," were given a still more powerful secondary armament of 7-6-in. guns—six placed in well-protected turrets at the bow, at the after part of the deck, and four in casemates between the decks. Six vessels, the "Courbet," "Danton," "Hatsuse," "Diderot," "Mirabeau," "Vergniaud" and "Voltaire," were laid down in 1907. All had Parsons turbines of 500 I.H.P., and a speed of 19-25 knots, and their main armament consisted of four 12-in., and twelve 9-4-in. guns, as shown above. The later French ships, "Courbet" and "Jean Bart" carry twelve 12-in. guns in six pairs, two forward and two aft on the middle line, one pair training over the other, and one pair on each side amidships as in "Dreadnought." They are of 23,000 tons displacement and 20 knots speed, and have an anti-torpedo boat armament of twenty-two 5-5-in. guns, all in casemates of 7-in. armour.

**Japan.**—Previous to the Russo-Japanese War Japan had provided herself with a number of excellent battleships built in Great Britain, such as the "Fuji" of 12,450 tons displacement, four 12-in. Guns Ironworks in 1894, the "Hatsuse," built at Elswick, the "Asahi," built at Clydebank, and the "Shikishima," built at the Thames Ironworks, all of about 15,000 tons displacement and laid down in 1897-1898. The dimensions of these vessels were: length 400 ft., beam 75 ft. 6 in., mean draught 27 ft. The I.H.P. was 15,000, giving a speed of 18 knots. The armouerbelt extended the full length of the ship at the water-line, and had a maximum thickness of 9 in.; between the top of the belt and the main deck, for a length of some 220 ft., was an upper belt 6 in. thick, which was continued by oblique bulkheads to the sides of the heavy-gun barbettes. The turrets were all twelve 6-4-in. guns, and one each side amidships and one aft, had armour 14 in. thick, and the conning-tower also was 14 in. thick. The armament consisted of four 12-in. 49-ton B.L. guns, two mounted in each barbette and loading in any position of training; fourteen 6-4-in. Q.F. guns in casemates on the main deck and six on the upper deck; and twenty 3-pdrs., besides smaller guns and four submerged torpedo tubes. The "Mikasa," laid down at Elswick, is a development of the "Hatsuse" class design, being 200 tons heavier and 6 in. more in draught. The principal difference was that the eight 6-4-in. Q.F. guns on the main deck were increased to ten in number, and instead of being in the casemates below, in a 6-in. armoured central battery, with 2-in. divisional screen bulkheads. The "Hatsuse" was destroyed in the war by a mine explosion; and the "Mikasa" was seriously damaged by mines. After the war she was accidentally sunk on the 10th of September 1905; she was, however, refloated on the 8th of August 1906, repaired and recommissioned. The Japanese fleet in 1910 contained
several vessels which were captured from Russia during the war, such as the “Iwami” of 15,515 tons (late “Orel”), the “Hizen” of 12,275 tons (late “Retvizan”), the “Segami” of 12,790 tons (late “Perevez”), the “Suwo” of 12,997 tons (late “Pobeda”), the “Tango” of 10,960 tons (late “Poltava”), and the “Iki” of 9700 tons (late “Imperator Nikola I”). The “Suwo”

24,000 H.P. are provided for a speed of 20 knots. It is noteworthy that this vessel was laid down on the 15th of May, 1905, while the “Lord Nelson” of 16,400 tons was not laid down until the 18th of May, 1905 and the “Dreadnought” of 17,900 tons not until the 2nd of October, 1905. The “Aki” also exceeds in displacement the “St Vincent,” laid down in 1907-1908, and her tonnage was not reached in Great Britain until 1909, when the “Neptune” was laid down. The “Aki” was followed by still larger vessels, the Kawachi and “Settsu,” both of 20,800 tons. The “Kawachi” is thus 900 tons greater than the Neptune, and she was laid down one day before that vessel. The general arrangement of armament and guns of these large vessels is shown in fig. 74: they are protected by armour of 12 in. to 5 in. in thickness, and in addition to twelve 12-in. guns they carry ten 6-in., twelve 4-7 in. and four 3-5 in.

Russia maintained in 1910 two fleets, one being in the Black Sea, prevented by treaty from passing through the Dardanelles, and the other, the main Russian Fleet, in the Baltic.

In 1882 three remarkable vessels were laid down for the Black Sea Fleet, the “Catherine II,” “Tchesma,” and “Sinope.” They were barbette ships of 10,180 tons displacement, with a compound armour belt of a maximum thickness of 16 in., armed with six 12-in. B.L. guns mounted in pairs on the upper deck in a large pear-shaped barbette, and seven 6-in. guns on the main deck; and having a speed of 16 knots. Other vessels built for this fleet were the “Twelve Apostles” of 8709 tons, the “George the Victorious,” 11,032 tons, the “Three Prelates,” 13,318 tons, the “Rostislav,” of 8800 tons laid down in 1895 and the “Panterleimon” of 12,682 tons laid down in 1897. The latest vessels built on the Black Sea are the “Ioann Zlatoust” and “Evstafi,” of 12,849 tons and 16 knots, carrying four 12-in., four 8-in., twelve 6-in., fourteen 12-pdr. and six 3-pdr. guns; both were laid down in 1903.

Of the main Russian Fleet outside the Black Sea only a few battleships survived the Russo-Japanese War; these included the “Pastorevich” of 13,000 tons, built in France in 1899, carrying four 12-in. guns in two barbettes, and twelve 6-in. guns in pairs in turrets; also the “Slava,” laid down on the Neva in 1902, 370 ft. long, of 13,516 tons displacement, 16,000 I.H.P. and 18 knots speed, her hull protected by armour of 9 in. to 4 in. in thickness. The “Slava” carried four 12-in. guns in barbettes having 10-in. armour, and twelve 6-in. guns in turrets having 6-in. armour.

In January 1903 Russia laid down the “Imperator Pavel I.” a larger and more powerful vessel than any then building by any other power, being of 17,400 tons displacement—almost that of the
“Dreadnought,” but laid down 2½ years earlier; she carries four 12-in. and fourteen 8-in. guns as well as twelve 4-7-in. guns arranged as shown in fig. 75, from which it will be seen that an attempt was made to protect almost the whole of the vessel above water with armour varying from 8¾ in. to 3 in. in thickness. Engines of 17,600 I.H.P. are provided for 18 knots speed. A sister vessel, “Andrei Pervozvannii,” was also laid down in 1903, but neither vessel was completed in time to take part in the war. In 1909 four vessels were laid down, which were again larger than any then building for any other power, viz. the “Sevastopol,” “Petropavlovsk,” “Gangut,” and “Poltava,” of 23,000 tons displacement, with Parsons turbines of 42,000 H.P. for 23 knots speed, 600 ft. long, 89 ft. beam, 27 ft. 3 in. draught, protected by 11-in. armour, armed with twelve 12-in. and sixteen 4-7-in. guns, the 12-in. guns being carried in four three-gun turrets placed at considerable distances apart on the middle line.

Italy.—The Italian navy has always contained interesting vessels embodying the independent thought and skill of her own designers. The “Duilio,” launched in 1876, and the “Dandolo,” launched in 1878, were 340 ft. in length, 16,400 tons displacement, and carried four 100-ton M.I. rifled guns, mounted in two turrets and capable of penetrating 22-7 in. of iron at 1000 yds. They had a central citadel 107 ft. in length, protected by 21½ in. of steel armour, with 18-in. armour on the turrets. Their engines were of 7900 I.H.P., giving a speed of 15 knots. In the “Italia” and “Lepanto,” launched in 1880 and 1883 respectively, side armour was dispensed with, a curved 3-in. armour deck, with its sides 5½ ft. below the water-line, being fitted from stem to stern, with armour glacis protection to the funnel openings, &c. This, in this deck; they carried four 100-ton breech-loading guns mounted in two barbettes arranged so as to permit all four guns to fire ahead, astern or on either broadside as in “Inflexible”; their displacement was 13,500 tons, their length 400 ft., and they had engines of 15,000 I.H.P. designed to give a speed of 18 knots. They were followed by three of the “Andrea Doria” class of 11,000 tons, launched in 1885, 1886, and 1887 respectively, with four 105-ton breech-loaders, and protected by an 18-in. belt of compound armour; and by the “Re Umberto,” “Sicilia,” and “Sardegrina” of 13,250 tons, launched 1888 to 1891, and armed with four 67-ton B.L. guns having a penetration of 27 in. of iron at 1000 yds. In 1897 Italy launched the second-class battleships “Ammiraglio di Saint Bon” and the “Emanuele Filiberto” of 9800 tons and 18 knots speed, carrying four 10-in., eight 6-in. and eight 4-7-in. guns and armoured with 10-in. to 4-in. armour. These were followed by the “Regina Margherita,” laid down in 1898, and the “Benedetto Brin,” laid down in 1899, two vessels of 13,426 tons displacement and 20 knots speed, of good freeboard, carrying an armament similar to that of the “Duncan” and in addition four 8-in. guns; the 12-in. guns are protected by 10-in. armour, the 6-in. guns and the ship’s sides by 6-in. armour with 3-in. side plating forward and aft. Four very notable vessels were next laid down—the “Regina Elena” (fig. 76, Plate XVII.) and “Vittorio Emanuele III.” in 1901, and the “Napoli” and “Roma” in 1903, each one a displacement of 12,625 tons, carrying two 12-in. and twelve 8-in. guns and carrying 17½ in. of armour; they were armed with a large number of small quick-firing guns; their machinery of 20,000 I.H.P. is provided for 16 knots speed, and their hulls are cut down, giving reduced freeboard as compared with “Benedetto Brin,” and the hulls and machinery are built as lightly as possible. For several years no new design was adopted, but in 1909 the “Dante Alighieri” was laid down of 18,700 tons displacement, an increase of 50% over that of the preceding vessels. She was reported to be 492 ft. long, 79 ft. beam, carrying twelve 12-in., eighteen 4-7-in. and sixteen 3-1-in. guns, turbines of 30,000 I.H.P. being provided for a speed of 23 knots, and side armour fitted 9 in. thick amidships tapering to 6 in. forward and 4½ in. aft. Three later vessels, the “Conte di Cavour,” “Giulio Cesare” and “Leonardo da Vinci,” are of 22,000 tons, 35,000 I.H.P., 23 knots, and carry thirteen 12-inch guns.

Austria.—Until quite recently Austria has made no attempt to maintain battleships of the first class. Three small battleships, the “Monarch,” “Budapest” and “Wien,” were laid down in 1893-1894, of 5550 tons displacement and 17½ knots speed, carrying four 9-4-in., six 6-in. and twelve 3-pdr. guns, with armour 10½ in. to 4 in. in thickness. In 1899 four more vessels, the “Habsburg,” (fig. 77, Plate XVII.), “Arpad” and “Babenberg,” were begun, of 8340 tons displacement and 19 knots speed, carrying three 9-4-in., twelve 6-in. and several smaller Q.F. guns and well armoured. In 1901 it was decided to build the “Erzherzog Karl Friedrich” and “Ferdinand Max,” of 10,600 tons and 19 knots, carrying four 9-in., and small Q.F. guns as well as the “Monarch,” but with the secondary armament increased to twelve

7.4 in. guns all well protected, while the next step was to vessels of a type very similar to the "King Edward VII." class, but of greater gun power and higher speed, with somewhat thinner armour and smaller coal capacity. These vessels, "Erzerzog Franz Ferdinand, " "Rădetzky" and "Zrini, " were being completed in 1910. Their arrangements of guns and armour are shown in Fig. 78. Battleships of far greater fighting value were laid down by Austria; of 20,000 tons displacement, 25,000 H.P., and 22 knots speed, mounting ten 12-in. guns, protected by 11-in. armour, and costing about 21 million sterling each.

Brazil.—For several years by mutual arrangement no battleships were added to the South American navies, but in 1906 Brazil ordered three vessels of 19,281 tons, 1380 tons heavier than the "Dreadnought", and finished; the two older of this class carry twelve 12-in. guns in place of the ten of the "Dreadnought", and can fire ten guns on either broadside, eight ahead and eight astern; they also carry fourteen 4-7-in. guns behind 9-in. armament on main deck, and eight behind thinner armour on the upper deck. The ship's side, barbettes and gun mountings are protected by 9-in. armour, the belt armour tapering to 4-in. forward and aft. The vessels are 500 ft. long, 83 ft. beam and 25 ft. draught; engines of 23,500 H.P., being provided for 21 knots. The leading vessel, the "Minas Geraes" (fig. 79, Plate XVIII.), was built at Elswick; she obtained about 21 knots on trial, and passed through all her severe gun trials with great success. Fig. 80 shows the general arrangements of guns and armour. The second vessel, the "Sao Paulo," was built at Barrow, and was also completed to the same design. The third vessel, the "Rio de Janeiro," which in 1910 was being built by the Elswick firm, has been redesigned to be 655 ft. in length over all, 92 ft. beam and 32,000 tons displacement on a draught of 26 ft. Her armament was to be twelve 14-in. guns, with a secondary armament of fourteen 6-in. guns, an anti-torpedo armament of fourteen 4-in. guns, as well as a number of smaller guns, and three submerged torpedo tubes. She was fitted with four screws and turbines of 45,000 H.P. to drive her at 225 knots. Her cost was reported to be almost £2,000,000, and in 1910 she was by far the largest vessel on the stocks.

Argentine Republic.—Early in 1910 the Argentine Republic ordered two vessels, the "Moreno," and "Rivadavia," of 28,000 tons, armed with twelve 12-in. guns, twelve 6-in. and sixteen 4-in. guns, to be built by the New York Shipbuilding Co. and the Forc River Shipbuilding Co., respectively. Their displacement is much greater than that of the largest battleships building at the time they were ordered, although they are 4000 tons smaller than the "Rio de Janeiro." They are 578 ft. long, 96 ft. beam, 274 ft. draught, and tonnage of 40,000 H.P. for speed on 80,000 tons, only second to the two vessels as in "Minas Geraes," but with the midship barbettes arranged so that the guns can fire on either broadside, giving a fire of twelve guns on either broadside, eight ahead and eight astern. The ship's side and the heavy guns are protected by 12-in. armour, and the 6-in. guns by...
SHIP

have entirely disappeared. When the final adoption of iron led to the remodelling of the details of construction by Sir E. J. Reed, the new system of construction was applied to the cruisers of the day, but no attempt was made till much later to give these cruisers any protection, nor was the question of their armament given the importance which it afterwards came to have. Lord Armstrong was one of the first to recognize the importance of developing this class of vessel. He considered the essential features of a cruiser to be high speed, protection without the use of side armour, a powerful armament and minimum size and cost; and his views were adopted by the Elswick firm in a large number of cruisers built for foreign Powers down to the introduction of high explosives, when side armour was advocated in place of, or in addition to, the armour deck. The cruisers built for the British navy prior to 1886—of which the principal types were such vessels as the "Inconstant," of 5780 tons (1866); the "Active," of 3080 tons (1867); the "Raleigh," of 5000 tons (1871); and the faster despatch vessels "Iris" and "Mercy," of 3730 tons (1875)—had been almost entirely unprotected; and although the "Comus" and "Leander" enabled more efficient protection to be provided with a much thinner belt than had previously been possible. The Elswick cruiser "Esmeralda" (second), built for Chile in 1893, was one of the first in which the use of side armour was revived. She was followed by other vessels of the armoured type built by the same firm for the Chilean and Japanese navies. In 1898 the "Cressey" class (fig. 84, Plate XXII.) was begun for the British navy, and since this date all cruisers of 9000 tons and above for the British navy have been provided with side armour.

In the United States the adoption of armour belts of the new material for cruisers came somewhat earlier than it did in the British navy, the "Brooklyn" (fig. 84, Plate XXII.), built in 1895, being so protected; and the development of the type has been very marked in recent years, the tendency being to go to larger displacements, in order to provide greater protection and heavier armaments, with each new class of vessel. Indeed, the first-class armoured cruiser of 1910 might be very well described as a high-speed battleship.

In the British navy, as might be expected, the demand for vessels to meet the varied and diverse requirements that necessarily arise in a fleet of such magnitude has led to the production of a number of types, each adapted to its own special duties. They may be classified as (1) unprotected cruisers; (2) protected cruisers of first, second, and third classes; and (3) armoured cruisers. Unprotected cruisers have neither side armour nor other protection against loss of buoyancy from injury by shot and shell. Protected cruisers have vertical side armour, but they have horizontal armour decks with strong sloping sides in the vicinity of the water-line, upon which coal is carried in minutely divided bunker compartments. Armoured cruisers have side or vertical armour in addition to protective decks. Each of these classes includes a number of groups of sister ships, but we shall confine ourselves to describing the main features of a representative ship in a few of the most important groups.

The protected cruiser of medium displacement affords a convenient starting-point, as the latest vessels of this type in 1910 were of about the same displacement as the largest first-class cruisers of thirty years before, and a comparison of representative ships of these classes illustrates the great advances made in thirty years in ships of approximately the same size; while a further comparison of these second-class cruisers (as the vessels of medium displacement are styled) with the first-class protected cruisers of the present day shows the growth in size and power of the largest units of the cruiser type during the same period. It should, however, be noted that while some second-class cruisers reached such a displacement (5600 tons) as to allow of this comparison being made, the great bulk of the vessels of this class were smaller. The "Mersey" is an early example of a vessel of this class which has been considered as service. Began in 1883, her principal dimensions are: length 300 ft., beam 46 ft., mean draught about 20 ft., and displacement 4050 tons. Protection to the vital parts of the ship is provided for by means of a protective deck a little above the level of the water-line, 2 to 3 in. in

classes had been given a partial protective deck, the Elswick-built "Esmeralda" (1883) (fig. 82, Plate XXIII.) may be quoted as the first vessel in which the important features of a complete protective deck and good protection to the guns were combined with high speed and a powerful armament. On the other hand, the "Impéria" and "Warspite," completed in 1885, of much greater displacement than the "Esmeralda," were provided with a partial belt of 10-in. compound armour in combination with a protective deck. Thus the necessity for protecting cruisers led to the introduction of two types—the "protected" cruiser, of which the "Esmeralda" may be taken as the pioneer, and the "armoured" cruiser, of which the "Impéria" and "Warspite" are early representatives; but while in the British navy the "protected" cruiser type was repeated and developed, the "armoured" type was discontinued, and with the exception of the "Orlando" class, built shortly afterwards, the whole of the cruisers built for the British navy for another fifteen years were of the "protected" type. In France and Russia, however, the armoured cruiser continued in favour, the "Dupuy de Lôme" of 1890, for the former, and the "Rurik" of 1892, for the latter, being vessels of this type.

The reintroduction of side armour in British-built cruisers came about when the improvement of armour by the development of the Harvey and Krupp processes of manufacture

Fig. 80.—Arrangements of Guns and Armour of "Minas Geraes."
thickness, in combination with a system of coal-stowage in bunkers along the water-line. She carried two 8-in. and ten 6-in. B.L. guns and four torpedo tubes. Her horse-power was 6000 (forced draught) and her displacement, 5800 tons. She could keep going at 12 knots, with a draught, with capacity for 900 tons of coal. The "Astraea," begun in 1899, may be taken as representing the second-class cruisers of that date. She is built of steel, sheathed and coppered, 450 ft. long, 53 ft. 8 in. beam, 25 ft. 6 in. mean draught, and carries two 6-in. Q.F. guns and eight 4.7-in. Q.F. guns, all on the upper deck and protected by shields, together with four torpedo tubes, two 10-in. and two 8-in. arc, and two cofferdams, which project through this deck, are shielded by 5-in. sloping coamings. The coal bunkers in the neighborhood of the water-line are minutely subdivided, and the stowage is arranged in such a way that in case one section should develop 9000 H.P. (under forced draught) and her speed is 19 knots.

Her coal stowage is 1000 tons.

The "Hermes" (fig. 85, Plate XX.) is one of the largest second-class cruisers in the world. She is 350 ft. long, 54 ft. beam, 20 ft. 6 in. mean draught, and 6500 tons displacement. She presents a striking contrast compared with the "Inconstant," built in 1866, of almost the same displacement. The "Inconstant" was fully rigged, and sailed almost as fast as she steamed; while the "Hermes" has no sail, and steams 20 knots, or 6 knots faster than did the older vessel. The "Inconstant" was entirely unprotected, except the 6-in. sides, whilst the "Hermes" is fully protected by a steel deck 1 ft. 3 in. thick, besides having coal protection. The "Inconstant"'s" main armament consisted of ten 9-in. and six 7-in. guns, and one 6-in. Q.F.; the "Hermes" of twelve 6-in. Q.F. guns, firing probably ten rounds to one of the "Inconstant"'s 9-in., and with a perforation of wrought iron of about one-third as much again. The "Hermes" is built of steel, sheathed and coppered. She carries also eight 4.7-in. Q.F. guns, and two 3-pdr.s, and two submerged torpedo tubes. She has Belleville boilers, developing 10,000 H.P., and giving her a speed of 20 knots.

She is a beautiful ship. The "Hermes," in external appearance, the four vessels of the "Arrogant" class (fig. 86, Plate XX.) possess certain features of special interest which distinguish them from all other second-class cruisers, in which class they are usually included. They are divided into three decks instead of two; the 320 ft. length, 25 ft. 8 in. beam, 15 ft. 6 in. mean draught, of which the "Diadem," built in 1895, is of 11,000 tons displacement, 435 ft. length, 69 ft. beam, 25 ft. 3 in. mean draught, and is adopted as the basis of the "Arrogant" class. That vessel consists entirely of 6-in. Q.F. guns, of which there are sixteen, twelve being protected by 5-in. casemates of Harveyzed steel, and the others disposed, two on the forecastle as bow chasers, and two on the quarter deck as stern chasers, all armament is protected by a steel deck 1 ft. thick, upon which is stowed the 1000 tons of coal which the vessel ordinarily carries, the full coal capacity being 2000 tons. She is provided with 32 water-tube boilers of the Belleville type, and her machinery develops 16,000 H.P., giving her a speed of 20.5 knots. The Canadian cruiser "Niobe" is one of the first four; in the last four ships the casemates are 6 in. thick, and the machinery is of greater power, viz. 18,000 H.P., giving a speed of a quarter of a knot faster.

Third-class protected cruisers included vessels varying in displacement from 1500 to 3000 tons. With a reduction of displacement comes a reduction in cost. Fifth-class cruisers, intended mainly for the protection of merchant ships, cost about $100,000 each, with a crew, a shorter time for building, and the many advantages attendant upon reduced size and draught of water. It has been found possible to embody in a ship of about 2000 tons displacement many of the features of the cruiser, and a large number of vessels of this class have been added to the fleet. Among these may be mentioned the "Barham," a typical small cruiser, which was built in 1889 of steel, of 1830 tons displacement; she is 280 ft. long between perpendiculars and 36 ft. 9 in. beam, and 12 ft. 8 in. draught of water. As originally completed, this vessel had cylindrical boilers and a H.P. of 4700, giving a speed of 17.5 kts. In 1898, her machinery was improved by being reboilered with water-tube boilers of the Thornycroft type, and with these a H.P. of 6000 is obtained, and the vessel reaches a speed of nearly 20 knots. The protection afforded by this is considered remarkable. The "Arrogant" class, two 10-in. Q.F. guns, one 8-in. Q.F., one 6-in. Q.F., and one 4.7-in. Q.F., all on the flat, and sloping sharply downwards near the water-line, where the thickness is increased to 2 in.; and above this deck the coal stowage is stowed in small ventilated bunkers. She carries an armament of six 4.7-in. Q.F. guns in shielded casemates, four torpedo deck, four 3-pdr.s, two machine guns and two above-water torpedo tubes. She carries 140 tons of coal in her normal condition, and her machinery develops 16,500 H.P., giving her a speed of 20 knots. The "Barham" was followed by several vessels of the "Tauranga" class, built for service in Australian waters, and the "Pearl" class for service in other waters, all of 2500 tons displacement, 19 knots speed, and 2500 H.P. for each vessel. In 1866-1869 nine smaller and faster cruisers were laid down, known as the "Pioneer" class, which might be taken to include the "Astraea" and the "Diadem" class, with the differences between them being small. These two classes were built in succession, the "Pioneer" class being 245 ft. long, 36 ft. 9 in. beam, 13 ft. 6 in. mean draught and of 2200 tons displacement. She has water-tube boilers of the small-tube type.
and engines of 7000 H.P., giving her a speed of 20 knots. She carried 2500 tons above the displacement, and has stowage for 550 tons. She has eight 4-in. Q.F. guns, eight 3-pdr.s, and two above-water torpedo tubes, and a 2-in. protective deck.

This type of cruiser reached its final development in the four vessels of the "Drake" class, laid down in 1902-1903, which were the last third-class cruisers designed by Sir William White. Three of the vessels, "Diamond," "Sapphire" and "Topaze," were fitted with compound engines of 9800 I.H.P. for 22 knots, and in the fourth, the "Amethyst," Parsons turbines were fitted. All were 360 ft. long, 40 ft. beam, 14 ft. 6 in. draught, and carried twelve 4-in. and eight 3-pdr. Q.F. guns. On trial the "Topaze," reached a maximum speed of 22 knots, while the "Amethyst," obtained 23-65 knots, an advantage of 1-38 knots per hour for the turbine with practically the same coal consumption, and with a distinctly lower rate of coal consumption at equal speeds for all speeds above 14 knots. This performance was regarded as a great success for Parsons turbines, and materially influenced the question of their adoption in succeeding vessels at home and abroad.

The "Drake," of 26,700 tons displacement, viz., the "Pathfinder," "Patrol," "Sentinel" and "Skirmisher," of about 2900 tons displacement, and 25 knots speed; 370 ft. long, with engines of 17,000 I.H.P., and carrying ten 12-pdr. and eight 3-pdr. Q.F. guns as well as two torpedo tubes. Two others laid down in 1903 were named "Forward" and "Foresight," and carried fourteen 12-pdr.s, and two 3-pdr.s, and obtained the 25 knots with 15,000 I.H.P.

The last two of the series — "Adventure" and "Attentive" (Fig. 89, Plate XIX.) — of 16,000 I.H.P. and 26 knots, were laid down at Elswick in 1904; they were 374 ft. long, 38 ft. 3 in. beam, 15 ft. 6 in. draught, and 2670 tons displacement, 16,000 I.H.P., carried ten 12-pdr.s and eight 3-pdr.s.

Four vessels, named "Boadicea," "Bel- longa," "Blanche" and "Blonde," were laid down in 1907-1909, of slightly larger dimensions, the "Blonde" being 385 ft. long, 41 ft. 6 in. beam, 13 ft. 6 in. draught, 3360 tons displacement, 18,000 I.H.P., 25 knots, and armed with ten 4-in. Q.F. guns and two torpedo tubes.

In 1909 five vessels of 45,900 tons displacement, 22,000 I.H.P., 25 knots speed, carrying two 6-in. and ten 4-in. Q.F. guns, with two torpedo tubes, were laid down and known as second-class protected cruisers of the "Drake" class. They are 430 ft. long, 60 ft. beam, 21 ft. 3 in. draught and protected by a 1-in. steel deck with 2-in. slopes. Fig. 90, Plate XIX., shows the "Newcastle," a vessel of this class built at Elswick. Four other vessels, the "Hannibal," "Hercules," "Hastings" and "Hastings," laid down six months later, were very similar, but slightly larger to give one knot more speed. The navy estimates for 1910-1911 provided for laying down five larger vessels of this type. The Australian cruisers "Melbourne" and "Sydney" are of the "Hannibal," class, while the new Canadian cruisers are of the later type.

Between 1870 and 1881, several armoured cruisers were laid down for the British navy, the most notable being those in England being the Armoured cruisers. "Chanak," of 5390 tons and 12 kts., laid down in 1873, the "Nelson" and "Northampton," of 2670 tons and 13 kts., laid down in 1874, and the "Impérieuse" and "Warspite," laid down in 1881. The two last-mentioned ships were provided with masts and a good spread of sails, and were the last large vessels to be so fitted for the British navy. The sails were not found to be of much service and were removed. These vessels were of 6400 tons displacement, 315 ft. long, and were protected by a partial belt amidships of 10-in. compound armour over a length of about 140 ft., with a protective deck above it 1 1/2 in. thick and transverse bulkheads at the ends of the belt 9 in. thick, the protective deck from the bulkheads to the ends of the ship being 3 in. thick. They had machinery of 10,000 H.P. and a speed of 16 1/2 knots. They carried four 9-2-in. B.L. guns in separate barbettes—one forward, one on each quarter—the bow barbette being armed with four smaller and machine guns, and six torpedo tubes. They were sheathed with wood and coppered, in order to be able to keep the sea for a long period without docking. The next vessels of the type were the "Drake," class, begun in 1885. Seven of these were launched in 1886 and 1887. They were much smaller than the laid down in 1899, were for several years the largest and fastest armoured cruisers afloat. They are of 14,100 tons displacement, 380 ft. long, 71 ft. beam, and 26 ft. mean draught. They are unarmoured, are protected by a Krupp steel 6-in. belt extending from barbette to barbette, and from 6 ft. below water to the height of the main deck, completed at the after end by a 5-in. bulkhead, and carried forward to the bow by 2-in. plating extending right up to the upper deck. There are two protective decks, the lower, being 5 in. to 2 in. in thickness, and the main deck, which is 1 in. thick. Their armament consists of two 9-2-in. B.L. guns in barbettes and gun-houses 6 in. thick on the middle line forward and aft, twelve 6-in. Q.F. guns in 6-in. casemates, and twenty-five 12-pdr.s, and larger guns, with two submerged torpedo tubes. Their H.P. is 21,000 with natural draught, steam being supplied by 30 Belleville boilers, and their speed is 21 knots. They carry 800 tons of coal at normal draught, with capacity for 1600 tons.

The four vessels of the "Drake" class (see Fig. 91, Plate XXIV.), "Impérieuse," being only 5600 tons displacement, 300 ft. long and 56 ft. beam, and 22 ft. 6 in. draught. They had a water-line belt of compound armour, 10 in. thick and nearly 200 ft. long; extending over the top of this, and sloping down forward and aft to the ends of the ship, was a deck 3 in. to 3 1/2 in. thick. Their armament consisted of two 9-2-in. B.L. guns—one forward and one aft instead of the four carried in the "Impérieuse" and "Warspite," but in other respects the same armament as the latter ships. They had engines of 4500 H.P. and a speed of over 18 knots. These vessels were all built from the designs of Sir N. Barnaby.

As already stated, between 1885 and 1898 no armoured cruisers were laid down for the British navy. The "Cressy" (Fig. 83, Plate XXIV.) class, commenced in 1894, consists of six vessels of 12,000 tons displacement, 440 ft. length, 69 ft. 6 in. beam, and 26 ft. 3 in. mean draught. They are built of steel, sheathed and coppered, have a belt of Harvized steel 11 ft. 6 in. wide, 250 ft. long, and 6 in. thick, with bulkheads 5 in. thick and 2 in. protective plating on the sides from the forward bulkhead to the stem. They carry two 9-2-in. B.L. guns in barbettes and gun-houses 6-in. thick, mounted on the middle line forward and aft, twelve 6-in. Q.F. guns in 6-in. casemates, and twenty-five 12-pdr.s, and smaller guns, with two submerged torpedo tubes. Their H.P. is 21,000 with natural draught, steam being supplied by 30 Belleville boilers, and their speed is 21 knots. They carry 800 tons of coal at normal draught, with capacity for 1600 tons.
great sea-keeping power and were superior in all respects to the vessels which caused them to be built. The first set comprised ten vessels of the "Monmouth" class, laid down in 1900 and 1901. Fig. 93 (Plate XXI.) gives a view of the "Cornwall," which may be taken as typical of the class. They are of 9800 tons displacement, length 440 ft., beam 66 ft., mean draught 24 ft. 6 in. They are armoured with a belt of 6 in. of Krupp steel over the main part of the length, diminishing in thickness towards the extremities; they carry fourteen 6-in. Q.F. guns, of which ten are in 4-in. casemates, and the others mounted in pairs in turrets and gun-houses 4 in. thick, forward and aft; they also carry ten 12-pdr., eleven small and machine guns and two submerged torpedo tubes. Their horse-power is 22,000, giving them a speed of 23 knots.

They were followed by six vessels of the "Devonshire" class, laid down in 1902, which were given greater gun power and better armour protection to meet the corresponding advances in foreign vessels. They were of 10,850 tons displacement, 21,000 H.P. and 23 knots speed; were armed with four 7-5-in. and six 6-in. Q.F. guns protected by 6-in. armour, and the armour belt was increased from 4 in. to 6 in. in thickness. These were the last armoured cruisers designed by Sir William White.

The next armoured cruisers built for the British navy, the six vessels of the "Duke of Edinburgh" type, laid down in 1903-1904, were of much greater power, of 13,550 tons displacement, 23,500 I.H.P. and 23 knots speed, and have a main armament of six 9-2-in. guns, mounted singly in barbettes. The secondary armament consists of ten 6-in. Q.F. guns in the first two vessels of the class, but in the remaining four vessels the ten 6-in. guns are replaced by four 7-5-in. guns. They also carry from twenty-five to twenty-nine 3-pdr.s and machine guns and three torpedo tubes. The guns and ship's side are protected by 6-in. armour. In 1903 the "Minotaur" class (fig. 94, Plate XXI.) was laid down, consisting of three vessels of 14,600 tons displacement, 27,000 I.H.P. and 23 knots speed, carrying an armament of four 9-2-in. guns mounted in pairs in 7-in. barbettes forward and aft, and ten 7-5-in. guns all on the upper deck in shallow barbettes of 6-in. armour, with 6 in. enclosed shields. The belt armour is 6 in. thick amidships, tapering to 4 in. forward and 3 in. aft. These vessels are 490 ft. long, 74 ft. and 75 ft. beam, 25 to 26 ft. mean draught, and are the last large cruisers to be propelled by reciprocating engines, or to be armed with 9-2-in. guns. They carry 1000 tons of coal on the load draught, and can stow 2000 tons of coal besides 700 tons of oil fuel.

The next cruisers to be built were the "Invincibles," which might have been classed as battleships on account of their heavy armament and substantial armour protection; the former greatly exceeding in power the armament of any battleship before the "Lord Nelson," and the latter exceeding that provided in any armoured cruisers. Their most striking feature, however, is their great speed, previously only reached by torpedo boats and torpedo boat destroyers, in which everything was sacrificed to obtain the highest possible speed. They were named "Invincible" (fig. 95, Plate XXI.), "Indomitable" and "Inflexible," and were laid down in 1906 at the yards of the Elswick, Fairfield and Clydebank Companies respectively. Their dimensions were:—length 530 ft., breadth 78 ft. 6 in., draught 26 ft., displacement 17,250 tons. They were armed with eighteen 15-in. guns mounted in pairs in four barbette turrets placed as already stated in describing the development of the "Dreadnought" design (see Table XIV. and fig. 96). Thus three pairs of guns can fire directly ahead, three directly astern, and the whole armament can fire on either broadside. In the "Invincible," built at Elswick, all the heavy guns are worked by electric power; in the other vessels they are worked by hydraulic power as usual in H.M. Navy. An anti-torpedo boat armament of sixteen 4-in. guns is provided. The 12-in. guns are protected by 8-in. armour, and a broad belt of side armour is fitted 7 in. thick amidships, and 4 in. forward and aft, associated with thick protective decks. All are fitted with Parsons turbines of 41,000 H.P. and obtained over 27 knots on trial without pressing the boilers. The high steaming power of these ships was shown by the "Indomitable," which conveyed King George V. and Queen Mary (then prince and princess of Wales) to Canada and back in 1908, and steamed on her return journey across the Atlantic—from Belleisle to the Fastnet—at an average speed of 25-13 knots, a record speed at the time for a transatlantic voyage.

It is interesting to compare the "Indomitable"'s performance on the voyage referred to above with that of the "Hero"—a screw line-of-battle ship of 91 guns and 600 nominal horse-power, when employed on a similar errand. This ship was considered a crack ship of her class in 1860, and in that year was selected to convey King Edward VII. (then prince of Wales) on a visit to Canada; she made the passage from Plymouth to St John's in 13 days under steam and sail, and this was considered an exceedingly good performance for a line-of-battle ship in those days.

In 1909 the "Indefatigable" of 18,750 tons displacement was laid down at Devonport; she is very similar to the "Invincible," with the same armament and certain minor improvements. She was followed in 1910 by the "Lion" at Devonport and "Princess Royal" at Barrow, each 660 ft. long, 88 ft. 6 in. beam, and of 26,300 tons displacement on a draught of 28 ft. Parsons turbines of 70,000 H.P. are provided to give a sea speed of 28 knots. Table XVII. contains further particulars of the British "Invincibles," from which it may be seen that the Australian cruisers "Australia" and "New Zealand" are similar to the "Indefatigable."

With regard to cruisers of other navies than the British, it may be said that the vessels constructed at Elswick exercised considerable influence in their development as well as of those of the British navy. The "Esmeralda" (fig. 82, Plate XXIII.) of 1883, built for the Chilean government, but bought by Japan in 1895 and renamed "Idzumi," was of 2900 tons displacement, had 600 H.P. and 19-3 knots speed, was protected by complete 1-in. steel deck, and carried the very heavy armament of two 10-in. B.L. guns, six 6-in. Q.F., two 6-pdr.s, seven smaller guns and three torpedo tubes. The "Piemonte" (fig. 97, Plate XXIV.), built for the Italian navy in 1888, had a displacement of only 2640 tons, but was of 13,000 H.P. and had a speed of nearly 22½ knots. She was protected by a steel deck of 3 in. maximum thickness, and carried six 6-in. Q.F., six 4½-in., ten 6-pdr.s, eleven smaller guns and three torpedo tubes, an armament which, as pointed out by Lord Armstrong, was capable of discharging in a given time twice the weight of shot and shell that could be fired by the largest war vessel then afloat.? The "Buenos

Aires," built in 1895 for the Argentine Republic, is 396 ft. in length and of 4800 tons displacement, her machinery developing 13,500 H.P., with special stokehold, and giving her a speed of 23 knots. She is protected by a complete deck 1½ in. to 3 in. thick, and carries a powerful armament of quick-firing guns, consisting of two 8-in., four 6-in., six 4½-in., twenty-two smaller guns and five torpedo tubes. The normal coal supply is 350 tons, and she can carry 1000 tons in her bunkers. Rather smaller than the "Buenos Aires," but of still later build (1901), is the Chilean cruiser "Chacabuco" (fg. 98, Plate XV.). She is a characteristic Elswick cruiser in design and general appearance, with a heavily armed upper deck and of moderate displacement. Her dimensions are: displacement 4500 tons, length 360 ft., breadth 46 ft. and draught 18 ft. She carries an armament of six 8-in., four 6-in., three 5½-in., four 4½-in., two 3½-in. guns, ten 15-pdr. guns, and two 47-in. torpedoes. She is protected by a strong armoured deck 1½ in. thick from flat to 40 in. to the slope, and by the 1000 tons of coal which forms her normal supply. Her engines develop nearly 16,000 H.P., and her speed is 23 knots.

In the matter of armoured cruisers also Elswick has taken a leading place—among the cruisers built by this firm being the "Esmeralda" (second), of 7000 tons, in 1895 for Chile; the "O'Higgins," of 8800 tons, in 1896 for the same state; the "Asama" and "Koishiki," of 8800 tons, in 1897 for Japan; and the "Kawakami" and "Iwate," in 1899, also for Japan. The "Idzumo" (fg. 99, Plate XXIII.), is 9750 tons displacement, 400 ft. long, 68 ft. 6 in. beam, 24 ft. 3 in. draught. She has 16,000 H.P. and a speed of 22 knots; is protected by a complete belt of Krupp steel 37½ in. thick tapering to 36 in. at the ends, a 24½-in. steel deck with a citadel above it 5 in. thick, and carries an armament of four 8-in., six 6-in., fourteen 4½-in., twelve 13-pdr., seven smaller guns and four torpedo tubes. Her protective belt and upper deck are of 1½ in. to 3 in. thick, and she has a casemate belt 3½ in. thick. Her engines develop 8800 H.P., and her speed is 19½ knots. In the armoured cruiser class the "protected" cruisers is smaller than in the British navy, as the "armoured" type established itself at an earlier date. The "Philadelphia," begun in 1888, may be taken as an example of the U.S. practice in the matter of armoured cruisers. The 14½-in. guns have twin screws and a horse-power of 8800, giving her a speed of 19-6 knots. She is protected by a steel deck 2½ in. to 4 in. thick, and carries twelve 6-in. B.L. guns (later converted to Q.F.), seven double 5-in. guns, twelve 4½-in. guns, and a number of smaller guns. They are protected by heavy steel decks and thin side armour. The "Columbia" developed 18,500 I.H.P. and 22-8 knots on trial, while the "Minneapolis" reached 20,860 I.H.P. and 23 knots; these powers and speeds were at that date the highest recorded for such vessels. The "Columbia" crossed the Atlantic at 18-4 knots in 1895, but the type has not been repeated in America although followed by the large cruiser (8,600 tons) of 1899 (Plate XVII.) the "Brooklyn." (fg. 84, Plate XXII.), begun in 1893, is of the "armoured" type. She is of 9215 tons displacement and 400 ft. long, has twin screws and develops 16,000 horse-power with forced draught, giving a speed of 19 knots. She is protected by a steel belt for two-thirds of her length 8 ft. broad and 8 in. to 3 in. thick, and a complete steel deck 6 in. to 3 in. thick. She carries eight 8-in. B.L. guns in pairs in 15-in. barbettes—disposed one forward, one aft, one on each beam, and a number of smaller guns. She has a steel conning tower, twenty smaller guns and five torpedo tubes. Her normal coal stowage is 900 tons, and she can stow 1650 tons in her coal space.

1903-1904 there were launched six armoured cruisers of the "California" class, of 13,700 tons, and in 1904-1905 three of the "St Louis" class, of 9700 tons. The former are vessels 60 ft. in beam and have not yet been brought up to speed, developing 23,000 indicated horse-power, and a speed of 22 knots. The latter are 424 ft. in length, 66 ft. beam and 23 ft. 6 in. draught, with engines of 21,000 indicated horse-power, and the same estimated speed, namely, 22 knots. Both classes have fourteen 6-in. Q.F. guns, but the larger vessels have in addition four 8-in. guns in two 6-in. turrets besides a heavy battery of smaller Q.F. guns. The "California" class are completely belted with armour having a thickness of 6 in. over the length amidships and 3½ in. to the ends, and a battery of 5-in. armour enclosing the 6-in. Q.F. guns, and extending to the upper deck. The "St Louis" class have a water-line belt for about one-half the vessel's length, with a similar battery above it, the whole of the armour being 4 in. thick of Krupp gun-steel. The "California" class is practically the English "Monmouth," with about a knot less speed, bow-plating omitted and a 4-in. battery added.

In 1903 two small armoured cruisers, the "Mississippi" or "Indiana," were laid down. The speed of 22 knots was retained, but the armament consisted of four 10-in., sixteen 6-in., twenty-two 14-pdr., twelve 3-pdr., &c., with four 21-in. submerged torpedo tubes. The armoured cruiser class were of 2650 tons displacement, but spread over a greater area, giving 5 in. uniformly on the belt and in 3 in. forward and aft; the citadel and casemates remain 5 in. thick, but the protection of the heavy guns is increased to 9 in.; in addition, the 14-pdr. battery on the upper deck is protected by 2-in. plating. The displacement is 14,500 tons. Two similar vessels, the "North Carolina" and "Montana," were laid down in 1905, but up to 1910 the United States had not proposed to lay down any cruisers corresponding in power and speed to the "Invincible." Germany.—Germany for many years built a number of small cruisers of moderate speed for service on distant stations, &c., and subsequently a series of very successful third-class and second-class cruisers of increasing power and speed. Seven vessels of the "Gazelle" class were launched in 1898-1900. The "Gazelle" was of 2588 tons, 6750 I.H.P. and 19½ knots speed; the "Niobe," a sister vessel of the same displacement, and 1½ knots slower, was of 2608 tons; several developed nearly 9000 I.H.P. and obtained 21½ to 22½ knots speed. The "Undine," "Arcona," and "Frauenlob," were of 2650 tons displacement, and all these vessels were all sheathed with wood and coppered. Seven vessels of the "Hamburg" class were laid down in 1902-1904, of 3200 tons displacement, having the same protection as the preceding vessels and carrying the same armament. The "Hamburg" was of 3550 tons displacement, but spread over a greater area, giving 5 in. uniformly on the belt and 3½ in. forward and aft; the citadel and casemates remain 5½ in. thick, but the protection of the heavy guns is increased to 9 in.; in addition, the 14-pdr. battery on the upper deck is protected by 2½-in. plating. The displacement is 14,500 tons. Two similar vessels, the "North Carolina" and "Montana," were laid down in 1905, but up to 1910 the United States had not proposed to lay down any cruisers corresponding in power and speed to the "Invincible."
Ship

In 1897 Japan commenced a new series of large and powerful Cruisers, the "Bliticher" (fig. 101, Plate XXII.), the first of the series, being of 15,500 tons displacement, an increase of more than 4000 tons beyond that of the preceding German vessels. She carries 8-2-in., eight 5-9-in., six smaller guns, and four submerged torpedo tubes, and is protected by 7-in. armour. Guns of 3200 L.H.P. were used. The beam was increased one foot to 98 ft., and the speed was increased to 25 knots. In the second vessel, the "Von der Tann" (fig. 102, Plate XXII.), the main armament was increased to eight 11-in. guns; she is 560 ft. long, 85 ft. beam, 27 ft. draught and 18,700 tons displacement. The trial speed was 25 knots, the 0.5-knot speed, and both power and speed were exceeded on trial.

The third vessel, the "Moltke," is of 25,000 tons displacement, 26 knots speed, armed with 12-inch, 11-inch guns, and cost 7,000,000.

France.—In France the line of development of the cruiser has been similar to that in Great Britain. In 1897 four third-class cruisers were built, of which the "Forbin" may be taken as a type: she was 312 ft. long, 30 ft. beam, 16 ft. draught, 1950 tons displacement, 8500 I.H.P. and 20 knots speed, protected by a 11-in. deck and a belt of 5-5-in. guns, and with a thickness of eight 3.5-in., five 5-in. and five torpedo tubes. These were followed by "Lavoisier," of about 2300 tons in 1893, and the "Estrées" and "Infanterie" in 1897. The latter were 321 ft. long, 39 ft. beam, 17 ft. draught, 4000 tons displacement, armed with two 5-5-in. and eight 3.5-in., four 5.5-in. and two 3-pdr. guns and three torpedo tubes; 8000 I.H.P. was provided for 21 knots speed.

In 1899-1900 France laid down the armoured cruiser "Dupuy de Lôme," of 6300 tons, 14,000 I.H.P. and 20 knots speed, carrying two 7-6-in., six 6-4-in. and several smaller guns; a protection deck 11 in. thick was fitted, and the whole side of the ship covered with a thickness of 5-5-in. armour. She was 22,000 tons displacement, armed with four 6-10.5-in. guns, four 4-7-in., and two 3-pdr. guns in two torpedo tubes; and was laid down in 1899 and completed in 1903.

Of armoured cruisers she possessed in 1910 only two, the "Taureg" ("ex. Pallada") and "Soya" ("ex. Varyag"). The "Taureg" was built at St Petersburg in 1899, of 6630 tons, 11,600 I.H.P., 20 knots speed, fitted with eight 6-in., twenty-two 25-cwt. and several smaller guns, and protected by an armoured deck 1 to 2 in. thick. The "Soya" was built at Philadelphia in 1899, of 6500 tons, 20,000 I.H.P., 23 knots speed, fitted with eight 6-in., twelve 25-cwt. and smaller guns, and protected by an armoured deck 1 to 2 in. thick. There is a somewhat similar to the above, "Schelewig-Holstein" (fig. 100, Plate XXIII.), laid down at Bremen in 1900, but with slightly less power and speed. She is 7000 tons displacement, 17,000 I.H.P., 21 knots, carrying two 8-in., eight 6-in. and a number of smaller guns, and protected by 8-in. armour.

In Japan, United States, and Russia were laid down the "Yukumo," and "Taikei," 440 ft. in length, 13,750 tons displacement, 22,700 I.H.P., and of 21 knots speed.
SHIP

These were the first cruisers laid down to carry the guns of a first-class battleship. Their armament includes four 12-in. guns mounted in pairs in two barbettes, one forward and one aft, twelve 6-in., guns in casemates and twelve 4.7-in. guns, and they have a complete armour belt 7 in. in thickness and 7 in. of armour on the barbettes (fig. 106). They were followed by the 22-knot cruisers "Kurama," laid down in 1905; and the "Ibuki," laid down in 1906, which are 10 ft. longer, of about 900 tons greater displacement, and 4500 more I.H.P., launched in 1899, are of 7400 tons displacement, 13,500 I.H.P., 20 knots speed; they are armed with one 10-in., two 8-in., fourteen 6-in., and a number of smaller guns, and are protected by armour disposed as shown in fig. 107; the belt, battery, and protection are all 6 in., the belt tapering to 4 in. in thickness at the bow and stern.

In 1905 Italy commenced a series of enlarged "Garibaldi" of 9830 tons and 22½ knots, carrying four 10-in. guns in barbettes forward and aft with a secondary armament of eight 7-in. guns in turrets on the upper deck amidships, the bases being extended to the fore. The four larger Garibaldi and the Amalfi and Pisa have the general arrangement of guns and armours in the Garibaldi, and were built as follows:—

I. Sloops.

II. Gun-vessels and Gunboats.

III. Torpedo-boats, Torpedo Gunboats and Torpedo-boat Destroyers.

The "Wild Swan" class, the first of which was launched in 1876 for the British navy, represents one of the earliest of the sloop type. The second-screw composite-built vessel of 1130 tons displacement and 170 ft. length, with a speed under steam of 10

![Fig. 106.—Arrangement of Guns and Armour, Japanese "Ibuki" and "Kurama."](image)

than in the "Tsukuba" type. The armament is also more powerful, twelve 6-in., guns being replaced by eight 8-in. guns mounted in pairs in barbettes, while the 4.7-in. guns are increased to fourteen in number. The "Ibuki" is fitted with turbines of 27,000 H.P., the "Kurama" with reciprocating engines of 22,500 I.H.P. The disposition of guns and armour are as shown in fig. 106. In 1910 Japan ordered of Vickers Co. an armoured cruiser of 27,000 tons and 72,000 H.P.

Russia.—Before the Russo-Japanese War, Russia had provided herself with a great variety of fast, well-armed cruisers of various sizes, including some very notable vessels. Of those which remained in 1910 may be mentioned the protected cruiser "Zhemchug," of 3100 tons, 17,000 I.H.P., 24 knots, carrying eight 4.7-in. guns; the "Askold," built at Kiel in 1900, 4500 tons displacement, 20,000 I.H.P. and 23 knots speed, armed with twelve 6-in., twelve 12-pdr. and other smaller guns; the "Diana" and "Aurora," of 6630 tons and 20 knots; the "Bogaty" and similar vessels launched 1901-1903, of 6675 tons displacement, 20,000 I.H.P., 24 knots speed, armed with twelve 6-in., twelve 12-pdr. and several smaller guns, and having a protective deck 1½ in. in thickness. The armoured cruisers, "Russia," of 12,200 tons and 20 knots, and "Cromotol," of 13,220 tons, 15,500 I.H.P. and 20 knots speed, carry four 8-in., twenty-two 6-in. and other smaller guns, and are protected by 6-in. armour. Since the war several vessels of this type have been built, including three of a new "Bayan" class, 7900 tons displacement, 19,000 I.H.P., 22 knots, armed with two 8-in., eight 6-in., twelve 12-pdr. and other smaller guns, and protected by 6-in. armour; and the "Rurik," built at Barrow in 1906, 490 ft. in length, 15,190 tons displacement, 19,100 I.H.P. and 21½ knots speed, armed with four 10-in. guns mounted in pairs in barbettes forward and aft, eight 8-in. and twenty 4.7-in. guns, and protected by a complete belt of armour 12 ft. deep, 6 in. thick amidships, tapering to 4 in. forward and 3 in. aft.

Italy.—Italy possesses several protected cruisers of the "Fiumente" type already described as well as a number of smaller vessels. She was in 1910 building scouts of the "Quarto" type of about 3500 tons displacement and 27 knots, armed with 4.7-in. and 12-pdr. guns. The most notable Italian cruisers are, however, those of the "Garibaldi" class, which are heavily armed, well armoured and of moderate speed. They have been developed from the "Marco Polo" type, which comprises three vessels; the "Marco Polo," launched in 1892, of 4500 tons, 19 knots, armed with six 6-in., ten 4.7-in. and several smaller guns, and protected by a 4-in. armour belt as well as a steel deck; the "Vettor Pisani" and the "Carlo Alberto," which are of 6400 tons, carry twelve 6-in., six 4.7-in., fourteen 6-pdr. and other smaller guns. The "Giuseppe Garibaldi," "Varese" and "Francesco Ferruccio," and other duties special vessels have been built. These types, and those included in the torpocraft-cnt division, may be conveniently grouped under three headings, as follows:—

![Fig. 107.—Arrangement of Guns and Armour, Italian "Giuseppe Garibaldi."](image)
SHIP

Figure 108.—Arrangement of Guns and Armour, Italian "Amalfi" and "Pisa.

Displacement, 180 ft. long, steamed at 13½ knots and carried an armament of six 4-in. Q.F. guns, four 3-pdr.s, and two machine-guns. They were launched in 1895. The screws, built of steel, sheathed and coppered. The "Condor" class, which comprises six vessels built between 1898 and 1901, are very slightly modified "Torchers," having the same displacement and 6 in. more beam, with the same length.

They were designed specially for service on rivers in hot climates; their draught is limited to 8 ft.; their sails are reduced to a very light fore-and-aft rig, and they are fitted with a complete shade deck of teak and felt. They were still on active service in 1910, but no new vessels had been laid down since 1897.

A number of gun-vessels have been designed for special services, among which may be mentioned the "Mosquito" (fig. 111, Plate XXVI.) and "Herald," two stern-wheel steamers for the Zambesi built by Messrs. Yarrow in 1899. They are of 80 tons displacement and 77 ft. long, having a speed of 10½ knots and carrying an armament of four 3-pdr.s and eight machine-guns. They are built in sections, each of which forms a separate pontoon, so that the whole vessel can be readily taken to pieces for transport and easily put together in the water. These two gun-vessels were ordered over to the Colonial authorities on the river Zambesi. Built for somewhat similar service, but of different design, are the four shallow-draught river gunboats of the "Sandpiper" class, which were built in 1897, also by Messrs. Yarrow. They are 88 tons in displacement, 100 ft. long and 20 ft. broad, and carry an armament of two 6-pdr.s and four machine-guns. Their speed is 9 knots, and they draw only 2 ft. of water, their screws working in arched tunnels, the summits of which are above the water-level outside. These arches always remain full of water, and serve the double purpose of enabling sufficiently large screws to be fitted for the economical propulsion of the vessel without increasing the draught, and of protecting them from damage. The "Woodcock" and "Woodlark" are larger vessels of the same type, designed for service on the rapid and shallow rivers of China. They were built by Messrs. Thornycroft in 1897, are 120 tons in displacement, 145 ft. long, 23 ft. beam and 2 ft. draught of water. They have twin screws, also carried in arched tunnels, and their speed is 15 knots. They carry the same armament as the "Sandpiper" class. In 1901 the "Teal" and "Moorhen," designed for service in China, were also constructed in sections, but are considerably larger than either the "Mosquito" or the "Woodcock," being about 186 tons displacement. They are twin-screw vessels, the propellers being in tunnels, as in the "Woodcock," and their speed is over 13 knots. Their furnaces will burn wood. They carry two 6-pdr.s and four machine-guns. The latest vessel of this type in 1910 was the "Widgeon," of similar construction, built by Messrs. Yarrow in 1904, and carrying the same armament. She is 160 ft. long, 24 ft. 6 in. beam, 2 ft. 5 in. draught, 195 tons displacement, 800 i.h.p. and 13 knots speed.

The gunboats of this class are generally light-draught gunboats. The only light-draught gunboat of the "Sultan" class, of which several have been built for service on the Nile. She has a displacement of 140 tons, a length of 143 ft., a beam of 24 ft. 6 in., a draught of only 2 ft. 8 in. and a speed of 12½ knots. Her armament consists of one 12-pdr., one howitzer, and four Maxima, and she is protected by a 4-in. bullet-proof breastwork.

The gunboats of other navies are generally similar to those described above. The Brazilian " Condor, " built in 1892, of steel, sheathed with teak and coppered, was

![Figure 108](image_url)

FIG. 113.—Plan of Nile Gunboat "Sultan.

165 ft. long and 800 tons displacement, and attained a speed of 14½ knots. She had an armament of four 4-in. guns, three 6-pdr.s, and four machine-guns, and carried a considerable spread of service weapons.

In torpedo gunboats and torpedo craft generally, possibily the last thirty years of the 19th century showed more development and greater diversity than in any other type of war vessel then existing. The first small high-speed boat we have any record of is the
Fig. 117.—Turbinia.

Fig. 120.—U.S.A. Bainbridge.

Fig. 121.—Japanese Niji.
"Miranda," built by Messrs Thornycroft in 1871. She was built of light steel, in 1871, and 21 ft. 10 in. long, and attained a speed of 16-4 knots with a single screw, the engine running at 355 revolutions per minute and indicating 58 H.P. The results obtained with her attracted much attention. In 1873 Thornycroft launched for the Norwegian government a somewhat larger boat, armed with a spar torpedo, which attained a speed of 15 knots. Owing to the introduction of machine-guns in warships as a defence against torpedo-boat attack, it was recognized that there was a very slight chance of a boat approaching sufficiently near to a vessel to successfully attack her by means of a towing or a spar torpedo, and the Whitehead torpedo fired from a revolving tube on the deck was accordingly adopted as the armament of future torpedo-boats. This rendered it unnecessary for the torpedo-boat to approach nearer than say 400 yds., and also enabled the torpedo to be fired without stopping the boat, a point of great importance. The first torpedo-boat for the British navy was built by Messrs Thornycroft four years later; she was called the "Lighthorse," was 75 ft. in length and 34 tons displacement, and engines giving nearly 500 H.P., and obtained a speed of 19 knots. She was armed with a single torpedo tube. The boats which followed varied somewhat as regards size and speed, but on the whole pursued the usual course of growing larger and more powerful with each new design. By 1885 the length had gone up to 150 ft., the displacement to 125 tons and the speed to 20 knots. This last was not the highest that had been obtained, some of the earlier and smaller boats having reached 211 knots; but the boats of 1885 carried a heavier armament, consisting of six 3-pdr., and three torpedo tubes, and were more serviceable and seaworthy craft. A very notable boat of this date was the "Swift," launched in 1885, afterwards known as No. 81, built by J. S. White of Cowes; she marked a great advance in seaworthiness and fighting power in combination.

Messrs Yarrow built for the Austrian navy in 1886 the "Falke," 135 ft. in length and 95 tons displacement, which obtained a speed of 22-4 knots on trial, and a similar boat for the British navy of 105 tons displacement, armed with a torpedo tube and three 3-pdr. guns, which attained a speed of 23 knots on trial. About the same time Messrs Thornycroft built the "Ariete" and "Royo" for the Spanish navy. These vessels had twin screws and water-tube boilers. The former attained a speed of 26 knots on the measured mile and 24-9 knots on a 2 hours' run, and the latter 25-5 knots on the measured mile and 24-6 knots on the 2 hours' run. In 1893 M. Normand built the torpedo-boat "Fortun" for the French navy, which attained a speed of 31-2 knots on trial, and the boats of the Normand type which followed her attained equally remarkable speeds. The maximum speeds for the British torpedo-boats up to the end of the 19th century, are given in Table XVIII. In these as before, the 33 to 34 knots, for the Normand and faster types of torpedo-boats were constructed. These boats were 160 ft. to 165 ft. in length, 17 ft. to 18 ft. beam, 83 ft. draught, 180 to 200 tons displacement, 2900 I.H.P., attained a speed of 25 knots and were armed with three torpedo tubes. In 1890 to 1900 boats of a new and still faster type were built with turbine machinery and burning oil fuel instead of coal. These boats, 36 in number, vary from 166 to 185 ft. in length, and from 173 to 185 ft. in beam, 51 to 61 ft. draught and 243 to 308 tons in displacement. They have engines of 3600 to 4000 H.P. giving speeds of 26 and 27 knots, and are armed with two 12-pdr. guns and three torpedo tubes. First ordered in 1899 at a cost of £50,000, as Coastal Torpedo-boat Destroyers, and given names such as the "Cricket," "Gaffly" and "Mayfly." They are now numbered throughout, i.e. from 1 to 36. The prefix O has been added to the number of such of the boats originally bearing these numbers as are still in existence, to distinguish them from the new type boats, vessels, the first of the English torpedo gunboats, came closely after her. The "Rattlesnake" was launched in 1886, with 525 tons displacement, and had a speed of 191 knots. She carried a more powerful armament than the torpedo-boats, namely, one 4-in., six 3-pdr., and 4 torpedo tubes. She was followed in 1888 by the "Sharpsword," with ten sister vessels, still larger and more heavily armed. They were 230 ft. long and 735 tons displacement, had engines developing 3500 H.P., giving a speed of 19 knots, and carried two 4-7-in. Q.F. guns, four 3-pdr., and two torpedo tubes. France built six vessels of the "Bombe" class and the "Legere" (a slightly larger vessel), and in 1891 to 1896 built five other torpedo gunboats of about 900 tons and 21 knots. The last was named La Hire, and was 241 ft. long, 27 ft. 6 in. beam, 12 ft. 9 in. draught, 900 tons displacement; was armed with six 9-pdr. and six 3-pdr. Q.F. guns and was provided with engines of 6400 I.H.P. for 23 knots. These vessels have no torpedo tubes. The torpedo cruiser "Fleurus," laid down in 1891, was armed with four torpedo tubes as well as five 3-9-in. and six 3-pdr. guns. She was also protected by a 13-in. protective deck and fitted with a belt of cellulose 3 ft. thick in the vicinity of the water-line. Her dimensions were: length 230 ft., beam 29 ft., draught 15 ft., displacement 1300 tons, I.H.P. 4000, and speed 18 knots.

"Cyclone" class. This class included eleven vessels (fig. 114, Plate XX.), were repeats of the "Sharpsword," except that they carried an additional torpedo tube and three machine-guns, with certain hull additions and more durable machinery, the displacement being increased to 810 tons, and the speed being reduced by a quarter of a knot. In 1893 a fourth series of this class of vessel was begun, known as the "Dryad" class, and considerably larger than the "Nigeras," being 250 ft. long and 1270 tons displacement. They are of 3500 I.H.P., have a speed of 18½ knots, and carry an armament of two 4-7-in. Q.F. guns, four 6-pdr., and three torpedo tubes. Five vessels of this class were built, the difference between their general appearance and that of the preceding classes being illustrated by fig. 115 (Plate XX.), which shows the "Hazard," which in 1910 was employed on special service in connexion with the reception and trials of British submarine vessels. In these ships the chief demands on the torpedo gunboat class the elements of strength and seaworthiness are developed at the expense of speed, and they combine in themselves some of the functions of the torpedo-boat with many of the most important features of the small cruiser. The most important increases of displacement are very largely due to additions to the hull, giving greater habitability and trustworthiness for continuous work at sea. It was thought that the speed shows a continuous falling off; but the "Sharpsword" class and subsequent vessels have been fitted with water-tube boilers in lieu of the locomotive boilers originally fitted, and some of them are in addition re-engined, with the result that the speed of 20 knots has not been obtained; but the ordinary weather met with at sea, would probably enable them to overtake craft of lighter types possessed of considerably greater smooth-water speed. These vessels have not been repeated, many of them have been sold, but all those remaining are actively employed on a variety of subsidiary but important services.
Torpedo-boat Destroyers were primarily, as their name implies, intended to meet and destroy torpedo-boats, their larger size, greater coal capacity, heavier armament, and higher speed enabling them to overtake such boats before they could complete their attack; but it soon became evident that these additional powers also enabled the destroyer to perform the duties of the torpedo-boat more efficiently than the latter was enabled with the advent of the destroyer the production of the smaller boat declined.

The pioneers of this type of vessel were the "Daring," "Decoy," "Havock," and "Hornet," the construction of which was entered upon in July 1892, the two first completed at Messrs Thornycroft, the other two at Messrs Yarrow's. They were thus contemporary with the "Dryad," the last of the torpedo gunboats. The success of these early ships was followed by a marked interest in the torpedo boats, and the following year (1893) six others were begun. One of these, the "Boyer," built by Thornycroft, attained a speed of 29-2 knots. A much greater number of destroyers (32 in all), nearly the whole of which were of 27 knots speed, were laid down in 1894, and the ensuing year (1895) saw a great advance in size, power and speed, thirteen destroyers being laid down, for each of which the contract speed was 30 knots. Similar vessels were constructed by various firms in England for foreign powers, and abroad by Messrs Schichau in Germany and M. Normand in France; the "Sokol" being constructed by Messrs Yarrow for the Russian navy. Over sixty destroyers of the 30-knot type were built for the British navy between 1895 and 1905, and in only three vessels with reciprocating engines—the "Albatross," the "Express," and the "Arab"—were speeds exceeding 30 knots contracted for. In 1896 an attempt was made to realize greater speeds, but it was found that the lift which the body of the ship could offer to the wind was insufficient to bear up the vessels against the wind, and, therefore, the speed of over 30 knots was not laid down in the contract.

Experience with the 30-knot destroyers led to a decision to order boats of greater speed and better sea-keeping qualities. In them the turn-back forward was replaced by a lofty forecastle, and it was laid down that the trials should be run with the boats more heavily loaded and more closely approaching their ordinary loaded condition on service. These changes were embodied in the "River" class, in which a trial speed of 35 knots under the modified conditions was provided for.

In 1902-1904 thirty-four destroyers of the "River" class were ordered and are provided for the following dimensions, &c.:

In 1908-1909 eight ocean-going destroyers of 33 knots of the "Tribal" class were ordered, ranging from 970 to 1045 tons displacement and armed with two 4-inch guns and two 18-inch torpedo tubes. In 1908-1909 sixteen ocean-going destroyers of the "Beagle" class were ordered, ranging from 1070 to 1205 tons displacement and armed with two 4-inch guns and two 18-inch torpedo tubes. In 1909-1910 twenty more ocean-going destroyers of the "Acorn" class, designed by Sir Philip Watts, were laid down; in these oil was again adopted for fuel and a speed of 36 knots obtained. These vessels are of 780 tons displacement, 240 ft. long, 25 ft. beam, 71 ft. draught, 13,500 turbine H.P., and carry two 4-in., four 12-pdr. guns and two 18-inch tubes. The new destroyers are fitted with Parsons turbines.

The chief particulars of the new destroyers are given in the following table:—

SHIP

been added to the fleets of foreign navies, the boats built by Messrs Schichau of Germany and Normand of France having especially achieved success in the attainment of high speeds on trial. The "Rainbridge" class (fig. 120, Plate XXV.), built for the U.S. navy in 1901, are 245 ft. long, 23 ft. 7 in. wide, draw 6 ft. 6 in. of water, and have a displacement of 420 tons. Their sea-going speed is 29 knots, and their armament consists of two 18-in. torpedo tubes, two 3-pdr. Q.F. guns, and five 6-pdr. The destroyers building in 1910 are of 472 tons with a speed of 29½ knots.

German destroyers are numbered consecutively, the numbers being prefixed by letters indicating the yard where built. Thus, S for Schichau works, Elbing; G, Germania works, Kiel; V, Vulcan works, Stettin. Numbers below 90 are appropriated for torpedo-boats. Two destroyers only have names, viz. S. 97, which also bears the name "Steipliner," and is fitted to serve as the emperor's yacht; and one without a number named "Taku," late "Hai-jing," taken from China in 1900, but built at the Schichau works in 1898. (The British navy list also contains the name of a destroyer "Taku," built at the same works in 1898, and also taken from China in 1900.) The German torpedo-boat flotilla is divided up into sections, each section led by a division boat of much larger size than the others. These division boats increased in size, from 226 tons displacement, 1800 I.H.P. and 21 knots speed in 1887, to 374 tons, 5500 I.H.P. and 28 knots speed in 1898. Division boats are numbered D 1 to D 10, and of these two bear names, D 1 that of "Carmen," armed with two 3.9-in. and four 9-pdr. guns and four torpedo tubes; Russia was building vessels of about 1000 tons and of 35 knots speed.

Submarine Boats.—About 1880 much attention began to be paid by several of the naval powers to the development of the submarine boat, the United States and France in particular.

The history of the subject goes back at least 300 years, but the first undoubted success with a submarine vessel was achieved by David Bushnell in America in 1775. It was worked by one man, for whom it provided just sufficient room; its general appearance, according to Bushnell's own description, bore some resemblance to two upper-tortoise shells of equal size joined together, the entrance to the vessel being represented by the openings in the swellings of the shells at the animal's head; the body of the vessel was constructed of wood. The operations on board were entirely manual. By an oar in form of a screw with its spindle passing through the top the boat was sunk or raised, by another oar at the after end it was propelled; a rudder was used for guidance, and in some cases for propulsion; valves admitted water when submergence was required, and hand pumps discharged this water when it was desired to come to the surface, and a detachable weight of 200 lb. was also supplied for emergency use. The air in the boat was capable of supporting the operator for thirty minutes; and as soon as he brought the boat to the surface, two air pipes, for discharge of foul and supply of fresh air, opened automatically. A compass, a pressure-gauge, and a sounding-line and lead were among the fittings. Behind the vessel was a large magazine containing 170 lb. of powder, and a time-control for exploding it. From the magazine was led a rope to a wood screw at the fore part of the crown of the boat, and this screw, being worked from within, could be driven into the object to be destroyed in such a manner as to keep the magazine required for the explosion in position after it had been detached from the boat. During the War of Independence the boat was submerged beneath the British warship "Eagle," and the operator attempted to attach the wood screw to her bottom planking; in this he failed, apparently simply because he did not let go his detachable weight and so get enough upward pressure to drive the screw into the plank. The magazine was released and exploded an hour afterwards, but at some distance from its intended position.

The problem of submarine navigation received the practical attention of Fulton during the time that he was making his experiments upon steam propulsion, and even at an earlier

SHIP

period. He constructed two submarine boats in France, and one in America. One of the former, the "Nautilus," was built with the direct encouragement of Napoleon in 1801. It was supplied with compressed air for respiration, and with it Fulton conducted a series of experiments under the direction of a commission of naval officers. He descended to a depth of 25 ft., and remained under water for fully four hours, placing below a vessel provided for the purpose a torpedo by which it was blown into fragments. As with his steam engine, so too with his submarine boats, the report of the commission charged with investigating him was not unfavourable that Fulton was much discouraged, and though he afterwards continued his labours in this direction, the results achieved by him were practically lost. Fulton’s boat, like Bushnell’s, was propelled by manual power, two horizontal screws being employed for propulsion, and two vertical screws for descending and ascending: it was built of wood with iron ribs, and was sheathed with copper.

The substitution of mechanical for hand power came later, and one of the first mechanically driven boats was the "Plongeur," built in France in 1863 from the designs of Charles Brun. This boat was a length of 46 ft. and a diameter of 12 ft., and was propelled by an 80-horse-power compressed-air engine. During the American Civil War the Confederates built a number of iron cigar-shaped boats; some were propelled by steam engines and some by hand. Each was armed with a torpedo containing 50 to 70 lb. of powder carried at the end of a spar. These boats were known as "David's," from their diminutive size as compared with the size of the ships attacked, and in 1864 one of the hand-worked boats, 50 ft. long, manned by a crew of nine men, successfully attacked the Federal ship "Hornet." and sank her by means of a spar torpedo, but in so doing was herself sunk. It is claimed that the loss of the boat was due to faulty handling and not to inherent defect. Against the protest of her builder, she was immersed only to the hatch coaming; and the cover being left open, she was swamped and sunk by the wave thrown up by the explosion.

About the same time another hand-worked submarine, called the "Intelligent Whale," 26 ft. in length and 9 ft. in diameter, attracted some attention in America. An officer with two other persons dived with her in water about 16 ft. deep; the officer, in diver’s dress, left the boat through a manhole in the bottom, placed a torpedo under a scow and blew the latter to pieces.

In 1875 Mr. J. P. Holland produced his first plan for a submarine vessel, and in 1877 he constructed a small experimental boat, which embodied features now accepted as essentials in American design. His plan ensured that when, for the purpose of diving, water was admitted into compartments of limited size, the total weight of the boat and its contents should still be a little less than the total buoyancy. Immersion was maintained by the action of horizontal rudders, which gave a downward tendency so long as the boat had any forward motion, and there always remained enough surplus buoyancy to bring the boat to the surface on the stoppage of her propelling machinery. Any weight consumed on board was automatically compensated for by admission of water, so that the total weight remained fixed and constant; while the confinement of the water to small compartments further secured a fixed centre of gravity. The securing of these qualities of fixed weight and fixed centre of gravity is essential, and the want of them has been a cause of failure in many other designs.

With the necessarily slight longitudinal stability possessed by a submarine boat, any change of centre of gravity in the fore-and-aft direction has a no able effect on the angle of trim; and such a change may readily occur, for instance, from the surging of water in a large ballast-tank not completely full.

An unintentional alteration of trim when the submarine boat is being propelled involves several possible dangers: in extreme cases the crew or some of the fittings may be thrown out of position, but in any case the path of the submarine is altered, and may tend either to too great immersion on the one hand, or to breaking the surface of the water on the other. From the risk of these dangers it is claimed by Mr Holland that his design is free. The first of his boats now under discussion was steered down and up inclines by her horizontal rudders, and motive-power was obtained from a petroleum engine. The tests to which she was subjected showed that inefficiency of the engine, difficulty of vision and trouble with the compass tended to destroy the boat’s usefulness.

In 1883 Mr Nordenfeldt, famous as an inventor in many directions, built a submarine boat at Stockholm. She had a length of 64 ft., a main diameter of 9 ft. and a displacement of 60 tons; she was propelled by a compound surface-condensing engine indicating 100 H.P., and on a measured-mile trial, not being submerged, attained a speed of 9 knots. Steam was supplied by an ordinary marine return-tube boiler, worked under forced draught, which could be fired as long as the boat was at the surface. Storage of steam was effected at the surface, and the steam thus stored was used to drive the engine in the submerged condition. To store sufficient steam two large tank reservoirs or cisterns were connected with the boiler, and the contents of boiler and tanks (8 tons of water in all) were raised to a temperature corresponding to 150 lb. pressure. In preparing for submergence the firing of the boiler was stopped, and the steam given off by the heated water in boiler and tanks sufficed to propel the boat for a period. The smoke was driven out through two channels, which passed round the hull and pointed astern. The material of the hull was mild steel, the frames being 3 in. by 3 in. by ½ in., and the plating ⅜ in. 10 ft. in thickness; the depth to which she could safely descend was about 50 ft. When ballasted ready for a descent on trial, the boat showed only a very small domed for observation above the level of the water, the reserve buoyancy represented by this dome being but 1 cwt. To overcome this reserve two propellers working on vertical shafts were fitted in sponsons, one on each side of the boat, nearly amidships. These propellers were driven by a 6-horse-power engine, and drew the boat under water to the desired depth; an automatic contrivance, set in motion by the water pressure outside the boat, closing the throttle-valve when the safety limit of depth was approached. On coming to rest, the reserve buoyancy brought the boat again to the surface. When propelled by the main engines in the submerged condition, the boat was kept horizontal by means of two bow rudders operated by a plumb weight. The crew consisted of three men only, this small number rendering unnecessary the employment of artificial means of maintaining a pure atmosphere. The scheme of attack was to approach the hostile ship running at the surface until the danger of discovery was imminent, then to descend to the "awash" condition with only the dome above water, and finally to go below the surface and advance to striking distance entirely submerged, rising if necessary once or twice to allow the direction to be adjusted by observations made from the dome "dawsh." The weapon of offence employed was a Whitehead torpedo, carried outside on the bow and discharged mechanically. Several larger boats were subsequently built from Mr Nordenfeldt’s designs; they all involved the same principles, but were in some details made more efficient both for attack and defence.

The three main points insisted upon by Nordenfeldt were: (1) that his method of storing energy gave him a reservoir which was not liable to get out of order, could readily be repaired if broken, and if damaged the knowledge of so much less than that possessed by an ordinary engineer; (2) that for submergence he relied on mechanical means easily controlled, adding, as a criticism upon the alternative method of descending by steering downwards, "I need only point out the great risk of allowing an object 100 ft. long and of great weight to proceed in the downward direction even at a small angle, as the impetus gained would very easily carry it beyond a safe depth so quickly that they might not have time to check it"; (3) that the bow rudders always secured a horizontal position when the boat was running submerged, which position he had found to be a sine qua non for a submarine boat.

Fig. 131.—British Submarine Flotilla at Portsmouth.
In response to an invitation for proposals for submarines, made by the U.S. government in 1887, designs by Holland and Nordenfeldt were submitted. After much consideration the proposals of the former designer were accepted, and formed the basis of the designs for the "Plunger" and the "Holland" and the six vessels of the "Adder" class. From what has been already stated, the criticism of Admiral Hichborn (chief constructor of the U.S. navy) will be understood when he characterizes Holland's method as a "steering-tender" or "diving" device, and Nordenfeldt's as a "down-haul" or "sinking" design. The great majority of modern boats are worked by the Holland method. The "Plunger" was authorized in 1903; she has a length of 85 ft., diameter 11 1/2 ft., light displacement 154 tons and load displacement 168 tons; she is of sufficient strength for a submerge of 75 ft., and when wholly submerged has a margin of buoyancy of 1 ton. In addition to her horizontal rudders for diving, she has two down-haul screws, fitted in opposition to Mr. Holland's recommendations; she may therefore be said to be a combination, for diving purposes, of both the Holland and the Nordenfeldt designs. The "Plunger" main engines are used for propulsion when she is navigated at the surface of the water. As originally designed they were triple-expansion steam engines, driving triple screws, but have since been altered to gasoline internal-combustion engines driving a single screw. These engines are also used for charging electric accumulators, from which alone motive-power can be obtained when the boat is submerged. The current for charging the accumulators is obtained from a dynamo of 70 H.P., which can always be run in the awash condition to keep the accumulators fully charged. In the awash condition, when the boat is otherwise air- and water-tight, communication is kept up with the outer air by means of ducts and a smoke-pipe, the former bringing in air for combustion and respiration, and the latter carrying off deleterious products of all kinds. For submerge special fittings are used to close these ducts and pipes, and to stop the gasoline generator. The main engine is then no longer available, and for propulsion power is drawn from the accumulators, the dynamo thus becoming a motor which derives current from the accumulators and itself drives the screw-shaft. As was the case with Mr. Holland's earlier boats, great attention is given to automatic control of weights, and water-ballast is admitted to compensate for any change such as would be produced by the discharge of a torpedo. With her original machinery the "Plunger" was to have had a surface speed of 15 knots; her anticipated speed awash or submerged is now 8 knots. To assist in determining the boat's direction a camera lucida is ordinarily provided, but for correcting this Mr. Holland prefers trusting to observations made during occasional rises to the surface; for this purpose the boat is provided with a conning tower 4 ft. high, protected with 4-in. steel. The "Plunger" is armed with Whitehead torpedoes, and has two tubes for discharging them. After many trials it was at last decided to build a repeat of the "Adder" to take her place, and this second "Plunger" was completed in 1903. The "Holland" is a smaller boat, having a length of about 54 ft., and was purchased in 1900. The official report on this vessel is that "she has shown herself capable of such perfect control in the vertical plane that she may be kept whilst moving within a few inches of any desired depth, and that she may be brought to the surface and submerged again in a very short time." A good idea of the general form of the "Holland" may be obtained from figs. 122, 123, 124 and 125 (Plate XXVII.), the last three of which represent this vessel when undergoing 125 ft. of submergence by her diving device.

The design of the six submarines of the "Adder" class is shown in fig. 126. They are of the following dimensions: length 63 ft. 4 in., diameter 11 ft. 9 in.; displacement for surface running 104 tons; submerged displacement 120 tons. The main features of this class are the same as for the "Plunger." The shell-plating is 7/8 in. in thickness, and the frames 33 in. by 3 in., with a spacing of 18 in. The main machinery is a four-cylinder single-acting balanced Otto gasoline engine, which at 360 revolutions will develop 160 H.P. and give the boat a speed of about 8 knots. For propulsion in the submerged condition an electric motor is used, working at 800 revolutions, and giving a speed of 7 knots, a single left-handed propeller being employed. The current for the motor is provided by storage batteries capable of supplying 70 H.P. for four hours; and these batteries are charged by the main engine. The requisite air supply is obtained when the vessel is at the surface, and is stored under a pressure of 2000 lb. by a pump driven by gearing off the main engine or main motor. Air at a pressure of 50 lb. is used for the expulsion of torpedoes, and the same agent, at various degrees of pressure, works the trimming and ballast tanks and some parts of the apparatus for respiration. Air from the storage tanks is taken off for the purpose of ventilation. The vessel is fitted with power and hand-steering gear, and there are automatic devices for securing a constant depth during submerge. Five Whitehead torpedoes, 45 cm. (about 18 in.) in diameter and 11 ft. 8 in. long, are provided, and there is an expulsion tube placed forward about 2 ft. below the light water-line.

The French submarine boat "Plongeur" has already been mentioned. A further advance in this direction was made in France in 1881, when a small submarine was completed by M. Goubet at Paris. An inspection of this vessel led to a system of the engineer for the Russian government, and several sets were built and delivered early in 1885. The length of a boat constructed by M. Goubet in 1885 was 16 ft. 5 in.; it had an oval section 5 ft. 9 in. in depth and 3 ft. 3 in. in breadth, and tapered to a point at each end. A longitudinal section of the boat is represented by fig. 127. The main portion of the hull was of bronze, cast in one piece, and at the centre of its length it was surrounded by a large dome having seven glazed openings. There was just sufficient room for an officer and a man seated back to back within it, their eyes in this position being level with the glass windows of the dome. All valves and other mechanism requiring regulation were brought within reach of these occupants, so that no movement on their part was required which might affect the trim and proper adjustment of the boat for any purpose. The reason of the domed arrangement was the means of respiration, and an air-pump removed the vitiated atmosphere. The motive-power was furnished by accumulators, the electric energy stored therein driving a screw propeller by means of a motor. No means of recharging these accumulators when exhausted was provided on board. Submersion was effected by admitting water into tanks divided by transverse bulkheads at sufficient intervals to prevent the surging of the water in the fore and aft directions. A pump expelled this water again when desired, and a safety weight attached to the bottom of the boat was ready for detachment in the presence of danger. A pressure gauge indicated the depth, and the air was regulated by the officer, who could regulate the opening of the inlet valves or the action of the pumps to maintain or vary this depth as desired. For controlling the boat in a horizontal direction a specially devised pendulum was employed, by means of which the boat was moved, of sufficiently running shaft was thrown into gear with a pump as soon as the boat departed appreciably from the horizontal plane. The action of the pump was reversible.
SHIP

and the clutch engaged it always in such a way that it drew water from a tank at the low end of the boat, and delivered it to a tank at the high end. Several other devices of great ingenuity were employed in the boat; notably a special form of universal joint introduced into the line of shafting. At the after end, close to the propeller, this universal joint was fitted in such a way that the screw could be set at an angle to the line of motion, and steering effected without the aid of a vertical rudder. A torpedo containing 100 lb. of dynamite or other explosive was carried outside the hull, and secured by a catch joint. This torpedo, on the submarine boat being manoeuvred into position, could be thrown off and allowed to rise and attach itself, by means of spikes, to some vulnerable part of the ship doomed to destruction. Retiring then to a safe distance, the submarine boat could explode the torpedo by the agency of an electric current.

Working in the light of his now considerable experience, M. Goubet built several other boats. These were of larger dimensions, having a length of 27 ft.; their material was also bronze, and they were cast in three pieces, the centre one having a thickness of 1 in., while the others were reduced to a little more than ½ in. at the ends. Possessing to a large extent the same contrivances as their predecessor, these improved boats were fitted also with an automatic apparatus for regulating the depth of submersion. In this regulator a piston is moved along a cylinder by the rotation of a rod with a screw thread cut in it, and so increases or diminishes the amount of water in the cylinder. The movement of the piston is effected by a small motor, and the direction of action of the motor is regulated by a commutator placed in juxtaposition to a pressure gauge. When the depth of submersion is too small, current is supplied to the piston so as to admit more water; when depth is too great, current is supplied in the opposite direction, and water is expelled. The speed attained by this boat was from 3 to 6 knots. Smaller boats of this type have been built for propulsion by manual power, but, however perfect the mechanism, the range of action of a submarine dependent on man-power for propulsion is very limited. Recent Goubet boats are being built, with motive-power, which is proposed to carry on board ship and lower from davits when required.

The "Gymnote" was constructed at Toulon in 1888. She is a steel vessel, with a length of 59 ft. and a displacement of 30 tons; being of an experimental character only, she has no weapon of attack. The maximum speed obtainable is 8 knots. The designs of the "Gustave Zéde" and of the "Morse" were both based on those of the "Gymnote," the former having a length of 148 ft. and a displacement of 263 tons. In both of these the hull is of bronze; one great advantage of this metal being that, like the bronze of the Goubet boats, it is non-magnetic in character, and cannot therefore disturb the equilibrium of the compass. With their large dimensions they were intended to formidible engines of war, and were furnished for attack with Whitehead torpedoes; of these latter they each carry three of 45 cm. (nearly 18 in.) diameter, discharging them by means of a torpedo tube. The "Morse" and the "Gustave Zéde," like the "Gymnote," possess only electric means of propulsion, the power being derived from batteries of accumulators. No power is provided in the vessels by which the accumulators can be recharged, so that the radius of action of these boats is necessarily very limited. The "Naval," designed by M. Laubeuf, and the outcome of a general competition in 1897, has a length of 112 ft. and a total displacement of 200 tons. She was built at Cherbourg in 1899, and is furnished with a triple-expansion steam engine, obtaining its steam from a water-tube boiler, heated by oil. As in the American submarines, this engine propels the boat when at the surface, and also drives a dynamo which recharges accumulators, the latter giving the reserve power for use in the submerged condition. A steam pipe supplies the torpedo, on the surface, and 8 knots when submerged. A new departure in the "Naval" is her double hull, the inner shell of which is of steel plate of sufficient thickness to resist any water-pressure to which the boat may be subjected. The inner shell, which is kept in the same position from the inner part, forms a protection to the inner against attack. An armoured dome surmounts the boat, cutting through the external shell, and is surrounded by a short and narrow telescopic funnel, which, as in the case of the American boats, must be withdrawn preparatory to diving. Control in this type is vertical only; by means of rudders, when diving, the use of two pairs of horizontal rudders, placed symmetrically—one pair forward, the other aft—was adopted. In the above arrangement it is claimed that the horizontal direction of the boat is ensured, the American course of inclining the axis is a telescope with the optical axis twice bent through a right angle by totally reflecting prisms or mirrors; and under diverse forms and various names, such as periscope, cleptoscope, hydroscope, optical tube, etc., it affords the principal means by which objects on the surface of the water can be seen at a distance from the interior of a submerged vessel. The problem of providing means for seeing at a distance through the water still awaits solution, although many different arrangements have been proposed, and will enormously add to the power of submarine boats as weapons of war.

By far the greater number of submarine boats in existence in 1910 were developments through a process of continuous experiment and improvement of the "Gymnote" and of the early Holland boats, although the process of evolution had been so rapid and extensive that the parentage of these modern boats is hard to recognize. There are, however, a considerable number of submarines built by the Lake Submarine Boat Co. of Bridgeport, U.S.A.; in the service of various naval powers. These boats are designed by Mr Simon Lake, who was also a pioneer in submarine boat construction, contemporary with Mr J. P. Holland in the United States of America. His earliest boat, the "Argonaut," was intended rather for running along the bottom in shallow water at a speed of 3 knots, and for sending out divers rather than for discharging torpedoes. For this purpose it was fitted with wheels for running along the bottom and with an air-right chamber having a hatch at the bottom which could be opened under water. The area of the bottom was made equal to that of the water outside. These features are still retained in many of the modern Lake boats, though these boats are now constructed like all other submarines, primarily for the purpose of submarine war.

Other boats which should be mentioned as having claims to distinctive features in matters of detail are those built by the Fiat San Giorgio Company of Milan, those built by the Seri di Lenore, and those built by the Germania Werft of Kiel, which are understood to embody the patents of M. d'Equerville. The Russian government also possesses several boats generally regarded as of a distinctive type designed by Professor Drnectrov.

Perhaps the most outstanding distinction between different submarine boats is the amount of their submerged displacement which is devoted to carrying water ballast. This, of course, ensures their reserve of buoyancy in the surface condition, which in different
 examples of boats varies from as little as 5% to as much as 60% of their surface displacement. It is obvious that the more water ballast carried, the less of some other weight of machinery or equipment can be carried on a given submerged displacement, and the weight carried ballast will itself impose some additional requirements which will best meet the requirements of the service for which the boat is intended. This fact has sometimes been lost sight of in discussions on this subject, which have tended somewhat to localize the whole of the difference character between boats of high reserve of buoyancy and those of low reserve, even to the extent of giving them the different names of "submersible" and "submersion." It is a task of the designer of submarines which has frequently been the subject of non-technical discussion, the desirability of this or that type of "low-rudders" or "hydroplanes." This question depends on the form of the boat, and the manner in which the problem is approached, is unsuitable for discussion except in relation to the ascertained tendencies of a particular form under the vertical hydrodynamical forces which are set up by its propulsion system.

Similar considerations apply to the questions whether a submarine boat should have a separate means of propulsion for surface-running distinct from that fitted for submerged propulsion, and if so, whether it should consist of steam or internal-combustion engines. On account of the very limited capacity of even the best modern electric accumulators, any submarine which is intended to have a considerable radius of action must necessarily have heat engines of some description for surface propulsion and for charging batteries.

As to the type of heat engine, France was the only country in which it used the internal-combustion engine in any great number of built submarines; and the general tendency was undoubtedly to use internal-combustion engines, of which those burning heavy oil are much less expensive in working than those using gasolene.

In the United States, in the boats which these engines are now fitted, there has been some improvement in the design of the agricultural design, in the design of the internal combustion engine. It is characteristic of all countries to keep secret the really important details of their submarine boats, to an even greater extent than those of ordinary warships. Some particulars, however, of the War vessels of the Royal Navy are given below, principally to illustrate the progress in size and power.

In France, in 1901, M. Romazzini, already referred to as the designer of the "Morse" and "Gustave Zédé," produced two other boats, the "François" and "Alégria," similar to the "Morse," four vessels of the "Sirène," "Triton," "Silure" and "Espadon," of a modified "Naval" type, were built from M. Laubeuf's designs in 1903. From 1904 to 1905, "Cigogne," a boat, of 175 tons surface displacement, were built in 1904, and two other still larger boats, the "Cercé" and "Calypso," in 1905. These boats each have a length of 181 ft., beam of 16 ft., depth of 10 ft.; have a submerged displacement of 450 tons on the surface, 480 tons submerged. Two Diesel heavy oil engines are fitted to give 111 knots speed on the surface and two electric motors for use when submerged. Four boats of the class "Morse," 180 in. in length, were completed in 1805. In 1901 twenty small submarines of the "Narada" type were constructed to M. Romazzini's design; they are 76 ft. in length and 280 tons displacement, and have a surface speed of 8 knots and a speed of 4.5 knots when submerged. Their motive-power is electrical both for surface and submerged propulsion, except in the case of two boats, the "Marseilles," which were fitted with Diesel engines for surface work. From 1905 to 1909, 34 boats of the "Pluviôse" type of twin-screw submarines designed by M. Laubeuf were laid down; they have a displacement on the surface of 392 tons, and have engines of 700 H.P. for surface work. They have a submerged speed of 16 knots and a speed of 7.5 knots when submerged. Eighteen boats of the class have triple-expansion engines, and each of the remainder has two Diesel heavy oil motors for submerged propulsion, while all have electric motors for use when submerged. Some of the steam-driven boats have traversed 730 m. in 82 hours, while the "Papin" with oil motors ran 1200 m. from Rochefort to Oran in six days without calling at ports. One genuine speedy boat of the same class is shown in the "Vendémiaire," one of the boats of this class. The twin-screw submarines of the "Emeraude" class, six in number, designed by M. Maugus and laid down in 1906, are of approximately the same size as the "Pluviôse," the "Sirene," and the two boats of the same class at have a submerged speed of 90 m. Sec. XXVIII., gives a view of C32, while fig. 130 shows D1 under weigh on the surface, and fig. 131 a flotilla in Portsmouth Harbour.

Gasolene engines for surface propulsion. D1, which also has heavy oil engines, was completed in September 1909, and was the first of a new series of boats for the design of which Sir Philip Watts was personally responsible. She passed through her trials, and seven of the class were in 1910. On the surface, she is driven by 375 H.P. gasolene engines, and 6 knots submerged, and armed with one torpedo tube. The large boats of the "Lake" type are driven by engines of 1200 H.P., and are stated to carry an armament of two 3-in. guns and two machine guns. The boats of the Germania class, the "Ostfriesen," of the Russian submarines under construction in 1910, are of 500 tons displacement on the surface.

Germany did not build submarines until 1910, when it was launched at the Germania Works, Kiel. It is 139 ft. long, 11 ft. 9 in. beam, 7 ft. 9 in. Draught and 240 tons on the surface, being...
SHIPBUILDING

When ships were built of wood and propelled by sails their possible sizes and proportions were limited by the nature of the structural material, while the type of structure had been evolved by long experience and was incapable of any radical modification. Speed depended so much on circumstances independent of the design of the vessel, such as the state of the wind and sea, that it was impossible to include a definite speed over a voyage or measured distance as one of the essential requirements of a design; and the speed actually obtainable was low even under the most favourable conditions when judged by modern standards. Stability depended principally on the amount of ballast carried, and this was determined experimentally after the completion of the vessel. Under these conditions there was no room for any striking originality of design. One vessel followed so closely on the lines of another, that the qualities of the new ship could be determined for all practical purposes by the performance of an almost identical vessel in the past. The theoretical science of shipbuilding, the object of which is to establish quantitative relations between the behaviour and performance of the ship and the variations in design causing them, was generally neglected.

With the introduction of iron, and later of steel, as a structural material for the hulls of ships, and of heat engines for their propulsion, the possible variation of size, proportions and propelling power of ships was enormously increased. In order to make the fullest use of these new possibilities, and to adapt each ship, as closely as may be, to the special purpose for which it is intended, theoretic knowledge has become of paramount importance to the designer. He has been forced to investigate closely those branches of the abstract physical sciences that bear specially on ships and their behaviour, and these mathematical and experimental investigations constitute the study of Theoretical Shipbuilding. It embraces the consideration of problems and questions upon which the qualities of a ship depend and which determine the various features of the design, having regard to the particular services that the ship will be required to perform; i.e. the requirements that must be fulfilled in order that she may make her various passages economically and with safety in all conditions of wind and sea, the best form for the hull with regard to the resistance offered by the water and the engine power requisite in order to attain the speed desired, the nature of waves and their action upon the ship, and the structural arrangements necessary in order that she may be sufficiently strong to withstand the various stresses to which she will be subjected. The determination of the most suitable dimensions to fulfil certain conditions involves the consideration of a different set of circumstances for almost every service; and here the experience gained in vessels of similar type, together with the known effect of modifications made to fulfil new conditions of each particular design, can be used as a guide. The requirements of economical working, safety, &c., determine the length, breadth, depth and form. The length has a most important bearing on the economy of power with which the speed is obtained; and on the breadth, depth and height of side, or freeboard, depend to an important degree the stability and seaworthiness of the vessel.

While, however, the importance to the ship designer of mathematical theories based on first principles and experiment can hardly be overrated, it should be observed that the circumstances and conditions postulated are invariably much less complex than those which surround actual ships. The applicability of the theories depends on the closeness with which the assumed conditions are realized in practice. The ultimate guide in the design of new ships must, therefore, still remain practical experience. To this experience theory is a powerful assistance, but can by no means replace it.

THEORETICAL SHIPBUILDING

Stability.

When a ship floats at rest in still water, the forces acting upon her must be in equilibrium. These consist of the weight of the shipbuil
ship acting vertically downwards through its centre of gravity and the resultant pressure of the water on the immersed hull.

If the ship be supposed removed and the cavity thus formed filled with water, then, since this volume of water is in equilibrium under the same system of fluid pressures, the resultant of these pressures must be equal and opposite to the weight of the water in the cavity and will therefore act vertically upwards through the centre of gravity of this portion of water. Defining the weight of water displaced by the ship as the displacement, and its centre of gravity as the centre of buoyancy, it is seen that the fundamental conditions for the equilibrium of a ship in still water are: (a) that the weight of the ship must be equal to the displacement, and (b) that its centre of gravity and buoyancy must be in the same vertical line.

A floating ship is always subject to various external forces disturbing it from its position of equilibrium, and it is necessary to investigate the stability of such a position, i.e., to determine whether the ship, after receiving a small disturbance, will tend to return to its former position, in which case its equilibrium is termed stable, or whether, on the other hand, it will tend to move still farther from the original position, when the equilibrium is termed unstable. The intermediate case, when the ship tends to remain in its new position, is a third state of equilibrium, which is termed neutral.

Of the modes of disturbance possible, it is evident that a bodily movement of the ship in a horizontal direction or a rotation about a vertical axis will not affect the conditions of equilibrium; the equilibrium is also stable for vertical displacements of a ship. The remaining movements, viz., rotations about a horizontal axis, can be resolved into rotations in which the displacement is unaltered, and vertical displacements, the effect of the latter being considered separately. Of the various horizontal axes about which a ship can rotate two are of particular importance, viz., (1) an axis parallel to the longitudinal plane of symmetry, (2) an axis at right angle to the plane, both axes being so chosen that the displacement remains constant; the stability of a ship with reference to rotations about these axes is known as the transverse stability and the longitudinal stability respectively. In the following account the consideration of stability is confined at first to these two cases; the general case of rotation about any horizontal axis whatever being dealt with later.

**Transverse stability.** Let fig. 1 represent a transverse section of a ship, WL being its water line when upright, and W'L' its water line when inclined to a small angle $\theta$ as shown.

Assuming that the displacement is unaltered, if $G$ be the position of the ship's centre of gravity and $B'$ the positions of the centre of buoyancy in the upright and inclined positions respectively, the ship acting on the ship consist of its weight $W$ vertically downwards through $G$ and the resultant water pressure equal to $W$ acting vertically upwards through $B'$. These constitute a couple of moment $W \times GZ$ where $Z$ is the foot of the perpendicular from the horizontal plane of the water line to the vertical through $B'$; the direction of the couple as drawn in the figure is such as would cause the ship to return to its original position, i.e., the equilibrium is stable for the inclination shown.

If $M$ be the intersection of the vertical through $B'$ with the vertical through $G$, the moment of the restoring couple is equal to $W \times GZ \sin \theta$, and $GM \sin \theta$ is termed the righting lever.

If, by moving weights on board, $G$ be moved to a different position on the original vertical through $B$, the original position of the ship will remain one of equilibrium, but the moment of stability at the angle of inclination $\theta$ will vary with $GM$. If $G$ be brought to the position $G'$ above $M$ the moment $W \times GZ'$ will tend to turn the ship away from the original position. It follows that the original position of equilibrium shall be stable for the given inclination if the centre of gravity shall be below the intersection of the verticals through the upright and inclined centre of buoyancy, and the moment of stability is proportional to the distance between these two points.

The inclination $\theta$ is made smaller the point $M$ approaches a definite position, which, in the limit when $\theta$ is indefinitely small, is termed the metacentre.

In ships of ordinary form it is found that for $10$ to $15$ degrees of inclination the inclination of the verticals through the centres of buoyancy $B$ and $B'$ remains sensibly at the metacentre $M$; and therefore within these limits the moment of stability is approximately equal to $W \times G \sin \theta$.

### Small inclinations.

Let $WL$, $W'L'$ (fig. 2) be the traces of the upright and inclined water planes of a ship on the transverse plane; $B$, $B'$ the corresponding position of the centre of buoyancy; $\theta$ the angle of inclination, supposed indefinitely small in the limit, and $S$ the intersection of $WL$ and $W'L'$; join $BB'$. By supposition the displacement is unchanged, and the volumes $WAL'$, $WSW'$, $LSL'$ are also equal. If $dW$ represent an element of length at right angles to the plane of the figure, $\gamma_1$, $\gamma_2$, the half-breathths one on each side at any point in the original water line, so that, if $\gamma_1$, $\gamma_2$, $SL'$, $SL$ be the areas $WSW'$, $LSL'$ differ from $\gamma_1 y_1$, $\gamma_2 y_2$, $\gamma_1 \gamma_2 \theta$ by indefinitely small amounts, neglecting which the volumes of $WSW'$, $LSL'$ are equal to $\int \gamma_1 y_1 dx$ and $\int \gamma_2 y_2 dx$.

Since these are equal we have

$$\int \gamma_1 y_1 dx = \frac{1}{2} \int \gamma_2 y_2 dx = \int \gamma_1 y_2 dx = \frac{1}{2} \int \gamma_2 y_1 dx,$$

i.e., the moments of the two portions of the water plane about their line of intersection passing through $S$ are equal. This line is also the axis of rotation, which therefore passes through the centre of gravity of the water plane. For vessels of the usual shape, having a middle line plane of symmetry and floating initially upright, for small inclinations consecutive water planes intersect on the middle line.

Again if $g_1$, $g_2$ are the centres of gravity of the wedges $WSW'$, $LSL'$, and the volume of either wedge, the moment of transference of the wedges $xg_1 g_2$ is equal to the moment of transference of the whole immersed volume $VBB'$ where $V$ is the volume of displacement.

But $Wxg_1 = \text{moment of wedge $WSW'$ about $S = \frac{1}{2} \gamma_1 y_1 \theta \ dx$,}$ and $xg_2 = \text{moment of wedge $LSL'$ about $S = \frac{1}{2} \gamma_2 y_2 \ dx$.}$ Adding, $\int [\gamma_1 y_1 + \gamma_2 y_2] \theta \ dx = xg_1 g_2 = VBB'$. But $BB'$ = $BM\theta$ to the same order of accuracy and $\int [\gamma_1 y_1 + \gamma_2 y_2] \theta \ dx$ is the moment of the water about the axis of rotation; denoting the latter by $I$, it follows that $BM = \frac{1}{I};$ i.e., the height of the metacentre above the centre of buoyancy is equal to the moment of inertia of the water about a line at right angles to the axis of rotation divided by the volume of displacement.

These quantities, and also the position of the centre of buoyancy can be obtained by the approximate methods of quadrature usual in ship calculations, and from them the position of the metacentre can be found.

If the ship is wholly immersed, or if the inertia of the water plane is negligible as in a submarine when diving, $BM = 0$, and the condition for stability that $G$ should be below $B$, the righting lever at any angle of inclination is then equal to $BG \sin \theta$.

During the process of design the position of the centre of gravity
is determined by the disposition of hull material and fittings, machinery, coal and all other movable weights, the position of which is necessarily fixed by other considerations than those of stability; but the height of the metacentre above the centre of buoyancy varies approximately as the cube of the breadth, and any desired value of GM is readily obtained by a suitable modification in the beam.

The metacentric height in various typical classes of ships at "normal load" is as follows:

The metacentric height adopted in steamships is governed principally by the following considerations:

(a) It should be sufficiently large to provide such a position of G as will give ample stability at considerable angles of inclination and sufficient range.

(b) Where ample stability at large angles is obtained by other means, the stability at small angles, which is entirely due to the metacentric height, should be sufficient to prevent forces due to wind on upper works, movement of weights athwartships, turning, &c., causing large and uncomfortable angles of heel.

(c) It should be sufficient to allow one or more compartments to become opened to the sea, through accidental damage, without risk of capsizing.

(d) It should, if possible, be sufficiently large in the normal condition of the ship to permit the greatest possible freedom in the stowage of a miscellaneous cargo without producing instability.

(e) On the other hand an excessive value causes, rapid and uncomfortable rolling among waves.

A ship having small initial stability is said to be "crank," while one possessed of a large or excessive amount is termed "stiff." The former type is generally found to be steadier and easier in rolling among waves; and for this reason when other circumstances permit, the metacentric height is usually chosen as small as possible consistent with safety and comfort.

The metacentric height is affected by an alteration in displacement or in position of the centre of gravity caused by loading or unloading cargo, fuel and stores. In consequence the stability has to be investigated for a variety of conditions, particularly that in which the metacentric height is a minimum. The change in the position of the centre of gravity can be readily determined from an account of the weights removed, added or shifted; and the height of the metacentre is obtained by calculating its position at a number of water lines, and drawing a curve of heights of metacentre above keel on a base of the draught of water. The results are conveniently embodied in the form of a metacentric diagram; the curves of height of metacentres and vertical positions of centres of buoyancy being set up from a line intersecting the water lines at 45°.

Figs. 3, 4 and 5 are the metacentric diagrams for a battleship, a vessel sharply curved at the bilge typical of a large number of merchant steamers, and a sailing ship of "Symondite" (or peg top) section; it will be observed that in the first and second the M curve is slightly concave upwards, and in the third sharply convex.

The buoyancy curve in all cases is nearly a straight line whose inclination at a particular water plane to the horizontal is equal to tan"Ah/V;" where A is the water plane area, and h the depth of the centre of buoyancy below the surface. The position of the metacentre at an intermediate water line is obtained from the diagram by drawing a horizontal line at the draught required, and squaring up from its intersection with the 45° line to meet the curve of metacentre.

With these curves are associated (though usually drawn separately) two others known as the curves of Displacement and of Tons per inch and expressed by AA and BB respectively in the above figures. These have the mean draught of water as abscissa (vertical), and
the displacement in tons and the number of tons required to increase the mean draught by 1 in., respectively, as ordinates (horizontal). The ordinate of the curve of displacement at any water line is clearly proportional to the area of the curve of tons per inch up to that water line.

The properties of the metacentric stability at small angles are used when determining the vertical position of the centre of gravity of a ship by an "inclining experiment"; this gives a check on the calculations for this purpose in the initial stages of the design, and enables the stability of the completed ship in any condition to be ascertained with great accuracy.

The experiment is made in the following manner:

Let fig. 6 represent the transverse section of a ship; let w, w be two weights on deck at the positions P, Q, chosen as far apart transversely as convenient; and let G be the combined centre of gravity of ship and weights. When the weight at P is moved across the deck to P′, and the published vertical of gravity of the whole moves from G to some G′ so that G′P′ is parallel to PQ′ (assumed horizontal) and equal to hW/W where h is the distance moved through by P′, and W is the total displacement. The ship in consequence heeled a small angle θ, the new vertical through G passing through the metacentre M; also G′M′=GG′ cot θ=hW/W cot θ, the metacentric height being thereby determined and the position of G then found from the metacentric diagram. In practice θ is observed by means of plumb bobs or a short period pendulum recording angles on a cylinder; the weight at P, w, is chosen so as to give a heel of from 3° to 5°, is divided into several portions moved separately to Q′. The weight at Q′ is replaced at the angle θ, or divide through again observed; and the weight at Q similarly moved to P′ where PQ′=hPQ′, and the angle observed; GM is then taken as the mean of the various evaluations.

In the case of small transverse inclinations it has been assumed that the vertical through the upright and the inclined positions of the centre of buoyancy intersect, or, which is the same thing, that the centre of buoyancy remains in the same transverse plane when the vessel is inclined. This assumption is not generally correct for large transverse inclinations but is nevertheless usually made in practice, being sufficiently accurate for the purpose of estimating the moments and ranges of stability of different ships, calculated under the same conventional system; this is all that is necessary for practical purposes.

With this assumption, there will always be a point of intersection (M′ in fig. 7) of the verticals through the upright and inclined centres of buoyancy, and the righting lever is, as before, GZ=GM′ sin θ.

In this case, however, there is no simple formula for BM′ as there is for BM in the limiting case where θ is infinitesimal; and other methods of calculation are necessary.

The development of this part of the subject was due originally to Atwood, who in the Philosophical Transactions of 1796 and 1798, advanced reasons for differing from the metacentric method which was published by Bouguer in his Traité du navire in 1746. Atwood's treatment of stability (which was the foundation of the modes of calculation adopted in England until about twenty years ago) was as follows:

Let WL, WL′ (fig. 7) be respectively the water lines of a ship when upright and inclined at an angle θ, S their point of intersection; B and B′ the centres of buoyancy; and g, g the centres of gravity of the equal wedges WSW, LSL, and h, h the feet of the perpendiculars from g, g on the inclined water line. Draw GZ, BR parallel to and passing through the limit of B′ in Z and R.

The righting lever is GZ as before; if W be the volume of displacement, and t that of either wedge, then

$$V\times BR = Wxh_b$$

also

$$GZ=BR-BG\sin\theta;$$

whence the righting moment or

$$W\times GZ = W\left(\frac{Vxh_b}{V} - BG\sin\theta\right)$$

This is termed Atwood's formula. Since BG, V and W are usually known, its application to the computation of stability at various angles and draughts involves only the determination of Vxh_b. A convenient method of obtaining this moment was introduced by F. K. Barnes, as follows:

In the diagram (fig. 7) it is assumed that the ordinates at θ is the moment of Vh_b with respect to GZ, a vertical line being drawn through GZ.

In the diagram (fig. 8) the principle of moments is applied to the distances of GZ, the righting lever, from the centres of buoyancy of the equal wedges W'TW', L'TL' at the water line W'L'. The moment of either wedge about the line B′B is zero, and the righting moments of W'L'A and W'L'A about B′B are therefore equal; since these volumes are also equal, the perpendicular distances of B′ and B from B′B are equal, or B′B is parallel to B′B.

The projection on the plane of inclination of the locus of the centre of buoyancy for varying inclinations with constant displacement is termed the curve of buoyancy, a portion BB′B″ of which is shown in the figure. On diminishing the angle θ indefinitely so that B″ approaches B′ to coincide, the line B′B″ becomes, in the limit, the tangent to the curve BB′B″, and coincides with the water line W'L′; hence the tangent to the curve of buoyancy is parallel to the water line.
investigated by Bouguer in his *Traité du Navire*. The points M'M'... on the curve are now termed pro-metacentres.

The length of the normal BM' or the radius of curvature of the curve of buoyancy at an angle θ, then \( d\beta d\phi = d\theta d\phi \)

is indefinitely small, \( d\beta d\phi = \theta \). Using Cartesian co-ordinates with B as origin and By, Bz, as horizontal and vertical axes, we have—

\[
\frac{dy}{d\theta} \cos \theta = \frac{dz}{d\phi} \cos \theta, \quad (1)
\]

\[
\frac{dy}{d\phi} \sin \theta = \frac{dz}{d\phi} \sin \theta, \quad (2)
\]

whence

\[
y = \int_0^\phi \cos \theta \, d\phi = \rho \tan \theta,
\]

and the righting lever \( GZ = \rho \sin \theta + (z - BM) \sin \theta \).

The radius \( \rho \) is (as for the upright position) equal to the moment of inertia of the corresponding water-plane about a longitudinal axis through its centre of gravity divided by the volume of displacement; the integration may be directly performed in the case of bodies of simple geometrical form, while a convenient method of approximation such as Simpson's Rules is employed with vessels of the usual ship-shaped type. As an example in the case of a box, or a ship with upright sides in the neighbourhood of the water-line, if \( BM = a \) and \( BM = eD \), then \( \rho = eD \tan \theta \);

whence

\[
y = \int_0^\phi \cos \theta \, d\phi = \rho \tan \theta,
\]

\[
z = \int_0^\phi \sin \theta \, d\phi = \rho \tan \theta,
\]

and

\[
GZ = (a - eD) \sin \theta + \rho \tan \theta \sin \theta;
\]

which relations will also hold for a prismatic vessel of parabolic section. It is interesting to note that in these cases if the stability for infinitely small inclinations is neutral, then, at \( \varphi = a \), the vessel is stable for small finite inclinations, the righting lever varying approximately as the cube of the angle of heel.

The application of the preceding formulae to actual ships is troublesome and laborious on account of the necessity for finding by trial the positions of the inclined water-lines which cut off a constant volume of displacement. To avoid this difficulty the process was modified by Kewich and Risbec in the following manner—Multiply equations (1) and (2) by \( V \phi d\phi \) and integrate;

we then have—

\[
d(Vy) = \rho \cos \theta \, d\phi,
\]

\[
d(Vz) = \rho \sin \theta \, d\phi,
\]

where I is the moment of inertia of the inclined water-line about a longitudinal axis passing through its centre of gravity. These formulae have been obtained on the supposition that the volume \( V \) is constant while \( \theta \) is varying; but by regarding the above equations as representing the moments of transference horizontally and vertically due to the wedges, it is evident that \( V \) may be allowed to vary in any manner provided that the moment of inertia \( I \) is taken about the longitudinal axis passing through the intersection of consecutive water-lines. In particular the water-lines may all be drawn through the point of intersection of the upright water-line with the middle line, and the moments of inertia are then equal to \( \frac{1}{2} \varphi \frac{dV}{dx} \) for both sides of the ship, \( \varphi \) being the half-breadth along the inclined water-line; the increase in volume is the difference between the quantity \( \frac{d}{dx} \frac{dV}{dx} \) for the two sides of the ship.

If \( V_a, V_b \) be the volumes of displacement at angles \( a \) and \( b \) respectively,

\[
V_a - V_b = \int_0^a \frac{dV}{dx} \left( \frac{1}{2} \varphi \right) \, dx,
\]

and substituting in (3) and (4) and integrating,

\[
y = \int_0^a \frac{dV}{dx} \left( \frac{1}{2} \varphi \right) \cos \theta, \quad (6)
\]

\[
z = \int_0^a \frac{dV}{dx} \left( \frac{1}{2} \varphi \right) \sin \theta, \quad (7)
\]

On eliminating \( V_a \) in (5), (6) and (7), \( y \) and \( z \) can be found.

This is repeated at different draughts, and thus \( V_a \) and \( z \) are determined at a number of draughts at the same angle, enabling curves of \( y \) and \( z \) to be drawn at various constant angles with \( V \) for an abscissa; from these, curves may be obtained for \( y \) and \( z \) with the angle \( a \) as abscissa for various constant displacements; \( GZ \) being equal to

\[
y \cos \beta + (z - a) \sin \alpha.
\]

From the foregoing it is evident that the elements of transverse stability, including the co-ordinates of the centre of buoyancy, position of pro-metacentre, values of righting lever and righting moment, depend on two variable quantities—the displacement and the angle of heel. The righting lever \( GZ \) is in England selected as the most useful criterion of the stability, and, after being evaluated for the various conditions, is plotted in a form of curves—(a) for various constant displacements on an abscissa of angle of inclination, (b) for a number of constant angles on an abscissa of displacement. These are known as curves of stability and cross curves of stability respectively; either of these can be readily constructed when the other has been obtained; which process is utilized in the method now almost universally adopted for obtaining \( GZ \) at large angles of inclination, a full description being given in papers by Merrifield and Amsler in *Trans. I.N.A.* (1880 and 1884). The procedure is as follows:

1. The substitution of calculations at constant angle for those at constant interval. A number of water-lines at inclinations having a constant angular interval (generally 15°) are drawn passing through the intersection \( S \) of the load water-line with the middle line on the body plan. Other water-lines are set off parallel to these at fixed distances above or below the original water-line passing through \( S \).

2. The volumes of displacement and the moments about an axis through \( S \) perpendicular to the water-line are determined for each draught and inclination by means of the Amsler-Laffon integrator, the pointer of this instrument being taken in turn round the immersed part of each section.

3. On dividing the moments by the corresponding volumes, the perpendicular distance of the centre of buoyancy from the vertical through \( S \) is obtained, i.e. the value of \( GZ \), assuming \( G \) and \( S \) to coincide.

4. For each angle in turn "cross curves" of \( GZ \) are drawn on a base of displacement.
The slope of the stability curve for small angles, the maximum righting lever with the angle at which it occurs, and the range or the inclination at which the stability vanishes are of particular interest, inasmuch as the curve depends principally on these features; and the effect on them, particulars of variation of freeboard, breadth and position of centre of gravity, is considered below.

The stability curve AA (fig. 12) is drawn for a box-shaped vessel of draught 10 ft., freeboard 10 ft. and beam 30 ft.; with C.G. in the water-plane. The curves EE, FF, GG are drawn for the same vessel, but with freeboard altered to 12$\frac{1}{2}$, 7, and 5 ft. respectively; it will be observed that freeboard has no influence on the stability at small angles, but has a marked effect on the range and maximum righting lever. An increase of freeboard is generally accompanied by a rise in the position of the centre of gravity; this is not included in the curves, but would actually reduce the stability to some extent. The effect of freeboard on the range and on the safety of ships is also illustrated by a comparison between the curves of stability (fig. 13) of the armoured turreted ships "Monarch" and "Captain," the latter of which was lost at sea in 1870. These vessels were similar in construction and dimensions except that the freeboard of the "Monarch" was 14' 0" and that of the "Captain" 6' 6"; the smaller freeboard of the "Captain" was associated with a slightly lower position of the centre of gravity and a greater metacentric height. The stability curve of the "Captain" in consequence rises rather more steeply than that of the "Monarch" up to about 14° when the deck edge is immersed; the righting lever then rapidly declines, and vanishes at 54°, in contrast to the "Monarch’s," where the maximum righting lever is doubled and range augmented 1.3 times by the additional freeboard. For the influence of the range in enabling a ship to withstand a suddenly applied force see "Dynamical Stability."

Again, for the box-shaped vessel previously considered, if the breadth is modified successively from 30 ft. to 35, 35 and 20 ft., other features remaining unaltered, the curves of stability then obtained are represented by BB, CC and DD in fig. 12. It is seen that alteration in beam affects principally the stability lever at moderate angles of inclination, while at 90° inclination the curves all intersect. Since at small angles GZ = GM$\delta$ (in circular measure) approximately, the initial slope of the curve is proportional to GM, and the tangent to this curve at the origin can be drawn by setting by the value of GM as an ordinate to an angle of one radian (57.3°) as abscissa, and joining the point to the origin. (See figs. 10 and 11.) The height of the metacentre above the centre of buoyancy will, ceteris paribus, vary with the cube of the breadth, and an increase of beam will result in a large increase of stability at moderate angles.

Finally, the effect of an alteration in the vertical position of the centre of gravity is illustrated by the three stability curves of a steam yacht in fig. 14, where the centre of gravity is successively raised 1 ft. In the condition corresponding to the fourth and lowest curve, the GM is negative (30 ft.), and so also are the righting levers up to 15° when the curve crosses the axis; from 15° to about 52° the GZ is positive, but above
that value it again becomes negative. In this case the stability is unstable at the upright position, and the ship will roll to an angle of 15° on either side where the equilibrium is stable. This peculiarity is not uncommon in merchant steamers at light draught. Ample stability at large angles and good range is provided in such cases by high freeboard; but, apart from any considerations of safety, water ballast is used to lower the centre of gravity to a sufficient extent to avoid excessive tenderness.

The properties of the loci of centres of buoyancy and of pro-
metacentres were fully investigated by Dupin in 1822, including also
the surfaces into which these curves develop when admitting
involutions, inclinations about transverse and "skew" axes. It
has been shown that the tangent to the curve of buoyancy
at any point is parallel to the corresponding water-line;
and assuming that the ship is only free to turn in a plane perpen-
dicular to the axis of inclination, the positions of equilibrium are
found by drawing from the centre of gravity all possible normals
to the buoyancy curve, or equally, all possible tangents to its evolve,
the metacentric curve, since the condition to be satisfied is, that the
centres of gravity and buoyancy shall lie in the same vertical. Again,

FIG. 15._Metacentric, Buoyancy and Flotation Curves of "Scrapis."

when the curve of statical stability crosses the axis, making an acute
positive angle as at P in fig. 14, the values of GZ on either side of
P are such as to tend to move the ship towards the position at 1,
and the equilibrium at P is stable. Similarly, when the curve
crosses the axis "negatively," as at the origin and Q, the equilib-
rium is unstable. Since the angle of intersection cannot be either
positive or negative twice in succession, on considering rotation in
ever directions, there are two positions of equilibrium of which
the upright only is stable. A self-righting life-boat exactly corresponds
to this condition, the vessel being capable of resting only in the
original upright position. If G is below Q, on the other hand, as at
G, there are again two positions of equilibrium of which the upright
only is stable. A vessel being unstable when upright. If G is at G there are again six positions of equilibrium; the
upright position is unstable, but a stable position is reached at a
certain angle on either side. This phase is often realized in merchant
ships when light, as already stated (side fig. 14). When G is exactly
upon P the curve of the metacentric curve, the equilibrium is
neutral; if it is at M, the ship is stable for finite inclinations, and if it is at a similar position for M1 (except that the neutral state
is then reached at 180°) and for P.

In all the above cases it will be observed that the positions of stable and unstable equilibrium are normal in number and occur
alternately. There are two exceptions:

1. When the moment of inertia of the water plane changes abruptly
so that the B curve receives a sudden change of curvature. This is
possible with bodies of peculiar geometrical forms, and two positions of
M then correspond to one position of the body; if G lies between
them, the equilibrium is stable for inclinations in one direction
and unstable for those in the opposite direction, and is then termed
"mixed."

2. When the equilibrium is neutral, this condition may be regarded
as the coincidence of two or more positions of equilibrium alternately
stable and unstable. The ship may then be either
stable, unstable or neutral for finite inclinations; in exceptional
cases she may be stable in one direction and unstable in the other,
resembling to some extent the condition of "mixed equilibrium."

The curves of buoyancy and flotation and the metacentric curve
for H.M. troopship "Scrapis" are shown with reference to the
section of the ship in fig. 15, and on an enlarged scale for greater

---

1 The curves of buoyancy and flotation and the metacentric curve
for H.M. "Scrapis" were obtained by practical investigation by the writer in 1871. The
results showed that Dupin's investigations, which were apparently purely theoretical,
had not fully disclosed certain features of the curves, such as the cusps, &c.
centre of gravity, or, as it is termed, the centre of flotation, the curve of flotation will be the locus of the projections of the centres of flotation on the plane of the figure, which curve touches each water-line.

From consideration of the slope of a ship's side around the periphery of a water-line, Dupin obtained the following expression for the radius of curvature of the curve of flotation,

$$\rho' = f(x) \tan \alpha \cdot dx$$

where $dx$ is an element of the perimeter, $\alpha$ the inclination of the ship's side to the vertical, and $\gamma$ its distance from the longitudinal axis through the centre of flotation. M. Emile Leclert, in a paper read at the Institution of Naval Architects, 1870, proved the equivalence of the above formula to the two following, which are known as Leclert's Theorem:

$$\rho' = \rho + \frac{dp}{dV}$$

where $I$ and $V$ are respectively the moment of inertia of the water-plane and the volume, and $\rho$ is the radius of the curve of buoyancy or $B'M'$. Independent analytical proofs of the formulæ were given in the paper referred to; and (Trans. I.N.A., 1894) a number of elegant geometrical theorems in connexion with stability, given by Sir A. G. Greenhill, include a demonstration of Leclert's Theorem as follows (in abbreviated form):

Let $B$, $B'$ (fig. 17) be the centres of buoyancy of a ship in two consecutive inclined positions, and $F$, $F'$ the corresponding centres of flotation. Draw normals $BM$, $B'M'$, meeting at the centre of metacentre $M$; and $FC$, $F'C'$, meeting at the centre of curvature $C$. Produce $FB$, $F'B'$ to meet $O$, to $OM$, $MC$.

Then $BM$, $CF$ and $B'M'$ are respectively parallel, and similarly also $BB'$, $FF'$; hence the triangles $MBB'$, $CCF'$ are similar and

$$\frac{BM}{BB'} = \frac{OB}{OF}$$

so that $O$, $M$, and $C$ are collinear.

If the displacement $V$ is now increased by $dV$, changing $B$ to $B'$, and $M$ to $M'$, then since the added displacement $dV$ may be supposed concentrated at $F$, $B'$ will lie on $OB$, and $dV$ may be shown similarly as before that $M'$ lies on $OC$. Further, considering the transference of moments, $BB' \times V = BF' \times dV$.

Draw MED parallel to $BF$, then

$$\frac{dV}{BB'} = \frac{ME}{MF} \frac{\rho'}{\rho} = \frac{d\rho}{dV}$$

$$\rho' = \rho + \frac{d\rho}{dV}$$

The curve of flotation resembles the curve of buoyancy in that not more than two tangents can be drawn to it in any given direction, but it differs in that its radius of curvature can become infinite or change sign. It contains a number of cusps determined by $\rho' = \frac{dV}{d\rho' = 0}$. These occur in an ordinary ship's shape at positions: (i) at or near the angles at which the deck is immersed or emerged (four in number); and (ii) at or near the angles of $90^\circ$ and $270^\circ$. There are, therefore, six cusps in the curve of flotation of an ordinary ship; they are shown in figs. 15 and 16 by the points $F_2$, $F_3$, $F_4$, $F_5$, $F_6$, $F_7$.

The following relations between the curves of buoyancy and of metacentres and the curve of statical stability are of interest, and enable the former curves to be constructed when the latter have been obtained. If $GZ'$, $GZ'$ (fig. 19) are the righting levers corresponding to inclinations $\theta$, $\theta + d\theta$, where $d\theta$ vanishes in the limit; $B'$, $B''$, the centres of buoyancy, $M'$ the metacentre; produce $GZ'$ to meet $B''M'$ in $U$.

Then, neglecting squares of small quantities,

$$d(GZ') = V'U = dGZ'$$

or vertical distance of $M'$ above $G = \frac{d(GZ')}{dGZ'}$.

Also $B'' = M'B''$;

$$Z'B'' - Z'B'' = MZ' - MZ'' = Z'U = GZ', \frac{dGZ'}{dGZ'}$$

or

$$GZ' = \frac{d(B''Z')}{dGZ'}$$

i.e. the vertical distance $(B'Z')$ of $G$ over $B$ is equal to $GZ'$.}

It follows that by differentiating the levers of statical stability and finding the slope at each ordinate the vertical distance of $M'$ over $G$ is obtained, and $M'$ may be plotted by setting up this value from $Z'$ above $GZ'$ drawn at the correct inclination; also that by integrating the curve of statical stability and finding its area up to any angle, the vertical separation of $G$ and $B'$ is obtained, and $B'$ may be plotted by setting down this value increased by $BG$ below $Z'$. 

![Diagram](image-url)
The work done in inclining a ship slowly so as to maintain a constant displacement (and avoid communicating any unnecessary movement of disturbance to the water) is given by the expression $W \times f_m \delta \theta$ where $M$ is the moment resisting the inclination. This may be written $\frac{W \times f_m}{G Z \delta \theta}$ and it has been shown above that this is equal to the weight multiplied by the vertical separation of the centres of gravity and buoyancy. This is otherwise evident since the work is the sum of the moments of the forces acting on the ship, viz., the buoyancy in the water and the displacement and the buoyancy; these are respectively equal to $W \times G \delta \theta$, and $W \times \delta \theta$ giving the value $W \left( Z' B' - BG \right)$ as before.

The dynamical stability of a ship at any angle is defined as the work done in inclining or lowering the ship to an equilibrium position; this is conveniently obtained by integrating the curve of statical stability as stated above. The dynamical stability can thus be calculated at various angles and a curve obtained, whose ordinates represent work done in foot-tons. The curve of dynamical stability is drawn for a battleship (normal condition) in fig. 10, and is there shown in relation to the curve of statical stability; it will be seen that the dynamical stability increases continuously until the righting moment vanishes, when it becomes a maximum.

A formula for the dynamical stability of a ship at any angle was given by Canon Moseley in a paper read before the Royal Society. In 1866, however, a model of a ship under his direction at Portsmouth Dockyard showed that the actual work in quickly inclining to a moderate angle agreed closely with that calculated in the case of a model in the position, which was obtained with a model of triangular section owing to the motion of the water set up, and also, probably, to the variation in displacement during the roll.

The presence of large righting couples at moderate angles of heel is of great importance in a sailing ship than in a steamship, since in the former it determines the amount of sail that can be carried unbalanced on either beam, and thereby influences the speed. A sailing ship in motion is subjected to the wind-pressures on the sails and the upper works of the ship, and to the water-pressures on the hull. When the ship is in steady motion, these forces are equal and opposite; and, so far as the stability is concerned, it is sufficient to determine the transverse resultant of the wind-pressure on the sails, and its moment, the water-pressure on the hull affecting only the speed and leeway of the ship.

The pressure on the sails depends on their form and area, their position, and the apparent velocity of the wind, i.e., the velocity relative to the ship. The pressure of the wind on the hull is obtainable similarly to that on the sails, but is usually neglected as the heeling moment is small. Experiments have been made to determine the wind-pressure on plates by Dines, Langley, Eliffet, Stanton and others, and tables giving the pressure on the plate, and thereby the pressure on the hull, have been published.

The normal pressure $R$ in pounds on a plate of area $A$ square feet exposed to face normally a wind of velocity $V$ feet per second is given by the formula $R = KAV$, where $K$ is a coefficient depending on the form of the plate, the wind-velocity, and the character and kind of the plate. In the case $K = 0.00037$, and of about 1 sq. ft. in area $K$ is about 0.0014, corresponding to a pressure of 1 lb per sq. ft. at about 16 knots. The coefficient increases slightly for larger dimensions of the plate. It has also been found that the departure from the square or circular form involving an increase in perimeter for the same area causes an increase in the mean pressure.

An alteration from the plane to the concave, analogous to the "bellying" of sails, is accompanied by a slight increase in the pressure per square foot of projected area; but for any large amount of concavity the increase is more than countera balanced by the decrease in the projected area.

No simple law exists connecting the normal pressure on a plate exposed obliquely to the wind with the angle of incidence; it is found that the results for air exhibit a good agreement with those for water, but the general equation is of the form $R = KAV \cos \theta$ where $	heta$ is the angle between the normal to the plate and the wind. At small angles of incidence up to about 20°, or even 40° (varying with the shape of the plate), the pressure varies directly as the angle; beyond this limit it is slightly diminished, afterwards increasing very slightly to a value which is almost constant for the remaining angles up to and including 90°. The centre of pressure for oblique impact lies between the leading edge and the centre of gravity of the area. In a plate 1 ft. square, it lies 0.34 ft. from the leading edge at 15° inclination and 0.4 ft. at 30° inclination, gradually approaching the centre of the plate as the angle of inclination is increased. A slight curving or concavity of the plate does not appear to have much influence on the normal component of the wind pressure.

The wind-pressure on the sails of a ship cannot be calculated with any degree of precision because existing information is insufficient to give the form of the sail and the variation in the wind in the three (b) the different positions in which the sails may be placed relative to the wind and to each other; and (c) the interference of adjacent sails with each other. On the other hand, conclusions based on these experiments are of value both in assisting in the intelligent appreciation of the effects of changes in the sail areas, sail positions, and in the form of rig, and in forming a comparison between the various sailings of ships and the general behaviour of vessels with which experience has been obtained.

The stability of a sailing vessel is usually estimated by assuming all plain sail to be placed in a fore and aft direction and to be subject to a normal pressure, which is supposed to vary directly to a wind of about 16 knots. The resultant pressure of the wind on the hull, with a normal rig and associated with the pressure due to wind-pressure arising from the fore part of the hull, is supposed to pass through the centre of gravity of the area of the immersed middle line plane (termed the centre of lateral resistance). If $h$ be the vertical distance between the centre of gravity of the ship and the centre of lateral resistance, and $a$ the angle of heel, the moment causing the heel is (on these assumptions)

$$ W \times G \frac{a}{h} $$

and the righting moment is approximately

$$ W \times G \frac{a}{h} $$

Hence

$$ \sin a = \frac{2240}{W \times G} $$

The reciprocal of this quantity or

$$ \frac{2240}{W \times G} $$

is a measure of the capability of the ship to stand up under her canvas spread and is termed the power to carry a sail. The value varies with different sizes and classes of ships and boats. It is relatively small in small boats and small yachts owing to the practicability of reducing the sail to some extent by lowering the mast. The value is also permissible in large yachts on account of their great range of stability. In boats and yachts it varies from 1 to 4 and in full-rigged sailing ships from 15 to 20.

The stability of sailing vessels at large angles of inclination varies considerably with the class of vessel. In racing yachts and other completely decked sailing boats whose ratios of beam to depth and draught are comparatively small, initial stability is obtained by lowering the centre of gravity with ballast fitted on the keel, and the range then extends to considerably over 90°; on the other hand, a number of half-decked or open sailing boats imber their gunwales with water when inclined to a moderate angle. With reference to this, Mr. Dixon Kemp in his Yacht Architecture remarks that the deck edge should not be immersed at an angle of heel less than 20°; some small centre-board boats whose gunwales are awash at 12° or 15° cause anxiety. With full-rigged sailing ships this angle is commonly 20° to 25°.

The effect of a sudden gust of wind on a sailing ship is obtained by equating the work done on the ship by the gust to her dynamical stability; and the angle by which the vessel is heeled over, is assumed to pass through the wind-pressures, the wind-pressures, their inertia and the water, and any change of displacement are neglected; the wind-pressure is assumed constant during the roll, in accordance with this, Mr. Dixon Kemp remarks that the deck edge is supposed less than 50°); the modification of the pressure due to the motion of the sail is also neglected.

Let $QFQ$ (fig. 20) be the curve of statical stability, the ordinates representing moments, and let the heeling couple due to the gust be represented by $OS$. If $N$ be the extreme angle of heel, draw $SPQ$ parallel to the base, cutting the curve at $P$, $Q$, and $PM$, $NQ$ perpendicular to the base. The work done by the wind in the area $OSUN$ and is equal to the dynamical stability of the ship or the area $OPQN$. Hence the areas $OPS$, $PQU$ are equal, and the extreme angle of heel is determined by this equality; the angle, $\phi$, and the pressure at which it is reached, lie on the initial and approximately straight portion of the curve, the extreme angle of heel ON is about twice $\phi$, and the angle of roll being supposed less than 50°; the modification of the pressure due to the motion of the sail is also neglected.

Let $OPQ$ (fig. 20) be the curve of dynamical stability when the wind is blowing with strength corresponding to $OS$; the intercepts of the ordinates below $SPUQ$, done working against the force of the wind, leaving the segments above $SPQ$ available for absorbing the heeling moment of the vessel at the position of the steady heel $PM$. As the strength of the gust is increased the points $P$ and $Q$ travel farther along the curve until $P'$, $Q'$ are reached, such that the areas $P'OQ$, $OT'$ are equal; the vessel will then come momentarily to rest at $Q'$ of $P'$, $Q'$ being unstable equilibrium, an increase in the wind-pressure causing her to capsize. It follows that a ship sailing in a wind of sufficient strength to cause a moderate angle of heel equal to $OM'$ will be on the point of capsizing if the wind should happen to drop and afterwards return suddenly with its
formers. A more dangerous, though improbable, case in which a gust of wind strikes the ship just as she has completed a roll to windward can similarly be investigated; it is found that the safe angle of steady heel under this condition is considerably less than that represented by OM. It thus appears that it is of the greatest importance that sailing vessels should possess large dynamical stability in order to provide against the risk of capsizing due to fluctuations in the wind-pressure. Although the neglect of the wind and water resistances in the above investigation materially modifies the quantitative results, the general conclusions point to the necessity for sufficient range and freeboard however large the righting levers may be at small inclinations.

The centres of effort and of lateral resistance have not the same longitudinal position, consequently a horizontal couple is produced which turns the vessel either into the wind or away from it. In the former condition the vessel is said to be "ardent," and in the latter to be "slack." In order that a vessel may be quick in going about and yet not require too large a helm angle on a straight course, she should be slightly "ardent," i.e., the true centre of effort should be slightly abaft the true centre of lateral resistance. The assumed and true positions of these centres differ to some extent, and on making allowance for this it is found that in the majority of vessels possessing slight ardenity the assumed C.E. lies slightly before instead of abaft the assumed C.L.R. In small sailing boats the points are usually very near together; but in a large number of sailing ships, including H.M. sloops, their distance apart is about 0.05 L, and in yachts about 0.02 L, where L is the length.

It may be noted in this connexion that the area of sail spread and the size of the ship are often connected by the coefficient which is known as the Driving Power. The value for small sailing boats and for yachts is about 200, and for full-rigged sailing ships from 80 to 100 (including plain sail only).

Longitudinal stability. Similar propositions are true in both cases, viz.:

1. Consecutive water-planes intersect an axis passing through the centre of rotation.
2. The height of the longitudinal metacentre M above the centre of buoyancy is equal to the moment of inertia about this axis divided by the volume of displacement of the ship.
3. The righting moment at any small angle of inclination θ (circular measure) is equal to W.G.M.θ.

In fig. 21 let WL be the water-line corresponding to the positions G and B, and conceive a longitudinal movement of a portion of the ship with its mean sea-level plane CD parallel to the horizontal plane EF, the points B and E being in the same vertical line above the water-line at the centre of flotation F.

the weights in the ship causing G to move horizontally to G' if G' be abaft G the ship will after trim by the stern until B moves to B', and vertically downwards until the centre of flotation has descended to W'L', intersecting WL at the centre of flotation F.

If L be the length of the ship between the draught marks, the change of trim (W'L'-4LL') is equal to L.θ, and the moment changing trim is W.G.G'y or W.G.M.θ; the change of trim in inches (other linear dimensions being in feet) is therefore

\[ W.G.G'y = W.G.M.θ \]

which is the moment required to change trim one inch. Since the longitudinal moment of inertia of the water-plane includes the cube of the length as a factor, the longitudinal BM is usually large compared

with BG, and the moment to change trim 1 in. in foot-tons is nearly equal to

\[ \frac{W.X.B.M}{L^2} \]

which is approximately constant for moderate variations of draught.

If a weight of moderate amount is placed at a distance a feet abaft the centre of flotation F, the bodily sinking in inches is

\[ \frac{W.X}{L^2} \]

the moment changing trim by the stern is W-foot-tons, and the change of trim is therefore \[ \frac{W}{T} \] inches, where T is the "tons per inch" and M the moment to change trim 1 in. If b be the distance of F abaft the forward end of the ship, the draughts forward and aft are increased respectively by

\[ \frac{W}{T} \left( \frac{L-2b}{2L} \right) \]

and

\[ \frac{W}{T} \left( \frac{L+2b}{2L} \right) \]

A ship provided with water-tight compartments is liable to have water admitted into any of them on account of damage received, or may require to carry water or other fluid in bulk as ballast or cargo. The effect of this addition on the draught and the stability is therefore of interest. There are three cases:

1. When the water completely fills a compartment;
2. When the water partially fills a compartment up to the level of the water-line, remaining in free communication with the sea; and
3. When a compartment is partially filled with water without any communication with the sea.

In the first case the water is regarded as a weight added to the ship; the mean sinkage is obtained from the displacement curve, the change of trim from the curves of inertia, and the angle of heel from the metacentric diagram, or (for large angles) the cross curves. In general, if the compartment filled is low in the ship, the stability is increased; if high, it is diminished.

In the second case, assume in the first place the compartment to be amidships, so that no heel or change of trim occurs, and to be moderate in size, so that the sinkage is moderate in amount. Let ABCD (fig. 22) be such a compartment bounded by water-tight bulkheads sufficiently high to prevent water reaching adjoining compartments. Let the water-lines be WEFL, W'GHL', before and after bilging; let A, a be the area of the whole water-plane WEFL and of the portion EF within the compartment respectively, in square feet; and let v be the volume contained in EBCF diminished by the volume of any solid cargo in the compartment. The buoyancy is reduced by an amount v by bilging, and the amount added through sinking must be equal to the amount so lost. If x be the sinkage in feet, then

\[ v = x(A-a) \]

so that the mean sinkage is equal to the buoyancy lost divided by the area of the intact water-plane. In the event of the compartment being so situated as to cause heel and change of trim, the total sinkage is found from the trim above as, and the effect of heel and change of trim superposed.

To obtain the heel produced, the position of the centre of flotation for the intact portion of the water-plane is found, and thence the vertical and horizontal positions of the new centre of buoyancy are deduced by taking account of the buoyancy lost through bilging, and then regained by the layer between the two water-planes. The moment of inertia of the intact water-plane is found about an axis through the new centre of flotation and thence the height of the new metacentre M' determined. The heel θ (assumed small) is found by equating the horizontal shift of B to sin θ X the vertical distance of M' above G, both being equal to the moment causing heel divided by the displacement. In a similar manner the change of trim is obtained. If the compartment bilged is large so that considerable changes in its area and that of the ship at the water-line result, the sinkage and alteration in stability are found by a tentative process, closer approximations to the final water-line being successively made.

The determination of the stability when bilged at or near the water-line is of special importance in warships owing to their liability to damage by gunfire in action, with the consequent opening up of a large number of compartments to the sea. Calculations are made of the sinkage and stability when the unarmoured or lightly armoured parts of the ship are completely riddled; the stability should be sufficient to provide for this contingency.

The third case, where the ship is intact but has compartments partially filled with water or other liquid, is of frequent occurrence. Practical illustrations occur in connexion with the filling and
emptying of water-ballast and oil-fuel tanks, and particularly in the case of ships fitted to carry large quantities of oil in bulk.

Let fig. 23 represent the section of a vessel fitted with a tank PQRS partly full of water. Let WL, wL be the upright water-lines of the vessel and tank, G the centre of gravity of the vessel and water combined, B the centre of buoyancy of the vessel, and b the centre of gravity of the water.

As the ship is filled successively through angles \( \theta_1, \theta_2, \ldots \) the centre of buoyancy B moves along the curve of buoyancy to \( B_1, B_2, \ldots \) the normals at which are tangential to the metacentric curve \( M_1, M_2, \ldots \). If the water in the tank could be kept from moving as the inclination proceeded, G would be fixed in the ship, and the righting levers would be \( GZ_1, GZ_2, \ldots \) those at small angles being equal to GM sin \( \theta \).

Actually, if the inclination be slowly performed, the water-level in the tank changes successively to \( w_1, w_2, \ldots \), maintaining a level surface at all times; its centre of gravity moves to \( b_1, b_2, \ldots \) thereby causing an apparent alteration in the combined centre of gravity G. Drawing \( b_1L \) perpendicular to the vertical through \( b_1 \) and calling \( W \) the weight of the water and of the water and ship combined, then at the angle \( \theta \) the line of action of the weight of the water \( wL \) has moved through a distance \( bL \) and the righting moment of the ship is diminished by an amount \( WbL \).

It is evident that the movement of the centre of gravity of the water in the tank is the same as would be the movement of the C.B. of a ship having the same form as the tank and water-lines corresponding to \( wL, w_1L, w_2L, \&c. \) The values of the levers \( b_1L, b_2L, \ldots \) can therefore be obtained by a process similar to that used for obtaining the righting levers of the ship; cross curves and thence ordinary stability curves being drawn for various heights of water and inclinations. If \( \theta \) be a small angle of inclination, the line of action of the weight \( bL \) will be such as to pass through the metacentre m corresponding to the water-line \( wL \) and determined by the formula \( bm = \frac{W}{P} \).

If the tank contains a fluid of specific gravity \( \rho \) the virtual rise of the centre of gravity is \( \frac{\rho}{\rho'} \). The loss of stability at small angles due to the mobility of the water is thus independent of the quantity in the tank, but is proportional to the moment of inertia of its free surface.

It is possible for a small quantity of water with an extensive free surface to render a ship unstable in the upright condition; the angle to which this large loss of stability extends depends, however, on the quantity of water in the tank, for the extent of the sideways movements of the centre of gravity G of the ship and water is minute if the tank be either nearly empty or nearly full, and the loss of stability at all angles above a small amount will then be inappreciable; the loss at moderate angles is usually a maximum when the tanks are about half full.

The assumption made above, viz. that the ship is inclined so gradually as to maintain a level water surface in the tank, is by no means in accordance with the actual circumstances during rolling; waves are then set up in the water, causing it to wash from side to side, so that the loss of stability may be either more or less than the amount calculated. To avoid danger of capsizing in still water, large tanks in a ship are filled or emptied in succession as far as possible, so that not more than one or two are partly full at the same time. Water-tight longitudinal partitions are also fitted in wide tanks in order to reduce the moment of inertia of the free surface. On the other hand tanks, partly filled with water, have been fitted and found effective in certain ships in order to reduce the rolling oscillations among waves.

Hitherto the stability of a ship has been considered only with reference to inclinations about any longitudinal or transverse axis. These are the cases which it is necessary to deal with in practice for the purpose of ascertaining the probable qualities as regards stability of a vessel by comparing the elements of its stability in the design stage with those of existing ships whose qualities have been tested by experience. For the exact theoretical consideration of the stability of a ship or any floating body, however, it is necessary to take account of the true line of the action of the buoyancy and not merely of its projection on the plane of inclination. The development of this part of the subject has largely been due to M. Dupin in his Mémoire de la stabilité des corps flottants and to M. Guyou in his Théorie du naufrage.

If a ship is inclined in all possible positions, keeping the displacement constant, the locus of the centre of buoyancy is a closed surface which is known as the surface of buoyancy; the curve of buoyancy for two-dimensional inclinations being the projection on the plane of rotation of the corresponding points on the surface of buoyancy. Similarly the envelope of all the water-planes is defined as the surface of flotation. The stability of a ship in all positions is known when (a) the form and dimensions of the surface of buoyancy, and (b) the position of the centre of gravity relative to it, have been obtained; the former depends entirely on the geometrical form of the ship and on the constant volume of displacement assumed, and the latter has to do only with the arrangement and magnitude of the component weights of the structure and lading. For an infinitesimal inclination the line joining the centres of buoyancy when upright and inclined is parallel to the water-plane, and the tangent plane to the surface of buoyancy is therefore parallel to the water-plane, i.e., it is horizontal, and the normal to the surface is vertical. If the initial position is one of equilibrium, the centre of gravity must lie on the normal. To determine the effect of a small disturbance from the position of equilibrium, it is necessary, as in the particular inclinations already considered, to find the line of action of the buoyancy for adjacent positions, i.e. to trace the normals to the surface of buoyancy to successive normals to this surface will not, in general, intersect; but, from the properties of curvature of surfaces, there are two particular directions of inclination for which adjacent normals to the surface will intersect the original normal, these directions being perpendicular to one another and parallel to the principal axes of the indicatrix of the surface of buoyancy.

If fig. 24 be a plan of the water-plane, \( Oxy \) the axis of inclination passing through two points of flotation \( Oy' \) and \( Ox' \) and perpendicular axes in and out right angles to the plane of flotation, then, from a consideration of the wedges of immersion and emersion for a small inclination \( \theta \), the travel of the centre of buoyancy B becomes:

\[
\frac{\partial}{\partial \theta} \left( \int_{y_x} x'y'd'x'd'y' \right) (or \text{BB} \text{ in fig. } 24) \text{ parallel to } Ox' \\
\frac{\partial}{\partial \theta} \left( \int_{y_x} x'y'd'x'd'y' \right) (or \text{BB} \text{ parallel to } Oy') \\
\frac{\partial}{\partial \theta} \left( \int_{y_x} x'y'd'y' \right) (or \text{BB} \text{ parallel to } Oy') \\
\frac{\partial}{\partial \theta} \left( \int_{y_x} x'y'd'y' \right) (or \text{BB} \text{ parallel to } Ox')
\]

These may be written:

\[
\int_{y_x} x'y'd'y' \left( \sin \theta - \cos \theta \right) \cos \theta \text{P} + \int_{y_x} x'y'd'y' \cos \theta \left( \sin \theta + \cos \theta \right) \text{P}
\]

where \( I_1' \) is the moment of inertia of the water-plane about \( Ox' \) and \( P \) the product of inertia about \( Ox' \) and \( Oy' \). For the principal axes of inertia of the water-plane \( Ox, Oy \) see Fig. 25, an angle \( \phi \) with \( Oy', Ox \) and if, from B as origin, axes \( Bx, By, Bz \) are drawn parallel to \( Ox, Oy, Oz \), then the co-ordinates of \( B' \) are as follows:

\[
x = -B_b \cos \phi - B_b \sin \phi \left( \cos \phi - I_x' \sin \phi \right)
\]

\[
y = B_b \cos \phi + B_b \sin \phi \left( \cos \phi + I_x' \sin \phi \right)
\]

\[
z = B_b \cos \theta - \frac{I_y}{I_x' - I_y'}
\]

Also:

\[
I_1' = I_x \cos^2 \theta + I_y \sin^2 \theta
\]

\[
P = \left( I_x - I_y \right) \sin \theta \cos \theta
\]
where $I_x$, $I_y$ are the principal moments of inertia of the water-plane. Hence

$$x = \frac{\theta}{V} I_x \sin \phi;$$
$$y = \frac{\theta}{V} I_y \cos \phi;$$
$$z = \frac{\theta}{2V} (I_x \cos^2 \phi + I_y \sin^2 \phi).$$

Eliminating $\theta$ and $\phi$, the locus of the centre of buoyancy for small inclinations of the ship becomes the elliptic paraboloid

$$\frac{x^2}{I_x/V} + \frac{y^2}{I_y/V} = \text{constant}.$$  

The equation to the indicatrix referred to axes parallel to $Bx$, By is therefore

$$\frac{x^2}{I_x/V} + \frac{y^2}{I_y/V} = \text{constant};$$

and the indicatrix is therefore similar and similarly situated to the momental ellipse of the water-plane, and the surface of buoyancy is everywhere symmetrical to all points within it. The quantities $I_x/V$ and $I_y/V$ are evidently equal to $BM_x$ and $BM_y$ (referring to inclinations about $Oy$ and $Ox$ respectively); and the indicatrix and momental ellipse become

$$BM_x + BM_y = \text{constant}.$$  

The angle $\psi$ that $BB'$ (the projection of $BB'$ on the plane of the indicatrix) makes with $SO$ is given by

$$\tan \psi = \frac{x}{y} \cot \phi;$$

hence the direction is conjugate to that of the axis of rotation with respect to the indicatrix.

This is illustrated in fig. 25, where the ellipse shown is the indicatrix; $OP$, the axis of inclination, $OQ$ the conjugate radius, and $ORM$ the perpendicular to the tangent. Draw $QN$ parallel to $OM$ to meet $OP$. The triangle $OMQ$ is similar to $BB'B''$; and they can be made equal by giving a suitable value to the constant in the indicatrix equation. In that case $ON$ is the projection on the plane of the normal to the surface at $B$, and the shortest distance between the normals at $B$ and $B'$ is equal to $ON = MQ = \frac{BB'}{\theta}$, since $ON$ or the axis of inclination is perpendicular to them both. Also, the length $BM'$ of the normal at $B'$ intercepted between $B'$ and the foot of the common perpendicular is equal to $ON$ since $\theta$ is the angle between the normals at $B$ and $B'$; if $\theta$ is divided into $I_x/V$ and $I_y/V$

$$\tan \phi = \frac{x}{y} \cot \phi;$$

hence the direction is conjugate to that of the axis of rotation with respect to the indicatrix.

This is illustrated in fig. 25, where the ellipse shown is the indicatrix; $OP$, the axis of inclination, $OQ$ the conjugate radius, and $ORM$ the perpendicular to the tangent. Draw $QN$ parallel to $OM$ to meet $OP$. The triangle $OMQ$ is similar to $BB'B''$; and they can be made equal by giving a suitable value to the constant in the indicatrix equation. In that case $ON$ is the projection on the plane of the normal to the surface at $B$, and the shortest distance between the normals at $B$ and $B'$ is equal to $ON = MQ = \frac{BB'}{\theta}$, since $ON$ or the axis of inclination is perpendicular to them both. Also, the length $BM'$ of the normal at $B'$ intercepted between $B'$ and the foot of the common perpendicular is equal to $ON$ since $\theta$ is the angle between the normals at $B$ and $B'$; it follows that

$$BM' = \frac{BB'}{\theta} = \frac{L'}{V},$$

an expression analogous to that obtained before for the case of small inclinations in the direction of the principal axes of the water-plane. It is worthy of note that the radius of curvature of the normal section of the surface of buoyancy through $Oy$ is, in general, less than $BM$; the latter being equal to $O{M^2}/2\theta$, and $\rho$ being equal to $O{R^2}/2\theta$; $\rho$ is also obtained by Euler’s expression—

$$\rho = BM' + BM.$$  

becoming equal to $BM$ for inclinations about the principal axes. Similarly the radius of curvature of the normal section through $Ox$ is, in general, greater than $BM$.

If the centre of gravity $G$ of the ship is coincident with $B$, the arm of the righting couple is $OM = \frac{x}{y} \theta$; and there is also a couple of lever $ON = \frac{1}{y} \theta$ in a perpendicular vertical plane. The resultant couple lies in a plane containing $OQ$, having a lever equal to

$$\frac{x^2}{I_x/V} + \frac{y^2}{I_y/V} = \text{constant}.$$  

In the general case when $G$ is situated at a distance $a$ above $B$, the righting lever becomes $

\frac{\theta}{2V} (I_x \cos^2 \phi + I_y \sin^2 \phi).$

The greatest angle of obliquity $(\alpha)$ occurs when $\phi$ is about $30^\circ$ and the plane of the couple is nearly coincident with the middle plane of the ship, and the value of $\alpha$ is greater than about $30^\circ$. It follows that if a weight is moved obliquely across the ship the axis of rotation is approximately longitudinal, except when the line of movement is nearly fore and aft; and in the latter case a small deviation from a fore and aft direction produces a large change in the position of the axis of rotation.

The direction of the axis of rotation is above expressed with reference to the position of the inclining couple in relation to the indicatrix of the surface of buoyancy; as, however, the couple is assumed small, the direction of the axis and the amount of inclination may equally be obtained by resolving the couple in planes perpendicular to the principal axes and superposing the separate inclinations produced by its components.

It has been shown above that the positions of equilibrium are found by drawing all possible normals to the surface of the buoyancy, and the condition for stability for an inclination in any direction is that the centre of gravity shall lie below the corresponding metacentre. The height of the metacentre varies with the moment of inertia of the water-plane about the axis of inclination, and the maximum and minimum heights are associated with the maximum and minimum moments of inertia, which again correspond to inclinations about the least and greatest axes of inertia respectively. If the centre of gravity lies below the lowest position of the metacentre (the transverse metacentre in the case of a ship when upright) the equilibrium is stable for all inclinations, and the condition is referred to as absolute stability. If the centre of gravity lies above the highest metacentre, the condition is one of absolute instability; if it lies between the highest and lowest metacentres, the condition is one of relative stability, the ship being stable for inclinations about a certain set of axes, and unstable otherwise.

The foregoing remarks apply to a vessel whose axis of inclination is fixed so that the component couple perpendicular to the plane of inclination is resisted. If, on the other hand, the vessel is free to move in all directions the resultant couple does not in general tend to restore the original position of equilibrium, although the component in the plane of inclination complies with the conditions above stated for absolute stability. If $m$ and $m_1$ be the greatest and least values of GM, the ratio of the component couples perpendicular to and in the plane of inclination, or tan $\alpha$ (fig. 25), is greatest when

$$\tan \phi = \frac{m_1}{m}$$

and then $\alpha = \frac{m_1 - m}{2\sqrt{m_1 m_2}}$.

If $m_1/m$, be small, this ratio is large, being equal to 4-93 in the numerical example above. In such cases the extent of the movement is such that, when a small initial disturbance cannot be readily determined by a statistical method, but the investigation of the work done in moving the vessel from one position to another appears to meet this difficulty.

This process is employed by M. Guyon in his "Théorie du navire", the stability of a ship in any condition being treated throughout from the dynamical standpoint. He proved that:

1. Owing to changes of position, without change of displacement, the potential energy of the system consists of a floating body and the water surrounding is a minimum when the weight of the body is equal to its displacement.

2. By changes of direction, without change of displacement, the potential energy of the system is equal to the weight of the body, multiplied by the vertical resolute of BG; when this distance is a minimum or a maximum the stability is respectively stable or unstable. A statistical proof of this has been given in the two-dimensional case.

The potential energy is thus equal to the dynamical stability.
SHIPBUILDING

increased by an arbitrary constant. If from any point B of the surface of buoyancy (fig. 26) a tangent plane be drawn, the declination of which to G, GN, is proportional to the potential energy, and the stability of the body is thus the same as that of the closed surface of buoyancy which is a solid capable of rolling on a horizontal plane. The locus of the foot of the perpendicular N is a circle (shown dotted in the figure); this surface resembles the surface of buoyancy in its general shape, but it is different, when GB is normal, i.e. at positions of equilibrium, B1, B2, B3, B4; it has the property that a radius GN drawn from G to a point on the circle through which the body is in its position at rest consists of two parts, and will then form a small flat ring; similar radii will form later at all other positions of absolute stability. Positions of absolute stability are those in which the energy is at a maximum, and which the body may reach if it is adrift in the position, i.e. that form the radius of a circle of which the body moves without external forces.

If the ship or body is supposed to move under no external forces, and the effect of any change in the displacement be neglected, the kinetic energy of the system can be expressed by $2m\dot{u}^2/2$, and the total energy by $(W+GN) + \frac{1}{2}m\dot{u}^2$; the latter is constant when there are no resistances, and steadily decreases if resistances are in operation. Neglecting resistance, when the body is momentarily at rest, $W+GN$ becomes $W_{L}$, where $\ell$ is a linear quantity; and throughout the motion GN is less than $l$ by $\frac{1}{2}\pi\mu^2m\dot{\theta}$. The effect of resistance is gradually to decrease $l$ or the maximum value of GN, and it may be exhibited graphically by the following conception. Imagine a sphere of water, with centre at G, to be originally entirely within the podaire and then to be capable of expanding until the whole surface is similar to that of the body. Then the body itself will remain within the podaire, and will then form a small flat ring; similar rings will form later at all other positions of absolute stability. Positions of absolute stability are those in which the energy is at a maximum, and which the body may reach if it is adrift in the position, i.e. that form the radius of a circle of which the body moves without external forces.

is less than $l$ and the position lies within the lake so bounded. The diminution of $l$ due to resistances has the effect of gradually drawing the body towards X'Y'. The body is originally placed near a position of absolute stability, the small lake on the one hand, and a boundary of the podaire on the other. The body is placed at rest near a position of absolute instability, the body in water will move freely from side to side and oscillate, until it reaches a position of absolute stability. Finally, if moving near a position of relative stability, the body will move freely from side to side until the body has been conducted to a position of absolute stability.

When regard is had to the surface of flotation it has been shown that in order that the displacement shall remain constant, consecutive waterlines must intersect on a line passing through the centre of gravity of the waterline or the centre of flotation. If the inclination take place from a given position in any possible directions, the lines of intersection with the original water-plane will all meet at the centre of flotation, which must, therefore, lie in the envelope of the water-planes, or the surface of flotation. The surface is therefore the locus of the centre of flotation for all possible inclinations. Since the curvature of the surface of flotation, which is the projection of the centre of flotation for inclinations about an axis perpendicular to the plane of projection, may change sign, the surface can also undergo similar changes in curvature and may be synclastic in certain parts and anti-clastic or saddle-shaped in others.

The relation between the surface of flotation and the stability of the ship is of great importance in the investigation of the ease with which the ship can be moved into horizontal positions by inclining the surface of flotation about an axis perpendicular to the plane of projection. The extension of the theorem of Leclerc to oblique inclinations contain no features of special interest or importance.

Rolling of Ships.

The action of the waves upon a ship at sea is such as to produce rolling or angular oscillations about a horizontal longitudinal axis, pitching or angular oscillations about a horizontal transverse axis, and heaving or translational oscillations in a vertical direction; also horizontal translations and rotations about a vertical axis which are not generally of an oscillatory character and will not materially affect the rolling. It is convenient when considering rolling to neglect the influence of the other accompanying oscillations, whose effect in most cases is slight in magnitude although complex in character.

The ship is in its first place conceived to be rolling in still water without any resistances in order to diminish the motion. The accommodation of motion for moderate angles of inclination within which the arm of the rolling couple is approximately proportional to the angle of heel (i.e. $2G\dot{\theta}/\eta$), is

$$\frac{\partial}{\partial \theta} = \frac{-\dot{\theta}^2}{\eta}$$

(1)

where $\dot{\theta}$ is the radius of gyration of the ship about the axis of rotation, $m$ the metacentric height, $\theta$ the angle of inclination and $g$ the acceleration produced by gravity. From this the time deduced for a single oscillation, from port to starboard, or vice versa, is

$$T = \sqrt{\frac{\eta}{\dot{\theta}^2}}$$

(2)

showing that the time of oscillation varies directly as the radius of gyration, and inversely as the square root of the metacentric height.

The value of $T$ is generally about 10 seconds in a large Atlantic liner, 7 to 9 seconds in a battleship, and 5 to 6 seconds in a small coastal liner. For a large modern warship is about one third of the breadth of the ship.

For unresisted rolling of ships among waves the theory generally accepted is that of Froude (see Proc. R. Inst. Arch., 1861 and 1862). Before his work, many eminent mathematicians had attempted to arrive at a solution of this most difficult problem, but for the most part their attempts met with scanty success; while Froude's results were imperfectly understood, and the forces impressed on a ship by waves could not be even approximated to. Froude's theory is based on the position that, when a ship is among waves, the impressed forces on her are to be placed normal to a water surface, which is assumed to be the surface passing through the ship's centre of buoyancy, and which is regarded as the effective wave surface, as far as the rolling is concerned. As in water at rest the ship is in equilibrium when her mast is normal to the surface of the water, so in waves she is in equilibrium when her masts are normal, instant by instant, to the effective surface of the wave that is passing her. While she at any instant deviates from this position, the effort by which she evades to return to the normal depends on the angle of deviation, in the same manner as the effort to assume an upright position, when forcibly inclined in still water, depends on the angle of inclination. Hence her stability (i.e. her effort to become vertical) in still water measures her effort to become normal to the wave at any instant on a wave. Froude made the assumptions that the profile of the wave was a curve of sines, and that the ship was rolling broadside on a regular series of similar waves of given dimensions and of given period of recurrence. He was aware that the profile of the wave would be better represented by a trochoid, but in his first paper he gave preference to prefer to the curve of sines. He also assumed that the ship's rolling in still water was isochronous, and that the period of the rolling was given by $T = \sqrt{\frac{\eta}{\dot{\theta}^2}}$ as obtained theoretically. On these assumptions the equation of motion is obtained by substituting, for the angle of inclination in still water, the instantaneous angle between the ship and the normal to the wave-slope, and thus becomes

$$\frac{\partial^2}{\partial \theta^2} - \frac{\partial}{\partial \theta} = \frac{\eta}{\dot{\theta}^2}$$

(3)

where $\dot{\theta}$ is the angle of ship's masts to the vertical, and $\Theta$ is the angle of normal to wave-slope to the vertical at the instant considered. $\dot{\theta}$ has to be expressed in terms of $t$, and is given by $\dot{\theta} = \Theta - \Theta_0$, where $\Theta_0$ is the maximum wave-slope, $T$ is the half period of the wave, and $\dot{\theta}$ is the angle of the wave at the distance equal to its length, and $t$ is the time dating from the mid-trough of the wave. Equation (3) can therefore be written

$$\frac{\partial^2}{\partial \theta^2} - \frac{\partial}{\partial \theta} = \frac{\eta}{\dot{\theta}^2} - \frac{\partial^2}{\partial \theta^2},$$

(4)

which is the general differential equation of the unresisted motion of a ship in regular waves of constant period. The solution of this is

$$\dot{\theta} = C_1 \sin \left( \frac{\Theta}{T} + C_2 \cos \frac{\Theta}{T} + \Theta_0 \right) \sin \left( \frac{\Theta}{T} + C_2 \cos \frac{\Theta}{T} + \Theta_0 \right),$$

(5)

where $C_1$ and $C_2$ are constants depending on the initial motion and attitude of the ship.

The last term of this expression,
represents the forced oscillations imposed on the ship by the passage of the series of waves during the time \( t \); and the first and second terms,

\[ C_1 \sin \frac{\pi}{T_1} + C_2 \cos \frac{\pi}{T_1} \]

are the same as the free oscillations of the ship in still water.

Equation (5) shows that the ship performs oscillations as in still water, but has superposed on these a series of oscillations, governed by the wave-slope and the relation existing between the period of the ship and that of the waves. The equation (5) becomes indeterminate. The correct solution to equation (4) is then:

\[ \theta = C_1 \sin \frac{\pi}{T_1} + C_2 \cos \frac{\pi}{T_1} + \frac{1}{2} \theta_0 \cos \frac{\pi}{T} \]

It is seen that at each successive wave crest and hollow the range of the oscillation is increased, so that the ship's hull would ineptly capsize, but for the effect of the resistances and the departure from synchronism at large angles of roll.

(b) When \( \frac{T}{T_1} = 0 \), in which case the ship is assumed to be quick in her movements, or the period of the wave is infinitely long as compared with that of the ship, the equation (5) becomes:

\[ \theta = \theta_0 \sin \frac{\pi}{T_1} \]

that is to say, the ship will behave very much as a thin flat board does on the surface of a wave, her masts being always perpendicular to the surface.

(c) If we choose the initial conditions in equation (5) so that the coefficients \( C_1 \) and \( C_2 \) are zero, the equation will become:

\[ \frac{\pi}{T_1} \]

Since \( \theta_0 \) the slope of the wave, is equal to \( \theta_0 \sin \frac{\pi}{T_1} \), the ratio of the ship's angle to the vertical to the angle that the normal to the wave-slope makes with the vertical, or \( \theta_0 / \theta \),

\[ \theta_0 / \theta = \text{constant} \]

That is to say, the ship forsakes her own period and takes up "forced" oscillations in the period of the wave. Under these conditions the ship's masts will lean towards the wave-crest if \( T \) is greater than \( T_1 \), and from the wave-crest if \( T \) is less than \( T_1 \).

Proude in his paper further showed how the successive angles of a ship's rolling may be exhibited graphically, and he touched on the influence of resistance in reducing rolling. The following is the summary he gave in 1862 of the conclusions he had reached:

(i) All ships having the same 'periodic time,' or period of natural roll, when artificially put in motion in still water, will go through the same sequence of movements when subjected to the same series of waves, whether this stability in still water (one of the conditions which govern the periodic time) be due to breadth of beam, or to deeply stowed ballast, or to any such peculiarity of form as is in practice destructive to the stability in still water.

(ii) This statement would be almost rigorously true if the oscillations were performed in a non-resisting medium, or if the surface-friction and keel-resistance, by which the medium operates to destroy motion, were of the same equivalent value for all the ships thus compared. It requires, however, to be modified in reference to the circumstance that of two ships having the same periodic time in still water, the comparative forms may be such that the one shall experience such resistance in a higher proportionate degree than the other, and the necessary modification may be expressed in terms of the relative behaviour when set in motion in still water. The vessel which is the more rapidly brought to rest by resistance in still water will in the greater degree resist the accumulations of angle imposed on her by consecutive wave-impulses, and will thus go through a maximum angle which onth would alike attain if oscillating in a non-resisting medium.

(iii) That ship will fare the best which, caeteris paribus, has the slowest periodic time.

(a) The waves which have a periodic time as slow as hers will have a greater length from crest to crest than those of quicker period; and, on the whole, long waves are relatively less steep than short ones. Now it is the steepness of the waves in a wave-series, not their height simply, which governs the rate at which angles of rolling will accumulate in a given ship when exposed to it.

(b) Of two ships one of which has periodic time rather slower than the waves in a given ratio, the quicker ship will accumulate the larger angles.

"(c) It will require a heavier or a more continued gale to rear waves which have the lengthened period.

"(d) When the gale has continued so long that the largest waves have outgrown the period of the ship, she will not thereby have been relieved, and the course of her own rolling is continued, since the larger waves carry on their surface smaller waves of every intermediate period (this, at least, I believe to be the case).

"(e) When the gale has ceased and the sea is going down, the slower ship of the two will go on rolling. As soon as she shall be released from waves of as slow a period.

"(iv) There are two, and only two, methods of giving a slow period to ship:

(a) By increasing her 'moment of inertia,' as by removing her weights as far as possible from her centre of gravity; an arrangement which for the most part can only be accomplished to a limited extent. The utmost that can be accomplished in the construction of a ship, and generally in her stowage, to any degree consistent with her performance of her regular duties, by simply raising her weights.

(b) As she goes on rolling up against the action of the wind on her sails, the steepest waves would pass under her without putting her in motion.

"(v) The conditions which govern pitching may be noticed here, though they have not been discussed in the paper.

"Were it possible, by concentrating her weights or by extending her plane of flotation, to give to the ship a period indefinitely quick for both longitudinal and transverse oscillations, as compared with the natural period of the waves, it can be demonstrated that she would acquire no cumulative oscillation, but would float always conformably to the mean surface of the wave which passes under her.

This condition, which is so unapproachable in practice in reference to transverse oscillations that the attempt to approach it will but develop the evils pointed out in (iii), is of necessity so closely approached in practice in reference to longitudinal oscillations, that these evils can only be escaped by approaching it as closely as is possible. The plunging of a ship whose weights are extended far fore and aft is but an incipient development of those phases of oscillation which have their proper development in transverse motion only. The best that can be desired in reference to longitudinal motion is that the ship's period, for longitudinal oscillation, shall be as quick as possible, and her position always as conformable to the possible cause of the wave-impulse, so that she would acquire no cumulative oscillation, but would float always conformably to the mean surface of the wave which passes under her.

I have insisted here, more prominently than in the body of the paper, on the circumstance that a total loss of stability, using that word in the ordinary sense of power of carrying sail, implies the power of also regarding rolling motion due to wave-impulse, because it has been pointed out to me that the attention of readers should be more strongly directed to it, not indeed as a representing fact, but rather as a representative fact, serving best the mind, by contact with an extreme conclusion immediately deducible from the theory, to appreciate its fundamental principles. And the proposition thus certainly furnishes a crucital test of whether the principles have been appreciated or not, and it supplies also a ready means of testing the theory by a crucial experiment. I must, in addition, express my own confident belief that any one who will try the experiment fairly will be equally convinced. I will feel it to be against the theory which leads to so paradoxical yet true a conclusion deserves at least a careful study. But the more practically useful aspect of the theory is that which presents to view the varying phases of the cumulative oscillation which a ship tends to undergo when exposed to various types of wave-series; the phases depending on the relation which her natural period of rolling, when set in motion in still water, has to each period of the wave-series. The breaking of each individual wave of the series—phases, in fact, which she would actually undergo but for the effect of surface-friction and keel-resistance; the nature and value of the coefficients, etc., for their determination, have been pretty fully dealt with in the body of the paper.

I will here only add a synoptical statement of the principal features which have been referred to in that part of the paper which referred to them, though they are pretty fully exhibited by the diagrams. By a 'complete phase' is meant that series of oscillations which the ship will undergo if the wave-series continues from the time when, for a moment, she is stationary and upright in a similar position, and is about to
recommence an identical repetition of the movements she has just completed. 

For the benefit of those who may glance at the appendix before they read the paper, I will mention that T is the number of seconds occupied by the ship in performing a single oscillation in still water, starboard to port, or vice versa; T1 is the number of seconds occupied by the wave in passing from hollow to crest, or crest to hollow. O is the number of degrees in slope of the steepest part of the wave; and p/q is the ratio T/T1, with the numerator and denominator converted into the lowest whole numbers that will express the ratio, where, however, it must be noticed that for T/T1 = 1, p/q must be taken as the limit of such a form as $\frac{p}{q}$. Then—

"(i.) The ship will complete the phase in the time $2\pi T$.  
(ii.) In completing the phase the ship will pass through the vertical position at the middle of the phase.  
(iii.) The ship will pass through the vertical position at the middle of the phase.  
(iv.) On either side of the middle of the phase there must occur, as equal maximum oscillation, the maximum, say $\theta$, which will approximately (but never in excess) = $\theta$.

"(v.) From these propositions it appears that if we compare two cases, in one of which the value of T/T1 is the reciprocal of its value in the other, the phase will in each case consist of the same number of oscillations similarly placed; but in that one in which the period of the wave is slower than the period of the ship, the angles of oscillation will be the larger in the ratio p/q or q/p, whichever is the greater. The following table expresses the results of the above propositions, as exhibited in the diagrams, based on the assumption that the period of the ship is in every case $T=5^{s}$, and that the maximum slope of the wave $O=9$ degrees:

<table>

The assumption made in equation (1) that

$$G = m \cdot \theta$$

is true if the sections of the ship in the vicinity of the water-lins are circular and are approximately true for generally for small angles of inclination as long as m is not small. If m be small, the relation does not generally hold.

In a wall-sided ship,

$$GZ = \sin \theta \left( m + \frac{1}{2} a t^2 \right)$$

where the BM is denoted by a; whence the equation for rolling through small angles becomes

$$\frac{d\theta}{dt} = \frac{\theta}{a} + \frac{GZ}{a} \cdot \theta$$

where $\theta$ and higher powers of $\theta$ are neglected.

Sections of other forms lead to a similar equation, but with different coefficients of $\theta$; the above equation is therefore typical of all others. This condition has been worked out fully by Professor Scrivanti, who obtained a solution in the following form:

$$T = \frac{2\pi}{\theta} \sqrt{\left( 1 - \left( \frac{1}{3} \right)^2 \cdot \frac{p}{q} - \left( \frac{13}{3} \right)^2 \cdot \theta \right)}$$

where $\theta$ is the maximum angle of roll. J is defined as the moment of inertia of the water-plane expressed in foot tons, i.e. equal to W a, where W is the displacement in tons. 1 is the mass moment of inertia of the ship about its axis of oscillation, and $\frac{p}{q} = \frac{\theta}{\theta + \frac{2\pi}{2}}$. Some numerical results for $T = \frac{2\pi}{\theta}$, where $T_m$ is the period found by the usual "metacentric" formuula and $\theta$ is 12°, are:

<table>
<thead>
<tr>
<th>$T_m$</th>
<th>1.04</th>
<th>1.31</th>
<th>2.98</th>
</tr>
</thead>
<tbody>
<tr>

<td>16.6</td>
<td>16.6</td>
</tr>
<tr>
<td>m ft.</td>
<td>3</td>
<td>4</td>
<td>3</td>
</tr>
</tbody>
</table>

When the metacentric height is zero, the formula becomes

$$T = \frac{1.67 \pi}{\theta} \sqrt{\frac{1}{2} - \frac{13}{3} \cdot \frac{\theta}{2\pi} \cdot \theta}$$

It has been assumed in the foregoing that the rolling in still water and among waves is unresisted; it remains to take into account the resistances which always operate during rolling. In still water these cause a degradation of the amplitude until the ship finally comes to a position of rest; and when a vessel is rolling among waves they cause a similar degradation of amplitude.

The earliest investigations of resisted rolling in still water were made by Froude in England, and by Bertin, Duhil de Bénaix, Risbec and Antoine in France. The method adopted was actually to roll the ship in still water and observe how the amplitude decreased roll by roll. Men were caused to run from side to side of the ship, their runs being so timed as to add to the angle of roll on each successive swing until the maximum angle obtainable was reached, when all movement on board was stopped, and the ship allowed to roll freely of itself until she came to rest. During this free movement a complete record of her angular motion was registered by means of a short-period pendulum and an electric timer, and from this a curve of "declining angles" was constructed, in which abscissae repre

The following equation for the angular motion of the ship:

$$\frac{d\theta}{dt} = K_0 \cdot \theta$$

where $K_0$ is a zero, a complete solution is

$$\theta = A \cdot e^{K_0 \cdot t}$$

where A and B are arbitrary, and the period T of resisted rolling is given by

$$T = \frac{2\pi}{\theta} \sqrt{\frac{1}{2} - \frac{13}{3} \cdot \frac{\theta}{2\pi} \cdot \theta}$$

It appears, therefore, that the period is slightly increased and the amplitude progressively diminished by the resistance. In actual cases $K_0$ is necessarily included in the differential equation, the complete solution cannot be conveniently expressed analytically, but it can be determined in effect either by any method of approxi

The diminution of amplitude can also be approximately obtained by

$$\frac{d\theta}{dt} = a \cdot \theta + b \cdot \theta$$

where $\theta$ is the extreme angle (in degrees) reached at any particular oscillation, n the number of oscillations, and a and b are coefficients equal to

$$K_0 = 2\pi W m^2 + \frac{4\pi}{3 \cdot 180} W m T^2$$

* Given by Sir W. H. White, F.R.S., in a paper read before the Institution of Naval Architects in 1895.
respectively. Froude gave his reasons for expecting the resistance to vary partly as the first and partly as the second power of the angular velocity. The latter part he considered would be due to surface-friction and the head resistance of keels and deadwood, and the

former to the resistance caused by the creation of a small wave at each roll, which, by travelling away from the ship, would cause dissipation of energy. Froude’s views have been confirmed by the accuracy with which the expression \( \frac{dW}{dn} = a.\theta + b.\theta^2 \) may be made to fit the curve of extinction of practically any ship by the judicious selection of the coefficients \( a \) and \( b \). M. Bertin has, however, preferred an expression equivalent to \( \frac{dW}{dn} = b.\theta^2 \), while other French investigators have preferred an expression equivalent to \( \frac{dW}{dn} = a.\theta \).

On substituting the value of \( a \) in equation (7) it becomes—

\[
\theta = aE_1 \sin \left( \pi t \sqrt{1 - \frac{c^2}{c^2 + \beta}} \right) \tag{9}
\]

a simplified form of the equation for resisted rolling when the coefficient \( b \) is neglected.

For the Revenge the following equations represent the curves of extinction given in fig. 29:

- For deep draught:
  - without bilge keels: \( -\theta = 0.0239 \theta + 0.0025 \theta^2 \)
  - with: \( -\theta = 0.065 \theta + 0.017 \theta^2 \)

- For light draught:
  - without bilge keels: \( -\theta = 0.015 \theta + 0.0028 \theta^2 \)
  - with: \( -\theta = 0.083 \theta + 0.019 \theta^2 \)

(\( \theta \) in all cases being measured in degrees and not in circular measure).

The large increase in the \( b \) coefficient after bilge keels had been fitted has given rise to considerable discussion. Mr R. E. Froude had experimented with a deeply submerged plane oscillating in water and he found that at a speed of 1 foot per second the resistance per square foot was 1.6 lb. Using this figure to calculate the work per swing from an extreme angle of \( \theta \), the head-resistance of the bilge keels is found to account for about one-fourth the energy lost in a single swing due to the increased value of the \( b \) coefficient in the above formula. The energy abstracted in this particular case is thus about four times greater than the theoretical head-resistance of the bilge keels. This discrepancy has been observed in many cases, and it appears that when bilge keels are added to a ship they become effective, not merely as flat surfaces moving with the ship and experiencing direct resistances, but also by indirectly influencing the stream-line motions which would exist about the oscillating ship, if there were no bilge keels. Another cause of the difference is that the bilge keels during the early portion of the swing set into motion a large mass of water, only a small proportion of whose energy is returned to the ship towards the end of the roll. This condition is accentuated when the vessel is in motion ahead, and owing also to the increase of other resistances at high speeds, a more rapid extinction is then obtained. It appears from experiments made on H.M.S. “Revenge” and on a torpedo boat destroyer that the extinction at a given angle of roll is given by a linear formula \( -\theta = a + b.\theta \), where \( a \) and \( b \) are coefficients independent of the speed of the ship.

Froude attacked the problem of resisted rolling in an inverse manner, endeavouring to ascertain what wave-series is required to keep the given ship at a given range of steady rolling with any assigned period, including the effect of resistance. He treated the problem in a direct manner by the process of “graphic integration,” an exact method of determining the motion of a ship, the elements of the ship’s rolling in still water and the wave-series acting upon her being given. Some interesting developments of the process were made by Sir William White in a paper read before the Inst. Nav. Arch. in 1881 on the “Rolling of Sailing Ships,” in which the action of the wind on the sails and the variation of the virtual weight of the ship on the wave are included. The effect of wind-pressure in heeling a ship is very much greater when she is at thecrest of a wave than when she is at the trough, because her virtual weight is less. This must be taken into account when dealing with sailing vessels; the reduction of virtual weight, and therefore of righting moment, at the crest of a wave being very considerable, although the heeling moments due to the wind suffer no such reduction.

The differential equation for rolling among waves including the effect of resistances varying as the first power of the angular velocity is

\[
\frac{dW}{dn} = a.\theta + b.\theta^2 + W_m \left( \theta - \Omega \right) \sin \left( \frac{\pi t}{T} \right) = 0,
\]

which becomes on substitution (\( K \) being expressed in terms of \( \theta \))

\[
\frac{d\theta}{dt} = a + b.\theta + W_m \left( \theta - \Omega \right) \sin \left( \frac{\pi t}{T} \right) \equal \frac{\pi t}{T} \cdot \frac{\pi}{\sin \left( \frac{\pi t}{T} \right)}\]

The general solution is

\[
\theta = aE_1 \sin \left( \pi t \sqrt{1 - \frac{c^2}{c^2 + \beta}} \right) + aE_1 \sin \left( \frac{\pi t}{T} - \beta \right) \tag{9}
\]

where

\[
\frac{1}{T} = \left( 1 - \frac{c^2}{c^2 + \beta} \right)^{\frac{1}{2}} + \frac{c^2 T^2}{c^2 + \beta} \quad \text{and} \quad \beta = \tan^{-1} \frac{c^2 T^2}{c^2 - 1}
\]

and \( A \) and \( \beta \) are arbitrary.

The first term represents a free oscillation of the ship, which in time dies out, leaving a forced oscillation in the period of the waves. From observations it is for that, owing to the departure from exact uniformity in the waves encountered, a ship seldom, if ever, completely forsakes her own natural period of rolls; for each slight alteration in the wave period \( T_1 \) introduces a term involving the free oscillation of the ship in the synchronizing conditions where \( T = T_1 \), the forced oscillation is represented by

\[
\theta = -\frac{\pi}{2a.\Omega} \cos \left( \frac{\pi t}{T} \right)
\]

the amplitude being limited entirely by the resistance; the phase is \( \frac{\pi}{2} \) before that of the wave slope. The vessel is then upright in mid-high, and inclined to its maximum angle on the crest and in the hollow of the wave. The maximum amplitude \( \theta \) is given by

\[
\frac{\theta}{\Omega} = a.\theta + b.\theta^2
\]

In 1894 and 1895 M. Bertin, at the Institution of Naval Architects, extended this relation to cases in which \( T_1 \) is not equal to \( T \), obtaining at the same time not simply the angles of steady rolling for these cases, but the maximum angles passed through on the way to the steady condition; to these maximum angles he gave the name of "spogged" rolls.

In 1888, the Institution of Naval Architects, Mr R. E. Froude, investigated the probable maximum amplitude of roll under the influence of a non-synchronous and non-harmonic swell. He imagined three identical ships, A, B and C, the first rolling in still water, and the two others placed in the same swell assumed recurrent in period \( 2T \), but not necessarily harmonic. Assuming resistance to vary as \( \theta^2 \), then denoting the vessels by suffixes, the effective wave slope by \( \theta_i \), and constants by \( K, K' \) and \( K'' \),

\[
\frac{d^2 \theta_A}{dt^2} + K\frac{d\theta_A}{dt} + K\theta_A = 0;
\]

\[
\frac{d^2 \theta_B}{dt^2} + K\frac{d\theta_B}{dt} + K\theta_B = K'\theta_A;
\]

\[
\frac{d^2 \theta_C}{dt^2} + K\frac{d\theta_C}{dt} + K\theta_C = K''\theta_A.
\]

1 See papers on this subject read before the Institution of Naval Architects in 1900 by Professor Bryan and in 1905 and 1909 by Mr A. W. Johns.

If at any instant
\[ \theta_1 = \theta_2 - \theta_3 \text{ and } \frac{d^2 \theta_1}{dt^2} = \frac{d^2 \theta_2}{dt^2} + \frac{d^2 \theta_3}{dt^2} ; \]
whence the above relations hold at the successive instants and consequently for all time. Hence the rolling of C differs from that of B in having the free oscillations of A in still water superposed upon it. If, therefore, it is possible to obtain any one motion in the swell, any other motion due to a different phase relation between ship and wave slope can be at once determined. A convenient motion in the swell to form a basis for obtaining other motions is the forced oscillation proper to the swell, i.e. the particular oscillation that is recurrent in the period of the swell. The amplitude of roll at an instant is therefore the sum of the amplitudes due to the forced oscillation and to an arbitrary free oscillation in still water. If the latter component be regarded as perfectly arbitrary there is no limit to the angle of roll obtained by postulating suitable initial conditions; to determine the practical limitation of rolling, however, it may reasonably be assumed that at or near the commencement of motion there will be a brief period of no roll roll obtained. the maximum angle of roll obtained will occur at no great time interval of this period after it. At the instant when there is no roll, the forced and free oscillations are equal in magnitude and opposite in phase, and the period of maximum (termed the "criterion") amplitude \( \theta_c \) will occur as soon as the two components are in phase; the time interval between the two conditions is \( T \), where \( n = \frac{\pi}{T} \).

It is assumed also that during the above interval—(1) the effect of the swell was sensibly the same as that of a simple harmonic wave, A being the amplitude of the forced oscillation (and of the initial free oscillation); (2) the extinction equation of the free oscillation \( \Delta \theta = \alpha \theta + \beta \theta^2 \) can be replaced by the simple form \( -\frac{d\theta}{dt} = E_0 \), where \( E = a + b \theta_0 \), approximately; this has been implied by the absence of terms containing \( \theta^2 \) in the differential equation above.

The amplitude of the free oscillation during the maximum roll is, from equation (8) \( \Delta \theta = \theta_c \); whence
\[ \theta_c = \lambda \left( 1 + \epsilon^2 \right) \]
Also, from equation (9), the forced oscillation is given by
\[ \theta = \lambda \left( 1 - \left( \frac{T}{T_1} \right)^2 \right) \left( \frac{2}{T^2} \right) \left( \frac{1}{E^2} \right) \]
From these equations \( \theta_c \) can be determined if \( T, T_1, a, b \) and \( \theta_c \) are given; conveniently if \( C \) is the bilge keel, \( \theta_c \) can be tentatively obtained.

The following table gives the criterion angle \( \theta_c \) and the angle of steady roll (A) for the "Revenge," both without and with bilge keels, obtained on the above-mentioned assumptions:

Among the conclusions reached by Mr. R. E. Froude in the case of a ship rolling in a uniform swell were:
However non-uniform initially, the rolling ultimately falls into the uniform forced oscillation; it does so the sooner, the greater the resistance, and with the fewer "cycles" or alterations of amplitude of rolling, the more nearly synchronous the swell with the ship. The amplitude of the ultimate uniform motion is that mean alternate maxima and minima of the preceding non-uniform rolling. If the rolling starts from zero, the maximum amplitude falls short of twice the ultimate uniform amplitude, the maximum being in phase with the maximum of the swell; and in a synchronous swell the maximum amplitude cannot exceed the ultimate uniform amplitude, unless it does so initially.
In two papers by Captain and Professor Kriloff of St. Petersburg, read before the I.N.A. in 1896 and 1898, the whole motion of the ship, including pitching and rolling, is dealt with; every variation which can reasonably be conceived is taken into account in these papers. Of the various appliances adopted to reduce rolling, the most important and successful are bilge keels. Some reference has already been made to the influence they exert on the rolling of ships as illustrated by H.M.S. "Revenge," in which there was one bilge keel on each side, 200 ft. in length and 3 ft. in depth, tapered at the extremities. The great value of bilge keels in diminishing rolling was pointed out by Froude and demonstrated by him in 1872 by experiment with the "Perseus" and the "Greyhound," which were alike in every essential respect, except that the former was not provided with bilge keels and the latter was. The general conclusion was that the rolling of the "Greyhound," was only about one-half that of the "Perseus." Bilge keels were used in warships until, in the design of the "Royal Sovereign" class, it was decided not to fit them, owing to the large dimensions of the vessels and the difficulties in certain circumstances of docking them if provided with bilge keels. Ultimately one of the class, the "Repulse," had them fitted for purposes of comparison, and the effect on her rolling was so marked that it was resolved to fit them to all the ships of the class. Before fitting them on the "Revenge," a careful programme was drawn up of experiments to be made before and after the bilge keels were fitted; and on carrying out this programme some valuable results were obtained. The experiments were made at Spithead in smooth water. The general effect of the bilge keels was to reduce the rolling to one-third of its former amount. When, instead of having no motion in the line ahead, the ship had a speed of 12 knots, an even greater reduction in the rolling was observed. Their effect on other qualities of ships is on the whole beneficial, and in many little, if any, reduction in speed has resulted from their use.

The experience of Great Britain with regard to bilge keels has been repeated in America. Bilge keels were omitted for the same reasons as they were in the "Royal Sovereign" class; they were afterwards fitted in the U.S.S. "Oregon," experimental investigation being made both without and with them, and the general conclusion arrived at was that the rolling was diminished by two-thirds by the adoption of the bilge keels.

A method for reducing rolling of ships in a sea-way by the use of water-chambers was devised by the writer in 1874 in connection with the design of the "Impulse" which was expected to be a bad roller. It consists in fitting one or more tanks across the ship of such shape that when filled to a suitable height with water the motion of the water from side to side of the vessel rolls is such as to retard the rolling. Let fig. 30 represent a series of transverse sections of a ship fitted with a water-chamber, in various positions in rolling from port to starboard; and suppose the water to move so as to be most effective in quelling rolling. Let G represent the centre of gravity of the ship including the water in the chamber, g the centre of gravity of the water in the chamber, and B the centre of buoyancy of the ship; and let the arrow in the sections indicate the direction in which the ship is rolling at the instant considered. In position No. 1 suppose the ship to have reached the extreme heel to port and to be on the point of commencing roll. Then the ship has reached the middle line on its way down towards the port side and the righting couple will be that due to the angle of heel, supposing the water to be a fixed weight amidships. In the position No. 2 the ship has turned towards the upright; the water will have moved farther down the incline, so that g will be some distance from the middle line on the port side and then B, and therefore G will also have moved out from the middle line on the port side; hence the righting couple will be less than what would correspond to the angle of heel if the water were a fixed weight amidships. In position No. 3 the ship has just reached the upright and will be moving with the maximum angular velocity; the water will have moved still farther down the incline, and g will be at a greater distance from the middle line on the port side, and therefore G will have moved farther out from the middle line on the port side; whereas the righting couple is still greater. It follows therefore that the weight of the ship and the upward pressure of the water will form a couple tending to retard the ship's rotation, although she is for the moment in the upright position. In the position No. 4 the ship is heeling over towards starboard and the centre of gravity is returning towards the middle line; but it and G are still on the port side, and the righting couple is therefore greater than that corresponding to the angle of heel of the ship and a fixed centre of gravity amidships. In the position No. 5 the ship has momentarily

![Fig. 30](https://via.placeholder.com/150)
come to rest at the end of the starboard roll, the centre of gravity of the water should have again reached the middle line, and the righting couple should be neither increased nor diminished by the water-chamber, except in so far as it affects the displacement and the vertical position of the centre of gravity. The same process is repeated on the ship's roll back from starboard to port. Thus the water-chamber reduces the angle of roll of the ship chiefly by modifying the righting couple acting upon her throughout the rolling; it increases the righting couple when it opposes the motion as the ship heels over, thereby reducing the amount of the heel, and on the return roll it lessens the righting couple and causes the ship to move more slowly than she otherwise would, so that she acquires less angular momentum on reaching the upright, and therefore tends to roll less deeply the other way.

Two water-chambers were originally contemplated in the old "Inflexible," but the space occupied by one of these was required for other purposes, and only one, the smaller of the two, which was 51 ft. long (across the ship), and 14 ft. wide (fore and aft), was finally fitted. This was shown to reduce the rolling by about 25%.

In addition to trials at sea to ascertain the diminution of roll by this means, still-water rolling experiments were carried out in the "Edinburgh" and compared with the results obtained with a model water-chamber on a linear scale of 1/200 loaded so that its period and stability corresponded to those of the ship. A close agreement was observed between the behaviour of the model and the ship; and this enabled the experiments to be carried out over a larger range of conditions than would have been practicable with the ship alone.

The model was supported on knife edges and connected to a paddle partially immersed in the water of a tank; this was adjusted to represent the natural extinction of roll in the ship without the water-chamber. The length of the chamber (in the ship) was 16 ft.; and widths of 43 ft., 51 ft. and 67 ft. were successively given to it. The displacement of the ship was about 7500 tons; the period to 10 seconds; and the metacentric height 7-52 ft. On experimenting with different depths of water, it was found that the maximum extiructive effect at all angles of roll was obtained with the depth at which the period of motion of the water from side to side of the tank is equal to the period of the ship. The best depths were found to be 2-3 ft. and 3-95 ft. with breadths of 43 ft. and 51 ft. respectively, thus agreeing closely with the theoretical formula, \( t = \sqrt{gh} \), for the speed of a solitary wave across the water-chamber. In these circumstances the water rushed across the tank in a breaking wave or bore, and consumed energy in its passage and through its violent impact with the sides of the tank. With other depths, the motion of the water, at moderate angles, took the form of a slope gently alternating from side to side at small angles of roll; and the effect was practically non-extiructive. With the critical depth the growth of the resistance to rolling commenced almost at zero angle; but, with other depths, the extinction was nearly nil, until a certain angle of roll was attained, whose amount increased with the departure from the critical depth.

At the larger angles of roll, the disadvantage of the departure from the critical depth was not marked. The resistance of the chamber increased considerably with the breadth; the value of the 51-ft. chamber was roughly twice that of the 47-ft. chamber at the critical depth of that, 43-ft. chamber.

In order to compare the effect of water-chambers with that of other methods of extinction, it is observed that the resistance due to the former increases slowly at large angles of roll. The effectiveness of bilge keels, on the other hand, increases rapidly as the angle of roll increases. It was found that, with 12° roll, the resistance of the water-chamber was equivalent to that of 2 ft. of additional bilge keel; but at 17° this was relatively about half as effective. With 3° of roll, however, the water-chamber was about 9 times as effective as the additional bilge keel. Fig. 31 shows the comparative rates of extinction under the various conditions.

Water-chambers have been successfully employed to limit the rolling motions at sea in ships of the old "Inflexible," "Edinburgh" and "Clyde" classes, and in other warships and merchant vessels.

Sir John Thornycroft devised an arrangement for overcoming the rolling motion of a ship amongst waves, consisting of a weight carried from side to side so as always to oppose the heeling caused by the wave slope. The weight was actuated automatically by apparatus controlled by two pendulums (or their equivalent), one of which—a long period pendulum—remained vertical, and the other—a short-period pendulum—placed itself perpendicular to the ship when the latter was rolling. This was fitted on a yacht of about 900 tons displacement, the moving weight being 8 tons; and the net effect in this case was to reduce the rolling by about one-half. (See Trans. Inst. Nav. Archs., 1892.)

An interesting application of the gyroscope to the diminution of rolling was devised by Dr O. Schlick, and fitted by him to the S.S. "See-bar." The principle of its action, the details of the gear, and a description of the trials are given in papers read before the Inst. Nav. Archs. in 1904 and 1907. Particulars of the "See-bar" were: length 116 ft., breadth 11-7 ft., draught 3-4 ft., displacement 56 tons, metacentric height 1-64 ft., and period of double roll (gyroscope at rest) 4-14 seconds. The by-wheel of the gyroscope was one metre in external diameter, weighed 1100 lb., and it ran at 1600 revolutions per minute; its axis was initially vertical, and the casing containing the pendulum was capable of revolving about a horizontal athwartship axis, the centre of gravity of the suspension lying slightly below this axis. A brake was fitted to control the longitudinal oscillations of the casing. When the wheel was revolving and the axis held by the brake, no effect was produced on the ship; but when it was free to oscillate over a horizontal plane the ship was allowed to oscillate freely in the middle-line plane the period of roll was lengthened to 6 seconds, but no other extiructive effect was obtained. By suitably damping the longitudinal oscillations of the gyroscope, however, an extiructive effect was obtained, and rolling was experienced; and during the trials made, the apparatus stopped practically all rolling motion.

The equations for the pitching motions of a vessel are identical in form with those for rolling, and the preceding remarks, in general, equally applicable to pitching. In a large number of ships the period for pitching is approximately one-half of that for rolling; but the actual difference is not always constant. Where control over the longitudinal positions of weights is possible, e.g., in small sailing vessels, weights are removed as far as possible from the ends in order to shorten the period, the safety of shorter period and boats therefore being increased; and the ship, nearly as parallel as possible to the wave slope (e. remarks by Froude ante).

The single period for heaving and dipping oscillations is equal to

\[ \sqrt{\frac{2}{T^2 - T^1}} \] when \( W \) is the displacement in tons, and \( T^1 \) the tons per inch immersion. When proceeding across waves of apparent semi-period \( T_2 \), forced heaving oscillations of semi-amplitude \( T_2^f/T_2 \) are obtained, where \( T \) is the single period of dip, and \( 2a \) is the maximum heave. Also, where \( T_2 \) is the amplitude of heave of the ship in and out of wave. These oscillations combine with the free heaving oscillations due to the circumstances of the initial motion, the resultant motion being of interest in connexion with the longitudinal rolling moments in the ship caused by the waves. (See section Strength.)

Pitching or rolling is frequently the cause of dipping oscillations, and the motion is then termed uneasy; this action may be of importance in ships whose sides near the water-line have a considerable slope to the vertical, since any rolling motion is then accompanied by vertical oscillations of the centre of gravity. It may also be shown that forced dipping oscillations of considerable amplitude are obtained when the period of roll (or pitch) in such cases approximates to twice the dipping period; the complex nature of the resistances attending the motion of the ship has, however, prevented a complete investigation of an interesting subject being thus far found so.

Interference also occurs between the rolling and pitching movements of a ship, when the centres of gravity of the wedges of immersion and emersion for moderate angles of heel are separated by a distance which is a large proportion of the water-line length, e.g., occasionally uneasy rolling of a peculiar character is caused thereby.

Resistence.

The resistance of a ship in steady motion, or the force exerted by the surrounding water on the hull, opposing its progress, is equal and opposite to the thrust of the propellers. The ship is supposed to move with a velocity equal to the speed of a wave front (8-76 ft. per sec. at about 8-5 knots) each of which is in some degree affected by the others. It is obvious, however, first to confine attention to the resistance of the hull, assuming the

---

Since the action and the reaction of the water pressure on the hull of a ship are equal and opposite, forward momentum is generated in the water at such a rate that the increase of momentum per second is equal to the total resistance. The water participating in the forward movement is termed the "wake;" the portion of the wake in the vicinity of the propeller is termed the "frictional effect upon the propulsion of the ship. Experiments were made by Mr. Calvert (Trans. Inst. N.A. 1893) to determine the wake velocity with a model of length 28 ft. and displacement 2.9 tons. The extent of the wake was measured at various positions in the vicinity of the ship, and its maximum velocity was observed to be o-07 times the speed of the ship. Abrasent the screw the mean velocity ratio over an area of the same breadth (34 ft.) of ship and depth equal to the radius of the screw (1.55 ft.) was 0-09, of which about 0-04 was ascribable to the frictional resistance. In Rep. Brit. Assoc. 1874 is contained an investigation by Froude of the extent of the frictional wake and its effects. Froude's experiments based on the equality of the resistance to the momentum added per second. It may be here observed that for any ship propelled in the ordinary manner at uniform speed the momentum generated in the sternward race from the propeller is equal and opposite to that of the forward wake due to Eddy. The motion of the water as a whole thus consists of a circulating disturbance advancing with the ship, and having no linear momentum.

The whole of the resistance at low speeds, and a considerable proportion of it at higher speeds, is due to surface friction, i.e. to the eddying belt surrounding the hull which is caused by the tangential power of the frictional resistance or "frictional skin. It is nearly independent of the form of the vessel; and is conveniently estimated from the results of experiments made by towing in a tank planks coated with various surfaces. The most important of such planks were those made by Froude in the experimental tank at Chelster Cross, Torquay. The object was to obtain the laws of variation of resistance with the speed, the length, the breadth, the depth below water, and the breadth of the ship. A glass cylinder, having an equal length, breadth, and depth of glass, was experimentally, by which the planks were joined to register the resistance: the planks were given a fixed edge at each end to avoid eddy making, and were fully immersed in order that no waves should be formed. The results of Froude's experiments appear in the "Report of the British Association" 1872 and 1874. In the following table the resistance varies, A the mean resistance per square foot of surface over the length stated, and B the resistance per square foot of the after end of the vessel. A and B refer to a velocity of 10 ft. per second in fresh water.

These results are in accordance with the formula:

\[ R = \text{f} n S^2 \frac{V^3}{L} \]

R being the frictional resistance, S the area of surface, V the speed, \( \text{f} \) the density of the water, \( \text{f} \) a coefficient depending on the nature and length of the surface, and \( \text{n} \) the index of the speed; the values of \( \text{f} \) and \( \text{n} \) can be readily obtained from the above table. It is seen that the resistance varies as the density of the water, but in the independent of its pressure; it diminishes as the length of the surface increases, on account of the frictional wake, which reduces the velocity of rubbing between the water and the surface towards the after end. The index is 1.83 for a varnished surface equivalent to the freshly painted hull. The results of Froude's experiments are closely corroborated by similar experiments undertaken by the late Dr Tideman.

When applying the data to ships of length greater than 50 ft., the coefficient \( \text{B} \), denoting the resistance 50 ft. from the bow, is assumed to remain unaltered at all greater distances astern. The velocity of rubbing is assumed equal to the speed of the ship, any slight variation due to stream-line action being neglected. The values calculated, can be estimated with sufficient accuracy by the formula:

\[ S = 1.7D + \frac{V^3}{L} \]

where V is the volume of displacement, L the length, and D the mean draught.

The resistance due to wave making, although inconsiderable at low speeds, is of importance at moderate and at high speeds; it constitutes the greater portion of the total resistance in fast ships.
By impressing, as above, a suitable velocity on the whole system of ship and water, the problem is reduced to one of steady motion in a stream flowing past a stationary ship. The stream tubes, originally of uniform width, become broader on approaching the bow of the ship, and attain their greatest breadth close to the stem. Proceeding aft, the tubes contract, and near amidships they become smaller than they were originally; an enlargement in the tubes again takes place near the stern. The changes in size and velocity in the stream tubes lead to corresponding alterations of pressure in accordance with the energy equation, which alterations appear as elevations and depressions of the surface forming what is termed the statical wave system. If this were a permanent system, no resistance to the motion of the ship would be caused thereby. The surface disturbance, however, is subject to the dynamical laws underlying the propagation of waves; in consequence the wave formation differs from the "statical wave" of the crest-lagging stern of the "statical" wave crest, and the ship being followed by a train of waves whose lengths are compatible to the speed attained. The energy within the water system is transferred backward relative to the ship at one-half its speed; the resistance experienced by the ship is due to the sternward drain of the wave energy which requires work to be done on the ship to replace that absorbed by the waves.

The form of the wave system is not susceptible of complete mathematical investigation; but the circumstances are approximately realized and the conditions considerably simplified when the actions of the bow and stern of the vessel are each replaced by the mathematical conception of a "pressure point." This consists of an infinitely large pressure applied over an infinitesimally small region of the water surface; it is assumed to move forward in place of the ship through still water, or, equally, to be stationary in a uniform stream. The resulting wave system has been investigated by Lord Kelvin and others. It is found to consist of a local disturbance surrounding the pressure point and depending on the pressure distribution combined with a series of waves which are confined within two straight lines drawn backwards through the pressure point and making angles of about $20^\circ \left(\frac{\tan^{-1} \frac{2}{\sqrt{3}}}{2}\right)$ with the line of motion. The waves within this region extend indefinitely astern with crests crossing the line of motion perpendicularly. The crest lines are slightly curved, convex to the pressure point, and at the bounding lines form cusps whose tangents are inclined to the line of flow at an angle of about $25^\circ \left(\frac{\tan^{-1} \frac{1}{\sqrt{3}}}{2}\right)$. The crest lines afterwards curve forward towards the pressure point. The distance apart of the transverse wave crests is equal to the length $l$ of wave appropriate to the speed $s$, as expressed in the formula $s = \frac{g/2s}{2}$. These results are of interest since they are in agreement in many respects with those of actual observation for ships and models. In fig. 32,

![Fig. 32.](image)

reproduced from a paper in the J.N.A. 1877, read by Froude, is shown the bow-wave system obtained from a model, which is also illustrative of that produced by ships of all types. It appears therefore that two types of waves accompany a ship: (1) diverging waves having sharply defined crests placed in echelon, the foremost wave alone extending to the ship; (2) transverse waves limited in breadth by the diverging crests and reaching the sides of the vessel throughout its length. These compare with the crest lines obtained in the above hydrodynamical investigation; the transverse and diverging waves correspond to the different portions of the crest lines which are respectively visible.

Since the bow diverging waves are not in contact with the ship except at the bow, the energy spent in their maintenance travels away from the ship and is lost. A diverging wave system of similar form is obtained when the ship is traveling at a speed greater than the wave speed, and the resistance due to the diverging systems of waves is therefore the sum of its components at the bow and stern, following a regular although unknown law, increasing with the speed, and depending considerably on the shape of the bow and stern.

On the other hand the interference between the transverse bow and stern wave systems produces a stern wave in combination with the ship; the resistance due to the resultant transverse wave action depends therefore on the phase relation between the waves of the component systems. The effect of interference on the wave resistance of two vessels was investigated by Froude (J.N.A., 1877) by the method of experiments on a series of models having the same entrance and run, but in which the length of parallel middle body was varied. At constant speed curves of resistivity resistance on a length base corresponding to the length of the models were obtained, the resistance increasing approximately equably to the wave length appropriate to the speed; the amplitude of the fluctuation diminished as the length increased. The resistance of a length $l$ at a speed $v$ with a very high speed of the power but it was also subject to a series of fluctuations whose magnitude and spacing increased with the speed. The results of these experiments were fully analysed in 1881 by Mr. R.E. Froude. The results are also in agreement with the observation by Lord Kelvin that the trough of the bow wave coincided with the crest of the component stern wave, the resultant wave system being of relatively small dimensions. Conversely, the resistance was abnormally increased when the crests of the bow and stern systems coincided. The fluctuation in the resistance thereby obtained was smaller when the length of middle body became greater, owing to the greater degradation of the bow wave system as the depth increased. For very considerable lengths of middle body, the height of the bow wave system at the stern was insufficient to produce interference or affect the resistance.

The power (V) of a wave is related to the length in feet ($l$) by the formula $V = \frac{1}{8l}$. If $l'$ be the distance apart of the component bow and stern waves (which is generally rather greater than the bow length of the ship), relatively small resistance would be anticipated when $V'$ is equal to the square root of a multiple of $36^2$; on the other hand when $V'$ was not greatly different from 1-8 $l'$, abnormal wave resistance would be developed. This result is of a greater extension of the experiments of ships of all classes; for economical propulsion at a speed $V$, the length $l$ of a ship should be generally equal to or slightly less than $V'$, corresponding to the "favourable" value of $V'$ of about 1-2 the ratio $\frac{V}{l}$; torpedo-boat destroyers and similar vessels of extremely high speed constitute an exception, the value of the ratio $\frac{V}{l}$ being there frequently as great as 4, which approximately coincides with the highest "favourable" value of $\frac{V}{l}$.

The foregoing description of the resistance experienced by ships through wave making makes evident that the conditions underlying wave resistance are too complex to enable its amount to be very satisfactorily estimated. Lord Kelvin, however, was able to establish the "similitude" enunciated by Newton, which is applicable with certain limitations to all dynamical systems. The extension of this principle forms the foundation of all methods employed practically for the purpose of keeping the resistance of ship. The principle states that in two geometrical and mechanically similar systems, whose linear dimensions vary as the squares of the velocities of the corresponding particles, and whose forces vary as their masses, the motions of the two systems will be similar. A proof of this theorem follows at once from the equations of motion for any particle. The law of comparison, which is the application (originally made by Froude) of the principle of similitude to the resistance of ships, is enunciated as follows:

If the linear dimensions of a ship be $n$ times those of its model, and the resistances of the latter be $R_1$, $R_2$, $R_3$, ..., at speeds $V_1$, $V_2$, $V_3$, ..., then the resistance of the ship at the corresponding speeds $V_1$, $V_2$, $V_3$, ..., will be $n^2R_1$, $n^2R_2$, $n^2R_3$, ..., and therefore the effective horse powers at corresponding speeds are increased in the ratio $n^4$.

It is necessary to establish that the conditions underlying the principle of similitude are satisfied by all the components of resistance, when the law of comparison is employed for the purpose of obtaining the ratio between the total resistances of two ships at corresponding speeds. When the component of resistance due to frictional resistance, the rounding of the form of the body and the air resistance, is attributable to normal pressures on various surfaces caused by changes of velocity in the water or air. It appears from Bernouilli's energy equation that the pressures per unit area and the square of the velocity are proportional to the square of the corresponding speeds, to the linear dimensions. The total pressures are therefore proportional to the cube of the linear dimensions, i.e. to the masses, thus complying with the primary condition regarding the condition of similitude.

Froude showed that a ship can be compared with a surface and as the 1-83 power of the speed, does not satisfy this condition. In the application of the law of comparison to ships and
models where the linear ratio is considerable, the residuary resistance already being independently calculated for ship and model from the results of Froude’s experiments. The law may, however, be extended without appreciable error to total resistance when the corresponding dimensions of the ships compared are not greatly different.

If it be assumed that the residuary resistance of a ship is capable of being represented as the sum of a number of terms of the form

\[ W = \frac{n}{2} \rho V^2 \frac{L}{g} \]

where is the displacement, it appears from the law of comparison that for each term of the expression and in the construction of approximate formulae of this type for residuary resistance allowance must be made for the length, breadth and depth of the ship, but the indices are found to vary irregularly with the speed and type of ship; at uneconomical speeds the form of the ship may be equal to or greater than 5, and at moderate speeds it may be less than 3. If is given an approximate mean value for at moderate speeds. A fact pointed out by Professor Biles in a paper read before the Institution of Naval Architects in 1881 is interesting in this connexion. When the resistance of a ship varies by an increase in the displacement by a proportionate enlargement of dimension will not cause an increase in the resistance for the same ship; if the resistance be increased by a higher speed than the 6th, the resistance would actually be reduced by increasing the displacement.

The accuracy of the law of comparison was verified by the “Greyhound” trials, carried out by Froude on behalf of the Admiralty (Trans. I.N.A., 1874). The “Greyhound” was a twin-screw slop 170 ft. long and of about 1160 tons displacement; the trials were made over a range of speeds extending from about 8 to 100 m.p.h. The ship was constructed about the line of equal draught and trim. She was towed from the end of a spar 48 ft. in length projecting over the side of the towing vessel, H.M.S. "Active"; this ensured that the towing force was applied perpendicular to the line of motion, increasing the “Greyhound” and influencing her resistance. A dynamometric apparatus was placed in the bow of the “Greyhound," and arranged so as to record the horizontal component of the tension in the tow rope; by means of this device the ship’s resistance was measured under various conditions, and her effective horse-power obtained. A “log ship” or small board, ballasted to sink a few feet and remain normal to the direction of motion, was towed to the end of a log line which was allowed to run freely out over the head of a spar during the trials. The slip of the “log ship” having been obtained during independent trials, the speed of the “Greyhound” was estimated from the change in resistance under the same circumstances. The frictional resistance on a base of speed were constructed for various conditions of draught and trim; the frictional resistance was estimated from the experiments on planks, and curves of residuary resistance were obtained. A model of the “Greyhound” on a scale of 1/14 full size, was also towed in the experimental tank under conditions corresponding to those of the ship; with the ship, the total resistance was measured, that due to friction was calculated, and the residuary resistance of the model was obtained. It was found, by assuming a particular value for the unknown frictional coefficient of the “Greyhound,” that a close agreement occurred between the residuary resistance of the ship and the model. The accuracy of the experiments in obtaining an experimental value for the coefficient of for a mixture of 1 calico and 1 varnish, which was probably equivalent to the condition of the ship’s bottom during the trials.

The experiments were carried out by Mr Yarrow (Trans. I.N.A., 1883). By these experiments, the residuary resistance of the boat was then about 3% in excess of that deduced by the law of comparison from experiments on a model.

As a result of the “Greyhound” trials, the accepted method of estimating the horse-power required for a new ship is by running a scale model under corresponding conditions in an experimental tank fitted and equipped for the purpose by the general subject.

Similar establishments have now been instituted by several foreign governments, the most important being that at Dumbarton and Messrs John Brown at Clydebank. The experimental tank now under construction at Toddington should prove an important and useful addition to the number of such establishments in this country. Its construction and equipment, it is hoped, will be available also for undertaking such private work as may be required by shipbuilding firms. Its inception is due to a committee of Inquiry set up by the Institution of Naval Architects, and the cost of installation is being defrayed by Mr A. F. Yarrow. The tank will form a part of the National Physical Laboratory, and its general control will be in the hands of officers of the latter.

The Admiralty experimental tank at Haslar is nearly 400 ft. long, 20 ft. wide and 9 ft. deep. The main experimental carriage spans the whole length of the tank, and carries a secondary railway on which the subsidiary carriage, which carries the experimental apparatus of different kinds, is adjusted in position. The main carriage runs on rails on the side walls, and can travel the whole length of the tank, from a stationary engine of ample power. Ordinary speeds range from 100 to 800 ft. per minute, while an extreme speed of 1200 ft. per minute can be obtained; the speeds are regulated by a highly satisfactory control system. The tank is divided into sections, some of which are made of hard paraffin wax, somewhat over 1 in. in thickness; they are cast in a mould, with an allowance of 1/2 in. for finishing. The carriage is fitted in the form of a bed of a machine in which a pair of revolving cutters, one on each side of the model, cuts out on its surface a series of level lines, whose contours are precisely similar to those on the drawing of the ship and may be used for the measurement of all the level lines have been cut in, the model presents the appearance of a series of steps, the bottom angles of which correctly represent the true form of the model should possess. The paraffin ridges between these level lines are trimmed off by the use of suitable tools and the outside surface made quite smooth with flexible steel scrapers. The model is ballasted to its required displacement and saddled with a frame. When the model has been in position in the towing tank, the towing-rod is then placed below the dynamometer. The towing-rod at the foreward end is then in a position to impart horizontal forces by a hard steel surface to a knife-edge on the dynamometer lever within the tank. Various corresponding arrangements to suit particular models are made, and the experiments recorded. Speeds and resistance corresponding to each experiment are deduced from these elements, a most necessary condition being that the speed shall be uniform throughout each experiment. By somewhat similar arrangements on a subsidiary carriage, the action of model screw propellers is tested either in an undisturbed water or behind a model, the speed, rate of rotation, retardance and thrust being measured.

An interesting account by Dr Glazebrook of some experimental tanks in various countries, together with particulars of some improvements made in their design, may be mentioned.

Of the very large number of experimental results that have been obtained from the trials of ships’ models in the tanks referred to above, comparatively few have been made public. In connection with the Torquay and Haslar tanks there are few of the reports by the elder Froude and Mr R. E. Froude that have been published by order or permission of the Board of Admiralty, chiefly through the Institution of Naval Architects. Among those which may be mentioned, the “Merkara” experiments recorded in 1874; the “Merkara” results in 1876; experiments on the effect produced on the wave-making resistance of the “Hotspur” by varying the draught in the experimental tank; results obtained from models of three merchant liners in 1881; papers in 1888 and 1892 on the “constant” system of notation of results of model experiments, used at the Admiralty Experimental Station; model experiments on the ship’s propeller by Mr R. E. Froude appeared in 1904. Some records of the experiments made at private and foreign experimental establishments have now been appearing.

Some of the most important of these experiments are described in these notes; it remains to show how they are applied in practice to obtain an estimate of the indicated horse-power required to drive a ship at any speed. If the resistance has been obtained from an experimental model, or inferred by the law of comparison from data obtained with a vessel of similar type, the effective horse-power is known; and by assuming a suitable value for the propulsive coefficient of the ship (vessel's frictional resistance is known) the results can be converted into horsepower on the sea. If model experiments or data for exactly similar ships are unavailable, the method of estimating the power which is most commonly used is one involving a relation between L.H.P., displacement, and speed, which is expressed by the following equation.

\[ \text{(Speed)}^3 \times \text{(Displacement)}^\frac{1}{3} = C \]

L.H.P. being called the Admiralty coefficient. The value of C varies considerably at different speeds even for the same ship. For it to be constant, the L.H.P. must vary as the cube of the speed; if resistance varied as the square of speed and speed, the condition of constancy would be fulfilled. Actually, owing to variations in the index of the speed to which the resistance is varied, the results given by the machinery and propellers, this method of estimating L.H.P. can only be used with great caution, care being taken that the values of C selected for comparison are taken from ships of fairly similar type, and of corresponding lengths and speeds.

Another means of obtaining approximate estimates of the power
required for ships of ordinary types is from curves of resistance drawn on a basis of simple functions of the speed, length and displacement, the curves being arrived at through the spots obtained from a large number of results of model experiments with different classes of ships. Curves of this character have been constructed by Mr. D. W. Taylor and Mr. A. W. Johns (Trans. I.N.A., 1907); the former series expresses the residuary resistance per ton of displacement in terms of \( V^2/W \); the latter gives the residuary horse-power divided by \( V^2/\) in terms of \( V^2/W \) and the prismatic coefficient.

### Volume of Displacement

**Area of Immersed Midship Section \( X \)**

The frictional resistance is calculated independently by Froude's or Tideman's tables.

To furnish data for estimating the I.H.P. of vessels covering a considerable range of type, a series of experiments on systematically varied forms of hull were made by Mr. R. E. Froude. The results were published by him in the *Trans. I.N.A.*, 1904, and are given in figs. 40 to 51. The forms of hull dealt with may be primarily divided into two groups, A and B, differing in Beam and Draught ratio; Draught being equal to 2:50 and 3:48 for A and B respectively. Each group is further divided into 6 types, differing in block coefficients, and the table following gives particulars of the coefficients for the models tried:

### Resistance

The hull characteristics for A are shown in figs. 33 and 34, and the mode of presenting these indicates the way in which the several types were formed, each being obtained from the type 1 model by successively cutting back its stern and bow. This cutting back is termed snubbing. A curve of areas of transverse sections is given (fig. 35, Plate 1) as well as the sheer draught. The lines of group B can be derived from A, by altering beam and draught scales in the ratio of 66/17 and 57/204 respectively. Each of the 12 forms which embodied these lines was the generator of a series, differing only in length proportion.

The curve of areas is an important item in the hull characteristics. Experiment shows that the resistance of a hull of given curve of areas, beam and water-line entrance, is practically unaltered however the lines may be altered as long as they are kept ship-shape, and no unfair features are introduced. It follows, therefore, that although the data correspond to a given type of lines, yet (consistently with the preceding conditions) they are capable of application over a wider field than at first sight seems likely, covering variations of draught, form of profile and transverse sections.

Regarding the foregoing statement of permissible variations of lines, alteration in Beam/Draught ratio has some effect. Comparison of the two groups A and B gives the effect of the variation in the Beam/Draught ratio tried; and it is found that *caeteris paribus* increasing Draught by 34% (i.e. from 2:59 to 3:48) increases the Beam/Draught ratio by about 4%. A brief and approximate statement of the results of some experiments with models of varying Beam/Draught ratio, by Lieut.-Colonel G. Rota, R.N. (see *Trans. I.N.A.*, 1905), is that beyond a value of Beam/Draught = 2.5 an increase of 10% in Beam causes about 1% to 2.5% increase in resistance (the lower value being appropriate to the higher speeds, and vice versa). This result accords with that deduced from the A- and B-group experiments.

By the aid of the law of comparison (and a correction for skin friction), the information provided can be used to obtain the E.H.P. for any size of ship of form included in the experiments (or covered by the same experiment) by using an experimentally determined suitable propulsive coefficient. An example is given below as an illustration. In practical application it is important to notice that the coefficients used in such calculations must be the total length of immersed form (i.e. of the curvatures at all) and not the distance between perpendiculars arbitrarily placed.

The data are here given (figs. 40-51, Plates III.-VI.) in the form of curves of residuary horse-power for ships of different forms, plotted for a given speed on a base of immersed length. The range in abscissae shows the amount of variation in length proportion tried in the experiments; and as regards speed range the group B is for general purposes the group of interest. The curves may be termed standard E.H.P. curves.

The block coefficients of the forms dealt with are lower than those of the greater proportion of merchant ships, and hence the data are not directly applicable to these. At higher speeds, however, the E.H.P. might be approximately estimated from these curves, by assuming a further degree of slamming appropriate to the required block coefficient; but at speeds which correspond to those of ordinary merchant ships (which are the lower speeds given in the diagrams) the effect of slamming is variable, and depends really upon the actual speed-length ratio (i.e. \( V/\sqrt{L} \)) of the ship we are dealing with.

In this connexion it may be noted that the diagrams not only afford a means of determining the I.H.P. of a given ship, but they may also be used to determine the minimum design speed so as to ensure the best possible conditions of displacement and speed, &c. For example, suppose a ship of given displacement is required to obtain a given speed, with a given maximum E.H.P. (or I.H.P., assuming an appropriate propulsive coefficient); then the former gives the proper scale for 1000 tons displacement (\( V/\sqrt{L} \), the ratio of the linear dimensions, is equal to \( 1000/\) and hence E.H.P. becomes 1) and speed (\( 1000/\)) times the given values).

An E.H.P. curve for the given speed is easily interpolated on the diagrams, and we can at once obtain for the given E.H.P. (1) the length for each type, (2) the type which gives the most suitable length, (3) the economy resulting from any additional length, (4) the type for a given fixed length which gives the speed with least E.H.P., and (5) by inspection at lower speeds, how alternative forms compare at these speeds.

The following points may commend themselves, from consideration of an instructive comparison shown in fig. 4, where for the B group, E.H.P. curves for types 1, 3 and 6 are drawn together. In drawing conclusions, it is clearly remembered that E.H.P. speeds and lengths are for a standard displacement, viz. 1000 tons; and so in applications for different displacements, these quantities all undergo a numerical change, dependent upon the change in displacement, the first point being the economy shown which is most marked at high speeds; and even at low speeds, for the shorter lengths the E.H.P. begins to increase rapidly with decrease in length. These speeds, on the other hand, the length being increased beyond a certain point, so also increase the reverse. The reason for this is clear. At the low speed-length ratio we are considering, the wave-making resistance is practically nil, the resistance being almost entirely due to skin friction and eddy making, &c. It is obvious that by continually reducing the transverse dimensions of a ship of constant displacement, we increase the wetted skin (in the limit when the transverse scale is zero the surface is infinite) and hence the resistance due to skin friction increases, so therefore does the total resistance. This point would be more evident if the diagrams had been continued to a greater length and lower speed-length ratio beyond the alteration in block coefficient.

At speeds above 20 knots, snubbing in the form dealt with is beneficial as regards performance. At lower speeds the effect depends on the length. Since it is at these lower speeds the ordinary type of merchant ship works, we may say that the point is doubtful for these, and depends upon the speed-length ratio. A better result might be obtained in such cases if the method of increasing the block coefficient were by the insertion of parallel middle body and an extension the results obtained an extension of an existing curve. (For this point see Mr. R. E. Froude's *1905 I.N.A. paper.*). A third point is the effect of change in speed. For a given length, the rate of increase of E.H.P. with speed grows less, but increases least for the more snubbed type. As an instance, for a 1000-ton ship at 25 knots (see fig. 36, Plate I.) the E.H.P. increases about 15% per speed of 6 at a length of 300 ft. (see fig. 36, Plate I.) The following table gives the increase in E.I.H.P. for the corresponding changes in speed, and the increase at a speed of 50 knots for each length given.

- The figures in columns (4) and (5) are the means obtained from the individual pairs of speeds; at intermediate speeds these may have different and constantly changing values—
### SHIPBUILDING

In the results hitherto recorded the depth of water has been supposed sufficient to prevent the resistances arising from the motion of a vessel on the surface from extending to the bottom of the ship. In these circumstances the resistance is unaffected by a moderate change in the depth. Conditions, however, frequently arise in which vessels are at high speeds in comparatively shallow water; and a marked alteration is then observed in the resistance and power corresponding to a particular speed. An investigation of the effect of shallow water on resistance is therefore of importance and interest; and a brief account of this part of the subject is here appended.

The change from deep to shallow water modifies the shape of the streamlines, many of which in deep water are considerably in planes normal to the surface of the hull; those in shallow water tend to lie more nearly in horizontal planes, owing to the reduced space under the bottom of the ship. In consequence, the velocity in the stream tubes in the vicinity of the ship is increased, and the changes of pressure and the "statical" wave heights are exaggerated. This causes an increase in the frictional resistance as the depth of water becomes less; but the effect on the residuary resistance is more complicated.

Firstly, the length $l$ of the waves corresponding to a speed $v$ is increased from that expressed by

$$v = \frac{gl}{2}$$

to be in accordance with the formula

$$v = \frac{2g}{π} \ln \left( \frac{2h}{b} \right)$$

where $h$ is the depth of the water, and the wave becomes of the type investigated by Scott Russell in canals and termed a "solitary wave" or a "wave of translation." When the depth of water is less than $\frac{v}{2}$, no permanent wave system of speed $v$ can exist. These changes in the wave length considerably affect the wave pattern and alter the speeds at which interference between the bow and stern systems has a favourable or unfavourable effect on the efficiency of propulsion.

In the second place the amount by which the speed of travel of the energy of the wave falls short of the speed of the ship is expressed by

$$\frac{v}{2} \left(1 - \frac{2 \sqrt{h}}{b} \sin \frac{2πh}{b} \right)$$

In deep water this difference of speed is $\frac{v}{2}$; in shallow water it diminishes, becoming zero at the critical depth producing a wave of translation.

Thirdly, the local disturbance immediately surrounding the ship is increased in shallow water, theoretical investigation showing that, at the critical depth above referred to, it becomes indefinite or is only limited by its own size and existing conditions of the wave accompanying the ship; the particles of a wave in very shallow water are moving appreciably in the direction of travel, which might lead to a reduction in the frictional resistance.

From these considerations it appears impossible to obtain, a priori, the net effect of shallow water on the resistance, owing to the divergent character of the component effects producing the final result. This difficulty is confirmed by the inconsistency of the readings frequently obtained during experiments in shallow water, pointing to instability in the conditions then existing.

A number of experiments have been carried out in shallow water with both ships and models; the most important are those by Constructor Paulus (Schleswig-Holstein District Club, 1903), Captain Rasmussen, Mr Yarrow, Herr Popp, and Major Hock. Many of these are recorded in the *I.N.A. Transactions*. A summary of the conclusions drawn from them is appended:

- The minimum depth of water that has no appreciable influence on the resistance increases with the speed and, in some degree, with the dimensions of the ship.
- At constant speed the resistance is, in general, greatest at the critical depth of water $\frac{v}{2}$. It is concluded, therefore, that the increase of resistance due to the enhanced dimensions of the wave then accompanying the ship is more than sufficient to offset the gain resulting from the diminished drage of energy from the wave system astern.
- At high speeds, when a considerable portion of the resistance is due to wave-making, the total resistance diminishes at depths lower than the critical depth, and is frequently less in very shallow water than in deep water.
- The "humps" in the curves of resistance on a base of

The curve shown in fig. 39, Plate II, results from plotting col. (6) to a base given by col. (3). Since the propulsive coefficient varies with the speed, it is preferable to take the E.H.P. from the curve and convert to I.H.P. using an appropriate coefficient, than to use a common coefficient by plotting a curve of I.H.P.

Fig. 52.—Speed trials of H.M. Torpedo Boat Destroyer "Cossack." At Maplin and Skelmorlie. Displacement 836 tons.
The changes of resistance produced by shallowness are accompanied by corresponding changes in the speed of revolution of the engines and in the trim of the vessel. These are illustrated by the curves in fig. 52, Plate VI., which are taken from a paper read before the I.N.A. by the writer in 1909, giving the results of some trials on H.M. torpedo-boat destroyer "Cossack." The data obtained from the various shallow water experiments are capable of extension to ships of similar types by the application of the law of comparison at corresponding depths (proportional to the linear dimensions) and at corresponding speeds. The influence of shallow water on the speed of a large number of ships can be thus obtained; but the data at present available are insufficient to enable a general law, if any exists, to be determined.

A further modification in the conditions arises when a ship proceeds along a channel of limited breadth and depth. Some interesting experiments were made in this connexion by Scott Russell on the resistance of barges towed in a narrow canal. He obtained (by measuring the pull in the tow rope) the resistance of a barge of about 6 tons displacement, for a mean depth of the canal of about 4½ ft., as follows:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

At the critical speed (8.2 m. per hour) corresponding to the depth, the resistance was in this case reduced; and at a higher speed a further reduction of resistance was observed. It is stated that the bow was then situated on a wave of translation extending to the side of the vessel which was considered as a line of travel, and that the resistance of the bow was then almost entirely due to skin friction.

When the water is not uniform, the resistance is altered by an amount depending on the acceleration, the inertia of the ship, and the motion of the surrounding water. In the ideal conditions a vessel wholly submerged in a perfect fluid, the force producing acceleration is the "virtual mass," which is the mass of the vessel increased by a proportion of the displacement; e.g. for a sphere, one half the displacement added to the mass is equal to the virtual mass. The acceleration of the virtual mass then moves as though it were a solid object in the water, and the resistance divided by the acceleration of the ship, varies considerably with the circumstances of the previous motion. The mean value of the virtual mass of the "Greyhound," obtained by Froude from the resistance experiments, was about 20% in excess of the displacement. This value is probably approximately correct for all ships of ordinary form, and is of use in estimating the time and distance required to make a moderate alteration in speed; the conditions during the stopping, starting and reversing of ships are generally, however, such as to make this method inapplicable.

Propulsion.

The action of a marine propeller consists fundamentally of the sternward projection of a column of water termed the propeller race; the change of momentum per unit time of this water is equal to the thrust of the propeller, which during steady motion is balanced by the resistance of the ship.

Assuming in the first place that the passage of the ship is not affected and is uninfluenced by the working of the propeller, let V be the speed of the ship, v that of the propeller race relative to the ship, and w the mass of water added to the propeller race per second. The thrust T is then equal to mw (v-V), and the force producing acceleration is the "virtual mass," which is the mass of the vessel increased by a proportion of the displacement; e.g. for a sphere, one half the displacement added to the mass is equal to the virtual mass. The acceleration of the virtual mass then moves as though it were a solid object in the water, and the resistance divided by the acceleration of the ship, varies considerably with the circumstances of the previous motion. The mean value of the virtual mass of the "Greyhound," obtained by Froude from the resistance experiments, was about 20% in excess of the displacement. This value is probably approximately correct for all ships of ordinary form, and is of use in estimating the time and distance required to make a moderate alteration in speed; the conditions during the stopping, starting and reversing of ships are generally, however, such as to make this method inapplicable.

The propeller race is equal to \( \frac{1}{2}m(w - V)^2 \); whence the whole energy supplied to the propeller in unit time is expressed by \( \frac{1}{2}m(w - V)^2 \), and the efficiency by \( \frac{w - V}{v} \). The quantity \( w - V \) is commonly termed the slip, and \( \frac{w - V}{v} \) the slip ratio; the latter expression being denoted by s, the theoretical maximum efficiency obtained on this basis becomes \( \frac{1}{2} \). It appears, therefore, that the maximum efficiency should be obtained with minimum slip; actually, however, with screw propellers the losses here disregarded entirely modify this result, which is true only to the extent that very large ships is accompanied by a low efficiency. The foregoing considerations show that, with a given ship, the higher the efficiency, the lower the speed; or, more generally, the higher the efficiency the lower the efficiency of the propeller, thereby the slip, the higher the efficiency generally obtained.

The type of propeller most nearly conforming to the fundamental assumption is the jet propeller in which water is drawn into the ship through a nozzle, and escapes through the jet, effectively producing the "Waterwitch" and a few other vessels which have been propelled in this manner; since, however, the quantity of water dealt with is limited by the size of the jet, it is clear that a permanent reduction of the resistance is required to produce the thrust, and the slip being necessarily large, only a very low efficiency is obtained. A second type of propeller is the paddle, or stern-wheel which operates by means of floats mounted round the circumference of a circular or rectangular form, of the jet propeller. Certain practical difficulties inherent to this form of propulsion render it unsuitable or inefficient for general use, and the most usual form of propeller is of screw type, which require large manoeuvring powers, e.g. to turn a ship, and are used in vessels that have to run in very shallow water. The screw, which is the staple form of steamship propeller, has an action similar in effect to the jet, but requires a far greater expenditure of power than the screw propellers, it is desirable to define some of the terms employed. The product of the revolutions and pitch is often called the speed of the propeller; it represents what the speed would be in the absence of slip. Speed of advance, on the other hand, is applied to the forward movement of the propeller without reference to its rotation; and is equal to the speed of the ship or body carrying the propeller. The difference between the speed of the ship and the speed of advance is termed the slip; and if the two former speeds be denoted by \( v \) and \( V \) respectively, the slip is \( v - V \) and the slip ratio (or properly the apparent slip ratio) \( \frac{v}{V} \).

The theories formulated to explain the action of the screw propeller are divisible into two classes—(i) those in which the action of the propeller is considered as that of a blade advancing through water (similar to the blade of an oar), and (ii) those in which the propeller is considered as producing a jet of water similar to the jet propeller. The action of the screw propeller is more easily illustrated. The action of the propeller is similar to that of a sheet of paper with which a jet of water is blown from a jet of water, and the resistance divided by the diameter is termed the pitch ratio.

The former theories are more easily illustrated. The action of the propeller is similar to that of a sheet of paper with which a jet of water is blown from a jet of water, and the resistance divided by the diameter is termed the pitch ratio.

The theories formulated to explain the action of the screw propeller are divisible into two classes—(i) those in which the action of the propeller is considered as that of a blade advancing through water (similar to the blade of an oar), and (ii) those in which the propeller is considered as producing a jet of water similar to the jet propeller. The former theories are more easily illustrated. The action of the propeller is similar to that of a sheet of paper with which a jet of water is blown from a jet of water, and the resistance divided by the diameter is termed the pitch ratio.
Mr R. E. Froude in 1908, it is probable that the effect of friction would be in the direction of giving higher efficiencies for large screws than for small. The results obtained with ships’ propellers are in general accordance with those deduced from model propellers, although the difficulties inherent in carrying out experiments with full-sized screws have hitherto prevented as exact a comparison being made as was done with resistance in the trials of the “Greyhound” and her model. Results of model experiments have been given by Mr R. E. Froude, Mr. D. W. Taylor, Sir John Thornycroft and others; of these a very complete series was made by Mr R. E. Froude, an account of which appears in Trans. Inst. Nav. Archs., 1908. Propellers of three and four blades, of pitch ratios varying from 0-8 to 1-5, and with blades of various widths and forms were successively tried, the slip ratio varying from zero to about 0-45. In each case the screw advanced through undisturbed water; the diameter was uniformly 0-8 ft., the immersion to centre of shaft 0-64 ft., and the speed of advance 300 ft. per minute. Curves are given in the paper which express the results in a form convenient for application. Assuming as in Froude’s theory that the normal pressure on a blade element varies with the area, the angle of incidence, and the square of the speed, the thrust \( T \) would be given by a formula such as

\[ T = a \frac{R}{R^2 - dR} \]

where \( R \) is the number of revolutions per unit time.

On rationalising the dimensions, and substituting for \( R \) in terms of the slip ratio \( s \), the “conventional” pitch ratio \( p \), the diameter \( D \), and the speed of advance \( V \), this relation becomes:

\[ T = \frac{a}{p} \frac{DV^2}{(1 - \beta^2)} \]

or \( H = -0.03216 \frac{DV^2}{B} \times (1 - \beta^2) \)

where \( H \) is the thrust horse-power, \( R \) the revolutions in hundreds per minute, \( V \) is in knots, and \( D \) in feet. The “blade factor” \( B \) depends only on the type and number of blades; its value for various “disk area ratios,” i.e. ratio of total blade area (assuming the blade to extend to the centre of shaft) to the area of a circle of diameter \( D \) is given in the following table:

<table>
<thead>
<tr>

</tbody>
</table>

The ratio of the ordinates of the wide tip blades to those of the elliptical blades varies as \( 4 / 3 \), where \( r \) is the radius from centre of shaft.

Curves of propeller efficiency on a base of slip ratio are drawn in fig. 53; these are correct for a 3-bladed elliptical screw of disk area ratio 0-45; a uniform deduction from the efficiency obtained by the curves of -02 for a 3-bladed wide tip and -012 for a 4-bladed elliptical screw must be made. Efficiency corrections for different disk area ratios have also to be applied; for a disk ratio of 0-70 the deductions are -06, -05, and -01 with pitch ratios of 0-8, 1-0, 1-2 and 1-4 respectively; for other disk ratios, the deduction is roughly proportional to disk area ratio. A very complete series of experiments have shown that the conditions under which cavitation is produced depend upon the depth of immersion and other factors, the critical pressure causing cavitation varying to some extent with the type of ship and with the diameter of the propeller; the phenomenon, however, provides a lower limit to the area of the screw below which irregularity in thrust may be assumed. A very complete series of experiments with other screws (whether model or full-size) become inapplicable.

From the experiments the coefficient \( a \) was determined, and the final empirical formula below was obtained:

\[ T = \frac{a}{p} \frac{DV^2}{(1 - \beta^2)} \]

or \( H = -0.03216 \frac{DV^2}{B} \times (1 - \beta^2) \)

where \( H \) is the thrust horse-power, \( R \) the revolutions in hundreds per minute, \( V \) is in knots, and \( D \) in feet.

The ratio of the ordinates of the wide tip blades to those of the elliptical blades varies as \( 4 / 3 \), where \( r \) is the radius from centre of shaft.

Curves of propeller efficiency on a base of slip ratio are drawn in fig. 53; these are correct for a 3-bladed elliptical screw of disk area ratio 0-45; a uniform deduction from the efficiency obtained by the curves of -02 for a 3-bladed wide tip and -012 for a 4-bladed elliptical screw must be made. Efficiency corrections for different disk area ratios have also to be applied; for a disk ratio of 0-70 the deductions are -06, -05, and -01 with pitch ratios of 0-8, 1-0, 1-2 and 1-4 respectively; for other disk ratios, the deduction is roughly proportional to disk area ratio. A very complete series of experiments have shown that the conditions under which cavitation is produced depend upon the depth of immersion and other factors, the critical pressure causing cavitation varying to some extent with the type of ship and with the diameter of the propeller; the phenomenon, however, provides a lower limit to the area of the screw below which irregularity in thrust may be assumed. A very complete series of experiments with other screws (whether model or full-size) become inapplicable.

The above figures refer to full speed and are affected by alteration of speed.

1 Higher values have been obtained for the propulsive coefficients of the most recent turbine-driven ships.

Strength.

The forces tending to strain a ship's structure include (1) the static forces arising from the imposition of the weight and buoyancy when afloat, and the weight and supporting forces when in dock or ashore; (2) the dynamic forces arising from the inertia of the ship and its lading under the accelerations experienced in the various motions to which the ship is liable, such as rolling and pitching in a sea way; and (3) local forces and water pressures incidental to (a) propulsion and steering, and (b) the operation of the various mechanical contrivances which it carries.

The straining actions of the forces, due to the distribution of the weight and buoyancy of the ship at rest and to the inertia of the ship in motion, constitute the only part of the problem of the strength of the structure which can be considered theoretically with any generality; the character of the internal reactions arising in the structure is so complex, that simplifying assumptions always have to be made in order to enable them to be calculated.

The results of theoretical calculations as to the general structural strength of ships are therefore of value for comparative purposes and to some extent for the approximate estimation of stresses actually liable to occur in the structure. The comparison of the theoretical calculations with the results of experience forms an invaluable guide to the proper distribution of material. In making such a comparison the necessity of providing sufficient strength, on the one hand, and of keeping down the weight, on the other hand, has to be borne in mind; the latter point being especially important in a ship, since its economical performance is roughly dependent on the difference between the weight of the structure and the total available displacement.

The greatest straining actions, to which vessels of ordinary forms and proportions are subject, are due to inequalities in the longitudinal distribution of the weight and the buoyancy. Let WWW (fig. 54) represent the weight, and BBB... the buoyancy per foot run of a ship plotted along the length AC; over the lengths Aa, be, de, FC the weight is in excess of the buoyancy, while from a to b, c to d, e to f, it is deficient. Acqure LLL, whose ordinates are equal to the differences between those of WWW and BBB, is termed a curve of loads, and represents the net load of the ship regarded as a beam subject to longitudinal bending. Shearing forces are produced whose resultant at any transverse section is equal to the total net load on either side of the section; they are represented by the shearing force curve FFF, whose ordinate at any transverse section is proportional to the area of the "loads" curve BBB... up to that section. Similarly, on plotting the areas of the shearing force curve as ordinates, a "bending moment" curve occurs near amidships; its effect in figs. 55, 56 and 57 is to cause the ends to fall relatively to the middle, such a moment being termed "hogging"; the reverse or a "sagging" moment is illustrated in figs. 57 and 59. Curves of a similar character are obtained in the still-water condition, but the bending moments and shearing forces are then generally reduced in amount.

The maximum bending moment is frequently expressed as a ratio of the product of the ship's length and the displacement; average values for various types of ships are tabulated below:

The conditions of equilibrium, viz. (a) that the total weight and buoyancy are equal, and (b) that the centre of gravity and the centre of buoyancy are in the same vertical transverse section, ensure that the end ordinates of the shearing force and bending moment curves are zero.

These curves are usually constructed for three standard conditions of a ship, viz. (i) in still water; (ii) on a trochoidal wave of length equal to that of the ship and height 2/3 of the length, with the crest amidships; and (iii) on a similar wave with the trough amidships. The curve of weight is obtained by distributing each item of weight over the length of the ship occupied by it and summing for the whole ship. Such a condition of the ship as regards stores, coal, cargo, &c., is selected, which will produce the greatest bending moment in each case. The ordinates of the curve of buoyancy are calculated from the areas of the immersed sections, the ship being balanced longitudinally on the wave in the second and third conditions. The shearing force and bending moment curves are then drawn by successive integration of the curve of loads. Typical curves are shown in figs. 55 to 59 for a first-class cruiser on wave crest, a torpedo-boat destroyer on wave crest (bunks empty) and in trough (bunks full), and a cargo vessel on wave crest (hold and bunks empty) and in trough (hold and bunks full). From these figures it is seen that the maximum bending moment occurs near amidships; its effect in figs. 55, 56 and 57 is to cause the ends to fall relatively to the middle, such a moment being termed "hogging"; the reverse or a "sagging" moment is illustrated in figs. 57 and 59. Curves of a similar character are obtained in the still-water condition, but the bending moments and shearing forces are then generally reduced in amount.

The maximum bending moment is frequently expressed as a ratio of the product of the ship's length and the displacement; average values for various types of ships are tabulated below:
The stresses at a transverse section due to bending are obtained from the usual formula \( M = \frac{2}{I} \), where \( M \) is the bending moment, \( I \) the moment of inertia of the section about the neutral axis, \( y \) the distance from the neutral axis of the point at which the stress is required, and \( p \) the intensity of stress. In calculating \( I \), a deduction from the area of plating in tension is made for rivet holes, and only the continuous longitudinal portions of the structure are assumed effective in resisting bending.

The stresses obtained by this method undergo considerable variation with class and size of ship. As regards the former, it is evident that the actual straining actions upon a ship necessarily vary with the type; and the stresses allowable, as calculated on a uniform basis of applied forces, must vary accordingly. The variation due to size is less obvious, but it is clear that the larger the ship, the less is the probability of encountering waves as long as herself; and, moreover, the proportion of height to length of the largest waves is generally less than that assumed. For these reasons greater calculated stresses are allowable in large ships than in small ships or in those of moderate size. The limiting stress frequently adopted for small ships is 6 tons per sq. in., which may be increased for portions in tension to 8 tons with high tensile steel; on the other hand, the calculated stresses in the largest vessels frequently exceed 8 tons compressive and 10 tons tensile.

The above method is now universally adopted for comparing the stresses in ships caused by longitudinal bending; although imperfect, it affords a reasonable basis of comparison between the longitudinal strengths of vessels, especially when, as is generally the case, the comparison is made between two ships of similar type. The relation between stress and strain has therefore to be investigated, which involves the experimental determination of the modulus of elasticity of the structure.

The assumptions on which the theory of bending is based are:

(a) At any transverse section the material lying on the neutral surface, which passes through the C.G. of the effective sectional material, is neither extended nor compressed.

(b) The material is homogeneous; and the layers comprised between adjacent surfaces parallel to the neutral surface act independently. (This is probably more nearly the case in a ship than in a beam of solid section.)

(c) The material situated at a distance \( y \) from the neutral surface is compressed (or extended) longitudinally by an amount \( \frac{E}{E_0} y \) of its original length; where \( E_0 \) is the curvature of the neutral surface if originally straight, or the alteration of curvature if originally curved.

(d) The stress is proportional to the strain and equal to \( \frac{E}{E_0} y \), \( E \) being Young's modulus for the material. It follows that the resultant longitudinal force across a section is zero, and the moment of the internal forces about the neutral axis (i.e. about the trace of the neutral surface in the section) is \( \frac{E}{E_0} y \), which is equal and opposite to the external bending moment \( M \).

(e) Taking axes \( O_x \) longitudinal, \( O_y \) vertical, since \( \rho \) is large, \( I \) may be replaced by \( \frac{d^2 y}{d x^2} \), and

\[
\frac{d^2 y}{dx^2} \frac{M}{I} = \frac{E}{E_0} y \]

\[
\text{or } E_0 \frac{M}{I} \text{ or } \varepsilon = \int \frac{M}{I} \text{ } dx \text{ } dx,
\]

giving the deflection \( z \) at any point.

The validity of the theory as applied to a ship was tested and confirmed in 1903 at Portsmouth Dockyard when experiments were made on H.M.S. "Wolf" by Professor J. H. Biles for the Committee on Torpedo-Boat Destroyers (see Trans. Inst. Nav. Archs., 1905). The principal dimensions of the "Wolf" are—length 210 ft., breadth 21.7 ft., draught 5.3 ft., and displacement 360 tons, with a coal capacity of 80 tons. Two sets of experiments were made—(i.) under a hogging moment when supported in dock on two cradles 10 ft. wide, spaced 26 ft. apart; centre to centre, and equidistant from the ship's centre of gravity, bunkers empty; (ii.) under a sagging moment when supported by similar blocks 120 ft. apart, bunkers full. The distribution of weight and buoyancy had previously been determined for each case so that the pressures on the blocks and the bending moments caused thereby could be accurately obtained. When thus supported the water-level in the dock was gradually lowered; and for successive water-levels spaced 6 in. apart the extension or compression of the plating was measured at various points of the structure by Stromeyer's strain indicators; the vertical deflections at various points of the length were also recorded. The observations were repeated several times, and the following are the general results:

(c) In the sagging condition the neutral axis was actually situated 7.55 ft. above the keel; the calculated distance was 7.6 ft. deducing rivet holes in parts in tension, and 7.7 ft. without such deduction. In the hogging condition the observed height was 7.2 ft., those calculated as before being 7.5 ft. and 7.6 ft. All shell and deck plating, gunwale and keelson angles, and the side girders and angles were included in the calculation for the moment of inertia. The calculated and observed positions of the neutral axis are thus in fairly close agreement.

(b) The actual vertical distribution of strain over a transverse section was approximately in accordance with the linear law assumed in the theory of bending.

(c) The modulus of elasticity \( E \) was obtained by equating the sum of the moments about the neutral axis of the stresses deduced from the observed strains to the bending moment.

(d) The value of \( E \) was also deduced from the deflections by means of the formula

\[
E_0 = \int \frac{M}{I} \text{ } dx \text{ } dx
\]

and its value under a sagging moment is in agreement with that found by (c). Under a hogging moment the mean value obtained from the deflection is less than that from the strain, showing that the curvature obtained from the deflections is greater than that to which the structure is actually bent.

The table at the top of the following page shows the values obtained for \( E \), the modulus of elasticity.

By observing the deflections of two vessels when loaded with ballast, the following values for \( E \) were obtained by T. C. Read and G. Stanbury (Trans. Inst. Nav. Archs., 1894), and are given for purposes of comparison:

C. = Compressive.  T. = Tensile.

It appears from these experiments that (at least in ships of similar character to H.M.S. "Wolf") the stresses corresponding to any particular external conditions closely agree with those calculated from the assumed moment of bending; on the other hand the waves encountered during the sea trials were such that the maximum stress then obtained was considerably less than that in the condition assumed for the standard calculations. Finally, the material of the ship was subjected in dock to a tensile stress of nearly 9 tons and a compressive stress of nearly 7 tons per sq. in. without distress.

While dealing with longitudinal bending, some of the refinements suggested for calculating stresses among waves may be cited, although the additional labour involved in their application has prevented their introduction in general practice.

Since the distribution of pressure in the water of a wave system differs from that in still water, the buoyancy of a vessel or the resultant vertical thrust of the water is then not equal to the weight of the water displaced, and the position of the ship when in equilibrium is the moment of the stresses upon it is greatly in consequence increased. By assuming the pressure at any point of the water to be in accordance with the trochoidal theory of wave motion, and undisturbed by the intrusion of the ship, the equilibrium position can be obtained and the modified stresses evaluated. This process was first applied to ships by Mr. W. E. Smith (Trans. I.N.A., 1883), who obtained the mathematical sum of the sagging and hogging moments on vessels placed in the trough by the forward end of a wave, thereby eliminating the effect of the distribution of weight; and compared it with the sum of the moments as ordinarily obtained. The correction for the ships considered involved a reduction of the bending moment to about 3/4 of the value calculated in the ordinary manner, and in a torpedo-boat destroyer a reduction of about 10% has been obtained. This reduction increases as the draught and fullness of the ships are increased, and the bending moment on a square-bilged ship deeply immersed is almost uninfluenced by wave motion, since the reduction in orbital motion at considerable depths below the surface ensures the bottom of a fairly deep ship being in comparatively undisturbed water.

In the foregoing the vessel is assumed to occupy at every instant a horizontal position on the wave with the correct displacement; a ship proceeding perpendicularly to the crests of a wave system will, however, undergo a heaving and pitching oscillations which lead to a further modification in the bending moment obtained (see paper by T. C. Read, Trans. I.N.A., 1890). Considering first the effect of pitching only, imagine the ship at her proper displacement (allowance being made for the angle of wave of the vessel as before), but momentarily out of her correct trim; the longitudinal restoring couple, due to the wedges of immersion and emersion, is balanced by the direct and indirect mass-accelerations about midship. The influence of the forward and after mass-accelerations about midship is then due to the directly and the indirectly reflexed acceleration to the corresponding parts of the ship.

These moments are therefore equal and opposite for each half of the ship and have no influence on the midship bending moment. It appears, therefore, that in the majority of ships whose departure from longitudinal symmetry is slight, pitching has little effect on the bending moment; nevertheless it considerably increases the bending moment at the ends.

The effect of heaving is investigated by obtaining the positions of equilibrium of the C.G. of the ship when on wave crest and in wave trough; intermediate positions of equilibrium are assumed to be given by y = a sin T = 

\[ W \text{ is the displacement,} \quad \rho \text{ the tons per foot immersion; the resistance to vertical motion being neglected. When} \quad T \text{ and} \quad T_1 \text{ are nearly equal, allowance has to be made for the resistance by using a process of graphic integration. On applying the correction to two} \quad T, \text{ and comparing the bending moments in their positions of the wave, given by the formula, with those in the equilibrium position, the effect on the maximum hogging moment was found small, but the sagging moment moderately fine vessel was increased by over 20% and that of a full vessel by about 10%}.

Allowance has also been made for the effect of the superposed heaving and rolling oscillations undertaken by a ship moving obliquely across the crests of a wave system (see papers by Captain Kriloff, Trans. I.N.A., 1896 and 1898).

The maximum calculated stress on vessels inclined to considerable angles of heel has been found in some instances to be slightly greater than that for the upright condition; and the stress on the material towards the ends is then usually more nearly equal to that amidships. In addition to the direct stresses on keel, bottom, and upper works arising from longitudinal bending, shearing stresses are experienced which in some cases are of appreciable magnitude. The intensity of shear stress in the side plating is equal to \[ \frac{FA^2}{2H} \text{ where} \quad F \text{ is the shearing force over the transverse section. At the moment about the neutral axis of the sectional area above or below a horizontal line through the point considered, and} \quad H \text{ the thickness of side plating. This stress is usually greatest at or near a quarter of the length from either end and at the height of the neutral axis, since here the relative moment of inertia of the two shearing stresses is the greatest in case the thickness of plating and arrangement of riveting have to be specially considered in relation to these shearing stresses. The shearing stresses due to transverse bending are not, in general, capable of definite determination; as, however, they are frequently severe when the ship is in dry dock, and may also attain considerable magnitude during heavy rolling, a means of comparing the transverse strength of vessels is of some interest. A transverse bulkhead forms a region of almost infinite transverse stiffness, and it is therefore difficult in ships internally subdivided by numerous bulkheads, to determine how far the stresses in intermediate sections are influenced by the neighbouring bulkheads. In many vessels carrying cargo, however, in which transverse bulkheads are widely spaced, a section midway along a hold may be so far removed from all bulkheads as to be uninfluenced by their local support; and the following method has been proposed for comparing the transverse strengths of such ships.}

Transverse bending.

A frame and a strip of plating one frame space in width are regarded as a stiff inextensible bar subjected to the known external forces and to the unknown tension, shearing force, and bending moment, at any fixed point. Let OP (fig. 60) be a portion of the framing under consideration, O being the keel, and Ox, Oy, horizontal and vertical axes. On consideration of the forces on the arc OQ, which are in
If the period of the force synchronizes or nearly synchronizes with the natural period of the structure, the amplitude is considerable, but otherwise it is of relatively small amount. If, therefore, the natural period of vibration has been found for a ship, the causes of vibration at various speeds can be readily traced, since marked vibration is usually attributable to a synchronizing source.

Vibration in a steamship is due to various causes, the principal of which are:

1. The reciprocating parts of the engines, if unbalanced, cause vibrating forces and couples in the ship's line and of two frequencies, one equal to, and the other twice, the speed of revolution, the latter being due to the secondary action introduced by the connecting rod. In twin-screw ships torsional oscillations in transverse planes may also require when the engines are working in opposite phase.

2. The rotating parts of the engines cause vertical and horizontal oscillations of frequency equal to the speed of revolution.

3. The vibration of the smoke, O, Q, R, due to causes, tends to cause torsional oscillation of the same frequency, particularly in single or two-cylinder engines.

4. Vibrations, principally at the stern, may result from an unbalanced and not recognized vibrations similar to those caused by the rotating parts of the machinery.

5. A screw propeller which experiences uneven resistance during its revolution is the cause of vibrations, whose frequency is the product of the revolution and the number of blades. Such resistances occur when (1) the blades pass too close to the hull; (2) when the screw breaks the surface of the water; and (3) when the supply of water to the propeller, that is, to the screw, is prevented from passing through the motion of the ship at the null surrounding the water. A thin uniform rod vibrating laterally has a minimum frequency (per minute) equal to \( \sqrt{\frac{4}{\pi^2}} \) (\( \sqrt{1020} \)) in this mode of vibration there are two nodes situated at a distance 224 L from either end. Vibrations of a higher order having three, four or more nodes are also possible, the frequencies increasing approximately in the ratio 1:2:3:5:4 &c. These variations are dealt with below; to obtain a corresponding result being obtained by direct mechanical investigation, recourse is therefore made either to direct experiments on ships, or to a "dynamic model. The instrument used for model testing is a smooth capsule with a weight suspended at one or more or more points, and held laterally in position, by springs, so as to have a long period of oscillation; pens or pencils attached to the weight record the vibrations upon revolving cylinders fixed to the vessel and fitted with time records. The formula (of the same form as that for a rod)

\[
N_n = \frac{E}{\pi^2 \rho W T^2}
\]

where \( N_\text{frequency per minute} \), was used by Dr Schlick for the vibration of ships; the value of e found by him for vertical vibrations was 1500 in vibration, while the value of 1400 was found when vibrations of the same type were measured in the model. The nodes were found to be at about a third of the length from the stern and about a quarter of the length from the after perpendicular. The frequency with three nodes was slightly less than the frequency of the unidirectional vibrations. The general and torsional vibrations were also observed; their minimum frequency is, however, generally considerably more than that of the vertical vibrations, and they are therefore generally of much smaller amplitude. (See papers in Trans. Inst. Nav. Archs. from 1884 to 1901, by Dr O. Schlick, and in 1895 by Mr A. Mallock.) The "dynamic model," suggested by Mr Mallock, forms a convenient means of approximately investigating the positions of the nodes and the frequencies of vibration of a ship. The formula given above suggests that by making a model of material whose modulus E and density \( \rho \) are known, and on a linear scale of \( \frac{1}{n} \), then if \( N_n \), \( \rho \) refer to ship and model,

\[
N_\text{model} = \frac{N_n \nu^2 \rho_w \rho_m \rho_w}{\frac{1}{n}^2 \cdot L \cdot \rho_m \cdot W_m}
\]

This relation is unaffected if the lateral distribution of material is changed in the model, provided that the weight of the model per foot run are unaltered at each point in the length; the model is therefore made solid and of rectangular or other convenient section, so that

\[
I_{\text{model}} = \frac{1}{12} \cdot \frac{1}{n}^2 \cdot L \text{ and } W_{\text{model}} = \frac{1}{12} \cdot \frac{1}{n}^2 \cdot \rho_m \cdot W_m
\]

the weight being also similarly distributed in a longitudinal direction over the ship. The vibrations of the vibrations obtained are by trial, giving the highest frequency for the model of vibration considered; these points are the nodes corresponding to the free vibrations when the model is unsupported, and the influence of the supports is thus eliminated. On comparison with the results obtained in a ship, the reliability of such model experiments has

Time of turning through 180°, 2 min. 31 sec.
been verified in a few cases, the value adopted for \( \mathbf{E} \), being that for a riveted structure or about 10,000 tons per square inch. In some model experiments made in the laboratory, the frictional resistance of the rudder to the water was found to be reduced, and owing to the rapid damping of the free vibrations and to a virtual increase in the mass-inertia caused by the concomitant motion of the surrounding water, which also reduces the rudder's inertia. The results of these tests are given in the table, and the dynamic model. The extent to which such results require modification cannot be determined until further experiments have been made.

For an approximate investigation of the forces in operation during the turning of a ship, the motion may be divided into three stages: (a) when the ship is still; (b) when the rudder is put on, and the pressures on the hull are those necessary to produce angular acceleration; (c) when the accelerative forces are combined with those caused by the resistance of the ship to rotation; and (d) when finally turning uniformly in a circular path. The characters of the forces acting during the stages (a) and (c) cannot be ascertained, and the type of motion under the complex conditions (b) and (d) will consist of a gradual replacement of the motion at (a) by that at (c).

Initially, when turning the helm over, the change in the stream line motion at the stern produces a pressure upon the rudder normal to its surface, which forms a second point of force at the rudder, being brought into action in the manner described by relation (13). After the deadwood is reached, there is generally an additional pressure upon the after deadwood caused by the widening of the stream lines approaching the rudder. The resultant of these pressures, and the force due to the unsymmetrical distribution of the screws, is a force \( F \) at the stern which may be resolved longitudinally and transversely into \( R \) and \( Q \), where \( R \) tends to reduce the speed of the ship and \( Q \) to turn the ship outward (fig. 63). The proportion of the force \( F \) due to the deadwood is unknown, but it is small in recent warships in which the after deadwood is considerably cut away and the portion due to the rudder pressure can be calculated from the resistance of experiments on plates moving obliquely through water.

If \( A \) is the area of the rudder in square feet, \( \theta \) the angle of helm and \( V \) the relative velocity in knots in which the water impinges on the rudder (assumed equal to the speed of the ship increased by the slip of the screw), then \( P \) (in tons) = \( k \cdot A \cdot V \sin \theta \), approximately where the mean value of \( k \) for small inclinations is \( \frac{1}{4} \) for a square rudder and about \( \frac{1}{10} \) for a rectangular rudder of breadth twice its depth \( k \) also varies with the angle of incidence; when the latter is greater than about 35°, the above formula becomes no longer applicable.

The conversion of the stream lines at the stern due to the angle of run, and the oblique and variable motion of the water caused by the screw propellers, modify the value of \( k \), as applied to the determination of the rudder pressure; but it is evident that with ships of fairly similar types the force causing initial turning varies with the shape of the rudder and approximately as its area, the angle of helm and the square of the speed.

The initial angular motion of the ship is due to the action of the component of the pressure on the rudder and deadwood, which is equivalent to a force \( Q \) at the centre of gravity tending to produce a lateral translation of the ship as a whole and a couple \( QBG \) tending to rotate the ship about the centre of gravity. Both the lateral and angular movements of the ship are accompanied by the motion of a mass of water, which may be regarded as virtually increasing the mass of the ship. The initial motion of the ship results from these quantities, thus increased, by \( W \) and \( I \) respectively, the initial lateral acceleration of the ship is equal to \( \frac{Q}{W} \), and its lateral speed at the end of a short interval of time \( \Delta t \), during which \( Q \) and \( W \) may be supposed to remain constant, is \( \frac{Q}{W} \Delta t \). At the same instant and under similar hypotheses the angular velocity about the centre of gravity is \( \frac{QBG}{W} \Delta t \). Hence a point \( O \) forward in the middle line of the ship taken so that \( \frac{Q}{W} \) CG BG \( O \) and \( \Delta t \) is, at the instant considered, at rest except for the motion of the ship ahead, which is due to the original speed of the ship before putting the rudder over, and the instantaneous motion of the component \( R \) of the rudder pressure during the time \( \Delta t \). The instantaneous centre of the motion of the ship must therefore be somewhere in the perpendicular at \( O \) to the line of motion of the ship, the point \( O \) thus corresponding to the "pivoting point" as previously defined for the steady motion of the ship in a circle.

The actual position of \( O \) cannot be calculated, as it depends on the previous motion of the ship, and \( W \) is a difficult term, not expressible in terms of, the moment of inertia \( I \) and mass \( W \) of the ship itself, but from the method by which it is determined it is clearly forward of the centre of gravity and so far the investigation is confirmed by observation, which shows that the first effect of putting the rudder over is to cause the stern of the ship to swing towards the side to which the helm is moved to a much greater extent than the bow moves forwards the ship's head.

If the time \( \Delta t \) be supposed to become infinitesimal, and the effect

---

F, Position of ship's centre of gravity when vessel had turned through 90°. Time from D, 49½ sec.
G, Position of ship's centre of gravity when vessel had turned through 180°. Time from D, 1 min. 20 sec.
of putting over the rudder being regarded as an impulse (measured by the finite product \( P \cdot d \)), delivered at the stern of the ship normal to the rudder, the resistance of the water to the rotation of the ship may be neglected, and the instantaneous centre of the turning motion (as distinguished from a location ahead) is the point \( O \) on a straight line \( GB \) perpendicular to the direction of the impulse, and such that \( GO \cdot GB = \frac{P \cdot d}{W} \); an expression for the position of \( O \) of the same form as obtained before.

In this case \( \frac{P}{W} = k \), where \( k \) is the radius of gyration of the ship about a vertical axis through the centre of gravity, and the point \( O \) is obtained by the geometrical construction shown in fig. 64, given by Professor W. M. Rankine, where \( GL = k \) and is perpendicular to \( GB \), and the angle \( \phi \) is the angle of heel.

The value of \( I \) is dependent on

1. the distribution of weight in the ship, being large when heavy weights are situated near bow and stern,
2. the length of the ship, and
3. the underwater form near the ends, being relatively large in fine ended vessels with large areas of deadwood. \( W \) is also dependent on the shape of the ship under water.

The handiness of a ship's rudder to respond to slight alteration of helm is generally denoted by the relationship \( Q \times OB = Q \times GB \times \cos \phi \), the moment of rudder pressure for a given angle, and \( I \) the virtual moment of inertia. If \( I \) is comparatively large, the vessel will turn slowly under helm until, gathering way, the rapidity of its motion is so large as to limit the value of \( I \) by the change of course to that desired. Unhandiness is usually experienced at low speeds (\( Q \) being then small) and also in shallow water, where the pressure is increased by the restriction in the flow of water from one side of the ship to the other. Improvement in the handiness in these circumstances has been obtained in certain ships with unbalanced rudders by filling in the after deadwood, the loss from the increased inertia being more than compensated by the greater turning moment due to the pressure on the after deadwood.

When the ship is turning steadily in a circle, if \( C \) (fig. 64) is the centre of rotation, and \( CO \) perpendicular to the middle line of ship, the motion is equivalent to a progression ahead with speed \( V \) (which is considerably less than the initial speed), combined with a rotation about the \( O \) pivoting point \( O \), which is generally situated slightly abaft the bow; the drift angle \( \phi \) is given by the relation

\[
OG = OC \tan \phi.
\]

The time of turning through 180° is \( \frac{\pi}{r} \) where \( r \) is the radius OC.

The forces acting upon the ship are now—the pressure \( P \) on rudder and deadwood (if any), the centrifugal force \( CV \cos \phi \), the thrust of the propellers, and the pressures on the hull. The last named consist of forces \( P \) forwards before \( O \), and \( P \) inwards about \( O \); of these \( P \) is usually negligible in amount; \( P \) cannot be directly estimated, but since work is done against it by the transverse forces of the after part of the ship, a reduction of speed results whose amount is largely dependent on the obliquity of motion at the centre of gravity, that is on the drift angle \( \phi \). Under full rate of speed, the speed when turning to the initial speed is often about 60 or 70\%; but in some quickly turning ships it is less than 50\%.

Of the remaining forces, the transverse component \( W \cos \phi \) of the centrifugal force is known since the final diameter of turning \( 2r \) is approximately the same as the tactical diameter. To obtain \( I \), it is to be observed that the water impinges on the rudder in a direction \( BF \) intermediate between \( BE \) (perpendicular to \( BC \)) due to the ship’s motion and \( BD \) due to the turning motion of the after part of the ship, a reduction of speed is produced that increases the effective rudder angle is approximately \( \theta \). The pressure on the rudder is therefore less than when helm is first put over and is further reduced on account of the diminution in the speed of the ship.

From experiments made with the object of measuring \( P \), when turning steadily, it is found that the pressure recorded was about one-tenth of the value calculated on the assumption of the ship retaining her original speed and effective rudder angle; when helm had just been put hard over, from one-half to one-third of the theoretical pressure was obtained. (See Bulletin of the Association Technique Marine, 1893; American Institute of Naval Arts, and Mar. Eng., 1893.) The transverse forces calculated on this basis for a battleship of 15,000 tons displacement when turning steadily under full helm are approximately—centrifugal force 200 tons, direct pressure 30 tons, total 230 tons, passing through a point on the middle line about 40 ft. abaft the centre of gravity.

The following equations applicable to the state of steady rotation can be obtained from the above considerations, neglecting \( P \), and the small couple due to \( R \):

\[
Q = Q + W \cos \phi.
\]

Fig. 64.

From (i) it is seen that a small vertical diameter will be obtained when \( Q \) is large compared with \( Q \); from (ii) it follows that the point \( M \) (fig. 65) should then be near \( G \). These conditions are realised in a ship whose resistance to leeway is considerable but concentrated about the middle of the length, such, for example, as a yacht having a deep water keel, or a boat with centre board and drop keel. In these instances the vessel may be regarded as virtually anchored by its keel, and the pointing point brought to a position in close proximity to the centre of gravity. Similarly tactical diameters of vessels of ordinary type are reduced by diminishing the resistance to lateral motion at the after end and by increasing it amidships or forward.

During the turning trials made with H.M.S. "Thunderer," observations were made of the heel caused by the transverse forces brought into play when turning. On first putting the helm over a small inward heel caused by the pressure of the rudder was observed; as the rotational speed of the ship increased this inclination was succeeded by a steady outward heel, amounting to about \( 1^\circ \) at knots speed. The latter is caused by the couple formed by the centrifugal force and the lateral resistance diminished by the (usually) small couple due to the rudder pressure. During some more recent trials carried out on the Yashima "the angle of heel was \( 8^\circ \) at full speed. Similar large inclinations are generally found with modern warships having small turning circles and high speeds and whose centres of gravity are also situated high up; at moderate speeds, however, the heel is of the order of a few degrees. During the heels quickly amidships when turning, the opposing couple due to the rudder pressure is removed or reversed and the angle of heel momentarily increased; instances of this have been recorded of ships of exceptional stability and comparatively large "rudder couples" collapsing through this cause.

The rudders used in ships are of two types:—(1) Unbalanced, shown in figs. 65, 67, 68; and (2) balanced, shown in figs. 66, 67 (at bow) and 69 to 74. An unbalanced rudder is in stable equilibrium when amidships and force is to have been applied to the rudder in order to place it at any angle to the middle line. It is supported at its forward edge by means of pintles working in gudgeons on the sternpost and owing to the simplicity of construction and to its property of returning quickly to the middle line when the tiller is released through any cause, this type is preferred when the force required to put the rudder hard over is sufficiently moderate to enable steering to be performed by hand or by an engine and gear of moderate size when steam steering is admissible.

With high speeds and large manoeuvring powers, the unbalanced type is generally unsuitable; and balanced rudders are adopted in order to reduce the force required and the work done to obtain large angles of helm. A balanced rudder is unstable amidships, and, if left free, comes to rest at a moderate angle on either side of the middle line. Slightly less than one-third of the area is usually placed below the axis; in stability tests in which the former has been put forward, difficulty has been experienced in bringing back the rudder to amidships. As shown in the figures, the method of support has varied in different ships; in many cases the upper pintle is placed some 6 or 8 ft. abaft the water-line, and is comparatively narrow longitudinally. Some what greater efficiency when using small or moderate angles of helm is obtained with rudders of this shape; as, for a given pressure...
on rudder, the turning moment on the rudder head, and the power required for working the rudder are also less. A type of balanced rudder devised by Professor Biles and adopted in some large Atlantic liners is shown in fig. 66. Broader and shallower rudders are adopted in warships owing to the necessity of keeping the whole of the steering gear below the water-line for protection.

Helm angle about 35° in all cases.

The unbalanced type was mainly used in British battleships up to H.M.S. "Formidable" (1901) and "Duncan" (1903) (fig. 67). In the "King Edward VII." class (1905) (fig. 68) the rudder was balanced, about one-fourth of its area being placed before the axis; balanced rudders supported at about mid-depth were fitted in the "Yashima" (1897) and the "Lord Nelson" class (1902) (fig. 69). In H.M.S. "Dreadnought" (1905) and recent "battleships" twin-balanced rudders are fitted immediately behind the inner propellers (fig. 70), to obtain additional steering effect from the propeller race, and to enable the ship to be steered from rest in getting under way. Owing to the higher speeds of first-class cruisers, balanced rudders were used; those fitted in "Diadem" (fig. 74), which had, in addition to the usual rudder at the stern, a double-balanced rudder in the bow, which could be drawn up into recesses in the hull; the two rudders were about 3 ft. apart and when in use worked together.

The results of the turning trials of some of the Experimental principal classes of warships are given in the following results:

In ships having unbalanced rudders and fitted with hand-steering gear considerable time is required to put the helm hard over at full speed; and consequently the tactical diameter and the advance are greater at high speeds than at low speeds. When steam-steering gear is provided the helm can usually be put hard over in from 10 to 20 seconds at any speed; and in modern warships the speed is found to have little influence on the path described when turning. In the case of torpedo-boat destroyers marked increases in the tactical diameter and in the advance occur at high speeds, the cause of which is not fully known. In such vessels of length 270 ft. and displacement 500 tons, the tactical diameter is about 350 yds. at 30 knots and 300 yds. at 15 knots.

A moderate variation in the mean draught has little effect on the course, but additional trim by the stern results in a greater space being required for turning.

By working one propeller ahead and the other astern the space required for turning may be shortened, but the time of turning is frequently increased. The character of the path described depends on the relation between the revolutions of the screws.

In a single-screw ship, with the propeller well immersed, the upper blades experience greater resistance to rotation than the lower blades, since the forward velocity at the fractional wake is greatest at the surface; hence a right-handed screw tends to turn the ship's head to starboard, and requires starboard helm. The reverse is occasionally experienced when the upper portion of the screw is incompletely immersed.

When a ship is going astern manœuvring is performed with some uncertainty, as the rudder is near the pivoting point.
**Process of Design**

When a shipbuilder is approached for the production of a new ship, he must be informed of the requirements of the case; the kind of trade or service in which the vessel will be engaged; her speed; if she is to be a steam vessel, the distance she must run on ordinary voyages without recoaling; the weight of cargo to be taken or the number of passengers to be carried, and the kind of accommodation required for them. Very frequently these requirements will include certain limits of size, draught, cost, or tonnage, which must not be exceeded. In addition it must be stated in what society, if any, she is to be classed, as this will determine the details of the scantlings to be employed. The shipbuilder will usually have, to guide him, the details of some successful ship or ships previously built to fulfil the same or similar conditions as in the vessel required, and he will probably know what measure of success or popularity the respective features of the vessel or vessels have earned on service. The dimensions can in this case be at once fixed to provide the necessary speed, strength, stability and seaworthiness, and the cost of the vessel determined. If the departures from some similar ship of known and approved qualities are small, the details of the new ship can be inferred directly from those of the similar ship, and modified drawings, specifications, &c., can be rapidly prepared and the building proceeded with. On the other hand, the departures from previous vessels or the usual practice may be very great, in which case much will depend on the shipbuilder's skill and judgment. Outline drawings must first be prepared to the dimensions which may be considered suitable, and the calculations are made on this assumed design. These will include estimate of the weights of the hull, of the machinery, equipment, &c.; and if it is not intended to class the vessel in some registration or classification society, questions of strength will have to be considered. If, however, the vessel is to be so classed, the determination of the structural strength may be omitted, as the scantlings required by the rules of such society are arranged to provide sufficient strength. If the calculations show that the dimensions assumed do not enable the required conditions to be fulfilled, the dimensions must be modified in the direction indicated by the calculations, and the calculations made over again. This process must be continued until a satisfactory result is obtained. As soon as the dimensions obtained for the vessel are found to be appropriate, more complete drawings are put in hand, and the final calculations pertaining to the displacement sheet, weights of hull and equipment, centre of gravity and trim, metacentric diagram and curves of stability and speed, are made. In the design of yachts the views of the owner, especially if he is a yachtsman of experience, must necessarily play an important part.

While President of the Royal Yacht “Alexandra” he was commanded on several occasions to wait on the late King Edward VII. to take his instructions. King Edward took a special interest in the design throughout and sketched in his own hand the shapes of the knee of head and stern. All leading details were shown to him in model and settled by him personally. At an important stage the King consulted the prince of Wales (George V.), whose views as to the principal dimensions were afterwards adopted.

In the case of the construction of large passenger ships the design often originates with the owner’s or steamship company's staff, and in some instances naval architects are employed, completed drawings and specifications being handed over to the shipbuilder with the order for the vessel. In other cases shipbuilders work in close connexion with the steamship companies, and the business relations are of a very simple character, the company being content to send an order, with a note of the principal dimensions and type of ship required, leaving the determination of all details of the design in the hands of the builders. The general practice lies between these two extremes. In any case, complete design drawings and detailed specifications are necessary for the shipyard operations, and if not prepared must be supplied by the shipyard staff. Sometimes outline drawings of the vessel on a small scale—including an elevation or side view, one or two plans of the main deck and other parts, and a short description of the vessel—are first prepared, and are called an outline or sketch design; but usually the information which constitutes a design comprises a sheer, profile and plans of each deck on a 1-in. scale, a midship section on a 1-in. scale, and a complete specification.

The sheer drawing gives the outside form of the ship. It consists of an elevation showing her longitudinal contour; the position of the water-line or line at which she will float, and certain other lines parallel to this and equally spaced below it, which are also called water-lines; a series of vertical lines equally spaced from stem to stern, called “square stations”; and certain other details: of a body plan showing the sectional form of the ship at the square stations, supposing her to be cut by transverse planes at these stations: and of a half-breadth plan showing the form of the ship at the several water-lines, supposing her to be cut by horizontal planes at the levels of these lines. The sheer plans give all the internal arrangements of the vessel, the holds or spaces set apart for cargo, the passenger accommodation, the positions of the engines and boilers, the accommodation provided for the crew, and other principal fittings.

In a warship there are no cargo holds or passenger accommodation, but the distribution of the armament and magazines, the armour, and other arrangements for the protection of the vessel against injury in action are carefully shown, and the appropriation of every portion of the internal capacity of the vessel is clearly indicated. The midship section shows the structural arrangements of the vessel, and usually the scantlings of the most important parts. The specifications is a statement of all the particulars of the vessel, including what is shown on the drawings as well as what cannot be shown on them; the quality of the materials to be used is described, and the scantlings of the same carefully recorded; and it is clearly stated how parts not manufactured by the shipbuilders are to be obtained.

When first formed the objects of register societies were simply the maintenance of a register in which was recorded for insurance purposes the main particulars of each vessel’s hull, machinery, equipment, &c., together with the names of owner, master and builder, as well as a designation or class represented by a symbol, which was intended to give to underwriters an indication of the strength, durability and general seaworthiness of the ship. As a natural sequence it became necessary for the register societies to formulate a series of regulations which would be acceptable to owners and builders of all the structural conditions that would entitle vessels to the highest class and the minimum rates of insurance. The register societies now provide the shipbuilder not only with a record of all the important structural characteristics of the ship, but also with such additional information as he requires for the design of his vessel, but they also fix the quality and strength of the material to be used, the shape of the vessel, the lines of the hull, the riveting of the attachments, the equipment of pumps, anchors, cables, &c., the dimensions and details of the principal parts of the machinery, and all the details of the boilers. Classification societies are thus technical bureaux of the highest value to the shipping community, whose rules are a reflex of the most advanced knowledge and whose methods encourage developments in structural design.

The principal registration and classification societies in 1910, and the number of vessels (fishing and steam) classed, were as follows:

- Lloyd's Register of British and Foreign Shipping, having its headquarters in London: 10,302 vessels.
- British Corporation for the Survey and Registry of Shipping, London, 710.
- Bureau Veritas International Register of Shipping, at Paris: 4,626.
- Germanischer Lloyd, at Berlin: 2,676.
- Norvik Veritas, Christiansand: 1,560.
- Registro Nazionale Italiano, at Genoa: 1,263.
- Record of American and Foreign Shipping, at New York: 1,139.
- Veritas Austro-Ungarico, at Trieste: 1,041.
- Great Lakes Register: 609.

Of these societies, Lloyd's Register, as at present constituted, has existed since 1824, at that date it superseded two rival institutions which had been founded by Kellner of Lloyd's Coffee-house, once situated in Lombard Street, in which underwriters met for business purposes, and from which in 1666 they issued their first publication. The first printed register was issued about 1726, a copy dated 1764 being still extant. The office of surveyors is referred...
to a register book of the date 1751, but there are evidences that in 1768 surveys were superintended by officers of the society. In 1799 surveys were stationed at twenty-four ports on the British coast. In 1827 the first staff of 155 surveyors was distributed over the principal home and foreign ports.

The Norske Veritas was established in 1864 by the various marine insurance clubs of Norway. Each club had its own separate staff of surveyors, on whose report to their club depended the class of the vessel and the premium to be paid. As ships rose in value and reinsurance became the rule, something had to be done for making classification, uniform. The British Bureau Veritas one uniform system of classing and valuing was substituted for the older methods. In the matter of rules this society kept pace with the American Bureau of Shipping, and rules for some small vessels were issued. Steel was accepted in 1867, experimentally, steel being then made by the Bessemer process. Steel by the Siemens-Martin process was accepted for some small vessels in 1877. Engineer surveys were first appointed in 1874. The society is voluntarily maintained by the shipping community.

Its branches are managed by a committee of sixty-one members—composed of shipowners who represent the important shipping centres of the country, and there are branch committees at Liverpool and Glasgow. In technical matters affecting the register the rules for the construction of ships and machinery the committee has the advantage of the co-operation of a body of representatives of prominent shipbuilders, engineers, steelmakers and foremasters, who are specially elected by the leading technical institutions of Great Britain. The society’s rules for steel ships were entirely revised so recently as 1909. The society has a total staff, at home and abroad, of 310 surveyors, of whom 232 are its executive servants.

In the case of a new vessel intended for classification, the plans for its construction are in the first place submitted to and approved by the committee; the building proceeds under the supervision of the society’s representatives of whom the whole is considered the vessel by the committee upon that surveyor’s report. The society issues annually to its subscribers a register book containing particulars of classification of vessels to which classes have been assigned. A register is published for each other class, containing vessels in the world of 100 tons and upwards, excluding those trading on the Caspian Sea, and wooden vessels on the Great Lakes of North America, are included in the work. This register contains particulars of vessels for sale, tonnage, dimensions, ownership, register, and of vessels of 30,000 tons or over. The society also publishes yearly a register of yachts, containing full particulars of the yachts of the world and other interesting data, a register of river vessels, which gives similar particulars of all American and Canadian yachts.

In the United Kingdom for the testing of anchors and chain cables are licensed by the Board of Trade to carry out these tests under the control of the committee of Lloyd’s Register. The assignment of freeboards of vessels, the survey of refrigerating machinery, electric light installation, &c., all come within the scope of the society’s activities.

The Bureau Veritas was founded in Antwerp in 1828, one of its principal aims being to make known to underwriters the qualities and defects of ships frequenting Dutch and Belgian ports. In 1851 the bureau was extended in influence spread to all countries where shipping or shipbuilding existed. It is now represented in over 250 districts comprising about 1,500 ports. In 1851 rules were drawn up for the construction of iron ships, and rules for steel came later. These rules were revised from time to time and recently have been remodelled and extended, so as to apply to vessels up to about 900 ft. in length. Special rules have been issued for vessels intended for navigation in inland waters, for yachts and for motor boats. Each staff of surveyors formed part of the organization from the beginning; and in the later days the professional experience of the surveyors was the only guide as to what was necessary and sufficient. With the lapse of time, and with increased variety of construction and complications of interests, something more than individual judgment and experience became necessary, and with the Bureau Veritas, its temporary quarters, its permanent premises, were introduced, and by their means a greater uniformity of practice was attempted and secured.

The British Corporation was founded in 1850, and obtained its charter in 1854. The British Bureau of Shipping and the assignment of freeboards; its first rules were issued in 1893. Its inception was due to the enterprise and influence of a number of leadin shipowners, shipbuilders and engineers throughout the British Empire, particularly in Glasgow and the West of Scotland, the first aim of the founders being to provide an independent society, thoroughly capable of dealing with the complicated questions which were likely to arise from the use of iron and steel. Among the pioneers who adhered to the British Corporation was the Liverpool Registry, which had then been independent, but had been absorbed into Lloyd’s Register some years before, and it was thought that the enormous shipbuilding interests of the country deserved encouragement. At present, the British Corporation is in the hands of a council, but a great society of Lloyd’s Register would have a beneficial influence on the shipbuilding of the country. Owing to the comparative absence of small vessels the relatively small number of vessels on the register represents 2,331,000 tons. The society is controlled by a committee of forty members—shipowners, shipbuilders and underwriters—and, in addition, there is a branch committee in Italy.
that the machinery also conforms with the requirements of the rules and has obtained a separate certificate.

Certain steam vessels obtain a certificate which includes the following tests for angle bars and other materials:

<table>
<thead>
<tr>
<th>Ultimate Tensile Strength</th>
<th>Elongation in Length of 8 in.</th>
<th>Temperature Test.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lloyd's Register</td>
<td>28 and 32 tons per sq. in.</td>
<td>Not less than 20% for plates $\frac{1}{4}$ in. thick and upwards.</td>
</tr>
<tr>
<td>British Corporation</td>
<td>27 and 32 tons per sq. in.</td>
<td>Sample heated to a low cherry red cooled in water at $80^\circ$ F. and held for a period of $\frac{1}{4}$ h, shall not crack.</td>

</tbody>
</table>

For plates less than $\frac{1}{4}$ in. in thickness the first four societies in the above table allow an elongation of 16%, the Bureau Veritas allows an elongation varying between 20% and 10% for plates between $\frac{1}{2}$ and 3 in. in thickness. The Record of American Shipping allows an elongation of 18% for plates weighing $\frac{1}{2}$ lb per square foot: the Germanischer Lloyd allows an elongation of 16% for plates between 10 mm and 5 mm in thickness and 14% for plates between 5 mm and 3 mm in thickness. For steel to be flanged cold Lloyd's Register and the British Corporation require a minimum tensile strength of 26 tons, and for sectional material such as angles, bulb angles and channels the tensile strength may be as high as 30 tons. For iron sheets the tensile strength must be 25 and 30 tons per square inch, with a minimum elongation of 25% on a gauge length of eight times the diameter of the bar. Hot and cold finishing tests for angle bars and other materials are also specified.

The regulation of certain matters connected with the design of merchant ships falls upon the Marine Department of the Board of Trade. The authority of the Board is the Merchant Shipping Act of 1894, which contains the necessary enactments. These matters include the measurement of tonnage, and provision for the safety and comfort of the crew. The former is discussed in a separate article (see Tonnage), but it may be mentioned here that the following countries have at various dates accepted the British rules for tonnage: United States, Denmark, Austria-Hungary, Germany, France, Italy, Spain, Sweden, Netherlands, Norway, Greece, Russia, Finland, Hayti, Belgium and Japan. The amount of deduction for propelling power varies in Spain, Sweden, Netherlands, Greece, Russia and Belgium, but it is granted to owners of ships to have the engine-room remeasured under the rules of allowance for engine-room relating to British ships. Special certificates are at present also issued, on application, to vessels trading to Italian ports, as the British government do not recognize certain sections of the Act of 1894 in regard to deductions from tonnage and exemptions from measurement. Special tonnage certificates are also issued for the Suez Canal, where the measurements of ships and deductions from tonnage are to be regulated by British government rules at least by the Board of Trade in their Instructions to Surveyors. With regard to safety and comfort the surveyors have to see, among other matters, that the crews are properly accommodated and the passengers not too crowded; that the boats and life-saving appliances are sufficient; that the lights and signals are in order; that the freeboard is sufficient and ship otherwise seaworthy; that grain cargoes are properly stowed; and that coal cargoes are adequately ventilated. Any question of doubt as to the strength of passenger vessels has to be referred to the Board of Trade, and in future midship sections, with all particulars marked thereon, are to be submitted in the case of all new, second-hand, or repaired ships. A survey for which passenger certificates are required. A passenger certificate is required whenever a steamer carries more than twelve passengers. In granting it the Board of Trade recognizes five different services of passage, viz., bulk-passengers, first-class passengers, second-class passengers, third-class passengers, and boats from the United States to Canada. The Board of Trade rules for scantlings are not published officially.

A Bill, known as the Load Line Act of 1869, dealing with the load line question, contained a clause requiring the draught of water to be recorded at which a vessel is floating when leaving port. This Bill did not pass; but in the following year the Merchant Shipping Code Bill was brought in, and the same provision, and, in addition, requiring a scale showing the draught of water to be marked on stem and stern post of British ships, became law in 1871. The same Act empowered the Board of Trade to record the draught of all sea-going ships on leaving port by surveyors duly authorized. In March 1873 a Royal Commission on "Unseaworthy Ships" was appointed by the British government, and one of the questions considered was that of the load line. In the final report in 1874 the conclusion was arrived at that a settlement of a load line should, if possible, be guided by the experience of other countries as a first consideration with the British Board. The commissioners were, however, of opinion that an act of parliament, framed to enforce any scale of freeboard, would be mischievous. They recommended, therefore, that the Board of Trade, as would be any universal rule for the safe loading of merchant ships.

In 1874, in a paper read before the Institution of Naval Architects by Mr. B. Martell, who was then the chief surveyor to Lloyd's Register, Tables of freeboard were suggested from data collected at all the principal ports in the United Kingdom. These tables were based on the principle of reserve buoyancy, and were intended to apply to the load line and the freeboard of British vessels. As an indication of the form of the vessel, it was suggested that a tonnage certificate should be used, in order that the tables might be adapted to all sea-going ships, whether at that time at sea or in port. In 1875 a short Act was passed, to remain in force only until October of the following year, which embodied as its chief feature the requirement of what was afterwards universally recognized as the "British Board freeboard." In 1876, after "M.P. the prime mover in securing legislation for the prevention of overloading in British ships," All British ships were to have the position of the "Freeboard line" shown on the side of the ship, and every foreign-going British ship was to have a circular disk marked below the load line, indicating the maximum draught to which it was intended to load. The Act in no way fixed the amount of freeboard; this was left to the owners. The provision was confirmed by a more comprehensive Act in 1876, which extended the compulsory marking of the deck line and disk to all British ships, except those under 80 tons engaged in fishing and the coasting trades, also excepting yachts or war vessels. Before this Act was passed the Board of Trade took action, by appointing a committee to consider the possibility of framing rules for the regulation of freeboard. The committee was to be composed of representatives of the Board of Trade, Lloyd's Register, and the Liverpool Underwriters' Registry. This attempt to establish an authorized scale of freeboard failed. Meanwhile the subject was not lost sight of; the commission of data was continued, investigations were carried out, and six-years later (in 1882) the committee of Lloyd's Register issued freeboard tables, and undertook to assign freeboards, on the basis of the tables issued, on owners making application for the same. In the course of three years 944 certificates were granted to them, and in the case of 775 of this number the owners voluntarily accepted the freeboards assigned. In December 1883 the Load Line Act was passed, which, while retaining the principles of the Act of 1876, required all British ships to be marked with respect to the load line in the United States on the Atlantic, the sailing from or to which in the winter was subject to the ship to a few inches additional freeboard. In 1898 they were further modified (a) to exempt ships over 330 ft. in length from the additional freeboard, and (b) to give some concession to turret-deck steamers; and (c) in some other minor matters. In 1906 the Shipping Laws were amended so that all foreign vessels loading at British ports required to be provided either with a freeboard assigned under the British tables, or under tables of a foreign country, as selected by the British Board. By the British Board of Trade as being equally effective with the British freeboard tables.

In the same year the British tables were revised throughout in the light of the experiences of previous years of practical administration, by a committee whose members were drawn from the Board of Trade and the three assigning bodies—Lloyd's, British Corporation, and the Bureau Veritas. Important modifications were
made in the freeboards for vessels with complete superstructures or a considerable extent of strong deck erections, and in those for large vessels, with the result that a considerable increase was given to the carrying capacity of British shipping. This was followed by a considerable development of the nominal dimensions of the British government—being practically the former committee—and eight German delegates. The conference resulted in an adjustment of the German freeboard tables previously in force, and Germany has carried through the freeboard changes which are recommended by the British government in an Order in Council dated 21st November 1908. France and Holland have adopted the British tables, and the loan an outcome of the work and the changes made in Germany, which will become international. Under the provisions of the Merchant Shipping Act 1906 the British load line regulations now apply to all foreign ships while they are within any port of the United Kingdom.

Ships laden with grain have to comply with rules of the Board of Trade, which provide that for single-decked ships there shall either be provision for feeding the hold, or there shall not be any grain in bulk, the remaining one-fourth being occupied by grain or other suitable cargo in bags, bales or barrels, supported on platforms laid on the grain in bulk. For ships with two decks, grain- or store-cases, and the ports and floors in the scantlings for certain grains are allowed, provided there are separate feeders for hold and 'tween-decks, or else sufficiently large feeders to the 'tween-decks, and fitments made for feeding to the feeders for the holds. In ships with two decks longitudinal grain-tight shifting-boards must be fitted where grain is carried either in bags or bulk; these shifting-boards must extend from beam to deck and from deck to beam, in the grain way, and be fitted between the beams and carried up to the very top of the space. The regulations also impose a fine not exceeding five pounds for every hundred cubic feet of wood carried as deck cargo which arrives in Britain, British or foreign, in any port of the United Kingdom between the 31st October and 16th April, provided no unforeseen circumstances, as defined by the Act, intervene. By deck cargo in this section is meant any deals, batters or other wood goods of any description to a height exceeding 3 ft. above the deck.

In 1890 a committee was appointed by the Board of Trade to deal with the spacing and strength of transverse water-tight bulkheads, the framing and arrangements for the necessary openings in them. A matter connected with this committee related to subdivision which should enable a ship to float in moderate weather with any two compartments in free connexion with the sea. The committee, while recommending the above as a standard for sea-going ships of not less than 425 ft. in length, and for cross-channel steamers irrespective of length, suggested less stringent conditions for sea-going ships of shorter length. There was no suggestion of enforcing such subdivision by law; but as a reward for complying some concession was to be allowed, under the Life Saving Appliances Act of 1888, as to the boats or life rafts to be carried. On the presentation of the report the matter was, however, allowed to drop, and the rules of Lloyd's Register and the other classification societies are therefore the only rules with practical influence. The subdivision required by Lloyd's Register for all steamers carrying more than 64 tons and at each end of the machinery spaces, and a bulkhead at a reasonable distance on either side of the centre line, making four in all. In addition for larger steamers other bulkheads have to be fitted, making the total as follows, namely:

<table>
<thead>
<tr>
<th>Length of Steamer</th>
<th>Bulkheads</th>
</tr>
</thead>
<tbody>
<tr>
<td>255 ft. to 335 ft.</td>
<td>5</td>

</tbody>
</table>

The positions of these additional bulkheads, and the height to which they are to be carried, are clearly stated, and the rules are given for their scantlings. These scantlings are suitable for purposes of safety in the event of accident; but it is understood that they have to be considerably increased when the bulkhead is also used to withstand frequently the pressure of oil or water ballast; a deflection of the plating which would do no harm in an emergency once encountered would certainly become a hindrance in the ordinary service of the ship. The foremost bulkhead of the ship receives the name of collision bulkhead, or sometimes fore-deck bulkhead, and is often made of heavy plating. In sailing ships the collision bulkhead alone requires to be fitted.

Practical

Practical shipbuilding requires a knowledge of the properties of the materials used in the construction of ships, and of the processes by which they are produced or prepared for use, so they may be suitably selected for the services for which they are intended; also a knowledge of the methods, means and machinery by which, after delivery of the shipyard, the materials are brought to the desired shape, erected in their proper relative positions, connected together, and completed so as to form a structure which shall fulfil the intentions of the design, whether large or small, merchant ship or warship. The varieties of ships are very great, and are constantly changing, and thus new problems continually present themselves to the shipbuilder. There is also an ever-increasing demand for rapid production, which necessitates a rigorous and constant search for simplification of methods of work, for labour-saving and time-saving machinery, for improved means of handling material in the shipyard, and for adapting workshops and factories which will more completely prepare and finish their various products before dispatch to the shipyard.

Whatever the size of the ship or the type to which she belongs, the general principles of construction remain very much the same in all cases. The following account applies to steel and iron shipbuilding. The external parts—the bottom, sides and decks—supply the strength required for the structure as a whole. The bottom and sides are spoken of as the shell or outside plating, and are, with the decks, kept to the required depth by means of frames, bulkheads, girders, the rafters in a roof or the ribs in the body. These are divided transverse frames or ribs, and beams where they run under the decks. The parts of the frames at the bottom of the ship, where they are made deep and strong to support her when she is docked or grounded, are known as floors, while the spaces between these floors are spoken of as the bilges. The transverse frames and floors are held upright in their proper relative positions by other frames which run lengthwise in the ship; one at the middle line being called the centre keelson, and others fitted at the sides, keelsons, bilge keelsons and side stringers. All the fore-and-aft lines are thus connected, and so bound together. Where tanks for carrying water ballast are built into the bottom of the ship, the centre keelson is called the centre girder, and the keelsons or bilge keelsons the side girders. In large merchant vessels, and in all war vessels, except the smallest classes, an inner bottom is provided for increasing the security against injury by grounding, and against ramming and torpedo attack in war vessels, in addition to forming tanks for carrying water, either as ballast or for use in the ship. In such cases the centre keelson is called the vertical keel, and the keelsons and girders are called keel timbers.

When the framing plates are placed longitudinally along the floors only extend between the keelsons, girders or longitudinals, and are attached to them by angle bars, the floors are called intercostal floors, and the keelsons, girders and longitudinals are said to be continuous; on the other hand, when the keelsons, girders or longitudinals extend only between the frames and floors they are called intercostal keelsons, girders and longitudinals, and the frames and floors are said to be continuous. In war vessels, except the smallest classes, much of the longitudinal framing is continuous; and the transverse framing, for the most part, is built up of angle bars upon the outer bottom and under the inner bottom, with short plates, called bracket plates, between them, attached to the longitudinals by short angle bars. Frames built up in this way are called bracket frames. In mercantile vessels the transverse frames both within and without the double bottom are usually continuous. Besides the transverse and longitudinal framing, there are partitions used for dividing up the internal spaces of the ship, which are called bulkheads; they are partial, complete, water-tight or non-water-tight, as the circumstances of the case require. In warships the transverse bulkheads are so numerous, in order to restrict as much as possible the entrance of water from damage in action, that they go a long way towards providing the necessary transverse strength, and the transverse frames are consequently made of thinner materials and fitted at greater distances apart than they otherwise would be. Transverse frames are from 36 to 48 in. apart in large warships, and from 24 to 33 and sometimes 36 in. in large merchant ships. At the extreme ends of the ship the shell plating on the two sides is attached to forgings.
or castings, which are known as the stem at the fore end, and the stern-frame or sternpost at the after end. The stem of a warship is generally made very massive, and projects under the water so as to form the ram.

The longitudinal framing is carried right forward and aft when possible, and the ends of the several frames are connected together across the ship by strong plates and angles, which are called knees or breasthooks, forward, and knees or crutches, aft. Additional supports, introduced to enable the vessel to withstand the heavy blows of the sea in bad weather, are called piping, stringers, piping knees, and piping beams, panning being the term applied to the movements which occur in the side plating if sufficient strength is not provided. Where the ends of the ship are very full, or bluff, the frames are sometimes inclined, or canted out of the transverse plane, so as to be more nearly at right angles to the plating; such are known as cant frames. At the stern a transverse frame, called a transom, is attached to the upper part of the sternpost to form a base for cant frames, or the overhanging part of the stern which is known as the counter. To assist the beams and bulkheads in holding the decks in their proper positions, vertical pillars are introduced in large numbers; but to avoid the loss of space and inconvenience in handling cargo, ordinary pillars are often dispensed with, and special pillars and deep deck girders are fitted instead.

The steel generally used in shipbuilding is known as mild steel. It is very tough and ductile, and differs from the hard steel, out of materials, which tools are made, in that it will not take a temper, i.e. if heated and plunged into oil or water, the sudden cooling has very little effect upon it, whereas with tool steels a great change takes place, the steel becoming very hard, and usually brittle. This quality of tempering depends chiefly on the amount of carbon in the steel, mild steel containing less than 0.25% of carbon of greater strength than mild steel is used occasionally in certain parts of warships. The extra strength is obtained generally by the addition of carbon, nickel or chromium, coupled with special treatment. The quality of the plates and bars used is tested by cutting off a small piece, say 2 in. wide, and bending them double by hammering, or in a press, until the bend is a semicircle whose diameter is three times the thickness of the strip. The strips are sometimes heated and piled up in a furnace to soften them sufficiently, and then may be cut from either side or the end of the plate. Strips are taken occasionally and hammered into various other shapes while hot and while cold, so as to ascertain the general quality of the material. To ensure its tensility, strips are taken and machined to give a parallel part about 2 in. in width, of at least 8 in. in length. Two centre-punch marks are made 8 in. apart, and the strip is secured in a testing-machine constructed so that the ends can be gripped by strong jaws which do not injure the parallel part. The jaws are then gradually pulled apart, the amount of the pull required to break the strip being registered, and also the extent to which the strip stretches in the length of 8 in. before breaking. The tensile strength varies between 26 and 32 tons per square inch, calculated on the original sectional area of the parallel part before breaking, and the elongation in the 8 in. is about 20%. The standard strength and elongation required by the principal registration societies have already been given. The steel used for making rivets is similarly tested; and samples of the finished rivets are also taken, and hammered into various shapes, hot and cold, to ensure that the material is of the best quality. To test the quality of the steel in the casting, small pieces, which are cast on for the purpose, are removed and tested in the same manner as described for the strips cut off from the plates; they are required to give about the same tensile strength, but a little less ductility, say 10% in length of 20% elongation in 8 in.

The sections of the iron and steel bars in common use are shown in fig. 75, and are named as follows:

B. T (Tee) bar.  F. Plain bulb bar.  K. Moulding.

The vertical, or central, portion in the I, T and bulb sections is spoken of as the web, and varies from about 3 in. to 9 in. in depth; the horizontal parts are called flanges; in an angle bar, both parts of the section are called flanges. The flanges vary in width from about 2 in. to 7 in. in the angle bar, and from 3 in. to 6 in. in the others. The thickness varies from about ¼ in. to ¾ in. These dimensions taken together are called the scantlings of such material. The thicknesses of the plates in common use generally lie between ⅛ in. and 1 in. Thicker or thinner plates are obtainable, but are not often used for merchant ships. These plates of varying sizes as required, the tendency being to use very large plates where possible, and widths of 5 ft. to 7 ft. are used in lengths of from 40 to 20 ft. Angle bars are used in lengths of from 20 to 80 ft. as required, or as may be limited by the means of transport between the steel works and the shipyard.

The various plates and bars are connected together by means of rivets of various forms. Specimens of the common kinds are shown in fig. 76. The heads and points have distinctive names, as follows:

(a) Countersunk head, chipped flush.  (d) Ordinary countersunk head.
(b) Snap head.  (e) Snap head with conical or swelled neck.
(c) Pan head with conical or swelled neck.  (f) Pan head.
(g) Countersunk point.  (g) Countersunk point.
(h) Rough hammered point.  (i) Snap point, hand work.
(j) Snap point, machine work.

The pan head rivet (k) with conical or swelled neck is the most commonly used, as it is convenient to handle and gives good sound work. The rough hammered point (h) is also very commonly used, is very effective and is readily worked. The pan head (d) and snap head (c), without cones under the heads, are only used for small rivets; the heads (A), (B), (C), (D), are used where considered desirable for appearance' sake, but (C) and (D) are also adopted when the riveting is done by hydraulic machinery, in which case the snap point (i) is also used. The countersunk point (g) is also used. The countersunk point (g) is used on the outside of the shell, and in other places where flush work is required. The snap point (l), for internal hand riveting, is used where desired for appearance, instead of the rough hammered point. The rivets have a diameter from about ¼ in. to 1 in., and the lengths are as required to go through the holes and give enough material properly to form the points. The diameter of the rivet is settled according to the thickness of the plates to be connected, being generally about ⅛ in. more than the thickness of the separate plates. The distance from centre to centre of the rivets is spoken of as the pitch, and is generally expressed in diameters. For connecting plates and bars in the framing, the pitch of the rivets runs generally to 7 diameters; for securing edges which must be water-tight, the pitch is from 4½ to 5, and, if they are to be oil-tight, 3 to 3½ diameters. In butts and edges of shell-plating the pitch varies from 3¾ to 4½ diameters.

Fig. 75.

Fig. 76.
In some positions rivets like the above cannot be driven into place and properly hammered up; resort is then made to rivets which have screwed points, called *tap rivets*, shaped as shown in fig. 77. That shown at (a) is used where it is necessary to make the surface flush; at (b) it is not necessary to remove the rivet for the purpose of obtaining the angle of plating; and when drove right up, the square heads fit into the holes cut in the plate and the surface hardened smokeless rivets of positions patterns (a) or (c) are used as may be required. The bodies of the rivets may be replaced by V-shaped cutters for this purpose. When the plates and bars leave the shearing and punching machine their edges are rough and slightly disordered, to remove which it is necessary in many cases to grind or smooth them. This is usually done by shearing edges provided for the purpose. In the most modern types the cutters are duplicated and the machine arranged to cut both ways. When it is required to cut a square edge free from flanges a small angle of cutting may be used. The machine is frequently used, but it is more usually done in a planing machine.

In shipbuilding a great deal of drilling must be done by hand, but, where it is possible, drilling machines are employed, and in a modern shipyard may drill a number of holes at the same time. For countersunk work it is necessary to make the hole funnel-shaped, as will be seen from fig. 77. The shape is a rapidly given to the holes already punched or drilled by means of a special drilling tool, which can be very easily and rapidly manipulated. The use of portable drills, to avoid hand labour, is rapidly increasing, and several types are manufactured by electric motors. An electric eye, which can be made to operate on the bar. The inclination of the roller is varied as the bar passes along, a dial and pointer giving the angle of bevel at all times, and a lever to hold it in the appropriate setting. The electric eye on the dial, manipulates the machine so as to give it the required bevel. It is afterwards completed on the slabs, the form being taken from the scrive-board in the usual way.

Another modern appliance is the shearing machine, which is used chiefly in connexion with the lapped butt of shell and other plating. Before its introduction it was usual to bring the ends of the plates together tightly and then, by a device called cover plates, to insert the latter and allow it to be driven into both plates with a proper arrangement of rivets (see fig. 78). It is now more usual in merchant ships to work overlap butts, some half of the weight of the butt-strap and riveting and other work being saved by this arrangement. As it is nearly impossible, as may be quite sightly, the difficulty with this system is that the passing plates on each side have their edges lapped over the ends of the lap, and in order that they may be brought close some machining is required; this is usually done by machining away the corners of the projecting butt so as to produce smooth surfaces for the side laps (see section at A, B, fig. 78). The machine used for this operation is a large shearing machine of the type shown in fig. 79, which can be placed in the shipyard, with the plates mounted on it, and one at a time they can be removed from behind and then passed through the machine. As already described, the usual method of working the shell-plating is by alternate inside and outside strakes of plating, the outside strakes overlapping the inside plates, and the same between them and the frames being filled in by ships or liners. These lines throughout the ship amount to a considerable weight, and the object of the jogging is to do away with the necessity for them. This is done by machine; heavy-pegging machines. It is described in section 5, fig. 79; the inside plate lies in the recessed portion of the plate formed by the jogging process, and the outside strakes are of the shell-plate type and are usually simulated by the other strakes, in which the inside of these strakes is the same as that used on the plates. The advantage of this system is very great, and it is very popular with shipbuilders. It is also employed in the manufacture of many other parts of merchant ships.
PRACTICAL]

SHIPBUILDING

963

purpose they are intended, so that they can be readily identified
and removed without loss of time. When required, they are taken
from the racks, and the edges, butts and rivet holes carefully
hoisted, except for plates under the bottom and counter, where a
wire rope is used.

At Newport News, in Virginia, the structures are differently
arranged, being on the cantilever travelling-crane principle. There
are five such structures in the yard; three of them are wood, the
last two of steel. The largest is 700 ft. long. One trestle structure, or
gantry, serves two building berths, and runs longitudinally between

marked upon them before they are taken to the machines where
the shearing, punching, drilling, shaping, &c., are carried out, after
which they are taken to their proper position in the
ship.

In many shipyards great attention has been given
to the questions of the economical handling of the
material, and very costly and novel appliances
are to be found in these yards for the
purpose. As an example mention may be made of
the overhead cranes fitted at the Union Ironworks of San
Francisco. A framework of wood is built up over the
entire building berth, the structure being well braced in
all directions for carrying two travelling girders.

There are four building berths fitted in this manner,
and the latest has a length of 408 ft., a clear breadth
of 80 ft., and clear height of 72 ft. A swing crane of
50 ft. spread at each end of the erection increases its
effective length to 500 ft. Each of the travelling girders
carries a trolley, with motion transverse to the ship;
five tons can be so lifted, and parts of the ship's structure
not exceeding this weight can be taken from the
ground anywhere in the neighbourhood of the structure
and conveyed to any desired spot in the ship. The
driving power is electric. The longitudinal travel of
the girders is 660 ft. per minute; the transverse travel of the trolley
and speed of lift, each 90 ft. per minute. A manila rope is used for

the two. On the gantry is mounted a double cantilever crane, having an effective reach of 95 ft. on each side of the centre; this outreach is sufficient for a ship 70 ft. broad on each side of the travel. These cantilevers and other American ships. The load that can be raised is 15 tons, and if necessary a bulkhead up to that weight can be lifted bodily into place. The speed of lift for this weight is 100 ft. per minute, and the hoist, which rides along side the gantry and can be swung to either of the two ends of it, can be raised or lowered at the rate of 500 ft. per minute, and of the whole crane longitudinally is 400 to 700 ft. per minute. All movements are made by electric power. Similar gantries are also to be found on Messrs. Swan, &c.-Tyne, but not so extensively used.

The view shown in fig. 80 (Plate VIII.) represents one of these structures as fitted in Messrs. Cramp's shipyard in Philadelphia. At the yard of Messrs. C. S. Swan & Hunter, on the Tyne, similar structures have been used since 1894; besides carrying cranes, these have standards and stiffening girders, from which ships under construction are shored for fairing. Roofs and sides are fitted to protect the ship, and the arrangement for distributing the weight of the cranes to the ground is ingenious. It has three in number, and serve for two berths; they are formed of steel lattice-work, with standards mostly 20 ft. apart. The clear height of roof is 83 ft., and clear breadth of berths 68 ft. and 73 ft., a roadway on the ground level is left free on each side of the berths inside the standards. Two revolving 3-ton electric cranes travel along paths suspended from each roof; their jibs have sufficient radius to lift material from the roadways and deposit it at the centre of the ship's building. The longitudinal speed of these cranes is 300 ft. per minute; speed of lift, 100 ft. per minute.

A third berth is served by a travelling cantilever crane on top of the adjoining hold, whose crane travels from 700 ft. and above the yard to the building, was introduced in 1897 (see fig. 81, Plate VIII.). In this case the structure takes the form of a travelling gantry or bridge over the building berth, the legs running on rails at a great height above the ground, and the gantry, which is traversed by the crane, has three traversing cranes and four 4-ton swing cranes. It was designed to facilitate the lifting of plates and portions of the structure into position, and also to support the derelict riveting and other appliances for the carrying out of the work. The success of the appliances, first used in the "Oceanic," has led to a further extension for other ships in hand.

**Course of Construction**

The first steps taken on the receipt at the shipyard of the design drawings and specifications, which have been generally described on page 957, have for their object the provision of detailed drawings of the structural arrangements, which will enable materials for the various parts to be ordered from the manufacturers, and of information for the guidance of the workmen in erecting the structure.

A wooden model of half the exterior surface of the ship, called the "half-block" model, is immediately prepared from the sheet drawing, generally to a scale of ½ in. to the foot for a large ship and a somewhat larger scale for a small one, and on its surface are carefully drawn the main frames, the edges and buttoes of the upper bottom or shell-plating, together with the positions of decks, longitudinals and other features which influence the detailed arrangement of the framing and shell-plating, the particulars of which are fixed by the draughtsmen of the ship and the midship and other sections. The work on this model is carried out concurrently with the laying off of the ship, which will be described presently, so as to be complete by the time the latter is sufficiently far advanced to enable full-sized measurements of the breadth of the plates to be obtained. The lengths of the plates are then measured from the model and the breadths from the mould loft floor, a small surplus on the net measurements being allowed to provide for inaccuracies; and the whole of the outer bottom platting ordered from the manufacturers.

The whole of the framing is also ordered, the lengths of the various parts being measured from the model, and should the case be necessary, the parts are sent to the builders and the parts to be made of the protective deck if it should have much curvature or sloping sides. All details of plating, framing, beams, carlings, hatchways, &c., will be shown on these models, and the dimensions of all the parts will be carefully measured off and the material ordered of the manufacturers; the breadths of the plating being obtained as in the case of the outside bottom plates.

For flat or nearly flat surfaces such as flat keel plates, vertical keel, bulkheads, decks, engine and boiler bearers, &c., the detailed arrangements of plating and frames are made on drawings, from which the dimensions are taken for ordering the material from the manufacturers; while the drawings themselves constitute working drawings which are issued for general guidance in building the ship.

Drawings of details of important structural castings or forgings, such as the stem, sternpost and shaft brackets, are also among the earliest to be taken up. The draughtsman is almost as busy when, they are large and complicated castings as in a warship, cannot generally be completed without information obtained from the mould loft floor.

Laying off is the name given to the process of drawing the lines of a ship to full size in plan and elevation in order to determine the exact dimensions of the most important and fundamental parts of the structure. The necessity for drawing the lines arises essentially from two causes: first, the measuring of a whole section of any horizontal plane parallel to the keel, and of such a size as to take in the full depth of the ship in its width. The building or room in which the floor is situated is called the "mould loft," and is an important adjunct to the shipyard drawing office.

The rationale of the methods of projection of points and lines and rabatment of planes used in laying off is subjected to a detailed examination in the various cases (figs. 82 to 92, illustrating the method of laying off), but it may be summed up in the statement that it is confined to a description of some of the detailed problems which occur in actual practice, the solutions being often approximations which do not find wide application.

In different localities and in the construction of different types of vessel, the extent to which the process of laying off to full size is employed varies considerably. In some yards laying off on a large scale is carried out on all large vessels, and even little vessels are laid out full size; in others it is only applicable to the larger vessels. The present work is limited to the Great Lakes vessels employed on the Great Lakes lakes, and has been selected for the sake of the simplicity of the methods used, for the detailed examination of the processes employed.

The formal title of various drawings, and the general form of the various types of drawings used in the construction of ships, have been described on p. 972. The essential points to be observed in each drawing are indicated when they first appear in the text.
SHIPBUILDING

PLATE VIII.

XXIV. 964.
other information required for laying the vessel off and making the necessary moulds being usually given on other drawings. The sheer drawing is next drawn, showing the whole vessel, the framing and plating being given concerning the form of the ship and other features of the design required for laying the vessel off, ordering the material for her construction and afterwards preparing the frames and timber, which is the object of the fairing process to correct, being proportional to the increase in scale in first copying. The process is simply described as "fairing" which is described below.

A straight line is drawn to represent the keel, this being a fixed straight batten nailed to the floor a short distance from the wall of the building to represent the load-water-line in the sheer and body plans. In the later stage of the drawing when the vessel is to be drawn with regard to it within the limits, on the floor and clear of the batten, the inner edge of which becomes the base-line of the sheer, half-breadth and body plans. The fore and after perpendiculars, the position of the forward and after perpendiculars, the distance between which defines the nominal length of the ship. The water-lines are 3 to 4 ft. apart. Intermediate square stations are then drawn from these and perpendiculars are dropped from the forward and after perpendiculars, the distance between which defines the station marks, the distance of the surface of the ship is rapidly altering; as at the ends and below the bilge. It is usual, and obviously sufficient in the sheer drawing as well as in the process of laying off, to show only one-half of the ship on one side of the longitudinal vertical plane of symmetry. Thus, in the half-breadth plan only the port side of the ship is drawn; and in the body plan, for greater clearness, the half ship is further divided, the part forward of the midship section, or square station at the middle of the length of the ship, being shown on the right of the middle line of that plan, and the part aft of the midship section on the left of the middle line.

Other Drawings.—The profile and plans and the midship section have also been described in this article. The profile and plans of H.M. yacht "Alexandra" are given on plates. Fig. 84, Plate XII., gives sections at two points showing the arrangement of decks, bulkheads, machinery, living spaces, storage spaces, etc.; figs. 86, 93, 94, 95 and 96, Plate X., give the plans of the promenade deck, upper deck, main deck, lower deck and hold respectively with important fittings shown upon them; figs. 88, 89, 90, and 91, and plate X., give sections of the ship showing the inboard works at stations E, D, C, B and A on the profile respectively; and on fig. 97, Plate XII., are shown all the vertical sections and scantlings of the framing and plating. Fig. 98, Plate XII., also gives the midship section of H.M. battleship "Lord Nelson."

Any two of the three plans of the sheer drawing may be taken to represent the form of the ship. The longitudinal view, or the "longitudinal Geometry, and are theoretically sufficient to define the shape of the vessel completely, but the three plans are practically necessary for the sake of clearness and accuracy. If a sheer drawing the lines may represent the intersections of planes with the surface of the framing of the ship, or with an imaginary surface having a mean position between the irregularities of the surface of the ship caused by the system of plating adopted. The former system is the more usual in the drawings of steel-built merchant ships, necessitating an allowance on all measured dimensions used in calculating displacement, &c.; the latter system is the more usually used in shipbuilding, where it is important to include the measurements of structural scantlings and material for the laying of a ship plated with raised and sunken plates strakes as described on p. 962, would be an imaginary surface midway between the outsides of the raised and sunken plates. The height of the bow and stern, which is the nominal height, are also shown to indicate to show displacement lines in contrast to the former system which shows " moulded " or frame lines. In the case of vessels with a plank sheathing over the bottom the names of the frames are given in the drawings as " Frame X."

As the primary object of the laying off of the ship is to ascertain the shape of the frames, the surface of the outside of the frames is always that which is laid off on the mould loft floor. If displacement lines are given in the sheer drawing a preliminary process of deriving from them the moulded lines is necessary before laying off on the floor. The process, to be strictly accurate, involves setting in the requisite distance along the normal to the surface shown in the sheer drawing. This is easily done at the midship section, where the normal to the surface lies in the plane of the section and coincides with the normal to the curve of the square station in the body plan, or at the practically vertical faces of the frames in the sheer drawing. The normal to the line in the water-line in the half-breadth plan. In other positions, however, it would be necessary to rabat a plane containing the normal on one of the planes of symmetry, and drawing the sectional view of the vessel, to find the projections of the point in the frame surface so obtained and of other similar points, and thus obtain the projections of curves on the frame surface, which by their intersections with ordinates to the middle vertical plane, give rise to the lines of maximum depth and water-lines corresponding to the moulded surface of the ship. Such a process, though simple, is more laborious than is necessary in the drawings of vessels where the position of sections is fixed by the length of the vessel, the water-line being constant for equal sections of the vessel, and the framing and plating being customarily to set in normal to each square station a distance slightly greater than the thickness of the plank and plating, the increased distance required being roughly estimated from a consideration of the obliquity of the water-lines, without producing any sensible error.

The frame lines having been obtained, it is customary at some shipyards to " fair " the body on paper on a larger scale than that of the sheer drawing, before laying off on the floor. This saves a certain amount of labour in fairing the full-sized body on the floor. It is well known to every experienced copyist how much it is the object of the fairing process to correct, being proportional to the increase in scale in first copying. The process is simply described as " fairing " which is described below.

The whole of this process of measurement and tabulation is frequently done in the drawing office, and the " lotsman " or person who makes the layout of the layout is supplied with the sheer drawing, but only with these tables of " offsets, " the tables for the lines in the sheer and half-breadth. The process, however, is the same in each case.
series of points on the several water, diagonal and buttock or bow lines corresponding to each square station, being held in position by nails, specially adapted for the purpose, lightly driven into the floor, the batten in each case being adjusted so as to lie in a fair curve. Usually the batten will not under these conditions pass through all the points found for the curve on account of irregularities introduced or magnified in the process of enlarging to full size, and it must be allowed to take up a mean position passing outside some of the points and inside others. All of the sections in the body plan are drawn in with chalk in this way. The section where the greatest breadth of the ship occurs, usually at or near the middle of the length, must have the line parallel to and half the moulded breadth of the ship from the middle line for a tangent, and no section must project beyond this line.

The intersections of each section thus drawn, with the water and other lines, are the vertical projections on the body plan of points, the horizontal projections of which lie in the horizontal trace of the transverse plane at the corresponding square station or ordinate in the sheer and half-breadth plans, and are at the same perpendicular intersection of the bow plane 1B with square station 2, and is the projection in the sheer of the intersection of water-line 2WL with the same bow plane. The water-lines and diagonals in the half-breadth and the diagonals and bow and buttock lines in the sheer may thus be drawn as fair lines by the help of battens, and if the lines do not pass through all the points obtained by projection from the body plan, the sections in the latter are rubbed out and new ones obtained from the lines in the half-breadth. This process should be repeated until the curves in both plans are fair and the intersections correspond accurately with one another as the projections of points in space.

No frame of the ship, however, is made to the curves of these water and diagonal lines, so that their true shapes are not required for any practical purpose except fairing the body. For the whole length of the ship, except about three to four twentieths at each end, space and labour are therefore saved and greater accuracy is ensured by using the contracted method of fairing. In this method the ordinates of the half-breadth are set only from 1th to 10th of their true distance apart, while the transverse

**Fig. 99.**

distances from the middle line of the half-breadth as the corresponding vertical projections are from the middle line of the body. For example, in fig. 99 P, and Q are the projections in the half-breadth of the same points of which p and q are projections in the body plan, and are found by making the ordinates of P, and Q, measured from the middle line of the half-breadth plane at square station 2 equal to the perpendicular distance of p and q respectively from the middle line of the body plan. Thus points in the projections in the half-breadth of the water and diagonal lines can be found from the body plan already drawn, and in order that the surface of the ship may be fair, the series of points corresponding to any water or diagonal line must lie on a fair curve. In the case of a diagonal the distance from the middle line of the body to the intersections of the diagonal with the square stations may be measured along the diagonal, and set off on the corresponding square stations in the half-breadth. This gives the true or rabatted form of the intersection of the diagonal plane with the ship's surface, and this, equally with the projected diagonal, must be a fair curve if the surface is fair. The diagonals are also projected into the sheer plan by measuring the height above the base-line at which each diagonal in the body plan cuts each square station, and setting up this height from the base-line of the sheer plan at the corresponding square station. The projections of the bow and buttock lines in the sheer plan are obtained in a similar manner. Thus in fig. 99 V is projection in the sheer plan of the measurements are made to full size as before, thus making the curvature of the water and diagonal lines sharper throughout the region over which it would otherwise be somewhat flat and indefinite. As the curvature of the contracted level and diagonal lines depends upon the differences between the lengths of the ordinates of the curves and not upon their actual length, a further saving of space is effected by measuring the distances to be set up as ordinates in the half-breadth not from the middle line of the body but from a point selected arbitrarily in each water or diagonal line, generally a few inches outside the midship section. By suitably varying the distances outside the midship section of these arbitrarily chosen points in the different water and diagonal lines, it can be arranged that the curves in the half-breadth do not interfere with one another, an advantage from the point of view of clearness. With the above modifications the process of fairing by the contracted method is precisely similar to that when the ordinates are their full distance apart.

In fig. 88 the diagonals 1D and 2D are shown laid off by the contracted method, the spacing of the ordinates in the contracted half-breadth being 1/10 of that representing the spacing in the diagram of the uncontracted sheer and half-breadth. In the contracted half-breadth the ordinates 4^1, 5^1, &c., are equal to the distances O, O, &c., measured to sections 4, 5, &c., in the body, O being a point arbitrarily selected in the diagonal 1D.

The principle of contracted fairing is sometimes extended by the

provision of a large drawing-board 4 or 5 ft. broad and long enough to take the whole length of the ship on a scale of 1/10th full size. The ordinates of the half-breadth and sheer being set off on the board to this scale, any line in which the difference between the greatest and least ordinates does not exceed the breadth of the board can be fairied thereon by this contracted method. This allows considerable lengths of the midship parts of diagonals and water-lines, and such lines as decks at middle and side, and any other lines of very flat curvature, to be fairied on the board, resulting in a great saving of time and labour, owing to the convenient height at which the board may be placed, and to greater accuracy, as the fairness of the lines can be better seen and judged.

At the forward and after ends of the ship the correct shapes of the water-lines are required in order to determine the shapes of the stem and stern-post, besides which the curvature of these lines is too great to permit of contraction of the abscissa scale.

![Diagram of ship's sections and lines](image)

**Fig. 100.**

by separate processes there shall be a considerable overlap throughout which the water and other lines in the two parts are identical in order to ensure the continuity of the surface.

The detailed drawings of the stem and stern castings already referred to must ensure that these castings shall form a fair continuation of the outside surface of the plating or sheathing. They are perhaps most complicated in the case of sheathed armoured warships where the surfaces of "rabbits" or recesses for housing the bottom and armour plating and the wood sheathing must also conform to the lines of the ship laid out on the floor. A sketch of the stem casting for an armoured, sheathed ship with a ram bow is given in fig. 100, the sections being shown in a wider scale than the elevations for the sake of clearness, except the section at the water-line AA, which is drawn to illustrate the method of ending the water-lines, similar sections being used for the displacement of the ship. The form of the stem is drawn in full size in the sheer plan on the floor in its correct position relatively to the fore perpendicular and water-lines by measurements taken from the sheer drawing, and the projections of the line of the inner angle of the rabbit for the shell plating, called the "middle of rabbit," marked in the figure, are drawn in the sheer and body plans as fair lines. It should be observed that in the figure the free ends of the middle of rabbit of plating are shown in side elevation as coincident lines on account of the smallness of the scale; they will not be generally coincident in a full-size drawing. The middle of the rabbit line is best fairied in an expansion drawing. In this method a batten is bent to the curve of the projection of the line in the sheer plan, and the position of the water-lines where sections of the stem have been drawn on it. The free ends of the middle of the rabbit line is then allowed to spring straight along a straight line drawn in any convenient position on the floor, and the positions of the water-lines are transferred from the floor to the floor. The distances such as "xh" in the section at AA are measured from each section in the drawing and set up in full size perpendicular to the straight line on the floor at the positions corresponding to the sections. A fairied line is then along the end perpendicular to the face of the deck at any position in the length of the stem and enable the projections of the middle of rabbit-line to be drawn accurately in the body and half-breadth plans.

To end any water-line such as AA in the half-breadth plan a perpendicular to the middle line of the half-breadth is drawn from the intersection of the line AA, with the projection of the middle line of the in the shear plan, and the distance "xh" taken from the body plan, or direct from the expansion of the middle of rabbit-line, is set out from the middle line of the half-breadth; the point "h" is the end of the water-line AA required. The water-lines having been drawn and ended in this manner, ordinates coinciding with the transverse frames are drawn in the half-breadth plan and their projections obtained and fairied in the body plan in order to define more closely the somewhat twisted surface of the ship in the neighborhood of the stem. These frame sections may involve correction and adjustment of the endings of the water-lines, which corrections are made subject to the condition that the projections and expansions of the middle of rabbit-line must remain fair curves. With the middle of rabbit thus fixed in proper relation to the fairied surface of the fore end of the ship, the sections of the stem by the water-planes can be reconstructed in the half-breadth plan by the help of the drawing of the stem and of any additional information contained in the specification as to the nature of the fastenings of the plank and planking in the casting and the length of the foreframes. Where the general direction of the stem is considerably out of the vertical, sections of the frame surface by planes normal to the fore edge of the stem are obtained by the help of the closely spaced frame sections, and rabated on the sheer plane; and sections of the stem casting constructed on them as in the case of the water-lines. In this way as many points as are required are obtained in the various lines in the surface of the stem, viz. the after edge of the casting, and the various angles of the rabbit, and these lines are fairied so far as they are continuous in the three plans. The shell and protective plating and plank sheathing are also put on outside the various sections of the frame surface for a short distance in the neighborhood of the stem, and the surface of the stem forward of the fore edge of the rabbit is fairied in with the outside surface of the ship.

When a batten mould is made to the outline of the stem plan, and the projections of the lines of the rabbits and of gulleling, position and shape of webs for connecting to decks and stringers and to the keel, lines of rabbits for connecting to led plates at the lower end and to the plate at the upper end (if the casting is not continued right up to the forecastle deck), the position of the fore perpendicular and load water-line are marked upon it. Sections of the casting taken from the floor are painted on the mould, the centre lines of the sections indicating the position where they are taken, showing more particularly the changes in shape of the casting at such positions as the upper and lower edges of the protective plating and the upper edge of the plank sheathing. The stem mould thus gives complete information for the preparation of the pattern for the casting. The positions of the fore perpendicular and load water-line marked on the stem mould are transferred to the pattern in the casting, and enable the stem to be erected in its correct position at the ship.

The after end of the ship is faired and the mould for the stern post and other castings prepared in a similar manner. The process of preparing the moulds for the stem and stern post is also generally similar to the above in the case of an unsheathed ship, but the castings are less complicated owing to the absence of the plank sheathing.

The whole of the 21 square stations which constitute the original body plan having been fairied as described above, it is usual to prepare the 21 square castings and to calculate the displacement and buoyancy of the ship from the lines laid off on the floor to ensure that in the process of fairing no departure of any consequence has been made from the original design. For this purpose the steps shall be taken, whether there be or not, must be put on by a process the inverse of that described as taking off the plank. If any serious departure from the original design should be discovered as the result of this calculation, the lines must be corrected and again fairied.
The transverse frame lines are the intersections with the frame surface of transverse vertical planes passing through the lines of intersection of the two exterior surfaces of the flanges of the frame angle bar, or of the web and flange of any other type of rolled section which may be used for the frame.

The distance between two adjacent frame lines, called the "frame space," is given in the specification, and the positions of the frames relatively to the ordinates are shown in the sheer plan of the ship. The frame space in a warship is commonly 4 ft. within the limits of the double bottom and 3 ft. forward and aft. In a merchant ship the spacing is usually less. The positions of the planes of the frames are set off along the middle line of the half-breadth plan, the proper scale being used in the contracted half-breadth, and ordinates are drawn to represent their traces in the half-breadth and sheer plans. The projections of the frame lines in the body are obtained from the intersections of the ordinates with the water and diagonal lines in the half-breadth and the bow and beam lines in the sheer plan in a manner already described in the case of the more widely spaced stations used in fairing the body. These frame lines in the body should require no further fairing if the work has been accurately done when using the original square stations, and they can be at once raised in on the floor.

As already stated, it is usual to dispose the transverse framing of a ship entirely in planes perpendicular to the trace of the load water-plane with the longitudinal plane of symmetry of the ship. This practice leads to a large and varying bevel being given to the frame bars at the ends of a vessel with a very bluff bow or stern, and it becomes a practical question whether it would not be better at such parts to dispose the frames in planes which are more nearly normal to the general surface of the ship and which need not be perpendicular to either of the three planes of reference. The disposal of frames in this way, more usually in planes perpendicular to the half-breadth planes only, when they are called "cants," is in common use in wood shipbuilding, it being of great economical importance that the timber frames shall be of square or nearly square section, but it is also adopted in iron and steel ships of unusual form or having special features, such as instance as a lifting screw propeller.

To lay off a cant frame or "cants" let the traces of the cant be $a'b'$, $ab$ in fig. 101. Let LL be the projections of a level line in the three planes intersecting $ab$ at $b$ in the half-breadth. Then $b_1$ in the sheer is the vertical projection of $b$, and a curve through all such points as $b_1$ is the projection in the sheer of the shape of the frame or, as it is called, of the moulding edge of the frame. $b_2$ in the body, where $ab_2$ is equal to the perpendicular distance of $b$ from the middle line of the half-breadth, is a point in the projection in the body plane; and $b_1$ where $ab_1$ is equal to $ab$ is the position of the point, when the cant plane is hinged about $a'b'$ until it is parallel with the body plane. Hence a curve drawn through all such points as $b_1$ is the true form of the moulding edge of the cant. To obtain the angle which the surface of the ship makes with the plane of the moulding edge, a plane parallel to that of the moulding edge and distant from it the width of the bevelling board must be laid off in a suitable position in the body plan. Let $g'e'$, $ge$ be the traces of such a plane where $af$, the normal distance between it and the plane whose traces are $a'b'$, $ab$, is the breadth of the bevelling board. The vertical projections of $c$, viz. $c_1$ and $c_2$, in the sheer and body are found in the same way as those of $b_1$; but in order to obtain the rabatted curve of the bevelling edge in such a position relatively to the moulding edge that the perpendicular distance between the two curves measures the bevelling in the same way that the perpendicular distance between two frame lines of the square body measures their bevelling, it is necessary to first project the bevelling edge on the plane of the moulding edge before rabatting the latter. The whole operation is effected by making $a_1 c_1$ in the body equal to $fe$ in the half-breadth, where $af$ is perpendicular to $ab$ and $gc$. A curve through all such points as $c_1$ is the bevelling edge laid off in the position relative to the moulding edge required, the bevellings being taken in a similar manner to those of the ordinary transverse frames.

Spots on the cant can also be obtained from diagonals as follows:—In fig. 102 let DD be the projections of a diagonal line in the three plans cutting the horizontal traces of the moulding and bevelling edges at $d$ and $e$ in the half-breadth. The projections $a_1$, $e_1$ in the sheer and $a_2$, $e_2$ in the body of the intersections of the diagonal line with the planes of the moulding and bevelling edges are obtained in the same way as in the case of the level line, and the method of obtaining the rabatted positions, when the plane of the moulding edge, with the bevelling edge projected upon it, is turned about $a_1 b_1$ until it is parallel to the body plane, is also analogous; but in this case the corresponding points of the moulding and bevelling edges are in different level planes $a_1 d_1$, $e_1 f_1$. Points in the rabatted curves of the moulding and bevelling edges of the cant may also be obtained from the intersections with bow and buttock lines, as shown in fig. 103, where $BB$ are the projections of the bow or buttock line in the three plans. The method is analogous to that described above when using level lines and as shown by the figure, $h_1$ and $k_1$ being rabatted positions of points in the moulding.

FIG. 92.—SECTION AT A.

Scale of Feet
and bevelling edges respectively; where $h_1 h_2$ is equal to $ah$ and $kbh_2$ to $fh$.

In fig. 104 let $AB, A'B'$ be the traces of the plane of the moulding edge of the frame in the sheer and half-breadth plans respectively. When, as in the figure, neither trace is perpendicular to the base line, the frame is said to be a double canted frame, or a double cant. Let $1L, 2L, 3L$ be the projections of level lines in the three plans, $P, Q, R$ in the sheer plan being their point of intersection with $AB$. The

Double canted frame.

horizontal projections of these points are found as indicated in the figure where $Q'$ on the middle line of the half breadth is the horizontal projection of $Q$. The line $Q'Q''$ parallel to $A'B'$ is the horizontal projection of the line of intersection of the double canted plane with the level plane $2L$, and $Q''$, obtained by the construction shown, is the vertical projection of the point where this line of intersection cuts the surface of the ship, $q''$ being the horizontal projection of the same point. The projections of other points in the intersection of the double canted plane with the surface of the ship are found in a similar manner by the help of other level lines; and the projections $s'$ and $s$ of the ending where the line of half side of the flat keel cuts the double canted plane are found by the construction indicated. The projections of the moulding edge of the double canted frame $s'q''s''q'$ in the sheer plan and $s'q''s''q'$ in the half-breadth are thus determined.

The true form of the moulding edge is laid off in the body plan by a double process of rabatment of the double canto plane, first about the trace $AB$ to bring it perpendicular to the sheer plan, and then about a normal to the sheer plan through $A$ to bring it parallel to the body plan, in the following manner. Set off $P_1, Q_1, R_1$ on the middle line of the body so that their distances from $A$ are equal to $AP, AQ, AR$ measured along the trace $AB$ in the sheer plan. Draw $AC$ in the sheer plan perpendicular to $AB$ and measure the heights parallel to $AB$ of the points $p_1, q_1$ and $r_1$ above $AC$. Draw level lines $1L', 2L', 3L'$ in the body plan at distances above the base line equal to these heights, and from the centres $P_1, Q_1, R_1$ describe circles cutting $1L', 2L', 3L'$ in $p_2, q_2, r_2$, &c., so that the radius $Q_2Q_2'$ is equal to $Q''q''$, &c. The curve $p_2q_2r_2$ is the true form of the moulding edge of the double cant laid off in the body plan.

The plane of the bevelling edge is parallel to that of the moulding edge and at a perpendicular distance from it suitable for use as the base of a bevelling triangle similar to that which is described for the ordinary frames. The width of the bevelling board is made equal to this perpendicular distance, corresponding to the frame space in the case of the ordinary frames, and the bevelling edge must be laid off so that the normal distance between it and the moulding edge can be used for marking the bevelling in the same way as the normal distance between consecutive frames of the square body is used.

To obtain the traces of the plane of the bevelling edge, in fig. 104 let $AB, A'B'$ be the traces of the moulding edge plane; $nm$ drawn perpendicular to $AB$ and $n'm'$ perpendicular to the axis are the traces of a plane perpendicular to the plane of the moulding edge and to the vertical or sheer plane. If $mM$ be drawn perpendicular to $nn'$ and equal to $n'm'$, $nM$ is the intersection of the planes $BAB'$ and $n'm'm$ rabatted on to the sheer plane, and $MN$ perpendicular to $n'M$ is the rabatted position of a line perpendicular to the plane of the moulding edge. Make $HH$ equal to the chosen distance of the bevelling edge plane from the moulding edge plane; draw $Kk$ parallel to $MM$ cutting $nm$ in $k$; through $k$ draw $DE$ parallel to $AB$ and through $D$, where $DE$ meets the base line, draw $DE'$ parallel to $A'B'$; then $DE, DE'$ are the traces of the plane of the bevelling edge arranged at the required perpendicular distance from the plane of the moulding edge.

In laying off the bevelling edge it is first projected on to the plane of the moulding edge, and the latter then rabatted into the body plane. To effect this operation the horizontal trace $Am_1$, of a plane perpendicular to the double cant plane and intersecting it in the vertical trace $AB$ must be drawn, which is done by the construction shown in fig. 104a, where $nm$ is, as before, perpendicular to $AB$ through any point $s$ in it other than $A$, and $n'm'$, drawn through $n'$, the horizontal projection of $s$, is perpendicular to $A'B'$. The projections of the traces with the several level planes of the plane of the moulding edge, such as $U''w''$ and the projections of the bevelling edge drawn in the sheer plane and $Pw''w''$ in the half-breadth are obtained in exactly the same way as in the case of the moulding edge. The projections such as $Qw''$, of the traces with the several level planes of the plane whose traces are $AB$ and $Am_1$, in fig. 104a are also drawn parallel to $Am_1$, through the horizontal projections of $P$, $Q$, $R$, &c. The vertical projection $w_1$ of the point $w''$, in which $Qw''$ meets $U''w''$ produced, is found and $Am_1'$ set up on the middle line of the body equal to the perpendicular distance of $w_1$ from $AC$. A level line $2L''$ in the body plan is drawn at a distance from the base line equal to the perpendicular distance of $w$ from $AC$ and a point $w_2'$ is found in it such that the radius $U_2w_2'$ is equal to $w_2w''$ in the half-breadth. $w_2'$ is then the rabatted position of the projection on the plane of the moulding edge of the point in the bevelling edge whose projections are $w$ and $w''$. Points $l_1, m_1, n_1$ corresponding to the projections $l$ and $l'$, $t$ and $t'$, $v$ and $v'$ are found in a similar manner and a curve drawn through $l_1m_1n_1$ is the bevelling edge laid off in the body plan in the correct relation to the laid off position of the moulding edge for the bevellings to be then.

Additional points in the rabatted shape of the double canted frame may be obtained by the use of diagonals when desired. In fig. 105 $AB, A'B'$ are the traces of the double canted plane; $cd, c'd'$ are the projections of a diagonal line in the body and
sheer and $c_n$ its reduction in the half-breadth plan. Draw $c e, c f$, the traces of a bow plane and through $d$ where it cuts the diagonal of the boat the draw the trace of a level plane $W L$. Find the intersection points $l, p, y$ of this plane with the diagonal plane at the bow and the bow plane. Then $e g, f g$ the intersection of $c e, c f$ with the bow plane is a point common to these two planes and to the bow plane. Since this point is common to the level plane $W L$ and to the bow plane $e f$, it belongs in the plan of the diagonal and double cant planes. In a similar manner $c m$ is a point in the same two planes. Therefore $e g$ is the projection of the intersection of these planes, and $m$ where $e g$ cuts $c m$ is a point where the double cant plane meets the diagonal plane of the double cant about $A B$, moves in the line $m B M$ perpendicular to $A B$. If now $m$ is projected on to $c o$, then $M$ taken in $m B M$ so that $m M = e c$, will be a point in the model circles of the framework to show $m$ to the framework. Similar points can be obtained for each diagonal. The plane of the bevelled edge is determined as previously described, and the bevelled edge laid off similarly to the moulding edge, except that provision must be made that it shall come in its right relation to the moulding edge for bevelings to be taken as in the previous case when laying off by level lines.

A method of determining and fairing the swell for the propeller shaft in a twin or multiple screw ship is shown in fig. 106. The projections of the centre line of shaft, which are given in the figure, are drawn in the planes of the sheer and half-breadth planes of the sheer drawing, and are drawn in the plans on the floor, the bow and stern wing planes, the plan of the centre line of shaft with the plane of each square station is found from the series of points on the straight line $a b$ in the figure. The radius from the centre of shaft required for the shaft tube and fittings at the boss frame, or frame where the shaft passes outside the ship, is found from the machinery specifications. This is increased by the thickness of the plank in the case of a wood-sheathed ship and of the plating for the wood sheathing to allow for clearance and for the obliquity of the shaft line, and a frame is selected for the boss frame such that a circle drawn with this radius, viz., $H$ in figure, is tangent to the trace of the centre line of shaft with the frame plane in question would just touch the frame line on the outer edge of the frame. The length and amount of projection beyond the ordinary frame lines of the shaft swell can be considerably reduced if the frames shaft the boss frame, viz., frame No. 14 in the figure are dished inwards as shown in the figure, thus allowing the required radius between the centre of shaft and the frame line to be obtained further forward from the frames were not dished. A similar method is used for finding the frame where the radius required round the centre of shaft will not cause any bossing in the frame line. Special attention must be given to the required radius at the back of the stuffing box bulkhead, where considerable space is required for the stuffing box and fittings, and at the after end of the shaft, where the line of the frame—may not be sufficiently clear of the inner bottom line to permit a sufficient depth of double bottom to be maintained without bossing out the frame line as shown by the small diagram in the figure. The frame, No. 2 in the figure, where the swell is to end, has been selected, a normal $m l$ to the frame line is drawn from $n$, the trace of the centre of shaft line with the plane of the frame line. A line is drawn through the centres of the line of shaft with the other frame planes, representing projections of the intersections with the frame planes of a plane through the centre of shaft. This plane is projected on to a diagonal plane having its traces with the body parallel to the trace of the plane, and the diagonal plane carrying the projection with it is rabbeted by the following process. A convenient line $X Y$ is selected perpendicular to the parallel traces in the plane of the frame line, at $X$ any point, the projection $X Y$ is drawn. The ordinates to $X Y$ are equal to the ordinates to the frame line $X Y$ is drawn at any convenient position on the floor, and the line $X Y$ is the frame spacing. The distances from $X Y$ in the body are measured along all such lines as are parallel to the line of shaft and to the unbossed frame lines, and these distances are set up from $X Y$ in the plan at the corresponding frame ordinates giving the straight centre line of shaft, and $G G$ the plan of the line of intersection of the plan through the centre of shaft with the frame line. Each mould is marked on it, or indicated by a straight-edged batten forming part of the mould, a convenient water-line and vertical line drawn on the floor. When the moulds are held in vertical planes separated by the length of the shaft the corresponding straight lines on the two moulds are made to lie in the same plane, or are "looked out of winding," giving the relation between the various ordinates, corresponding to that marked $k$ at No. 8, are used as radii for describing the outer part of the section of the shaft swell at the corresponding square stations in the body plan, the trace of the shaft line being the centre at each frame from which the circular arc is described. The outer part of the section of the swell thus formed, $e g, c c$ at the boss frame in figure, is joined up to the general run of the frame line to which it belongs by arcs of circles $d$ struck with the same radius as the outer part. The radii for the hollowed-out frame lines abaft the boss frame are obtained in a similar manner. One or more diagonals cutting the swell plane are drawn and rabbeted in the half-breadth plan to test the fairness of the altered lines, but no further alteration should be required if the swell has been drawn in the manner described above.

The sectional shape of the boss frame casting is shown in the plan in fig. 106, and the outline of the palm which is secured to the floor plate of the boss frame is shown by the line $k k$, $k k$, in the body plan. This part of the casting is fashioned solely for mould for boss frame casting.

The fore and after part of the shaft struts, or "A" brackets, as they are sometimes called, is shown on the design drawings, and the scantlings of the hollow cylindrical boss which carries the shaft, bearing and of the arms which connect the boss to the ship's structure are given in the specification. The detailed drawing appears in these pages showing these particulars together with the shape of the palms worked on the inner end of the bracket arms to connect them to the ship's structure, and it is only necessary to obtain from the lines of the ship laid off on the floor the exact relation of the positions of the surfaces of the palms to one another and to the centre of the shaft. For the purpose of the line of centre of shaft with transverse planes at the forward and after ends of the boss are marked in the body plan, and a batten mould is made in each of these planes showing the centre of shaft, the direction of the two arms and the position where they are crossed by the frame line at the edge of the ship, or, if the lower arm connects to a web or palm on the stern post, as is frequently the case, in a ship with a rising keel line aft, the position of the edge of this palm and the direction of its surface. Each mould is marked on it, or indicated by a straight-edged batten forming part of the mould, a convenient water-line and vertical line drawn on the floor. When the moulds are held in vertical planes separated by the length of the shaft the corresponding straight lines on the two moulds are made to lie in the same plane, or are "looked out of winding," giving the relation between the
the position of the palms and the direction of centre of shaft. Guided
by these moulds and the detailed drawing, the pattern for casting the A brackets is made.

The inner bottom consists of the plate and longitudinal sight edges are drawn in the body plan on the floor by measuring their distances from the middle line along each frame line in the half-

block model, on which they have been already arranged, and joining them by straight line, those points are marked off round the corresponding square stations in the body.
The points so found should lie on fair curves, if the sight edges have been carefully placed. In case of any errors in the work so far, in the course where discontinuities in the curves may occur, as where a plate sight edge crosses a longitudinal sight edge to avoid an acute intersection. The edges of the sunken strakes of plating are drawn parallel to the frame in the middle line, and the angles between them and as already stated, the breadths of the bottom plates are measured between the lines of plate edges so found and used in ordering the materials for the formers.

The surface of the inner bottom is defined relatively to the outer bottom by the depth of the vertical keel and longitudinal frames given in the specification. The outline of the vertical keel is also shown in the sheer drawing, and the general shape of the inner bottom by the midship section, which is often supplemented by a section through the engine-room where the double bottom is locally made deeper. The surface of the longitudinal is arranged so that its trace with the plane of each square station is approximately normal to the curve of the square station; taken in conjunction with the method of drawing the sight edges so that the whole effect may be regarded as much as possible like a plane. This is approximately the same thing as generating the surface of the longitudinal by the normal to the ship’s surface as it moves along the sight edges, as was described in the depth. There is no effect on the plane of any section normal, and when the longitudinal are fitted on a raised strake of outer bottom plating, are greater by the thickness of that strake than the distance to be found from the frame line to the inside of the frame on the inner bottom. The latter is usually worked with the stokes of plating disposed “clinker” fashion, or is sometimes flush with edge strips fitted on the underside. Points in the sections of the inner bottom frame surface by the lines of the square stations are obtained by setting in the depth of the longitudinals, and the surface of the inner bottom is fitted by diagonal and water lines in the same manner as the outer frame surface. On the exception of the space where the depth of the double bottom is increased, and where there are usually plane surfaces to take the structure under the engine bed, and a cylindrical recess to provide clearance for the engine cranks, these special features must be arranged separately, so also is any bosoming of the inner bottom at the after end to allow clearance for the shaft tube and fittings.
The plate edges already arranged on the model of the inner bottom must be transferred to the floor and faired in the same way as those of the outer bottom; and the breadths of the plates measured from the floor must be used in ordering the material from the manufacturer.

Before and abaft the double bottom the transverse frames may consist of zed bars, split at their lower ends for the insertion of a floor to lengthen or reduce in depth, and are intercostal between the frames until they meet with flats or fore and aft bulkheads, or they are continued as deep zed bars slotted over the narrower trans-
verse frames behind, in which the thickness does not require any process of general fairing; but the upper parts of the floor plates are drawn on the floor, and are faired locally throughout the lengths of the ship where they maintain a uniform character.

The freeboard forward and aft and amidships is generally given in the specification and can be measured from the sheer drawing. The breadths of the sections and by the through sections shown in the sheer drawing, the heights of the intersections of the beam at middle with the square stations are marked on the corresponding square stations of the contracted sheet plan and faired in with the profile of the water lines, projected to the middle line of the body plan. The round up or camber of the midship beam of each deck is shown on the midship section and is expressed as a sine of half the arc and the breadth of the beam at the level of the beam the chord. A mould is readily constructed to these data, and is applied so that the chord is perpendicular to and its plane parallel with that of the body plan. When the centre of the arc coincides with a point projected from the beam at middle line the arc cuts the corresponding square station at a point in the projection of the beam-end line. The points in the beam-end line so found are connected by a line which is tested by projection into the contracted sheet plan, and the line is then raised in the body plan.

The shaft and propeller deck in a battleship is shown in the sheer drawing. Throughout that part of the length of the ship covered by the main armour belt, which rests on this deck, the deck edge usually lies in a water plane. The middle part of the deck also lies in a water plane, except where it is raised up over the engines, and the slopes sides form cylindrical surfaces. The straight lines of the sides and middle part of the deck section are joined by arcs of circles of uniform radius, and this part of the deck is necessarily fair in profile. The nature of the deck and of constructing the sections of its surface. At the ends of the ship the beam-at-middle and beam-at-side lines are copied from the sheer drawing and faired on the floor and the beam surface between these points may be faired by one or more boltless butt and lock joints.

The surface of the framing behind the main armour belt in a war-
ship, arranged as shown by the midship section depicted, is parallel to the surface of the model and distant from it by the thickness of armour and wood backing plus the thickness of plating behind armour, generally a double thickness of plating flush jointed. This distance, less the thickness of the armour, is the outer edge of the plating and the thickness of the plates, is set in normal to the surface shown by the lines on the floor in wake of the armoured side by approximate methods similar to those applied in tank construction. The relationships of the frames and the sections of the beam lines behind the armour in the body plan are thus obtained and drawn in. The frames are usually single zed bars extending vertically from deck to deck and are completely defined by these lines without the necessity of drawing any inside surface.

Projections of the intersection of the surface of the frames behind armour with the beam surface of the deck at the top of the frames and with the plate surface of the deck at their heels are drawn in the half-breadth plan, and expansion drawings of the frame surface are prepared in a manner somewhat similar to that which will be seen in the plan of the expansion of the expansion of the separate armour plate, except that in the present case the whole length of the surface is expanded in two or three 4-in. scale drawings. The point of the frame to which the position of the frame lines, and of any longitudinal girders which may be fitted to the main truss, and in the frame drawing, also the approximate positions of the armour plate butts and edges and of the armour bolts. The butts and edges of the plating behind armour are ranged on this drawing and the dimen-
sions of the plates measured therefrom in ordering them from the manufacturers.

This protective plating beyond the ends of the main armour belt usually projects from the ship’s side and is secured without wood backing direct to the shell plating, which is worked in two thicknesses flush jointed in place of the protective plating. In this case the frame lines behind the armour are not shown either on the half-breadth plan, or with the separate armour plate, and the disposition of the butts and edges of the plating behind armour and of the armour itself is arranged on the half-breadth model; but only the plating behind the armour is ordered to dimen-
sions taken from the model.

It is important that the detailed information given the shapes and dimensions of the armour plates should be in the hands of the manufacturers as early as possible on account of the time required for the manufacture of this material. As, more, laying off the moulds for the armour of a warship.

In general, however, the armoured side is very little twisted and can be dealt with for practical purposes as a developable surface, which case the necessary information can be obtained by a process of laying off as described below, which, though obviously only approximate, is found by experience to be sufficiently accurate for practical purposes.

In fig. 107 the portion of the body plan shows sections of the armour surface by planes of the frames, which are generally 2 ft. apart behind the armour, and the half breadth shows projections of the upper and lower edges of the sections of the frames and the point of the middle of the main beam at the level of the middle of the deck; but is generally allowed to be about 1 in. below it, so as to make sure of getting in the armour, in spite of possible small inaccuracies in building the rest of the structure, which might result in the exact position of the middle of the two deck. The lower edge of the armour follows the deck edge, which is usually a level line throughout the length of the belt; but is kept an inch or two above it to avoid making the armour plates with a sharp edge to fit the acute angle formed by the beam edge and the deck, and which would be a serious point of weakness. The armour, in fact, usually rests on the deck as shown by the midship section depicted. The butts of the armour are arranged “brick fashion,” that is, the butts of one strake at the middle of a plate in the adjacent
strake, and each butt should be as close as possible to one of the vertical frames behind armour in order to allow the armour bolts to be sufficiently near the butt of the plate. At the same time it is convenient both for manufacturing purposes and for erecting the plates at the ship, to have the butt surfaces as nearly as possible normal to the surface of the plates. The butts are therefore arranged in vertical planes whose traces in the half-breadth plan lie in direction between the normals to the projections of the upper and lower edges of the plate. The lengths of the plates are made as great as possible, taking into consideration the capacity of the manufacturer's rolls and of the appliances for handling them during erection at the ship.

To lay off any plate such as that of which the projections of the intersections of the planes of the butts with the surface of the armour are ab, cd in the body plan and ab, cd in the half-breadth, a straight line YY is drawn in the body plan so that its direction lies between the directions of the normals to ab and cd at the points where they cut YY, and a straight line XX is drawn in the half-breadth plan similarly lying between the normals to o, c, and b, d and approximately at the centre of the plate.

Battens are bent to the curves of Yb, cd, aXc, bXd and the points named are marked on the battens so as to give the lengths of Y, Y, X, X, &c., measured round the curves. A pair of rectangular axes OX, OY are then drawn in any convenient position on the floor and the points o, b, c, d found such that the co-ordinates of o, ab, cX, dX, of o, yb, Xb, Yb, and Xc, of o, db, Yd, Xd. The figure abcd obtained by joining the points so found is straight lines is regarded as the expanded shape of the surface of the plate. A flexible batten mould is made to this figure and is used by the manufacturer to mark the four corners of the plate and thus to get its superficial size. A pair of moulds such as N are made, one to the top and the other to the bottom of the plate in the half-breadth plan, showing the curvature of the edge and the direction of the butts; and another pair such as M, one at each butt, showing the curvature of the edge of the butt plane and the sectional shape of the top and bottom of the plate. The butt moulds are made to the section of the surface of the plate by the plane of the frame, which is indistinguishable from the section by the very slightly inclined plane of the butt. Each of the butt moulds serves for the two plates which join at the butt, but each edge mould refers only to one plate. Each batten mould, of which all are straight lines which lie in one plane or, as it is technically expressed, are "out of winding" when the moulds are in their proper position, are also made to fit on the butt and edge moulds as P, Q in the figure. By means of these moulds the manufacturer makes each separate plate to its correct curvature and twist, while the top and bottom "out-of-winding" moulds for two or more consecutive plates have a common straight line drawn on them as l in the figure, to fix the relative position of the plates when they are erected at the manufacturer's works to prove the correctness of their shape.

A drawing is also made showing superposed expansions of the back and front surfaces of the armour without any necessity for extreme accuracy, as these surfaces are fully defined by the moulds. The butts and edges of the plates with numbers identifying each plate with its moulds are shown on this drawing.

The specification gives particulars of the dimensions of the bolts to be used and lays down the general principle of their distribution, e.g. one bolt to so many square feet of armour. The bolts are approximately arranged in accordance with the expansion of the plating behind armour. For the purposes of the present drawing their positions must be definitely fixed sufficiently clear of the frames behind armour to allow space for putting on the nuts. With vertically arranged frames projection of the bolts from this point only is of importance from this point of view. The projections of the normals to the plate surface representing the centre lines of the bolts are drawn in the half-breadth plan, and shifted if necessary to give the required clearance of the normals to the positions of the centres on the back of the plates are then measured along the curved sections of this surface in the body and half-breadth plans from the nearest edge of butt, and these distances are indicated in figures on the drawing.

The positions of any holes for the fastenings of top and bottom edge covering plates, or of any fittings to go on the outside surface of the armour are also shown in figures on the drawings of the plates and butts of the plates on this drawing. All holes must be drilled and tapped in the plates by the manufacturer before the final hardening process which renders the material unworkable.

The drawing also shows the plate in each strake selected as the "shutter in" or last plate to be fitted in place. This plate is not finally completed by the manufacturer until all the rest are in place on the ship and moulds have been made to the space which remains to be filled up.

The moulds for screen bulkhead armour are prepared in a similar manner to the process of specification when not actually plane, is cylindrical with a vertical generating line and therefore accurately developable.

For barbette armour nothing more than a drawing is usually necessary, the barbette being circular for its plan, the surface cylindrical and the top in a horizontal plane. The information issued from the Mould Loft for the guidance of the workmen in the shipyard has been generally passed over in the foregoing description, which has been devoted principally to the information prepared for the guidance of manufacturers of material, but it is not intended to imply that all the material is ordered before erection is begun. Much of the information for the erection of the frames and other parts of the structure, including the keel and transverse and longitudinal frames amidships, may be given before the ends of the ship are faired on the floor. Keel battens are provided giving the spacing of the transverse frames throughout the length of the ship, the lines defining their positions on the battens being marked with the distinguishing numbers by which the frames are identified on all the drawings, moulds and information accompanying the specification, and serves as information for its erection.

Section moulds are made in accordance with the frame lines in the body plan for guidance in shaping the flat keel plates transferred and on these the edges of the adjacent plates are also marked.

The practice, at one time quite common, of making batten moulds to each frame line on the Mould Loft, has been abandoned by the workmen employed bending the angle or zed bars, and the method of shaping and assembling the parts of the frame, is now almost entirely superseded by the use of the "scriveboard." Each batten mould, when issued, showed the outline of the frame, or of the part of the frame between two longitudinals, the shape of the floor plate or bracket plates, the position of the plate edges and other points necessary for completing the frame ready to go into its place at the ship.

The scrive-board is an auxiliary mould loft floor constructed conveniently near the frame line being slabs of hard wood, copied on it, with certain modifications or additions adapting it to the practical needs of the shipyard work, the whole of the body plan as laid off on the Mould Loft floor. For convenience in copying the lines so made it can be divided into portable parts and taken to the Mould Loft to have the lines copied on it, and then transported to its proper position and put together again. Otherwise it is a fixture in its proper

position; but the process of copying the frame lines on it is one of measuring on battens the ordinates of their intersections with water and covering these with the same in either case. All of the frame lines are shown on the scrive-board, and the complete section of the frame surface for both sides of the ship is shown at each station. To avoid confusion of lines either a separate board is used for the fore and after bodies, or they are drawn on the same board with their centre lines parallel and a few feet apart, and one of the two bodies inverted. All the lines already referred to as having been laid off in the shipyard are placed in the loft floor, including the lines of outer edges of all transverse frames, the inner edges of all in the double bottom, and the upper edges of all floor plates outside the double bottom, the projections of plate edges of inner and outer bottoms, and on longitudinal bulkheads, projections of beam at side lines for all decks, and of the intersection of the beam surface of the protective deck by the plane of each frame, and also all the planed and eased in on its side. The scrive-board thus gives complete information of the shape and dimensions of every part of each transverse frame. To completely define the frame the "beveling" is required in addition, that is, the angle between the two flanges of the angle bar on the edge of the frame connecting it to the outer or inner bottom plating. The bevelling is usually given at the plate edge; but any other convenient bevelling spots may be chosen and their positions marked on the frame lines. To obtain the bevelling at any spot a normal is drawn to the frame line in the body plan at the spot; the distance from the frame line is measured along this normal to its intersection with the line towards the midship section, and this distance is set up as one of the sides containing the right angle in a right-angled triangle of which the frame space is the base. The angle of the hypotenuse is taken as the bevelling at that station. The straight lines marked on the side of the board and the straight edge of the board representing both the bevelling and its supplement. In the frame bars there is no doubt as to which of these two angles the workmen are to regard as the true bevelling, since the flanges of the frames are all turned towards the midship section, so as to make the true bevelling always greater than a right angle, or "standing" angle is the preferred, in distinction to "under" bevelling, which is less than a right angle.

Special bevelling frames are used in marking the bevelling boards, by which the construction of the triangles is reduced to setting off the normal measurement between the frame lines and drawing the hypotenuse directly on the bevelling board. The flanges of the angle bars on the inside edge of the frame, or the reverse frame bars, unmarked positions (that is towards the midship section) on the flanges of the frame bars, throughout the double bottom, in order to facilitate the construction of the bracket frame. Where the longitudinal surface is considered as the true bevelling, these angles on the inner bottom is the supplement of that of the frame angles. But throughout the double bottom neither bevelling differs much from a right angle. When the longitudinal tapers in breadth and the edges must be taken for the inner angles, a method similar to that already described for the frame angles. Outside the double bottom the reverse angle, or inner part of the split zed bar, is either unconnected to anything but the floor plate, or else connected to a horizontal flat, and does not require bevelling.

The bevellings of the short angle bars which connect the bracket or floor plates of the transverse frames to the longitudinal surface are avoided by measuring in the body plan at the middle of the intersection of the transverse frame with the plane of a frame station the normal distance to its intersection with the plane of the new station (that towards the midship section) on the frame station, and setting it up as one side of a right-angled triangle of which the frame space is the base.

To check the spread of the transverse frames during their erection, half-breadth staffs and height of breadth staffs are inserted at the keel, loft or off the scrive-board. These give the co-ordinates of the intersections of the longitudinal sight edges with the frame lines in the middle horizontal part. On the horizontal arm of the mould vertical lines are drawn at a given distance from the middle line at each frame station.

It is essential that the shape of the longitudinal frames should be obtained with considerable accuracy, especially when half-breadths and heights measured to their sight edges are largely relied upon for keeping the transverse frames to their designed spread during erection.

As already stated, the longitudinal surface does not much differ from a surface generated by the normal to the ship's surface as it travels along the curve of the longitudinal sight edge of the surface generated by the normal is developable and the sight edge is a line of curvature, which is approximately ensured by the method of drawing it, and it is found by experience that no error of practical importance is involved in drawing the surface of the longitudinal by the following approximate method.

Fig. 180 shows part of the body plan in which the frames lines are numbered 1 to 7, the projection of the longitudinal sight edge is shown by a b c d e f g, and the projections of the traces of the longitudinal surface with the planes of the frames are shown by the straight lines o1 o2 o3 o4 o5 o6 o7, all of the same height, and both off the scrive-board. These lines show the coordinates of the intersections of the longitudinal sight edges with the frame lines in the middle horizontal part. The curves o1 b1 c1 d1 e1 f1 g1, and o2 b2 c2 d2 e2 f2 g2 both cut all the traces at right angles, so that they are involutes of their envelope. Their positions are chosen at convenient distances beyond the inside and outside of the group of frame lines, which defines the shape and length of longitudinal which is to be developed in one operation.
Parallel straight lines $A_1G_1$, $A_2G_2$, the distance between which is equal to the normal distance between the two involutes in the body plan, are drawn in any convenient position on the floor, and perpendicular ordinates, 1, 2, 3, 4, 5, 6, 7, drawn between them distant the frame space apart. The longitudinal is developed in this plan on the assumption that when its surfaces are expanded, the involutes $a_1 b_1 g_1$ and $a_2 b_2 g_2$ will coincide with the straight lines $A_1 G_1$ and $A_2 G_2$ respectively. Taking $g_2 b_2$ in the body, represented by $G_2 G_3$ in the plan, as the fixed end of the longitudinal isometric, the shape of the surface to be unrolled, the lengths $g_2 b_2$, $g_3$, &c., are measured along the curve of the involute and set off along the lines $5, 6, 7, &c.$, in the plan giving the points $F_3, E_2, D_3$, &c., which represent with sufficient approximation the true position of the points of intersection of the line $a_1 b_1 g_1$ with the corresponding marks on the batten. The points $F_3 E_2 D_3 G_2 A_2$ are obtained by the other involution in a similar manner, and the lines $F_3 E_2, E_2 D_3, D_3 G_2, G_2 A_2$, obtained by joining corresponding points are regarded as the expanded positions of the traces of the longitudinal surface with the planes of the frames. The distances $G_2 G_3, F_3 F_2, E_3 E_2$, &c., then become $a_2 b_2$, $a_3 b_3$, &c., in the body, and the curve $G F E D C B A$ through the points so found is the expanded sight edge of the longitudinal. The distances $G_0 G_3, F_2 F_3, E_0 E_2$, &c., are then made equal to $g_1 b_1, g_2 b_2$, &c., in the body, and the curve $G F E D C B A$ through the points so found is the expanded sight edge of the longitudinal. This method, in which the involutes $a_1 b_1 g_1$ and $a_2 b_2 g_2$ are replaced by straight lines perpendicular to the trace, from which the longitudinal is to be unrolled, may be used; but, without assuming any substantial simplification of the process, the accuracy is so much less than that of the method described above, that it is not safe to lay off more than two or three plates of the longitudinal in one length by it.

When the longitudinal is much twisted, as, for example, when the longitudinal surface at its ends is to be made continuous with a deck flat, which is not normal to the surface of the ship, it is generally desirable to use the more laborious but reliable method of "mocking up." In fig. 109 the curves numbered 1 to 6 are projections of frame lines in the body plan. $a b c d e f$ is the projection of the sight edge of the longitudinal breaking into the longitudinal with the planes of the frames throughout the length which is to be mocked up. Trapezoidal frames made of four straight battens nailed together at the corners, such as $X Y Z E$ in the figure, are made to show the relative position of the traces of the longitudinal surface and of the level plane with the plane of each frame. The outer and inner ends of the trace of the longitudinal surface are marked on the upper batten of each frame as at $a$, $e$, and a point $O$, fixing the lateral position of each batten frame relatively to a convenient straight line perpendicular to the planes of the ship's frames, is marked on the lower batten. A diagonal plane such as $D D$ can be used instead of the level plane, for convenience in allowing smaller and better-shaped batten frames to be used; and the process is precisely the same.

The ship, when erected on its bases $X Y$ in planes perpendicular to the floor, parallel to one another and distant the frame space apart, with the points $O$ in all the frames lying in one straight line perpendicular to the batten frames. The upper edges of the upper battens then define the true shape of the longitudinal surface in three dimensions, and a fair curve through the points $e$, &c., marked on the battens represents the outer edge, and through points $a$, &c., the inner edge.

Whether the shape of the longitudinal has been obtained by development on the floor or by the mocking-up process, batten moulds are made to the outline of each plate, the buttoes being arranged so as to give the longitudinal the true horizontal, giving the shift of butts of bottom plating and longitudinals. Cross battens are fitted to mark the position of each transverse line of longitudinals, and for marking the inside space to stiffen the mould, and to carry marks or figures indicating the shape and dimensions of the lightening hole, which occurs between each pair of frames in non-watertight longitudinals. These moulds are used by the workmen in the construction of the frames, when the longitudinal is erected at the ship.

The normal sectional shape of the bilge keel in a sheathed ship consists of a single steel plate in the middle of the section covered over by wood trimmed to shape. The plate lies in a diagonal plane and is readily laid off by rabattting the diagonal plane. This gives the true form of the intersection of the bilge keel plate with the surface of the frames, and the outer edge of the plate is obtained by setting out from the inner edge of the bilge keel plate plus an allowance for the thickness of the shell-plating.

In an unshathed bilge keel is of triangular section, as shown in the body plan in fig. 109, and it is formed by two steel plates, a central plate, which is fitted to the frame by angle bars at their inner edges, the space being between the plates being filled with wood. In this case the middle plane of the bilge keel is shown, as shown by $2 D$ in the figure. The depth of the bilge keel at each frame plus the allowance for shell-plating is set out from the frame line along the diagonal, giving the vertex of the section of the keel at each frame station. A triangular mould is produced to the section of the bilge keel shown in the section drawing and is applied with its vertex coinciding with the points on the floor found as described above and with its centre line coinciding with the diagonal, and the traces of the sides of the keel are drawn at each frame station $a b, c d, &c.$ as shown in the figure. The surface of each side of the keel is then developed in the same way as the surface of a longitudinal except that in this case, since the lines are projected from the ship's bow to the stern, the longitudinal become straight lines, and the development is strictly accurate. A mould to each plate of the bilge keel, similar to the mould for a longitudinal plate, is prepared from the expansion of the bilge keel on the floor and issued for the guidance of the workmen. A triangular batten mould, made to show the angle between the diagonal plane, in which the centre of the bilge keel lies, and the horizontal, and having marked on it a point to be set at a given distance from the middle line plane of the bilge keel, is to be used as the basis of all the moulds, and the position of the bilge keel, is also issued to enable the position of the centre line of the bilge keel to be sighted-in on the bottom plating of the ship. The obtaining information for laying-out the plan of the ship is mostly in the form of drawings, which are largely descriptive rather than dimensioned, inasmuch as the frames and beams of a ship being once erected all other principal parts have to conform to them and any difference which may occur between their shape as erected and as laid off on the mould loft floor.

All the drawings of the structure and of the fittings must be pushed on and issued to the shipyard in good time. Very much of the success achieved in actual building will depend upon the efficiency of the drawing office, and the rapidity with which the various detailed working plans can be supplied for guidance. These plans must be accurate and complete, and must be ready as soon as required. The drawing-office staff has the oversight of weights actually worked into the ship, a careful record of which should be kept. Each firm has its own system of work in these departments, but experience shows that the more thorough and systematic the work in the drawing office and its subdivision the better may the result be. Another important record is the cost of the materials and labour. In all shipyards careful account is kept of workmen's time, whether employed on piece or by the day. Many different systems are in vogue; but whatever the system, the aim is to record the cost of the labour in each trade, and the detailed cost of various parts of the ship.

The work connected with laying-off and obtaining materials, &c., is going on in the office, where the handy labourers, prepare the ground for the keel blocks, lay the blocks at the proper height and inclination, and secure them against being floated away by the tide or being accidentally tripped while the ship is building. The blocks consist
of several pieces of tough redwood, 3 to 6 ft. in length, and are held in the height required. The top block is called the cap-piece, and is of oak or other hard wood. The blocks are spaced about 4 ft. apart for ships of medium size, and somewhat less for larger vessels. The framing is usually of a flat keel, consisting of a single timber, called the inside keelson. Sometimes it is continuous, especially in large ships and in warships. The frames are then cut by it, and the floor-plates are attached to it by short angle bars. After the centre keelson, the side keelsons are laid and erected. The rabbets are cut for the shores supporting the deck beams, being riveted at their heads to the beams and at their heels to the keelson, inner bottom or sternpost. These shovelform boards or rabbets, with the weepholes at their heel, are laid over the rabbets and are held in place by short angle bars or struts attached to the inside keelson and inner bottom. In a ship fitted with an inner bottom the procedure is somewhat more complicated, as the transverse frames cannot be lifted into place as a whole. There are many varieties in the arrangements in such cases; one frequently adopted is shown in fig. 101, in which the inner bottom extends out to the turn of the bilge. This figure shows the general construction of the vessel, including the framing at a bulkhead and elsewhere, the bulkhead itself with all transverse partitions, the double bottom with its inside keelson and inner bottom. At the centre line, immediately over the flat keel plates, there is a vertical girder, the full depth of the double bottom, and this girder is secured to the inner bottom by continuous double-angle bars. This centre girder may or may not be water-tight, according to the desired tank arrangements. The transverse frames are in four parts; the two lower parts are built up of an inner and an outer keelson, the two upper parts of the double bottom, which is a continuous girder of special construction; and the two upper, from the margin plates to the top-sides. The lower parts consist of a floor-plate with angle bars, and at its edges for attaching it to the inner and outer bottoms, the centre girder and the margin plate. The bulkheads of these floor-plates are solid, and the angle bars are united and made water-tight; elsewhere they are lightened by holes, and the angle bars at their upper and lower edges and ends are separate pieces. The upper parts of the transverse framing consists of a frame and a girder, and each has a plating-plate riveted on, and to one another along their deep flanges, with their shallow flanges standing the reverse way to one another. The shell-plating is attached to the shallow flange of the frame bar. Between the centre girder and the margin plate on each side of the ship there are three intercostal girders, the plates of which are connected by short angle bars to the floors and to the shell and inner bottom plating; and between the margin plates and the lower deck on each side there are three stringers, consisting of intercostal plates attached by short bars to the outer plating, and three continuous angle bars riveted to part of the intercostal plates which extend beyond the respective stringers.

In the course of erection, after the flat keel plate is laid upon the blocks, and the centre girder placed upon it, the two lower parts of the frames, which have been constructed alongside, are put into position by means of their outer keelsons being riveted to the sides of the foundry. The intercostal girders and margin plates are then fitted. The lower edge of the margin plate is brought close to the outer edge of the lower deck, and is secured to the latter by special rivets — shell-plating, while its upper edge is flanged for the purpose of being attached to the inner bottom plating. The ship at this stage gives the impression that a flat pontoon is being constructed.

When the margin plates are up and fairied and as desirable, riveted, the upper parts of the frames on each side are erected and the fairing proceeded with as before. The beams are now got into their position in the frames, and the outer keelsons are riveted to the sides of the blocks. The plates are fitted and riveted, usually cut completely through the transverse frames, and special brackets are provided to maintain the transverse strength. The chief advantages derived from cutting the frames by the margin plates is the saving of framework, and moreover the rapidity with which this part of the work can be proceeded with.

As soon as the keelsons and stringers are riveted, and the ship by its means sufficiently stiffened, the outside or shell plating is commenced. The plating squad is supplied with a drawing showing the disposition of the butts in each line of plates; and the line bars are worked up to the exact shape of the edges and butts, and the positions of all the rivet holes in the frames. From these moulds the edges and butts and the holes are marked off, the holes are punched, and the bars are filed and set to shape, furnacing being resorted to only when the curvature is too extreme to be obtained with cold. The line bars are then worked up to the finished shape, the strakes alternately (see a, fig. 79). The inside strakes, which are worked first, are templated off the ship, and lie directly on the flanges of the frame bars. The outside or overlapping
plates are then worked, and are templated from the place they are intended to occupy on the ship, and are kept at the proper distance from the frames by liners or slips of the same thickness as the adjacent inside plates. Towards the ends of the ship the number of strakes of plating must be reduced, as the girth along the frames is much less than over the midship portions. Stealers are introduced for this purpose; they are single plates, which at one end receive the butts of two plates, and at the other the butts of only one. By them two strakes are merged into one.

The number of plates requiring to be furnished is small in comparison with the whole number, but there are always some at the after end of the ship, especially in the neighbour-hood of the bow (for the stern tube) and the counter, and a few at the forward end of most ships. As each plate is got ready, it is taken to the ship, hoisted into position, and temporarily secured by the platers by means of bolts and nuts. As the work of plating proceeds, and the weight of the ship increases, extra shores are put into place, and bolts are erected by the shipwrights, to keep the structure to its shape and prevent local and general "unfairness." The shell-plating in way of the intended bilge blocks is completed at as early a period as possible, and painted, so that when once the bilge blocks are in place they need not be disturbed until immediately before launching. While the platers are at work on the shell-plating, other squads of riveters are engaged on the deck-plating and internal work, such as the bunkers, engine and boiler bearers, the shaft tunnel, casings and, in the later stages, the hatches, houses on deck, etc., and as much as possible of the internal work is done before the shell shuts out the day-light. As the work is completed by the platers, it is ready for the riveters and caulkers; and these trades follow on without delay, except in some parts of the casings and decks in way of the machinery, which are left portable, and taken down after the launch, to allow the machinery to be put in place.

The platers usually work in squads, composed generally of three platers, a marker-boy and a number of helpers or labourers, the number of whom depends on the size and weight of the plates, and the nature of the work to be done on them, and also on the facilities of the yard for handling such material. On the work of a large vessel many of these squads would be employed. The riveters also work in squads, a squad consisting of two riveters, one holder-up and one heater-boy, with sometimes a catcher, i.e., a boy to pass on the heated rivets when the distance from the rivet-hearth is great. Pneumatic riveting has not made great progress in Great Britain. Hydraulic riveting has a limited extent is adopted, especially in the case of work that can be taken to the machine, such as frames, beams and other parts; but in shipbuilding the large proportion of the riveting is done by hand. In the Royal dockyards platers' work is done by shipwrights, and riveting is not considered a trade, though regarded as skilled labour. Shipwrights also lay the blocks, erect the ribs, shroud and fair the ship, but labourers construct the stages. Driller's work consists in drilling by hand or by portable electric or pneumatic drills holes which it is not convenient or possible to punch or drill before erection; they also rime out and countersink punched and drilled holes when this is necessary. Portable electric or pneumatic drills are used when possible in some shipyards, and three-cylinder hydraulic engine drills are employed for some purposes, such as in cutting armour bolt holes in thick plating behind armour. The caulkers follow closely upon the riveters, and generally work singly.

A very important part of a caullker's duty is water-testing. In the large oil-tank steamers, possibly 8000 tons of water are used for testing one ship alone, and about the same amount for a large war vessel. This water is pumped from the sea or river into the compartment to be tested. In the case of an oil vessel, each compartment is filled right up, and a pressure put on by means of a stand pipe, carried for a considerable height above the highest part of the tank; any leakage found must be made good by the caullker, and the tank rested until it is perfectly water-tight. The double bottoms of merchant ships, and the smaller compartments and double bottoms of war vessels, are filled up and tested by a head of water rising a few feet above the load water-line. It is not usual to fill all the larger compartments, such as boiler and engine rooms in war vessels, or the machinery compartments and cargo holds in merchant ships; but water at a high velocity is played on the bulkheads by hose, to test the water-tightness and the strength. An occasional test, however, is made by filling a typical large compartment with water to a height of some feet above the load water-line. Angle-smiths form beam knees where these are welded, and generally all angle-bar work where heating in a smith's fire is required. It is usual to defer the painting of certain parts of the steel structure of a ship as long as possible, so

FIG. 110.—Great Lake Cargo Steamer; midship portion, in perspective.

FIG. 111.—British Cargo Steamer; midship portion, in perspective.
in certain circumstances it forms a galvanic couple with the steel plate. For warships the British Admiralty requires the removal of this scale from these parts by immersing the plates in a weak solution of hydrochloric acid. Red and white lead, oxide of iron and oxide of zinc form the bases of most of the paints used on steel ships.

**Structural Arrangements.**

The following are particulars of ships recently built at New London (Conn., U.S.A.) on the longitudinal system: The great centre girder, which in all vessels prior to these has been in the form of an I girder, is formed of a double II or box; that is, these vessels

composed of angle bars riveted together. At certain parts of the structure, where the heave of the sea will tend to strain the ship, the frames are double and made very strong. The outer surface of these frames is a shell composed of plates of 1 in. thickness. These enormous plates are arranged to give a maximum of strength, and the riveting of them to the frames and to each other is receiving the utmost care.

These ships have continuous longitudinal bulkhead on the centre, extending from the inner bottom to the main deck. The side plating of the shell, with this longitudinal bulkhead, form three vertical members of the ship, with the frame. The lower part of the girder are formed by the upper and main decks, which are laid with heavy steel plates. This great girder is designed to support a full cargo when suspended by long sea waves at either end. The side girders are kept in place by three intermediate decks between the tank and the main deck, making in all five complete decks, each covered with heavy steel plate. The plates supporting all these decks are of channel steel, and fitted to every frame by large bracket plates. One of the many notable features in the construction of these vessels is the distribution of the water ballast. Various conditions of trim and sinkage are obtained. The double bottom is divided longitudinally into three water-tight divisions and transversely into about twelve, making in all thirty-six separate tanks. In addition to these there are the fore, after peak tanks and side tanks between the main and 'tween decks, about one quarter of the vessel's length from either end. The latter tanks are really fitted for the purpose of controlling the ship's stability and seaworthiness.

The vessels are divided transversely into thirteen water-tight compartments, while the longitudinal bulkhead is water-tight in the machinery space, which makes the upper deck. In all fifteen water-tight compartments. The engine-rooms are completely independent of each other; so are the boiler-rooms; but access is had from one to the other by water-tight doors. The coal can gravitate direct to the stokehold floor. The method of pillaring is somewhat novel. . . . Strong girders run under the transverse beams and are supported at wide intervals by built stanchions. By this means the least possible trouble is experienced in stowing the cargo.

Fig. 110 shows the construction of a typical American Lake steamer, a diagram of which is given in the article *American Red-crest Lake steamer*.

For half the length or more of the ship is of the same transverse section, the frames being made identical in form. The outer plating is about 1 in. thick generally, but it is thicker at the garboards, flat keel and sheer strake, and becomes thinner generally towards the ends of the vessel. The frames are made of four separate pieces—two across the bottom and one up each side. These across the bottom consist of a 15-in. channel bar, with deep flanged brackets of 17½ lb plating connecting their inner ends to the centre keelson and their outer ends to the bilge and tank top. Extending up each side the frames consist of 6-in. channel bars of 17 lb per foot, worked 24 in. apart in the ordinary frames, and 15-in. channel bars of 3½ lb per foot, worked 8 ft. apart, and called belt or special frames. The frames are all connected to the tank top and to the upper deck-plating by flanged bracket plates 17½ lb per square foot; and the belt frames are stiffened by hold beams of 1 section, 12 in. deep and 35 lb per foot, attached to each by deep flanged brackets of 17½ lb plating, as indicated, and supported in the middle by stanchions or pillars of similar section. The stanchions are attached to the tank top by double clips of 6-in. angle bar, and to the upper deck beams by direct riveting and by flanged brackets of 15 lb plating. Each belt frame is thus complete in itself, and very readily erected after the tank top is completed. The tank top is of 20 lb plating amidships and under the loading hatches and 17½ lb elsewhere. The margin plate is a continuation of the tank top, is made of 17½ lb plating, and flanged against the shell. The centre keelson is of about 22½ lb plating and about 3½ ft. deep; the side keelsons of 17½ lb and slightly less, so that the margin plate extends from the inner bottom to the centre keelson, with the rise of floor on the outside, say 3 in. in the half-breadth of the ship, there is a small fall of the tank top towards the bilges, say 6 in. in the half-breadth, so as to drain the hold to the water-courses over the margin plate. The centre keelsons are connected to the tank top and the outer bottom, being attached to the tank top and the flat keel by heavy double angle bars, and well stiffened by the flanged floor brackets, which are connected to the keelson by heavy double angle bars to the tank top, and the floors by fore-and-aft angle bars 3 in. by 3 in. of 7½ lb per foot, and stiffened by vertical 6-in. angle bars at every frame. At the lower edge the keelson plates are connected to fore-and-aft intercostal channel bars.

![Fig. 112.—Cunard Liner "Campania"; midship portion, in perspective.](image-url)
15 in. deep of 33 lb per foot, riveted to the sheel-plating, which, with the channel floors, give very great local support to the bottom. This system of framing extends practically throughout the length of the vessel; thus the bottom is very strong, and very large ballast tanks are formed, having a capacity of nearly 3000 tons. The upper deck is plated, and the stringers are made specially heavy, to compensate for the strength lost by cutting wide hatchways.

Fig. 113 represents a modern British cargo steamer of ordinary construction, of about the same breadth and depth as the American Lake steamer just described, and it will be interesting to note the differences between the two vessels. These differences, so far as the outside form is concerned, are chiefly that the British cargo steamer has deck erections, topsides and a main deck, whereas the Lake steamer has scarcely any deck erections and no topsides, while her hold extends from the top of the inner bottom to the upper deck; they are due to the fact that the latter ship is only required to traverse inland waters, where heavy weather is not met with, whereas the former is an ocean-going vessel, and must be prepared to meet all conditions of wind and sea. As to the differences in the details of construction, they are chiefly that in the American Lake steamer the bottom framing, which is of great depth, consists of deep channel-frame bars, above which the longitudinals are continuous, instead of the usual transverse framing in the British ship, extending between the outer bottom and tank top; and that the margin plate continues the surface of the tank top out to the side, instead of being nearly vertical, as in the British ship. The system adopted in the American steamer conduces to security in case of grounding in the shallow waters through which she has to pass.

The general construction of a large passenger vessel is shown by fig. 112, which gives a perspective sectional view of the framing, &c. of the Cunard liner "Campania." The transverse frames and the girders or longitudinals extend in depth from the outer bottom plating to the inner bottom plating. The centre keelson, the second longitudinal from the middle line, and the margin plate on each side, are continuous, the transverse frames being fitted between them and attached to them by angle bars. The first and third longitudinals from the middle line are intercostal, being fitted in short pieces between the frames and attached to the

Fig. 113.—Details of Framing and Bulkheads.

Fig. 114.—Breast-hook and Panting Stringers.

floor-plates by short angle bars. The floor-plates have large holes cut in them to lighten them, and to give access to the different spaces for inspection, painting, &c., and smaller holes for watercourses. From the margin plate the transverse frames consist of stout channel
bars extending to the upper deck; each tier of beams is securely riveted to them, and their lower ends are connected to the margin plate by strong brackets. At intervals the channel-bar frames are replaced by deep built-up frames, the frequency of which depends on local requirements. Heavy side stringers of the same depth as the deep frames run fore and aft, to stiffen the side between the bilges and the first plated deck. Where the deep frames are cut by these stringers, the strength of the frames is continued by gusset plates, as shown.

Some further structural arrangements usually adopted in British ships are shown in figs. 113 to 115. Fig. 113, to which reference has already been made, shows in detail the construction of a bulkhead, with the framing in wake of it, and the same details at an ordinary frame; also the stringers, beams, pillars, &c. The bulkhead itself stops at the tank top, being secured to it by double angle bars, and the floor immediately beneath it is made watertight. It would involve very costly work to make the bulkhead water-tight if the side and bilge stringers were made continuous; these have therefore been cut, and the continuity of the longitudinal strength is maintained, as far as possible, by the large brackets shown in the plan. Besides bulb stiffeners, the bulkhead is provided with built-up vertical stiffeners at AB and a built-up horizontal stiffener at CD. Fig. 114 shows the arrangement for special strengthening at the extreme fore end of a vessel, between the collision bulkhead and the stem, and below the main deck, these consisting chiefly of panting stringers, panting beams and breast hook. Fig. 115 shows the general arrangement of stern framing of a single-screw ship, including the shaft tunnel. A water-tight door, which can be closed when necessary from above the level of the outside water, shuts off communication between the engine-room and tunnel; the form of the stern post and aperture frame casting is shown, with its attachment to the centre keelson and other details.

Figs. 116 and 117 show the arrangements of the stern and bow framing of the "Campania," which may be taken as those usually adopted in large passenger steamers of this class.\(^1\) In both transverse framing becomes deeper and stronger as the extremities are approached, while the decks and side stringers are all continued to the extremities, finishing in strong breast-hooks, and additional stringers, breast-hooks and panting beams are introduced. It is worthy of note that the rudder and steering gear are in this vessel entirely under water, so that the may be used for war purposes without running the risk of disablement by the rudder or steering gear being struck by projectiles. Above the water the stern is finished off so as to have the appearance of being fitted with an ordinary rudder. This important departure from the usual practice was first introduced by Professor Biles in the "City of Paris," and the "Campania" and her sister the "Lucania" were in 1902 the only British ships so fitted.

Fig. 112 gives in perspective the general structural arrangements of the Japanese cruiser "Izumo," and figs. 118-121 (Plate XIV) are from photographs of the vessel in course of construction. It will be seen that the departures from the structural arrangements of a merchant ship are very considerable. As already pointed out, lighter scantlings are used in warships than in ordinary merchant ships. This is effected by more carefully devised and more costly arrangements of framing and plating, and by making the structural features necessary in a warship for protection, &c., serve also for local and general strength.

\(^1\) We are indebted to the late Dr Elgar, F.R.S., for these and other plans of the "Campania."
local support to the bottom as well as general strength to the vessel. There are in a warship so many structural features, such as water-tight bulkheads and flats, that the latter are needed for the necessary subdivision, armour decks, plating and framing behind armour, &c., which are made to contribute to the strength of the structure as a whole, that the strength of the shell-plating and the transverse framing can be proportionately reduced.

In a merchant ship there are many considerations which require the structure to be stronger and heavier than would be necessary to withstand the wind and waves which she may encounter. The continual change of cargo and of disposition of cargo necessitates special local strength throughout. The custom, often pursued, of grounding vessels to discharge cargo, and their liability to touch the ground in the ports they frequent, make the provision of great strength in the floors and the shell-plating essential. Other considerations affect the decks, and call for local strength in them with corresponding increase of weight.

Most warships, except gunboat, torpedo and other small craft, have double bottoms, chiefly for protection against damage in action, but also against accidental grounding. The space between the bottoms is divided into a large number of compartments by making some of the frames and longitudinals water-tight.

The lower bottom extends on each side to the turn of the bilge, and from that point is carried up vertically as a wing bulkhead, as shown in fig. 122. The wing spaces thus formed being occasionally utilized for coal-bunkers. The framing, consisting of frame bars, reverse frame bars and frame plates or brackets, is usually carried up in a fair curve to the armour shell, suppose the vessel to be an armour-clad, as in fig. 122. From the edge of the armour, which is generally about 5 ft. below the load water-line, a change in structure is made, and the framing behind the armour is set back from the outside of the ship sufficiently to admit of an internal skin of steel plating (often worked in two thicknesses), seal backing, upon which the armour is embedded, and the armour itself, to be carried with the surface of the armour flush with the shell-plating. The vertical frames behind armour are spaced 2 ft. apart, and the longitudinals are made intercostal, the whole having exceptional strength, to support the armour. Above the armour another change is made, the frames being brought again to the outside of the ship, and the topside plating directly attached to them becoming flush with the outside of the armour. There is generally a strong deck, called the protective deck, extending from stem to stern in the form of a turtle back, the lower edges being at the armour shelf on each side of the ship, and the top of the arch forming the first deck above water, as indicated in fig. 120. With a view to maintaining its defensive power where it has to be perforated for tunnels and air shafts, armour gratings, or armour bars as they are called, are fitted in the openings. As much water-tight subdivision as possible is introduced throughout the ship, but for communication between the various compartments openings are provided in the bulkheads, having water-tight doors which can be closed either from a position close to the door or from a deck above water, or from both. Below the protective deck are the engine and boiler spaces, magazines, shell-rooms, submerged torpedo rooms, and steering-gear. A passage is provided on each side of the ship just below the protective deck, for the supply of ammunition to the secondary armament.

Fig. 118 shows the "Idzumo" partially in frame, looking forward from the after extremity: the frames below the armour deck over a considerable length of the ship are complete, and a number of the beams which carry the armour deck are in place. Fig. 119 shows the ram stern, which has just been placed in position. The collision bulkhead and the framing below the armour deck are for the most part in place. Fig. 120 gives the top of the armour deck, which is nearly completed, as seen from the fore end, with the forward citadel bulkhead in course of construction. Fig. 121 shows the after part of the vessel, which is not so far advanced as the forward portion shown in fig. 120. In fig. 121 the framing has been carried to a bulkhead near the after extremity, the rudder post is in place, and the bearing for the rudder head can be seen in the foreground. The construction of the armour deck is proceeding, and the after citadel bulkhead is also well advanced, though no backing is yet upon it, as in the case of the forward bulkhead, but the base of the redoubt which carries the after turret is erected.

The fittings in a ship cannot be fully described in the present article, but we shall conclude with some account of the auxiliary machinery. Two ordinary arrangements of steering-gear fitted in merchant steamers are shown in fig. 123. In the first example a three-quarter circular grooved rim, keyed to the rudder head, carries the steering-chains, which are led forward one on each side of the hatches to the steam engine, placed in this case in the engine-room casing, and controlled by shifting from the bridge. The usual steering-wheel is fitted on the bridge, and actuates the controlling valve of the steam engine by means of the shafting. The second example is very similar to the first: a quadrant is keyed on the rudder head, and worked by chains led over pulleys one on each side of the ship to the steam gear, which in this case is placed on the bridge, close to the wheel. In all such cases gear is also provided by which in an emergency the ship can be steered by hand, by steering-wheels placed close to the rudder head, as indicated in the figures.
In a warship the arrangement is different, as it is necessary to keep the steering gear below the water-line for protection. The breadth available at the rudder head is as a rule not sufficient for a tiller or quadrant to be fitted. Fig. 124 shows a frequently adopted. A crosshead of sufficient size is keyed on to the rudder head, and is worked by connecting rods from a similar crosshead placed a little farther forward, where the breadth of the ship is sufficient to allow a tiller to be worked. The tiller is worked by a block or carriage, which is drawn across the ship on a guide, at the same time sliding upon the tiller, which is machined for the purpose. The block-and-guide arrangement is known as Rapson's slide. The block is hauled to and fro across the ship by a chain, which passes round a sprocket wheel upon a shaft, which is driven in either direction, as required, by the steering-engine. In fig. 125 the arrangement is shown which has been for a considerable period adopted in large merchant ships and has in recent years been adopted in ships of the British navy. It is known as screw steering gear. On the same central shaft there are right- and left-handed propellers indicated on the plan, by which blocks A and B are made to travel always in the opposite direction when the shaft is rotated. These actuate the crosshead on the rudder E by means of the rods C and D, one of which will communicate a thrust and the other a pull, and vice versa according to which way the shaft is made to rotate. The shaft may be actuated either by hand-gear or by steam by means of the clutch F. In many cases the steam steering-engine is placed in the engine-room, to avoid heating the after-compartments by the steam pipes, and for the sake of easier control by the engineers.

Amongst the auxiliary machinery usually fitted in passenger and other well-found vessels may be mentioned the windlass for working the cables and weighing the anchors; a warping capstan forward in connexion with the windlass, and another aft with its own engine; steam winches for handling the cargo and baggage, and for hoisting coal on board; and occasionally steam cranes, fitted either in addition to or in place of the winches. Then there are the electric light, pumping, ventilating and refrigerating installations. Hydraulic power is employed in many cases, especially for cranes, but here the source of the power is necessarily a steam engine, which is usually placed in the main engine-room. Electric power sometimes replaces steam for operating some of the machines enumerated above; for instance, ventilating fans are now generally driven by electric motors in passenger and war ships. A large number of comparatively small fans are used, each supplying air to a particular part of the ship.

In warships the amount of auxiliary machinery has been very greatly increased in recent years. On each side of the deck amidships there is generally a steam winch for raising and lowering the boats, one of the principal functions of the mast in the modern warship being to carry the derrick used for this purpose. Electric motors are fitted for working the after-capstans, ash hoists, sometimes the winches, and the workshop machinery; also to traverse, elevate and work the guns, and bring the powder and projectiles up from the magazines to the guns. But for the heavier guns, the steering-gear, and certain other purposes, hydraulic power or steam is still preferred.

The writer is indebted to Mr H. G. Williams, Mr Lloyd Woollard and Mr A. W. A. Cluett for valuable assistance in preparing this article.

(P. W.A.)

SHIPKA PASS, in Bulgaria, a pass in the Balkans, celebrated as the scene of fierce fighting in the Russo-Turkish War of 1877-78. The main road from Rumelia to Bulgaria, leading from Sistova by Tarnova and Eski Zagn to Adrianople, crosses the Balkans near the village of Shipka, and this passage was of necessity an important point in the Russian plan of operations. The road does not pass between high peaks, but crosses the main ridge at the highest point; it is therefore not a pass in the ordinary sense of the word. Near the summit, running parallel, and close to the road is a series of three ridges, some 300 ft. high, and about 2 m. from north to south, which formed the position for a force holding the pass. It was originally held by a Turkish force of about 4000 men with 12 guns, prepared to resist the Russian advance. On the 17th of July they repelled a feeble attack from the north, and the following day faced round and drove back an attack by Gurko from the south. These attacks were to have been simultaneous, but Gurko, having met with unexpected resistance, was a day late. Though so far successful, the Turks evacuated their strong position, and it was occupied by the Russians on the 19th of July.

They were first attacked by Suleiman Pasha towards the end of August. Having concentrated with Reouf Pasha and driven Gurko across the Balkans at the end of July, he moved to the Shipka on the morning of the 21st of August, and attacked. The Russian force there, including five battalions of Bulgarians, then numbered 5000, but that day a regiment from Selvi brought their numbers to 7500, and this force held the position against 30,000 Turks for three days, when heavy reinforcements arrived. The fighting continued till the morning of the 26th, when Suleiman, his troops being exhausted, and having lost 10,000 men, entrenched himself in the position he then occupied in a semi-circle round the southern end of the Russian position. Having called up more battalions from Yeni Zagra, after a four days' artillery bombardment, he attacked on the 17th of September, and was repelled with a loss of 3000 men.

There was no more fighting on the Shipka till the general advance of the Russians after the fall of Plevna. Radetzky's command of about 60,000 men advanced from Gabrova on the 5th of January, in three columns. Radetzky, with the central column, moved by the main road and attacked the Turks, who still faced the position on the summit, while Skobelev and Mirski, crossing by trails some 3 m. to the west and east of the Turkish position, attacked their reserves on the far side, about Shipka and Shenova, where Vessil Pasha (who had succeeded Suleiman in command) had formed an entrenched camp. These flank columns made their way over the mountains, deep in snow, and Mirski attacked alone on the 8th of January, as Skobelev's advance had been delayed. But the following day both columns attacked, and after fierce fighting the Turks surrendered. The force on the summit had that day repulsed, with heavy loss, a frontal attack by Radetzky, but they were included in the surrender. Their numbers were 36,000, including 6000 sick and wounded, and 93 guns. The Russian losses were 5800.

Not only were the Turkish attacks on the Shipka unsuccessful, but they were made without object. At the end of July, when Suleiman forced Gurko back over the Balkans, the moral equilibrium and the plan of operations of the Russians had been upset by the second battle of Plevna, and the Shipka ceased to have any strategic importance for the time being. Had Suleiman at that time followed Gurko and joined Mehmet Ali, or moving round acted with Osman against the Russian flanks, the evacuation of the Shipka would have been compulsory. Suleiman, knowing nothing of strategy, preferred to act independently, and his action was supported by the still more ignorant ministers at Constantinople. The Shipka was merely a geographical point until the Russians committed themselves to advance, but, fortunately for them, the Turks chose to waste an army in fighting it throughout the critical period of the operations. As with Osman at Plevna, it was Constantinople that forbade Vessil
Pasha to withdraw his forces at the beginning of January, compelling him to wait to be swelled up. The Turkish tactics were equally unsound. Suleiman divided his forces and used up his troops in costly frontal attacks on Mt. St Nicholas, the southern and strongest point of the position, whereas a well-supported flank attack would probably have met with success. The manner in which he sacrificed his men earned for him the name of the 'Shipka butcher.'

J. H. V. C.)

SHIPLEY, JONATHAN (1714–1788), bishop of St Asaph, was educated at Reading and Oxford. He was ordained about 1738, and acted as tutor in the household of the 3rd earl of Peterborough. In 1743 he became rector of Silchester and Sherborne St John, Hampshire, and prebendary of Winchester. He was appointed to a canonry of Christ Church, Oxford, in 1748, and in 1760 to the deanery of Winchester and the living of Chilbolton, Hampshire, which he held in addition to his earlier preferments. In 1769 he was consecrated successively bishop of Llandaff and of St Asaph. He was much concerned with politics, and joined the Whig party in strong opposition to the policy of George III. towards the American colonies. In 1779 he was the only bishop to advocate the abolition of all laws against Protestant dissenters. He died on the 6th of December 1788. His brother, William Shipley (1714–1803), originated the Society of Arts; and his son, William Davies Shipley (1745–1826), became dean of St Asaph.

SHIPLEY, an urban district in the Shipley parliamentary division of the West Riding of Yorkshire, England, on the south bank of the Aire, 3 m. N. by W. of Bradford, on branches of the Great Northern, Midland, and North Eastern railways. Pop. (1901) 25,573. The manufacture of worsted is the principal industry, and there are large stone quarries in the neighbourhood. The parish includes Saltaire, so named after Sir Titus Salt, who established large alpaca manufactories, opened in 1853.

SHIP-MONEY, a tax, the levy of which by Charles I. of England without the consent of parliament was one of the causes of the Great Rebellion. The Plantagenet kings of England had exercised the right of requiring the maritime towns and counties to furnish ships in time of war; and the liability was sometimes commuted for a money payment. Notwithstanding that several statutes of Edward I. and Edward III. had made it illegal for the crown to exact any taxes without the consent of parliament, the prerogative of levying ship-money in time of war had never fallen wholly into abeyance, and in 1619 James I. aroused no popular opposition by levying £40,000 of ship-money on London and £8,550 on other seaport towns. The fleet of Charles I. during the first three years of his reign was, says S. R. Gardiner, 'largely composed of vessels demanded from the port towns and maritime counties. The idea of universal ship-money to be levied in every county in England seemed to him to be requisite for further extension of the crown's power.' Accordingly, on the 11th of February 1668, Charles issued writs requiring £173,000 to be returned to the exchequer by the 1st of March for the provision of a fleet to secure the country against French invasion and for the protection of commerce, and every county in England was assessed for payment. This was the first occasion when the demand for ship-money aroused serious opposition. Lord Northampton, lord-lieutenant of Warwickshire, and the earl of Banbury in Berkshire, refused to assist in collecting the money; and Charles withdrew the writs. It will be seen, then, that the statement of Hallam—that in 1634 William Noy, the attorney-general, unearthed in the 'Tower of London musty records of ship-money as a tax disused and forgotten for centuries.—has no real foundation. It was, it is true, the suggestion of Noy that a further resort should be had to this expedient for raising money when, in 1634, Charles made a secret treaty with Philip IV. of Spain to assist him against the Dutch; and Noy set himself to investigate such ancient legal learning as was in existence in support of the demand. The king had obtained the advice in support of the legality of the writ from Lord Keeper Coventry and the earl of Manchester, but the writ was issued in October 1634 and directed to the justices of London and other sea ports, requiring them to provide a certain number of ships of war of a prescribed tonnage and equipment, or their equivalent in money, and empowering them to assess the inhabitants for payment of the tax according to their substance. The distinctive feature of the writ of 1634 was that it was issued, contrary to all precedent, in time of peace. Charles desired to conceal the true aim of his policy, which he knew would be detected by the country, and he accordingly alleged as a pretext for the impost the danger to commerce from pirates, and the general condition of unrest in Europe. The citizens of London immediately claimed exemption under their charter, while other towns petitioned the king for a remission of the amount of their assessment; but no resistance on constitutional grounds appears to have been offered to the validity of the writ, and a sum of £104,000 was collected. On the 4th of August 1635 a second writ of ship-money was issued, directed on this occasion, as in the revoked writ of 1628, to the sheriffs and justices of inland as well as of maritime counties and towns, demanding the sum of £268,000, which was to be obtained by assessment on personal as well as on real property, payment to be enforced by distress. This demand excited growing popular discontent, which now began to see in it a determination on the part of the king to dispense altogether with parliamentary government. Charles, therefore, obtained a written opinion, signed by ten out of twelve judges consulted, to the effect that in time of national danger, of which the crown was the sole judge, ship-money might legally be levied on all parts of the country by writ under the great seal. The issue of a third writ of ship-money on the 9th of October 1636 made it evident that the ancient restrictions, which limited the levying of the impost to the maritime parts of the kingdom and to times of war or imminent national danger, had been finally swept away, and that the king intended to convert it into a permanent and general form of taxation without parliamentary sanction. The judges again, at Charles's request, gave an opinion favourable to the prerogative, which was read by Coventry in the Star Chamber and by the judges on assize. Payment was, however, refused by Lord Saye and by John Hampden (q.v.), a wealthy Buckinghamshire landowner. The case against the latter (Rex v. Hampden, 3 State Trials, 823) was heard before all the judges in the Exchequer Chamber, Hampden being defended by Oliver St John (q.v.) and Robert Holborne, and lasted for six months. Seven of the twelve judges, headed by Finch, chief justice of the common pleas, gave judgment for the crown, and five for Hampden; though two of the latter—namely, Bramston, chief justice of the king's bench, and Davenport, chief baron of the exchequer—based their judgment on technical grounds which did not touch the constitutional question at issue. The judgment of the court practically abrogated the right of parliament to control supply; and the necessity for curbing the royal prerogative in regard to taxation, thus rendered arbitrary by legal decisions, became more obvious in the decision on the legality of the writ of 1634 directed to Charles I., which after the Hampden trial grew increasingly formidable. In 1639 Charles ventured again to issue a writ of ship-money, but for the comparatively small sum of £70,000. In 1641, by an Act of the Long Parliament (17 Car. I. c. 2), introduced by Selden, the illegality of ship-money was expressly declared, and the Hampden judgment annulled.

SHIPPARD, SIR SIDNEY GODOLPHIN ALEXANDER (1838–1902), British colonial administrator, was the eldest son of Captain William Shipppard, 29th Regiment. He was educated at King's College school and Oxford. Taking his degree in 1863, he was called to the bar as a member of the Inner Temple in 1867. He then entered upon a long career in South Africa. He was attorney-general of Griqualand West, and 1877, when he was made acting recorder of the High Court of Griqualand. From 1880 to 1885 he sat as a judge of the Supreme Court of Cape Colony; and he was British commissioner on the Anglo-
German commission in 1834–1835 for settling the claims of British subjects at Angra do Pequeno and other parts of the south-west coast. Shippard, while at Oxford in 1872, had discussed with Cecil Rhodes the plan of the projected British advance in south central Africa to the Cape. The annexation of Damaland and Namaqualand the first step in a design to secure for Germany territory stretching from ocean to ocean—a design which if executed would have been fatal to the British position in South Africa. Consequently when after the Warren expedition of 1885 he was chosen to organize the newly acquired British possessions in Bechuanaland he saw in his appointment an opportunity for forestalling the Germans, and also the Boer adventurers who likewise sought to be beforehand with Britain in the countries north of Bechuanaland. From his home in London he kept up a friendly correspondence with the Matabele king Lobengula with the object of attaching him to the British cause. At the end of 1887 he went to Graham’s Town with the hope of inducing the high commissioner (Sir Hercules Robinson—afterwards Lord Rosmead) to sanction the conclusion of a treaty with Lobengula binding that ruler not to cede any part of his territory to any other power than England. "I used all my power of persuasion," Sir Sidney writes, "but failed to induce Lord Rosmead either to act on his own responsibility in the matter or to approach Her Majesty’s government on the subject. As a last resource I telegraphed to Mr Rhodes, who was then busily engaged at Kimberley, to come down at once to Graham’s Town and try the effect of his eloquence. He came, and by taking upon himself all pecuniary responsibility succeeded in obtaining the requisite sanction" (see article “Bechuanaland," by Sir S. Shippard, in British Africa, London,1890). The treaty was signed and British interests secured. Shippard was thenceforth freer to devote himself to the special interests of Bechuanaland, which he governed with conspicuous success. He held the chief official position there from 1885 to 1895, being administrator, chief magistrate and president of the Land Commission for British Bechuanaland, and resident commissioner for the Bechuanaland Protectorate and the Kalahari. He was created K.C.M.G. in 1887. In 1896 he played an unofficial part in the negotiations between Sir Hercules Robinson and the Johannesburg reformers after the Jameson Raid. He then returned to England, where he died on the 29th of March 1902.

**SHIPPING.** To the floating log and paddle of the primeval fisherman must be attributed the growth of the great industry of merchant shipping. The hollowing of a log and the addition of a skin sail would before long serve to convert the embryo craft into a vessel navigable in the smooth and narrow waters which lapped the shores of the Mediterranean and the far distant East. The coastal villages had need of worked stone knives, of beads and of skins for winter coverings, to be obtained by barter for their fish and salt. Passing from settlement to settlement dotted on the shore, the traders found in the local skiffs a convenient alternative to the rough and tedious tracks along the winding or indented coast. In course of time they established themselves at the coastal settlements and built or purchased craft for their own use. As populations and their needs increased, the traders, gaining confidence by experience, built larger vessels and extended the area of their barter, sailing in companies, for mutual safety and defence. Of the early days of this traffic, as developed in the East, we have but little information, but in the Eastern seas, apparently, the Chinese usually came no farther than the coast of Malabar. The Malays seem in all ages to have traded with India and probably with the coast of Africa. In the Indian Ocean the Arabs were the principal carriers. Greatest of all the ancient navigators nearer to the West were the Phoenicians, the hardy sons of Tyre and Sidon. To the remarkable maritime ascendancy of Tyre Ezekiel xxvii. bears eloquent testimony. King Solomon’s undertaking for the building of the temple was largely founded on the support of Phoenician Hiram. Much later, but still some 2000 years ago, ships had become a common means of transport and were of no small size, since the centurion charged with the conveyance of St Paul to Rome (Acts xxvii.) found at Myra an Alexandrian ship about to sail with wheat for Italy, which was able to take on board, besides the cargo, the whole of the company, making a total of 276 souls in all. Then, as now, ships were but links in a mighty chain of commerce on the land, a commerce for which the ports were centres of collection and distribution. The products of India and Europe were conveyed from east and west in stages by inland or coastal routes with which in their entirety India and Europe alike were unacquainted (Vincent). And, generally, in the ancient days ocean commerce ceased with the summer season, and sea-borne goods from the distant east to the remote west found their way from entrepôt to entrepôt. These entrepôts were great trading centres, the advantageous situation of London. Foreshadowing, having before the days of the Roman conquest marked it out as a convenient emporium for the northern traders.

The Phoenicians, especially, for centuries pushed their commerce farther and farther afield, establishing factories and trading ports which in time grew into independent settlements. Cadiz, the ancient Gadir, was one of such, and from Gadir or more northern settlements the Phoenicians visited Britain, bartering merchandise for tin at Cornwall or the Scilly Isles. Amongst the various nations of the south, between whom the great shipping heritage of the Phoenicians was in course of time divided, the Ráidians rose to great importance. By these notable traders was drawn up a code of maritime laws, many of which were embodied in the Roman law, and eventually, at or about the time of Richard I., became a foundation for the Law of Oleron, which is in some part adopted at this day. Emerging from the constant struggles in the Mediterranean and Adriatic, the Venetians, Genoese and Pisans attained to great prosperity and renown, the reputation of the Genoese ship-builders creating from time to time a demand for their ships on the part of the nations struggling for maritime supremacy in the channel and the North Sea. The once familiar English word "argosy" dates from the appreciation of the vessels built at Arguze or Ragusa, a Dalmatian city on the Adriatic. The proximity of Italy to the Holy Land tended greatly to the prosperity of the Italian shipping.

In very early days the commerce of northern Europe was principally carried on by inland routes. With the increase and civilization of the populations, the cities on the navigable rivers and on the sea found the advantage of ocean commerce, and strove for supremacy in trade. In Britain many an ancient seaboard town, from Bristol to far north Inverness, largely owing its prosperity to the great trade which with the eastern countries became important as a trading centre. The English merchants were not without ships, but the foreign traders were enterprising and wealthy, and in their emulation for the renowned English wool and for English hides were prepared to venture much. In those days and for several centuries later the history of shipping was a history of arbitrary restraints, of claims for exclusive rights of trading and navigation, and of pretext of various kinds, resulting in captures and burnings, in embargoes and confiscations in port and in fierce reprisals. The merchantman was a more or less armed vessel prepared alike for aggression or defence, a condition of affairs to which has probably to be attributed the occasional construction of vessels of a tonnage then remarkable. The ships of Spain and Portugal, of England and the Netherlands—of French shipping for a considerable period there was comparatively little—homeward bound from Indian ports and factories and from the New World’s trading settlements from time to time were preyed on by one another. The Algerian and Barbary corsairs, with nothing to lose and everything to gain in merchandise and captives, were the dread of all. The Dey of Algiers had his harem in the British isle of Gibraltar, and from still farther north—and within the straits. The insurance of the voyagers against capture and the payment of head-money for their ransom was a well-established system of the times.

In England, the Cinque ports, in consideration of valuable privileges, were specially engaged to hold vessels at the service of the state, but on need arising the ports at large were called upon for ships and men. These demands at times became oppressive. Thus we read that in 1371 it was complained in parliament
that owing to the demands of the king the merchants were being ruined and their mariners driven into other trades. The size or measurement of ships was assessed on the weight of their cargo, and the first step in the present system of tonnage measurement. Ships sailed in fleets, one or more of their masters being appointed admirals, to be obeyed by all the company. In times of special maritime disturbance an armed fleet convoyed the merchantmen, much, no doubt, to the added cost of transport. The great source of England’s wealth was her wool, of which the abundance and fineness gave rise to a wide demand. Staples or licensed entrepôts or marts were set up for this and other produce at certain towns in England, and overseas, English merchants associating themselves at such foreign staples. In like manner foreign trading societies located themselves under certain privileges and obligations at English marts, to the great increase of shipping, more especially of foreign bottoms. About the middle of the 15th century a considerable use sprung up for shipping in the carriage of African slaves to Portugal, their captors being the Moors. In later years this melancholy trade found large employment for the ships of Liverpool, Bristol and London, trading with the distant west. Pilgrimages, too, were bringing profit to the ships of London and other of the Channel, being engaged on the one hand to the shrine of St James of Compostela and on the other to that of St Thomas of Canterbury.

From times remote the fishing industry produced a hardy race of shipmen, the maritime nations being all more or less engaged in an enterprise rendered doubly lucrative by the want of flesh meat and the regulations of Holy Church. Thus in very early days the northern seas were thronged with rival fishing fleets, which, from about the middle of the 15th century, began to find their way to the banks of Newfoundland. At the close of the 16th century the whale was being pursued by rival fishermen on the Greenland coasts. Queen Elizabeth, for the maintenance of shipping and the increase of fishermen and mariners, forbade the eating of flesh on Wednesdays and Saturdays, an order from time to time subsequently revived. Sir Walter Raleigh, in his statement to King James, lamenting English commercial supineness as compared with the enterprise of the Dutch, declared that 20,000 vessels of all nations were engaged in fishing off the British coasts, of which vessels the Dutch owned 3000; and no doubt they formed a valuable mercantile and naval school.

The great discoveries of the renowned Spanish and Portuguese navigators in the reign of Henry VII. awoke in the maritime states a new spirit of commercial enterprise and emulation, in which Henry and his successors took an active part. A royal grant of navigation and discovery was given to the Cabots, then settled at Bristol, and “ divers tall ships ” of London, Southampton and Bristol traded direct with the Mediterranean ports, though the English merchants generally employed foreign vessels for this trade. A “ tall ” ship was apparently a vessel carrying topmast with yards and square sails, an important development of the simpler pole-mast rig of earlier times. Henry VIII. and Ferdinand of Spain entered into a league, primarily aimed at France, under which it was agreed to police the seas in protection of their shipping, the English fleet to watch the sea to Gibraltar, and Spain to guard the Mediterranean. The Corporation of the Trinity House was now established, in great part for the deepening of the Thames and to supply shipping with the ballast gained in the process, though the vessels actually London-owned were apparently few in number. Most English ships of burthen were then obtained by purchase at the South Baltic ports, where the great Hanse town, Lübeck, was the centre of an enormous trade. The Hanse towns, indeed, practically carried on the trade of England. In the time of Elizabeth, England began to achieve commercial independence. Great building of ships took place, for which bounties were granted by the queen, and Elizabeth set herself against the Hanseatic league. At the close of her reign the Steelyard was shut up, and the Dutch were competing successfully with the Hanse towns, of which “ ...their teeth were out and the rest but loose.” In the early days of commerce the risks were considerable to be borne by individuals, who accordingly associated themselves as companies of merchant adventurers for the purposes of their particular trade, exclusive rights and privileges being granted to them by their own sovereign, and corresponding liabilities on the part of the foreign states or cities traded with. In England certain of these societies, notably the company of Russian merchants, the Turkey merchants and, for long, the East India Company, occupied positions of influence and importance, the last-named company especially becoming possessed of much shipping, including large vessels, well armed, for prize-making or defence. The needs of trade and shipping were for long but little understood or often arbitrarily obstructed, but as a broad general principle it was recognized by them that their trading interests required for their protection special privileges and concessions. Thus the patent granted by Elizabeth to the African adventurers in 1588 was expressed to be on the ground that “the adventuring of a new trade cannot be a matter of small charge and hazard to the adventurers in the beginning.”

At the middle of the 16th century Antwerp was at the zenith of its great prosperity. It was described as the general storehouse of the world, and it was stated that so many as 2500 vessels might be seen lying in the Scheldt at one time. These, however, were, as we have seen, for foreign, Antwerp being a mart or emporium to which other nations traded. Towards the close of the century this great city’s peaceful population was, in the name of Holy Church, crushed under the iron heel of Christian Spain. Its traders fled from cruelty and torture largely to Amsterdam, about this time the northern entrepôt for Portugal’s East India trade. The Hollanders, profiting by the decline of the Hanse towns, were now greatly devoting themselves to shipbuilding and to foreign trade. They, like the English, hampered in their navigation by hostile and unfriendly occupation of the ports of refuge and supply at the two great southern capes, were bent on discovering a north-east or north-west passage to the East. This enterprise and the desire for gems and precious metals, as to the existence and abundance of which there were many false beliefs, added greatly to the knowledge of the distant seas and shores, on which many settlements were being established. To such settlements the attention of the French was now directed, with much encouragement to their shipping by the powerful Richelieu. The East Indian settlements and shipping of the Portuguese were being persistently harassed by the advancing Dutch, while the rich treasure ships of Spain were laid wait for and captured by English shipping, greatly to the Spanish loss. But the Dutch especially were prospering. Amsterdam, a vast trade centre supplied by Dutch shipping, had between 1571 and 1650 trebled itself in size. So far back as 1603 Sir Walter Raleigh, in his statement to King James, had complained that the vessels of the Dutch, by reason of their greater capacity and smaller crews and consequently lower freights, were cutting out the English ships or driving them into the Newcastle coal trade. By such enterprise the Hollanders gradually became the carriers for the English merchants. English bottoms were neglected and English seamen took service with the Dutch. Affairs for English shipping had about 1650 reached a crisis. There existed, moreover, great animosity between the English and the Hollanders.

In the defence of the national shipping the great Navigation Act was in 1661 placed upon the British statute-book. Under this far-reaching act the trade between England and her colonies and the British coasting trade was strictly confined to English bottoms, English owned and manned substantially by English seamen. The act contained further provisions in support of British shipping, the effect of which was greatly to prejudice foreign shipping in its competition for the British carrying trade. It is not impossible that some of the regulations of the act may have proceeded from the animosity already mentioned (Adam Smith). From the point of view of the Dutch, indeed, it was a “ vile act and order,” to be resisted at all costs. From the prolonged hostilities which ensued England finally emerged supreme at sea. For some time the French, under the powerful encouragement of Richelieu and
SHIPPING

subsequently of Colbert, had been devoting themselves to colonial enterprises both across the Atlantic and in distant India, to the eventual important increase of French shipping, whilst on the other hand Spanish shipping was declining. As the result of the Navigation Acts and its successful implementation, the increase had taken place in English tonnage, which in 1688 was said to be nearly double that of 1666. In the war with France this increase was greatly in favour of her privateers, which in two years are stated to have captured 3000 British ships as against but 67 which were taken from France, a result in part attributable to her employment of Dutch vessels. About this time Inverness, long devoted to shipbuilding, had obtained a high reputation for its ships.

In 1701 England’s private shipping numbered 3281 vessels, of a total burden of 261,222 tons and carrying 5560 guns. London leading with 560 ships of 84,882 tons, Bristol coming next with 165 of 17,338 tons, Liverpool being seventh on the list with 102 ships. Thirty years later London’s ships had increased to 1417, ranging from 15 tons to a great ship of 750 tons owned by the South Sea Company, but the majority measured less than 200 tons. In 1765 we read that the Dutch, Danish and Swedish ships were generally larger than the English vessels and that they had succeeded in outshining England as the carrier of Lisbon’s Mediterranean trade. In 1714 an act was passed, and at subsequent dates revived, offering public rewards for improved methods of ascertaining longitude at sea, and John Harrison (“that heaven taught artist”) received in all £20,000 for the invention of a chronometer which was successful to a degree of accuracy beyond that for which the act provided. Towards the second half of the 18th century the foundations were laid of the present great shipping industry on the Great Lakes. Oak timber of large size was now becoming scarce in England, and in the interests of the navy restrictions were placed upon the East India Company as regards its use. British merchant shipping, too, had apparently outgrown the supply of seamen, for towards the close of the century it was permitted to British vessels to carry foreign seamen to the extent of three-fourths of the crew. The traffic in African negroes gave much employment to British shipping. The war with America led to the harring of British commerce by American privateers cruising off the English coasts. War premiums were very high and the insurance obtainable was insufficient. Partly on this account and partly owing to the demand for shipping, vessels of new and various capacities were provided for transport and other public services, whilst many more were sailed as privateers, the Thames was now full of foreign vessels loading British cargoes. During the absence from the West Indies of the British fleet under Admiral Byron, engaged in conveying homewards the West Indian merchantmen, two valuable British islands were captured by the French. The hostilities of the rival states were being fought out at sea, with peaceful commerce as their objective. The seas swarmed with privateers, armed and equipped as sordid speculative enterprises, occasional rich prizes stimulating the greed of many citizens, not a few of them, no doubt, the owners of ships and merchandise which had in like manner fallen to the enemy. The French privateer “Bordelais,” captured by the English in 1790, is reported to have taken in four years 149 prizes, of the net value of £1,000,000 sterling (Mahan). Between May 1756 and July 1757 a total of 772 French vessels was captured by the British, whilst 637 British ships were taken by the French. It was declared in the House of Lords in February 1778 that the value of the British captures of American vessels had amounted to £1,800,000, against which that of British shipping captured by America had been £1,800,000. Towards the close of the prolonged hostilities which concluded in 1815 Liverpool and Glasgow were holding public meetings and urging upon the admiralty and the throne that they were being ruined by the want of protection to their shipping. In 1786 an act was passed (26 Geo. III. c. 86) for the encouragement of shipping, in which the personal liability of shipowners, till then unlimited, was in certain cases of their loss of cargo now limited to the value of the vessel and her freight, the first of progressive acts of the like nature. Smuggling was for long the cause of serious loss to the national revenue, and an act was passed declaring forfeited any British sloops or cutters found within four leagues of the coast if provided with a bowsprit exceeding two-thirds of the beam.
owing to the superior advantages of iron hulls, not yet constructed in
America, the United States now further lost place as ocean
carriers. In 1868 the chief employment of her ocean shipping
was on the Atlantic coast and in the Gulf of Mexico. Steam-powered vessels resulted in the estab-
lishment of many coaling stations in distant ports, with
much employment of shipping to supply them. Towards the
middle of the 19th century British shipowners were greatly
alarmed at proposals to repeal the navigation acts, and in spite
of their petitions and remonstrances, and of demands that the
bill, eventually introduced, should at least require reciprocity,
in 1849 the proposed measure became an act, the coastal trade
being in 1854 similarly thrown open, this latter measure being
initiated by the need for British shipbuilding. A number of the
vessels of the Crimean War (Lindsay). Probably in no small degree owing to the discovery of gold in California and Australia about
this time, and to the further employment provided for shipping
by the Crimean War and by the necessities of the Indian Mutiny,
the direful forebodings of British owners as to the consequences of
the repeal of the Navigation Act were far removed. In 1856
the Treaty of Paris and its appended Declaration pronounced,
amongst other notable clauses affecting maritime warfare, the
abolition of privateering. To this great treaty much of the
maritime status of the maritime states was due. AD The British,
United States and Spain, however, not yet being signatories.
The altered conditions as between warships and merchant vessels,
and the disabilities imposed by neutrality laws have, however,
in themselves done very much to render privateering as formerly
conducted no longer possible. But the Declaration, notwithstanding,
the employment of duly commissioned merchant vessels may still be resorted to by the state for the destruction
of commerce and for other belligerent purposes.
In 1858, after great difficulty and outlay, Brunel's huge ship the
"Great Eastern" was floated on the Thames. The vessel,
having a length of 679 ft. and a burden of 15,337 tons gross and
13,344 tons net (Lloyd's Register) and being provided with six
sail-carrying masts, was furnished both with a screw propeller
and with paddles. Highly successful as an engineering enterprise,
commercially she was from the first a ruinous failure. Under
the remarkable development of the Atlantic passenger traffic,
however, the size of steamships steadily and continually increased.
In 1873, as the outcome of a prolonged public agitation con-
ducted by Mr Samuel Plimsoll, an amendment to the Merchant
Shipping Act was passed (39 & 40 Vic. c. 80), making it a penal offence to knowingly
send a ship to sea unseaworthy, and requiring a loadline to be
fixed on British vessels, the line to be indicated on ocean going
vessels by what is now universally known as the Plimsoll mark.
The opening in 1869 of the Suez Canal created a revolution in
the eastern shipping trade. Year by year steamships increased
greatly in number and in burden. With improved conditions of
steam navigation the supplementary use of sails was generally abandoned, masts being retained only for signalling purposes and as
attachments for cargo hoists. New conditions in ship con-
struction, the commercial demand for expedition and the manufac-
ture of new articles of commerce together resulted in an
increased risk of fire on ships both at sea and in port, with great
loss primarily to underwriters, more especially by the flooding
of holds full of valuable cargo. To overcome this danger steam-
ships are being increasingly equipped with apparatus which
on the outbreak of fire enables the holds to be filled with a fire-
extinguishing gas. The invention and adoption of refrigerating
machinery and insulated holds resulted in the development of
a vast trade in frozen meat and perishable produce.
The triumph of Germany in the Franco-Prussian War in
the Fatherland a spirit of industrial enterprise which greatly
increased the population of her manufacturing areas. The
supplies required by the prosperous industrial populations and the
national demand for raw materials for the manufactur-

In consequence of an act passed by the French government to
grant bounties on sailing vessels constructed and owned in France,
the owners of such vessels found it to their profit, the bounty
being assessed on distances sailed, to engage in long voyages,
with the earning of freight as a secondary consideration. This
procedure being found to operate prejudicially on the freight
earnings of sailing vessels generally, and more especially in the
Pacific trade, an international meeting of the owners of sailing
vessels was held at Paris in 1893, with the result of the formation of
the Sailing Ship Owners' International Union to maintain
rates of freight. French owners identifying themselves with the
measures decided on by the union in the common interest, Influenced, no doubt, by German example, certain French
steamship companies about this time decided to grant preferential
combined tariffs on goods sent from inland centres of production
in France for shipment by their vessels, to the great dissa-
atisfaction of the owners of foreign steamers loading for similar
destinations at French ports.
Early in 1902 a shipping pool or "combine" was effected in
the case of certain important British steam lines engaged in
the North Atlantic trade. The combine, involving vast capital
values, was engineered by a well-known New York business house largely interested in American railways. In England it was variably attributed to a resolve on the part of American traders to share in the transport of the national trade; to a purpose evidenced by a number of steamers which were named to effect economies by a consolidation of management, and to a scheme intended to benefit certain great American railways. The transaction gave rise to much comment in Great Britain, being by not a few regarded as contemplating the eventual transfer of the lines to American ownership. And indeed, though the steamers continued to be under the British flag, the extent to which they remain substantially under British ownership cannot be affirmed. It was stated in 1898 that on completion of its building programme the combined fleet of the American line possessed only 1,159,704 tons, as compared with 3,798,000 tons of vessels operating under the British flag.

The general adoption of steampships in place of sailing vessels was gradually followed by their separation into two classes, one devoted to a fixed service on regular lines of employment, the other to promiscuous trade. The former class are now known somewhat vaguely as "liners," ranging, however, from the first-class mail and passenger steamer on the one hand, to the regular cargo steamer on the other. To the second class belong the "seekers or tramps" which come and go wherever profitable employment occurs, and which more especially lay themselves out to be chartered to carry full cargoes of coal, timber, wheat, nitrate, jute and such like. These vessels, some of which are of great capacity, are frequently in competition with the liners. This competition sometimes results in "cut rates" of freight, to the serious loss of the great shipping firms and companies. With the establishment of regular lines, moreover, there grew up competition between rival lines, with similar results. A solution was found by the creation of working agreements between rival lines at agreed rates of freight, but the lines thus associated were still exposed to the attacks of "tramps" upon what the liner owners regarded as their privileged trade. Fierce conflicts from time to time ensued, with great disturbance of the freight market and with consequent loss or inconvenience to the merchants themselves. As the result, shipping "rings" or "conferences" were created in many trades, the owners of the liners undertaking to provide the traders with a regular service accompanied by advantageous conditions, whilst the traders undertook to ship only by the conference steamers. In order to ensure this support, the shipowners instituted the system of deferred rebates, under which each merchant, at the end of a year or other fixed period, should be entitled to a discount or rebate on the amount of freight paid by him during such period, provided that he should have shipped no goods at all by steamer outside the conference, the discount only to be paid after a further fixed period of six or nine months, during which time also he should rigidly support the conference lines. In the event of failure to comply with the conditions, a merchant is exposed to forfeiture of the rebate, and in addition to measures in the nature of a boycott on the part of the conference lines. Notwithstanding, attempts are from time to time made by steamers outside the ring to gain admittance, with the consequence of occasional freight wars, and with the incidental result that goods are sometimes carried, for example, from America to a British colony at lower rates of freight than similar goods manufactured in England. Mainly on account of complaints made against the working of the South African ring, a British royal commission was in 1906 appointed to take evidence and report upon the subject generally.

With the growth of populations and the development of means of transport, both by land and sea, a great increase arose both in production and consumption, and competition became very keen for markets, both home and foreign. In this competition the cost of carriage is always an element of great importance, even though the freight payment may bear but an insignificant relation to the value of the goods carried. For in modern trade rivalries every penny saved in charges counts with the importer, and if goods of a similar kind can, by reason of lower transport charges, be obtained a fraction cheaper from one industrial centre than from another, the tendency is to give the preference to the centre or country which can deliver most cheaply to the consumer. Trade follows cheapness, and, with the world's industrial development, the striving for cheapness took at the outset the form of economies in production. The day of small trade with large profits was passed, and producers of all kinds now aimed at a large output at diminished cost, and contended themselves with a smaller ratio of profits on a larger business. The utmost economy was studied with a view to successful competition, especially in overseas markets; and in this struggle for the cheapening of supplies the cost of transport became an important element. The fact was recognized that the ship is but a link in the chain of connexion between producer and consumer, and the system of "through" bills of lading was introduced, under which a particular consignment of goods was removed from the port of shipment to the port of discharge by vessels of the carriers, with the consent of the owners, without any intermediate stage of change of ownership or of the medium of transport.

With this increase in the volume of traffic went a growth in the number and size of the vessels employed in the carriage of goods in conjunction with other lines, with the object and effect of cheapening the transport as a whole. Individual shipowners, in order to obtain cargoes for their ships, were in turn driven to devise economies in transport, with the result that rates of freight were continually reduced. In modern ocean carriage size means cheapness, the transport of a given weight of cargo being cheaper in a single vessel than in two vessels each of half the size. For not only does this concentration of carrying power effect economy of officers and crew, with their wages, provisions and accommodation space, but in shipbuilding also size makes for cheapness. Thus, if, for example, two steamers each carrying 2000 tons will cost together say £40,000, a single vessel of equal carrying capacity can be supplied for £35,000. Or, put another way, if for £40,000 two steamers can be built to carry between them 4000 tons, for the same sum a single vessel can, it is stated, be provided to carry 4700 tons. Consequently, the size of vessels is continually on the increase, and no sooner is a navigable channel at such cost made deep enough than new vessels of greater dimensions are constructed. Vessels larger are constructed, and shipowners complain anew that the harbour depth provided is insufficient. The constant demand for greater depths resulted in the production of mammoth dredgers of which, also, the size and power are continually increasing. At the present time it is the navigable depth of ports and canals, and the need of adequate dry docks, rather than the obtaining of cargoes, which are the controlling factors in the size of great ocean vessels. But the heavy interest on the capital cost of these vessels and their working expenses call for the utmost dispatch in their loading and discharge, and with the simultaneous arrival of several vessels of large tonnage, the question of prompt discharge is one of great and increasing difficulty. For many modern steamers will carry 10,000 tons of cargo, and some a great deal more; so that, with old-type railway trucks carrying ordinarily only about 8 tons, it not infrequently happens that the discharge of the ship, equipped though she be with remarkable facilities for landing her cargo and assisted by discharge into barges, is impeded owing to deficiency of shore clearance. If 8 tons be taken as the capacity of an ordinary railway truck and 30 trucks be allowed to be attached to a train, it will be obvious that a single modern cargo ship will require a vast procession of rolling stock to clear her cargo. A single cargo of 10,000 tons, for example, will require some 1250 railway trucks for its removal; or, allowing 6 yards' length to the truck, 7500 yards of rolling stock, without engines and vans. And, in fact, congestion of shipping owing to delays is frequently the cause of bitter complaint in the case of certain ports. Trucks of much increased capacity are now being introduced, but for various reasons their adoption is very slow. In ports that argues the argument is sometimes heard that the backwardness of this or that port will result in the trade being driven elsewhere: the ships, it is said, will remove it. But the ship is but the blind instrument of trade, to come and go where and as trade calls it. The ship will, however, sooner or later require a higher rate of freight for ports of slow despatch, and this increased expense in transport will undoubtedly operate in favour of rival ports. For the ports themselves are but stepping-stones to or from a market or industrial centre, and the market will always select the cheapest route for its trade.
With the increase of populations in the Old World and the development of new countries, the transport of emigrants and of travellers for business and for pleasure became a highly important and lucrative source of employment for steamship

 Công việc tăng của dân số trong thế giới cũ và phát triển của các quốc gia mới, vận chuyển người di cư và du lịch trở thành một nguồn việc làm quan trọng và sinh lợi cho các công ty tàu lái.

 It is now indeed becoming a common practice on the part of ocean steamship companies to employ a surplus or superseded vessel of their fleet solely in carrying holiday tourists to a succession of foreign ports. In regular traffic the demand for increased speed and greater security and comfort on the part of ocean travellers resulted in the competitive evolution of passenger steamers of dimensions and draught which create an increasing strain on port and dock authorities.

 Công việc cao hơn đã trở nên phổ biến đối với các công ty tàu lái biển, bởi việc thuê thêm hoặc đóng lại tàu, để chỉ vận chuyển du khách nghỉ lễ đến các quốc đảo. Trong giao thông định kỳ, sự yêu cầu từ du khách di chuyển biển đã dẫn đến sự cạnh tranh trong việc phát triển tàu của kích thước và độ nổi, tạo ra một áp lực ngày càng tăng lên cho cảng và bến đỗ.

 These remarks must not be concluded without mention of the important part played in the evolution of modern shipping by the system of marine insurance and by the rules of classification. For the cost of insurance is a heavy tax on the profits of the shipowners, and only by providing vessels of the best construction and maintaining their reputation can owners gain the advantage of low insurance rates. And not only so, but by the merchants also, to whom insurance premiums are a no less serious consider-

 Những nhận xét này không thể kết thúc mà không men- tion của vai trò quan trọng của hệ thống bảo hiểm hải quan và các quy tắc phân loại trong việc phát triển giao thông hiện đại. Doanh nghiệp tàu biển phải chịu một thuế nặng lên lợi nhuận, và chỉ có việc cung cấp tàu có chất lượng tốt và duy trì uy tín của mình, chủ tàu mới có thể giành được lợi ích từ việc giảm cước bảo hiểm. Và không chỉ vậy, mà còn nhờ các thương nhân khác, người trả phí bảo hiểm là một vấn đề quan trọng. 

...tion; vessels of the highest class and reputation are insisted on with a view to cheap cargo insurance, inferior ships being consequently placed at a serious disadvantage. On the other hand, the rules of construction and classification of the Society of Lloyd's Register (a body altogether distinct from the Corporation of Lloyd's) are most exacting, and any failure to comply with the rules of the Register or "Book," which, moreover, are in a constant state of scientific evolution, may involve withdrawal of the vessel's class, a result which would be fatal to her cheap insurance as well as to her employment in successful competition for freights. With its skilled surveyors at foreign, colonial and home ports, the great society offers every facility for the classing of the whole world's shipping and foreign as well as British owners are fully alive to the importance of a strict com

...tion; tàu của cấp cao và uy tín cao được yêu cầu dùng để hoàn thiện bảo hiểm hàng hóa, tàu hạng thấp sẽ bị đặt vào trạng thái không cạnh tranh. Mặt khác, các quy tắc xây dựng và phân loại của Society of Lloyd's Register (Nhà cung cấp tư cách hoàn toàn không liên quan đến Nhà cung cấp tư cách Lloyd's) rất nghiêm ngặt, và bất kỳ vi phạm nào các quy tắc của Register hay "Sách," các quy tắc này đang trong trạng thái không ngừng thay đổi, có thể dẫn đến việc rút khỏi class của tàu, một kết quả sẽ gây hại lớn cho bảo hiểm Lage thấp của tàu cũng như việc thuê tàu vào cuộc đua việc thuê tàu. Với các kỹ sư chuyên nghiệp ở nước ngoài, thuộc địa và trong nước, tổ chức này cung cấp mọi tiện ích để phân loại toàn bộ thế giới tàu hàng và cả tàu nước ngoài và người sở hữu tàu Anh cũng nhận được sự nhận thức đầy đủ về sự quan trọng của việc tuân thủ các quy tắc này.

 ...
Her most sensational prophecies had to do with Cardinal Wolsey, the duke of Suffolk, Lord Percy and other men prominent at the court of Henry VIII. There is a tradition that on one occasion the abbot of Beverley, anxious to investigate the case for himself, visited Mother Shipton’s cottage disguised, and that no sooner had he knocked than the old woman called out “Come in, Mr Abbot, for you are not so much disguised but the fox may be seen through the sheep’s skin.” She is said to have died at Clifton, Yorkshire, in 1561, and was buried there or at Shipton. Her whole history rests on the flimsiest authority, but her alleged prophecies have had from the 17th century until quite recently an extraordinary hold on the popular imagination. In Stuart times all ranks of society flocked in to hear her; and referring to her supposed foretelling of the Great Fire, Pepys relates that when Prince Rupert heard, while sailing up the Thames on the 20th of October 1666, of the outbreak of the fire “ he said was, ‘now Shipton’s prophecy was out.’” One of her prophecies was supposed to have menaced Yeovil, Somerset, with an earthquake and flood in 1859, and so convinced were the parishioners of the truth of her prognostications that hundreds moved from their cottages on the eve of the expected catastrophe, and a perfectly fine town in front of the county to see the town’s destruction. The suggestion that Mother Shipton had foretold the end of the world in 1881 was absurdity the cause of the most poignant alarm throughout rural England in that year, the people deserting their houses, and spending the night in prayer in the fields, churches and chapels. This latter alleged prophecy was one of a series of forgeries to which Charles Hindley, who reprinted in 1862 a garbled version of Richard Head’s Life, confessed in 1873.

SHIRAZ—SHIRÉ

SHIRAZ, the capital of the province of Fars in Persia, situated in a fertile plain, in 29° 36′ N., 52° 32′ E., at an elevation of 3100 ft., 156 m. by road N.E. by E. from Bushire (112 m. direct). According to Eastern authorities Shiraz was founded in A.D. 693 by Mahommed b. Yusuf Thakefi, a brother of the famous Hajjaj. It is approached on the south from the Persian Gulf through lofty and difficult mountain passes (highest 7400 ft.) and on the north through chains of hills which separate the plain of Shiraz from that of Mervadsch, where the ruins of Persepolis are. It is surrounded by a low mud wall flanked by towers, and a dry ditch, and measures about 4 m. in circumference. There are six gates. The town is divided into eleven quarters (mahalleh), one of which is exclusively inhabited by Jews and called Mahalleh Yahudi. The population of Shiraz is estimated at 60,000, but in 1854 it was 53,007, of which 1070 were Jews. The houses of Shiraz are, in general, small, and the streets narrow. A great bazaar, built by Kerim Khan Zend, forms an exception to this; it is about 500 yds. in length and has a vaulted roof 22 ft. high, and contains many spacious shops well supplied with goods and merchandise. There are many mosques, the most notable being the old Jama, a foundation of the Saffarid ruler Amr b. Leith in 904, now in a state of ruin; the new Jama, generally called Masjed-i Nau; the New Mosque, built by Atabeg S’ad b. Zengi, c. 1200; and the Jama i Vakil, built by Kerim Khan Zend in 1766. Shiraz still possesses the title “Dar ul im,” the “Seat of Knowledge,” and has many colleges (madressah), the oldest being the Mansurieh built in 1278 by Seyed Sadr ed din Mahommed Dastktei; the Hashimiyeh and Nizamieh date from the middle of the 17th century, the college called M. i Agha Baba was begun by Kerim Khan Zend, c. 1750, but finished in 1823 by Agha Baba Khan Mazanderani. Of the twenty caravanserais, or more, which Shiraz has, the oldest is that called Car Chiragh Ali, built in 1678. There are several shrines of Imam-zadehs, the most venerated and rich being that of Seyed Ahmed, commonly known as Shah Chiragh, a son of Músá Kázm, the seventh imam of the Shíites. It was built c. 1240 by Atabeg Abu Bekr. Two of Shah Chiragh’s brothers and a nephew also have their graves at Shiraz. Within the town and in close proximity to it are many pleasant gardens (bagh), among them the B. Jaljel Nema (Kerim Khan 1766), where C. J. Rich, the British resident at Bagdad and explorer of Babylon and Kurrashan, died on the 5th of October 1821, and the adjoining B. i Nau (1810); B. i Takhti i Kajar (built 1687 by Atabeg Karajeh under the Seljuk Malik Shah; restored 1754 by order of Agha Mahommed Khan, the first Kajar ruler); B. i Dilgusha (restored 1785), &c. Close to the last-mentioned garden is the Sadiyeh, an enclosure with the tomb of the celebrated poet S’ad, and in a cemetery near the northern side of the town stands the Hafizieh, with the tomb of the likewise celebrated poet Hafiz, a sarcophagus supposed to be the work of Young Wolsey, the poet’s father, but only a very small quantity of it is exported, and religious scruples still prevent its manufacture on a large scale. The climate of Shiraz is agreeable and healthy in the winter, but unhealthy in the spring and summer. July is the hottest month with a mean temperature of 85°F. February the coldest with 47°F. The lowest temperature observed during a number of years was 21°F, the highest 113°F, showing a difference of 92°F between extremes. The mean annual temperature is 65°F. Earthquakes of frequent occurrence; those in modern times which caused great loss of life and destruction of property happened in 1825 and 1853. Shiraz is the residence of a British consul (since 1903) and has post and telegraph offices. On a hill adjoining the Dilgusha garden stand the ruins of an old castle known as Kal’ah i Bender (a corruption of Fahn-dar), with two wells hewn in the rock to a depth of several hundred feet. (A. H.-S.)

SHIRÉ, a river of East Central Africa, the only tributary of the Zambezi navigable from the sea. The Shiré (length about 370 m.) issues from the southernmost point of Lake Nyasa and almost immediately enters a shallow sheet of water called Malombe (Pa-Malome), 18 or 19 m. broad and 12 or 13 m. long. A shifting bar of sand obstructs the end of Malombe nearest Nyasa, but does not prevent navigation. Below Malombe the bed of the Shiré deepens. The river flows through a mountainous country, and in its descent to the Zambezi valley forms rapids and cataracts, rendering its middle course for a distance of 60 m. unnavigable. The most southern and the finest of these cataracts is called the Murchison Cataract or Falls, after Sir Roderick Murchison, the geologist, who identified himself during the mid-Victorian epoch with geographical exploration in Africa. In passing the cataracts the Shiré falls 1100 ft. From the station called Katunga, a short distance below the cataracts, shallow-draught steamers can navigate the river when in flood (January-March) to its junction with the Zambezi, and thence proceed to the Chinde mouth of the main stream. About 130 m. above its confluence with the Zambezi the Shiré is joined from the east by a smaller stream, the Ruo river, whose headwaters rise in Mount Mlanje. At the junction of the Ruo and Shiré is the town of Chirono, and here is an extensive swampy region and game reserve known as the Elephant Marsh. The scenery of the Shiré valley is very picturesque; the slopes of the plateau forming bold, rocky crags overhanging the water. The river is bordered with small islands usually covered by thick grass. A little before the Zambezi is reached the country becomes flat. The Shiré joins the main river in about 35° 25′ E., 17° 50′ S., at a point where the Zambezi is of great width and presents in the dry season many narrow winding channels, not more than 3 ft. deep, with intervening sandbanks.

The lower part of the Shiré is in Portuguese territory; the upper part is in the British Nyasaland Protectorate, to which it
is the natural highway. At the lowest point in British territory, on the west bank of the river, is Port Herald, whence a railway runs past Chiroro to Blantyre. Below Port Herald the Shire is navigable all the way to the sea.

See Zambezi and British Central Africa.

Shire, one of the larger administrative divisions, in Great Britain, now generally synonymous with "county" (q.v.), but the word is still used of smaller districts, such as Richmondshire and Hallamshire in Yorkshire, Northamshire and Hexhamshire in Northumberland. The Anglo-Saxon shire (O. Engl. scir) was an administrative division next above the hundred and was presided over by the earldorman and the sheriff (the shire-reeve). The word scir, according to Skeat (Ejyma Dlt., 1910), meant originally office, charge, and, in its connection with the word scire, to know, and was the root of "scir" in "scirens," the 8th century (Wright-Walker, Anglo-Saxon and Old English Vocabularies, 1884, 40-32) is found procuratio, scir. Skeat compares O. Engl. scirian, to distribute, appoint, Ger. Schirmmeister, steward. The usual derivation of the word connects it with "shear" and "share," and makes the original meaning to have been a part cut off.

Shirley (or Shereley), Sir Anthony (1565-1645), English traveller, was the second son of Sir Thomas Shirley (1542-1612), of Wiston, Sussex, who was a member of parliament, a judge of the navy, and had a set of meritorious and momentous deeds, and who was heavily in debt when he died in October 1612. Shirley's imprisonment in 1603 was an important event as in consequence thereof the House of Commons successfully asserted one of its privileges—freedom of its members from arrest. Educated at Oxford Anthony Shirley gained some military experience with the English troops in the Netherlands and also during an expedition to Normandy in 1591 under Robert Deverie, earl of Essex, who was related to his wife, Frances Vernon; about this time he was knighted by Henry of Navarre (Henry IV. of France), a proceeding which brought upon him the displeasure of his own sovereign and a short imprisonment. In 1596 he conducted a predatory expedition along the western coast of Africa and then across to Central America, but owing to a mutiny he returned to London with a single ship in 1597. In 1598 he led a few English volunteers to Italy to take part in a dispute over the possession of Ferrara; this, however, had been accommodated when he reached Venice, and he decided to journey to Persia with the twofold object of promoting trade between England and Persia and of stirring up the Persians against the Turks. He obtained money at Constantinople and at Aleppo, and was very well received by the shah, Abbas the Great, who made him a mira, or prince, and granted certain trading and other rights to all Christian merchants. Then, as the shah's representative, he returned to Europe and visited Moscow, Prague, Rome and other cities, but the English government would not allow him to return to his own country. For some time he was in prison in Venice, and in 1605 he went to Prague and was sent by the emperor Rudolph II, on a mission to Morocco; afterwards he went to Lisbon and to Madrid, where he was welcomed very warmly. The king of Spain appointed him the admiral of a fleet which was to serve in the Levant, but the only result of his extensive preparations was an unsuccessful expedition against the island of Mitylene. After this he was deprived of his command. Shirley, who was a count of the Holy Roman Empire, died at Madrid some time after 1635.

Sir Anthony's elder brother, Sir Thomas Shirley (1564-1620), was knighted while serving in Ireland under Sir William Fitzwilliam in 1589. In 1601 he was chosen a member of parliament, but his time was mainly passed in seeking to restore the shattered fortunes of his family by piratical expeditions. In January 1603 he was captured by the Turks and he was only released from his captivity at Constantinople in December 1605. One of his sons was Henry Shirley (d. 1627) the dramatist, who was murdered in London on the 31st of October 1627, and one of his grandsons was Thomas Shirley (1638-1678), the physician and writer.

Sir Anthony's younger brother, Sir Robert Shirley (c. 1581-1626), went with his brother to Persia in 1598, remaining in that country when the latter returned to Europe in 1599. Having married a Circassian lady he stayed in Persia until 1606 when the shah sent him on a diplomatic errand to James I. and to other European princes; after visiting Cracow, Prague, Florence, Rome and Madrid, he reached England in 1611 and had an interview with the king. In 1613 he went again to Persia, but in 1615 he returned to Europe and resided for some years in Madrid. His third journey to Persia was undertaken in 1627, but soon after reaching that country he died at Kazvin on the 13th of July 1628.

Sir Anthony Shirley wrote: Sir Anthony Shirley: his Relation of his Travels into Persia (1613), the original manuscript of which is in the Bodleian Library at Oxford. There are in existence five or more accounts of Shirley's adventures in Persia, and the account of his expedition in 1596 in the English print was published in 1614 by R. Holmester. See also The Three Brothers: Travels and Adventures of Sir Anthony, Sir Robert and Sir Thomas Shirley in Persia, Russia, Turkey and Spain (London, 1825); E. P. Shirley, The Shirley Brothers (1849), and the same writer's Stemmata Shirliana (1841, again 1873).

Shirley (or Shereley), James (1596-1666), English dramatist, was born in London in September 1596. He belonged to the great period of English dramatic literature, but, in Lamb's words, he "claims a place among the worthies of this period, not so much for any transcendent genius in himself, as that he was the last of a great race, all of whom spoke nearly the same language, with nearly the same accent, and in all of whom was a combination of qualities which was not in any of the succeeding ages." Shirley's career of playwriting extended from 1625 to the suppression of stage plays by parliament in 1642. He was educated at Merchant Taylors' school, St John's College, Oxford, and Catherine Hall, Cambridge, where he took his B.A. degree in or before 1618. His first poem, Echo, or the Unfortunate Lovers (of which no copy is known, but which is probably the same as Narcissus of 1640), was published in 1618. After proceeding to M.A. he was, Wood says, "a minister of God's word in or near St Albans." In consequence apparently of his conversion to the Roman Catholic faith he left his living, and was master of St Albans grammar school from 1623-1625. His first play, Love Tricks, seems to have been written while he was teaching at St Albans. He removed in 1625 to London, where he lived in Gray's Inn, and for eighteen years from that time he was a prolific writer for the stage, producing more than thirty regular plays, tragedies and comedies, and showing no sign of exhaustion when a stop was put to his occupation by the Puritan edict of 1642. Shirley's sympathies were with the king in his disputes with parliament and he received marks of special favour from the queen. He made a bitter attack on Prynne, who had attacked the stage in Histioriamat; and, when in 1634 a special masque was presented at Whitehall by the gentlemen of the Inns of Court as a practical reply to Prynne, Shirley supplied the text—The Triumph of Peace. Between 1636 and 1640 Shirley went to Ireland, under the patronage apparently of the earl of Kildare. Three or four of his plays were produced by his friend John Ogilby in Dublin in the theatre in W找回r Street, the first ever built in Ireland and at the time of Shirley's visit only one year old. On the outbreak of war he seems to have served with the earl of Newcastle, but when the king's fortunes began to decline he returned to London. He owed something to the kindness of Thomas Stanley, but supported himself chiefly by teaching, publishing some educational works under the Commonwealth. Besides these he published during the period of dramatic eclipse four small volumes of poems and plays, in 1645, 1653, 1655 and 1659. He was a drudge for Ogilby in his translations of the Iliad and the Odyssey, and survived into the reign of Charles II., but, though some of his comedies were revived, he did not again attempt to write for the stage. Wood says that he and his second wife died of fright and exposure after the great fire, and were buried at St Giles's-in-the-Fields on the 29th of October 1666.

Shirley was born to great dramatic wealth, and he handled it freely. He constructed his own plots out of the abundance of materials that had been accumulated during thirty years of unexampled dramatic activity. He did not strain after novelty of situation or character, but worked with confident ease and buoyant copiousness on the familiar lines, contriving situations
and exhibiting characters after types whose effectiveness on the stage had been proved by ample experience. He spoke the same language with the great dramatists, it is true, but this grand style is sometimes employed for the artificial elevation of commonplace thought. “Clear as day” becomes in this manner “day is not more conspicuous than this cunning”; while the proverb “Still waters run deep” is ennobled into—

“The shallow rivers glide away with noise—

The deep are silent.”

The violence and exaggeration of many of his contemporaries left him undamaged, his scenes are ingeniously conceived, his characters boldly and clearly drawn; and he never falls beneath a high level of stage effect.

Shirley's tragedies are: *The Maidens Revenge* (acted, 1626; printed, 1659); *The Trayer* (licensed, 1631; printed, 1635), which Dyce reckoned as Shirley's best tragedy; *Love's Cruelty* (1631; printed, 1640); *The Duke's Mistake* (acted, 1636; printed, 1638); *The Politician* (acted, 1639; printed, 1655); *The Cardinal* (acted, 1641; printed, 1652), a good example of Shirley's later style, and characterized by Edmund Gosse as perhaps the last great play by the giants of the Elizabethan age. His comedies are: *Love Tricks, or the School of Complement* (licensed, 1625; printed under the latter title, 1631); *The Wedding* (licensed, 1626; printed, 1630); *The Comely Mistakes* (acted, 1630; printed, 1632); *The Winter's Tale* (acted, 1628; printed, 1632); *The Grateful Servant* (licensed in 1626 as *The Faithful Servant*; printed, 1630); *Changes: Or Love in a Maze* (acted, 1631; printed, 1637); *The Ball* (acted, 1637; printed, 1639); *The Bird in a Cage* (acted and printed, 1633), ironically dedicated to William Prynne; *The Young Admiral* (licensed, 1633; printed, 1637); *The Gnome's Speech* (acted, 1637), apocryphal and unconnected with the command of Charles I. who is said to have invented or proposed the plot; *The Example* (acted, 1634; printed, 1637); *The Opportunity* (licensed, 1634; printed, 1640); *The Coronation* (licensed, 1635, as his, but printed, 1640, as by Fletcher); *The Lady of Pleasure* (licensed, 1635; printed, 1637); *The Constant Maid*, of love will find out the way, printed in 1640 under the former title with St Patrick for Ireland; *The Royal Master* (acted and printed, 1638), an excellent comedy of intrigue, with an epilogue addressed to Strafford; *The Doublet Heir* (printed, 1652), licensed as Rosamia, or Love's Victory in 1640; *The Gentleman of Venice* (licensed, 1669; printed, 1675); *The Despots* (acted and printed, 1673); *The Sisters* (licensed, 1642; printed, 1653); *The Humorous Courtesys* (perhaps identical with *The Duke*, licensed, 1631), printed, 1640; *The Court Secret* (printed, 1653). Poems (1646), by James Shirley, contained “Narcissus,” and a masque dedicated to the Judgment of Paris, entitled *The Triumph of Beauty*. A Contention for Honour and Riches (1633) appeared in an altered and enlarged form in 1659 as *Horatio and Mammon*. In 1653 a selection of his pieces was published as Six New Plays. He wrote the magnificent entertainment presented by the members of the Inns of Court to the king and queen in 1633, entitled *The Triumph of Peace*, the scenery being designed by John Aikin and the costumes by W. Lavender and the Ives. In this kind of composition he had no rival but Ben Jonson. *His Contention of Ajax and Ulysses* (printed, 1659) closes with the words: “Thus ends the story of a day in the life of W. Lavender and the Ives.”

The standard edition of Shirley's works is *The Dramatic Works and Poems of James Shirley*, with Notes by William Gifford, and Additional Notes, and some Account of Shirley and his Writings, by Alexander Dyce (6 vols., 1813). A selection of his plays was edited (1888) for the ”Mermaid” series, with an introduction by Edmund Gosse.

**SHIRLEY, WILLIAM** (1604-1771), colonial governor of Massachusetts, was born at Preston in Sussex, England, on the 2nd of December 1604. He studied law, entered the Middle Temple, emigrated to Massachusetts in 1731, was appointed "surveyor and governor-general of the Province of New England except Connecticut" in 1734, and in 1741, while representing Massachusetts in a boundary dispute with Rhode Island, was appointed governor. His efforts to secure a permanent fixed salary for himself (of $1000) were unsuccessful; and his attempt to prevent the further issue of paper money also involved him in a controversy with the General Court; but their relations were not unfriendly after 1743. The most important event of his administration was the conquest of Louisburg in 1745. The expedition was undertaken on his suggestion and its success was largely due to his energy and enthusiasm: in September 1740 $183,650 (English) in coin was brought to Boston to cover the outlay of Massachusetts, and largely through Shirley's influence this was used for the redemption of outstanding paper money, thus re-establishing the finances of the province, a subject to which Shirley had given much attention. Both in the colonies and in England, whither he returned in 1749 on leave of absence, Shirley kept up an active agitation for the expulsion of the French from the whole of Canada. He went back to Massachusetts as governor in 1753; led an unsuccessful expedition against Fort Niagara in 1755, and after the death of General Edward Braddock (1775) until June 1756 was commander-in-chief of all the British forces in America. In September 1756 he was recalled to England and was succeeded as governor by Spencer Phips. He was governor of the Bahamas until 1770, then again returned to Massachusetts and died at Roxbury on the 24th of March 1771. He published a Journal of the Siege of Louisbourg (1745), and *The Conduct of General William Shirley Briefly Stated* (1758).

**SHIRREFF, EMILY ANNE ELIZA** (1814-1897), English pioneer in the higher education for women, was born on the 3rd of November 1814, the daughter of a rear-admiral. Both she and her sister Maria (Mrs William Grey) took a keen interest in bettering women's equipment for educational work, and, in 1858, she published *Intellectual Education and its Influence on the Character and Happiness of Women*. Before that the sisters had written in collaboration a novel, *Passion and Principle* (1841), marked with that serious sense of the deficiencies in women's education, to remedy which they did so much, and *Thoughts on Self-Culture addressed to Women* (1859). In 1856 Emily Shirreff was for a short time honorary mistress of Girton College, and she served for many years on the council of that institution and of the Girls' Public Day School Company. She took a leading part in establishing and developing the Maria Grey Training College for teachers and in the work of the Practical Education Society, of which she was the president. She was a firm believer in Froebel's system and wrote a short memoir of him, and several books on kindergarten methods. She died in London on the 20th of March 1897.

**SHIRT,** an undergarment of linen, silk, cotton and flannel for the upper part of the body, usually only applied to such a garment worn by men, though the term is becoming common as used of a plain form of blouse worn by women, the American "shirt-waist." The word is apparently Scandinavian in origin and is an adaptation of the Icel. *skyrt*, Dan. *storte*, properly a short garment, and is derived from the root *skir*—to cut off; it is cognate with Ger. *Schürz*, apron, and the same root is seen in "short," "sheer" and "skirt;" the last word is now used of that part of a woman's garment which reaches from the waist to the feet, but properly means the lower part of the shirt, hence, edge, border of anything.

**SHIRVAN,** a small district of the great province of Khorasan in Persia, N.W. of Meshed and W. of Kuchan. It is under the (acted, 1626) government of Khazaristan, and comprises the towns of the same name and twelve villages with a population of 12,000. It produces cotton, wheat and a little silk. Shirvan, the capital, is situated on the river Atrek, in 37° 24' N., 59° 56' E. at an elevation of 3,500 ft. Its inhabitants are of the Turkish Garal' tribe and number about 7,000. There are post and telegraph offices.

**SHOA,** the southern of the three principal provinces of the Abyssinian empire. Shoa from about the middle of the 10th century till nearly the close of the 13th century was the residence of the Abyssinian sovereigns, who had been driven out of Axum, their former capital. About 1528 Shoa was conquered by Mahommadian invaders and was for over a century afterwards a prey to Galla raiders. In 1682 it was reconquered by an Abyssinian chief, but remained independent of northern Abyssinia until 1825 when the emperor Theodore reduced it to submission. In 1880 Menelik II., king of Shoa, on the death of the emperor John, made himself master of the whole of Abyssinia. The capital, Adis Ababa (q.v.), is the seat of government for the whole empire (see Abyssinia).

**SHOCK,** or Collapse, in surgery, the enfeebled condition of body which comes on after a severe physical injury, such as a blow upon the head or a kick in the abdomen, or as the result of grievous mental disturbance, as on seeing a ghastly sight or
SHODDY—SHOE

hearing sad news. It is the condition which the prize-fighter desires to inflict upon his adversary by giving what is called the "knock-out blow" upon the point of the jaw, over the heart or in the lower part of the chest. In severe shock the individual falls "all of a heap," as the saying is, which is exactly expressed by the word "collapse" (\textit{colapsus, collabor}, fall in ruins). The explanation of the condition is that the heart is suddenly deprived of its power to pump blood up to the brain which, like the face itself, is left anaemic and has no power to send out control to the muscles. The blood at once sinks into, and remains stagnant in, the large veins of the abdomen. And inasmuch as the condition of collapse is due to anaemia of the brain, it is met with in the cases of shock where the shivering is so violent that the blood circulation has been sustained, as in the "flooding" of child-bed, the giving way of an aneurism, or the opening of some large blood-vessel. It may also supervene on the rupture of a gastric ulcer, and is then the result of the injury to which the network of nerves in the interior of the abdomen has been subjected by the sudden escape on to them of the contents of the stomach.

In severe shock the patient is pale, and bathed in clammy perspiration; his sensibility is blunted; his pulse is small and weak, sometimes indeed, it is imperceptible, and even on laying the ear to it the heart, no cardiac impulse may be felt. The person is unable to make any exertion, but lies indifferent to external circumstances, and can be roused only with difficulty or not at all. He complains of a feeling of cold, and he may have a distinct shivering. These symptoms may continue for some hours. The first evidence of improvement is that he shifts his position, becomes restless and complains of the injury. Perhaps he vomits. The pulse becomes stronger, and he then passes from the state of shock into that of reaction. If the improvement continues, recovery takes place; but if it is only transient, he sinks back again into a drowsy condition, which may end in death, for it must be clearly understood that shock may end fatally. Sometimes there is no rallying, death following the injury immediately. In cases where there is no reaction, the patient gradually becomes weaker, and his pulse feeble, till death ensues. Shock is due to an impression conveyed to the medulla oblongata, by which the nerve-centres are so affected that a partial paralysis of the voluntary and involuntary muscular fibres in the body takes place, the patient being, perhaps, unable to lift his arm or move his leg. The respiratory functions are performed wearily, and the muscle of the heart contracts feebly. The walls of the blood-vessels lose their tonicity and the vessels dilate, the blood collecting in the large venous trunks, more especially of the abdomen. The vessels of the skin being emptied of blood, marked pallor ensues. The heart beats feebly because its nervous energy is lowered, and because it has not a sufficient quantity of blood upon which to act. An understanding of these facts gives the general indications for treatment, which comprise external stimulation over the heart by mustard poultices or turpentine stupes; elevation of the limbs—to cause the blood to gravitate towards the heart, and so to the brain; manual pressure on the abdominal cavity from below upwards—to encourage the flow of blood from the overloaded abdominal veins into the heart. In urgent cases an injection may be given into the veins of warm water in which table salt (60 grains to a pint) is dissolved. These different measures may be supplemented by the administration of stimulants by the mouth, or, if the patient cannot swallow, by subcutaneous injection of brandy, ether or a solution of strychnine. In all probability many men have been left for dead upon the field of battle who were only in a state of extreme collapse; in the future many such cases will be saved by the prompt injection of ether over the region of the heart.

In syncope from mental emotion the weakened heart cannot drive a sufficient quantity of blood to the brain; the patient feels dizzy and faint, and falls down insensible. The condition is transitory and the remnant posture, assisted if need be by elevation of the limbs, causes the blood to gravitate to the heart, which is thereby stimulated to contract. A sufficient quantity of blood is then driven to the brain, and the insensibility passes off. If the patient is in the sitting posture when he feels faint, his head should be depresed between the knees, which will cause the blood to flow to the brain, and the faintness will pass off. Otherwise he should be laid flat on his back, his head being kept low. When a collapsed person is put to bed, no pillow should be allowed, and the foot of the bed should be raised above the level of the head.

(E. O.*)

**SHODDY**, in origin probably a factory term and first applied to the waste thrown off or "shed" during the process of wool manufacture. It is now the name given to a special type of fabric made from remanufactured materials, \textit{i.e.} materials which have been torn up or "ground up"—as this operation is termed technically—into a fibrous mass, and respun and rewoven. The term "shoddy" is sometimes applied to all fabrics made of such remanufactured materials, of which there are many types, such as "mungos," "extracts," "flocks," \&c., but strictly it should be confined to a cloth produced from fabrics originally made from English and the longer cross-bred wools. Mungo is produced from fabrics originally made from Botany and short fine wools; extract is the wool fibre obtained from goods originally made from mungo yarn, and which has been "extracted" by sulphuric acid or some other agent; and flock mostly comes from milling, raising and cropping machines. There are some few other particular types of minor importance.

The operations of converting rags, tailors' clippings, \&c., into these remanufactured materials are as follows: dusting, to render the subsequent operations as healthy and agreeable as possible; seaming \textit{i.e.} taking out every little bit of sewing thread (unless the rags are for extracting) in order that a good "spin" may result; sorting into the various qualities and colours; oiling, to cause the fibres to glide upon one another, and thus separate so far as possible without breakage; and finally grinding, \textit{i.e.} tearing up into a fibrous mass which may be readily spun into threads. The last-named operation is usually spoken of as "grinding," but really it is anything but grinding, being more of a teasing-out operation, the object being to preserve the length of the fibre so far as possible. The remanufactured materials are necessarily very short in fibre, so that it is usually necessary to mix, \textit{i.e.} "blend," some better material with them to carry the bulk through the machines into the yarn. With this object in view, sometimes good wool or mulls (the short from combing), but more often cotton, is employed. The yarns thus spun are in the majority of cases woven into pieces as weft yarns, the warps usually being cotton; but there are some exceptions, a really good mungo blend being readily woven as warp.

Upon the whole the "cheap and nasty" idea usually associated with the term "shoddy," in reference to these remanufactured materials, is quite a mistake. Some most excellent cloths are produced, and when price is taken into consideration it must be conceded that the development of this industry has benefited the working classes of Great Britain and other countries to a remarkable extent. Many are now well clothed, who, without the advent of the remanufactured materials, would have been clothed in rags.

**SHOE** (a word appearing in the Teutonic languages in various forms, as Ger. \textit{Schuh}, Swed. and Dan. \textit{sko}, sometimes supposed to come from an unknown root \textit{sha} or \textit{sko}, cover), a covering for the foot. The simplest foot-protector is the sandal, which consists of a sole attached to the foot, usually by leather thongs. The use of this can be traced back to a very early period; and the sandal of plaited grass, palm fronds, leather or other material still continues to be the most common foot-covering among oriental races. Where climate demanded greater protection for the foot, the primitive races shaped a rude shoe out of a single piece of untanned hide; this was laced with a thong, and so made a complete covering. Out of these two elements—SOLE without upper and upper without sole—arose the perfected shoe and boot, consisting of a combination of both. The boot
proper differ from the shoe in reaching up to the knee, as exemplified by such forms as jack-boots, top-boots, Hassian boots and Wellington boots, but the term is in England now commonly applied to "half-boots" or "ankle-boots" which reach only above the ankle. A collection illustrating the numerous forms and varieties of foot-covering, formed by Jules Jacquemart, is in the Cluny Museum in Paris.

**Wooden Shoes.**—The simplest foot-covering, largely used throughout Europe, is the wooden shoe (sabel) made from a single piece of wood roughly cut into shape. This is still in use in the midland counties of England. Clogs, known also as pattens, are wooden soles to which shoe or boot uppers are attached. Sole and heel are made of one piece of wood and being made quite thick, and a little longer and broader than the desired size of shoe. The outer side of the sole and heel is fashioned with a long chisel-edged implement, called the clogger's knife or stock; a second implement is used to round the grainings at the edges, which are an inch deep and wide round the side of the sole; and by means of a hollower the contour of the inner face of the sole is adapted to the shape of the foot. The upper of heavy leather, machine sewed or riveted, are fitted closely to the groove around the sole, and a thin piece of leather-binding is nailed on all round the edges, the nails being placed very close, so as to give a firm durable fastening. These clogs are of great advantage to those who work around horses or mules, and being made of the best and highest grade of fir wood, are light, strong, and easily kept clean. Of late years, the soles have been raised above a quarter of an inch for the comfort of the wearer. When both the upper and sole are completed, the whole is turned over and an arch is sawed into the inside of the sole, and this arch is hinged to the shoe by a piece of leather. Wellingtons and riding boots are also made of wood, and are used by the sandy ground in the counties of Essex, Hants, and Surrey. The American federal army in 1803, adopted the wooden shoe to prevent the treading of the soles on the sharp stones in the mountains. The wood is now mostly used for soldier's marching shoes, and is also invaluable for the making of horse-shoes.

**Manufacture of Leather Shoes.**—There are two main divisions of work comprised in ordinary shoe-making. The minor division—the making of "turn shoes"—embraces all work in which there is only one thin flexible sole, which is sewed to the upper while outside in and turned over when completed. Slippers and ladies' thin house-boots are examples of this class of work. When the divisions of the upper are united to an insole and at least one outside, with a raised heel, this is comprised in the main class, and includes all work done in the factories, and is equal to the production of machinery. The shoemaker after measuring the feet, cuts the upper leather according to the size and pattern. These parts are fitted and stitched together by the "rigging" machine. When the parts of the upper have been united, and the edges trimmed to the utmost precision, the shoe is now done by hand. The sole "stuff" is then cut out and assembled, consisting of a pair of innersoles of soft leather, a pair of outer soles of firmer texture, a pair of welt or bands about 1 in. broad, of flexible leather, and long and short pieces for the insole seams. These the "maker" lowers by steeping in water. He attaches the insoles to the bottom of a pair of wooden lasts, which is modelled to the exact size of the boots to be made, fastens the leather down with lasting tacks, and, when it is dried, draws it out with the innersoles till it takes the exact form of the last. There are three methods for doing this: the so-called "rilling," or "screwing," has come into extensive use since the standard screw machine was introduced in America by the McKay Sewing-Machine Association, of Boston, Massachusetts, and in Europe by the Blakes and Goodyear Company, of London. The standard screw machine, which is an American invention, though the idea was anticipated by a Frenchman named Blanchon in 1856, is provided with a reel of screws-threaded brass wire, which by the revolution of the reel is inserted into and screwed through outsole, upper edge and insole. Within the upper a head presses against the insole directly opposite the point of the screw, and the instant screw and head touch the insole, the screw is drawn tightly in the leather and the innersole, and they add materially to the durability of the soles. The principal disadvantage of the use of standard screwed soles is the great difficulty met with in removing or levelling down the remains of an old sole, unless new innersoles are fitted.

The various forms of sewing-machine by which uppers are closed, and their important modifications for uniting soles and upper, are described in the following article. But the first suggestion of machine sewing was an English idea. The patent secured by Thomas Saint in the English Patent Office in 1796, while it foreshadowed the most important features of the modern sewing-machine, indicated more particularly the devices now adopted in the sewing of leather. After the introduction of the sewing-machine for cloth work its adaptation to stitching leather both with plain

thread and with headed waxed thread was a comparatively simple task. The first important step in this more difficult problem of sewing together soles and uppers by a machine was taken in the United States by Lyman R. Blake in 1856. Blake's machine was ultimately perfected by the McKay Company and became almost immediately the most successful and lucrative inventions of modern times. Blake secured his first English patent in 1859, his invention being thus described: "This machine is a chain-stitch sewing-machine. The holes or notches are made by a needle running outwards from any part of the interior of the machine or carrying round the toe of a shoe; but a principal interest in it is the discovery of Gordon McKay (1821-1903), in conjunction with Blake effecting most important improvements in the mechanism, and they jointly in 1860 procured United States patents which secured to them the monopoly of wholly machine-made boots and shoes for a period of twenty-one years. On the outbreak of the Civil War in America a great demand arose for boots and, and, there being simultaneously much labour withdrawn from the market, a profitable field was opened for the use of the machine, which was now capable of sewing a sole right round. Machines were leased out to manufacturers by the McKay Company at a royalty of from 3d to 3 3/4 cents on every pair of soles sewed, the machines themselves registering themselves alone. The income of the association from royalties in the United States alone increased from $38,746 in 1863 to $589,073 in 1873, and continued to rise till the main patents expired in 1884, when they were in use in the United States about 1800. Blake-McKay machines sewing 50,000,000 pairs of boots and shoes yearly. The monopoly secured by the McKay Company barred for the time the progress of invention, but still many other sole-sewing machines were patented. Among the most important of these is the Goodyear welt machine—the first mechanism adapted for sewing soles on lasts and boots and shoes. This mechanism originated in a patent obtained in 1862 in the United States by August Destory for a process whereby leather soles were made. Blake-McKay was successful until then in hand by Charles Goodyear, son of the well-known inventor in indiarubber fabrics. This device was first applied in the process of sewing of the Goodyear machines, and the machine now is capable of sewing a sole right round, which sewed with a chain-stitch from the channel of the sole through the welt and upper, and a little later still it was followed by the "rapid outsole lock-stitch machine," which united the outsole with the welt through the same mechanism. Improvements have continually effected in the Goodyear system and numerous accessory mechanisms have been brought out, until there is now not a single operation necessary in shoemaking, however insignificant, for which machinery has not been devised. In consequence the range of machines employed in a modern shoe factory is very extensive, the various operations being highly specialized, and there being minute subdivision of labour. Through the fundamental principles were not in all cases of American origin, American inventors were foremost in developing such machinery, and America took the lead in employing it to the supersession of handwork in shoemaking. When English makers, in about the seventh or eighth decade of the 19th century, were forced by the pressure of economic necessity to do the same, they found that the suitable machinery was controlled by American makers, from whom therefore they had to hire it on the payment of royalties and under stringent conditions which rendered it difficult for them to use machines of any other maker, even if available, on pain of the whole plant being stripped from their factories. The British United Shoe Machinery Company, the English branch of the United Shoe Machinery Company, of Boston, Mass., thus maintained a practical monopoly of the supply of machinery for shoemaking in Great Britain. However, by the opening of the 20th century English makers began to assert themselves and to show that they could produce machines able to compete effectively with those from America. The loosening of the American monopoly thus began was asked by the Patent Act of 1907, section 27 of which provided that a patent may be revoked if the article is not manufactured "to an adequate extent" in Great Britain. The McKay machine (first manufactured in America), while section 38 prohibits the insertion in a lease of conditions excluding the lessee from using articles or processes not supplied or owned by the lessor.

Rubber Shoes.—The manufacture of indiarubber galoshes,1 shoes, fishing boots, &c., forms an important branch of the indiarubber industry, especially in America, where rubber overshoes, colloquially known as "rubbers," are extensively worn, and where fully 1000 different shapes and sizes are said to be produced. A so-called 1833 the Roxbury India Rubber Company was constituted to work the discovery that indiarubber dissolved in turpentine and mixed with lampblack formed a varnish which gave a hard waterproof surface when applied to leather, but the process failed because the varnish melted with heat and cracked with cold. This defect was remedied by Charles Goodyear (1800-1860), who found that when sulphur was combined with the rubber by the aid of heat the product ("vulcanized rubber") was not only stronger but retained its elasticity through a wide range of temperature. His patent, taken out in 1844, was the foundation of various American rubber industries including that of rubber boots and shoes. Guttapercha has also been used instead of leather for the outer soles of boots.

SHOE-BILL, a huge African bird from the White Nile, the *Balaleiceps rex* of ornithology, now regarded as a giant heron. It was first brought to Europe by M. Parkyns and described by J. Gould in the Zoological Proceedings (1851, pp. 1, 2, pl. xxxv.)

As an abnormal pelican. This view was disputed by Reinhardt (op. cit. 1860, p. 377), and wholly dispelled by W. K. Parker in the Zoological Transactions (iv. pp. 269-351), though these two authors disagreed as to its affinities, the first plac ing it with the storks, the last assigning it to the herons. In singularity of aspect very birds surpass *Balaleiceps*, with its gaunt grey figure, some 5 ft. in height, its large head surmounted by a little curled tuft, the scowling expression of its eyes and its huge bill in form

---

1 The galosh or galosh was originally a wooden shoe or clog, but later came to mean an overshoe (cf. R. Holme, *Armoury*, 1685: "Galoshes are false shoes, or covers for shoes"). The word is adapted from the French galoch, from Low Lat. *galaedepium*, a wooden shoe, Gr. *kaloskopion*, shoemaker’s last, from κέλος, wood, and ποός, foot.
not unlike a whale's head—this last suggesting its generic name—but tipped with a formidable hook. The shape of the bill has also prompted the Arabs to call it, according to their idiom, the “father of a shoe.” It forms large flocks and frequents dense swamps. The flight is heron-like, and the birds settle on trees. The fish is edible, and so is the flesh, especially when smoked. It is a fat fish in the earth, roughly limed with herbage, and from two to twelve chalky white eggs are laid. (A.N.)

**SHOEBURYNESS**, a promontory on the coast of Essex, England, the point at which the coast-line trends north-eastward from the estuary of the Thames. It gives name to a school of gunnery, where officers are instructed and experiments carried out. The railway station (39 m. E. from London, the terminus of the London, Tilbury and Southend railway) bears the same name, but the parish is South Shoebury; North Shoebury is a parish situated nearer to Southend-on-Sea. The church of St. Andrew retains some ornate Norman work, but is mainly a Perpendicular reconstruction. On the seaward side of the Ness there is a large ancient earthwork which is attributed to the Norsemen through a reference in the Saxon Chronicle (894) under the name Scoeburg. The parish is in the S.E. parliamentary division of the country. Pop. (1901) 4681.

**SHOFAR, SHOOFAR or SHOFER**, the ancient ram's horn trumpet of the Hebrews, sometimes also translated cornet in the English Bible. The shofar consisted of a natural horn turned up at the bell end, and, having a short conical bore of very large calibre, it would be capable of producing at most the fundamental octave and twelfth. The shofar has continued in use in the Jewish synagogue until the present day, being blown with great solemnity once every year at the impressive service held on the Day of Atonement. The shofar was more generally used by the Israelites than the other horn Kerem, and although figuring largely as a signal instrument in battle, and used for rousing the people against the foe, it can hardly be regarded as a military instrument, but rather as the token of God's presence in their midst, to give them the victory as in the case of Joshua and Gideon. It was the shofar that was used to call the people together on a solemn feast day (Ps. lxxx. 3). (K.S.)

**SHOGUN** (Japanese for “generalissimo”), in Japan, originally merely the style of a general in command in the field, a title which only gradually came into existence at the beginning of the 8th century, the mikado himself having previously been regarded as the only authority. The rise of a military class and of shoguns (generals) was development connected with it, and this development culminated in 1192 in the supremacy between the Minamoto and Taira clans (see JAPAN: History). In 1192 the emperor Takahira made the Minamoto leader, Yoritomo, a Sei-i-tai-shogun (“barbarian-subjugating generalissimo”) or general-in-chief, and this office became stereotyped in the hands of successive great military leaders, till in 1603 Lyéyasu Tokugawa became shogun and established the Tokugawa dynasty in power. The shogunate from that time till 1867 exercised the de facto sovereignty in Japan, though in theory subordinate to the mikado. The revolution of 1867 swept away and abolished the shogunate and restored the mikado’s supreme authority.

The term “Tycoon,” which was commonly used by foreigners in the 19th century, is merely a synonym for shogun, being the English rendering of the Japanese taito or taikun, “great lord.”

**SHOLAPUR**, a city and district of British India, in the Central division of Bombay. The city is 164 m. S.E. from Poona by rail. Municipal area, about 8 sq. m.; pop. (1901) 75,288. Since 1877 it has ceased to be a military cantonment. Its great fort, of Mahommedan construction, dates from the 14th to 17th centuries. The large bazaar is divided into seven sections, one of which is used on each day of the week. There are two municipal gardens, with fine tanks and temples. It is an important centre of trade, with three cotton mills.

The District of Sholapur has an area of 4,524 sq. m. Except in Karmala and Barsi subdivisions, in the north and east, where there is a good deal of hilly ground, the district is generally flat or undulating; but it is bare of vegetation, and presents everywhere a bleak treeless appearance. The chief rivers are the Bhima and its tributaries—the Man, the Nira and the Sina—all flowing towards the south-east. Lying in a tract of uncertain rainfall, Sholapur is peculiarly liable to seasons of scarcity; much, however, has been done by the opening of canals and tanks, such as the Ekruk and Ashit tanks, to secure a better supply of water. The rainfall is considerable, the largest irrigation work in the Deccan. In 1901 the population was 720,977, showing a decrease of 4% in the decade. The principal crops are millet, pulse, oil seeds and cotton. There are manufactures of silk and cotton cloth, and blankets. The chief trading mart is Barsi. Pandharpur is a popular place of pilgrimage. The Great Indian Peninsula railway runs through the district, with a junction for the Southern Maharratt railway, and another junction for the Baris light railway, recently extended to Pandharpur.

Sholapur passed from the Bahmani to the Bijapur kings and from them to the Mahrattas. In 1818, on the fall of the peshwa, it was ceded to the British, when it formed part of the Poona collectorate, but in 1838 it was made a separate district.

**SHOOTING**, as a British field sport, may be said to have existed for at least two hundred years, though it is only within the last half century that it has attained its present importance. In many parts of Great Britain the importance of the sporting rights of an estate now more than counterbalances its agricultural value, while enormous sums are annually devoted to the artificial production of game. Taking all contingent expenses into consideration, the average cost of every head of game killed may be taken as not less than three shillings. A hand-reared pheasant can scarcely be brought to the gun for less than seven to eight shillings; and these birds in particular—and partridges and wild duck to a lesser, but steadily increasing, extent—are reared in tens of thousands every year. So far, the grousé alone among recognized British game-birds has defied all attempts at artificial production, but it is probable that in course of time this will also yield to the modern taste for big bags.

The enormous head of game now preserved, and the correspondent development of the art of gunmaking, has to a great extent revolutionized the sport of shooting, the modern tendency being all in favour of “driving,” i.e. bringing the game to the sportsman, instead of the sportsman to the game. While this has undoubtedly raised the standard of marksmanship, it has equally deteriorated the exercise of such minor woodcraft as is required for small game shooting under present conditions.

In this article it is only possible to touch on the various forms of the sport of shooting most in vogue. First must be placed grousé-shooting, admittedly the finest form of sport with the gun obtainable in the British Islands. It is customary to speak of this as though it were merely confined to Scotland, but grousé are found in every English county north of the Trent, as well as in Shropshire, Wales and Ireland, while in a good season as many are probably killed in Yorkshire alone as in any two Scotch counties put together. Practically all English grousé are killed by driving, the practice of which is fast extending to Scotland. On the undulating English and Lowland moors this has undoubtedly resulted in largely increasing the stock of grousé, but it is questionable whether it has been equally successful on the more rugged hills of the Highlands. Save in a few specially favoured localities, such as the Moy Hall moors in Inverness-shire, grousé-driving in Scotland has by no means produced the marvellous results achieved on the English moors, while far too many lessees of Scottish shootings resort to the suicidal policy of only driving their birds when the latter have become too wild to lie to dogs. In legat’s days a moor for driving care should be taken to avoid placing a row of butts against a sky line: where possible these should be placed in a depression of the ground, which not only serves to conceal them from the birds, but also ensures higher and more difficult shots. For these reasons, on very flat stretches of ground the butts are sometimes excavated after the manner of a rifle pit with a low parapet, but in the writer’s experience these are not to be specially recommended. It is in all cases advisable to refrain from placing a line of butts on very stony or...
rocky ground, owing to the possibility of an accident from glancing or deflected shot-pellets. Much of the success of a day's grouse-driving depends on the manner in which the drivers are handled, and especially on the "flankers," whose business it is to turn in such birds as show a tendency to break away from the butts.

Some simple rules for the guidance of the shooter may be mentioned in connexion with grouse-driving. He should remain motionless in his butt, without attempting to conceal himself by crouching, until the moment arrives for him to throw up his gun, when he should refrain from dwelling on his bird, or reserving his fire until it is close upon him—the latter a very common error among beginners. An excellent method of determining the range at which to open fire is to mark some conspicuous object, a tuft of heather or a stone, about 40 yards in front of one's butt, before the commencement of the drive. Above all the shooter should concentrate his attention only on birds coming at him, and not concern himself with those that have passed his butt; in nine cases out of ten by the time he has turned to fire they will be 60 or 70 yards away, and the only result of his shot will be to wound, but not kill; apart from the cruelty of such a proceeding, it should be remembered that these "pricked" birds are a fruitful source of grouse disease. A good retriever is essential to enjoyment in grouse-driving, where only a limited time is available for picking up dead birds. The modern fashion is in favour of spaniels for this work, but a large wavy-coated retriever is usually preferable, as being less likely to tire or "potter." It is customary on some moors to burn the heather round the butts with a view to facilitating the recovery of dead birds, but this has also the disadvantage of rendering the butts more conspicuous to the grouse, which soon come to know the dangerous zone. In August grouse can be driven without much difficulty, but later in the season, and especially in a high wind, pack after pack will go straight back over the beaters' heads sooner than face the guns. Enormous bags of driven grouse are occasionally made on the Yorkshire moors. During the season over 1300 brace have been killed in a single day at Broomhead near Sheffield, and there are several other well-known moors where, in a good season, 1000 brace are obtainable in a day's shooting. Grouse driving is believed to have been first practised in a very modified form on the English moors as early as 1805, but its usage did not become general until fifty or sixty years later.

Grouse-driving over dogs, though lacking the excitement of grouse-driving, and not requiring the same high standard of skill in shooting, is none the less incomparably the higher form of sport. Owing to the almost universal wildness of all modern game-birds, its general practice is now almost entirely confined to the Highlands, where, especially on the western seaboard, grouse will lie to dogs practically throughout the season. Except on very ill-watered moors, where they suffer more than other breeds of dogs from thirst, large big-boned setters are preferable to pointers for grouse-shooting, as the latter are more easily affected by cold and damp, and in the writer's experience are more easily fatigued. Care should of course be taken always to work one's dogs up wind when possible, and in hot, still weather to beat the higher ground thoroughly, with a view to killing down the old cocks and barren hens which resort there. In stormy weather grouse naturally seek the lower slopes of the moors.

Partridge-shooting over dogs is a most delightful form of sport, popularly supposed to be extinct nowadays, but there are happily many parts of England where it is still practised in suitable localities. None the less, modern agricultural practices do not lend themselves to the use of dogs in partridge-shooting, and the most general custom is to drive the birds off the pastures and stubbles into the root crops where they can be walked up in line, a rather uninteresting method of shooting. Care should of course be taken always to walk across the drills; and where birds are wild, and time does not press, it will occasionally be found advantageous to work a field in a series of gradually diminishing circles. Much valuable time is often wasted in partridge-shooting in the search for dead and wounded birds; this can be obviated to a large extent by observing the golden rule that as soon as a bird is down the line should halt, and the dogs, whose business it is to retrieve the game, be allowed to do so, unassisted—or more correctly unhampered. A retrieves bird cannot be found within a small time, and this should proceed, leaving a keeper and a steady dog behind to search for it. Where game is plentiful it is always advisable to employ one man with a couple of retrievers for the sole purpose of remaining behind the line to retrieve lost or running birds. As with all game, the modern tendency is to drive partridges: a form of shooting that of all others exacts the highest test of skill, not only on the part of the shooter, but also of the keeper who organizes the proceedings. To these requirements must be added a suitable tract of country for the purpose, and a large head of game; given all these essentials, partridge-driving is a delightful amusement; without them it is usually a fruitless and wearisome undertaking.

In driving, the birds should be gradually and quietly collected into one large root-field, and sent from this over the guns, who should, when possible, always be placed in a grass-field where dead or wounded birds are more easily retrieved. Another field of roots should be at a convenient distance behind the guns for the purpose of gathering the birds, which, unless the wind be specially unfavourable, can then be brought back to them in a return drive. Long drives are not advisable; the more partridges can be kept on the wing, and the coves broken up, the better. Where partridge-driving is carried on on a large scale, it is a good plan to supplement such hedge-rows as are convenient for the purpose by narrow belts of coniferous trees. These, if wired in to prevent disturbance by foxes, dogs, &c., not only provide admirable nesting-ground for winged-game, but afford better concealment for the guns, and cause the partridges to offer higher and more attractive shots. In shooting driven partridges, the sportsman should stand as far as practicable to the side of the line and concentrate his attention on the bird which first tops it. A driven grouse or rocketing pheasant will fly straight towards the shooter without swerving when he raises his gun, but not so the partridge, which can twist in the air almost like a snipe; it is this peculiarity, coupled with their startling scream, that proves so disconcerting to the young sportsman. Especial care should always be taken that the guns stand in a perfectly straight line within sight of one another: neglect of this precaution has often led to serious accidents.

Frequent changes of habit is beneficial on estates where a large head of partridges is preserved, and it is advisable to kill off superfluous cock-birds before the commencement of the breeding-season, though when partridges are reared artificially a better plan is to catch them alive, and use them as foster-mothers, a duty they perform admirably.

The pheasant, once one of the rarest British game-birds, has now, thanks to artificial production, become almost the commonest, and to shoot it over dogs among the hedge-rows in October, as was formerly the practice, would be a manifest absurdity. Under modern conditions it can only be dealt with satisfactorily as a "rocketer," i.e., a bird flying high and fast towards the shooter. As such, the pheasant has no superior, provided only it fly high and fast enough, but otherwise it is a rather uninteresting sporting-bird which invariably elects to seek safety by running rather than flight. Like the modern pheasant itself, the rocketer is a more or less artificial creation, and considerable organization is necessary to produce it in perfection. It is only of late years that keepers have recognized that sportsmen place little value on the mere multitude of a day's bag, as compared to the difficult or "pretty" shots they may obtain. Much, therefore, depends on the management of covert-shooting, the handling of the beaters, the disposition of the "stops," and the pains taken to ensure high-flying pheasants, or the reverse. When the configuration of the coverts permits of it, pheasants should always be driven down-hill to the guns; on flat ground the latter should stand at such a distance from the covert-side as to permit
the birds to rise high, and get well on the wing. This is sometimes attained by cutting away the undergrowth at the end of the covert where it is purposed to flush the birds, but this is also liable to make them break back over the beaters. Where pheasants exist in large quantities, "false coverts" of tree or fat lopping should always be placed at the flushing-point; the birds should be collected as quietly as possible in these, and then sent forward over the guns in small quantities at a time.

Of other recognized British game-birds—as distinct from wildfowl—it is only necessary to dwell on the most beautiful of them all, black-game. These, though far more widely diffused than the red grouse, are not nearly so numerous. This is possibly due to altered agricultural conditions, the laying to pasture of much of the arable land which formerly fringed the Lowland moors, and the consequent surface-drainage which is responsible for the destruction of many young birds; but the chief cause lies in the wholly inefficient close-time afforded, which should be extended by at least a month. Black-game and grouse-shooting differ in no way in their methods, though the former are far more difficult birds to handle by driving, while really fascinating sport can be obtained by stalking the old cocks with a miniature rifle.

Plumage: black-game are practically confined to the summits of the higher Scottish hills, which are usually reserved for deer-forests, and, therefore, offer no opportunity for sport. Shy game, they may correctly be described as autumn and winter migrants to them. The varieties then to be shot are the full-snipe, the jack-snipe and the great or solitary snipe; but the latter is exceedingly rarely met with, and the jack-snipe is becoming scarcer every year. Neither of these latter varieties breeds in the United Kingdom. Snipe are exceedingly erratic in their movements, which are largely influenced by the weather; like the woodcock they are here to-day and gone to-morrow. They haunt moor, or marshy localities, and the finest snipe shooting in the British islands is to be found on the Irish bogs. In hard frost they should be sought near running water. As a general rule a dog is not used to find snipe, but where this may be considered necessary, a well broken Irish water-spaniel is to be recommended. These are the most intelligent of dogs, can be trained to point and retrieve as well, and are capable of standing wet and cold with impunity. It is a generally accepted axiom that snipe should be walked up, down wind, since they offer an easier mark when rising against it, but in the writer's experience this is more than counterbalanced by the fact that snipe, which are particularly susceptible to noise, lie far better when approached up wind. To kill snipe well is the most difficult knack in shooting, and one to which few men, however good shots they may be at other forms of game, rarely attain.

Woodcock are rarer birds than snipe, and even more erratic in their movements. Large quantities of them usually arrive in England with the first November combination of an easterly gale and a full moon, but they cannot be depended on to stay more than a few hours in the locality where they alight. In Ireland, however, they are far more constant in their habits, and it is here that the largest bags of woodcock are made in the United Kingdom. Though woodcock are properly forest, or covert-haunting birds, in many parts of Ireland and the Western Highlands of Scotland they frequent the open bogs and moors, where they are shot over pointers or setters. Otherwise no particular rules can be laid down for their pursuit, beyond the fact that they are very conservative in their choice of a haunt, and that year after year cocks may be found in the same spot. Woodcock are usually esteemed difficult birds to shoot, but more are missed from over-sagerness on the part of the shooter than from the difficulty of the shot they present. Still in thick covert they undoubtedly require a quick hand and eye acting in unison, to kill them neatly and promptly.

Of quadrupeds or ground-game, only three varieties, the roe-deer, the hare and the rabbit, are preserved for sport with the shot-gun in the United Kingdom. The roe-deer, in England and Ireland, is chiefly associated with Scotland so far as shooting is concerned. It is essentially a forest-loving animal, and is usually killed by driving it up to a line of guns, when, if close enough, it will drop to an ordinary charge of No. 5 shot, but a hundred of Bul. or No. 1 is a far-preferable, and more efficient, gauge to use. Roe-deer are not easy animals to move in a direction in which they suspect danger, and the more quietly a drive is conducted, the greater the chance of success. A few men walking carelessly through a wood, i.e. as if beating were not their object, will drive roe, and especially the cunning old bucks, with far greater certainty than an array of shouting, stick-rapping beaters.

Far finer sport, however, in every sense of the expression, can be obtained by stalking roe-bucks during the summer season with a small-beat rifle, carrying a hollow-nosed, and not a solid bullet. The most suitable opportunity for this is at sunrise or sunset, when the roe will be found feeding in the more open spaces in the woods. The same animals will nearly always be found in the same locality, but they are exceedingly wary creatures, and the old bucks are quite as difficult to stalk as a red-deer stag.

The hare no longer exists in the same quantities as formerly; indeed in many parts of Great Britain it is practically extinct, the result of the Game Act of 1831. No special methods are employed for shooting hares, nor is any great skill requisite for doing so, but sportsmen should always bear in mind that unless hit in the head or heart hares are not easily killed dead, and should, therefore, refrain from firing long shots at them, especially when they do not offer a broadside shot.

It is to be presumed that the Ground Game Act was specially directed—and with reason—against rabbits more than hares, but the former show little or no evidence of being affected by it. Yet from every point of view, except perhaps that of shooting, they are far less valuable, and more noxious, animals, which ravage alike the young plantations of the landlord and the crops of the tenant farmer. Where they are preserved in large numbers, the most usual method of shooting them is to ferret them out of the burrows as short a time as possible before the day fixed for shooting, and then fill in the mouths of the holes with well beaten soil, which should also be drenched with paraffin or tar to deter the rabbits from digging their way in again. If this be carefully done, and plenty of covert—coarse grass, bracken or gorse—be available, in fine dry weather the rabbits will lie out for two or three nights, but in the event of heavy rain or especially snow, nothing will prevent them going to ground again. Where natural covert is scarce, it can be supplemented by strewing bushwood and fir-loppings under which rabbits will readily shelter. In beating for rabbits, the beaters should not merely tap with their sticks, but should thrust them into the clumps of grass and underwood; otherwise many rabbits will be passed over. When rabbits are driven up
to a line of guns in covert, the latter—if no winged game is expected—should stand just inside the edge of the wood, with their backs to the beaters, and take the rabbits after they have passed. This not only induces the rabbits to face the open, but precludes the possibility of an accident to the beaters. Capital sport can be enjoyed in the summer evenings by stalking rabbits with a pea-rifle in a suitable locality, i.e. where no danger to human beings or live-stock can be caused by a stray or deflected bullet. A disused quarry or sand pit is an ideal place for such sport.

One branch of shooting remains to be touched on, namely, wild-fowling, which again must be classed under two totally distinct headings, shore or flight shooting, and shooting afloat with a swivel punt gun. In flight shooting, the sportsman stations himself at a point over which the birds will probably pass at sundown or daybreak in their passage from or to the sea, when going to or leaving their inland feeding places. Success in flight-shooting must, therefore, depend very largely on chance or luck, but given a fair proportion of the latter, it is a fine, wild sport. One essential requirement is a well-trained and thoroughly intelligent dog, and here again no better can be than an experienced man. His methods of working, and the rules of guidance can be laid down for shore-shooting; the districts are unhappily few and far between where even a moderate bag of edible wild-fowl can be made nowadays, and experience alone can give that knowledge of their habits which is essential to success. Wild stormy weather which drives the birds off the sea is best for shore-shooting.

Punt-gunning or wild-fowling afloat is a sport confined to an exceedingly small number of people, professional or amateur, and is as distinct from ordinary inland shooting as deer-stalking from pigeon-shooting. It may be briefly described as the art of shooting wild-fowl on the sea, or in estuaries of rivers, from a flat-bottomed punt carrying a heavy, fixed gun, weighing anything from 70–170 lb, the muzzle of which rests in a revolving crutch in the bow of the boat, and firing a charge of 1–2 lb of shot. A punt may be either single- or double-handed, i.e. to contain one or two people, and it is perhaps unnecessary to add the fowl are shot sitting, or just as they rise from the water. It is a sport that contains a considerable element of danger, and requires great powers of endurance and a strong constitution no less than good nerves, and it has been rightly termed a science in itself. What can be learnt by a patient apprenticeship under an experienced teacher.

The art of shooting cannot be learnt theoretically, and can only be acquired by experience and practice. The beginner should, however, from the first seek to avoid an ugly or cramped style, which, once developed, is very difficult to get rid of, and should bear in mind that, in firing at a moving object, his purpose should be not to place his charge of shot where such object is at the moment he pulls the trigger, but whether it will be by the time the shot reaches it; in other words the game should run or fly into the circle of pellets. Nor should he seek to effect this by dwelling on his game with his gun at his shoulder—a practice not only clumsy but exceedingly dangerous—but by firing at an imaginary point in front of it. Practice alone can teach the knack of doing this properly; to some men it seems a natural gift, while others do not acquire it in a life-time. A sound digestion is the surest aid to successful shooting, for unless the nervous system be in perfect tune, brain, eye and hand cannot act in that spontaneous sympathy necessary to quick and pretty marksmanship.

Probability of shooting under game, a very common fault among sportsmen. Excessive chokes is to be deprecated; a patcern of 140 for light barrels, and 160 for the left barrel will be found amply sufficient, and a load of 40–42 grains of nitro-powder with 1 or 1½ oz. No. 5½ unchilled shot will meet all ordinary requirements of the shooting field. A thoroughly good hammerless ejector gun can be obtained from a first-class London gunmaker for 35–45 guineas, and a pair for £75 to £100, but these prices are capable of considerable modification or the reverse. Single-trigger guns are the latest fashion, but no special advantage can be claimed for them.

The bibliography of shooting is very extensive, but the following works can be cited as standard ones on the subject: The "Badminton Library" "Shooting—Hints to Young Shooters," by Sir Ralph Payne-Gallwey; the "Fur and Feather" series of publications; The Gun and its Development, by Greener; and for wild-fowling, Colonel Hawker's evergreen Instructions to Young Sportsmen; The Art of Wildfowling, by Abel Chapman; The Foiler in Ireland, by Sir Ralph Payne-Gallwey; and The Wildfowler, by Folkard.

Big Game.

The pursuit of large game, whether for food or sport, has ever exercised the greatest fascination for mankind, and with the rapid opening up of vast continents hitherto unexplored, and the introduction of breech-loading rifles, it has assumed an importance within the last few decades that bids fair to render it a thing of the past before the end of the current century. The present generation has seen the bison, which formerly roamed the American prairies in countless millions, wiped off the face of creation; the veldt of Southern Africa, which teemed in equal proportions with big game of every description, has become a pastoral country, where a few of the commoner varieties still persist, but are suffering from the same conditions as the semi-wild deer of the Scottish Highlands; and even the jungles of Hindustan, save where jealously preserved by native potentates, show signs of exhaustion as regards the larger fauna. True, wherever the white man holds sway, the danger of extinction has been recognized; close-times have been instituted; reserves set apart wherein the animals may breed unmolested, and the number of each species that may be killed, restricted; but it is doubtful whether these laws, wholesome and well-intentioned as they are, can do more than retard the ultimate destruction of big game outside such reserves as the Yellowstone Park in North America. Within the pale of this no rifle is ever fired, and the game has prospered correspondingly, but once let a single head of it wander outside the restricted area, and its doom is sealed. Moreover, there are still vast tracts in Africa, and to a limited extent in other parts of the globe, where big game forms the staple meat supply of the aboriginal inhabitants, who, in addition, are no longer dependent on their primitive weapons of the chase, but are equipped with more or less efficient firearms. Great regions are however still to be found, of which sportsmen have as yet barely touched the fringe. The dense forests of Western Africa are practically unexplored, much less shot out, and Central and Eastern Asia, the Dutch East Indies, and Borneo and Sumatra, offer an almost virgin field for sport with big game. Save for the Barren Grounds of the Arctic regions and some parts of the extreme north-west—though Alaska now enjoys particularly stringent game laws—the North American continent is fast becoming denuded of big game; but in Europe, within a week's journey of London, the mountains of the Caucasus and the forests at their feet are only known to a handful of intrepid explorers. It will thus be seen that although good trophies, whether of hide or horn, are yearly becoming scarcer, fair sport is yet obtainable in those parts of the world where big game is indigenous, though the days are long past when a sportsman could shoot at his own discretion over the whole of Africa or North America, or when the globe-trotter visiting India could count on big game shooting as forming part of his programme.

Indeed, in view of the increased, and increasing, facilities for world travel, and the prevalent fashion for sport, it is probable that in course of time big game shooting will be universally...
conducted on modern European lines; i.e., wild animals will be carefully preserved by the state and private owners, and where the latter do not care to exercise the sporting rights they will be let to the highest bidder, and big game shooting will, as with Scottish deer stalking, become exclusively a pastime of the wealthy or luxury classes. Already large tracts in the wilder parts of the Eastern States of America have been acquired by rich men, over which they jealously preserve the sporting; and with the opening up of railway communication in the south of Africa to the Zambesi, and in the north to Khartoum, the dawn of another century may not improbably see shooting-boxes advertised “to let for the winter months,” dotting the very countries where Osowel, or Baker, found a virgin field for their rifles within the last few decades. Distasteful as such a state of things may seem to the present generation of sportsmen, some thing more or less approaching it will inevitably come to pass; and where climatic conditions or inaccessibility forbid its adoption, big game will become extinct at the hands of native races or white “professional” hunters. Carpe diem must undoubtedly be the motto of the big game shofter of the present day, who requires genuine wild sport under the highest possible conditions. Even at present it is essential that he should obtain the fullest information as to the existing game laws in the part of the world he intends to travel in, the whole of North America and practically three-fourths of Africa being governed by stringent regulations respecting the preservation of big game. Every state in the North American Union, and in some cases every county in a state, has its own close-times and game laws, and the same is true of Canada. Moreover, heavy fees for licences to kill big game are now exacted in all parts of the world where game laws exist. In the United States the cost of this varies very much, the present highest charge being $50 for a “non-resident” sportsman, while in addition in some states he is not permitted to hunt unless accompanied with a qualified guide. Full information on these points can be obtained gratis on application to the Board of Agriculture at Washington, where every assistance is given with the greatest courtesy, and which further issues admirably compiled pamphlets dealing with the whole question of game-preservation. Infringement of the United States Game Laws entails exceedingly heavy penalties, amounting in the most extreme case to two years’ imprisonment plus a fine of $5000.

In Canada the highest charge is $100 in Manitoba, while in Africa it varies from £50 in the Sudan and British and German East Africa to £100 in Bechuanaland. Moreover, it must be borne in mind that these fees only permit the killing of a limited number of specified animals. Still, excellent as these laws undoubtedly are, their value must remain enormously discounted as long as the sale of game and skins by aboriginal or professional hunters is permitted; it is they, and not the heavily taxed foreign sportsman, who are responsible for the threatened extinction of big game.

So far as Asiatic sport is concerned, British India, save to those furnished with credentials to native potentiats or high government officials, offers scant opportunity as regards big game to the itinerant sportsman, who must now wander farther afield into Central or North-Eastern Asia, Borneo, Java and the wilder parts of Assam or Burma; but the greater portion of the first-named locality is only open to persons duly authorized by the Russian government.

Although South America and Australia offer little attraction for sport with the rifle, big game of varying species is thus indigeneous in every part of the world.1 It is obviously impossible within our limits to deal at any length with either its habits or the various methods of hunting it. Brief allusion will be made, however, to the chief varieties of it found in the various continents and the necessary equipment for their pursuit.

Europe contains big game in greater variety and quantity than is generally supposed. The last survivors of the aurochs or European bison still roam the forests of Lithuania and the

---

1 Except in New Zealand, where red-deer have, however, been introduced and afford magnificent sport.

---

Caucasus: elk are found in Scandinavia, Russia and Eastern Prussia, and red-deer are common to the whole of the continent. Of the more Alpine kinds of big game, reindeer exist in the chamois in the mountainous districts of Central and Southern Europe; wild sheep in Corsica and Sardinia; while a few of the European ibex still linger in the royal preserves of the Italian Alps. A variety of ibex is fairly plentiful in Spain, and wild goats are found in South-Eastern Europe. Of the carnivora, bears, wolves and lynxes, though not often met with, still exist in fair numbers in most of the mountainous countries of Europe, though the first-named animal is practically the only one afford ing opportunity for sport with the rifle. Gluttons or wolverines are found in Scandinavia, and the lynx of this species still exhibit the carefully preserved forests of Central Europe. The reason for this continued supply of big game is that the whole of the European continent has been for centuries under private, communal or state preservation. The’ Caucasus, which though geographically in Europe, can hardly with fairness be held to be so as regards sport, further contain such purely Asiatic varieties of big game as tigers, leopards and tahr, and but for the savage character of the country and its inhabitants, and the obstacles thrown in the way of the sportsman by the necessarily less probable nature of the visit of English sportsmen than is at present the case. In civilized Europe, Scandinavia, Spain and the Mediterranean islands probably offer the best field for the big game hunter of moderate means, though the last named localities still enjoy an enviable reputation for brigandage.

Among useful works of reference dealing with big game shooting in Europe the following may be cited: Wild Spain, by Chapman, and Wild Norway by the same author; Flood, Fell and Forest, by Sir Henry Pottinger; Savage Scenata and Sports in the Crimea and Caucasus, by Phillips Woolley; Tyrol and the Tyrolese, by Baillie-Grohmann; the volumes of the “Badminton Library” dealing with the subject, and especially Short Stalks, by E. N. Buxton.

The physical geography of so vast a continent as Asia, no less than its varying climatic conditions, naturally produce many different species of big game, ranging from the Alpine to the purely tropical. When it is remembered that the continent includes the frozen tundras of the Arctic Circle, the steaming plains of Hindustan, the treeless wastes of the Pamirs and the dense jungles of Burma, together with the highest mountains in the world, it will be readily seen how varied must be its fauna. Among the carnivora, the tiger and the leopard or panther are found practically throughout Asia, save in the extreme north and north-west; while lions, though exceedingly rare, still exist in Guzeght and parts of Persia and Mesopotamia. The usual methods of tiger-shooting in British Asia are, when the game has been located, either to drive it to the sportsmen by means of natives acting as beaters, or else to force it into the open with a long line of elephants, which also serve to carry the shooters; the choice of methods must, of course, depend on local conditions. The second practice is not a form of sport within the reach of men of moderate means, who, indeed, except as the guests of some native potentate, are not likely to have the opportunity of indulging in tiger-shooting at all. In localities where neither of these methods is feasible, it is usual to tie up a live animal as a bait, and sit up over it during the night in a machan or platform lashed to the nearest tree; but this is usually an unsatisfactory and disappointing proceeding. In parts of Asia other than British possessions, tigers are found as far apart as the shores of the Caspian Sea and the island of Saghalian. Europeans recover with difficulty from the bites of a tiger, since blood-poisoning is the almost inevitable result owing to the septic condition of the animal’s teeth and claws, and a supply of antiseptic lotion and solution should always form part of the tiger-shooter’s equipment. Panthers, though more plentiful than tigers, are less frequently bagged, as they are exceedingly difficult animals to beat out of covert; they are usually killed by sitting up over a bait, or by smoking them out of the caves they frequently make their homes. A wounded panther has the reputation of being a more dangerous animal than a tiger. Other varieties of the felines are the cheetah, the clouded panther,
the lynx, and most beautiful and rarest of all, the ounce or snow leopard only found above the snow line.

Of other Asiatic carnivora the bears are the most important from the sportsman's point of view. A great variety of them exists, ranging from the great Kamchatkan bear to the small blue bear of Tibet, but the methods of their pursuit call for no special mention.

The Indian elephant is rather smaller than the African variety, and has other well-marked differences, the chief as regards shooting being the fact that the cavity at the top of the trunk is not protected by the roots of the tusk as in the African elephant, thus enabling a frontal shot to reach the brain. This point, one at the side of the temple, and another at the back of the ear, are most usually selected for their aim by Indian sportsmen, who do not favour the shoulder shot so commonly employed in Africa.

A charging elephant can often be turned by a well-planted, though not necessarily fatal, bullet, but a really determined animal, especially a female with a calf, will not cease its attack until either it or the hunter be killed. Though elephants will usually fly from the report of a rifle, the sound of a human voice will often make them charge.

Four varieties of rhinoceros, of which two are one-horned, and two double-horned, are found in Asia, ranging eastwards from Assam through Burma and Siam as far as Sumatra. The rhinoceros is almost invariably found in heavy grass swamps, and can consequently only be hunted by means of elephants. It is usually beaten out by means of a long line, but is occasionally tracked to its lair on a single elephant. In common with many animals of the deer and antelope tribes, the rhinoceros always deposits its droppings in the same place, a peculiarity which enables native shikaris to locate it with tolerable ease.

Although a rhinoceros, even when wounded, will rarely charge home, it has a peculiarly terrifying effect on tame elephants, and specially trustworthy ones are necessary for this sport.

The Indian rhinoceros differs in many important details from the African variety.

Of bovines, Asia produces the buffalo, three species of the gaur—miscalled the Indian bison—and the yak, the latter a rather uninteresting beast of the chase only found on the open ground of the Tibetan plateau. Very different is the pursuit of the gaur in the dense forests of India and Burma, where it is usually stalked on foot; and to track a wounded bull through thick jungle affords one of the most exciting experiences of big game shooting. Such an animal will almost invariably turn at right angles to its trail, and watch for its pursuer, whom it will charge from a distance of perhaps a few yards, even feet. The wild buffalo, too, is an exceedingly plucky animal, and will on occasion even attack a European,—whose smell appears distasteful to it,—unlike the gaur it shares with the tame variety.

The numerous species of deer and antelope scattered over the continent of Asia are usually obtained by stalking, but the former being essentially forest-haunting animals, while the latter are usually found on open ground, the methods of approaching them naturally vary with local conditions. Of deer the best known are the sambar, the chital and the swamp deer, but the Hangul or Cashmere stag, the Altai wapiti and the Maral or Asiatic red deer afford the finest trophies. Of Asiatic antelope the handsomest and commonest variety is probably the blackbuck, found practically all over India as far east as Assam.

To many sportsmen the most fascinating form of Asiatic big game shooting is the pursuit of the many varieties of wild goats and sheep, common to the various mountain ranges and high-lying plateaus of the continent. While such sport lacks the risk of attack from the animal hunted, it exacts remarkable powers of endurance and perseverance on the part of the hunter, coupled in most cases with the dangers inseparable from Alpine climbing.

There is scarcely a mountainous or elevated part of Asia which does not contain a variety of wild goat or sheep, of which the best known are the ibex and markhor of the Himalayas and Hindu Kush among the former, and the Oris Poli and O. Ammon of Tibet among the latter. As a general rule all wild goats can only be obtained under conditions which exact the highest mountaineering qualities on the part of the stalkers, but with regard to the sheep of the vast tablelands of High Asia—"the roof of the world"—a good deal of work has to be done on pony back, as the rarefied atmosphere of these great altitudes precludes much physical exertion. Exception, however, in this respect must be made of the burshel—Oris Nahuro—which haunts the same inaccessible crags as the ibex or markhor. The sportsmen who essays to bag an Oris Poli, or O. Ammon, who probably have had ample opportunity of testing his climbing powers on the march from India to his shooting-ground.

Ibex-shooting begins with the melting of the snows on the lower slopes, and ends in June, when the flies and the flocks of native herdsmen, driven to the Alpine pastures, force the wild animals to seek ground absolutely inaccessible to man. "First come first served" is a recognized rule in Himalayan shooting, and once a sportsman has claimed a nullah, or mountain valley, by priority of possession, it is his alone as long as he chooses to retain it; consequently the "race for the nullahs" in early spring is not the least exciting part of Himalayan big game shooting.

In addition to ibex, markhor and such animals, the season's bag should also include two varieties of bear, and, with extreme good fortune, an ounce or snow leopard.

Like the fox in Great Britain, the wild boar is never shot in any part of British Asia where it can be hunted on horseback.

Thanks to the improvements in modern firearms, and particularly to the adaptation of cordite ammunition to sporting rifles, the battery necessary for Asiatic big game shooting has been considerably reduced, both in weight and number of weapons required. It is not long since 8-, or even 4-bore rifles, weighing respectively 18 and 24 lb., or at least a .577 Express, were considered indispensable for the pursuit of the pachyderms and larger bovines, yet nowadays a 450 rifle of 11 lb. weight, in conjunction with cordite powder, is held amply sufficient for the heaviest or most dangerous game, the penetration or expansion of the bullet being regulated by the extent of its covering of cupro-nickel or steel. For soft-skinned animals, deer and mountain game, a .250 or .303 magazine rifle is the most useful weapon, and it may be confidently said that the introduction of these and similar small-bore rifles has extended the killing zone in stalking by at least 100 yds. For forest or jungle shooting a 10- or 12-bore Paradox gun is an admirable weapon, capable of use as a rifle against large and dangerous animals, or as an ordinary shot gun for small game. A double-barrelled rifle is essential for dangerous game, the saving of time, short as it is, in merely shifting the finger from one trigger to another, being an enormous advantage as compared with the action of ejecting and re-loading from a magazine. Finally it may be said that a sportsman would be completely equipped for big game shooting in Asia, or indeed any part of the world, with one of these soft-skinned rifles, a 10- or 12-bore Paradox gun and a .250 or .303 magazine rifle.

As regards the rest of his outfit, if he propose to shoot in any part of British Asia, he can procure this on the spot, as well, and far cheaper, than in England.

Useful works dealing with big game shooting in Asia are: Baldwin, Large and Small Game of Bengal; Forsyth, Highlands of Central India; Sanderson, The Deer and Game Birds of the Wild Beasts of India; Kinnloch, Large Game Shooting in Tibet, etc.; MacIntyre, Hindu Kós; Steindale, Natural History; Demidoff, Sport in Central Asia; Ronaldshay, Game Hunting in the Pamirs; and Fife-Cookson, Tiger-Shooting in the Doon and Uwar.

The shooting field of African big game is the antelopes, which exist in great variety; such widely different animals as the noble sable antelope and the tiny dik-dik being classified among them. African gazelles and antelopes may be roughly divided into two classes, those found on plains or open ground, and those frequenting forest or bush, and the methods of hunting them naturally vary with the locality. Still, as a general rule, it may be said that not only the finer animals, but also the more vulnerable and less available species of small game, afford more enjoyable sport in the stalk, combined with the advantage of a climate free from malaria. There is practically no part of Africa where antelopes do not exist in one variety or,
another, but probably British East Africa or Somaliland offer the best field for sportsmen. On open ground a good deal of hunting can be done on horseback—except in those districts where the tsetse fly exists—and antelopes are occasionally ridden down, but a very stout-hearted horse is required to overtake such animals as sable antelopes, eland and gemsbok. Caution should always be exercised in approaching the larger varieties of antelope when at bay, whether wounded or not, as some of them, notably the roan and sable, and the oryx, are inclined to be very savage, and will charge desperately home. It is said that even a lion is chary of attacking the oryx, owing to its long tapers, like bamboo. The African carnivora include the lion, leopard, cheetah, hyena and other smaller varieties, but it is only necessary to deal with the first named, which, where not exterminated or driven away by civilization, may be said to be common to the whole continent. As with all game, big or small, the conditions of lion-shooting vary with the locality; thus, on the open plains of Somaliland, lions can be spied from a distance and stalked on foot, or even ridden to bay on horseback, while in densely bushed districts, unless chanced on in open ground, the most usual method is to sit up at night over a halt or kill, inside a zareba of thorn bushes. This method, however, makes aiming with any degree of accuracy a matter of difficulty, but a German, Herr Schillings, has demonstrated the use of a flashlight in such circumstances. Lions frequently lie up or shelter in detached patches of scrub, whence they may be driven by a “bobbery” pack of dogs, or as a last resource the bush may be set on fire, the sportsman having previously concealed himself down wind. Lions when emboldened by hunger will fearlessly attack human beings, especially at night, and, like tigers that have once developed a taste for human flesh, become positive scourges of their neighbourhood. Mr F. C. Selous, than whom there are few better authorities, considers the lion the most dangerous of all African big game, a distinction that other writers award to the buffalo.

Of the pachyderms the commonest is the rhinoceros (R. bicornis), usually termed the black rhinoceros to distinguish it from the so-called “white” variety now almost extinct. Though the first-named is by no means so widely distributed as formerly, it is still plentiful in Equatorial Africa, and to a lesser extent in Somaliland. It bears rather a mixed character for ferocity, but most hunters agree that while it will charge with little or no provocation, it does so blindly, and rarely turns to renew the attack. This is probably due to its exceedingly poor sense of sight, but its sense of smell is correspondingly extraordinarily acute, while an additional cause that renders it a difficult beast to stalk is the presence of the “rhinoceros birds” which are its almost invariable companions, and which warn it of danger. Though so huge an animal, the rhinoceros is easily killed by a bullet in front of the base of the ear, or midway along the neck, the shoulder shot is only employed when the hunter has stepped aside to avoid a charge. The hippopotamus is still plentiful throughout most parts of uncivilized Africa. In narrow rivers where they can be shot from the bank, they are easily killed by a brain-shot, the best spot to aim at being the base of the ear. If the bullet be properly placed the animal will sink to the bottom of the stream and rise to the surface within a few hours. Hippopotami are nocturnal feeders, and can be occasionally shot at night when at a considerable distance from water; but owing to the difficulty of placing the bullet accurately, they are apt to escape wounded. Hippopotamus shooting does not rank high as a sport, but the meat, when young, is excellent, and the huge size of the animal enables a hunter to provide a large number of followers with food; this can be the only excuse for killing these comparatively harmless animals in any number.

Elephants still exist in considerable numbers in parts of Africa, but, unless more stringent methods of protection are afforded, their ultimate extermination at the hands of professional ivory-hunters, white or coloured, is inevitable. What can be done in the preservation of elephants is shown in Cape Colony, where elephants, which have been rigidly protected for many years, now exist in considerable, and increasing, quantity. Elephants have an extraordinarily keen sense of smell, which, coupled with their habit of roaming over vast expanses of country, forms their chief safeguard against the relentless persecution to which they are subject. They may be hunted either on foot or horseback; where feasible, the latter is the preferable method, as it not only enables the hunter to follow up his quarry with greater ease—and when startled, or wounded, elephants will travel enormous distances—but in open country gives him a better chance of escape from a charge. The heart, or broadside, shot is usually employed. Incredible as it may seem, these enormous creatures can be taken by a bullet placed in the heart of the body, delivered from a .303 rifle. A weapon of heavier calibre is, however, to be recommended, and a .450 rifle, or 10 or 8 bore Paradox gun, are most suitable; the closer the hunter can safely get to the animal the better. A charging elephant can usually, but not invariably, be turned by a shot in the chest; to fire at the head is useless.

The buffalo (Bos caffer), formerly one of the commonest of African wild animals, has been practically exterminated in many parts by the plague of rinderpest, but is still plentiful in the malignant swamps between the mouths of the Limpopo and the Zambezi, and even more so in the Beira district of Portuguese East Africa. Like most wild animals, the buffalo is naturally disinclined to take the offensive, but when roused to action, it will pursue a hunter with relentless ferocity, and is held by many authorities to be the most dangerous of African big game. The greatest care should therefore be exercised in following up a wounded animal, or in approaching one that is apparently dead, for as long as a spark of life lingers in it, it will endeavour to destroy its destroyer. A wounded buffalo will nearly always make for the nearest thicket, where it will await its pursuer, and in such circumstances, it should be left alone for an hour or two, when it will probably lie down, and be less active in attack owing to its wound having stiffened. A charging buffalo always carries its head at such an angle that a frontal shot is useless, unless the bullet penetrates through the nose into the throat or chest; a .500 or .450 rifle with a solid bullet, or an 8-bore Paradox gun is the best weapon for buffalo-shooting. Other varieties of the African bovines are the smaller, Abyssinian, the Senegalian, and the dwarf, or Congo buffaloes.

The only other species of African big game calling for special mention is the giraffe, which is usually ridden down and killed by a raking shot at the root of the tail; but except when required for food or specimens, the destruction of this inoffensive animal, which offers no trophy of the chase, is to be deprecated. Great numbers are annually destroyed by professional skin hunters, and their carcasses left to rot. Bears, though little known, exist in North-West Africa, and the ubiquitous wild goat, or ibex, is also found in the north of the continent. A .450 cordite rifle, a .500 small bore, and a 10 or 8 bore Paradox gun, is an ample battery for African big game shooting.

Useful books of reference for African shooting are: Selous, A Hunter's Wanderings in Africa; Travel and Adventure in S.E. Africa, by the same author; Baker, Wild Beasts and their Ways; Swayne, Seventeen Trips through Somaliland; Powell Cotton, Through the Adventure in the Congo Free State, A Sport of Adventure to Abyssinia; Melissa, Lion Hunting in Somaliland; Wilson, East Africa and its Big Game; Neumann, Elephant Hunting in East Equatorial Africa; Hay, Western Barbary; Bryden, Kool and Pigs in Africa; Mills's, A Breath from the Veldt; Thomson, Through Mazzar-land, and Theodore Roosevelt, African Game Trails (N.Y. 1910).

Big game in North America has been rapidly disappearing for several decades before the advance of civilization armed with breech-loading rifles. Among the carnivora, bears and pumas are the only species that need be taken into account as far as shooting is concerned. Of the former three varieties exist, the grizzly, rarely found east of the Rocky Mountains, the brown bear, and the black bear, common to practi-
SHOOTING

cally the whole of the continent, though now rarely killed in the Eastern states. The best country for bears is Alaska, where the
grizzly grows to an enormous size, and the Kodiak Island bear
is probably the largest variety of its genus in the world, except
perhaps the Yezo bear of Japan. In Alaska, bears are frequently
shot along on the river-banks, to which they resort in autumn to
feed on the salmon which then crowd the rivers. Otherwise
no fixed rule can be laid down for American bear-shooting; the
quarry may be hunted with dogs, which “tree” the black bear,
or bring the grizzly, which is unable to climb, to bay; it may be
ekilled over a half; it may be spied and stalked; and, most commonly
of all, it may be accidentally “jumped” and shot by the hunter.
The neck or heart is the most vulnerable spot to aim for, but
bears are very tenacious of life, and astonishingly active, despite
their clumsy appearance. Their eyesight is bad, but their sense
of smell and hearing very acute. The biggest of grizzlies will
rarely charge unprompted, unless it be a female with cubs, but
when molested or wounded it will push its attack home with the
greatest temerity, and caution should always be exercised
in approaching a wounded animal, even when apparently
inoffensive.

Of North American Ceridae the finest is the wapiti, invariably
miscalled elk, once as plentiful as the bison, but now extinct east
of the Rockies, where, though still fairly abundant, it is found in
saddly diminished numbers. It is especially common in Van-
couver, but as is almost invariably the case with insular deer,
the heads are small compared to those of the mainland. Wapiti-
hunting is probably the finest sport in America, not only from
the magnificent trophy these splendid deer afford, but also on
account of the beautiful country they frequent in the United
States; open rolling ranges of hills interspersed with patches of
timber. Wapiti are almost invariably killed by stalking during
the rutting-season, when the big bulls betray themselves by their
defiant challenge. The largest deer in the world is the North
American moose, which, except for a difference in size, is precisely
the same animal as the elk of Northern and Eastern Europe.
It is essentially a forest-haunting animal, which in the Eastern
States and Canada is frequently killed by “calling” i.e. imitating
the call of the cow, and so attracting the rutting bull to within
shot of the hunter. This is usually effected by means of a species
of trumpet made of birch-bark, and in this art of “calling”
both white men and Indians become exceedingly skilful. In
Alaska, where the finest moose are found, they are usually
stalked or “still-hunted” on foot, and to “still-hunt” these
animals in dense timber successfully is a most delicate piece
of wood craft. Unless struck in a vital part a wounded moose will
travel enormous distances, but a single shot in the heart, or
better still, the neck, is usually fatal. A wounded moose can be
dangerous and should be approached with caution.

The North American caribou, which is practically the same
animal as the European and Asiatic reindeer, may be classed
into two varieties: the Barren Ground caribou, found in the north,
and the Woodland caribou, found all over the forests of Canada,
and in a few localities in the United States. The former is
probably the only wild animal existing on the American continent
in practically the same numbers as formerly, while the latter,
thanks to careful preservation, is still abundant. The Barren
Ground caribou of the northern regions of North America are
frequently hunted by white men. They form the staple food of
the natives of Arctic North America, and huge quantities of
them are killed during the spring and autumn migration, especial-
ally when swimming lakes or rivers. The woodland caribou is
easily stalked in fairly open ground, and a bullet in the heart or
neck will kill the largest bull. Caribou and reindeer are the only
animals of the Cervidae in which the females have horns as
well as the males. The two most widely separated districts of
Canada, Newfoundland and British Columbia, probably afford
the best ground for woodland caribou. Other American deer
are the mule, or black-tailed, and the Virginian, or white-tailed,
both of which exist throughout the continent, but the latter, which is essentially a denizen of thick forest, is much the
most difficult beast to stalk. It is occasionally “hounded” or
hunted with dogs, which drive it to runways where the hunter
has previously concealed himself. A smaller variety of the
black-tail is found on the Pacific coast.

The prongbuck, invariably, but incorrectly, styled an antelope,
is a sporting little animal only found on open plains. It was
formerly exceedingly plentiful, but is now sadly diminished in
numbers. It can only be obtained by fair stalking, and the shot
has almost invariably to be taken at long range. It affords
excellent sport when coursed with greyhounds. It is the only
hollow horned ruminant which annually sheds its horns.

Now that the bison is extinct as far as shooting is concerned,
the only bovine of North America is the musk ox or the Arctic
Circle, but few sportsmen care to undergo the discomforts
attendant on the pursuit of this animal, which moreover is an
exceedingly uninteresting beast of sport and offers but a poor
trophy. The same may be said of the Rocky Mountain goat,
a curious animal, which zoologically is an antelope, and which,
though its pursuit exacts great powers of endurance and moun-
taineering ability, is so stupid, or self-confident a creature, that
practically no science is required to stalk it. Very different
is the chase of the magnificent big horn or wild sheep, now scarce
in the United States, but fairly plentiful in the Kootenay district
of British Columbia, and which, when killed by fair stalking,
affords a trophy that may be considered the Blue Ribbon of
American big game shooting. It is occasionally hunted with
dogs, which hold it at bay until the hunter can get within range,
or it may be killed by watching the so-called “licks,” or beds of limestone clay, to which these animals are fond of resorting,
and which they lick or gnaw, presumably as a form of corrective.
Big horn, varying according to locality, are found as far north
as the shores of the Bering Sea, and south to Northern Mexico.
The only other wild animal of North America that needs mention
is the puma or panther. This is invariably hunted with dogs,
which “tree” it or hold it at bay until the arrival of the hunter,
while a good pack of daschhunds will kill it themselves.
To seek it without the aid of dogs is useless, and it is therefore
an uninteresting beast of sport. Certain American writers
have claimed a rather spurious courage for the puma, but the
genral consensus of opinion is that it is a skulking, cowardly
beast.

No special battery need be taken to America; a .303 rifle is
sufficient for all the big game of the continent, but a .400 or .450
cordite rifle is probably preferable for dealing with the big
Alaskan grizzlies.

Useful works of reference for American shooting are: Roosevelt,
Hunting Trips of a Ranchman; Van Dyke, The Still-Hunter; Pike,
The Barren Grounds of Northern Canada; Grohmann, Camps in the
Rocky Mountains; Caton, The Antelope and Deer of America; American Big
Game Hunting (edited by Roosevelt); Davis, Caribou Shooting in
Newfoundland; Buxton, Short Stalks; Whitehead, Camp Fires of
shutters; and two volumes of the “Badminton Library” dealing
with the subject.

Although two or three sorts of unimportant deer are found in
South America, as well as the puma and jaguar, it does
not call for special mention in respect of big game
shooting, an extraordinary fact in view of the enormous
size of the continent. The best work of reference is Kennedy,
Sporting Sketches in South America.

Arctic big game shooting appeals to such a small class of
sportsmen, and is so limited in its variety of game, that it need not be touched on here. Full information
on the subject can be found in the works of Lamont,
Nansen, and other Arctic explorers.

Some of the finest deer stalking in the world can be obtained
in New Zealand, by those able to spare the time for so long a
journey.

Big game shooting is not only an exceedingly expensive
amusement, but one of which the cost has been continually
increasing, and no expedition of any length outside
Europe could be enjoyed under an expenditure of from
£200 to £400; but in view of the enormous difference in
local conditions, no less than individual requirements;
no hard and fast scale can be laid down. East Africa
and Somaliland are probably the most expensive localities in which
to hunt, on account of the numbers of porters, and followers, with which a sportsman is obliged to encumber himself, while British India is relatively the cheapest. South of the Zambezi in Africa, it is usual to transport stores and equipment in an ox-wagon, and though the initial cost is heavy, great part of this can be recouped by selling the equipment at the end of the trip. No matter in what part of Africa it is purposed to hunt, it is advisable to bring everything; camp-equipment—Weissman tent, mosquito curtains, camp bedstead, table and chair—and all stores from England should be packed in strong boxes, each branded with the nature of its contents, to weigh when full 65 lb, the weight an African porter can conveniently bear. Beads and presents for natives should not be overlooked. In India, on the other hand, nearly everything can be procured cheaper and better there than in England, while as regards North America, as indeed everywhere, the expense of a shooting trip varies largely with locality; the outfit of wagons, horses and attendants requisite for Wyoming or Montana, being useless in British Columbia or Alaska, where everything has to be "packed" on Indian porters. Of Central or Northern Asia it is difficult to speak with any degree of accuracy as regards expense; but on this important point, no matter in what part of the globe an expedition may be planned, information should be sought from only the latest and most reliable authorities.

The hunter's personal equipment, rifle, clothing, saddlery, &c., should be the best procurable. Where a camp bed is not practicable, a warm sleeping-bag should be taken. Clothing must of course be adapted to the climate, but flannel must always be worn next the skin, and a choker belt is a necessity. A long-sleeved shirt bearing shoulder-straps on the cool side of warmth; a chill can be contracted in the tropics just as easily as in a temperate clime, and is far more dangerous in its effects. A small medicine-chest should form part of the equipment, and must medicaments now be obtained in easily portable tablets. Warburg's fever tincture, and quinine, are essential in tropical or malarious districts. Cheap rubber-soled shoes, to be thrown away when worn out, are excellent; felt rocks or otherwise can be made from an English shooting-boot. Good field-glasses are preferable to telescopes, on account of their compactness. Now that big game shooting has become the "fashion," and facilities for world travel are increasing every year, people are prone to enter on the sport with but vague ideas as to its dangers, hardships and responsibilities. Presumably no one not of sound constitution would undertake an expedition to, say, Central Africa, or Asia, but even granted this necessary qualification, he may be naturally unfeathered to deal with the discomforts and drawbacks inseparable from big game shooting, even under the most favorable circumstances. He may be unaccustomed to the "bull's-eye" of a stationary iron target, yet this is a very different matter from finding the shoulder of an animal moving through surroundings which closely assimilate with its own colouring, or from identifying the "beast" with exactness, the spot to be shot at being the neck, or perhaps the ears, of an infuriated wild-beast. In such a situation, if eye, hand, or nerve fail him, the odds are that the creature will kill him instead of his killing it, for, as the saying goes, "the man or woman who has become reconciled beyond endurance, will hunt a human being as a terrier does a rabbit." In dealing with coloured retainers, whether Asiatic or African, the hunter should above all remember that he is a white man, and exact implicit obedience and respect, by combining firmness with scrupulously fair treatment. Again, to instance a minor, but none the less important, essential, how many would-be big-game hunters are there who can trust themselves to find their direction by a compass, or steer a course at night by the aid of the best-known constellations? Yet this is merely one of a hundred other requirements necessary to travel in a wild country.

SHOP, a term originally for a booth or stall where goods were sold, and in most cases also made, now used chiefly in the sense of a room or set of rooms in a building where goods are displayed for sale and sold by retail, also the building containing the rooms. Another application of the word is to the building or rooms in which the making or repairing of articles is carried on, a carpenter's shop, a repairing-shop, at engineering works and the like. In America, in the smaller towns and rural districts the "shop" is usually styled a "store" (O.F. storer, Late Lat. staurum, instaurare, to build, construct, in later use, to provide, necessary). While in America in the larger cities the word "store" is commonly applied to the places of sale, in English usage "store" has in recent years been recognized for the large retail places for universal supply.

SHORE, JANE (d. 1527), mistress of the English king Edward IV., is said to have been the daughter of Thomas Wainstead, a prosperous London mercer. She was well brought up, and married young to William Shore, a goldsmith. She attracted the notice of Edward IV., and soon after 1470, leaving her husband, she became the king's mistress. Edward called her the merriest of his concubines, and she exercised great influence; but, says More, "never abused it to any man's hurt, but to many a man's comfort and relief." After Edward's death she was mistress to Thomas Grey, marquess of Dorset, son of Elizabeth Woodville by her first husband. She also had relations with William Hastings, and may perhaps have been the intermediary between him and the Woodvilles. At all events she had political importance enough to incur the hostility of Richard of Gloucester, afterwards King Richard III., who accused her of having practised sorcery against him in collusion with the queen and Hastings. Richard had her put to public penance, but the people pitied her for her loneliness and womanly patience; her husband was dead, and now in poverty and disgrace she became a prisoner in London. There Thomas Lymon, the king's solicitor, was smitten with her, and wished to make her his wife, but was apparently dissuaded. Jane Shore survived till 1527; in her last days she had to "beg a living of many that had begged if she had not been." More, who knew her in old age when she was "lean, withered and dried up," says that in youth she was "proper and fair, nothing in her body that you would have changed, but if you would have wished her somewhat higher." Her greatest charm was, however, her pleasant behaviour; for she was "merry in speech, and never answered but in a cheerful manner." She had a great regard for all animals, and was always prompt to protect them. The king, in exasperation, was once seen to strike her. She made up her mind to take a journey, and was with difficulty prevailed with not to do so. She was possessed of extraordinary knowledge, and was a great favourite with the king. She was a great reader, and is said to have been the first woman who ever wrote in English. She died in 1527, and was buried in the church of St. Mary-le-Bow, London.

SHORE, a word meaning (1) the margin or edge of land when bordering on a large piece of water, whether of an ocean or sea or lake, "bank" taking its place when applied to the borders on either side of a river; for the legal aspect of the "shore," i.e., the space bordering on tidal waters between high and low water mark, see FORESHORE; (2) a prop of timber, used as a support, temporary or permanent, for a building when threatening to fall or during reconstruction (see SHORING), and more particularly a timber support placed against a ship's side when building on ship or before launching, and when ready for launching on the slips; the props which are the final supports knocked away at the moment of launching are called the "dog-shores," one of the very numerous uses of "dog" for mechanical devices of many kinds (see SUR-BUILDING). Both words are to be derived ultimately from the same source, viz., the root seen in "shear," to cut off; in sense (1) the word means a part cut or "shorn" off, an edge, and appears in M.Eng. as shore, from O. Eng. xeacan, to cut, shear; in sense (2) it is of Scandinavian origin and is an adaptation of the Nor. skor, a piece of timber cut off to serve as a prop or stay.

SHOREDITCH, an eastern metropolitan borough of London, England, bounded N.W. by Islington, N.E. by Hackney, E. by Bethnal Green and Stepney, S. by the City of London, and W. by Finsbury. Pop. (1901), 18,637. It is a poor and crowded district extending east and west of Kingsland Road, and has a large artisan population. Chain-making, cabinet work, and other industries are carried on. An old form of the name is Soersditch, and the origin is lost, though early tradition connects it with Jane Shore, mistress of Edward IV. The parliamentary borough of Shoreditch includes the Hoxton and Haggerston divisions, each returning one member. In Hoxton is the Shoreditch technical institute. The borough council consists of a mayor, 7 aldermen and 42 councillors. Area, 657-6 acres.
SHOREHAM, a seaport in the Lewes parliamentary division of Sussex, England, near the mouth of the river Adur, 6 m. W. of Brighton on the London, Brighton & South Coast railway. Part of the structure (fig. 1) of the town is usually pushing or liable the by the building. The town is sometimes known as New Shoreham, in distinction from the village of Old Shoreham, a mile up the river, which was the former port. The church of St Mary the Virgin lacks almost the entire nave, but the remainder shows fine working from Norman to Early English. Of no less interest is the church of St Nicholas, Old Shoreham, a cruciform Norman structure retaining some remarkable early woodwork. There are public gardens containing a museum and theatre. The trade of the small port is chiefly in coal, pump and timber. Shipbuilding is also carried on. The important public boys' school of St Nicholas, Lancing, near Shoreham, is part of a wide scheme which within the district includes the middle-class school at Hurstpierpoint, that for sons of tradesmen, &c., at St Saviour's, Ardingly, and the girls' school of St Michael's, Bognor. The scheme was originated by the Rev. N. Woodward in 1849. It seems probable that soon after the Conquest the increasing prosperity of New Shoreham (Searesham, Sorham, Schotham) resulted in the decay of Old Shoreham, and that the borough grew up within the walls. Shoreham owed its early importance to the natural harbour formed by the river Adur. In the time of the Confessor it was held by Azor of the king, but in 1066 was among the lands granted to William de Braose. From here Charles II. escaped to Fécamp after the battle of Worcester, 1651. It became a port of great consequence in the 13th and 14th centuries, but in the 15th and following centuries was much reduced, doubtless owing to the encroachment of the sea. The port revived during the reign of George II., when acts were passed for securing and improving the harbour. Shoreham was called a borough in 1336. In 1368 there was a mayor, and the "mayor and bailiffs of Shoreham" are mentioned in a Close Roll of 1346, but no charter of incorporation is known. The town adopted the Local Government Act of 1888 in 1866. It returned two members to parliament from 1205 until it was disfranchised in 1885. In the reign of Edward I., William de Braose held at Shoreham by prescriptive right weekly markets on Wednesdays and Saturdays, and a two-days' fair at the Exaltation of the Holy Cross. In 1702 the market-day was Saturday and a fair was held on the 25th of July, but these are not now held. Ship-building has always been the chief industry, and was largely carried on in the 13th and 14th centuries.

SHORING (from "shore," a prop), an operation connected with building. It is often necessary before actual building is begun to support adjoining premises while the work of excavating for underground apartments is being carried out. The art of shoring comprises the temporary support of buildings, and may become necessary because of the failure or settlement of some portion of the structure or for the purpose of uplifting the upper portion while alterations are being made in the lower. There are several different forms of shoring, each adapted to suit peculiar circumstances. Much of the shoring for ordinary cases is done with heavy, roughly sawn timbers strongly braced together, but for especially heavy work steel members may be introduced and prove of great value. There is the trouble in connexion with their use, however, that connections between steel members are not made with the same facility as between pieces of timber.

The form of shore in most general use is that known as the raking shore. It consists of one or more timbers sloping from the face of the structure to be supported and bedded upon the ground. As the ground is usually of a more or less yielding nature, a stout timber plate termed a sole-piece, of sufficient area to withstand being driven into the soil, is placed to receive the base of the raking timber or timbers. A wall-plate, with the object of increasing the area of support, is fixed to the face of the wall by means of hooks driven into the wall. Where space is available an angle-iron is the best to adopt for the main shore, the auxiliary members ranging in their slope from 45° to 75°. In many cases, especially in towns, the angle of slope is governed by outside influences such as the width of the footway. Raking shores are erected in "systems" of two or more members placed in the same vertical plane at right angles to the face of the wall. The different members rise fanwise from the sole-plate to support the wall at different levels. The distance horizontally between the systems depends on the condition of the building being propped up, and also upon the spacing of its window and other openings. The usual spacing is 10 ft. or 15 ft. apart, but this distance has often to be varied according to the positions of the openings in the wall. The application of the shores should be carefully made and support given only where there is a corresponding thrust inside, such as from a floor or roof, as without this the shore is liable to act more as a destructive agent than a supporting one, and cause further damage. The purpose is to have the effect of pushing it over. The members, therefore, should be so placed as to meet the wall at a point somewhat below the floor or roof, so that if their length were continued they would meet and support the end of the floor or roof inside. Perhaps the best idea of the positions and functions of the various component parts of a system of raking shores can be obtained from a description of the various members, coupled with some little study of the illustrations (fig. 1). The names of the different timbers are therefore set out here, and against each part is given a short description of its use and position.

Raking Shore, or Raker.—This is a piece of timber sloping up from the sole-plate to the wall-piece. For a detailed drawing of the connexion between the raker and wall-plate see fig. 2. The top and longest shore is often formed in two pieces, in form it can be more conveniently handled. The upper piece is termed the raking shore or raker, and the lower member which supports it is known as the back shore. At the junction of the raker and back shore a pair of folding wedges is introduced and driven in to give the head of the shore a firm bearing against the needle and wall-plate above. The sole-piece has already been mentioned as the timber base upon which the shores take their bed or bearing. It usually consists of a piece of 11 by 3 plank, but when the ground will or the load supported very great it should be bedded on a platform of timber to spread the weight over a large area. The sole should be placed sloping down towards the building at something less than a right angle (say 80°) with the inside of the shore to enable the latter to be gradually levered to a firm bearing with the aid of a crowbar. Wedging should not be resorted to or the already shaky building may sustain further injury from the vibrations. When in position the foot of the shore is fixed by dog-irons to the sole-piece, and for additional security a cleat is spiked on the sole tight up to the shore to prevent any slipping.

Braces.—When more than one shore takes a bearing upon the sole-piece the feet of the several members are stiffened and braced either by having rough boarding nailed right across them or by being bound together with a number of rounds of hoop-iron. For further strength a plate of 1-in. boards, 6 to 9 in. wide, are taken across from the wall-plate to the topmost shore and spiked to each intervening member, binding the whole together. These braces could be fixed below the junctions of the heads of the shores with the wall-plate. The wall-plate has already been referred to. It is usually a deal 9 in. wide by 3 in. thick, secured tightly against the face of the wall with wrought-iron wall hooks, forming a good abutment for the shores and serving to spread the support.
afforded by them. Holes are cut through this plate to receive the needles (or joggles as they are sometimes termed) to distinguish them from the needles used in dead shoring, which are large horizontal members usually of balk timber), which are pieces of wood about 1 ft. long and 4 in. square in section, cut with a shoulder to butt against the wall-plate. A portion of a brick or stone is removed from the wall and the end of the needle is passed through the rectangular hole in the wall-plate and fitted into the recess in the wall.

**Fig. 3.—(1/2 in. to foot.)**

The head of the needle projects about 4 1/2 in. beyond the face of the wall-plate and forms an abutment for the head of the shore. The head of the shore is notched to fit the underside of the needle to prevent any movement sideways. If this is not done the shore is liable to be acted upon by the wind and be blown down. A small block of wood, cut somewhat after the fashion of a wedge and termed a cleat, is fixed above the needle to keep the latter quite firm. Cleats are used also in other positions to keep timbers in position. Wedges are used to obtain a tight bearing for the rider shores and are used at their base. As little force as possible must be employed in driving them as vibration is liable to injure the already weakened wall.

**Fig. 4.—(1/2 in. to foot.)**

**SHORING**

**Fig. 5.—(1/2 in. to foot.)**

**Fig. 6.—(1/2 in. to foot.)**

Horizontal shores, or flying shores as they are more often termed by the workman, may be employed for spans up to about 35 ft. They are used to support the party walls of the houses adjoining the premises being rebuilt. They are erected during the pulling down operations and removed as the new building is raised and there is no further need for them. A system of flying shores consists of one or more horizontal timbers, sometimes known as dog shores, cut in tightly between the wall-plates fixed with hooks to the faces of the walls of the adjoining buildings (fig. 3). These horizontal members are supported at each end by cleats and needles fixed in the wall-plate as described for raking shoring. The shores are supported in their length by inclined braces springing from needles fixed near the lower ends of the wall-plates and serving to strut the shore at a point about a third of its length from the wall. Corresponding braces are carried from the upper surface of the shore and abut against needles at the upper ends of the plates. Straining pieces are secured to the upper and lower faces of the shore to serve as abutments for the ends of the braces. The best angle for these braces is one of 45°, but a smaller inclination than this is frequently adopted. Wedges are inserted, usually at the end of the fiber so as to tighten this up between the wall-plates, and sometimes between the braces and the straining piece, and carefully driven to tighten up the whole and cause each timber to find a close bearing. If the adjoining premises are of considerable height and especially if it is proposed to undertake extensive excavations, the systems of flying shores may need to be somewhat complicated, each consisting of several horizontal members spaced from 10 to 13 ft. apart and well strutted one to another and to the wall-plate (fig. 4). In the application of this form of shoring, as in raking shores, the same rules apply as regards placing the shores on the face of the wall in a proper position to obtain a solid abutment on a floor or roof on the other side. The members should be securely dogged and spiked together to form a homogeneous framework capable of resisting the attacks of a strong wind, which in an exposed position will sometimes destroy a poorly constructed framework.

Horizontal shores should be adopted wherever possible in preference to raking shores. Besides being more economical, they are more convenient and more effectual than rakers springing from the ground, especially if the height of the building is considerable and the span at the most not much over 30 ft. Apart from the economy effected, they present a direct resistance to the thrust and are an obstacle in the way of any building operations that may be carried on below them, so that there is no risk of their being accidentally disturbed, whereas the feet of raking shores are generally in the way of the workmen, and if not disturbed by accidental blows from materials or carts will likely be loosened and rendered useless by the digging and pumping which is going on around them.

Needle shoring is the next method of temporary support to come under consideration. It is known also as vertical shoring and dead shoring, and is the means usually adopted to support temporarily...
the upper portion of the walls of a building when it is found necessary to reconstruct the foundations or to make large openings in the lower parts of the wall, as, for example, when putting a shop front in an existing building. This form of shoring consists of horizontal members of balk timber termed needles (very different from the needles used in raking and flying shoring), which are passed through holes in the wall to be supported at a sufficient height to give full length of the insertion of any arch or lintels that may be necessary above the opening it is proposed to cut (figs. 5 and 6). The needles are supported at each end by an upright timber or dead shore, one on each side of the wall to each needle. These should not be allowed to rest upon any floor or vault but be carried down to a solid foundation and set upon and securely dogged to a timber sleeper running parallel to the wall. If it is not practicable to take the inner dead shore through intervening floors down to the solid ground in one piece, and it is necessary for its base to be set upon the floor or upon sleepers placed on the floor, the strutting must be continued in a direct line below it until a firm foundation is obtained. Between the needle and the head of the dead shores folding wedges are inserted to force the horizontal supporting balk firmly up to the underside of the masonry. Connections between the dead shores and the needles and sleepers are made with wrought iron dogs. The spacing of the systems of dead shoring depends to a large extent upon the material with which the wall is constructed; for brickwork they should be placed at intervals not greater than 6 ft. With this form of shoring especially it is often found necessary to adopt other methods auxiliary to the main shoring. These take the form of raking or flying shores from the face of the building. All the openings in the wall above should be well strutted between their reveals to prevent any alteration of shape taking place. Inside the building vertical shores or strutting must be carried up independently in a direct line between the floors with head and sole plates at floor level and ceiling. This strutting must start from a firm foundation at the bottom of the building and be tightly wedged up so as to relieve the wall of any weight from the floors and roof. To obviate settlement as much as possible, work done in underpinning should be built slowly with Portland cement mortar mixed in strong proportions. Before the shoring is removed at least a week should elapse to allow the work to set hard and firm. Then the needles should be carefully loosened and removed and the holes from which they were withdrawn made good. The remainder of the props can then be "struck," leaving the raking or flying shores until the last. If possible this work should be spread over several days, an interval of a day or two being left between the removal of each portion of timbering to allow the work gradually to set on its new bearings.

Shoring should be the subject of careful calculation to ascertain the most suitable sizes of timbers and to determine the most appropriate points of support. This is not always done, however, and much work of this character is carried out by rule of thumb methods. The usual result is that the timber used is of a much greater size than is really necessary, although as the material is not much injured and is available on removal for re-use this fact is not of great consequence. Such methods perhaps work very well for ordinary buildings, but in special cases they may very well lead to shoring being constructed in too fragile a manner, with serious results. Some rules which experience has shown to work satisfactorily for ordinary work are given below, together with the approximate scantlings of the timber required.

**Rules and Sizes for Raking Shores.**—Walls 15 ft. to 30 ft. high should have 2 shores to each system; if 30 ft. to 40 ft. in height, 3 shores each system; if 40 ft. or more in height, 4 shores, with an additional shore for each 10 ft. increase. Shoring is rarely seen more than 5 shores high. The angle of the main shores is usually about 60°, and none of the timbers should exceed an angle of 75°. Some of the lower shores will slope much less than this, at angles between 40° and 60°. The systems should not be placed at a greater distance apart than 15 ft. It is often found convenient to place them at the piers between window openings. As regards the sizes of the timbers used for walls 15 ft. to 20 ft. high, the shores may be 4 in. or 5 in. square in section; for walls 20 ft. to 30 ft. high, 5 in. by 6 in., or 6 in. by 8 in.; for walls 30 ft. to 35 ft. high, 12 in. by 6 in., or 8 in. by 8 in.; for walls 40 ft. to 50 ft. high, 12 in. by 9 in.; for walls above this height 12 in. by 9 in.

**For Horizontal or Flying Shores.**—For spans not exceeding 15 ft. the principal struts may be 6 in. by 4 in.; with raking struts 4 in. by 4 in.; for spans exceeding 15 ft. but not exceeding 35 ft. the size of the principal strut should be 8 in. by 6 in. and the raking struts from 6 in. by 4 in. to 9 in. by 6 in.

Interesting examples of shoring on a large scale may frequently be seen applied to large buildings in the course of repair or restoration. The rebuilding of the foundations of the retro-choir and lady chapel of Winchester cathedral which was carried out in the autumn...
of 1906 necessitated the erection of a very elaborate and complicated arrangement of shoring to uphold the masonry while the work of underpinning the walls was being carried on. The foundations of the eastern portions were therefore found to be demolished into large blocks, the fact being laid upon a bed of soft marl only 10 ft. below the surface of the ground, in spite of the fact that at a depth of 16 ft. a hard solid stratum of gravel, at least 6 ft. thick, is arrived at. The difficulties were further increased by the extremely variable nature of the ground, with hard boulders and a mass of soft material, as to the sustaining power of their proposed foundation, and so to ensure stability, as they thought, strengthened it by placing below the masonry horizontal layers of beech trees, filling up the interstices between the trees with hard materials, until they were able to prevent the gradual sinking, through succeeding centuries, of the heavy mass of masonry. This not only affected the footings of the building, but caused fissures of an alarming nature in the masonry of pillars and walls. Under the direction of Mr. T. G. Jackson a carefully designed arrangement of shoring was applied, consisting of raking shores, lying shores and needling, for the purpose of the underpinning. The large designed shores were laid on an inclined plane, and underpinning and vaulting while they were undergoing repair. The foundations were found to be much undermined by water, which filled the excavations made for the underpinning of the Institute of Civil Engineers in 1883. It was necessary to employ a diver to deposit cement concrete in bags upon the gravel bed to which the new foundations are taken down. The illustration (fig. 7) readily explains the external shoring above described, while fig. 8 shows the interior shoring of the presbytery.

memory Principles of Carpentry; E. Blagrove, Shoring and its 
Application. (J. Br.)

SHORNCIFLE, a military station in Kent, England, on a high ground immediately north of Sandgate and 3 m. W. of Folkestone.

It was first established in 1803, when Sir John Moore here trained the troops which afterwards formed the Light Division. It is now, however, in a very deserted condition. Its position was never of much strategic position on the flank of the French invader who was expected at the time to descend upon the English coast.

SHORT, FRANCIS JOB (1837—1907), English engraver, was born at Stourbridge, Worcestershire, on the 19th of June 1857. He was educated to be a civil engineer, and was engaged on various works in the Midlands until 1881, when he came to London as assistant to Mr Baldwin Latham in connexion with the Parliamentary Inquiry into the pollution of the river Thames. He was elected a Associate member of the Royal Institute of British Architects in 1883. Having worked at the Stourbridge School of Art in his early years he joined the National Art Training School, South Kensington, in 1883. He also worked at the life class under Professor Fred Brown at the Westminster School of Art, and for a short time at the Schools of the Royal Institute of Painters in Water-colours. His real life-work now became that of an original and translator engraver. He was a keen student of the works of J. M. W. Turner; and his etchings and mezzotints from Turner's Liber Studiorum (1885 seq.), wonderful examples of painting and drawing undivinable skill were among the first results of this period. His excellent impressions, showing the deepest sympathetic study of the originals combined with a full knowledge of the resources of engraving and unwearied patience. Short received the highest praise and constant advice and encouragement from Ruskin, and the co-operation of students of Turner such as Mr W. G. Rawlinson and the Rev. Stepford Brooke. After completing the series from the existing plates of Turner's Liber Studiorum, Short turned to the subjects which Turner and his assistants had left incomplete. Several fine plates resulted from this study, bearing the simple lettering "F. Short, Sculp., after the W. M. Turner, R.A.," which told very little of the work expended on their production even before the copper was touched. Short also reproduced in fine mezzotints several of the pictures of G. F. Watts, "Orpheus and Eurydice," "Diana and Endymion," "Love and Death," "Hope," and the portrait of Lord Tennyson, all remarkable as faithful and imaginative renderings. His own fine quality as a water-colour painter made him also a sympathetic engraver of the landscapes of David Cox and Peter de Wint. His subtle drawing of the receding lines of the low banks and shallows of river estuaries and flat shores is seen to perfection in many of his original etchings, mezzotints, and aquatints, notably "Low Tide and the Evening Star" and "The Solway at Mid-day." Other plates that may be mentioned are—

"Gathering the Flock on Maxwell Bank," a soft-ground etching; "The Ferry over the Byth," "Walberswick Pier," soft-ground; "Dutch Greenegrocery," "Noon on the Zuilder Zee," "De- 
venter," "Strolling Players at Lydd," "An April Day in Kent," and "Staintes," all etchings; "A Wintry Blast on the Stour-
ridge Canal," "Peveril's Castle," and "Niagara Falls," dry 
points; "The Curfew," "A Span of old Battersea Bridge," and "Sunrise on Whitby Scaur," aquatints; "Eolith, Putney 
Bridge," "The Weary Moon was in the Wane," "Salway Fishers," "The Lifting Cloud," and "A Slant of Light in Polper-
bour," mezzotints. Short was elected A.R.A. in 1906 when the rank of associate-engraver was revived. As head of the Engraving School at the Royal College of Art, South Kensington, he had great influence on younger engravers. Short was elected to the Royal Society of Painter-Etchers and Engravers in 1885, and took a prominent part in conducting its affairs. In 1910 he succeeded Sir Seymour Haden as president. He received, amongst other distinctions, the gold medal for engraving at the Paris International Exhibition, 1889, and another gold medal (Rappel) 1900.

The Etched and Engraved Work of Frank Short, by Edward F. Strange (1908), describes 285 plates by the artist. (C. H.*)

SHORTHAND, a term applied to all systems of brief hand 
writing which are intended to enable a person to write legibly 
at the rate of speech. Synonyms in common use are steno-
graphy (from στενός, narrow or close), and tachygraphy (from ταχύς, swift), or occasionally brachygraphy (from βραχύς, short). Greek and Roman Tachygraphy.—The question of the existence among the ancient Greeks of a system of true tachygraphy, that is, a system of shorthand writing, has not yet been solved. From surviving records we know that there were, both in the 4th century B.C. and in the early centuries of the Christian era, as well as in the middle ages, systems in practice whereby words could be expressed in shortened form by signs or groups of signs occupying less space than the ordinary method of longhand writing. But such systems appear to have been systems of brachygraphy or stenography, that is, of 
shortened writing, which were not necessarily also systems of tachygraphy properly so called. If, however, as there is some reason to believe, the Roman system of tachygraphy, as 
exhibited in the Tironian notes (see below) was derived from a 
Greek system, it may fairly be inferred that the latter system was also a developed system of tachygraphy. But, be that as it 
may, no very early specimens of Greek shorthand have hitherto come to light; and the key to the decipherment of the steno-
graphic inscriptions in the waxen book of the 3rd century in the British Museum (see below) still remains to be discovered. We 
are therefore in the dark whether we have in this MS. an example of true tachygraphic writing. Here it may be noticed that 
certain records of Diogenes Laertius have been taken to imply that 
Xenophon wrote shorthand notes (τροχομειατικα) of the lectures of Socrates; yet a similar expression in another passage, 
which will not bear this meaning, renders it hardly possible that 
tachygraphy is referred to. 

The surviving records of Greek shorthand are not very numerous, although they are scattered through a long period of time, beginning with the 4th century B.C. and extending to the 14th century. They have been arranged in three groups. At the head of the first group, which embraces all that has been found dating down to the 3rd 
century, is a remarkable inscription preserved on a marble slab discovered by the Acropolis of Athens in 1884, which is 
attributed to the 4th century B.C.; and it is on this discovery that 
the actual claim of tachygraphy to have been practised among the 
early Greeks chiefly rests. The inscription describes a system, or rather part of a system, whereby certain vowels and consonants can be expressed by strokes placed in various positions. But here, too, it has been urged that we have the explanation of a system of shorthand writing only, and that the tachygraphic symbols described also belong a few specimens of shorthand writing on papyri of the 2nd and 3rd centuries, and, above all, the most important MS. of ancient Greek tachygraphic symbols hitherto discovered. This is the waxen 
book already referred to (Brit. Mus., Add. MS. 33,727), consisting of seven wooden tablets coated with wax on both sides, and two covers thus coated on the inner sides, which seems to have been the exercise-
book of a shorthand scholar who had been taught by papyrus symbols, which in places are repeated again and again as if for practice.
In these symbols we may have an actual system of tachygraphic shorthand, and not a mere syllabary; but unfortunately they have not come down in this form.

The second group of examples of Greek shorthand is confined to a few fragmentary papyri and wax tablets ranging from the 4th to the 9th centuries, and the fragments do not give us any idea of the tachygraphic Greek tachygraphy of the 10th century. First stands the Paris MS, of Hermonenes, with some tachygraphic writing of that period, of which some fragments are still extant, but not deciphered. The largest amount of material is found in the Vatican MS, 1809, a volume in which as many as forty-seven pages are covered with tachygraphic writing of the 11th century, Cardinal Angilbert. Mai first published a specimen of it in his Scriptorium veterum nova collectio, vol. vi. (1832); and in his Novae patrum bibliothecae tom. secundus (1844) he gave a second, which, in the form of a marginal note, contained a fragment of the book of Enoch. But he did not quote the number of the MS, and it has only been identified in recent years. The tachygraphic portion of it has been the subject of special study by Dr Githbauer for the Vienna Academy. It contains fragments of the works of St Maximus the Confessor, the confession of St Cyprian of Antioch, and works of the pseudo-Dionysius Areopagita. There are also certain MSS, written at Grottaferrata belonging to the same period.

But here again this medieval shorthand is not a tachygraphy in the true sense of the word, but a syllabic system having very little in common with the ordinary tachygraphy in hand in respect of rapidity of writing, excepting that the scribecute could pack more of the text into a given space. The medieval system therefore cannot be regarded as a development of any ancient system of tachygraphy, but rather as a stunted descendant or petrified fragment, as it has been called, of an earlier and better system. Other medieval varieties or phases of Greek shorthand have also been traced in the 14th and even in the 15th century.

Evidence that in the medieval handwriting among the Romans is to be found in the writings of authors under the empire. It appears to have been taught in schools, and, among others, the emperor Hadrian had been skilled therein. According to Suetonius the first introduction of shorthand signs or notae was due to Ennius; but more generally Cicero's freedman M. Tullius Tiro is regarded as the author of these symbols, which commonly bear the title of Notae Tironianae. The Tironian notes belonged to a system which was actually tachygraphic; that is, each word was represented by a character, alphabetic in origin, but having an ideographic value. The notes, as we have them, have come down to us in a medieval dress, and are probably amplified from their shapes of early times with various discrétional additions which attached to them after the practice of the system had died out. But in the medieval manuscripts in Tironian notes a syllabic system was made use of in such cases; and hence arose variations in different countries in the syllabic method of expressing words; an Italian system, a French system and a Spanish system, each with its own identification. Such a system of writing is comparable with the "African" and "Italian" varieties of the medieval Greek shorthand system noticed above.

There is, however, one important difference between the Tironian notes and the ordinary medieval shorthand in the use of shorthand signs. In the former, the treatment of the traditional employment was, especially in the chanceries of the Merovingian and Carolingian dynasties of the Frankish empire; and a limited use of them was made by the officials of the royal domain in France. The Tironian systems generally accompany the subscription of the referent, the earliest instance being in a diploma of Chlothar II. A.D. 625. From the 9th to the 12th century, these fragments were frequently used to give brief indications referring to the composition of the deed, the name of the person moving for it, that of the official revising it, &c. Such uses may be regarded as safeguards against forgery. A more extensive use of the shorthand signs may be noted in the notarial records of Roman and Italian monarchs. Official MSS. were written in these characters as, for example, the formulæ of the chancellor of Louis the Pious. They appear in subscriptions, often attached to the rubrics (see Diplomatic, p. 220). Sometimes they were used as a conventional notation at the beginning of a deed; sometimes they themselves formed the invocation or a pious formula. Such notes continued to appear in royal deeds down to the end of the 9th century; and so inverter had been derived from the employment of these characters for shorthand to the extension of learning on the part of the scribes. Even in the 11th century a few notes lingered on, their meaning fast dying out.

In the 10th century all practical acquaintance with the shorthand systems of Greece and Rome faded completely away, and not till the beginning of the 17th century can the art be said to have revived. But even during that interval systems of writing seem to have been practised which for speed approximated to modern shorthand.

Shorthand in English-speaking Countries.—England was the birthplace of modern shorthand. The first impulse to its cultivation may possibly be traced to the Reformation. When the principles of that movement were being promulgated from the pulpit, there was a pressing need for a means of keeping track of the sermon. This need suggested the idea of accelerated writing. It is certainly striking that in the early systems so many brief arbitrary signs are provided to denote phrases common in the New Testament and Protestant theology. In the early systems of Dr Timothy Bright and Peter Bales almost every word is provided with an arbitrary sign. Dr Bright (c. 1551-1615) was a doctor of medicine who afterwards entered the church. His Characterie. An Arte of

1 For instances, see Zeilige's Geschichte u. Lit. der Geschwindeschreib- kunst (Dresden, 1878), p. 67, and for John of Tilbury's system (c. 1175), see especially Charthoud, No. 3. and Hermes, viii. p. 353.

2 The Bodleian Library contains the only known copy of Bright's book. For a description of the system, see Phonetic Journal (1884).

3 In the case of the British, 16th century and later, the number indicates the number of letters which could be written under each letter of the alphabet, and therefore the signs written had to be made of an equal number of letters. By adding certain external marks these signs were applied to other words: thus by writing a dot in one of two positions with a, b, c, d, &c. There were four to twelve letters to each word, and with dots and lines on the characters forty-eight words could be written under each letter of the alphabet if necessary. Thus the sign for h with different terminal marks and written in four different directions signified a number of different words. This system of writing was called subtiligraphia, and its alphabet was called alphabetum tironianum. By the dot and lines on the characters the sound was indicated, and the writing and speaking of the same sound was called elocutores.

4 For examples of Bales' method, see the group of words in dozen hanlons, of which three are given under the head of "steam" and the others to be placed between each letter in their appropriate situations, so as to distinguish the words from each other.
Shorthand, Swift and Secret Writing by Character (1588), which set forth a system of writing by character or shorthand, was dedicated to Queen Elizabeth, who rewarded the author with a Yorkshire living, and granted to him the sole right for fifteen years of teaching and printing books "in or by Character not before this tyme commonly knowne and use by any other our subjects" (Patent Roll, 30, Eliz. part 12). Peter Bales (1547-1610) promised his pupils that "you may also learn to write as fast as a man speaketh, by the Art of Brachigraphie by him devised, writing but one letter for a word"; his "Art of Brachigraphie" is contained in his Writing Schoolemaster (1590). Only with a gigantic memory and by unremitting labour could one acquire a practical knowledge of such methods.

The first shorthand system worthy of the name which, so far as is known, appeared in England is that of John Willis (d. c. 1627), whose Art of Stenographic (London, 14 editions from 1602 to 1647) is substantially based on the common alphabet; but the clumsiness of his alphabetic signs, and the confused laborious contrivances by which he denotes prefixes and terminations, involving the continual lifting of the pen, would seem to render his method almost as slow as longhand. Of the numerous systems which intervened between J. Willis's and Isaac Pitman's phonography (1837) nearly all were based, like Willis's, on the alphabet, and may be called, a, b, c systems. But seven were, like phonography, strictly phonetic, viz. those by Tiffin (1759), Lyle (1762), Holdsworth and Aldridge (1766), Roe (1802), Phineas Bailey (1819), Towson (1831) and De Stains (1589). A few general remarks apply largely to all the a, b, c systems.

Each letter is designated by a straight line or curve (vertical, horizontal, or sloping), sometimes with the addition of a hook or loop. C and q are rejected, k being substituted for hard c and s for soft c. Signs are provided for ch, sh, th. G and j are classed under one sign, because in some words g is pronounced as j, as in giant, gem. Similarly each of the pairs f, v and s, z has only one sign. A few authors make the signs for j, s, z heavier than those for f, t, s. Some class p and t, d and each under one sign. The stenographic alphabet is therefore—a, b, d, e, f, g, h, i, j, k, l, m, n, o, p, r, s, t, u, w, x, y, ch, sh, th. Letters which are not sounded may be omitted. Gh, ph may be counted as j in such words as cough, Philip; but the th in thing is never distinguished from the ths in them. Thus the a, b, c systems are largely phonetic with respect to consonant-sounds; it is rather with regard to the vowels that they disregard the phonetic principle. No attempt is made to provide adequately for the many vowel-sounds of the language. Thus the signs for ike and tick, for rate and rat, &c., are the same. In the case of vowel-sounds denoted by two letters, that vowel is to be written which best represents the sound. Thus in meat the e is selected, but in great the a. In some a, b, c systems, including the best of them (Taylor's), a dot placed anywhere does duty for all the vowels. This practice is, of course, a fruitful source of error, for paster, and paper, gas and goose, and hundreds of other pairs of words would according to this plan be written alike. In the early systems of Willis and his imitators the vowels are mostly written either by joined characters or by lifting the pen and writing the next consonant in another line. In all preceding respects these plans are bad; for lifting the pen involves expenditure of time, and vowels expressed by joined signs and not by marks external to the word cannot be omitted, as is often necessary in swift writing, without changing the general appearance of the word and forcing the eye and the hand to accustomed themselves to two sets of outlines, vocalized and unvoiced. In the better a,b,c systems the alphabetic signs, besides combining to denote words, prefixes and suffixes. Thus in Harding's edition of Taylor's system the sign for d, when written alone, denotes do, did, the prefixes de-, des-, and the terminations-dom, -end, -ened, -ed. This is a good practice if the words are well chosen and precautions taken to avoid ambiguities. Numbers of symbolical signs and rough word-pictures, and even wholly arbitrary marks, are employed to denote words and entire phrases. Symbolical or pictorial signs, if sufficiently suggestive and not very numerous, may be effective; but the scheme of "figures" is objectionable because they are so difficult to remember. In many shorthand books the student is recommended to form additional ones for himself, and so of course make his writing illegible to others. The raison d'être of such signs is not far to seek. The proper shorthand signs for many common words were, so clumsy or ambiguous that this method was resorted to in order to provide them with clearer and easier outlines. For the purpose of verbatim reporting the student is recommended to omit as a rule all vowels, and decipher his writing with the aid of the context. But, when vowels are omitted, hundreds of pairs of words having the same consonant skeleton (such as minister and monastery, frontier and furniture, libel and label) are written exactly alike. This is one of the gravest defects of the a, b, c systems.

John Willis's system was largely imitated but hardly improved by Edmond Wills (1618), T. Shelton (1620), Witt (1630), Dix (1633), Maud (1635), and Theophilus Metcalfe (1635). T. Shelton's system, republished a great many times down to 1687, was the one which Samuel Pepys used in writing his diary. It was adapted to German, Dutch and Latin. An advertisement of Shelton's work in the Mercurius Politicus of 3rd October 1650 is one of the earliest business advertisements known. The book of Psalms in metre (206 pages, 2½ x 1½ in.) was engraved according to Shelton's system by Thomas Cross. Metcalfe's Radio-Stenography, or Short-Writing, was republished again and again for about a hundred years. The 35th "edition" is dated 1653, and a 55th is known to exist. The inefficiency of the early systems seems to have brought the art into some contempt. Thus Thomas Heywood, a contemporary of Shakespeare, says in a prologue 4 that his play of Queen Elizabeth "Did through the seats, the boxes and the stage So much that some by stenography drew A plot, put it in print, scarce one word true."

Shakespeare critics would in this manner explain the badness of the text in the earliest editions of Hamlet, Romeo and Juliet, Taming of the Shrew, Merry Wives of Windsor, and Henry V. Perhaps a study of J. Willis's system and of E. Willis's (which, though not published till after Shakespeare's death, was practised long before) may shed light on corrupt readings of the text of these plays. Rich's system (1646, 20th edition 1792) was republished with slight modifications by Addison, including W. Addy, Stringer, and Dr Philip Doddridge (1759 and three times since). The New Testament and Psalms were engraved in Rich's characters (1659, 956 pages, 2½ x 1½ in., 2 vols.), and Addy brought out the whole Bible engraved in shorthand 4 (London, 1687, 396 pp.). Locke, in his Treatise on Education, recommends Rich's system; but it is encumbered with more than 300 symbolical and arbitrary signs. In 1847 it was still used by Mr Plowman, a most accomplished Oxford reporter.

In 1672 William Mason, the best shorthand author of the 17th century, published his Pen Pluck'd from an Eagle's Wing. The alphabet was largely taken from Rich's. But in his Art's Advancement (1682) only six of Rich's letters are retained, and in his Plume Volante (1707) further

1 The first edition, published anonymously, is entitled The Art of Stenographic, and contains certain rules, to the capacities of the meanest, and for the use of all professions, the way to Compendious writing. Wherein is annexed a very easy Direction for Stenography, or Secret Writing, printed at London in 1602 for丘尔布特. The three known copies are in the Bodleian and British Museum libraries.

2 See a paper by J. E. Bailey, "On the Cipher of Pepys' Diary," in Papers of the Manchester Literary Club, vol. ii. (1876). Shelton (1601-1650) is not to be confounded with the translator of Don Quixote.

5 See M. Levy's Shakspeare and Shorthand (London), and Phonetic Journal (1885), p. 34.

6 This curiosity is described in the Phonetic Journal (1885), pp. 158, 196. The Bodleian Library has a copy.
SHORTHAND

changes are made. Initial vowels are written by their alphabetic signs, final vowels by dots in certain positions (a, e at the beginning; i, y at the middle; o, u at the end), and medial vowels by lifting the pen and writing the next consonant in those same three positions with reference to the previous. Mason employed 423 symbols and arbitraries. He was the first to discover the value of a small circle for ſ in addition to its proper alphabetic sign. Mason's system was republished by Thomas Gurney in 1740, a circumstance which has perpetuated its use to the present day, for in 1737 Gurney was appointed shorthand writer to the Old Bailey, and early in the 19th century W. B. Gurney was appointed shorthand-writer to both Houses of Parliament. Gurney reduced Mason's arbitraries to about a hundred, inventing a few special signs for particular combinations. The Gurneys were excellent writers of a cumbrous system. Thomas Gurney's Brachygraphy passed through at least eighteen editions.

In 1767 was published at Manchester a work by John Byrom, sometime fellow of Trinity College, Cambridge, entitled The Byrom. Universal English Shorthand, distinguished for its precision, elegance, and systematic construction. Byrom had died in 1763. Having lost his fellowship by falling to take orders, he made a living by teaching shorthand in London and Manchester, and among his pupils were Horace Walpole, Lord Conway, Charles Wesley, Lord Chesterfield, the duke of Devonshire and Lord Camden. Shorthand, it is said, procured him admission to the Royal Society. He founded a stenographic club, to the proceedings of which his journal,1 written in shorthand, is largely devoted. In the strangers' gallery of the House of Commons in 1728 Byrom dared to write shorthand from Sir R. Walpole and others. In 1731, when called upon to give evidence before a parliamentary committee, he took shorthand notes, and, complaints being made, he said that if those attacks on the liberties of shorthand men went on he "must have a petition from all counties where our disciples dwell, and Manchester must lead the way." Thomas Molyneux popularized the system by publishing seven cheap editions between 1703 and 1825. Modifications of Byrom's system were issued by Palmer (1774), Nightingale (1811), Adams (1814), Longmans (1816), Gawtress (1819), Kelly (1820), Jones (1832) and Roffe (1833). Byrom's method received the distinction of a special act of parliament for its protection (15 Geo. IV. c. 23, for twenty-one years from 24th June 1812). To secure linearity in the writing and facility of consonantal joins he provided two additional signs for b, h, j, w, x, sh, th, and three for i, e, i, o, u, represented by a dot in five positions with respect to a consonant. Practically it is impossible to observe more than three (beginning, middle and end). With all its merits, the system rapidly lost the continual recurrence of the loop seriously retarding the pen.

In 1788 was published An Essay intended to establish a Standard for a Universal System of Stenography, by Samuel Taylor (London).2 This system did more than any of its predecessors to establish the art in England and abroad. Equal to Byrom's in brevity, it is simpler in construction. No letter has more than one sign, except w, which has two. Considering that five vowel places about a consonant were too many, Taylor went to the other extreme and expressed all the vowels alike by a dot placed in any position. He directs that vowels are not to be expressed except when they sound strong at the beginning and end of a word. Arbitraries he discarded altogether; but Harding, who re-edited his system in 1823, introduced a few. Each letter when standing alone represents two or three common short words, prefixes and suffixes. But the list was badly chosen: thus m represents my and many, both of them adjectives, and therefore liable to be confounded in many sentences. To denote in and on by the same sign is evidently absurd. Taylor's system was republished again and again. In Harding's edition (1823) the vowels are written on an improved plan, the dot in three positions representing a, e, i, and a tick in two positions o, u. Several other persons brought out Taylor's system, in particular G. Oedd, whose book was re-edited or republished not less than sixty-four times, the later replications appearing at New York. The excellence of Taylor's method was recognized on the Continent: the system came into use in France, Italy, Holland, Sweden, Germany, Portugal, Rumania, Hungary, &c.

The Universal Stenography of William Mavor (1780) is a very neat system, and differs from Taylor's in the alphabet and in a more definite method of marking the vowels. A, e, i, are indicated by commas, o, u, y, by dots, in three places. Arbitraries, respect to a letter, namely beginning, middle and end. Other systems were introduced by J. H. Lewis (1812) and Moat (1833). The vast mass of a, b, c systems are strikingly devoid of originality, and are mostly imitations of the few that have been mentioned. Nearly all may be briefly described as consisting of an alphabet, a list of common words, prefixes and suffixes, expressed by single letters, a list of arbitrary and symbolical signs, a table showing the way of joining any two letters, a few general rules for writing and a specimen

fender,

This practice is quite safe in the case of curves, but
a straight stroke should not be lengthened in this way when there
is danger of reading it as a double letter. The lineal consonantsigns may stand alone to represent certain short and common
words as in many of the old, a, b, c systems, with this difference,
that in the old systems each letter represents several words, but in
in almost
every case, only one.
phonography,
By writing the
horizontal strokes in two positions with respect to the line (above
and on) and the others in three positions (entirely above, resting
on and passing through the line) the number is nearly trebled, and
very brief signs are obtained for some seventy or eighty common
short words (e.g. be, by, in, if, at, it, my, me, &c.). A few very
common monosyllables are represented by their vowel-marks, as

Three principles which remain to be noticed are of such importance
and advantage that any one of them would go far to place phonography at the head of all other systems. These are the principles
of positional writing, similar outlines and phraseography.
(i) The
first slanting stroke of a word can generally be written so as either
to lie entirely above the line, or rest on the line, or run through the

method second position '""K
(2) Another way of distinguishing
between words having the Same consonants but different vowels
to vary the outline. The possibility of variety of outline arises from
the fact that many consonant sounds have duplicate or even triplicate
For instance, r has two lineal signs and a
signs, as we have seen.
hook sign, and so each of the words carter, curator, creature and creator
obtains a distinct outline. A few simple rules direct the student
to a proper choice of outline, but some difference of practice obtains
among phonographers in this respect. Lists of outlines for words
having the same consonants are given in the instruction books;
the Reporter's Assistant contains the outline of every word written
with not more than three strokes, and the Phonographic Dictionary
gives the vocalized outline of every word in the language. Aided
by a true phonetic representation of sounds, by occasional vocalization, variety of outline, and the context, the phonographic verbatim
1
reporter should never misread a word.
(3) Lastly, phraseography.
It has been found that in numberless cases two or more words may
be written without lifting the pen. A judicious use of this practice
position

combines with the

Under, \.

letter,

Phonography is so legible that the experiment of handing the
shorthand notes to phonographic compositors has often been tried
with complete success. A speech of Richard Cobden, on the Corn
Laws, delivered at Bath on iyth September 1845, and occupying an
hour and a quarter, was reported almost verbatim, and the notes,
with a few vowels filled in, handed to the compositors of the Bath
Journal, who set them up with the usual accuracy. A notice of the
occurrence appeared the next day in the Bath, Journal, and was
immediately transferred to the columns pf The Times and other
newsptpers. Mr Reed tried the same experiment with equal success,
the notes being handed to the compositors in their original state
(Phonetic Journal, 1884, p. 337).

,


promotes legibility, and the saving of time is very considerable. Words written thus should be clearly conducted in sense and awkward joinings avoided. Such phrases are: I am, I have, you are, you may, it would, it would not, we are, we have, we have not, my dear friends, as far as possible, for the most part, and many thousands of others. For the sake of obtaining a good phraseogram for a common phrase, it is often advisable to omit some part of the consonant outline. Thus the phrase you must recollect that may very well be written (you must recollect that). Lists of recommended phraseograms are given in the Phonographic Phrase Book, the Legal Phrase Book and the Railway Phrase Book.

Specimens of Phonography. Corresponding Style.

\[
\begin{align*}
\text{Key.} & \quad \text{If all the feelings of a patriot glow in our bosoms on a perusal of those eloquent speeches which are delivered in the senate or in those public assemblies where the people are frequently convened to exercise the birthright of Britons—we owe it to shorthand. If new fervour be added to our devotion, and an additional stimulus be imparted to our exertions as Christians, by the eloquent appeals and encouraging statements made at the anniversaries of our various religious societies—we owe it to shorthand. If we have an opportunity in interesting judicial cases, of examining the evidence, and learning the proceedings with as much certainty, and nearly as much minuteness, as if we had been present on the occasion—we owe it to shorthand.}

Key (the phraseograms being indicated by hyphens).—Characteristics of the Age.—The peculiar and distinguishing characteristics of the present age are in every respect remarkable. Unquestionably an extraordinary and universal change has commenced in the internal as well as the external world—in the mind of man as well as in the habits of society, the one indeed being the necessary consequence of the other. A rational consideration of the circumstances in which mankind are at present placed must show us that influences of the most important and wonderful character have been and are operating in such a manner as to bring about if not a reformation, a thorough revolution in the organization of society. Never in the history of the world have benevolent and philanthropic institutions for the relief of domestic and public affection; societies for the promotion of manufacturing, commercial and agricultural interests; associations for the instruction of the masses, the advancement of literature and science, the development of true political principles, for the extension in short of every description of knowledge and the bringing-about of every kind of reform—been so numerous, so efficient and so indefatigable in their operation as at the present day.

An enumeration made in 1894 showed that 95% of British newspaper reporters used Pitman's system; but there are still numerous varieties preferred by individuals. Of the systems published since the invention of phonography, the principal are A. M. Bell's Stenophonography (Edinburgh, 1852), Professor J. D. Everett's (London, 1877), Pocknell's Legible Shorthand (London, 1881), and J. M. Sloan's adaptation (the Sloan-Duployan) of the French system of Duployé (1882). More recent essays in English shorthand are almost entirely in the direction of script characters connected with vowels, as contrasted with the geometric forms and disjoined vowels of Pitman's phonography. The majority are founded on the French system of the brothers Duployé, but Cursive Shorthand (Cambridge, 1889), by Prof. H. L. Callendar, and Current Shorthand (Oxford, 1892), by Dr Henry Sweet, may be noted as original methods, the first having a phonetic, and the second both an orthographic and a phonetic basis.

The distinctive features in recent shorthand history have been the widely extended employment of the art, the increased attention paid to instruction and the growth of stenographic societies. Throughout the civilized world the systems employed are those of the leading authors of the 19th century; earlier systems have now a numerically small number of practitioners. Shorthand has become an almost indispensable qualification for the amanuensis, and practical stenographic ability is a necessary equipment of the typewriter operator. In professional and commercial offices, and more recently in the services, dictation to shorthand writers has become general. Shorthand has been included among examination subjects for the army, navy, civil service and medicine in the United Kingdom, and to a certain extent in other countries. Its inclusion in the Technical Instruction Act of 1889 was the first recognition of shorthand by the British parliament, and it was subsequently comprised in the codes of elementary day and evening continuation schools. It first became an examination subject for secondary schools in the Oxford Local Examination in 1888, but the Society of Arts has examined students of polytechnics, &c., in shorthand since 1876. Examinations in connexion with the phonographic system of Isaac Pitman date from 1845.

In 1887 the tercentenary of the origin of modern shorthand by Timothy Bright and the jubilee of Isaac Pitman's phonography were celebrated by the holding of the first International Shorthand Congress in London. Subsequent congresses were held at Paris (1889), Munich (1890), when a statue of Gabelsberger was unveiled; Berlin (1891), Chicago (1893), Stockholm (1897), Paris (1900), &c. These gatherings have promoted the improved organization of stenographic practitioners in the respective countries. After the first congress, three national organizations were established in Great Britain by Pitman writers, which take the place of the Phonetic Society (established in 1843 and dissolved in 1865). In America the formation of national associations for reporters and teachers followed the fifth congress.

As regards speed in shorthand writing, it may be mentioned that at the exhibition at Olympia (London) in 1908, the "World's Shorthand Championship" was awarded for 220 words a minute for five minutes. But it has been claimed that a rate of 250 words a minute has been accomplished. It may be pointed out, however, that such a rate cannot be wanted for any practical purpose, since the fastest public speaker never speaks anything like 250 words a minute, even though for demonstration such a thing could be done. The average rate of public speaking is from 120 to 150 words a minute.

Foreign Shorthand Systems.

To complete the history of the subject, the following notes on systems introduced in various European countries may be useful. German.—C. A. Ramsay's Tachographia (Frankfort, 1679, and several times afterwards until 1743) was an adaptation of T. Shelton's English system. Mosengell (1797) first practically introduced short-
Adaptations of Gabelsberger's method have also come into use in other countries.

In 1884, Habib Hosain, at the Mahomedan Educational Conference of 1905 in India, introduced a system of Urdu and Hindi shorthand, called "Habib's Samā,' for which he was awarded a gold medal. Pitman's system has also been adapted for some Indian languages.

Authors.—J. W. Zehl's Geschichte u. Literatur der Gesetzschreibkunst (Dresden, 1878) contains a historical sketch of the use of shorthand up to 1878. A. von Beyme, A. A. E. Krieg's and F. F. E. Krieg's systems. A. A. E. Krieg's system, E. Krieg's system (reprinted in the Phonetic Journal of 1884), J. E. Rockwell, contains a very complete and accurate bibliography of English and American shorthand publications, a chronological list of 483 English and American shorthand authors, a full bibliography of shorthand literature in all languages, a number of lithographed specimens, and a useful index. Circulares of Information of the Bureau of Education, No. 2, 1884 (Washington, 1885), by J. E. Rockwell, contains a very complete and accurate bibliography of English and American shorthand publications, a chronological list of 483 English and American shorthand authors, a full bibliography of shorthand literature in all languages, a number of lithographed specimens, and a useful index. Circulares of Information of the Bureau of Education, No. 2, 1884 (Washington, 1885), by J. E. Rockwell, contains a very complete and accurate bibliography of English and American shorthand publications, a chronological list of 483 English and American shorthand authors, a full bibliography of shorthand literature in all languages, a number of lithographed specimens, and a useful index.

The author draws largely on J. H. Lewis's Historical Account of the Rise and Progress of Stenography (London, 1816). Other histories of shorthand are by F. X. Gabelsberger (prefixed to his Anleitung zur deutschen Rechtszeichenkunst, Munich, 1834), A. Fossé (prefixed to his Cours théorique et pratique de sténographie, Paris, 1849), Scott de Martinville (Paris, 1849), M. Levy (London, 1862), and F. Anderson (London, 1882). Here too should be mentioned J. Heger's Bemer- kennswörter über die Stenographie (Vienna, 1841), generally historical, and A. A. E. Krieg's system, E. Krieg's system (reprinted in the Phonetic Journal of 1884), J. E. Rockwell, contains a very complete and accurate bibliography of English and American shorthand publications, a chronological list of 483 English and American shorthand authors, a full bibliography of shorthand literature in all languages, a number of lithographed specimens, and a useful index. Circulares of Information of the Bureau of Education, No. 2, 1884 (Washington, 1885), by J. E. Rockwell, contains a very complete and accurate bibliography of English and American shorthand publications, a chronological list of 483 English and American shorthand authors, a full bibliography of shorthand literature in all languages, a number of lithographed specimens, and a useful index.

There are...
which is deeply mystical and imaginative, has for its central idea the dangers of bigotry and superstition, and the necessity of intuitive religion to progress and culture. It is a work full of opulent colour and crowded life, no less than of philosophy and spiritual beauty. Shorthouse’s work was always marked by high earnestness of purpose, a luxuriant style and a genuinely spiritual quality. He lacked dramatic oratory and his manner of expression, before he had almost every other quality of the born novelist. He died at Edgbaston on the 4th of March 1903.

SHOSHONG, a town in the British protectorate of Bechuanaland, formerly the chief settlement of the eastern Bamangwato. It is about 200 m. N.N.E. of Makete and 30 m. N. of Shoshong Road Station on the Cape Town-Bulawayo railway. The site is situated 3000 ft. above the sea in the valley of the Shoshong, an intermittent tributary of the Limpopo. The site was originally chosen as the headquarters of the Bamangwato as being easily defensible against the Matabele. At the time of the declaration of a British protectorate in 1885 Shoshong had 20,000 to 30,000 inhabitants, including about twenty Europeans. Being the meeting place of trade routes from south and north it was of considerable importance to early explorers and traders in South-Central Africa, and a mission station of the London Missionary Society (preceded for many years by a station of the Herrmannsburg Lutheran Missionary Society) was founded here in 1882. Owing, however, to the scarcity of water at Shoshong, Khama, the chief of the Bamangwato, and most of his followers removed about 1890 to Palapye—50 m. N.E. of Shoshong—and later to Serowe to the north-west of Palapye. Like Shoshong, these places are built in valleys of tributaries of the Limpopo. Shoshong was not entirely deserted and has a population of about 800 (see BECHUANALAND).

SHOTTS, a mining and manufacturing parish of Lanarkshire, Scotland. It comprises eight villages, parts of two others, and the town of Cumbernauld (the original Shotts or Old Shotts) and is served by the North British and Caledonian railways. Pop. (1871) 11,957; (1901) 15,562. The parish contains large ironworks, tile, fire-clay and brick-works, and quarries, and includes the Lanark district asylum and a fever hospital. The curious name of Omoa is supposed to have been given to his property by some soldier or sailor who had settled here after the wars in Honduras, of which Omoa is a seaport. Matthew Baillie (1761-1823), famous for his researches in morbid anatomy, and Janet Hamilton (1795-1873), the wife of Dr. Sh., are both in the parish of Shotts.

SHOULDER (in O.E. sculder, cognate with Ger. Schulter, Dutch schouder, Swed. skuldra, &c.; the root is unknown), the name of that part of the body of man and animals where the upper arm or fore-leg articulates with the collar bone and shoulder-blade (see JOINTS).

SHOVEL, SIR CLOWDISLEY [or Clowdesley Shovel as he seems to have spelt the name himself] (c. 1560-1707), English admiral, was baptised at Cockthorpe in Norfolk on the 25th of November 1560, and went to sea under the care of his kinsman Sir Christopher Mylns. He set himself to study navigation, and, owing to his able seamenship and brave and open-hearted disposition, became a general favourite and obtained quick promotion. In 1674 he served as lieutenant under Sir John Narborough in the Mediterranean, where he burned four men-of-war under the castles and walls of Tripoli, belonging to the pirates of that place. He was present as captain of the "Edgar" (70) at the first fight at Bantry Bay, and shortly afterwards was knighted. In 1690 he convoyed William III. across St George’s Channel to Ireland; the same year he was made rear-admiral of the blue, and was present at the battle of Benskey Head on 20th July. In 1692 he was appointed rear-admiral of the red, and joined Admiral Russell, under whom he greatly distinguished himself at La Hogue, by being the first to break through the enemy’s line. Not long after, when Admiral Russell was superseded, Shovel was put in joint command of the fleet with Admiral Killigrew and Sir Ralph Delaval. In 1702 he brought home the spoils of the French and Spanish fleets from Vigo, after their capture by Sir George Rooke, and in 1704 he served under Sir George Rooke in the Mediterranean and co-operated in the taking of Gibraltar. In January 1704 he was named rear-admiral of England, and shortly afterwards commander-in-chief of the British fleets. He co-operated with the Earl of Peterborough in the capture of Barcelona in 1705, and commanded the naval part of the unsuccessful attempt on Toulon in October 1707. When returning with the fleet to England his ship, the “Association,” at eight o’clock at night on the 22nd of October, struck on the rocks near Scilly, and was seen by those on board the “St George” to go down in three or four minutes’ time, not a soul being saved of 800 men that were on board. The body of Sir Cloudesley Shovel was cast ashore next day, and was buried in Westminster Abbey. It is said that he was alive when he reached the shore at Porthclicke Cove, but was murdered by a woman for the sake of his rings.

See Life and Glorious Actions of Sir Cloudesley Shovel (1707); Burnett’s Own Times; various discussions in Nones and Queries, 7th series, vols. x. and xi.; and T. H. Cooke, Shipwreck of Sir Cloudesley Shovel (1883).

SHOVEL (O.E. scof, from root of scyf, to shove, push, cf. Ger. Schaufel, also Schäpppe, scoop), an implement or tool, consisting of a broad flat blade with edges or sides turned up fixed to a wooden handle terminating in a bow like a spade. It is used for lifting or removing such loose substances as coal, gravel, etc.

SHOVELER, formerly spelt SHOEYER, and more anciently SHELIVER, a word by which used to be meant the bird now almost inavariaibly called Spoonbill (g.v.), but in the latter half of the 16th century transferred to one hitherto generally, and in these days locally, known as the Spoon-billed Duck—the *Anas clypeata* of Linnaeus and *Rhynchospatia* or *Spatula clypeata* of modern writers. All these names refer to the shape of the bird’s bill, which, combined with the remarkably long *lamellae* that beset both maxilla and mandible, has been thought sufficient to distinguish it from the Linnaean *Spatula clypeata*. Except for the extraordinary formation of this species, which carries with it a clumsy look, the male Shoveler would pass for one of the most beautiful of this generally beautiful group of birds. As it is, for bright and variegated colouring, there are few of his kindred to whom he is inferior. His golden eye, his dark green head, surmounting a breast of pure white and succeeded by underparts and flanks of rich bay, are conspicuous; while his deep brown back, white scapulas, lesser wing-coverts (often miscalled shouldors) of a glaucous blue, and glossy green speculum bordered and white present a wonderful contrast of the richest tints, heightened again by his bright orange feet. On the other hand, the female, excepting the blue wing-coverts she has in common with her mate, is habited very like the ordinary Wild-Duck, *A. boschas*. The Shoveler is not an abundant species, and in Great Britain its distribution is local; but its numbers have remarkably increased since the passing of the Wild-Fowl Protection Act in 1876, so that in certain districts it has regained its old position as an indigenous member of the Fauna. It has not ordinarily a very high northern range, but inhabits the greater part of Europe, Asia and America, passing southwards, like most of the *Anasidae* towards winter, constantly reaching India, Ceylon, Abyssinia, the Antilles and Central America, while it is known to have occurred at that season in Colombia, and, according to Gould, in Australia. Generally resembling in its habits the other freshwater ducks, the Shoveler has one peculiarity that has been rarely, if ever, mentioned, and one that is perhaps correlated with the structure of its bill. It seems to be especially given to feeding on the surface of the water immediately above the spot where diving ducks (*Palaestina* etc.) employ themselves beneath. On such occasions a pair of Shoelers may be watched, almost for the hour together, swimming in a circle, about a yard in diameter, their heads turned inwards towards its centre, their bills immersed vertically in the water, and engaged in sifting, by means of the long *lamellae* before mentioned, the floating matters that are disturbed by
their submerged allies and rise to the top. These gyrations are executed with the greatest ease, each Shoveler of the pair merely using the outer leg to impel it on its circular course.

The genus *Sorex* includes, in North America, species of the family *Soricidae*, all possessing the characteristic light blue "shoulders," have been described: one, *S. platyurus*, from the southern parts of South America, having the head, neck and upper back of a pale reddish brown, freckled or closely spotted with dark brown, and a dull bay livery; a second, *S. capensis*, from South Africa, much lighter in colour than the female of *S. dyspeza;* a third and a fourth, *S. hypogea* and *S. variegata*, from Australia and New Zealand respectively—these last much darker in general colouration, and the males possessing a white crescentic mark between the bill and the eye, very like that which is found in the South-American Blue-winged Shrew. (Cystura mexicana), but so much lighter in each other that their specific distinction has been disputed by good authority.

A. N.

**SHREVEPORT.** A city and the capital of Caddo Parish, Louisiana, U.S.A., on the Red river, in the N.W. part of the state, near the Texas border. Pop. (1890) 11,979; (1900) 16,013, of whom 8,532 were negroes; (1910 census) 28,015. It is the second city of the state in population. It is served by the Vicksburg, Shreveport & Pacific, the Houston & Shreveport, the Kansas City Southern, the St. Louis & South-Western, the Louisiana Railway & Navigation Company, the Texas & Pacific (main line and two branches), the Louisiana & Arkansas, the Kansas City Southern, and the Missouri, Kansas & Texas railways and by boats on the Red river. In the city are the State Charity Hospital (1872), the T. E. Schumpert Memorial Hospital (1910), the Genevieve Orphanage (1890) and the Shreveport Training School (1908). Owing to its situation and excellent transportation facilities the city has a large trade. The surrounding country is a rich agricultural region, mainly devoted to the production of cotton, for which Shreveport is the principal shipping point. Live-stock and cattle products are trade items of importance. The situation of the city (about 170 m. from Dallas, and somewhat farther from Little Rock, Houston, and New Orleans) makes it a natural centre of wholesale trade of varied character, and the development since 1906 of the important Caddo oil and gas fields north of the city has added greatly to its industrial prominence. The city contains planing mills, cotton gins, compresses and cotton-seed oil mills, machine and railway shops, and ice and molasses factories. In 1905 its factory product was valued at $2,921,923 (87.8% more than in 1900). Shreveport was settled about 1835, incorporated as a town in 1839, and chartered as a city in 1871. It was named in honour of Henry Miller Shreve (1785-1854), a native of New Jersey, who in 1815 ascended the Mississippi and the Ohio rivers to Louisville in the "Enterprise," the first steam vessel to make this trip, introduced improvements in the steamboat, and in 1826-1841 had charge of river improvements of western rivers, removing during this period the great Red river obstacles. After the capture of Baton Rouge, the state capital, and New Orleans by the Unionists in 1862, Shreveport was occupied by the Confederate officials of the state. In the spring of 1863 and again in that of 1864 it was the objective of combined naval and land expeditions made by the Union forces up the Red river under command of Admiral David D. Porter and General N. P. Banks, the Confederate commander in Louisiana being General Richard Taylor, with General E. Kirby Smith in charge of the entire Trans-Mississippi department. In 1863 Shreveport was not seriously threatened. In 1864 when the Federals were within two marches of the city they were worsted by Taylor at Mansfield (on the 8th of April); on the next day the Confederates in their turn met with a demoralising repulse at Pleasant Hill.

**SHREW.** A term applied to the species of the family *Soricidae* of the mammalian order insectivora (q.v.), but in the British Isles to the common and lesser shrews (Sorex araneus and *S. minutus*).

The common shrew, or, properly, shrew-mouse, which in England is by far the commoner of the two, is a small animal about the size of a mouse, which it somewhat resembles in the shape of its body, tail and feet. But here the resemblance ends, for, unlike the mouse, it possesses a long and slender muzzle, with prominent nostrils, which project far beyond the lower lip; the small eyes are almost concealed by the fur; the ears are wide, short and provided internally with a pair of deep folds, capable when laid forwards of closing the entrance; the tail, which is slightly shorter than the body, is quadrangular in section and clothed more or less densely with moderately long hairs, terminating in a short tuft, but in old individuals almost naked; the feet are five-toed, the toes terminating in slender, pointed claws. The dentition is very peculiar and characteristic: there are in all thirty-two teeth, tipped with deep crimson; of which twelve belong to the lower jaw; of the remaining twenty ten occupy each side of the upper jaw, and of these the first three are incisors. The first incisor is large, with a long anterior canine-like cusp and a small posterior one; then follow two small single-cusped teeth; which are succeeded by three similar progressively smaller teeth, the first being a canine and the other two premolars; the next, a premolar, is large and multi-cuspid, and this is followed by three molars, of which the third is small with a triangular crown. In the lower jaw there are anteriorly three teeth corresponding to the seven anterior teeth above, of which the first is almost horizontal in direction, with its upper surface marked by three notches, which receive the points of the three upper front teeth; then follow two small teeth and three molars. The body is clothed with closely set fur, soft and dense, varying in colour from light reddish to dark brown above; the under surface of both body and tail being greyish; the basal four-fifths of all the hairs above and beneath are dark bluish grey. On each side of the body, about one-third of the distance between the elbow and the knee, is a gland covered by two rows of coarse guard hairs, which secrete a fluid with an unpleasant cheesy odour, and which is protective, rendering the creature secure against the attacks of predaceous animals.

The lesser or pigmy shrew (S. minutus) is not so abundant in England and Scotland, but common in Ireland, where the other species is unknown. It appears at first sight to be a diminutive variant of that species, which it closely resembles in external form, but the third upper incisor is shorter, or not longer than the next following tooth, whereas in *S. araneus* it is longer, and the length of the forearm and foot is less in the former species than in the latter.

Both these shrews live in the neighbourhood of woods, making their nests under the roots of trees or in any slight depression, occasionally even in the midst of open fields, inhabiting the disused burrows of field-mice. Owing to their small size, dark colour, rapid movements and nocturnal habits, they easily escape observation. They seek their food, which consists of insects, grubs, worms and slugs, under dead leaves, fallen trees and in grassy places. They are pugnacious, and if two or more are confined together in a limited space they invariably fight fiercely, the fallen becoming the food of the victorious. They are also exceedingly voracious, and soon die if deprived of food; and it is probably to insufficiency of food in the early dry autumnal season that the mortality among them at that time is due. The breeding-season extends from the end of April to the beginning of August, and five to seven, more rarely ten,
SHREWSBURY, EARLS OF—SHREWSBURY, DUKE OF

young may be found in the nests; they are naked, blind and toothless at birth, but soon run about snapping at everything within reach.

The alpine shrew (S. alpinus), restricted to the alpine region of Central Europe, is slightly longer than the common shrew and differs in its longer tail, which exceeds the length of the head and body, in the colour of the fur, which is dark on both upper and under surfaces, and in the large size of the upper antepenultimate premolar.

The water-shrew (Neomys fodiens), the third species inhabiting England, differs from the common shrew in being larger with a shorter and broader muzzle, smaller eyes and larger feet adapted for swimming—the sides of the feet and toes being provided with comb-like fringes of stiff hairs. The tail is longer than the body, and has a fringe of moderately long regularly ranged hairs, which extend along the middle of the under surface from the end of the basal third to the extremity. The fur is long and dense, varying in colour in different individuals; the prevailing shades are dark, almost black, brown above, beneath more or less bright ash tinged with yellowish; but occasionally we find individuals with the under surface dark-coloured. In the number and shape of the teeth the water-shrew differs from the common shrew: there is a premolar less on each side above; the bases of the teeth are more prolonged posteriorly; and their cusps are less stained brown, so that in old individuals they often appear white. This species is aquatic in habits, swimming and diving with agility. It frequents rivers and lakes, making burrows in the banks, from which when disturbed it escapes into the water. Its food consists of water insects and their larvae, small crustaceans and probably the fry of small fishes. It is generally distributed throughout England, is less common in Scotland and not recorded in Ireland.

The geographical range of the common shrew is wide, extending eastwards through Europe and Asia to Amurland. The lesser shrew extends through Europe and Asia to Sakhalin Island; and specimens of the water-shrew have been brought from different parts of the world. Another species, found in Siberia the common shrew is abundant in the snow-clad wastes about the Olonok river within the arctic circle. Other species of red-toothed shrews are restricted chiefly to North America, where they are found in greater variety than in the Old World, though Neomys is not represented. Its place is taken by Sorex palustris east of the Rocky Mountains, and S. hydrodromus in Unalaska Island, which, like the water-shrew, have fringes of teeth on the feet, but the unfringed tail and dentition of the common shrew. Of the American forms S. bendiri is the largest. Other red-toothed shrews belonging to the genus Blarina, distinguished from Sorex by the dentition and the shortness of the tail, are common in North America. All red-toothed shrews (except the aquatic forms) closely resemble one another in habits, but the short-tailed North American shrew supplements its insectivorous fare by feeding on beechnuts. In destroying numbers of slugs, insects and larvae, shrews aid the farmer and merit protection. Although their odour renders them safe from rapacious animals, they are destroyed in numbers by owls.

SHREWSBURY, EARLS OF. The earldom of Shrewsbury, one of the most ancient in the English peerage, dates from the time of William the Conqueror. Roger de Montgomery (c. 1030-1094), son of another Roger de Montgomery, known as "the Great," was a councillor of William, duke of Normandy, before his invasion of England, and was probably entrusted by William with the government of Normandy during the expedition of 1066. Roger came to England in the following year and received extensive grants of land in different parts of the kingdom. Obtaining a great estate in the county of Shropshire, he became the pre-eminent residence at the castle of Shrewsbury, he like his successors was generally styled earl of Shrewsbury. He probably exercised palatine authority. He was the founder of Shrewsbury Abbey in 1083. His first wife was Mabel, daughter of the seigneur of Belesme and Alençon; hence his son Robert, who, after the death of another son, Hugh, succeeded to the earldoms of Shrewsbury and Arundel, was generally known as Robert de Belesme (q.v.), one of the most celebrated of the feudal nobles of the time of Henry I. Robert having crossed to Holland to aid his English estates and honours in 1102, the earldom of Shrewsbury was next conferred on John, 5th baron Talbot, whose descendants have borne the title to the present day. (See Talbot; and Shrewsbury, 1st Earl of, below.)

SHREWSBURY, CHARLES TALBOT, DUKE OF (1660-1718), only son by his second wife of Francis Talbot, 11th earl of Shrewsbury, was born on the 24th of July 1660. His mother was a daughter of Robert Brudenell, 2nd earl of Cardigan, and the notorious mistress of the 2nd duke of Buckingham, by whom his father was killed in a duel in 1668. Charles was a godson of King Charles II., after whom he was named, and he was brought up as a Roman Catholic, but in 1679 under the influence of Tillotson he became a member of the Church of England. On his father's death in 1688 he succeeded to the earldom of Shrewsbury; he received an appointment in the household of Charles II., and served in the army under James II. But in 1687 he was in correspondence with the Prince of Orange, and he was one of the seven signatories of the letter of invitation to William in the following year. He contributed towards defraying the expenses of the projected invasion, and having crossed to Holland to join William, he landed with him in England in November 1688. Shrewsbury became a secretary of state in the first administration of William and Mary, but he resigned office in 1690 when the Tories gained the upper hand in parliament. While in opposition he brought forward the triennial bill, to which the king refused assent. In 1694 he again became secretary of state; but there is some evidence that as early as 1690, when he resigned, he had gone over to the Jacobites and was in correspondence with James at St Germaines, though it has been stated on the other hand that his later political views were decided on account of his connexion for reasons of policy. However this may be, William appears to have had no suspicion of Shrewsbury's loyalty, for on the 30th of April 1694 the latter was created marquess of Alton and duke of Shrewsbury, and he acted as one of the regents during the king's absence from England in the two following years. In 1696 definite accusations of treason were brought against him by Sir John Fenwick, which William himself communicated to Shrewsbury; and about this time the secretary of state took but a small part in public business, again professing his anxiety to resign. His plan of 1690 was a genuine one, and in 1700 the king reluctantly consented to his retirement into private life.

For the next seven years Shrewsbury lived abroad, chiefly at Rome, whence in 1701 he wrote a celebrated letter to Lord Somers expressing his abhorrence of public life and declaring that if he had a son he "would sooner bind him to a cobbler than a courtier, and a hangman than a statesman." On the accession of Queen Anne the whig leaders made an ineffectual attempt to persuade Shrewsbury to return to office. When, however, at last he did return to England in 1707 he gradually became alienated from his old political associates, and in 1710 he accepted the post of lord chamberlain in the Tory administration to which the queen appointed him without the knowledge of Godolphin and Marlborough, while his wife was at the same time made a lady of the bedchamber. After a diplomatic mission to France for the purpose of negotiating preliminaries of peace, Shrewsbury became lord lieutenant of Ireland in 1713; but he was in London in July 1714 during the memorable crisis occasioned by the impending death of Queen Anne. On the 27th of July, when the queen was dying, he appeared before her and received his long-delayed dismissal from the office of lord treasurer. On the 30th Shrewsbury and other ministers assembled at Kensington Palace, and being admitted to the queen's bedchamber Bolingbrooke recommended the appointment of Shrewsbury to the vacant treasurership; Anne at once placed at staff of that high office in the duke's hands. When
the queen died on the 1st of August Shrewsbury was thus in a position of supreme power with reference to the momentous question of the succession to the crown. He threw his influence into the scale in favour of the elector of Hanover, and was powerfully influential in bringing about the peaceful accession of George I., and in defeating the design of the Jacobites to place the son of James II. on the throne. His disinclination for the highest political offices remained, however, as great as before; and having resigned the lord-lieu tenancy and the lord-lieutenancy of Ireland, he was appointed lord chamberlain. This place he resigned in July 1715, and he died on the 1st of February 1718.

The duke of Shrewsbury was one of the greatest noblemen of the time of Queen Anne. Strikingly handsome in person, his demeanour was dignified and his manners full of grace and courtesy. Swift described him as "the finest gentleman we have," and as "the favourite of the nation," while William III. spoke of him as "the king of hearts." Like most of his contemporaries he endeavoured to keep himself in favour both with the exiled house of Stuart and with the reigning sovereign in England; but at the two critical junctures of 1688 and 1714 he acted decisively in favour of the Protestant succession. At other times he appeared weak and vacillating, and he never withstood the dictates either of his whim or of his affection, though he co-operated with each in turn. His magna nis disposition saved him from the vindictiveness of the party politician of the period; and the weak health from which he suffered through life probably combined with a congenital lack of ambition to prevent his grasping the power which his personality and talents might have placed in his hands.

In 1705 Shrewsbury married Adelaide, daughter of the Marquis Paleotti of Bologna. This lady, who is said to have had a great many engaging qualities besides many accomplishments, was the subject of much malicious gossip. She was also the widow, or as some declared, the mistress of a Count Brachiano; and Lady Cowper reported that the lady's brother had forced Shrewsbury to marry her "after an intrigue together." After Shrewsbury's return to England the duchess became conspicuous in London society, where the caustic wit of Lady Mary Wortley-Montagu was exercised at her expense. On the accession of George I., the duchess of Shrewsbury became a lady of the bedchamber to the princess of Wales, a position which she retained till her death on the 29th of June 1756. Shrewsbury left no issue by his marriage, and his place was filled in the earldom of Shrewsbury passing to his cousin Gilbert Talbot (see Talbot).

SHREWSBURY, ELIZABETH TALBOT, COUNTESS OF (1518–1608), better known by her nickname "Bess of Hardwick," was the daughter and co-heiress of John Hardwicke of Hardwicke in Derbyshire. At the age of fourteen she was married to a John Barlow, the owner of a large estate, who did not long survive the marriage, and as his estates had been settled on her and her heirs, she became a wealthy widow. She remained single until 27th August 1549, when she married Sir William Cavendish, who, to please her, sold his lands in the south of England and purchased the Chatsworth estates in Derbyshire. Six children were born of the marriage, three sons and three daughters. One of the sons was the founder of the ducal family of Devonshire, and another of the ducal family of Newcastle. Sir William Cavendish having died on the 25th of October 1557, her third husband was Sir William St Lo (or St Loe or St Lowe), captain of the guard to Queen Elizabeth and owner of an estate at Tormarton in Gloucestershire. She insisted that his lands should be settled on her and her heirs, and when Sir William died without issue, she made good her claim to all his property to the detriment of his sister and cousins. Bess of Hardwick was now the wealthiest subject in England. Her income was calculated to amount to £60,000, which was relatively a far more important sum than it is to-day. She still retained much of her good looks; her charms and her wealth outweighed her reputation for rapacity, and she was much sought in marriage. With the approval of Queen Elizabeth, who was not by habit a matchmaker, she was married in 1568 for the fourth time to George Talbot, 6th earl of Shrewsbury. Bess made her usual good bargain as to settlements, and also insisted on arranging marriages between two of her children—William Cavendish and two of the earl's by a former marriage. In 1574 the countess took advantage of a visit of the countess of Lennox to marry her daughter Elizabeth to Charles Stuart, the younger son of the Lennoxes and brother of Lord Darnley, the second husband of the queen of Scots. She acted without the knowledge of her husband, who declined to accept any responsibility. As the Lennox family had a claim to the throne this match was considered as a proof of the ambition of the countess of Shrewsbury, and she was sent to the Tower by the queen, but soon released. The child of the marriage was James VI., who was treated with the most tenderness by his grandmother treated at first with favour but later on with cruelty and neglect.

By this time the earl of Shrewsbury and his wife were on very bad terms with one another, and the former tried to obtain a divorce. The countess revenged herself by accusing him of a love intrigue with the queen of Scots, a charge which she was forced to retract before the council. In the meantime she had told some filthy scandal about Queen Elizabeth to Queen Mary, who made use of it in the extraordinary letter she wrote some time in 1584. In 1581 the countess of Shrewsbury went to live apart from her husband, with whom she was afterwards reconciled formally by the queen. After his death in 1590 she lived mostly at Hardwicke, where she built the noble mansion which still stands. She was indeed one of the greatest builders of her time at Hardwicke, Chatsworth and Oldcoates. It is said that she believed she would not die so long as she was building. Her death came on the 13th of February 1608 during a frost which put a stop to her building operations. She was buried in All Saints' Church, Derby, under a fine monument with a laudatory description which has been published. A number of portraits of her exist at Hardwicke, one taken in her youth, while the second, by Cornelius Jansen, engraved by Vertue, represents her as an old woman. She had no children except by her second husband, and to them she left the vast estates she accumulated by her successive marriages.

See White Kennett, Memoirs of the Cavendish Family (London, 1708); and Mrs Murray Smith (Miss E. T. Bradley), Life of Arabella Stuart (London, 1869); Mrs Stepney Rawson, Bess of Hardwicke (1910).

SHREWSBURY, JOHN TALBOT, 1ST EARL OF (d. 1453), was second son of Richard, 5th baron Talbot, by Ankaret, heiress of the last Lord Strange of Blackmore. He was married before 1404 to Maud Neville, heiress of the barons Furnival, and in her right summoned to parliament from 1409. In 1421 by the death of his niece he acquired the baronies of Talbot and Strange. From 1404 to 1413 he served with his elder brother Gilbert in the Welsh war. Then for five years from February 1414 he was lieutenant of Ireland, where he held the honour of Wexford. He did some fighting, and had a sharp quarrel with the earl of Ormond. Compounding was then against him both for harsh government in Ireland and for violence in Herefordshire. From 1420 to 1424 he served in France. In 1425 he was again for a short time lieutenant in Ireland. So far his career was that of a turbulent lord of the Marches, employed in posts where a rough hand was useful. In 1427 he went again to France, where he fought with distinction in Maine and at the siege of Orleans; but his exploits were those of a good fighter rather than of general, and it was his stubborn rashness that was chiefly to
Shrewsbury

189

Blame for the English defeat at Patay in June 1429. After Patay, Talbot was four years a prisoner. On his release he became one of the foremost of the English captains. In 1434 he recovered the city of Clermont, next year took part in the siege of St. Denis, and in 1436 by reducing and harrying the revolted Pays de Caux saved Normandy. He was rewarded with the offices of captain of Rouen and marshal of France. During five years as a dashing fighter he was the mainstay of the English cause. His chief exploits were the defeat of the Burgundians before Crotory in 1437 and the recovery of Harfleur in 1440. In 1442 during a visit to England he was created earl of Shrewsbury. In November he was back in France besieging Dieppe; "for to foul with his men that they could no longer live with him" and was forced to break the siege (Chronicles of London, p. 150). In March 1445 he was once more sent to Ireland, where he used his old methods, so that the Irish said "there came not from the time of Herod any one so wicked in evil deeds." In 1449 he served for a short time in Normandy. When in 1452 the Gascons appealed for English help, Shrewsbury was the natural leader of the expedition. He landed in Aquitaine on the 17th of October. Bordeaux and the surrounding district returned guilfs to his old allegiance, and in the following year Shrewsbury captured Fronsac. In July the French besieged Castillon. Shrewsbury hurried to its relief, and with foolhardy valour attacked the enemy in their entrenched camp without waiting for his artillery. The English and Gascon footmen charged in vain in face of the French cannon, until Shrewsbury and the flower of his troops had fallen. This happened in July 1453 and was the end of the English rule in Gascony. Shrewsbury's fighting qualities made him something of a popular hero, and in the dogged of the day he was "Talbot our good dog," whose valour was brought to nought by the treason of Suffolk. But in truth though a brave soldier he was no general. He was twice married, his second wife being Margaret, eldest daughter of Richard Beauchamp, earl of Warwick. He was alleged to be eighty years old at his death; probably he was about sixty-five.

Bibliography.----For Shrewsbury's French campaigns see especially the Chronique de E. de Montrelet, Jehan de Waurin and Matthieu d'Escouchy (all these are published by the Société de l'Histoire de France), and the Chronicles of London (ed. C. L. Kingsford, London, 1905). Also H. Ribaudié, Conquête de Gascogne (1866); J. T. Gilbert, Viceroy of Ireland (1885); and J. H. Wylie's Henry the Fourth (1884-1898) for his early career. (C. L. K.)

Shrewsbury, a municipal and parliamentary borough, market town and the county town of Shropshire, England. Pop. (1901), 28,395. It is situated on both banks of the river Severn, but mainly on a peninsula formed by the river on the left bank. It is served by the London & North-Western and Great Western railways, being 163 m. N.W. from London. The companies use a joint station, and jointly work the line S. to Hereford. There is water communication eastward by the Shrewsbury canal, and by the Severn below the town. Eastward from the peninsula the English bridge crosses the river, westward the Welsh bridge; southward the Kingsland and Greyfriars bridges. The joint railway station is on the peninsula, and is reached from the south by a massive iron bridge. The streets, many retaining ancient names curiously corrupted, are hilly and irregular, but strikingly picturesque from their number of antique timber houses, among which may be mentioned that in Buttercough, formerly the town residence of the abbots of Lilleshall; the council-house overlooking the Severn, erected in 1610 for the presidents of the council of the Welsh marches; and the two adjacent mansions of Robert Ireland and Richard Owen, citizens c. 1500. Of the town ramparts built in the reign of Henry III. the principal remain is a portion to the south-west, used as a public walk, on which stands a square embattled tower. The castle built by Roger de Montgomery was dismantled in the reign of James II., and is modernized as a residence, but there remain the archway of the interior gateway, the walls of the inner court and two large round towers of the time of Edward I. The rich abbey of St Peter and St Paul was also founded by Roger, on the site of an earlier church. Of the abbey church (Holy Cross) the nave of massive Norman work remains, especially imposing owing to the warm red stone in which it is built; there are further two Early English arches and the western tower. Of the monastic buildings little is left, save a remarkable roofed pulpit of ornate Decorated work. Among other churches St Mary's, founded in the 10th century, is a fine cruciform structure with a lofty tower and spire, displaying examples of various styles of architecture from early Norman to Perpendicular, the base of the tower, the nave and the doorways being Norman, the transept Early English and the aisles 15th century, while the interior is specially worthy of notice for its elaborate details, its early stained glass, including a Crucifixion, and its ancient monuments. Some 10 ft. of the spire fell in 1894, severely injuring the church and necessitating extensive restoration. St Julian's was originally built before the Conquest, but rebuilt in 1748, except the tower, the older portion of which is Norman and the upper part of the 13th century. St Alkmund's also dated from the 1oth century, but was rebuilt towards the close of the 18th century, with the exception of the tower and spire. It has a beautiful half-timbered rectory. St Giles's, originally the church of the leper hospital, dating from the time of Henry I., was altered at various periods. The hospital chamber remains, and bears a name of the Pest Basin, because the citizens cast alms into it in the 16th century during the visitation of the plague, which, according to tradition, first appeared here. The old church of St Chad, supposed to have occupied the site of a palace of the princes of Powis, was destroyed by the fall of the tower in 1788, and of the ancient building the bishop's chancel alone remains. The new church of St Chad was built on another site in 1792. Shrewsbury is not fortunate in its ecclesiastical architecture of the late 18th century. There are slight remains of a Franciscan house (Grey Friars) founded in 1291, of an Augustinian friary (1253) and of a Dominican house (1222). The old buildings completed in 1630 for the grammar school of Edward VI., founded in 1551, are now occupied by the county museum and free library, the school having been removed in 1882 to new buildings in the suburb of Kingsland S. of the river. It takes rank among the first public schools in England. The ground it occupies in Kingsland was formerly the scene of the Shrewsbury show, a pageant and festival held during the festival of Trinity. Among the principal secular buildings of the town are the fine market house in the Elizabethan style (completed according to an inscription over the northern arch in 1595), the shire hall and guildhall (rebuilt in 1837, and again, after a fire, in 1883), the general market and corn exchange (1860), and the drapers' hall, a timbered structure dating from the 16th century. The principal benevolent institutions are the county infirmary (1747), Millington's hospital (1734) and the eye, ear and throat hospital (1881). A monument to Lord Clive, who was member for the borough 1761-1764, was erected in the market-place in 1860, and a Doric memorial pillar to General Lord Hill in 1816 at the top of the Abbey Foregate. The town race-course occupies a portion of the "Soldiers' Piece," where Charles I. addressed his army in 1642. To the south-west of the town is a park of 23 acres, known as the Quarry, with beautiful avenues of lime-trees, descending to the river. Glass-staining, the spinning of flax and linen yarn, iron-founding, brewing, malting, the preparation of brawn and the manufacture of the well-known Shrewsbury cakes are now the principal industries. Shrewsbury is a suffragan bishopric in the diocese of Lichfield, and the seat of a Roman Catholic bishop. The parliamentary borough returns one member. The town is governed by a mayor, 10 aldermen and 30 councillors. Area, 3572 acres.

Shrewsbury (Pengwernia, Scrobybury, Salopshire), then known as Pengwern or Pengwyn, was the capital of the kings of Powis during the 5th and 6th centuries, but was taken in 770 by Offa king of Mercia, who changed its name to Shrewsbury (Scrobybury). Owing to its position on the Welsh borders it became one of the chief cities of the Saxon kings, and a mint was established here in the reign of King Æthelstan. After the Conquest the town was included in the earldom of Shrewsbury, and the Domesday Survey shows that the Saxon burgesses
Sundevall, northern general 1645. parliament During considerable succeeding wealth Linnaeus in a 1283 the was Charles which it is. The according England, is England, or. Few nearly is. On these few, with others included in the genus Lanius, which there is no room here to specify, have, according to their respective power, the very remarkable habit (whence they have earned their opprobrious name) of catching insects, frogs, lizards or small birds and mammals, and of spitting them on a thorn or of fixing them in a forked branch, the more conveniently to tear them in pieces and eat them. The shrikes belong to the Passerine family Laniidae, the limits of which are doubtful, but which is divided into five sub-families: Gymnorhinhinae, Malacanotoninae, Pachycephalinae, Laniinae and Prionopinae. The Laniinae or true shrikes occur in the Old and New Worlds, the other sub-families are limited to the Old World. The shrikes and their immediate allies are active and powerful birds, with stout bills often strongly hooked. Their diet is chiefly insects and small frogs, lizards and mammals, but they also take seeds and fruits. The “greenlets” of North and South America are active and fearless birds, similar in general habits to the Laniidae and formerly regarded as forming a sub-family of that group, but now placed in a separate family the Vireonidae. (A. N.)

SHRIMP, a name applied in general to the smaller crustaceans of the order Macrura and in particular to an edible species found on the coasts of northern Europe (Crangon vulgaris). The shrimps and their allies are distinguished from the larger Macrura, such as the lobsters and crayfishes, by greater development of the paddle-like limbs of the abdomen or tail, which are used in swimming. The abdomen is usually sharply bent between the third and fourth segments and has a characteristically humped appearance when straightened out.

The common shrimp is found abundantly on the coasts of the British Islands, in shallow water wherever the bottom is sandy. It is 2 or 3 in. long, slightly flattened and with the rostrum or beak, in front of the carapace, very short. It is of a transverse variation in colour, speckled white, brown and black, and resembles the sand in which it lives. On many parts of the coast the shrimp fishery is of considerable importance. The instrument generally employed is a bag-shaped net attached to a semicircular hoop, provided with a long handle and pushed over the surface of the sand by a fisherman wading in the water at ebb-tide. When boiled, the body becomes of a brownish colour and on this account the species is sometimes termed the “brown shrimp.” The name of “pink shrimp” is given to Pandalus montagui or annulicornis, which turns red on boiling and which resembles in form the larger “prawns” having a long rostrum or beak, saw-edged above and below. The smaller species of Leander, especially L. squilla, are sold as “cup-shrimps” in some places.

The larger shrimp-like crustaceans are generally known as “prawns,” the name being especially applied in Britain to the species Leander serratus, formerly called Palaemon serratus, which is highly esteemed for the table. In warmer seas many other kinds of prawns are caught for food. These are generally species of the genus Palaemon (like P. carnatus of the Mediterranean), which are distinguished from all those already mentioned by having pincers on the first three, instead of only on the first two pairs of legs. The large river-prawns of the genus Palaemon particularly observable in Eastern examples—barred with dusky markings. The quill-feathers of the wings, and of the dorsally black, with mostly the former, though what there is of the latter shows very conspicuously, especially at the base of the remiges, where it forms either a single or a double patch. Much smaller than this is the red-backed shrike, L. collurio, the best-known species in Great Britain, where it is a summer visitor, and, though its distribution is rather local, it may be seen in many parts of England and occasionally reaches Scotland. The cock is a sightly bird with his grey head and neck, black cheek-hand, chestnut back and pale rosy breast, while the hen is distinguished by a dull brown, barred on the lower plumage. A more highly coloured species is called the woodchat, L. auriculatus or rutilus, with a bright bay crown and nape, and the rest of its plumage black, grey and white. This is an accidental visitor to England, but breeds commonly throughout Europe. All these birds, with many others included in the genus Lanius, which there is no room here to specify, have, according to their respective power, the very remarkable habit (where those that have earned their opprobrious name) of catching insects, frogs, lizards or small birds and mammals, and of spitting them on a thorn or of fixing them in a forked branch, the more conveniently to tear them in pieces and eat them. The shrikes belong to the Passerine family Laniidae, the limits of which are doubtful, but which is divided into five sub-families: Gymnorhinhinae, Malacanotoninae, Pachycephalinae, Laniinae and Prionopinae. The Laniinae or true shrikes occur in the Old and New Worlds, the other sub-families are limited to the Old World. The shrikes and their immediate allies are active and powerful birds, with stout bills often strongly hooked. Their diet is chiefly insects and small frogs, lizards and mammals, but they also take seeds and fruits. The “greenlets” of North and South America are active and fearless birds, similar in general habits to the Laniidae and formerly regarded as forming a sub-family of that group, but now placed in a separate family the Vireonidae. (A. N.)

SHRINE—SHRIMP 1019

paid the same danegeld as in the reign of Edward the Confessor. Until Wales was annexed to England in the 13th century, S. was a group of the civil border towns, and as such it was besieged by Owen Gwynnedd in 1667, but was relieved by William the Conqueror. In the reign of Henry I. it was garrisoned by Robert de Belesme, but surrendered to the king in 1120. It was several times burnt by the Welsh and was taken and held by them from 1215 to 1221. During the Welsh war in the reign of Edward I., the king made the town his headquarters, and in 1283 David, the last native prince of Wales, was tried and condemned to death by a parliament held here. In 1403 Henry Percy, son of the earl of Northumberland, was defeated and killed at Shrewsbury by Henry IV. At the beginning of the Civil War, Charles I. stayed in the town for some time, but it surrendered to parliament in 1645. The first extant charter, dated 1190, is a grant by Richard I. to the burgesses of the town at a fee farm of 40 marks, but Henry II. is known to have granted an earlier charter which was confirmed by King John in 1200. The same king granted two other charters, one in 1200 giving the right of electing the reeves, and the other in 1205 providing that their lands and tenements should be governed by the “laws of Bretueil, the laws of the Baronies and the laws of the English.” Henry II. in 1217 granted a gild merchant with a house. Besides these charters there are numerous confirmations before the incorporation charter of Elizabeth of 1586. Charles I. in 1638 altered the corporation to a mayor, 24 aldermen and 48 assistants. In 1684 the burgesses surrendered their charter to the king and received a new one in the following year which, however, did not change the form of government. From 1295 to 1885 Shrewsbury returned two members to parliament, but then the number was reduced to one. See H. Owen and J. C. Blakeway, A History of Shrewsbury (1825); Thomas Phillips, The History and Antiquities of Shrewsbury (1837); Victoria County History, Shropshire.

SHRIKE, a bird’s name, so given by Turner (1544), but solely on the authority of Sir Francis Lovell, for Turner had seen the bird but twice in England, though in Germany often, and could not find anyone else who so called it. However, the word1 was caught up by succeeding writers; and, though hardly used except in books—for butcher-bird is its vernacular synonym—it not only retains its first position in literary English, but has been largely extended so as to apply in general to all birds of the family Laniidae and others besides. The name Lanius, in this sense, originated with C. Gesner2 (1555), who thought that the birds to which it gave he had not been mentioned by the ancients. C. J. Sundeall, however, considers that the Malacocroanen of Aristotle was one of them, as indeed Turner had before suggested, though repelling the latter’s supposition that Aristotle’s Tyrranou was another, as well as P. Belon’s reference of Calliprion. These species designated as shrike by Turner is the Lanius excisitor of Linnæus and nearly all succeeding authors, nowadays3 commonly known as the greater butcher-bird, ash-coloured or grey great shrike—a bird which visits the British Islands pretty regularly, though not numerously, in autumn or winter, occasionally prolonging its stay into the next summer; but it has never been ascertained to breed here, though often ascertained to have done so. This is the more remarkable since it breeds more or less commonly on the continent from the north of France to within the Arctic Circle. Exceeding a song-thrush in linear measurements, it is a much less bulky bird, of a pearly grey above with a well-defined black back passing from the forehead to the ear-coverts; beneath it is nearly white, or—and this is

1 Few birds enjoy such a wealth of local names as the shrikes. M. Rolland (Fauna pop. de la France, ii. 145-151) enumerates towards of ninety applied to them in France and Savoy; but not one of these is applicable to our wilderness.

2 He does not seem, however, to have known that butcher-bird was an English name; indeed it may not have been so at the time, but subsequently introduced.

3 He was not well known by the name of Würper, Rae and Charlton, it was in their day called in many parts of England “Wierangle” (Ger. Würpangel and Würger, the strangler); but it is hard to see how a bird which few people in England could know by sight should have a popular name, though Chaucer had used it in his Assembly of Foules.
SHRINE—SHROPSHIRE.

Sandstone and Shineton Shales are the local representatives of the Cambrian system. These are followed by the Ordovician formations which occupy three areas: the Breidden Hills, the Shelve district and the Caer Caradoc district, and include strata referable to the Arenig, Llanvirn and Silurian periods. The sandstones, shales, grits and volcanic ashes, with dolerite intrusions. The Silurian rocks which follow unconformably are represented in the Long Mountain and Clun Forest regions by sandstones and shales, and also in the Rock Edge district and at the Monk Mylne Hill (Wenlock) for the schists of Rushton, the lavas and ashes of the Wrekin, Caer Caradoc and Pontesford, and the purple slates, grits and conglomerates of the Longmynd. The Wrekin Quartzite, Comley

SHRINE

Small Titterstone, and are abundant in the sea round our coasts, are often called "Opossums" from the fact that the eggs are provided with a ventral pouch or "marsupium" in which the eggs and young are carried.

(‚T. C.A.

The name of shrims is sometimes given to members of the order Schizopoda, which differ from most of the Macrura in having swimming branches or exopodites on the thoracic legs. In particular the Schizopoda of the family Mysidae, which are abundant in the sea round our coasts, are often called "Opossums" from the fact that the eggs are provided with a ventral pouch or "marsupium" in which the eggs and young are carried.

(F. kerin, Ital. scrobige), the term given to the repository or chest to hold sacred relics. Sometimes shrims are merely small boxes, generally with raised tops like roofs; sometimes actual models of churches; sometimes large constructions like that at St Albans, that of Edward the Confessor at Westminster, of Ste Genevieve at Paris, &c. Many are covered with jewels in the richest way, such as the example at St Taurin, at Evreux in Normandy, and that of San Carlo Borromeo, at Milan, of beaten silver; the largest series are those entered in the enamel catalogues. Sometimes the term is given to the chapel in which the shrine is deposited.

SHROPSHIRE (Salop), a western county of England on the Welsh border, bounded N. by Cheshire and a detached portion of Flint, E. by Staffordshire, S.E. by Worcestershire, S. by Herefordshire, S.W. by Radnorshire, W. by Montgomeryshire and N.W. by Denbighshire. The area is 1343 sq. m. The name of Salop, in common use, comes from an early name of the county town of Shrewsbury. Towards the west Shropshire partakes of the hilly scenery of Wales, from which several ranges are continued into it. South of the river Severn and partly in Montgomeryshire, the Breidden Hills rise abruptly in three peaks; and in the south-west there is a broad range of rough rounded hills known as Clun Forest, extending from Radnorshire. South and west of the Severn there are four other principal chains of hills extending from S.W. to N.E.—the Long Mynd (1674 ft.), west of Church Stretton; the Caradoc Hills, a little to the north, which are continued across the Severn and terminate in the isolated sugarloaf hill of the Wrekin (1335 ft.); Wenlock Edge, east of Church Stretton, a sharp ridge extending for 20 m., and at some points rising above 1000 ft.; and the Clive Hills near the south-eastern border (Brown Clive, 1805 ft.; Titterstone Clee, 1749 ft.). The remainder of the county is for the most part pleasantly undulating and well cultivated. It lies almost entirely in the basin of the Severn, which enters from Montgomeryshire and flows eastwards to Shrewsbury, after which it turns south-eastward to Ironbridge, and then continues in a more southerly direction past Bridgnorth, entering Worcestcr near Bewdley. The scenery on its banks is striking at some places, as near the finely situated town of Bridgnorth, but it is spoilt in one of the most beautiful stretches, that near Coalbrookdale, by the great factories in the neighbourhood. Its principal tributaries within Shropshire are: from the right the Rea, the Cound and the Borle; from the left the Vyrnwy, a well-known trout-stream forming part of the boundary with Montgomeryshire, the Perry, the Tern, which receives the Roden, and the Worfe. The Dee and its tributary the Ceiriog touch the north-western boundary of the county with Denbighshire. In the south the Teme, which receives the Clun, the Onny and the Corve, flows near the borders of Herefordshire, which it occasionally touches and intersects. Salmon are taken in the Severn, and the Teme with its tributaries are frequented for trout and gravel fishing. There is a cluster of picturesque mere or small lakes in the north-west near the borders of Denbighshire, of which the largest is Ellesmere, and there are a number of others in various parts of the county.

Geology.—The Pre-Cambrian rocks of Shropshire include the great series of the Coalbrookdale and Long Mynd formation. The Coalbrookdale and Wenlock Beds, the schists of Rushton, the lavas and ashes of the Wrekin, Caer Caradoc and Pontesford, and the purple slates, grits and conglomerates of the Longmynd. The Wrekin Quartzite, Comley

Shropshire (5271). The more important towns not mentioned above are Broseley, Coalbrookdale, Madeley (this parish including Ironbridge and Coalport) and Much Wenlock, which are embraced wholly or in part by the borough of Wem; market Drayton (5167) and Shifnal (5321). Lesser towns are Clun (5165) which gives name to Clun Forest, and Cleebrury Mortimer (1810) in the south. The county is in the Oxford circuit, and assizes are held at Shrewsbury. It has one court of quarter sessions, and is divided into 18 petty sessional districts. The boroughs of Bridgnorth, Ludlow, Oswestry, Shrewsbury and Wenlock have separate commissions of the peace and courts of quarter sessions. There are 267 civil parishes. Shropshire is divided between the diocese of Lichfield and Hereford, with a small part within the diocese of St Asaph, and contains 284 ecclesiastical parishes or districts, wholly or in part. There are four parliametary divisions—Mid or Wellington, North or Newport, South or Ludlow, and West or Oswestry, each returning one member, while Shrewsbury returns one member.

History.—The district which is now Shropshire was annexed to the kingdom of Mercia by Offa, who in 763 constructed Watt's Dike to defend his territory against the Welsh, and in 779, having pushed across the Severn, drove the King of Powys from Shrewsbury, then known as Pengwern, and secured his conquests by a second defensive earthwork known as Offa's Dike, which, entering Shropshire at Knighton, traverses moor and mountain by Llanymynech and Oswestry, in many places forming the boundary line of the county, and finally leaves it at Bron y Garth and enters Denbighshire. In the 9th and 10th centuries the district was frequently overrun by the Danes, who in 874 destroyed the famous priory of Wenlock, said to have been founded by St Milburg, granddaughter of Penda of Mercia, and in 896 wintered at Quatford. In 912 Ethelred, the lady of Mercia, erected a fortress at Bridgnorth against the Danish invaders, and in the next year at Chinford. Mercia was mapped out into shires in the 10th century after its recovery from the Danes by Edward the Elder, and Shropshire stands out as the sole Mercian shire which did not derive its name from its chief town. The first mention of it in the Saxon Chronicle occurs under 1000, when the king crossed the Thames and wintered there. In 1016 Edmund Ethelred plundered Shrews-

bury and the neighbourhood.

After the Conquest the principal estates in Shropshire were all bestowed on Norman prelates, pre-eminent among whom is Roger de Montgomery, the 1st earl of Shrewsbury, whose son Robert de Belesme forfeited his possessions for rebellion against Henry I., when the latter bestowed the earldom on his queen for life. At this period a very large portion of Shropshire was covered by its vast forests, the largest of which, Worf Forest, at its origin extended at least 8 m. in length, and 6 m. in breadth, and became a favourite hunting-ground of the English kings. The forest of Wrekin, or Mount Gilbert as it was then called, covered the whole of that hill and extended eastward as far as Sheriff Hales. Other forests were Stiperstones, the jurisdiction of which was from time immemorial annexed to the barony of Caus, Wyre, Shirlot, Clee, Long Forest and Brewood. The constant necessity of defending their territories against the Welsh prompted the Norman lords of Shropshire to such activity in castle-building that out of 186 castles in England no less than 32 are in this county. Of these the most famous are Ludlow, founded by Roger de Montgomery; Bishop's Castle, which belonged to the bishops of Hereford; Clun Castle, built by the Fitz-Alan; Cleebrury Castle, built by Hugh de Montgomery; Caus Castle, once the barony of Peter Corbett, from whom it came to the Barons Straford; Rowton Castle, also a seat of the Corbetts; Red Castle, a seat of the Audleys. Other castles were Bridgnorth, Corfeham, Holgate, Pulverbatch, Quatford, Shrewsbury and Wen.

Among the Norman religious foundations were the Clunia
c Priory at Wenlock, re-established on the Saxon foundation by Roger Montgomery in 1080; the Augustinian abbey of Haugh-
mont founded by William Fitz-Alan; the Cistercian abbey of Buildwas, now a magnificent ruin, founded in 1155 by Roger, bishop of Chester; Shrewsbury Abbey, founded in 1083 by Roger de Montgomery; the Augustinian abbey of Lilleshall, founded in the reign of Stephen; the Augustinian priory of Wombridge, founded before the reign of Henry I.; the Bene-
dictine priory of Alberbury founded by Fulk Fitz-Warin in the 13th century; and Chirbury Priory founded in the 13th century.

The fifteen Shropshire hundreds mentioned in the Domesday Survey were entirely rearranged in the reign of Henry I., and only Overs and Conover retained their original names. The Domesday hundred of Rueset was replaced by Ford, and the hundred court transferred from Alberbury to Ford. Hodnet was the meeting-place of the Domesday hundred of Odenet, which was combined with Recordin, the largest of the Domesday hundreds in the county, to form the hundred of Caus, and the latter also including part of the Domesday hundred of Pimhole in Staffordshire. The hundred of Baschurch had its meeting-place at Baschurch in the time of Edward the Confessor; in the reign of Henry I. it was represented mainly by the hundred of Pimhill, the meeting-place of which was at Pimhill. Oswestry represents the Domesday hundred of Mercete, the hundred court of which was transferred from Maesbury to Oswestry. Munslow hundred was formed in the reign of Henry I., but in the reign of Richard I. a large portion was taken out of it to form a new liberty for the priory of Wenlock, the limits of which correspond very nearly with the modern franchise of Wenlock. The Domesday hundred of Alnoldestreu, abolished in the reign of Henry I., had its meeting-place at Membrefeld (Morville). The hundreds at the present day number fourteen.

Shropshire was administered by a sheriff, at least from the time of the Conquest, the first Norman sheriff being Warin the Bald, whose successor was Rainald, and in 1156 the office was held by William Fitz-Alan, whose account of the fee-farm of the county was entered in the pipe roll for that year. The shire court was held at Shrewsbury. A considerable portion of Shropshire was included in the Welsh marches, the court for the administration of which was held at Ludlow. In 1397 the castle of Oswestry with the hundred and eleven towns pertaining thereto, the castle of Isabel with the lordship pertaining thereto, and the castle of Dalaley, were annexed to the principality of Chester. By the statute of 1535 for the abolition of the marches, the lordships of Oswestry, Whittington, Maibroke and Knockin were formed into the hundred of Oswestry; the lordship of Ellesmere was joined to the hundred of Pimhill; and the lordship of Down to the hundred of Chirbury.

The boundaries of Shropshire have otherwise varied but slightly since the Domesday Survey. Richard's Castle, Ludlow, and Fitz-Alan, however, were then included in the Herefordshire hundred of Cutsenor, while several manors now in Hereford-
shire were assessed under Shropshire. The Shropshire manors of Kings Nordley, Avelley, Claverley and Worfield were assessed in the Domesday hundred of Saisdon in Staffordshire; and Quat, Romsley, Rudge and Shipley in the Warwickshire hundred of Stanlet. By statute 34 and 35 Henry VIII. the town and hundred of Aberton, till then part of Merionethshire, were annexed to this county.

Shropshire in the 13th century was situated almost entirely in the dioceses of Hereford and of Coventry and Lichfield; and formed an archdeaconry called the archdeaconry of Salop. That portion of the archdeaconry in the Hereford diocese included the deaneries of Burford, Stottesdon, Ludlow, Pontes-

bury, Clun and Wenlock; and that portion in the Coventry and Lichfield diocese the deaneries of Salop and Newport. In 1555 the Hereford portion included the additional deanery of Bridgnorth; it now forms the archdeaconry of Ludlow, with the additional deaneries of Montgomery, Bishops Castle and Church Stretton. The archdeaconry of Salop, now entirely in the Hereford diocese, includes the deaneries of Conover, Edgmond, Ellesmere, Hodnet, Shifnal, Shrewsbury, Wen, Whitchurch and Wrockwardin. Part of Welsh Shropshire is included in the diocese of St Asaph, comprising the deanery of Oswestry in the archdeaconry of Montgomery, and two parishes in the deanery of Llangollen and the archdeaconry of Mezham.
The early political history of Shropshire is largely concerned with the constant incursions and depredations of the Welsh from across the border. The Saxon Chronicle relates that in 1053 the Welshmen slew a great many of the English warriors at Westbury, and in that year Harold ordered that any Welshman found beyond Offa’s Dike within the English pale should have his right hand cut off. Various statutory measures to keep the Welsh in check were enforced in the 11th and 12th centuries. In 1379 Welshmen were forbidden to purchase land in the county save on certain conditions, and this enactment was reinforced in 1400. In 1379 the men of Shropshire forwarded to parliament a complaint of the felonies committed by the men of Cheshire and of the Welsh marches, and declared the gale of Shrewsbury Castle to be in such a ruinous condition that they had no place of imprisonment for the offenders when captured. In 1442 and again as late as 1535 acts were passed for the protection of Shropshire against the Welsh. But apart from the border warfare in which they were constantly engaged, the great Shropshire lords were actively concerned in the more national struggles. Shrewsbury Castle was garrisoned for the empress Maud by William Fitz-Alan in 1138, but was captured by Stephen in the same year. Holgate Castle was taken by King John from Thomas Mauduit, one of the rebellious barons. Ludlow and Shrewsbury were both held for a time by Simon de Montfort. At Acton Burnell in 1283 was held the parliament which passed the famous Acton Burnell statute, and a parliament was summoned to meet at Shrewsbury in 1398. During the Percy rebellion Shrewsbury was in 1403 the scene of the battle of Radnor’s Cot, in which Hotspur was slain. On the outbreak of the Civil War of the 17th century the Shropshire gentry for the most part declared for the king, who visited Shrewsbury in 1642 and received valuable contributions in plate and money from the inhabitants. A mint and printing-press were set up at Shrewsbury, which became a refuge for the neighbouring royalist gentry. Wem, the first place to declare for the parliament, was garrisoned in 1645 by Richard Baxter. Shrewsbury was forced to surrender in 1644, and the royalist strongholds of Ludlow and Bridgnorth were captured in 1646, the latter after a four weeks’ siege, during which the governor burnt part of the town for defence against the parliamentary troops.

Shropshire is noted for the number and lustre of the great families connected with it. Earl Godwin, Sweyn, Harold, Queen Edith, Edward the Confessor and Edwin and Morcar are all mentioned in the Domesday Survey as having held lands in the county before the Conquest. The principal landholders at the time of the survey were the bishop of Chester, the bishop of Hereford, the church of St Remigius, Earl Roger, Osbern Fitz-Richard, Ralph de Mortimer, Roger de Laci, Hugh Lasne and Nicholas Mediucis. Earl Roger had the whole profits of the Conover hundred and also owned Alnestred hundred. The family of Fitz-Alan, ancestors of the royal family of Stuart, had supreme jurisdiction in Oswestry hundred, which was exempt from English law. Richard Fitz-Scrob, father of Osbern Fitz-Richard and founder of Richard’s Castle, was lord of the hundred of Overs at the time of the Conquest. Gatacre was the seat of the Gataces. The barony of Pulverbatch passeth from the Pulverbatchs, and was purchased in 1193 by John de la Pole. The family of Cornwall were barons of Burford and of Harley in 1259. The family of Lestrange owned large estates in Shropshire after the Conquest, and Fulk Lestrange claimed the right of holding pleas of the crown in Wrockworth in 1202. Among others claiming rights of jurisdiction in their Shropshire states in the same year were Edmund de Mortimer, the abbot of Cumbermere, the prior of Lanhorne, the prior of Great Malvern, the bishop of Lichfield, Peter Corbett, Nicholas of Audley, the abbot of Lilleshall, John of Mortayn, Richard Fitz-Alan, the bishop of Hereford and the prior of Wenlock.

The earliest industries of Shropshire took their rise from its abundant natural resources; the rivers supplying valuable fisheries; the vast forest areas abundant in timbers; the coal and iron in the products of the county had been exploited from remote times. The lead mines of Shelve and Stiperstones were worked by the Romans, and in 1220 Robert Corbett conferred on Shrewsbury Abbey a tithe of his lead from the mine at Shelve. In 1260 licence was given to the Clee Fell Company, of which Robert de Crecy was a member. Arncroome received the profits of a coal-mine at Caynham. Iron was dug in the Clee Hills and at Wombourne in the 16th century. Wenlock had a famous copper-mine in the reign of Richard II, and in the 16th century was a centre of copper mining; the limestones at Lilleshall and at Ditton Priors, Caynham and Donnington. As the forest areas were gradually cleared and brought under cultivation, the county was more exclusively agricultural. In 1343 Shropshire wool was rated at a higher value than that of the English county, and in the 13th and 14th centuries Buildwas monastery exported wool to the Italian markets. Shropshire has never been, as the counties of the north of England and the north of Scotland were, a cotton manufacturing county, and the old handloom clothing trade arose about Shrewsbury and Bridgnorth, and Oswestry was famous in the 16th century for its fine Welsh cottons.

Antiquities—The ecclesiastical ruins and buildings of Shropshire are of various and interesting periods. The buildings the finest remains are those of Shrewsbury Abbey, Lillleshall near Newport, Much Wenlock Abbey and Bromfield priory near Ludlow (see the town). Besides these, Haughmond, 5 m. N.E. of Shrewsbury, an Augustinian foundation of the 12th century, has left extensive remains including a chapter-house, hall, monks’ well and other domestic buildings. Of Buildwas Abbey, on the Severn above Coolebrookdale, a Cistercian foundation of 1135, there are fine Norman and Early English remains of the church and chapter-house, together with the abbot’s house and other cloister buildings. Among the larger towns, those of Bridgnorth and Llanymynech, with their market places, are of interest. Among village churches, those of Stottesdon and Stanton Lacy in the south of the county, show considerable traces of pre-Conquest construction. Of the Norman remains of those of Newport, where the fragments from Uriconium are incorporated, Claverley E. of Bridgnorth, Holgate or Holgate in Corvedale and Clun, are good examples, but there is a remarkable number of Norman doors and fonts throughout the county. The church of Cluchery Mortimeria good Early English character and that of Tong near Shifnal fine Perpendicular with a splendid series of tombs, while the churchyard cross at Bitterley, near Titterstone, is a beautiful specimen of the work of the 14th century. The solitary church of Battlefield, N. of Shrewsbury, marks the scene of the fight between Henry IV, and the Percies in 1403. The remains of castles are generally slight, but the noble ruins at Ludlow, a notable ruin of the 13th century. The castle at Bridgnorth and the castle at Holgate are Norman. Of the 13th century are those at Hopton near Clun and Acton Burnell, S.E. of Shrewsbury, where Edward I. held parliament in 1263, Middle Castle between Shrewsbury and Wen shows small ruins of the 14th century. At Moreton Corbet on the Roden, N.E. of Shrewsbury, there is an old castellated mansion, but by far the finest example of this type in the county, and one of the best in England, is Stokesay Castle near Craven Arms. This beautiful relic dates from the 13th century, and is almost perfect, having a large hall and massive southern tower, and a remarkable half-timbered gateway. Shropshire is also rich in domestic and rural architecture, and in timbered and panelled houses. Shropshire has many beautiful examples of half-timbered architecture. Among old country mansions may be specially noted the splendid Pitchers Hall, near Shrewsbury and Benthall Hall, near Broseley, dating from 1535.

SHROUD (O. Eng. scrud, garment; cf. Icel. skrud, in the second sense of rigging, allied with “shred,” O. Eng. scrode, a piece, strip), originally a word meaning garment, clothing or covering, but now applied to the garment in which a dead body is wrapped preparatory to burial, a winding sheet. The shroud is usually a long linen sheet wrapping the entire body. This was formerly dipped in melted wax (Lat. cera, hence the name cerements) and written more generally as “seracloth or searcloth” and “cerements.” In nautical usage the Icelandic meaning of skrudth, Gäste, rigging of a ship, has been adopted in English; the “shrouds” of a ship are the set of
ropes which stretch from the heads of a ship's masts to the sides as Ropes or Ropes (see Roping).

SHROVE TUESDAY, the day before Ash Wednesday, the first day of Lent, so called as the day on which "shift" or confession was made in preparation for the great fast. Skeat (Elyn. Dict.) derives the word "shrive" of which "shrove" is the past tense, ultimately from the Lat. scribere, to write, to draw up a law, and hence to prescribe (cf. Ger. schreiben), through the Anglo-Saxon scrifan, to shove, impose a penance, to judge. Shrove Tuesday is called the French Mardi gras, "Fat Tuesday," in allusion to the fat ox which is ceremoniously paraded through the streets. The Germans know it as Fastenedienstag. It is celebrated in Catholic countries, as the last day of the carnival, with feasting and merrymaking, of which, in England, the eating of pancakes alone survives as a social custom, the day having been called at one time "Pancake Tuesday." The association of pancakes with the day was probably due to the necessity for using up all the eggs, grease, lard and dripping in stock preparatory to Lent, during which all these were forbidden.

SHRUB. (1) A bushy plant whose stem is woody and branches out thickly from the ground, not attaining sufficient height to be called a tree; this smallness of vertical growth is natural or is effected by cutting and lopping at an early stage or at stated seasons. The term is loose in application and the line between shrubs, trees and certain woody herbaceous plants is not easy to draw. The holy, the yew, the laurel, if allowed to grow from a single stem, become trees, other plants such as rhododendron, syringa, the eucalyptus are properly shrubs. The word is the same as "scrub," low, stunted undergrowth, in O. Eng. "shrub;" the root, which is also seen in "shrimp" and "shrive," means to contract. Many English place-names contain the word, the most familiar being Shrewsbury (Scrob-lesbyrig) and Wormwood Scrubs. (2) The name of a drink or cordial, now rarely found except in country districts. It is made of currant juice boiled with water and sugar to which some spirit, usually rum, is added. Another form of the drink is made of rum, orange and lemon juice, pel, sugar and water. The word is an adaptation of the Arabic sharb or sharab, beverage, drink, sharabi, he drank, and is thus directly related to "sherbert" and "syrup" (q.v.).

SHUFFLEBOARD, or SHOVEL-BOARD (originally "shove-board"), a game in which wood or metal disks are "shoved" by the hand or with an implement so that they shall come to a stop on or within certain lines or compartments marked on the "board"—a table or a floor. It was formerly very popular in England, especially with the aristocracy, under the names shove-groat, slide-groat and shovel-penny, being mentioned as early as the 15th century. It was a favourite pastime at the great country houses, some of the rooms having benches of exquisiteworkmanship. That at Chartley Hall in Staffordshire was over 30 ft. long and was made up of 260 pieces. Shuffleboard enjoys considerable vogue in the United States, the board being from 28 to 30 ft. long and from 18 to 20 in. wide, of pine, poplar or white wood, with a gutter 4 in. wide extending entirely round the board. The surface is slightly sanded and sometimes oiled. About 5 in. from each end of the board is drawn a line called the deuce line. Each side, whether composed of two or four persons, used four disks of polished brass or iron, generally about 2 in. in diameter and ¾ in. thick. When two persons play they shove first from one end of the board and then from the other; but when four play one of each side remains permanently at each end. The disks, four of which are marked A and four B, are shoved alternately by each side. A disk resting between the deuce line and the end of the board is in and scores two. One protruding over the end sufficiently to be lifted by the finger is called a ship and counts three. A disk resting on the board but not crossing the line counts one. In scoring only the best of the eight disks counts, unless one side has two that are better than their opponent's, in which case both count. The side first scoring 21 points wins.

A variety of shuffle-board is very popular as a deck game on board steamers and yachts. It is played by pushing wooden disks by means of crutch-shaped cues, or shovels, into which the disks fit, so that they come to a stop within the lines of a large rectangle drawn with chalk on the deck and divided into squares numbered from 1 to 10 with an extra square nearest the player, numbered 10. The game is usually 21 points.

SHUKRIA, a large tribe of African nomads living in the "Island of Meroë," i.e. the country between the Atbara and the Blue Nile. The family name of the principal branch of this tribe is Abu Sin, and Gedaref, an important town in the centre of Shukria country was formerly called Sulk Abu Sin.

SHUMLA (Bulgarian Shumen, Turkish Shumus), a fortified town of Bulgaria, 50 m. W. of Varna, on the railway from Trnovo to Shumla Road (a name given to a station on the Varna-Rustchuk railway by the English builders of the line). Pop. (1906) 22,290, about one-third being Moslems. The town is built within a cluster of hills, northern outliers of the eastern Balkans, which curve round it on the west and north in the shape of a horse-shoe. A rugged ravine intersects the ground longitudinally within the horse-shoe ridge. From Shumla roads radiate northwards to the Danubian fortresses of Rustchak and Silistra and to the Dobrudja, southwards to the passes of the Balkans, and eastwards to Varna and Balchik. Shumla has, therefore, been one of the most important military positions in the Balkan Peninsula. A broad street and rivulet divide the upper quarter, Gorni-Mahle, from the lower, Dolni-Mahle. In the upper quarter is the magnificent mausoleum of Jezairi Hassan Pasha, who in the 18th century enlarged the fortifications of Shumla. The principal mosque, with a cupola of very interesting architecture, forms the centre of the Moslem quarter. The town has an important trade in grain and wine, besides manufactures of silk, red and yellow slippers, ready-made clothes, richly embroidered dresses for women, and copper and tin wares. In 811 Shumla was burned by the emperor Nicephorus, and in 1087 it was besieged by Alexius I. In 1388 the sultan Murad I. forced it to surrender to the Turks. In the 18th century it was enlarged and fortified. Three times, in 1774, 1810 and 1828, it was unsuccessfully attacked by Russian armies. The Turks consequently gave it the name of Gazi ("Victorious"). In 1854 it was the headquarters of Omar Pasha and the point at which the Turkish army concentrated (see CRIEMEW WAR). On the 22nd of June 1878 Shumla capitulated to the Russians.

SHUSSHA, a town, formerly a fortress, of Russian Transcaucasia, in the government of Elissavetpol, in 30° 46' N. and 46° 25' E., 170 m. S.E. of Tiflis, on an isolated rocky eminence, 3865 ft. above sea-level and accessible only from one side. Pop. about 25,000, consisting of Armenians and Tatars. Shussha was formerly the capital of the khanate of Kara-bagh. The town is locally renowned for its carpets, and the district for its excellent breed of Kara-bagh horses. Leather and silk are also made. The fortress, constructed in 1760, successfully withstood a siege by Aga Mahomed of Persia in 1795, but was constrained to surrender two years afterwards. In 1805 Ibrahim Khan of Kara-bagh invoked the protection of Russia, but the annexation was not completed until 1822.

SHUSHTER, a district and town of the province of Arabistan (former Khuzistan) in Persia, S. of Dizful, and N. of Ahvaz. The district contains the town of the same name and 22 villages, and, including about 3500 nomad families of the Kunduzi, Saad, Anafia and Ali Kethir tribes, has a population of about 15,000, and pays a yearly revenue of £6000. The district produces grain, opium, cotton, wool, limes (their juice, made into green extract, is exported in little earthenware jars), and manufactures gilims (woollen carpets without pile).

The town of Shushter, with a population of 1,5000, is situated at the point where the river Karun, after breaking through the Fedeckil hills, bifurcates into the Gerger canal, flowing E., and the Shuitait river flowing W. of it, in 32° 3' N. and 48° 53' E., and built on slightly elevated ground which rises gradually from the south-west to the citadel, Kalah Salas, standing in the

Considered to represent the Sele of Ammianus Marcellinus (xiii. c. 6, 26), a city in Susiana, and of Ptolomy (Tab. v.).
SHUTER—SHUTTLE

north-eastern corner on a sandstone hill ending with a precipice about 50 ft. in height towards the river on the north. The ground covered by the citadel measures nearly 350 by 150 yds., and the town occupies a space of a square mile.

At the point of the divergence of the Gerger from the Karun, 600 yds. above the town, an artificial dike constructed of large blocks of hewn stone is thrown across the opening of the former. It was known as the Band i Kaisar (the Caesar’s Dike), but after having been repaired by Mahommed Ali Mirza, a son of Fath Ali Shah, in the early part of the 19th century, it was called Band i Shahzadeh, or Prince’s Dike. A little distance below this dike begins the artificial cutting in the sandstone rock and at half a mile from it is a second band, 60 yds. long, 65 ft. high, which completely blocks the progress of the stream. It has a roadway on the top, and, as it connected the town with the village Bulaiti (now deserted) on the other side, was called Pul i Bulaiti, i.e. Bridge of Bulaiti. At a short distance above it some tunnels have been pierced in the rock below the canal level on either side of the Gerger. From the point where the principal river parts with the Gerger down to a point 500 yds. below the citadel the river bed was paved with great flags of stone, the pavement being called Shadurvan. At the end of the pavement stand the band and bridge ascribed to the Roman emperor Valerian. The band is called Band i Mizan, the bridge Pul i Kaisar. The bridge has been built and rebuilt several times and its forty-one arches differ in material, style and size. Its length is 560 yds., and its roadway is 7 yds. wide. Seventy yards of band and bridge were swept away in 1885. Between the bridge and the Gerger opening and cut into the rock on which the western part of the citadel stands is a tunnel leading to a canal formerly called Darian, now Minab, i.e. Mian-do-ab, "between two rivers," because it waters the district south of the town lying between Gerger and Shutait. With the break of the band in 1885 the level of the main river has fallen and the Minab canal is not properly filled, causing much damage to cultivation in the district.

Persian tradition has it that Ardashir (either Artaxerxes of the old Persian kings or Ardashir of the Sassanians) built the first dike across the river in order to raise the water of the river to the level of the Darian canal. The dike became destroyed and was renewed under the Sassanian Shapur I. By Roman workmen sent for by Valerian who had been captured by the Persian king in 260. That Valerian had a part in constructing these remarkable works does not rest upon any historical basis; we may, however, believe that the Sassanian Ardashir, or his son Shapur I., finding that the river, having its bed in friable soil, was daily getting lower and finally threatened to leave the town and the Mian-do-ab district dry by not filling the Darian canal, engaged Roman workmen. The Gerger canal was cut and the river diverted from west to east of the town. The old river then became emptied and its bed was raised and, to prevent further erosion and washing away of the soil and a consequent fall of the river, was paved with huge flags. Then the Band i Mizan and the great bridge were erected across the river and finally a dam was constructed across the Gerger canal, where is now the Pul i Bulaiti, so as to turn back the Karun into its original channel, but, later, by means of sluices and tunnels, the flow of water was regulated in such a manner that two-sixths of the water flowed east and four-sixths west of the town. This gave rise to the later appellations Do-Dank and Chahar Dank, i.e. two-sixths and four-sixths for the Gerger and Shutait respectively.

SHUTTER (O. Eng. shuter, &c.; from the same word as "shut"), a boat-shaped implement used in weaving to pass a thread of weft to and fro between two lines of warp. The origin of this implement is lost in the mists of a remote antiquity, and yet it was long preceded by the loom. Several wall paintings at Thebes depict looms that are apparently provided with a hooked rod for drawing weft through the warp, but with such a device either two weft threads would be simultaneously placed in one division of the warp, or the selvages would be imperfect. Since neither of these conditions obtain in the ancient Egyptian fabrics that have been recovered, it may be concluded that some other plan was also adopted. Netting needles have been found in Egyptian tombs, and as these would be more suitable for weaving than a hooked rod, it is conceivable they were so employed. Or a spinning spindle charged with weft might be conveyed through the warp, as was customary, at a much later period, with Greek, Roman and other weavers. So long as a shuttle was thrown from hand to hand, the breadth of cloth which one weaver could produce was limited to his ability to reach from selvage to selvage of the piece. But from 1733, when John Kay invented the "fly shuttle," these implements have been made straight, and propelled mechanically, also, to secure light running, they have been mounted upon rollers which project slightly on the underside. Shuttles are now made in various forms and sizes from box, and other hard-grained, smooth woods, as well as from vulcanised fibre and metals. For silk weaving by hand, they are approximately 12 in. long by 1 in. square in section, and weigh about 3 oz.; those for calico weaving by power, are about 12½ in. long, 1½ in. wide, 1½ in. deep, and weigh about 9½ oz.; they are also provided with conical steel tips which abut upon short coiled springs let into the shuttle. The construction, fixing and control of shuttle tongues that hold the weft, together with numerous devices for putting the thread under an elastic tension, have formed the subjects for many patents. The tongues intended to hold cops are split to form a spring whose strength suffices to fix the cop in position while the thread is drawn from the outer end through a porcelain eye in the shuttle front, the tension being regulated by deflection.

The small shuttles employed to weave ribbons, and other narrow goods, are bowed in front, recessed to hold a spool of weft, and have an eye fixed at the centre of the bow for the thread to pass through as it unrolls. These shuttles are formed into sets, which correspond with the number of fabrics to be manufactured simultaneously and may be placed on one level, or in tiers; in either event, all in one horizontal plane are moved to and fro together across different webs, by means of racks and pinions; for a rack is inserted lengthwise in each shuttle, and by engaging the racks with intermittently driven pinions, the shuttles receive their requisite movements.

For further information regarding weaving and looms, see Weaving and Weaving Machinery.
