**SOUTHWOLD**, a municipal borough and watering-place in the Lowestoffe parliamentary division of Suffolk, England, 12 m. S. by W. of Lowestoffe, the terminus of the Southwold railway, which connects with the Great Eastern at Halesworth. Pop. (1901), 2800. The church of St Edmund's is a Perpendicular flint structure. In 1500 a pier 270 yds. long was constructed, and serves as a calling-place for pleasure steamers. A fine common south of the town is used for golf, lawn-tennis, cricket, and other sports. The town is governed by a mayor, 4 aldermen and 12 councillors. Area, 612 acres. Southwold (Suwell, Swell, Suthwold) owes its origin and prosperity to its herring fisheries, which were considerable in 1856, while the importance of its harbour increased with the decay of Dunwich. In 1461 the men of the town, tenants of the manor which had been granted by the monks of Bury St Edmunds to Gilbert, earl of Clare, and had passed to the Crown with the honour of Clare, claimed exemption from toll, portage and similar dues as their prescriptive right. An act of 1459 incorporated the bailiffs and commonalty of the town and exempted them from harbour dues. These liberties were confirmed in 1505 by Henry VIII., who also granted the corporation the town and manor, to hold at fee-farm with certain rights of jurisdiction. Confirmatory chapters were granted by Henry VIII., Edward VI., Elizabeth, James I. and Charles II., and the town was governed by a royal charter of 1689 until the Municipal Reform Act of 1835. The weekly market, now the property of the corporation, was granted to the abbot of St Edmunds as lord of the manor in 1227 together with a yearly fair on the vigil of the feast of St Philip and St James. A fair is still held on Trinity Monday. In 1672 Southwold Bay, usually abbreviated as Solebay, was the scene of a battle between the English fleet under the duke of York and the French fleet under Admiral de Grasse. The English suffered much, but the Dutch withdrew.

See *Victoria County History*; *Suffolk*, T. Gardiner, *An Historical account of Dunwich, Blisburgh and Southwold*.

**SOUTHWORTH, EMMA DOROTHY ELIZA NEVITTE** (1819-1890), American novelist, was born in Washington, D.C., on the 26th of December 1819. She studied in a school kept by her stepfather, Joshua L. Henshaw, and in 1840 married Frederick H. Southworth, of Utica, N.Y. After 1843 she supported herself by teaching. Her first story, "The Irish Refugee," was published in the *Baltimore Saturday Visitor*. Her first novel, "Retribution," a serial for the *National Era*, published in book form in 1846, was so well received that she gave up teaching and became a regular contributor to various periodicals, especially the *New York Ledger*. She lived in Georgetown, D.C., until 1876, then in Yonkers, N.Y., and again in Georgetown, D.C., where she died on the 30th of June 1899.

Her novels numbered more than sixty; some of them were translated into German; in 1859 a four-volume edition of fifty-five volumes was published in Philadelphia. They include *The Deserted Wife* (1850); *Mark Sutherland* (1853); *Hickory Hall* (1855); *Unknown* (1874); *Gloria* (1877); *The Trail of the Serpent* (1879); *Nearest and Dearest* (1881); *The Mother's Secret* (1883); *An Exile's Bride* (1887); *The Hidden Hand* (1888); and *Broken Pledges* (1891).

**SOUSVRE, EMILE** (1806-1854), French novelist, was born on the 15th of April 1806. He was the son of a civil engineer, a native of Morlaix. He was by turns a bookseller's assistant, a private schoolmaster, a journalist, and master at the grammar schools of Brest and of Mulhouse. He settled in Paris in 1835, where he was made (1848) professor in a school for the instruction of civil servants. He began his literary career with a drama, played at the Théatre français in 1838, *Le Siège de Misolongo*. In novels writing he did much better than for the stage, although he deliberately aimed at making the novel an engine of moral instruction. His best work is undoubtedly to be found in the charming *Derniers Bretons* (4 vols. 1835-1837) and *Foyer breton* (1844), where the folk-lore and natural features of his native province are worked up into story form, and in *Un Philosophe sous les toits*, which received in 1851 a well deserved academy prize. He also wrote a number of other works—novels, dramas, essays and miscellanies. He died in Paris on the 7th of July 1854.

**SOUVRE, GILLES DE, MARQUIS DE COUTANVAUX, BARON DE LEZINES** (c. 1545-1670), marshal of France, belonged to
an old family of the Perche. He accompanied the duke of Anjou to Poland in 1573, and was appointed master of the wardrobe and captain of Vincennes when Anjou became Henry III. He remained in favour, despite the opposition of the queenmother, Catherine de Médicis, fought at Coutras, defended Tours against the Leaguers, was named chevalier de Saint Esprit and governor of Touraine (1583), and was one of the first to recognize Henry IV. (1589) who subsequently entrusted him with the education of the dauphin. Louis XIII rewarded him with the title of marshal in 1613. He died in Paris in 1626.

SOUZA-BOTELHO, ADÉLAIDE FILLEUL, MARQUISE DE (1761-1836), French writer, was born in Paris on the 14th of May 1761. Her mother, Marie Irène Catherine de Buisson, daughter of the seigneur of Longpré, near Falaise, married a bourgeois of that town named Filleul. It was reported, though no proof is forthcoming, that Mme Filleul had been the mistress of Louis XV. Her husband became one of the king's secretaries, and Mme Filleul made many friends, among them Marmontel. Their eldest daughter, Julie, married Abel François Poisson, marquis de Marigny (1727-1781); Adélaïde married in 1779 Alexandre Sébastien de Flahaut de la Billarderie, comte de Flahaut, a soldier of some reputation, who was many years her senior. In Paris she soon gathered round her a salon, in which the principal figure was Talleyrand. There are many allusions to their liaison in the diary of Gouverneur Morris. In 1785 was born her son Auguste Charles Joseph de Flahaut (q.v.), who was generally known to be Talleyrand's son. Mme de Flahaut fled from Paris in 1792 and joined the society of émigrés at Mickleham, Surrey, described by Mme de Flahaut in a letter to Marigny in 1794). Her husband remained at Bouligne, where he was arrested on the 29th of January 1793 and guillotined. Mme de Flahaut now supported herself by writing novels, of which the first, Adèle de Sévange (London, 1794), which is partly autobiographical, was the most famous. She presently left London for Switzerland, where she met Louis Philippe, duke of Orleans. She travelled in his company to Hamburg, where she lived for two years, earning her living as a milliner. She returned to Paris in 1798, and on the 17th of October 1802 she married José Maria de Souza-Botelho Mouro e Vasconcellos (1759-1823), Portuguese minister plenipotentiary in Paris. Her husband was recalled in 1804, and was offered the St Petersburg embassy; but in the next year he resigned, to settle permanently in Paris, where he had many friends, among them the historian Sismondi. He spent his time chiefly in the preparation of a beautiful edition of the Lusiads of Camoens, which he completed in 1817. Mme de Souza lost her social power after the fall of the First Empire, and was deserted even by Talleyrand, although he continued his patronage of Charles de Flahaut. Her husband died in 1825, and after the accession of Louis Philippe she lived in comparative retirement till her death on the 15th of April 1856. She brought up her grandson, Charles, duc de Monty, her son's natural son by Queen Hortense. Among her later novels were La Comtesse de Fargy (1822) and La Duchesse de Guise (1831).

Her complete works were published in 1811-1822.

See Baron A. de Maricourt, Madame de Souza et sa famille (1907); Lettres inédites de J. C. L. de Sismondi , , et de Madame de Souza (Paris, 1863), ed. St René Taillander; Sainte-Beuve, Portraits de contemporains and Stendhal, Vie de Gouverneur, Les Maîtresses de Louis XV. (1860) and J. F. Marmontel (1804).

SOVEREIGNY, originally an adjective, meaning "supreme," especially having supreme or paramount power. The word in Middle English was soyreain or soyreain, and was taken through Old French from Low Latin superanus, chief, principal. The intrusive "g" is, which is due to a popular confusion of the termination of the word with "reign," dates, according to Skeat, from about 1570. The form "soveran," borrowed by Milton from Italian sovrano, sopranò, is chiefly found as a poetical usage. As a substantive "sovereign" is applied to the supreme head of a state (see SOVEREIGNTY), and to the standard English gold coin, worth 20 shillings or £1 (see POUND). The gold sovereign was first struck in the reign of Henry VII. (1483); it was of gold of the standard fineness (094-8) and weighed 240 grains. It bore the figure of the king crowned, in royal mantle, seated on the throne, and holding the sceptre and orb. The sovereign was coined in successive reigns until that of James I., when the name "unite" was given to the coin to mark the union of the two kingdoms. The gold coinage of the kingdom was, until 1816, a secondary part of the monetary system, but in that year the silver standard was discontinued and a gold standard adopted. The sovereign was chosen as the new unit of the currency, and the first issue took place in 1817. Its weight was fixed at 123-274 grains; its fineness at 916-66 or twenty-two carats. These standards of weight and fineness are those still in force. At the same time was issued the half-sovereign, of weight in proportion.

The weight of 0343 sovereigns is exactly equivalent to twenty Troy pounds, and the weight of each individual sovereign is calculated on this basis. The sovereign is eleven-twelfths pure gold and one-twelfth alloy, copper being usual. The light colour of early Australian sovereigns was due to the use of silver instead of copper. Five-pound pieces were coined in the reign of Queen Victoria and Edward VII. They were also authorized in the reign of George III. (as were two-pound pieces), but the dies were not completed before the death of that sovereign. Specimens were, however, subsequently struck. There were also some pattern pieces struck in the reign of George IV. Two-pound pieces were issued in the reign of George IV.; they were struck in the reign of William IV., but not issued for circulation; they are current coins of the reigns of Victoria and Edward VII.

See also Mint; Money.

SOVEREIGNTY. The word sovereignty (Fr. souveraineté) is said to be derived from the medieval Latin word suprœmitas, i.e. suprema potestas, supreme power. (See Skeat's Etymological Dictionary as to various forms of the word, and Meyer, Lehrbuch des deutschen Staatsrechts, 15, as to its derivation.)

Soeverignty may be viewed in three ways: there is the historical explanation of its origin and growth, its rude beginning in the savage horde, its completion in the modern state; there is the analytical or juridical explanation; there is also what (for want of a better phrase) may be called the organic explanation of sovereignty.

The following are some of the chief stages in the history of sovereignty: While society is in a rude and only tribally organized there is no distinct sovereignty, no power which all persons habitually obey. Thus there is no sovereignty among wandering groups of Australian savages: each family is isolated, each horde is a loose and unstable collection. When the horde has become a tribe there may exist no definite sovereign. Distinct in time of war, the power of the chief may be fluctuating and faint in time of peace; even in time of war it may be subject to the authority of a council. Tribes of the same ethnic stock may form a sort of federation, permanent or temporary. "With the council of the confederacy," it has been said, "and, more generally, in the confederacy, sovereignty arises and the true political tradition is evolved" (F. H. Giddings, Principles of Sociology, p. 285).

When the city and the state are conterminous the seat of sovereignty becomes defined. Such was the condition of things in Greece, as considered by Aristotle in his Politics. He discusses the question what is the supreme power in the state (3. 10), which he defines as an aggregate of citizen (3. 1), and he recognizes that it may be lodged in one, a few, or many. In his view the distinctive mark of the state is not so much sovereignty (7. 4) as self-sufficiency; a state is not a mere aggregate of persons; it is a union of them sufficient for the purposes of life (7. 8); sufficiency being "to have all things and to want nothing" (7. 5. 1). The Roman jurists say little, and only incidentally, as to sovereignty. But in the middle ages, under the influence of the Roman law, and with the belief in the existence of an empire entitled to universal sway, an absolutist theory of sovereignty was developed in the writings of the jurists who revived the study of that law: the emperor was sovereign; "quod principi placuit legis habet vigorem" (Institutes, I. 2. 6).

Those jurists often justified the plenitude potestatis conceded to the emperor by the fact that he stood at the head of Christendom.
SOVEREIGNTY

Among the theories prevalent in the middle ages was one that mankind formed a unity, with the pope and the emperor at the head of it: the universal Church and the universal emperor ruled the world (Rehm, Geschichte der Rechtswissenschaft, p. 198). Even to Leibnitz, writing in the 17th century, it seemed that “totum Christianitatem unam velut Rempublicam componere, in quæ Caesaris auctoritas alique competit” (Göpfr, 4, 340). When the power of the emperor was weakened, and the idea of a universal ruler was gone, a new test of sovereignty was applied—that of external independence; the true sovereign states were universitates superiorm non recognoscentes. There were times and countries in the middle ages in which the collective power of the community was small: many of the great corporations were virtually autonomous; the central authority was weak; the matters as to which it could count upon universal obedience were few. In such circumstances the conception of sovereignty was not perfect. It has been suggested that the modern conception of it was evolved from the quaintest between three powers: the Church, the Roman Empire, of which the individual states in Europe were theoretically provinces, and the great landowners and corporations. Whatever may be the truth as to this, the modern theory is first clearly stated in Jean Bodin’s book On the Commonwealth (French ed., 1576; Latin version, 1586), which was the first systematic study of sovereignty. Bodin defines the state thus: “República est familia- arum rerumque inter ipsas communium, summa potestate ac ratione moderata multitudo.” His theory, which corresponded on the whole to the state of the time of Louis XI., was a theory of despotism. It may be also described as a type of the mechanical or juridical theory of sovereignty. According to Bodin, there is in the state unlimited one power: “Majestas est summa in cives ac subditos legisbus soluta potestas” (i. 8). There exists a central force from which are derived all the powers which make or give effect to laws; a power which he describes sometimes as “majestas summa potestas summum imperium.” This was the conception expressed by Bossuet, “Tout l’état est en la personne du prince,” or in Louis XIV’s saying, “L’état c’est moi.”

One favourite theory was that sovereignty originated in a social contract. It was assumed that the individual members of society, by express or implied pact, agree to obey some person or persons; sometimes it is described as an unqualified handing over; sometimes it is a transfer subject to qualifications, and with notice that in certain contingencies this will be withdrawn. Gierke, in his book Johannes Althusius und die Entwicklung der naturrechtlichen Staatslehre, shows (p. 76) that the conception of a treaty or agreement as the basis of the state was in the middle ages a dogma which passed almost unchallenged, and that this theory was universal among the nations of Europe up to a later period. It is to be found in the writings of Thomas Aquinas (De Regimine principum, 266), Marsilius of Padua, Buchanan, J. de Mariana, and F. Suarez. It is the kernel of the theories of Hobbes, Rousseau, Filmer and Locke. Among the clearest and most logical exponents of this theory was Hobbes, who in his Leviathan expounded his notion of an agreement by which absolute power was irrevocably transferred to the ruler. Fufendorf, with some variations, states the same theory. In his view there is a pactum unionis, followed by a pactum subjectionis. The best-known exponent of this theory of the Louisian of sovereignty is L. Rousseau, who assumes the existence of a pactum social, the terms of which are: “Chacun de nous met en commun sa personne et toute sa puissance sous la suprême direction de la volonté générale; et nous recevons encore chaque membre comme partie indivisible de tout” (Du Contrat social, 1. c. 6).

It is convenient for the jurist to assume that in every state is one determined or determinable authority in which is vested sovereignty, and from which all other authorities derive their power. The assumption is not true of some states; the legal authority is divided among several persons or bodies. It is at best an unwieldy assumption, and the true historical reality is that of an interdependence of states. It is necessary, therefore, for the modern physiologist to treat discussions as to sovereignty much as modern physiologists treat discussions as to “vital force” or “vital principle.” Comte, Spencer, Bagehot, Durkheim and Giddings, for example, refer to it, if at all, only briefly and incidentally; they conceive society as an organism, or at all events as a growing whole, no one part or force being the cause of all others, and all interacting; society is not the product of any agreement or of force alone, but of a vast variety of interests, desires and needs. Now the state or government comes at a certain stage of organization: small groups are drawn together over which corporations fall into line; a national feeling develops; eventually the state as we know it is formed. Sovereignty is a resultant of many forces. It may not exist as to some regions of conduct; as to others it may be weak and mutable; only in certain conditions is the sovereign power supreme as to all matters of conduct.

Among the different senses in which “sovereign” has been used are the following:

a. “Sovereign” may mean titular sovereign—the king in the United Kingdom, the kaiser in Germany.

b. The legal sovereign: the person or persons who, according to the law of the land, legislate or administer the government.

c. The political or constitutional sovereign: the body of persons in whom the actual power at any moment or ultimately resides. Sometimes this is designated “the collective sovereignty.”

d. Sovereignty is also used in a wider sense, as the equivalent of the power, actual or potential, of the whole nation or society (Gierke, 3. 668). The relation between real and nominal sovereignty was familiar to medieval writers, who recognized a double sovereignty, and distinguished between (1) the real or practical sovereignty resident in the people, and (2) the personal sovereignty of the ruler (Adolf Dock, Der Souveranitatsbegriff, &c., p. 13). By many writers sovereignty is regarded as resident not in any one organ, but in the Gesamtperson of the community (Maitland, Political Theories of the Middle Ages, 183). Sometimes sovereignty is defined as the organized or general will of the community (Comothesca, Conception juridique de l’état, p. 96). Sovereignty is the organized will of an organized independent community. . . . The kings and parliaments who serve, as its vehicles.” “Sovereignty resides in the community” (Woodrow Wilson, p. 1448). The same theory is often expressed by saying that the majority in a community, or a particular group, in fact, rules (Guizot, Representative Government, i. 167). This was the doctrine of the French Revolution. “Saches que vous êtes roi et plus des rois,” said a revolutionary orator cited by Taine. It was the language of the founders of the American constitution and contemporary political writers; the language, for example, of Paine: In republics such as there are established in America the people is the sovereign power, of the people and by the people: there is no control and which controls all others, remains where nature placed it—in the people” (Discussions on Government, 1.6). The same theory assumes a more subtle form, especially in the writings of Hegelians. Sovereignty is with them a term descriptive of the real will of the community, which is not necessarily that of the majority. “If the sovereign power is to be understood in this fuller, less abstract sense, if we mean by it the real determinant of the habitual obedience of the people, we must look for its sources much more widely and deeply than the analytical jurists do; it can no longer be said to reside in a determinate person or persons, but in that impalpable congeries of the hopes and fears of a people bound together by common interest and sympathy, which we call the common will” (Green’s Works, 2. 404). “Though it may be misleading to speak of the general will as anywhere, either actually or properly, sovereign . . . yet it is true that the institutions of political society are an expression of, and are maintained by, the general will” (2. 409).

Sovereignty is used in a further sense when Plato and Aristotle speak of the sovereignty of the laws (Laws, 4. 715; Politics, 4. 4; 5. 55). Thus Plato remarks: “I see that the state in which the laws are lords, and the rulers are the inferiors of the laws, has salvation.” (See also Gierke, Genossenschaftsrecht, 8. 8.) Even in medieval writers, such as Bracton, is found the notion
SOVEREIGNTY

that the king is subject to the laws: "Bracton knows of no sovereign in the Austrian sense, and distinctly denies to the royal authority the attribute of being incapable of legal limitation " (J. N. Figgis, The Divine Right of Kings, p. 13). We find the same expressed by many German jurists, i.e. the idea of a state which exists only in the law and for the law, the personal life is but a legal order regulating public and private relationship (Gierke iii., x.).

Among the definitions of sovereignty may be quoted these: "That which decides in questions of war and peace, and of making or dissolving alliances, and about laws and capital punishment, and exile and fines, and audit of accounts and examinations of administrators after their term of office " (Aristotle, Politics, 4. 4. 3). "Suprematum illi tribuo qui non tantum domi subditos manu militari regit, sed et qui exercitum extra fines diure et armis, foederibus, legationibus, ac caeteris jure gentium functionibus aliëquid momenti ad rerum Europae generallum summam conferre potest " (Leibnitz, Opera, 4. 333). "La souveraineté est celle qui sert à exprimer l’indépendance d’un état aussi bien à l’intérieur qu’à l’extérieur " (F. de Martens, Traité du droit international, translated by A. Léo, 1883, i. 378). "L’indépendance complète qui peut se manifester à deux points de vue; l’un extérieur, l’autre intérieur (Frenz Despagnet, Droit international public, 1894, p. 80). "Sovereignty as applied to states imports the supreme, absolute, uncontrollable power by which any state is governed " (T. M. Cooley, Constitutional Limitations, p. 201). "Social control, manifesting itself in the authoritative organization of society as the state, and acting through the organs of government, is sovereignty " (Giddings, Elements of Political Science, p. 217). The sovereign is "Absolut unabhängig und nur durch sich selbst beschränkt und beschränkbar " (Zorn, Völkerrecht, p. 4. See the collection of definitions in Der Souveränitätsbegriff im Boden, &c., by Dr Adolf Dock (1897), p. 7, and in La Conception juridique de l’état, by Combotecra, p. 90). Many of these definitions describe an ideal state of things rather than realities. Some of the definitions would apply to the authority of powerful religious bodies in certain periods of history, or of illegal associations, such as the Mafia, which have terrorized the community.

Territorial sovereignty is used in a variety of senses. Often the phrase is the equivalent of sovereignty. It may mean a state of things such as existed in the middle ages, in which ownership and sovereignty were not clearly separated: when he who was owner had sovereign rights incident thereto, or, as it was sometimes phrased, when sovereignty inhered in the territory, when the king was the supreme landowner (Maine, Ancien Law, p. 106; Figgis, pp. 11, 14); when all political power exhibited proprietary traits; and was incident to the ownership of land (Maitland, Township and Borough, p. 37). Territorial sovereignty is thus defined by Leibnitz: "Superioritatem territorialem in summo subditos coercendi jure consistere " (Opera, 4. 358. See Laband, i. c. 8).

Certain propositions are often stated with respect to sovereignty. One of them, stated by Rousseau (Du contrat social, 2. c. 2), is that it is indivisible: a proposition true in the sense that in regard to the same matters at the same time there cannot be two sovereignties, but not true in the sense in which it has often been employed, namely, that in the last analysis of society there are some persons or person who control all conduct and are habitually obeyed as to all matters. Rather we may say with Maine, "Sovereignty is divisible, but independence is not. " To hold sovereignty not to be divisible is for juridical purposes not a working theory; states part, permanently or temporarily, with few or many of the rights and powers comprehended in sovereignty; to speak of it as undivided in the case of Crete, Egypt or Tibet is to do violence to facts.

A frequent deduction from the theory of the indivisibility of sovereignty is that there cannot be double allegiance; in other words, no one can be the subject of two states. This deduction is not in fact true. With the existing differences in the laws of modern states as to nationality, persons may be, and are, subjects of two or more states. In the native states in India there may be said to be double allegiance. C. L. Tupper, in his Our Indian Protectorate, refers to "the double allegiance of the subjects of our Indian protectorates" in India; and he explains that the native rulers are themselves subject to the Indian government. For all purposes of our relation with powers the subjects of Indian native states must be regarded as subjects of Her Majesty "(Our Indian Protectorate, 1893, p. 353). Such double allegiance is apt to exist in times of transition from one sovereignty to another; for example, in the 18th century, in the British possessions in India, the Mogul was said to exercise a personal sovereignty. As Sir William Scott remarked in the Indian Chief, 3 C. Rob. 22, it hardly existed otherwise than as a phantom: the actual authority to be obeyed was exercised by the East India Company. The natives of protected states owe not only allegiance to them, but also certain duties, ill defined, to the protecting state.

Another deduction from the same proposition is that any corporation or private body which appears to exercise sovereign powers together with the state does so only by delegation. This theory is thus stated by Burke (Works, 7. 286) with reference to the East India Company: "The East India Company itself acts under two very dissimilar sorts of power, derived from two sources very remote from each other. The first source of its power is under charters which the Crown of Great Britain was authorized by act of parliament to grant, the other is from several charters derived from the emperor of the Moguls . . . . As to those of the first description, it is from the British charters that they derive a capacity by which they are considered as a public body, or at all capable of any public function. . . . This being the root and origin of their power, renders them responsible to the party from whom all their immediate or consequential powers are derived."

A further proposition often stated with respect to sovereignty is that it is unlimited: a proposition which is not true of the legal or political sovereign. In all states are limits, more or less definite, to such powers, according to the character of the subjects and the relations of the state to foreign powers. Even despotism is tempered by assassination and the liability of revolution (Dicye, Law of the Constitution, 6th ed., p. 75). A third proposition, often expressed with respect to sovereignty, is that it cannot be alienated: a proposition thus stated by Rousseau: "Je dis que la souveraineté, n’étant que l’exercice de la volonté générale, ne peut jamais s’alléner " (Du contrat social, 2. 1; Figgis, p. 89).

According to one view, sovereignty is not the distinctive note of a state. Many communities usually regarded as true states do not possess it. There are sovereign and non-sovereign states; are connections in law being both. In the many criteria, sovereignty is not a necessary attribute of a state (Laband, Das Staatsrecht des deutschen Reiches, 1. 87; Jellinek, Die Lehre von den Staatenverbindungen, p. 37; Meyer, Lehrbuch des deutschen Staatsrechtes, p. 5; Ullmann, Völkerrecht, 29. See the contrary view presented by Professor Burgess, Political Science or Constitutional Law, 1. 22; Political Science Quarterly, 3. 123; Georges Streit, Revue de droit international, 1900, p. 149). Any division or classification of states must be imperfect. The fact is that there may be an indefinite number of what Merigian (i. 204) terms political "collectivités secondaires"; that the attributes summed are themselves not separable and divided in the many ways; that there may be new forms of combinations between states or parts of states; and that their morphology is subject to no hard and fast rules.

The phrase half sovereign states was invented by J. J. Moser to describe states possessing some of the attributes of sovereignty. Under this class are grouped very diverse communities. There are states which possess some attributes of sovereignty, but no others; states possessing internal autonomy, but not externally independent; states which are less than the independence of others. These are states which have certain of the attributes of sovereignty, but are subject to servitudes or burtens imposed by treaty, usage,
SOVEREIGNTY

or force. Feudalism had a phraseology to express the varieties of feuds which existed under it; modern international law has no generally-accepted terminology for the still greater variety of states which now exist. These varieties tend to multiply, and it is difficult to reduce them all to a few types. The theory that states are equal, and possess all the attributes of sovereignty, was never true. It is still more at variance with the facts in these days when a few great states predominate, and when the contact of western states with African and Asiatic states or communities gives rise to relations of dependence falling short of conquest. The division into federations, confederations and alliances is not complete. Jellinek has suggested this classification ("Die Lehre von den Staatenverbünden, p. 58"); (a) Unorganized associations, including—(1) treaties; (2) occupation of the territory of one state and administration by another, as in Benin and the Congo; (3) treaties of the old Holy Roman Empire which provide for the perpetual neutrality; (b) Der Staatenbund, the feudal state, of which Jellinek gives the Turkish Empire and the old Holy Roman Empire as examples. (b) Organized associations, including—(1) international commissions ("internationale Verwaltungsvereine", such as international postal and telegraph unions, &c.); (2) the Staatenbund or confederation of states; (3) real unions of states as distinguished from personal; (4) the Bundesstaat or federal state. Most of the existing varieties may be conveniently ranged in the following classes:

1. States which have complete independence, complete autonomy, external and internal, and which are recognized in international law as sovereign states.

2. States which have complete external independence, but are more or less subject permanently to other states as to their internal affairs. Of this class there are now few examples. However, such states as permit, permanently or normally, of interference by others on behalf of certain classes of subjects may be described. The general principle is that a treaty does not detract from sovereignty. As Jellinek expresses it, "Der Staatenvertrag bindet, aber er unterwirft nicht" ("Gesels und Verordnung, p. 23)." He also says, "Nec regi aut populo jus demit summj imperti."—

3. States which enjoy complete autonomy as to internal affairs, but which are more or less subject to other states as to foreign relations. Some writers would place in this category all states forming part of a true confederacy. It includes states which are united temporarily—cases of inorganic unity, to use Jellinek's expression. It includes also permanent alliances or organic unions. These are some examples:

a. Protectorates and Soverритори.—The status of certain states, such as Bulgaria and Rumelia and the late South African Republic, were peculiar. Even before the independence of the two first-named states, they undoubtedly were for many purposes sovereign. The unions between a superior and inferior state, e.g. the relations of the vassals to the king of the old Holy Roman Empire, and the relations of the Ottoman Porte to its Christian provinces. In the middle ages the question was often mooted whether states subject to feudal superiors, or the states forming the empire, were sovereign. According to one common definition they were not: a true sovereign state was universitas quae non superiorem recognoscit, "Celui est absoluement souverain qui ne rien tient après Dieu que de l'espèce. S'il tient d'autrui il n'est plus souverain." The prevalent opinion was that sovereignty was compatible with many things, such as were possessed by the Reich over the princes of Germany; that there might be fiefs held in full sovereignty; and that vassal states, when subject to them, had not always the same degree of independence. That was the view of Grotius (1. 1. ch. 3, 23, 2), who holds that the nexus feudalis is consistent with summum imperium.

4. States which have, by treaty or otherwise, parted with some portion of their sovereignty and formed new political units: what Herbert Spencer calls "compound political heads," or, to use Austin's expression, "composite states." The most important examples of this class consist of federal or composite states which by treaty or otherwise have surrendered certain of their powers, or which have created a new state (Staatenbund). For many years one of the burning questions in the politics of the United States was the question whether the individual states of the Union remained sovereign. According to the theory of J. C. Calhoun, the states had entered into an agreement from which they might withdraw if its terms were broken, and they were sovereign. According to the theory expounded in the "Federalist," the individual states did not, after the formation of the constitution, remain completely sovereign: they were left in possession of certain attributes of sovereignty, while others were lodged in the Federal government; while there existed many states, there was but one sovereign. Even if the origin was a compact or contract, after the "United States" were formed by a "constitutional act" there no longer existed a mere contractual relation: there existed a state to which all were subject, and which all must obey (von Stengel, "Staatenbund und Bundesstaat; Jugahru für Gesetzgebung, p. 156; Cooley, "Principles of Constitutional Law", 21, 102). According to Austin: "In the case of a composite state or a supreme federal government, the several united governments of the several united states together with a government common to these several societies, are jointly sovereign in each of these several societies and also in the larger society arising from the federal union, the several governments of the several united societies are jointly sovereign in each and all." (5th ed., vol. 1, p. 255). In point of fact, there are fields of action in which A is sovereign, others in which B is sovereign, and certain others in which A and B are jointly or alternately sovereign. To take the American constitution, for example, the states are sovereign as to some matters, the Federal government as to others.

5. Another division includes anomalous cases, such as Cyprus or Bosnia, in which one government administers a country as to which another state retains certain powers, theoretically large.

6. The territories governed or administered by chartered companies form a class by themselves. Nominally such companies are the delegates of some states; in reality they act as if they were true sovereigns.

According to modern usage the appellation "sovereign state" belongs only to states of considerable size and population exercising without control the usual powers of a state, e.g. able to declare peace or war. Leibnitz, discussing this subject in his "Novissima rerum natura" (Opera, vol. 2, p. 77), says: "Haec valde etiam dubito, an possit Republicae illi Italiae, quam vocant Sancti Marini oppidum, concedi supremae, tametsi jure liberam esse nemo negat," a remark which would apply also to the republic of Andorra, "Ili tantum vocantur souverains ou potestats, qui territorium majus habent, exercitumque educere possunt: atque hoc demum illud est, quod ego voco suprematum, et Gallos quoque arbitor, cum rebus ad jussum spectantibus, pace, bello, foederibus sermo est, et ipsi aliquos vocant souverains, eos non de urbibus libris quales, nec eis in territorium dominus, quae facile Medicis etiam emere potest, sed de majoribus illius potestatibus, quae bellum inferre, bellum sustinere, propria quodammodo vi stare, foedera pangere, rebus aliarum gentium cum autoricitate intervenire possunt." 4-359.

With this view may be compared that of a writer in the "Law Magazine" (1899) xxxv, 30, who argues that the republic of San Marino is a state in the full sense. It is sometimes suggested that self-governing colonies are to be regarded as true states. Undoubtedly some of them can no longer be regarded as colonies in the old sense. The self-governing colonies forming part of the "multi-cellular British state," as F. W. Maitland describes it ("Political Theories of the Middle Ages, p. x."), have an essentially "state-like character." If Liberia is a state, the same may surely be
it is true the British colonies have not the power of declaring war or peace, or regulating the foreign policy of the empire; and the Crown may disallow a measure passed by the dominion parliament (J. G. Bourinot, Constitution of Canada, 1888, p. 75; A. H. F. Lefroy, Legislative Power in Canada, 244). Colonial legislatures are said to have delegated powers. It is more accurate to say that as to certain matters the legislature of the Canadian Dominion is sovereign, and as to certain others that it is not (Lefroy, 244; Quick and Garran, Australian Commonwealth, 328; Dicey, 106); and as to some matters they are in fact, if not in form, universitas superiorem non recognoscet (Quick and Garran, 310); or that they are states in process of making. Occasionally the expression "subject of a colony" is now used (Low v. Routledge, L.R. 1 Ch. 42; Lefroy, Legislative Power in Canada, 329). It has been decided by the judicial committee of the Privy Council (London, 1899) that the Canadian Legislative Power in Canada, and delegates of the Imperial parliament (A. B. Keith, Responsible Government in the Colonies, p. 81). At all events, the self-governing colonies may be classed as "half sovereign states" or "quasi-sovereign."

Many attempts have been made to enumerate the attributes of sovereignty, i.e. the regalia, prerogatives, &c., as they were called. For example, Bodin gives a list of the properties of majestas or sovereignty: (a) "Legem universis, &c., singulis civibus dare poisse;" (b) bellum indiciare aut pacem inire; (c) to appoint and change magistrates; (d) power to make and annul treaties; (e) power of pardon; (f) raising revenue; (g) coin money" (De republica, vol. i. ch. 10). Leibnitz, with the middle ages in view, divides the attributes or faculties into two classes: regalia majora and regalia minora. Hobbes (Levitation), analysing these attributes, enumerates twelve attributes. "These," he says, "are the marks which make the essence of sovereignty, and which are the marks whereby a man may discover in what man, or assembly of men, the sovereign power is placed or resided." He also describes them as "inseparable rights." Bluntschli (Allgemeine Staatslehre, i. 575) enumerates the attributes as follows: (a) (b) independence; (c) power to determine constitution; (d) right of legislation; (e) action through deposed organs; (f) irresponsibility. All of these enumerations are open to the objection that they merely describe the action of the state at a particular time, or indicate a theory of what an ideal state should be.

Authors.—The literature of the subject is immense; every book on political science, from Republic of Plato and the Politics of Aristotle, has dealt with or touched sovereignty. A few of the modern works are: J. C. Bluntschli, Allgemeine Staatslehre (Munich, 1882); Otto Gierke, Das deutsche Genossenschaftrecht (Berlin, 1887-1888); J. Austin, Lectures on Jurisprudence (3rd ed., London, 1889); Sir H. Maine, "Minute on the Káthávaras States" (1884); part iii. of A. E. C. Balfour, 1913; and Early History of National Sovereigns (1875); P. Laband, Staatsrecht des deutschen Reiches (Freiburg-im-Breisgau and Tübingen, 1876); R. von Mohl, Encyclopädie der Staatswissenschaften (2nd ed., Tübingen, 1872); O. Gierke, Johannes Althaus (Breslau, 1880); G. Jellinek, Die Lehre von den Staatsverbindungen (Vienna, 1882); G. Meyer, Lehrbuch des deutschen Staatsrechts (Leipzig, 1879); H. Rosin, Staatssouveränität (1883); K. Gariep, Allgemeines Staatsrecht (1882); T. M. Cooley, Constitutional Limitations (2nd ed., 1896); Jellinek, Ueber Staatsfragmente (1896); J. B. Westerkamp, Staatsbund und Bundesstaat (Leipzig, 1892); J. R. Green's Works (London, 1892); W. W. Fowler, City State of the Greeks and Romans (London, 1891); Salomon, L'occupation des territoires sans maîtres (Paris, 1896); A. V. Dicey, Law of the Constitution (6th ed., 1902); X. Camacho, La Conception juridique de l'état (1890); H. Rehm, Allgemeine Staatslehre (Berlin, 1899); J. W. Burgess, Political Science and Constitutional Law (Boston, 1899); C. E. Merriam, History of the Theory of Sovereignty since Rousseau (New York, 1900); J. Bryce, Studies in History and Jurisprudence (1891, 1901); E. V. D. Willoughby, Abhängigkeitsverhältnisse unter den modernen Staaten (1896); W. W. Willoughby, The Nature of the State (New York, 1896); Clause, Die Lehre von den Staatsbundesformen, (Jena, 1887); The Principles of International Law, The Philosophical Theory of the State (1899); J. B. Moore, Die Internationale Recht (Washington, 1906), i. 18 seq.; "Notes on Sovereignty," American Journal of International Law 1907, i. 105; W. R. Scott, "The Government in the Colonies of the Galapagos," Baty, International Law (1909).
It was long recognized that the precision which is of the essence of good sowing could be better attained by mechanical means, and as early as 1662 a sowing-machine was invented by Joseph Locatelli in Carinthia. In England the early history of mechanical sowing is chiefly connected with the name of Jethro Tull, who about 1730 invented the corn-drill. Cooke's drill brought out in 1783 was the definite precursor of the modern drill. The drill, besides depositing the seed at a uniform depth, sows it in parallel rows at equal distances from one another and thus makes possible the use of the horse hoe and facilitates the suppression of weeds amongst growing crops, the latter advantage being specially marked in the case of root crops. The "cup-feed" and the "force-feed" are the commonest and most generally useful types. The cup-drill consists of a long box carried upon wheels and divided diagonally into two sections by a partition. The forward section contains the seed which drops through apertures, the size of which can be regulated by slides, to the bottom section. A spindle geared to the ground-wheels by cogs passes longitudinally through the centre of this section and carries disks, round the rims of which are fitted small cups. As the horses pull the drill forward, the spindle and disks revolve and the cups scoop up the seed and pour it into the funnels; thence it proceeds down a series of tubes or "spouts" and drops into shallow furrows traced by small coulters travelling immediately in front of the streams of seed. The coulters can be raised or lowered by levers and are kept down to their work by weights or presses, which can be regulated according as deep or shallow sowing is required.

In the United States the maize or Indian-corn crop excels all others in value, and machines used in planting and handling this crop are of great importance. Corn (maize) is sometimes listed or planted in a continuous row like wheat, and for this purpose a machine known as a lister is employed.

In its general construction this machine is a sulky plough, having a double mould-board, which turns the furrow in both directions. Immediately behind the plough is a sub-soller for deepening the furrow, and penetrating to the moist soil below the surface. A seed-box is mounted on the plough beam, and is provided with a feed-plate operated by a shaft geared to one of the wheels. The seed is delivered to the furrow in rear of the mould-boards and covered by two shovels fixed behind which turn the soil back into the furrow.

It is, however, more common to plant maize in hills, which are spaced equally from each other and form rows in both directions, so that a cultivator may be driven between them. This work is done by a machine called a check-row corn planter.

In using the corn planter, a wire, having buttons attached thereto, at intervals corresponding to the distance between the hills, is first stretched across the field and anchored at its ends. This wire is then placed upon the guide rollers at the side of the machine and passes between the jaws of a forked lever, which is connected at its other end with a rock-shaft passing across the machine and serving to oscillate a feed-plate in the bottom of each seed-hopper. As the buttons on the check-wire strike the forked lever, the latter is drawn to the rear and causes the feed-plate to drop the seed through the tubes into the open space between the plates of the furrowing shoe. A reel at the rear of the machine is used to take up the check-wire as the planter progresses.

In another corn planter the check-wire is dispensed with, and the machine is provided with a shaft carrying two reels, the blades of which are at a distance apart equal to the distance between the hills of corn, and thus measure the intervals at which the corn is to be dropped. A rod, extending from the side of the machine, and carrying a small wheel, marks the next row and serves as a guide to the driver.

**SOYER, ALEXIS BENOIT** (1809-1858), French culinary artist, was born at Meaux-en-Brie, France, in October 1809. After five years' apprenticeship as a cook near Versailles, he was engaged by a well-known Paris restaurateur, and soon became chief cook. Leaving France at the revolution of 1830, he went to London and joined his brother in the kitchen of the duke of Cambridge. Subsequently he was cook in several noblemen's kitchens, and in 1837 was made chef to the Reform Club, London. In 1847, having written several letters to the press on the famine in Ireland, he was commissioned by the government to establish kitchens in Dublin. In 1850 he resigned his position at the Reform Club, and the following year opened Gore House, Kensington, as a restaurant, but this venture did not prove a success. In 1855 he offered, through the medium of The Times, to proceed at his own expense to the Crimea and advise on the cooking for the British army there. His services were accepted by the government. On returning from the front he lectured at the United Service Institution on cooking for the services, and reformed the dietary of the military hospitals, and of the emigration commissioners. He
died in London on the 5th of August 1838. Soyer was the inventor of the steam cooking wagon, and the author of a variety of cookery books. His wife, Elizabeth Emma Soyer, acquired considerable popularity as a painter, chiefly of portraits.

**SOZOMEN,** the name of a famous 5th-century church historian. Hermias Salamancus (Salaminius) Sozomenus (c. 400–443) came of a wealthy family of Palestine, and it is exceedingly probable that he himself was born and brought up there—in Gaza or the neighbourhood. What he has to tell us of the history of South Palestine was derived from oral tradition. His grandfather, he tells us, lived at Bethel, near Gaza, and became a Christian, probably under Constantius, though he is not certain where. It is possible that he had an acquaintance of the grandfather, one Alaphon. Both men with their families became zealous Christians. The historian's grandfather became within his own circle a highly esteemed interpreter of Scripture, and held fast his profession even in the time of Julian. The descendants of the wealthy Alaphon founded churches and convents in the district, and were particularly active in promoting monasticism. Sozomen himself had conversed with one of these, a very old man. He tells us that he was brought up under monkish influences and his history bears him out. As a man of his period he knew few things of his own day, and his work was to be also a monument of his reverence for the monks in general and for the disciples of Hilarión in particular. After studying law in Corinth he settled down as an advocate in Constantinople, where he wrote his Ἐκκλησιαστικὴ Ἑτορία about the year 440. The nine books of which it is composed begin with Constantine (337) and come down to the death of Honorius (423); but according to his own statement he intended to continue it as far as the year 439 (see the Dedication of the work). From Sozomen himself (i. 17), and statements of his exponents Nicephorus (Historia ecclesiastica, v. 275 sqq.), it appears that Sozomen was induced by a personal desire to compose down to that year, and that consequently it has reached us only in a mutilated condition, at least half a book being wanting. (Güldenpflüng, Theodoros von Kyrrhos, p. 12 sqq., holds that Sozomen himself suppressed the end of his work.) A flattering and bombastic dedication to Theodosius II. is prefixed. When compared with the history of the ecclesiastical historian Socrates (q.v.), it is plainly seen to be a plagiarism from that work, and that on a large scale. Some three-fourths of the materials, essentially in the same arrangement, have been appropriated from his predecessor without his being named, the other sources to which Sozomen was indebted having been expressly cited. But it is to his credit that he has been himself at the trouble to refer to the principal sources used by Socrates (Rufinus, Eusebius, Athanasius, Sabinus, the collections of epistles, Palladius), and has not unfrequently supplemented Socrates from them; and also that he has used some new authorities, in particular sources relating to Christianity in Persia and to the history of Ariánism, monkish histories, the Vita Martini of Sulpicius, and works of Hilarión. The whole of the ninth book is drawn from Olympiodorus.

If we forbear to blame Sozomen for other faults, it cannot be said that he approves of Socrates' freer attitude towards Greek science, and that he wished to present a picture in which the clergy should be still further glorified and monasticism brought into still stronger prominence. In Sozomen everything is a shade more ecclesiastical—only a shade—but not in Socrates. Perhaps also he wrote for the monks in Palestine, and could be sure that the work of his predecessor would not be known.

Sozomen is an inferior Socrates. What in Socrates still betrays some vestiges of historical sense, his moderation, his reserve in questions of dogma, his impartiality—all this is wanting in Sozomen. In many cases he has repeated the exact words of Socrates, but with them he has passed almost into mere phrases. The chronological scrupulousness of the earlier writer has made no impression on his follower; he has either wholly omitted or inacurately repeated the chronological data. He writes more wordily and diffusely. In his characterizations of persons, borrowed from Socrates, he is more dull and colourless. After Socrates he has indeed repeated the caution not to be too rash in discerning the finger of God; but his way of looking at things is throughout more diffusely.

**SPA,** a town of Belgium, lying less than 20 m. S.E. of Liége and in the same province, famous for its mineral springs, which are said to have been discovered in 1535. They have been known to have medicinal qualities since that time. They were first discovered in 1326. They are supposed to have given the common name of "spa" to such resorts. The town is situated 885 ft. above sea-level and the heights above the valley reach 1100 ft. In the 18th century it was the most fashionable resort in Europe for the medicinal use of such waters, being visited by Peter the Great of Russia, Gustavus III. of Sweden, and Joseph II. of Austria. In 1807 much of the town was burned down, while the principal buildings, the Casino and the Pouchon, are quite modern. Spa has not held its own with its many French and German rivals, but it still attracts about 20,000 visitors annually. (Pop. 1904), 7750.

**SPACE AND TIME,** in philosophy. The metaphysical problems connected with Space and Time are so similar and have been so closely conjured in the history of thought that they may well be treated together. They are clearly distinguishable from the psychological, which relate to the modes whereby our spatial and temporal conceptions have been formed and to the analysis of the materials of which they are composed (see PSYCHOLOGY). In an exhaustive treatment of Space and Time by far the largest share of the work rests with the psychologist. The business of the metaphysician is to determine what is the proper relation of our minds to the temporal and spatial conceptions. The first tendency of thought is to treat Space and Time as having objective existence in the same way as the ordinary things that compose our world, and this we may call the objective method. Simple as it appears to be, it discloses formidable difficulties, which may be illustrated by a consideration of Newton's famous account of "absolute, true and mathematical time" as something which "in itself and from its own nature flows equally" and with no liability to change. Now, if mathematical time as thus described is merely an abstraction used to facilitate mathematical calculations, no objection can be taken to it. But if Newton meant to assert that Time is a flowing stream no less actual than the Thames, his assertion is open to fatal objections. All admittedly real streams, such as the Thames, have a definite beginning and an ending. But where is the source of Time and where is its outlet? Every real stream has boundaries at its sides. What are the boundaries of Time? Every real stream has certain definite qualities: water is rather heavy and translucent, and produces certain effects upon bodies plunged into it. What are the specific qualities of Time? How are things in time affected by their immersion in time so as to be different from things not in time? And if it be asserted that time has such specific qualities, by what sensus do we perceive them? We may fairly assume that none of these questions can be answered intelligibly by one who holds the Newtonian position. And thus we are justified in the conclusion that time is not a real
stream at all, but something which is said to behave like a stream only in some metaphorical sense. Similar difficulties arise if we try to attribute a like objective reality to Space. We can imagine no boundaries to Space; it seems to have no active specific qualities and we have no sense-organ for perceiving it.

The thinkers of antiquity saw these difficulties without solving them. Their whole treatment of philosophic problems was objective; and, so long as Space and Time are treated objectively, not much can be done with them. Plato has great difficulty in explaining the relation between Space and his Ideas: Aristotelic contents himself with defining Space as “the first unmoved limit of the containing body,” a definition which helps us very little: nor do we get more light from later Greek philosophy. As to Time, there was always a tendency in Greek thought to treat it as in some sense unreal. Time was seen to be intimately connected with change, and it was just their liability to change that made ordinary mundane things unreal, as contrasted with the unchanging steadfastness of the Platonic Ideas. And the pantheistic One-and-All of Plotinus is plainly incompatibility with the reality of Time. In all pantheistic systems, Time belongs to mundane existence and Eternity to the transcendent Reality.

Modern philosophy is distinguished from ancient mainly by its greater subjectivity; and thus it was not long after the rise of modern philosophy that thinkers began to turn to the subjective method of explaining Space and Time, that is, to regard them as real only to our minds. Its use begins effectively with Berkeley, though prepared for to some extent by earlier writers such as Hobbes. Berkeley’s treatment is most definitely clear in the case of Space; for his attack upon materialism made it necessary for him to affirm the ideality of Space as well as of Matter. But he takes a similar line of argument with Time, declaring it to be nothing but the succession of ideas. The merit of the subjective method was that it made men see the importance of psychology. If Space and Time exist only in the human mind we must analyse the human mind to explain them. The work of the English psychologists such as the Mills and Bain attaches itself to subjectivist principles.

A distinct epoch in the history of the subject was made by the work of Kant, whose solution of the problems may be classed as transcendental. He argued that Space and Time are not given by experience, but are rather conditions of all our experience, being in his terminology a priori, that is, supplied by the mind from its own inward resources. They do not belong to things-in-themselves, but to things-as-we-know-them, or phenomena. Their validity consists in the fact that all men have them and that they are absolutely necessary conditions of human intelligence. As he expresses it from his peculiar point of view, Space is the form of outer sense, Time of inner sense.

The prevalence of German philosophy in Great Britain during the last quarter of the 19th century has given these Kantian principles a great currency, interrupting the more truly characteristic psychological tendency of British thought. That prevalence is now passing away. No one now holds the full Kantian position; which, in the case of Space, is refuted by the simple consideration that our spatial conceptions depend upon our sensuous perceptive powers; and that, consequently, the spatial conceptions of the blind, for example, are quite different from those of ordinary men. If Kant is right, and Space is a pure form unaffected by all specific differences of content; it would follow that a man born with one sense only, say that of touch, would have the same space-conception as the rest of us; a conclusion too plainly absurd to need refutation. What an apriorist can still maintain is that in our conceptions of Space and Time there are elements which cannot be explained by the psychologist as having developed out of anything else, and must therefore be regarded as innate endowments of the mind. This is a position not unreasonable in itself, and one, at least, which does not interfere with the detailed work of the psychologist.

The way with these problems which commends itself to the present writer and seems fully in harmony with the general tone of contemporary thinking may, if a distinctive catchword be desired, be termed the humanist method. By this is meant that the study of the human mind comes first; that we put no metaphysical questions till we have learnt what the psychologist has to teach us; and that in our explanations of metaphysical realities we should be as anthropomorphic as possible. In the case of Space this leads to a result which is largely negative. When we ask what objective reality corresponds to our conception of Space, the answer must be analogous to that which we give respecting the various sensible qualities of the external world. We cannot suppose that Colour, for example, exists objectively as we experience it; evidently it is altogether relative to the organs of vision which we happen to possess. But we must believe that the objective world has a quality in some way correspondent to the quality of Colour. So with Space. Space as we know it is altogether relative to our actual, muscular and visual powers of perception. But the fact that our spatial perceptions and conceptions enable us to deal successfully with objects requires us to believe that the objective world has an arrangement of its own corresponding to spatial arrangement, though we are unable to imagine what it can be. Space cannot be objectively real, because of the difficulties disclosed above in the criticism of the “objective” method, and we are unable to put anything definite in its place. With Time the case is somewhat different. Our conception of Time is based on our experience of Change, combined with memory and anticipation. Now Change is an experience which we feel directly in our personal consciousness: consciousness is not spatial, but it is mutable. This direct experience is a guarantee of the reality of Change, and justifies us in attributing it in some degree to ultimate objective reality.

See S. H. Hodgson, Space and Time; H. Bergson, Essai sur les données immédiates de la conscience; J. E. MacTaggart, Studies in the Hegelian Diacritic. (H. Sr.)
Nine Muses. Lo Spagna was alive in 1528, but he appears to have died before 1536, as in that year a pupil of his named Doni completed a fresco in S. Jacopo, near Spoleto, which Lo Spagna had begun.

**SPAHIS (in Persian Sipārā, meaning warriors, and synonymous with Sepoy)** originally the holders of fiefs in Central Asia who yielded personal military service to their superior chief. In time the term came to be applied to the soldiery furnished in their own stead. A similar institution existed in Turkey, and the "Spahis" were the light irregular cavalry which from the time of Sultan Amurath I. (1526) down to the beginning of the 19th century formed the flower of the Turkish army; and it is calculated they numbered about 130,000. "Spahis" is the term now applied to certain native cavalry regiments in Algiers and Tunis, officered by Frenchmen.

**SPAIN (España), a kingdom in the extreme south-west of Europe, comprising about eleven-twenths of the Iberian Peninsula, in addition to the Balearic Islands, the Canary Islands, and the fortified station of Ceuta, on the Moroccan coast opposite to Gibraltar.** Each of the two island groups forms one of the forty-nine provinces of the kingdom, although the first named belongs geographically to Spain. Ceuta and the islands of the South Atlantic (exclusive of its colonies) had a population of 18,667,674, and a total area of 194,700 sq. m. It is thus rather more than twice the size of Great Britain, nearly 50,000 sq. m. larger than Japan, and nearly 85,000 sq. m. larger than Italy and Sicily. Exclusive of the Canaries its area is 191,593 sq. m. On all sides except that of Portugal the boundaries of continental Spain are natural, the Peninsula being separated from France by the Pyrenees and on every other side being surrounded by the sea. On the side of Portugal a tract of inhospitable country led originally to the separation between the two kingdoms, since as it was depopulated, the separation of the populous maritime tracts from the Moors to be carried out independently of that of the eastern kingdoms, which were also well peopled. The absence of any such means of intercommunication as navigable rivers affords has favoured the continuance of this isolation. The precise line of the western frontier is formed for a considerable length by portions of the chief rivers or by small tributaries, and on the north (between Portugal and Galicia) it is determined to a large extent by small mountain ranges. The British rock of Gibraltar, in the extreme south of the peninsula, is separated from Spain by a low isthmus known as the Neutral Ground.

By the relinquishment of Cuba and the cession of Porto Rico to the Philippine and Sulu Islands, and Guam, the largest of the **Colonial Possessions.** Ladrone, to the United States, as a consequence of the war of 1898, and of the remaining Ladrone or Marianne Islands, together with the Caroline and Pelew Islands, to Germany by a treaty of the 8th of February 1899, the colonial possessions of Spain were greatly reduced. Apart from Ceuta, Spain possesses on the Moroccan seaboard Melilla, Alhucemas, Peñón de la Gomera, Ifni, and the Chafarrinas islands. Besides these isolated posts Spain holds Rota and Oruc, a stretch of the Saharan coast, and its hinterland lying between Morocco and French West Africa; the Muni River Settlements or Spanish Guinea, situated between French Congo and the German colony of Cameroon; Fernando Po, Annobon, Corisco and other islands in the Gulf of Guinea. Spain has given to France the right of pre-emption over any of her West African colonies.

1. **General Survey of the Spanish Kingdom**

**Physical Features.**—The coast-line on the north and north-west is everywhere steep and rocky. On the north there are numerous small indentations, many of which form convenient harbours, although the current flowing along the coast from the west often leaves in the still water at their mouths obstruction bars. The best harbours are to be found on the rías or fjord-like indentations in the W. and N. of Galicia, where high tides keep the inlets well scoured; here occur the fine natural harbours of Pontevedra and Vigo, Coruña and Ferrol. Less varied in outline but more varied in character are the Spanish coasts on the south and east. The seaboard is generally flat from the frontier of Portugal to the Straits of Gibraltar. Between the mouth of the Rio Tinto and that of the Guadalquivir the shore is lined by a series of sand-dunes, known as the Arenas Gordas. Next follows a marshy tract at the mouth of the Guadalquivir known as Las Marismas, after which the coast-line becomes more varied, and includes the fine Bay of Cadiz. From the Straits of Gibraltar a bold and rocky coast continues almost to Cape Palos, a little beyond the mouth of the Guadalquivir, and on to the south of Cabo de Palos a line of flat coast, beginning with the narrow strip which cuts off the lagoon called the Mar Menor from the Mediterranean, bounds half of the province of Alicante, but in its northern half this province, becoming mountainous, runs out to the lofty headland of Cape de la Nao. The whole coast of the Bay of Valencia is low and ill provided with harbours; and along the east of Catalonia stretches of steep and rocky coast alternate with others of an opposite character.

**Surface.** There is a marked increase in height towards the north of Spain, both in the interior mountains and in the mountain ranges stretching on the whole from central Spain to the west. The northern half of the table-land, made up of the provinces of Leon and Old Castile, has an average elevation estimated at about 2700 ft., while the southern half, made up of Estremadura and New Castile, is slightly lower—about 2600 ft. On all sides except the table-land as a whole is remarkably isolated, and hence the table-land and the river valleys that lead down from it to the Mediterranean are of great agricultural and commercial importance. The isolation on the side of Portugal has already been mentioned. On the north-west the valley of the Ebro and a series of valleys farther south, along both of which military operations have taken place from an early period, open a communication between Leon and the hill country of Galicia, which explains why this province was united to Leon even before the conquest of Portugal from the Moors. The valleys across this continental mountain, in the west, are comparatively numerous, and several of them are crossed by railways. The two most remarkable are the Pass of Pajares, across which winds the railway from Leon to Oviedo and the seaport of Gijón, and that of Resines leading down to the deep valley of the Besaya, and crossed by the railway from Valladolid to Santander. In its eastern section the chain is crossed by the railways from Burgos to Bilbao and San Sebastian; the last-named line winds through the wild and romantic passes of the Sierra Morena and the Sierra de Abarzuza (formerly the province of Burgos) before it traverses the Cantabrian chain at Liébana.

On the north-east and east, where the edge of the table-land sweeps round the coast, wide coastal plains, interrupted by the valley of the Ebro and the Bay of Valencia, and is crowned by more or less isolated mountains, some of which have been already mentioned. On the north-east, by far the most important communications with the Ebro valley is by the valley of the river Trigo, which has always formed a military route of the highest consequence, and is now traversed by the railway from Madrid to Saragossa. Farther south the mountains clustered on the east of the table-land towards the Ebro, in the Sierra de Albarracín, Sierra de Gúdar, and the Sierra Nevada, long retarded communication between Valencia and Madrid extremely difficult, and the principal communications with the east and south-east are by the routes through the ranges of the Sierra de Gúdar and the Sierras de Canigo, and the Pyrenees in the Pyrenean range. Above the ranges of the Pyrenees the Rhône (g. t.) makes a marked descent in the hill country which connects the interior of Spain with the Sierra Nevada.

In the south the descent from the table-land to the valley of the Guadalquivir is again comparatively gradual, but on the eastern half of the Sierra Morena the passes are few, the most
Important being the Puerto de Depeñaperros, where the Rio Magaña, a sub-tributary of the Guadalimar, has cut for itself a deep gorge. This is one of the two important passes which separate the Province of Madrid from the rest of Spain. Between Andalusia and Estremadura farther west the communication is freer, the Sierra Morena being broken up into series of small chains.

The mountains belonging to the table-land the most continuous are those of the Cantabrian chain, which stretches for the most part from east to west, parallel to the Bay of Biscay, but ultimately bends round towards the south between Leon and Cordova. The main crest of this chain, and of the neighbouring parts of the table-land, is the number of the parameras or isolated plateaux, surrounded by steep rock walls. The chief plateaux of this group are those of Sigüenza and Soria, round the headwaters of the Douro, separate the mountains of the so-called Iberian system on the north-west from the table-land from the eastern portion of the central mountains of Spain, and give name to the Carpenito-Vetonica, the most easterly is the Sierra de Guadarrama, the general trend of which is from south-west to north-east. It is the Montes Cardetani of the ancients, and a portion of it (due north of Madrid) still bears the name of Carpenanos. Composed almost entirely of granite, it has an aspect when seen from a distance highly characteristic of the mountains of the Iberian Peninsula, in general, the presence of a saw-like (sierra) broken up into numerous sections. Its mean height is about 5520 ft., and near its centre it has three summits, the highest (named the Pico de Peñalara) rising to a height of 9610 ft. The chief passes across the range are those from Madrid to Segovia (8725 ft.) in the north, from Navacerrada (5837 ft.), near Peñalara, and Guadarrama (5010 ft.), a few miles farther south and west; these are crossed by carriage roads. The railway from Madrid to Segovia passes through a tunnel cl. The mountain passes traverse the southern half of the range through a remarkable series of tunnels and cuttings.

The irregular surface, filled with hills and parameras, separates the Sierra de Guadarrama from the Sierra de Gredos farther west. This is the loftiest and grandest sierra in the whole series. Its culminating point, the Plaza de Almanzor, attains the height of 8770 ft., not far short of that of the highest Cantabrian summits. Its general trend is east and west; towards the south it sinks precipitously, and on the north it descends with a somewhat more gentle slope towards the longitudinal valleys of the Tormes and Alberche. The river Tagus rises not far from the summit, and traverses the southern portion of the range through a remarkable series of tunnels and cuttings.

The Sierra de Gredos has a road across it connecting Avila with Talavera de la Reina by the Puerto del Pico; but for the most part there are only bridle-paths across the Gredos and Gata ranges, and no railway communication is possible from the Sierra de Gredos to the Sierra de Gata, the westernmost and the lowest of the Spanish sierras belonging to the series. These hilly intervals between the more continuous sierras greatly facilitate the communication between the well-populated provinces of the north-west and the south-west. The Sierra de Gredos is a road across it connecting Avila with Talavera de la Reina by the Puerto del Pico; but for the most part there are only bridle-paths across the Gredos and Gata ranges, and no railway communication is possible from the Sierra de Gredos to the Sierra de Gata, the westernmost and the lowest of the Spanish sierras belonging to the series. These hilly intervals between the more continuous sierras greatly facilitate the communication between the well-populated provinces of the north-west and the south-west.

On the southern half of the table-land a shorter series of sierras, consisting of the Montes de Toledo in the east (highest elevation Tejaldillas, 456 ft.), and the sierras of San Pedro, Montanchez and Guadaluste in the west (highest elevation Cabeza del Moro, 3100 ft.), separates the basins of the Tagus and Guadiana. The southern system of mountains bounding the Iberian table-land—the Sierra Nevada (q.v.)—is even less of a continuous chain than the two systems last described. As already intimated its least continuous portion is in the west. In the east and middle portion it is composed of a countless number of irregularly-disposed undulating mountains all nearly equal in height.

Even more important than the mountains bounding or crossing the table-land is the system which are here referred to as the semi-island of Madrid, viz. the Pyrenees (q.v.) in the north-east, the Sierra Nevada (q.v.) and the coast ranges in the south. The transverse valleys are formed by junction of a number of longitudinal valleys of the Alpujarras (q.v.), into which open also on the other side the transverse valleys from the most easterly of the coast sierras, the Sierra Contraviesa and the Sierra de Almijara. These ranges are continued farther west by the Sierra de Alhama and Sierra de Aldalazja. Immediately to the west of the last-named is the gorge of the Guadalhubre, which affords a passage for the railway from Malaga to Cordova; and beyond that gorge, to the west of the Mediterranean, lies the small but interesting but in the western Pyrenees, the river Ebro. Ranges of this belt are referred, from their included fossils, to the Cambrian, Ordovician and Silurian systems. They range through a vast region of Andalusia, Estremadura, Castile, Salamanca, Leon and Asturias, and they consist of slates, greywackes, quartzites and diabases. Grits, quartzites, shales and limestones referable to the Devonian system are found in a few scattered areas, the largest and most
SPAIN

The Lower Carboniferous rocks of Spain consist partly of limestones, and partly of shales, sandstones and conglomerates like the culm of Devonshire. It is in these rocks of the provinces of Navarre and Huesca that the coal-mines of Rio Tinto are worked. The Upper Carboniferous is formed to a large extent of sandstones and shales, with seams of coal; but beds of massive limestones are often intercalated, and some of these contain Palæozoic and other fossils like those of the Russian Pusse limestone. The system is most extensively developed in the north, covering a considerable space in Asturias, whence it stretches more or less continuously through the provinces of Leon, Palencia and Santander. Another tract, about 500 sq. kilometres in extent, runs from the province of Cordova into that of Badajoz. It is in this area that the important coal deposits of Pena-rojo are found. There are some smaller areas containing little or no coal, but showing by the included plant-remains that the strata undoubtedly belong to the Carboniferous system.

The Permian is probably represented by some of the red sandstones, conglomerates and shales in the Pyrenees, in the Serrania de Cuenca, and in Andalusia. The Triassic system is well developed in the north of the peninsula along the Cantabrian chain and eastwards to the Mediterranean. It is composed of red and variegated sandstones, dolomites and marls, traversed in some places by oolithic rocks, and containing deposits of gypsum, aragonite and rock-salt. It thus resembles the Trias of England and Germany. In the south-east, however, and at the mouth of the Ebro, limestones are found containing a fauna similar to that of the alpine Trias. These strata are overlain by members of the Jurassic series, which are especially conspicuous in the eastern part of the peninsula between Castile and Aragon, along the Mediterranean border, and in Andalusia, and likewise along the eastward face of the Pyrenees. The Jurassic—Andalusia belongs to the Mediterranean facies of the system; the Jurassic of the rest of Spain is more nearly allied to that of north-western Europe. The Cretaceous system is distributed in four great districts: the largest of these extends through the kingdoms of Murcia and Valencia; a second stretches between the two Castiles; a third is found in the Basque Provinces and in Asturias; and a fourth spreads out along the southern slopes of the Pyrenees from Navarre to the Mediterranean. The lower members of the Cretaceous series include an important fresh-water formation (sandstones and clays), which extends from the Cantabrian coast through the provinces of Santander, Burgos, Saragossa and Logroño, and is supposed to represent the English Wealden series. The higher members comprise massive hippurite limestones, and in the Pyrenean district representatives of the upper subdivisions of the system, including the Danian.

Deposits of Tertiary age cover rather more than a third of Spain. They are divisible into two great series, according to their mode of origin in the sea or in fresh-water. The marine Tertiary accumulations commence with those that are referred to the Eocene series, consisting of nummulitic limestones, marls and siliceous sandstones. These strata are developed in the basin of the Ebro, and in a belt which extends from Valencia through Murcia and Andalusia to Cadiz. Marine Miocene deposits occupy some small tracts, especially on the coast of Valencia. But most of the sandy Tertiary rocks of that district are Pliocene. The Tertiary strata of Andalusia are specially noteworthy for containing the native silver of Herrerias, which is found in a Pliocene bed in the form of flukes, needles and crystals. But the most extensive and interesting Tertiary accumulations are those of the great lakes which in Oligocene and Miocene time spread over so large an expanse of the table-land. These sheets of water extended in the third section of the table-land, in the centre of the country, including the basins of the Ebro, Júcar, Guadiana, Guadalete, and Guadalquivir, where they have left behind them thick deposits of clays, marls, gypsum and limestone, in which numerous remains of the land-animals of the time of their existence have been preserved.

Quaternary deposits spread over a large part of the country. The largest tract of them is to be seen to the south of the Cantabrian chain; but another, of hardly inferior extent, extends from the Sierra de Gredos to the Guadarrama, and from Madrid to Cáceres. Some of these alluvial accumulations indicate a former greater extension of the snowfields that are now so restricted in the Spanish sierras. Remains of the reindeer are found in caves in the peninsula. Eruptive rocks of many ages occur in different parts of Spain. The most important tract covered by them is that which extends from Cape Cadiz to Cape Trafalgar, and which spreads over a large area of Portugal. They likewise appear in Castile, forming the sierras of Gredos and Guadarrama; farther south they rise in the mountains of Toledo, in the Sierra Morena, and across the provinces of Cordova, Seville, Huelva and Badajoz, as far as Evora in Portugal. Among the minor areas occupied by them may be especially mentioned those which occur in the Trinastic districts. Of rocks included in the eruptive series the most abundant is granite. There occur also quartz porphyry, antracite, porphyrite, diabase (well developed in the north of Andalusia, where it plays a great part in the structure of the Sierra de Cazorla); Cañones, spingyites (the latter containing an enormous mass in the Sierra de Ronda), trachyte, liparite, andesite, basalt. The last four rocks occur as a volcanic series distributed in three chief districts—that of Cape Gata, including that of the coast of Andalusia, and the south of Murcia, that of Catalonia, and that of La Mancha.

Climate.—In accordance with its southerly position and the variety in its superficial configuration, Spain presents within its borders examples of every kind of climate to be found on the northern hemisphere, with the sole exception of that of the torrid zone. As regards temperature, the heart of the table-land is characterized by extremely great as well as extremes of temperature. The northern and north-western maritime provinces, on the other hand, have a climate as equable, and as moist, as that of the west of England or Scotland. The climates of the different provinces are distinguished. The first zone is that of the table-land, with the greater part of the Ebro basin. This is the zone of the greatest extremes of temperature. Even in summer the nights are often decidedly cold, and on the high parameras it is not a rare thing to see hoar-frost in the morning. In spring cold, wetting mists occasionally envelop the land for entire days, while in summer the sky is often perfectly clear for weeks together. At all seasons of the year sudden changes of temperature, to the extent of from 30° to 50° F., are not infrequent. The air is extremely dry, which is all the more keenly felt from the fact that it is almost constantly in motion. At Madrid (2150 ft. above sea-level) it freezes so hard that in winter the sea and the ships which sail in the river of the Buen Retiro; and, as winter throughout Spain, except in the maritime provinces of the north and north-west, is the season of greatest atmospheric precipitation, snowfalls are frequent, though they seldom amount to much. The high lands of the Pyrenees, on the other hand, are not only extremely warm but almost rainless, the sea-winds being deprived of their moisture on the edge of the plain. In July and August, plain and mountain, Madrugada are sunburnt wastes; the roads are several inches deep with dust; the leaves of the few trees are withered and discoloured; the atmosphere is filled with a fine dust, producing a haze known as calima, which converts the blue of the sky into a dull grey. In the greater part of the Ebro basin the heat of summer is even more intense. The treeless mostly steppe-like valley with a bright-coloured soil acts like a concave mirror in reflecting the sun’s rays downward, and the air above the districts to which the valley is enclosed prevents to a large extent the access of winds.

The second zone is that of the Mediterranean provinces, exclusive of those of the extreme south. In this zone the extremes of temperature are less marked, the summers are warm, and the winters decidedly cool, especially in the north-east.

The southern zone, to which the name of African has been given, extends the whole of Andalusia and the southern half of Murcia and the province of Alicante. In this zone there prevails a genuine sub-tropical climate, with extremely warm and almost rainless summers and mild winters, the temperature rarely falling below zero. Of all the zones of Spain this region is not the most southerly district but the bright-coloured steppes of the coast of Granada, and the plains and hill terraces of the south-east coast from Murcia to the mouth of the Guadalquivir. Snowrare hard snows); it is said that at Malaga it now falls only once about twenty-five years. The winter, in fact, is the season of the brightest vegetation; after the long drought of summer the surface gets covered once more in late autumn with a fresh green vairies, bright-coloured flowers, and so it remains the
SPAIN

[GENERAL SURVEY]

whole winter through. On the other hand, the eastern part of this zone is the part of Spain which lies between the Pyrenees and the sirocco, a moist and less noxious east wind.

The fourth zone, that of the north and north-western maritime provinces, presents a marked contrast, and they resemble the eastern zone of Italy, for the temperature is mild and equable; the rains are abundant and fall chiefly in autumn, as in the west of Europe generally. Three of the greatest lakes in the world are situated in this zone, and this region, especially in summer, is marked by a great variety of flowers, especially by the Eucharis, the crocus, and the lily.

The northern maritime provinces, in accordance with their climate, have a vegetation resembling that of central Europe. Here only the deciduous trees are found rich in foliage. The trees which are seen in English fields, and here only do forests of oak, beech and chestnut cover a large proportion of the area. The extraordinary abundance of ferns is noteworthy, and one of the most beautiful is the Spanish pine (Pinus hispanica), the Corisca pine (P. Laricio), the Pinosapo (Abies Pinoapo), and the Quercus Tavosa, the last belonging to the slopes of the Sierra Nevada. Besides the date-palm the dwarf-palm grows spontaneously in some parts of the south, but it nowhere makes up a large element of the vegetation.

The Spanish steppes deserve a special notice, since they are not confined to one of the four botanical provinces, but are found in all of them except the eastern one. They are (1) that of Old Castile, situated to the south of Valladolid, and composed chiefly of hills of gypsium; (2) that of New Castile, in the north-eastern part of La Mancha; (3) that of the plains of Almeria, occupying the upper part of the basin of the Ebro; and (4) the littoral, stretching along the south-east coast from Alicante to the neighbourhood of Almeria; (5) the Granadine, in the east of Upper Andalusia (the Kings and the mountains of the Axarquía); and (6) the Antequera region, on both sides of the valley of the Jénil and Genil. All of these were originally salt-steppes, and, while the soil is still highly impregnated with salt, have only a sparse covering of shrubs, mostly members of the Salicaceae, with thick, greyish green, often downy leaves. A different aspect is presented by the grass steppes of Murcia, La Mancha, the plateaus of Guadix and Huecar in the north, and the small areas which are covered chiefly with the valuable esparto grass (Macrophloia lanicina).

Flora.—The vegetation of Spain exhibits a variety in keeping with the differences of climate just described. The number of endemic species is exceptionally large, the number of monotypic genera in the Peninsula greater than in any other part of the Mediterranean domain. The endemic species are naturally most numerous in the mountains, and above all in the loftiest ranges, the Pyrenees and the Sierra Nevada, but it is a peculiarity of the Spanish table-land, as compared with the plains and table-lands of other Mediterranean countries, that it possesses a considerable number of endemic plants and plants of extremely restricted range. This fact, however, is also in harmony with the physical conditions above described, being explained by the local varieties, not only of climate, but also of soil. Altogether no other country in Europe of equal extent has so great a wealth of species as Spain. According to the Pedronus florae hispaniceae of Willkomm and Lange (completed in 1880), the number of species of vascular plants has ascended to exist in the country was 5906.

Spain may be divided botanically into four provinces, corresponding to the four main climatic zones. In the table-land province (including the greater part of the Ebro valley) the flora is composed chiefly of species characteristic of the Mediterranean region, and largely of species confined to the Peninsula. The principal of these are the Halimodendron hispanicum, which gives its name to this province by the growth over large tracts of evergreen shrubs and large herbaceous plants belonging to the Cistineae and Labiateae. Areas covered by the Cistineae are known to the Spaniards as jarales, and those of the Labiateae as lasortes. In the north of the province (the islands of the Sierra Morena, where the Ibanhun bush (Gutia linaderifus) is specially abundant; those covered by the Labiateae are known as tomillares (from tomillo, thyme), and occur chiefly in the south, south-west and east of the table-land of New Castile. In the central parts of the same table-land huge thistles (such as the Onopordum nurnerus), centaureas, artis and other Compositea are scattered in great profusion. From the level parts of these table-lands there are almost entirely absent. On the lofty parameras of Soria and other parts of Old Castile the vegetation has an almost alpine character.

The southern or African province is distinguished chiefly by the abundance of plants which have the tropical climate of the south-western coast, and in the south of Murcia, Alzantica and Almeria the aspect is truly African, fertile oases appearing in the midst of rocky deserts or barren steppes. A peculiar vegetation, consisting mainly of low shrubs with fleshy glossy leaves (like the Cistineae and non-sulphurous greenery), covers the swarm of the Guadalquivir and the salt-marshes of the south-west coast. Every-where on moist sandy ground are to be seen tall thickets of Atrundo densa.

The Mediterranean province is that in which the vegetation agrees most closely with that of southern France and the lowlands

Its extraordinary lack of population differentiates Spain from every other country possessed of equal natural advantages and an historic civilization. Spain occupies an unsurpassed geographical position; its resources are rich, varied and to some extent unexploited; its inhabitants include the Basques and Catalans, noted for their commercial enterprise, and the Catalans, noted for their industry. Nevertheless this country, which appears, more than 2000 years ago, to have supported a population nearly twice as numerous as its present inhabitants and larger than that of the United Kingdom in 1901, is almost as thinly peopled as the most deserted province of Ireland (Connaught 94.5 inhabitants per sq. m.). The population of Spain falls from the native foundation, possibly from the earlier Visigothic invasion. The Moors decimated the native population; when they in turn were expelled, the country lost not only a numerically large section of its inhabitants, but an important base to develop its wealth. The Wars of the 16th, 17th and 18th centuries, and the vast potentialities of fortune which drew men to the Spanish colonies in America, caused a further serious drain upon the population.

The communications in Spain were only improved during the 19th century. In 1808 there were little more than 500 m. of carriage roads; in 1908 the aggregate length of the state, provincial and municipal roads was about 40,000 m. But there are 20,000 m. of railroad, and the country mining—is retarded by the want of good roads. In the mountainous districts, where there are only narrow paths, frequently rather steep, it is still not uncommon to meet long trains of pack-mules, which for strategic reasons the Spanish gauge was made different from that of France; and military considerations long postponed the construction of any railway across the Pyrenees. The roads which wind through the Pyrenees from Andorra, Navarre and the Aragon frontier, and through the channels of an important traffic, although great inconvenience was caused by the snow which blocks the passes in winter. In 1882 the French and Spanish governments proposed to overcome the difficulty by constructing two tunnels, one through the Pyrenees, Oloron, through the Canfranc Pass, and through an international tunnel which was to be built at Somport; the other from the Ariège railway system to the Spanish northwestern province of Lérida. The first line was completed on the Spanish side as far as Jaca, the second was only surveyed; both were opposed by the ministries of war in the two countries concerned. The matter was again under consideration of the governments when in 1896 the French minister for foreign affairs, and on the 18th of August 1904 a convention was signed providing for the construction of (1) the Jaca to Sort line, (2) a line from Ax les Thermes in the Ariège to Ripoll in Catalonia, and (3) a line from Sort to Sort, and thence to Lérida. The Spanish government agreed to finance the Lérida-Sort section by 1915, and the Noguera Pallaresa valley line by 1921. The line from Ripoll to Sort, in junction with the French railways would be effected through the Port de Salau. All three schemes were ratified in 1904 by the Cortes and the French Chambers. Seventy percent of the railways of Spain, and an even larger proportion of the tramways and narrow-gauge railways, especially in mining districts, have been constructed and worked by private enterprise. The foreign railways and tramways have been placed on the same footing as in other civilized countries. In 1907 the number of letters and post-cards carried in the inland lines was 133,201,000, in the international service 44,219,000. The length of state roads and other roads was 60,818 m. in 1923 to 85,757 m. in 1931. In 1907 there were 84 urban telephone systems and 71 inter-urban circuits.

**Railway—Agribusiness** is by far the most important Spanish industry. In general it is in a backward condition, and is now much less producive than in the time of the Romans and again under the Moors. The expansion of the latter people in many places is attributed to the adoption of various crops, introduced to this day. Aragon and Estremadura, the two most thinly peopled of all the old provinces, and the eastern half of Andalusia (above Seville) have all suffered a population in this manner, later occupiers never having been able to rival the Moors in respect of the density of nature, as in Aragon, or in taking advantage of its fertility, as in Andalusia and the Tierra de Barros. In some districts the implements used are still of the rudest description. The plough is merely a pointed stick shod with iron, crossed by another stick which serves as a share, scratching the ground to the depth of a few inches. But the regular importation of agricultural implements betokens an important improvement in the condition of agriculture since the introduction of railways, and in every province there is a royal commissioner of supervising and encouraging this branch of industry. Among other agricultural improvements is the introduction of agriculture to the royal school at Aranjuez, to which is attached a model farm, is of special importance. Of the soil of Spain 79.6% is arable, consists of plains, level basins, and great terraces; well adapted for the cultivation of rice, potatoes, olive trees, cypress and pine gardens, 20-8 to fruit, 17-7 to grass, 3-7 to vineyards and 1-6 to olives. The land is subdivided among a very large number of proprietors; over 3,400,000 farms or estates were assessed for taxation in 1903. The agricultural provinces of Spain are divided into three: those of Valencia and Catalonia, in both of which the river valleys are thickly seamed with irrigation canals and the hill-slopes carefully terraced for cultivation. Neither province is soil naturally fertile, and nothing but the laborious industry of the farmers has converted the barren soil of the riverine districts of Valencia and of the new territories brought under cultivation, has converted them into two of the most productive regions in Spain. In the Basque Provinces and in Galicia the cultivable area is quite as fully utilized, but in these districts the difficulties are not so great. The least productive tracts, apart from Aragon and Estremadura, are situated in the south and east of New Castile, in Murcia, and in Lower Andalusia—the marshes or marismas of the lower Guadalquivir and the arenas gordas between the Atlantic and the Mediterranean. Here the cultivation is for cattle, at least in the case of certain crops. Almost all kinds of vegetables and garden-fruits, oranges, rice, hemp and other products are generally grown solely or mainly on irrigated land, whereas most kinds of grain, vines and olives are cultivated chiefly on dry soil. The water used for irrigation is sometimes derived from springs and rivers in mountain valleys, whence it is conveyed by long canals (acequios) along the mountain sides and sometimes by lofty aqueducts to the fields on which it is to be used. Sometimes the water of entire rivers or vast artificial reservoirs (pantanos) is used in feeding a dense network of canals (azudes) in the basins of Aragon and Navarre, where water from the Ebro, the Duero, the Navia, the Anisclo, and other rivers, in Valencia and Murcia are known by the Spanish name of huertas (gardens), in Andalusia by the Arabic name of tégas, which has the same meaning. Many of the old irrigation works—such as the Alhama Tunnel, the Guadalquivir Aqueduct, and many others from the Moorish period, while new ones are still being laid out at the present day. Where no running water is available for irrigation, water is often obtained from wells by means of waterwheels (noria) of simple construction. In most cases such wheels merely have earthenware pitchers attached to their circumference by means of wires of esparto, and are turned by a horse harnessed to a cowrie wheel. Where water is available to the rivers, many arsienian wells have been sunk for irrigation. In all, about 9% of the entire surface of Spain is artificially watered, but in 1900 the government adopted plans for the construction of new canals and irrigation works, especially in Granada, with a greatly increased area of arid or semi-arid land under irrigation. The irrigated portions of the Ebro and Tago valleys yield twelve times the yield and produce that of the same land in the south of Spain.
champion of horses and mules. Both of these grains are cultivated in all parts, but chiefly on the more level districts of the two Castiles of León and Leon, and on the plains of the Guadalquivir basin. Oats and rye are cultivated only in the higher parts of the country, and are sown mainly for feeding horses and mules, the latter as a breadstuff. Maize also is cultivated in all the provinces; nevertheless, it is limited in its sowing to the plains of the Guadalquivir and in the Atlantic provinces, and other products generally yield a more profitable return where irrigation is pursued. Rice is cultivated on a large scale only in the swampy lowlands of Valencia. Among cereal crops, there is a preference in the littoral districts of the Miliana, including both the common millet (Panicum miliaceum) and the so-called Indian millet (Sorghum vulgare, the jowai of India, the duraah of Africa), and even in (la Alpujarra). Castile, where the cultivation of rice is on the increase.

**Vegetables.**

The vegetables grown in Spain are of many kinds. As the climate is mild, and grass is never wanting, the country is covered with green throughout the year. The vegetables of the Mediterranean countries are grown in all the provinces, and the cultivation of those which are grown on the northern plains is also important. The vegetables grown on the higher plains are generally those which are not adapted to the southern climates. The vegetables grown on the higher plains are generally those which are not adapted to the southern climates. The vegetables grown on the higher plains are generally those which are not adapted to the southern climates. The vegetables grown on the higher plains are generally those which are not adapted to the southern climates.

**Fruits.**

The fruits which are grown in Spain are of many kinds. The principal ones are the orange, lemon, grape, and apricot. The orange is the most abundant fruit, and is grown in all the provinces of the Mediterranean countries. The lemon is also abundant, and is grown in all the provinces of the Mediterranean countries. The grape is grown in all the provinces of the Mediterranean countries, and is the most abundant fruit. The apricot is also abundant, and is grown in all the provinces of the Mediterranean countries.

**Livestock.**

The only animals belonging to Spain still noted for their excellence are mules and asses, which are recognized as among the best to be found anywhere. Goats are mostly bred in the mountainous districts, and the size of the herd is often more for the milk than for the meat. Sheep are also important, and are usually found in large numbers. Cattle, though not so abundant as in other parts of Europe, are of good quality, and are often kept for their hides, which are among the best in the world.
All except a small fraction of the copper ore is obtained from the province of Huelva, in which lie the well-known mines of Tharsis and Rio Tinto (q.v.). The lead ore is obtained chiefly in Murcia and Jaén. The silver mined in the province of Jaén is partly silver-bronze and partly from rock-salt, of which last there is an almost exclusively subcribed in Germany, France, Belgium, Switzerland, and the United States, just as, in the 19th century, the railways and mining industries had been mainly financed by British investors, and the Valencia silk industry by French. Another feature of Spanish industry is the recognition of the growing importance of combinations of producing companies designed to take advantage of the high tariff, and to restrict competition, lower expenses and increase the price of goods. The minor industries of salt, petroleum and metallurgical industries were subjected to this prande, but in no case was it possible to secure a complete monopoly.

Commerce.—Possessing varied resources and being favourably situated for commerce, Spain can be expected to maintain a leading place among the trading communities of Europe. This it did at one time, when the treasure acquired by the discovery of America and the conquest of Mexico and Peru was squandered away, and when Spain was confined to the monopoly of the silfer trade to the New World. Hundreds of thousands of Moors were driven out from the country on subsequent occasions, and in the act Spain lost the best of her agriculturists and handicraftsmen. The Spaniards of the day, inspired by the hope of rapidly acquired wealth and the love of adventure, embarked upon a career of discovery, and agriculture and manufacturing industry fell into contempt. The loss of all her possessions on the American mainland in the early part of the 19th century dealt a severe blow to the foreign commerce of Spain, from which it only recovered about 1850, when imports and exports began to increase. After the re- duction of the duties on British goods by the Bourbon Government, the Bourbon Government stopped the operation of the tariff law of the Revolution and reverted to protection. In 1882 a Liberal cabinet revived the system of a gradual reduction of import duties to a fixed maximum, and for a time Spain increased her exports to several other nations, which were followed by a treaty with Great Britain in 1886. The foreign commerce of Spain rapidly developed in the decade 1882–1932, Great Britain, France and the United States figuring at the head of the imports, Great Britain and France at the head of the exports. The exports of Spanish wines to France alone amounted to £12,000,000 annually. When France and other European nations abandoned free trade for protective duties, there was a strong movement set in in Spain in favour of protection. In 1890 the Conservative cabinet of Señor Canovas raised the duties on agricultural products, in 1891 it denounced all the treaties of commerce which included them, and in 1892 a new tariff law established considerably higher duties than those of 1882—in fact, duties ranging from 40% to 300%. The subsequent revision of the tariff, completed in 1906, involved no serious departure from the economic policy adopted in 1890.

The following table shows the value of Spanish imports and exports for a number of representative years after 1848:

The principal exports include metals and other minerals; wine, sugar, fruit and other alimentary substances, cattle and its manu- factures, wheat and flour, tobacco, hemp, flax, and other fibres, timber and wrought wood. The principal imports include grain, dried fish and other food-stuffs; livestock and animal products; machinery, vehicles and ships; stone, minerals, glass and pottery; drugs and chemical products; textiles and raw cotton. Great Britain, France, the United States, Germany and Portugal, named in the order of their importance, are the chief consumers of Spanish exports. The chief exporters to Spain (in the same order) are Great Britain, France, Cuba, Germany and Portugal. The foreign trade of the country is of course carried on mainly by sea, and of the land commerce by far the largest proportion is with former colonies, many of which seem to have been given fresh impetus. Many English and French steamers have been purchased abroad and nationalized. In 1905, the mercantile marine consisted of 449 steamships of 434,846 tons and 541 sailing vessels of 85,583 tons. The sailing vessels are decreasing in numbers in the exterior trade, but not in the coasting.
trade, which is decidedly developing and occupying more craft. It is carried on exclusively under the Spanish flag. The fishing fleets, which consist of about 600 ships, is also largely engaged in this commerce, and constitutes a hardy and active coast population. In 1905 19,722 ships of 16,953,267 tons entered, and 18,033 of 14,412,355 tons cleared.

Banking and Credit. — The Bank of Spain (Banco de Espana) has a capital stock of 45,000,000 pesetas, and a reserve of 60,000,000, and commenced operations in 1851. It has carried on the business of bank of issue, and at times, especially since 1885, when its foundation after the Restoration, and its privileged note issue has had to be gradually and very largely increased by legislative authorizations, especially in 1891 and 1898, as its relations with the Colonial and of the Bank of Mexico. It is in the services rendered by the bank to the public would ever have justified the growth of the note issue first to thirty millions sterling in 1885 and to sixty millions sterling in 1899 and 1900. At the close of the 19th century the remedied bank charter, which is only to expire in 1921, authorized a maximum issue of 100,000,000, on condition that the bank keeps cash against the note issue in silver and gold. The value of the notes in circulation reached 100,000,000, and equal to half the amount issued above that sum. Gold has practically disappeared from business of every kind since 1881, when the premium began to rise; it reached a maximum of 10% during the war with America. Afterwards it dropped to about 30 in 1900. Bank-notes and silver coin have been practically the currency for many years.

The government of weights and measures was officially adopted in Spain in 1859 and the decimal monetary system in 1871. In the case of the weights and measures the French names were also adopted, with only the necessary local modifications, and in older times remained in use, notably the quintal (101.4 lb avoirdupois), the libra (1-014 lb avoirdupois), the arroba (31 imperial gallons for wine, 21 imperial gallons for oil), the fanega (34 imperial bushels). In the case of the currency the Spanish names were retained, the peso being divided into 100 centimos. The peseta is divided into 100 centimos. According to its par value 25-25 pesetas are about equal to £1, but the value of the peseta fluctuates with that of the silver in circulation, especially after the introduction of the notes. The coinage of the peseta is also current. Before the introduction of the decimal monetary system the peseta was the fifth part of a peso duro, which was equal to 20 reales de vellor, or rather more than a 5 franc piece. The only paper currency was the notes of the Bank of Spain.

Finance. — Spanish finance passed through many vicissitudes during the 19th century. In the reigns of Ferdinand VII. and Isabella II. the creditors of the state had to suffer several suspensions of payments of their dues, and reductions both of capital and interest. During the Revolution, from 1868 to 1874, matters culminated in bankruptcy. Payments of interest were only in part resumed after the Revolution. The measures of King Alphonso XII. proposed arrangements to consolidate the floating and treasury debts of the Peninsula in the shape of $70,000,000 of 4% stock, redeemable in 40 years, and to reduce and consolidate the debt in the form of stock redeemable in 50 years, the stock being of the form of $78,840,000 of exterior 4% debt—except from taxation under an agreement to that effect with the council of foreign bond-holders—lease, and perpetual interior 4%. The colonial debts were not included in those plans. The debts of Spain were further increased in 1891 by a consolidation of $10,000,000 of floating debt turned into 4% towards the beginning of this period, pursues towards the end.

The floating debt of Spain has grown considerably, being about $50,000,000 in 1890.

Constitution and Government. — Spain is an hereditary monarchy, which was established by the Cortes and became the fundamental law of the 30th of June 1876. This law fixes the order of succession as follows: should no legitimate descendant of Alphonso XII. survive, the succession devolves first upon his sisters, next upon his aunt and her legitimate descendants, and finally upon the legitimate descendants of the brothers of Ferdinand VII. “unless they have been excluded.” Should all lines become extinct, the nation may elect its monarch.

The sovereign becomes of age on completing his or her sixteenth year. He is inviolable, but his ministers are responsible to the Cortes, and none of his decrees is valid unless countersigned by a minister. The sovereign is grand-master of the eight Spanish orders of knighthood, the principal of which is that of the Golden Fleece (Toison de Oro), founded in 1431 by Philip of Burgundy. The chain of this order surrounds the royal arms, in which are included, besides the arms of Castile, Leon, Granada, and the lilies of the royal house of Bourbon, the arms of Austria, Sicily, Savoy, Brabant and others. The national colours are red and yellow. The flag is divided into three horizontal stripes, two red stripes with a yellow one between, bearing the royal arms.

The legislative authority is exercised by the sovereign in conjunction with the Cortes, a body composed of two houses—a senate and a chamber of deputies. The senate is composed of members of three classes: (1) members by right of birth or office—princes, nobles who possess an annual income of 60,000 pesetas ($2,400), and hold the rank of grande (grandee), a dignity conferred by the king either for life or as an hereditary honour, captains-general of the army, admirals of the navy, the patriarchs of the Indies, archbishops, cardinals, the presidents of the council of state or of the Supreme Court, and other high officials, all of whom must have retained their appointments for two years; (2) members nominated by the sovereign for life; and (3) members elected three by each of the 49 provinces of the kingdom, and the remainder by academies, universities, dioceses and state corporations. The members belonging to the first two classes must not exceed 180 in number, and there may be the same number of members of the third class. The senatorial electors in the provinces are (1) delegates of the communes and (2) all the members of the provincial council, presided over by the governor. The lower house of the Cortes was elected by a very limited franchise from 1877 to 1890, when the Cortes passed a reform bill which became law on the 29th of June 1890. This law re-established universal male suffrage, which had existed during the Revolution, from 1869 to 1872.

Under the law of the 29th of June 1890 every Spaniard who is not debarred from his civil and civic rights by any legal incapacity, and has resided consecutively two years in his parish, becomes an elector on completing his twenty-fifth year. Soldiers and sailors in active service cannot vote. All Spaniards aged 25 who are not clerks in holy orders can be elected.

The same electoral law was extended to the municipal elections.

The executive administration is entrusted to a responsible minister, in which the president generally holds no portfolio, being usually the chairman of the council of state, the chief of the departments. The ministerial departments are: Foreign affairs, finance, justice, science, interior, war, education and fine arts, marine, public works, and agriculture and commerce. Under the secretary of state for the interior the civil administration in each province is headed by a governor, who represents the central power in the provincial council (diputacion provincial) which is also elected by universal suffrage. The provincial councils meet yearly, and are permanently
represented by a committee (comisión provincial), which is elected annually to safeguard their interests. Every commune or ‘freguesia’ has an elected conselho (q.v.), which has complete control over municipal administration, and is empowered to levy and collect taxes. Its members are styled regidores or concejales, and half their number is elected every two years. They appoint an alcalde or mayor from among themselves to act as president, chief executive officer, and justice of the peace.

In the larger towns the alcalde shares his reponsibilities with several permanent officials called tenientes alcaides. The fundamental law of 1876 secures to ayuntamientos, and to the provincial councils, an autonomy which is complete within its limits. Neither the executive nor the Cortes may interfere with the local administration, but when the local authorities exceed their legal power to the detriment of public interests, this provision of the constitution has not always been strictly observed by the government.

Law and Justice.—Spanish law is founded on Roman law, Gothic common law, and the national code proclaimed at the meeting of San Cortes at Toro in 1501 (the Leyes de Toro).

The present civil code is the 1st of May 1889, for the whole kingdom. The penal code dates from 1870, and was modified in 1887. The commercial code was put into force on the 22nd of May 1889, and became complete with the internal code of criminal procedure on the 22nd of June 1882.

There is a court of first instance in each of the 495 partidos judiciales, or legal districts, into which the kingdom is divided. From this inferior court proceed the audiencias criminales, or courts of appeal. There is in Madrid a Supreme Court, which is modelled upon the French Cour de Cassation, to rule on points of law when appeals are made from the decisions of inferior courts, or when the civil jurisdiction is called in question. When a party acts under the law of the 20th of April 1888 established trial by jury for most crimes and delicts, 49 audiencias criminales, one in each province, was created. Each of these courts is composed of three judges. The administration of justice is public. The parties to a suit may be represented by counsel. The state is always represented in every court by abogados fiscales, public prosecutors, and counsel who are homologados.

Religion.—Roman Catholicism is the established religion, and the Church and clergy are maintained by the state at an annual cost of about £1,600,000. The relations between Church and state, and the position of the religious orders, were defined by the concordat of 1851, remaining practically unchanged until 1910. There are ten archbishoprics (Toledo, Madrid, Burgos, Granada, Santiago, Saragossa, Seville, Tarragona, Valencia and Valladolid) and forty-five bishoprics. The archbishop of Toledo is the primate of the number.

Monastic communities is about 3,250, including some 600 convents for men and 2,650 for women. Most of the religious orders carry on charitable and educational work. The monthly income of the monks is about 10,000, the nuns 4,000. The immense majority of the people are professed adherents of the Roman Catholic faith, so that, so far as numbers go, Spain is still the most 'Catholic' country in the world. The liberty of conscience and the freedom of the press were granted during the Revolution, from 1868 to 1877, the Church lost ground, and anti-clerical ideas prevailed for a while in the centres of republicanism in Catalonia and Andalucia; but a reaction set in with the Restoration. The government of the Restoration showed the Church much favour, allowed the Jesuits and religious orders of both sexes to spread to an extent without precedent in the century, and to take hold of the education of more than half of the youth of both sexes in all classes of society. This revival of Church and monastic influence began during the reign of Alphonse XII, 1877—1888, and considerably increased afterwards under the regency of Queen Christina, during the long minority of Alphonso XIII, the godson of Pope Leo XIII. Spanish codes still contain severe penalties for delicts against the state religion, as writers frequently discover when they give offence to the ecclesiastical authorities. Blasphemy is punished by imprisonment. The bishops sit in the upper council of education, and exercise much influence on public instruction. Since 1899 all boys have been obliged to attend lectures on moral instruction during six out of seven years of their curriculum to obtain the B.A. degree. Canon law and Church doctrine form an obligatory part of the studies of men qualifying for the bar and magistracy. By the constitution of 1876 non-Catholics were permitted to hold their lives in the republic, and the state guarantees to them the same rights as did their relatives in private, without any public demonstration or announcement of their services. The same rule applies to their schools, which are, however, numerously attended, in Madrid, Seville, Barcelona, and many of the provincial capitals; and of many of the Roman Catholics also. A proposition to abolish these restrictions was made by the government in 1910 (see History, below).

Education.—A law of the 17th of July 1857 made primary education free for the poor, and compulsory on all children of school age, originally fixed at six to nine years. It proved impossible to enforce this statute, and the majority of Spanish children are still illiterate, though in decreasing proportion at each census. The primary schools for both sexes are kept up by the municipalities, at an annual cost of 2,000,000l. The national government contributes a small subvention. The secondary schools, of which there are many, are run by provincial councils, are styled institutes and are mostly self-supporting, the fees paid by the pupils usually cover the expenses of such establishments, which also receive a certain amount of state aid. There are 6,000 endowed grammar schools in the hands of religious orders or corporations of education and an advisory council. A law passed on the 1st of July 1902 requires that all private schools must be authorized by the state, and arranges for their periodical inspection, for the enforcement of proper sanitation and discipline, and for the appointment of a suitable staff of teachers. Among the institutions affected by this law are numerous Jesuit and other ecclesiastical schools for boys, and a Jesuit university at Deusto, near Bilbao, whose pupils have to pass their final secondary examinations and to take all degrees in the state establishments as free scholars. The education of girls has been much developed not only in the state schools but even in the educational institutes of the Church, especially those of the upper and middle classes. Many girls attend the provincial institutes, and some have successfully gone in for the B.A. degrees of the secular universities.

Defence.—The Spanish army is recruited by conscription. Liability to service begins with the first day of the calendar year in which the twentieth year is completed. Except in extraordinary circumstances, the war ministers have seldom called for more than forty to sixty thousand men annually, and of this contingent all who can afford to do so buy themselves off from service at home by payment of £60, and if drafted for colonial service by payment of £80. The period of service for all arms is twelve years—three with the colours, then the first-class reserve, six in the second-class reserve, which contains the supernumerary and reserve officers and men, and is liable to one month's training in every year. The war ministers can, and frequently do, send on unlimited furlough, or place in the first-class reserve, men who have not completed their first three years, and thus a considerable saving is made. Brothers can take each other's place in the service, and eldest sons of aged parents, or sons of widows, easily get exempted. Spain is divided into seven military regions or army corps. The strength of the regular army for many years varied between 95,000 and 100,000 in time of peace, and during the Carlist wars, 1859-1870, it increased to nearly 140,000. The six infantry regiments of mountain guns, and nearly 350,000 during her more recent wars. For 1890-1900 the figures were only 80,000. The active army is divided into 56 regiments of the line with 2 battalions each, 20 battalions of rifles or cazadores, 2 Baleric Islands, 1 Melilla, 4 African battalions of light infantry, 2 battalions of rifles in the Canaries. The cavalry includes a squadron of royal horse guards, 28 regiments of the line, remount and dépôt establishments, 4 regional squadrons in Majorca, the Canaries, Ceuta, Melilla. The artillery comprises 12 regiments of field artillery, 10 horse artillery, 3 regiments and an independent division of mountain guns, and 2 regiments of garrison artillery. The royal engineers are 4 regiments of sappers and miners, 1 of pontoniers, 1 battalion of telegraph engineers, 1 of railway engineers with cyclists, 1 balloon corps, and 4 colonial corps. Other permanent military forces are 197 officers, 1,640 mounted and 16,556 foot gendarmes, mostly old soldiers, and 14,156 carabineers, all of them old soldiers. The regular army, at the close of the wars in 1868, had 26,000 officers and about 400 generals, but a law was afterwards made to reduce their numbers by filling only one out of two death vacancies, with a view to reach a peace establishment of 2 marshals, 25 lieutenant-generals, 50 divisional- and 140 brigadier-generals, and 15,000 officers. The total strength of the field army may be estimated at 220,000 combatants. The military academies are Toledo for infantry, Segovia for artillery, Valladolid for cavalry, Ávila for commissariat, Escorial for carabineers, Getafe.
for civil guards, besides a staff college styled Escuela Superior de Guerra at Madrid. Numerous fortresses guard the Portuguese frontier and the passes of the Pyrenees, but many of these are ill-armed and obsolete.

The navy is recruited by conscription in the coast or maritime districts, which are divided into three naval captaincies-general, those of Ferrol, Cadiz and Cartagena—at the head of which are vessels armed with 24 or 32-pounders, 2 armoured cruisers, 5 protected cruisers, 5 destroyers and 6 torpedo-boats. All the larger vessels were old and of little value.

The chief authorities on flora and fauna are M. Willkom, Ilustraciones flores hispanicas insularumque Balearum (2 vols., Stuttgart, 1881-1892); M. Colmeiro, Comunicación de las plantas españolas (Madrid, 1885); G. de la Puerta, Botánica descriptiva, &c. (Madrid, 1891); B. Merino, Contribución a la flora de Galicia (Tuy, 1897); A. Chapman and W. J. B. Buck, Wild Spain (London, 1899), and the subsequent volumes (London, 1902). Modern social and political conditions are described by G. Rouxier, L’Espagne en Espagne (Paris, 1897); E. Pardo Bazán, La España de ayer y la de hoy (Madrid, 1899); L’Espagne: politique, littérature, arme, &c., numéro spécial de la Nouvelle Revue Internationale (Paris, 1900); J. R. Lowell, Impressions of Spain (London, 1900, written 1877-1880 when Lowell was American minister to the court of Spain); F. Gotor de Baraja, Nuestras costumbres (Madrid, 1900); R. de Uzeta, Croca, Psicología del pueblo español (Madrid, 1902); V. Amiral, El Catalánismo (Barcelona, 1902); J. Alonda y Mira, Relaciones de solemnidades y fiestas públicas de España (Madrid, 1900), and other works. The following periodicals may be noted: Hist. e Inf. del Alava, &c.; V. Gay, Constitución y vida del pueblo español (Madrid, 1905, &c.); H. Havelock Ellis, The Soul of Spain (London, 1908).

A comprehensive account of such matters as population, industry, commerce and shipping, work and workmen, trade and commerce, telegraphs, railways, education, constitution, law and justice, public health, &c., may be found in the following works; all those of which the place and date of issue are specified are published annually in the Boletín del Instituto Geográfico de España (Madrid, 1890-1905; Movimiento de la población de España; British Foreign Office Reports (annual series and miscellaneous series, London); Estadisticas de las obras públicas y de las obras de ultramar y potencias extranjeras, formed by the dirección general de Aduanas; Annual Reports of the Council of the Corporation of Foreign Bondholders (London); Estadística mineral de España; Memorias y documentos del Ministerio de la Guerra (2 vols., Madrid, 1903); Estadística de la administración de justicia en el criminal durante; Boletín mensual de estadística demográfica-sanitaria de la península y islas adyacentes (Madrid, monthly); Estadato general y armada para el C. Fernandez Duero, Armada desde la unión de los reinos de Castilla y de Leon (9 vols., Madrid, 1895-1903); Boletín oficial del ministerio de marina. (K. G. J.)

HISTORY

A.—Ancient to A. D. 606. Primitive Inhabitants.—The origin and character of the early inhabitants of the Peninsula are unknown; recent conjectures on the subject, which have been many, are more bold than probable, and we must await the result of further excavations of prehistoric sites and further inquiries into the native inscriptions before we can hope for much certainty. The Romans, whose acquaintance with the country began in the 3rd century B.C., mention three races: Iberians (in the east, north and south), Celts (north-west) and Celtiberians (centre), but the classification does not help us far. The usage of the strange and ancient Basque tongue on the western slopes of the Pyrenees and in Vizcaya (Biscay)—a tongue which is utterly unlike in Vezic or Italian or any "Indo-Germanic" language—suggests that the Iberians may have been an older people than the Celts and alien from them in race, though the attempts hitherto made to connect Basque with ancient traces of strange tongues in the Basque lands have not yielded clear results. On the other hand, numerous place-names show that parts of the Peninsula were once held by Celtic-speaking peoples, and it is, of course, possible that the Celts and Iberians had long before the Christian era formed a mixed race in certain regions. Of other ancient races little trace can be detected. The Phoenicians were here traders and not settlers; the Greeks, though they planted early colonies on the Gulf of Lyons, occupied hardly any site south of the Pyrenees, and the seeming likeness in name of Saguntum (q.v.) and the Greek island Zancithus is mere coincidence. It is possible, however, that after the Roman conquest italians drifted in, and it is fairly certain that after the Roman Empire fell German conquerors brought German settlers, though in what numbers no wise man will guess. The Phoenicians probably reached Spain long before our historical knowledge of the Peninsula begins, possibly as early as the 11th century B.C.

One of their earlier settlements, Gades (now Cadiz), has been called the oldest town in the world (or Europe) which has kept a continuity of life and name from its first origin. But the Phoenician exploitation of Spain dates principally from after the rise of Carthage (q.v.), the great Phoenician city of North Africa. Carthaginian "factories" were planted on many Spanish coasts; a Nova Carthago (New Carthage, mod. Cartagena) formed a Carthaginian fortress with the best harbour of south-eastern Spain. The expansion is attributed chiefly to the second half of the 3rd century B.C., and to the genius of the Carthaginian statesman, Hamilcar Barca, who, seeing his country deprived by Rome of her trading dominion in Sicily and Sardinia, used Spain, not only as a source of commercial wealth, but as an inexhaustible supply of warlike troops to serve in the Carthaginian armies. But Rome had already her eyes on the Spanish men and mines, and, in the second Punic War, drove Carthage finally and completely out of the Peninsula (201 B.C.).

Spain was divided Spain into two "spheres of administration" (provinciae), Hither or Citerior, that is the northern districts which were nearer to Italy, and Republican Further or Ulterior, the south. To each "province" a "period," Period 200-278 B.C. was sent yearly a governor, often with the title consul, the commands were full of military activity. The south, indeed, and in particular the fertile valley of Andalusia, the region of the Guadalquivir (Beatos), then called Baetica, was from the first fairly peaceful. Settlements of Italian veterans or of Spanish soldiers who had served for Rome were made at Hispalis (Seville) and at Carteia near
Gibraltar, and a beginning was made of a Romanized provincial population, though in a somewhat half-hearted way. But in the north, on the high plateau and amidst the hills, there was incessant fighting throughout the greater part of the 2nd century B.C., and indeed in some quarters right down to the establishment of the empire. The Carthaginians had extended their influence no great distance from the eastern coast and their Roman successors had all the work to do. In the long struggle many Roman armies were defeated, many commanders disgraced, many Spanish leaders won undying fame as patriot chiefs (see NUMANTIA). Even when one Roman succeeded, the incapacity or the perfidy of his successor too often lost the fruits of success. But though its instruments were weak the Republic was still strong, and the struggle itself, a struggle quite as much for a peaceful hinterland as for aggrandizement and annexation of fresh land, could not be given up without risk to the lands already won. So the war went on to its inevitable issue. Numantia, the centre of the fiercest resistance, fell in 133 B.C. before the science of Scipio Aemilianus (see SCIPIO), and even northern Spain began to accept Roman rule and Roman civilization. When in the decade 80-70 B.C. the Roman Sertorius (q.v.) attempted to make head in Spain against his political enemies in Rome, the Spaniards who supported him were already half Romanized. There remained only some small districts of very remote parts of the northern hills and on the western coast. Some of these were cleared out by Julius Caesar, governor here in 61 B.C., who is said also to have made his way, by his lieutenant Crassus, to the tin mines of the north-west in Galicia. Others, especially the hill tribes of the Basque and Asturian mountains facing the north coast, were still unquiet under Augustus, and we find a large Roman garrison maintained throughout the empire at Leon (Legio) to overawe these tribes. But behind all this long fighting, pacification and culture had spread steadily. The republican administration of Spain was wise. The Spanish subjects were allowed to retain their gods, their own languages, their own customs, their own institutions. So far as the Roman culture could be accepted by Rome, and, though the mineral wealth doubtless fell into the hands of Roman capitalists, the natives were free from the tithes and tithe system which caused such misery and revolt in the provincial territory of Sicily. On the other hand, every facility was given them to Romanize themselves; there was no competing influence of Hellenic or Punic culture and the uncivilized Spaniards accepted Roman ways gladly. By the days of Cicero and Caesar (70-44 B.C.) the southern districts, at least, had become practically Roman: their speech, their literature, their gods were wholly Latin. Indeed, as Cicero and Strabo and other writers of these and the next few years unanimously testify, Galicia, once Phoenician, gained, by Caesar's favour and the intercession of Balbus, a Roman municipal charter as municipium: that is, its citizens were regarded as sufficiently Romanized to be granted both the Roman personal franchise and the Roman city-rights. It was the first city outside of Italy which obtained such a municipal charter, without the usual implantation of Roman citizens (either poor men needing land or discharged veteran soldiers) from Italy. Tiberius (or Tiberius possibly) reorganized the administration of Roman Spain. Henceforward there were three provincial vicinates: (a) the north and north-west, the central table-land and the east coast as far south as New Carthage, that is, all the thinly-populated and unquiet hill country, formed the province of Tarraconensis with a capital at Tarraco (Tarragona) under a legatus Augusti pro praetore with a legion (VII. Gemina) at Leon and some other troops at his disposal; (b) the fertile and peaceful west formed the province of Lusitania, very roughly the modern Portugal, also under a legatus Augusti pro praetore, but with very few troops; (c) the fertile and peaceful south formed the province of Baetica, called after its chief river, the Baetis, under a proconsul nominated by the senate, with no troops. These divisions (it will be observed) exactly coincide with the geographical features of the Peninsula. Substantially, they remained till the end of the empire, though Tarraconensis was broken up at different dates into smaller and more manageable areas. Augustus also accelerated the Romanization of the land by planting in it many municipalities (coloniae) of discharged soldiers, such as for example Augura Emerita (modern Mérida), which declares by its name its connexion with time-expired veteran's night in that province. Augustus, and later, the procurators were appointed to control the revenues and also to look after the mines, which now became imperial property, while a special proconsul administered the Balearic Islands. The two principal features of the whole country during the imperial period are its great prosperity and its contributions to Roman literature. Shut off from foreign enemies (though occasionally vexed by pirates from Africa), secluded from the wars of the empire, it developed its natural resources to an extent unequalled before or since. Its iron and copper and silver and lead were well-known; it was also (according to the elder Pliny) the chief source whence the Roman world obtained its tin and quite outdistanced in this period the more famous mines of Cornwall. But such commercial prosperity characterized many districts of the empire during the first two centuries of our era. Spain can boast that she supplied Rome with almost her whole literature in the silver age. The Augustan writers had been Italians. When they passed away there arose in their places such writers as the Ciceronian, the epic poet Lucan, the epigrammatist Martial, the literary critic Quintilian, besides a host of lesser men. But the impulse of the opening empire died away and successful commerce drove out literary interests. With the 2nd century the great Roman-Spanish literature ceased: it was left to other regions which felt later than Spain the stimulus of Romanization to enter into the literary tradition. Of statesmen the Peninsula was less prolific. The emperor Trajan, indeed, and his relative and successor Hadrian, were born in Spain, but they were both of Roman stock and Roman training. The 1st century also saw a decline in the prosperity of Roman Spain. The confiscation of Septimius Severus and the ravages of barbarians in the middle of the 3rd century have both been added as causes for such a decline. But while we need not doubt that the decline occurred, we can hardly determine either its date or its intensity without careful examination of the Roman remains of Spain. Many of the best Roman ruins—such as the aqueduct of Segovia or the bridge of Alcantara—no doubt date from before A.D. 200. Others are probably later, and indicate that prosperity continued here, as it did on the other side of the Pyrenees in Gaul, till the later days of the empire—perhaps even till the fatal winter's night in 406-7 when the barbarians burst the Rhine frontier and flooded Gaul and even Spain with a deluge from which there was no recovery. (F. J. H.)

B.—From A.D. 406 to the Mahommedan Conquest. The Barbarian Invasion and the Visigothic Kingdom.—With the irruption of the Vandals, the Suebi and the Alans, the history of Spain enters on a long period of division and confusion which did not end even with the union of the chief kingdoms in the marriage of Isabella and Ferdinand at the close of the 15th century. The Function of the barbarian annexations was to cut the communications of commerce, and the nerves of the imperial administration, thereby throwing the invaded country back into a fragmentary condition from which a new order was to arise in the course of centuries. This function was effectively discharged in Spain by the Vandals and their associates, who plundered far and wide, and then by the Visigoths, who appeared as the "foederati," or duly commissioned defenders of the Romans. The first-comers cannot be said to have conquered the country in the sense that they established a rule of their own. They were not numerous enough for the execution of such a task, even if they had possessed the capacity. When in 428 Gaiseric, king of the Vandals (q.v.), accepted the invitation of Boniface, the count of Africa, and passed out

The Empire, (27 B.C.-A.D. 406.)
of Spain to found the Vandal kingdom of Carthage, his whole horde numbered only 80,000 persons, including old men, women and children, and runaway slaves who had joined him. The Suebi, who remained, were certainly not more numerous. Such small bodies could not have occupied so extensive a territory, even if they had scattered themselves in driblets all over its surface. What they did was to rove about in hordes, plundering or levying blackmail. The irredentist inhabitants had been trained to such an habit of acting for themselves by the imperial despotism, and could only flee or submit. There is probably some truth in the assertion of Salvian that many of the subjects of the empire preferred poverty among the barbarians to the tyranny of the imperial tax collectors. This would be pre-eminently the case with the smaller landowners who formed the "curiales," and who were in reality serfs of the fisc, for on them fell the main weight of taxation, and they were confined to their position by oppressive laws. The great landowners who formed the "ordo senatorius" had almost as much to fear from the agrarian revolt as from the barbarian; they were indeed acting with the Suebi, as from the barbarians. In time some of them took to "living barbarously"—that is to say, they fortified their villas, collected an armed following and sought for their lives, families and property. In some districts the inhabitants reverted to a state of tribal independence. This undoubtedly was the case in the north, where the Asturians and Basques, the least Romanized part of the population, appear from the beginning of the age of barbarization as acting for themselves. In the mountain country of Cuenca, Albacete, and the Sierra Nevada the Visigoths were nominally Romanized, but they were independent in the middle of the 6th century. But if there lay in this revival of energy and character the germ of a vigorous national life, for the time being Spain was thrown back into the state of division from which it had been drawn by the Romans—with the vital difference that the race now possessed the tradition of the Roman law, the municipalities, and one great common organization in the Christian Church.

No help was to be expected from the empire. Unable to aid itself it had recourse to the Visigoths (see Goms). Ataulfus (q.v.), the successor of Alaric, and the husband of Basilia, daughter of the emperor Theodosius, whom he married against the wish of her brother Honorius, entered Spain in 412, as the ally of the empire. He was murdered in 415, but after the speedily ensuing murder of his murderer and successor Sigeric, Wallia (415-419), who was elected to the kingdom, continued his work. He destroyed the Alans, and drove the Vandals and Suebi into the north-west. Then he handed Spain back to the imperial officials, that is to say, to weakness and corruption, and marched with all his people into the Second Aquitaine, the south-west of modern France, which had been assigned to them by Honorius as a home and a reward. From this date till the very end of the reign of Amauricius (511-531), the seat of the Visigothic kings was at Bordeaux, or Toulouse or Narbonne, and their main interests were in Gaul. They continued to intervene in Spain and to extend their influence over it. But for an interval of more than twenty-five years they stood apart. Southern Spain was overrun and plundered by the Vandals before their departure for Africa. In 456 Theodoric II. (453-466) entered Spain as ally of Avitus, whom he had himself raised to the empire in Gaul. He defeated the Roman senators of the Tarraconensis and the Suebi, putting their king to death, and advanced as far as Tarragona, but he was recalled to Gaul, and his return was accompanied by outrages against the Roman cities. Majorian (457-461), the last capable emperor of the West, proposed to make Spain the basis of his attack on the Vandals at Carthage till his fleet was destroyed by them in the harbour of Carthage. The fratricidal murderer and successor of Theodoric, Euricius (466-485) followed his brother's policy in Spain. With the extinction of the Western Empire (476 or 479) the kings of the Visigoths became more and more the representatives of authority, which they exercised on Roman lines, and with an implied or formal deference to the distant emperor at Constantinople. But the continued existence of the obscure Suevic kingdom in the north-west, the effective independence of several districts, and the rule of others by the Roman senators, proves that the regions actually under Visigothic rule were not extensive. After the defeat and death of Alaric II. (485-527) at Vouillé the shattered Visigothic power was preserved from destruction at the hands of the Frankish king Clovis (q.e.v.) by Theodoric, the Gothic king of Italy. But on his death the pressure of the Franks began again. Amauricius (507-537) fled from Narbonne, to meet the usual violent end of a Visigothic king at Barcelona.

The line of the Visigothic kings of Spain begins, strictly speaking, with his successor Theudis (531-548), an Ostrogoth appointed by Theodoric to act as guardian of Amauricius. He was the last Visigothic king of Spain for he had acquired great possessions in the valley of the Ebro by marriage with a Roman lady. It was a Roman crown, government, and not a people, which was established in Spain with Theudis. The Visigoths had been much Romanized during their establishment in Gaul, and we hear of no exodus as having accompanied Amauricius. The example of Theudis is enough to show that the law of the Theodosian code which forbade the marriage of Romans and barbarians was not regarded by the Goths. It remained indeed unaltered, as many laws have done since, long after it had become a mere dead letter. The government which came with Theudis, and fell to ruin with Roderic, may be described as having been at once Roman and bad. In so far as it was affected by the Visigoths it was influenced for the worse. Their monarchy was elective. Until the death of Amauricius the choice was confined to one family, but he gave it to the Frankish kings. Theudis and his son Theudis II. were both pious, and the nobles, Visigothic seniores, and Roman seniores seized every opportunity to keep it elective. Spain presented a forecast of the anarchy of Poland. Of the twenty-three kings between Theudis and Roderic five were certainly murdered, one was deposed, and three were tussured by tricks or open force. Of the others some were passing phantoms, and the records of the later times of the kingdom are so obscure that we cannot be sure of knowing the names of all who perished by violence.

The administration which these kings of unstable authority had to direct was essentially the Roman system. The great owners, whether nominally Visigothic or nominal Romans, retained their juridical rights. The seniores or senatores—continued to enjoy all the privileges and exemptions of the "ordo senatorius" in the last days of the empire. They lived surrounded by multitudes of semi-servile coloni, or farmers, bound to the soil, of actual slaves, and of bucellarii, who were free swordsmen to whom they gave rations (buccellatum, soldiers' bread, or buccella, a portion). The curiales remained as before the victims of the fisc. How far the fact that Theudis and the four next sovereigns were Arians affected their government is not very clear. It prevented them from enjoying the active support of the Christian clergy. But it is not doubtful whether Christianity had spread much beyond the cities. We hear of the conversion of pagans down to the last days of the Visigothic kingdom. The spread of Mahomedanism was so rapid in the first years after the conquest that it is impossible to believe that the country had been thoroughly christianized.

Theudis, who made his headquarters at Seville, endeavoured to complete his mastery of the diocese of Spain by occupying Mauritanian Tingitana, but he was defeated by the imperial officers at Creta. He was in due course murdered at Seville by Theudigisil (548-549) who was himself promptly slain. The reigns of his two successors, Agila (549-554) and Athanagild (554-567), coincided with the reign of Justinian and the temporary revival of the Eastern Empire. Athanagild called on the imperial officers to help him against Agila, and paid for their assistance by the surrender of the province of Baetica. On his death there was an obscure interregnum of five months, which ended by the election of Liuvia (567-572), the governor of Narbonne, the surviving remnant of the Visigothic power to the north of the Pyrenees. Liuvia did not come to Spain, but associated his brother Leovigil (567-586) with him. The reigns of Leovigil and of his son Recared are the greatest in the list of the Visigoth kingdom in its Visigothic occupation. A son of Theudis, Honorius (412), was the ally of the empire in Gaul.
Spain. The father was manifestly a man of great energy, who owed his unruly nobles by murder, forced the Orosipedian to recognize his superiority, swept away the Suevic kingdom which had lingered in the north-west, and checked the raids of the Basques. To secure the succession in his family he associated his sons Hermenegild and Recared with himself. He was the first Visigothic king who wore the crown, and it would appear that he threw off all pretence of allegiance to the empire. The series of the Visigothic gold coins begins with him, and it is to be noted that while the earliest are struck in the name of the emperor Justinian, the Imperial superscription disappears in the later. Leovigild drove the imperial officers from Seville and Cordova, threatened the life of his son, and occupied the coast. His son Hermenegild, to whom he entrusted the government of Baetica, was married to a Frankish princess. Intermarriages had not been uncommon between Frank and Visigoth, but they had rarely led to any other result than to subject the Arian ladies who were sent from Spain, or the Catholic ladies who came from France, to blows and murder by their husbands and their husbands' families. Ingunda, the Frankish wife of Hermenegild, with the help of Leandro, archbishop of Seville, the brother and predecessor of the more famous Isidore (q. v.), persuaded her husband to renounce Arianism. He revolted against his father, was reduced to submission and executed in person.

The reign of Recared (586–601) is famous in Spanish history for the establishment of Catholicism as the religion of the state. Recared must have seen from the example of the Franks that the support of the Church was a great element of strength for the Crown. He made the change at the Third Council of Toledo. If Recared hoped to secure the perpetuation of his dynasty he was mistaken. His son Liuvic the second (601–603) was murdered by an Arian reaction headed by Wittier (603–610). The Catholics regained power by his overthrow, but they could not give stability to the state. A succession of obscure "priests" kings, who are but names, followed: Gunthemar (610–612), Sisebut (612–620), Recared II. (620–621), Swintella, associated with his son Recimmer (621–631), Sisnand (631–636), Chintilla (636–640), Tulga (640–641), Chindaswinth (641–652), Recceswinth (649–672). The growing weakness of the Merovinigians saved them from serious attack, though not from occasional invasion on the north. The prostration of the empire in the East by Avar and Persian invasions enabled them to drive the imperial officers from the coast towns. But the kingdom was growing internally weaker. The nobles were strong enough to prevent the monarchy from becoming hereditary. The Church seemed to exert great power, but it had itself become barbarized by contact with kings and nobles. Violent persecutions of heretics and of the numerous Jews brought in new elements of discord. Wamba (672–680) is credited with an attempt to reform the state, but he was tiansured while unconscious from illness or poison, and disappeared into a religious house. His successors are again but names, Eufic (680–687) and Egica (687–701). Witiza (697–710) has more substance. He was in aftertimes denounced as a monster of vice, whose sins accounted for the Mahomedan conquest. Contemporary speak of him with respect, and he appears to have been more of a man than the great kings. He longed to corrupt the gentry of the clergy and the persecution of the Jews, and who resisted the dictation of the pope. His reign ended in turmoil, and perhaps by murder. With Roderic, whose "tumultuous" election was the work of Witiza's enemies, the line of the Visigoth kings is considered to have ended.

The Visigoth kingdom presents an appearance of coherence which was very far from corresponding to the reality. At the head was the king, surrounded by his household of leudes, and aided by the palatines, great officers of state imitated from the imperial model. At the head of the provinces, eight in number, were dukes, and the cities were governed by counts. Both were, at least in theory, officers named by the king and removable by him. The king was advised by councils, made up by a combination of a senate of the great men, and of the ecclesiastical councils which had met under the Roman rule and that of the tolerant Arian kings. The formation of the council was not complete until the establishment of Catholicism as the state religion. But from the reign of Recared till the Arab invasion they met sixteen times in all, generally at Toledo in the church of Santa Leocadia. Purely ecclesiastical matters were first discussed by the clergy alone. Then the great men, Visigoth and Roman, joined with the clergy, and the affairs of the kingdom were debated. The Lege Visigothorum were elaborated in these councils (see GERMANIC LAW). But there was more show than reality in this parade of government by free discussion and by law.

The Mahomedan Conquest.—How utterly weak it was can be seen from the fact that the Visigoth kings could not even check the Arab invasion of 711. The danger from Africa had been patent for half a century. During the reign of Witiza the Moslem masters of northern Africa had pressed the town of Ceuta, the last remnant of the Byzantine possessions, very closely, and it had been relieved by supplies from Spain. Only the want of ships had prevented the Mahomedans from mastering the town, and crossing the straits, and now this deficiency was supplied by the Christians themselves. It seems to be certain that Julian, the imperial count or governor of Ceuta acting in concert with the family and faction of Witiza, who sought his help against Roderic, was successful in import the Berber Tariq (Tārin) across the straits. Tariq, the general of the caliph's governor in northern Africa, Mūsā b. Nosair, was invited as an ally by the conspirators, who hoped to make use of him and then send him back. He came with a small force, but with the certainty of finding allies, and on being joined by another detachment of Berbers marched inland. On the 10th of July 711 he met Roderic near the Lago de la Janda between Medina Sidonia and Vejer de la Frontera. He had perhaps already been joined by Spanish allies. It is at least certain that in the battle the enemies of Roderic passed over to the invader. The Visigoth king was routed and disappears from authentic history. There is some probability that he did not perish in the battle, but escaped to fall two years later, at Seguoyuela near Salamanca, in action with Merwan the son of Mūsā. A single blow delivered as much by Christian as by Moslem hands, sufficed to cut the bond which seemed to bind the kingdom together, and to scatter its fragments all over the soil of the Peninsula. Through these Arab conquests Tarik marched without a single check of importance. Before the end of 711 he had advanced as far north as Alcalá. Cordova fell to a detachment of his army. In 713 Mūsā joined his lieutenant, and the conquest of the south was completed. Mérida was the only town which offered an honourable resistance. During 713 and 714 the north was subdued to the foot of the mountains, and when Mūsā and Tarik were recalled to Damascus by the caliph the progress of the Moslems was not delayed. In 718 they crossed the Pyrenees, and continued their invasions of Gaul till they met the solid power of the Austrasian Franks at Poitiers 732 (see CHARLES MARTEL and CALIPHATE, b. §§ 6, 10). The rush of the Mahomedan flood sent terror all over Europe, but the little opposition it encountered, the Pyrenean country, and, the victory, though genuine, was more spurious than substantial. That the lieutenants of the caliph at Damascus should take the place of the Visigoth kings, their dukes and counts seemed to many no loss and to a still greater number a gain. The great landowners, to whom patriotism was unknown and whose religious faith was tepid, were as ready to pay tribute to the caliph as to render service to one of their own body who had become king by violence or intrigue. On the part of the Arabs, who, though a small minority of the invaders, were the ruling element, there was a marked absence of proselytizing zeal. They treated the occupation of Spain as a financial speculation more than as a war for the faith. The Arab, though he produced Mahomedanism, was the least fanatical of the followers of the Prophet; and was not only willing but desirous to leave to all men who would pay tribute the free exercise of their religion. He cynically avowed a greater liking for the poll tax
paid by the Christian than for his conversion. The Spanish Roman and the Visigoth, so-called, of that epoch of poorness of spirit, accustomed as he was to compound with one master after another, saw nothing dishonourable in making such an arrangement. That it was made was matter of record. In Murcia the duke whom the Arabs knew as Tadmir became a tributary prince, and his family retained the principality for generations. He no doubt contrived to induce the Arabs to recognize him as the owner of what had been public domain, and made an excellent bargain. The family of Witiza did obtain possession of an immense stretch of the land of the state in Andalusia on condition of paying tribute. One of them, by name Ardalast, was deprived of his holding at a later date on the ground that he held more land than could be safely left in the hands of a Christian. Every wise landowner made the law and the mahomedan princes of the cities followed their example. Nor was submission and payment of tribute all that they were prepared to give. Many professed themselves converts to Mahomedanism. In the north one great Visigoth family not only accepted Islam, but founded a dynasty, with its capital at Saragossa, which played a stirring part in the 8th and 9th centuries, the Beni-Casi, or Beni-Lope. To the mass of the population the conquest was, for the present, a pure gain. The Jews, escaped from brutal persecution, were the eager allies of the Arabs. As the conquerors swept away the Roman fiscal system, which the Visigoths had retained, and replaced it by a poll tax (which was not levied on old men, women, children, cripples or the very poor) and a land tax, the gain to the downtrodden serfs of the fisc was immense. They acquired personal freedom. Add to this that a slave who professed Islam could secure his freedom, at least from slavery to a Christian master, that Arianism had not been quite root out, that the country districts were still largely pagan, and it will not appear wonderful that within a generation Mahomedan Spain was full of renegades who formed in all probability a majority of its population and a most important social and political element. The Arabs at first were content to take a fifth of the land to constitute the public domain, or ibnaws, out of which fees held on military tenure were provided for the chiefs of the conquering army.

If this moderate policy had been or could have been steadily pursued, the invaders would in all probability have founded a lasting state. But it could not be pursued, since it required for its application a consistency, and a power to act on a definite political principle, of which the Mahomedan conquerors were absolutely destitute. Nor had Spain been conquered by a single race. The invaders were a coalition of Arabs, Syrians and Berbers. The Arab was incurably anarchical, and was a noble who had no personal pride except the tribal one. That their personal dignity must be asserted and recognized was the first article in the creed of those descendants of the heroes of the desert. They looked down on the Syrian, they thought the Berber a lout and a plebeian, they scorned the renegade, and called him a slave and son of a slave. They fought out the old tribal rivalries of Arabia on the banks of the Guadalquivir and on the Vega of Granada. They planted the Berber down on the bleak, ill-watered, and wind-swept central plateau. He revolted, and they strove to subdue him by the sword. He deserted his poor share of the conquered land, and in many cases returned to Africa. The conflict for the caliphate (g.r.) between Omayyad and Abbasid removed all shadow of control by the head of the Mahomedan world, and Spain was given up to mere anarchy. The treaties made with the Christians were soon violated, and it seemed as if Islam would destroy itself. From that fate it was preserved by the arrival in Spain of Abdurrahman (Abdarrahman b. Moawiya) the Omayyad (738), one of the few princes of his house who escaped massacre at the hands of the Abbasides. With the help of his clansmen among the Arabs, and to a large extent of the renegades who counted as his clients, by craft, by the sword, by keeping down the fanatical Berber element, and by forming a mercenary army of African negroes, and after thirty years of blood and battle, Abdurrahman founded the independent amirate, which in the 10th century became the caliphate of Cordova. It was an Oriental monarchy like another, strong when the amir was a strong man, weak when he was not, but exceptionally rich in able men. Its rulers had to fight the Arab nobles as much as the Christians, and the real basis of their power was their slave army of negroes, or of Christian slaves, largely Slavonians sold by their German captors to the Jew slave traders of Verdun, and by them brought to Spain. These janissaries at first gave them victory, and then destroyed them.

Such a kingdom as this needed only attack from a more solidly organized power to be shattered. The Christian enemies of the Mahomedans were for long weak and no less anarchical than themselves, but they were never altogether wanting, and they had, what the Arab and Berber had not, a tradition of law and a capacity for forming a recognized polity and a state. They are to be sought for along the line of the mountains of the north. In the centre were the Basques, dwelling on both sides of the Pyrenees, who kept against the Mahomedan the independence they had vindicated against the Visigoth. On the east of the Basques, along the line of the Pyrenees, were others of kindred blood, who also kept a rude freedom on the slopes and in the valleys of the mountains. The Arab passed through them, going and returning to and from Gaul, but he never fully conquered them. The names of their leaders Garcia Jeminez and Inigo Arista are altogether legendary. But here were the roots of the kingdom of Navarre, of Sobrarbe and Aragon. In the earliest times their most pressing foe was not the Arab or Berber so much as the Carolingian. It was at their hands that Charlemagne (g.v), while returning from his expedition to Saragossa, suffered that disaster to his rearguard at Roncesvalles which is more famous in poetry than important in history. With the aid of the Spanish Moslem Beni-Casi the Basques drove off the counts and wardens of the marches of the Carolingians. On the eastern extremity of the Pyrenees the Franks found no native free population. Here, mainly under the leadership of Louis the Pious, they formed theMarca Hispanica, where Frankish counts and wardens of the marches were posted to guard the ground. By the reign of Charles the Fat a principality had been founded, Wilfred the Hairy—the Comte Velless—so called because his countship was poor and covered with scrub wood, and not because the palms of his hands were covered with hair as the legend has it—became the founder of the counts of Barcelona.

The greatest destiny was preserved for the Christian remnant which stood out to the west of the Basques, in the mountains of Asturias. Pelayo, whom they chose for king, and his victory of Covadonga, are well nigh as legendary, and are quite as obscure as Garcia Jeminez and Inigo Arista. Yet it is certain that in this region were planted the seeds of the kingdom of Castile and Leon, the dominant power of the Spain of the future. The total silence of the contemporary chronicle, called by the name of Isidore of Beja, shows that in the south of Spain, where the writer lived, nothing was known of the resistance made in the north. The next Christian authorities belong to the latter part of the 9th century. It is therefore with the warning that the dates can only be given as probably correct that the three first Christian kings can be said to have reigned from 718 to 757. Pelayo (718-737), his brother Favila (737-739)—of whom we only know that he is said to have been killed by a bear while hunting—and Alphonso I, the Catholic (739-756) stand as little more than names. While the invasion of Gaul was still going on Manuza, the chief of the Berbers settled in north-western Spain, had revolted against the caliph’s lieutenants. In 740 came the great general revolt of the Berbers. In 750 plague, following on drought and famine, swept away thousands of conquered and conquerors alike. Amid the general desolation Alphonso I. duke of Cantabria and son-in-law of Pelayo, constituted the kingdom which the Arabs called Galicia. It answered closely to the old Roman province of the same name extending from the Bay of Biscay to the line of the Duero, from the ocean to the foot of the Pyrenees. Internally it was divided into two belts. Along the shores of the bay, and in the valleys of the mountains to the north and west it was inhabited;
but a great belt of desolation separated it from the regions in which the Moslem were fighting out their own quarrels. Alphonso swept all through that region, already more than half depopulated, slaying the lingering remnants of the Berbers, and carrying back the surviving Christians to the north. Behind that shield of waste the Christian kingdom developed; from the death of Alphonso I to the reign of Ramiro II (931-950) it was subject to no serious attack, though raids on the frontier never ceased. Norse pirates appeared on the coast in the 9th century, but made no permanent settlements. As the population grew, it pushed down to the plain of Leon and Castile. The advance was marked by the removals of the capital forward from Cangas de Oza to Oviedo, from Oviedo to Leon, and by the settlement of the adventurous Norsemen into the ancient Bardulia, which from their "peels," and towers of strength, gained the name of Castilla—the counties. Burgos became its centre. The Montaña (hill country) of Burgos, and in particular the district called the Alfoz of Lara, was the cradle of the heroes of the Castilian share in the reconquest—the Almoravids, and the judge of the people, Lain Calvo, the infantes of Lara, the bastard Mudarra, and Ruy Diaz of Bivar, in whose lives legend and history are mingled beyond disentanglement, and of whom some are pure figures of romance. By a process which was going on elsewhere in Europe the frontier settled down to a new equilibrium. The Norsemen in the east became the county of Barcelona, so the chiefs of Bardulia became the counts of Castile, then the count of Castile, the rival of the king at Leon, and in time the king of Castile, and head of Christian Spain.

There is much in the internal history of that kingdom which stands apart from the general development of western Europe, from which it was shut out. In all the long period from Pelayo to Ramiro II only one event occurred which had much tendency to bring the Christians of the north-west into close relations with their neighbours. This was the recovery, or, in strict ecclesiastical language, the "invention" of the body of St James the Apostle in the reign of Alphonso II. The shrine at Santiago in Galicia was accepted in an age when evidence and criticism were words of little meaning, and it attracted pilgrims, who brought trade. But, apart from this opening for foreign influence, the Christians were left to develop their order untouched by alien examples, and they developed from the Visigoth monarchy. The men who raised Pelayo on the shield believed themselves to be electing a successor to Roderic, and indeed they were. They arranged for a time to call themselves Goths, and to claim a Gothic descent, which had become for them very much what descent from the companions of the conqueror was to Englishmen of the 14th or 15th centuries and later—another name for nobility of blood. There was the same king possessing theoretically almost absolute power, both administrative and legislative; the same nobles who limited his effective power by rebellion, their constant effort to keep the crown elective, and his no less steady, and by the 10th century victorious, effort to make it hereditary; the same distinction between the few free, who are also the rich owners of land, and the many serfs who are partly free, but not as a rule allowed to dispose of their persons as they please. But the fact that every arm was needed for the raids on the frontier, and to provide settlers who should also be garrison for the regained lands, worked for freedom. The serf, who was also a soldier, revolted against bondage. The chief who had to "people" a new and exposed township had to tempt men by freedom and secure rights to follow his banner. The influences which by the 13th century had abolished serfdom in western Spain were all at work before the reign of Ramiro II. In spite of revolts and of fratricidal struggles a state was formed. To the east of it, the Navarrese, having rid themselves of the Carolingian counts and marchers, had made a kingdom in their mountains, and beyond them the little free territories of the central Pyrenees were advancing, in subordination to the Navarrese king at Pamplona. The Arab called them the Christians of Al Frank, and distinguished them from the Galicians.

The 10th century and the first years of the 11th saw a great set-back of the Christian revival. Dissensions among themselves coincided with an energetic rally of the Moslem power. From the foundation of the amirate by Abdur rahman I. (758-790) to the beginning of the reign of Abdurrahman III. (902-951) Mahomedan Spain had shared the usual fortunes of an Oriental monarchy. A strong amir, such as Abdurrahman I. or his grandson Hakam I. (796-822), could enforce obedience by arms, or by murder, but it was the rule of the most pugnacious and the hardest hitter. Even with him it was often only apparent. On the upper frontier, which is now Aragon, the "Visigoth" Beni-Casí ruled, doing homage and paying tribute intermittently, which Christian or nominally Christian fathers had been their followers before the conquest. The "Moors," so called, who afterwards filled the kingdom of Aragon were of native blood. Toledo, relying on the immense military strength of its position, was more often in rebellion than in subordination. The massacre which Hakam I. effected by a lavish use of fraud cowed it only for a time. Abdurrahman III. found it independent again when he came to the throne, and had to besiege it for two years before it yielded. The renegades grew in numbers, and in faith. Under the influence of orthodox Berber teachers the tribes who had hitherto been attached to the Islam or to the Almoravide, or to the Almohade form of the religion, turned to a winebiber much suspected of heterodoxy, to expel thousands from his capital. Part went to people the town of Fez, newly founded in the Morocco, by the Idrisites. Part wandered eastward to found a Mahomedan state in Crete. Under the stimulus of Berber fanaticism the toleration first shown to the Christians was turned to persecution. A counter fanaticism was aroused in them, and for years the "Martyrs of Cordoba" continued to force the often reluctant cadis to behead them, by blaspheming the Prophet. The relations of the amir to the Christian bishops were very much those of the Ottoman sultan to the Greek patriarch. There were Spaniards who, like the Greeks of the Phanar, were the servile instruments of their Moslem master. Under Abdurrahman II. (832-852), who spent his life listening to a favourite and highly accomplished Persian tenor and in the company of dancing girls, and under Mahomed I. (852-886), the niggardly Mondhir (866-888), whose time was short, and Abdallā (885-912), who was feeble, the amirate was torn to fragments.

From this state of anarchy the amirate was saved by Abdurrahman III. (912-961), the Akbar of his race. He came to the throne when a half century of war and murder had produced exhaustion. The country was swarming with brigands, and the communications were so dangerous that seven years had been known to pass during which no caravan travelled from Cordova to Saragossa. There was a disposition on all hands, save among the irreconcilable Christians of the Sierra de Ronda, to accept peace under a capable master. The Arabs were beaten down, and the renegades had gained most of what they fought for when the aristocracy was cowed. Abdurrahman III., an Oriental ruler of the great stamp, industrious, resolute, capable of justice, magnanimous, and a warrior without pretension to chivalry, was obliged to give all that his people wanted. The splendour of his reign is a commonplace. He restored order even in the Ronda, and then he took the field against the Christians. He obeyed the rule which has called upon all the intelligent governors of Spain to make sure of the African coast by occupying it. He saw the Christian princes of the north become his vassals and submit to his judgment in their quarrels. But within a period not so long as his own life his dynasty was extinct and his kingdom in fragments.
conflicts between Leon and Castile, rendered the only formidable Christian kingdom powerless. Even on Hakam's death the power of the caliphate was exercised for some thirty years with great vigour. In his old age, one of his wives Sobh (the Daybreak), a Basque, bore him the first son born in his harem. To this baby Hakam II. (976-1010) he left the government, which went to the sultana, and her trusted agent Ibn Abi 'Amir Mahommeh ben Abdallah—an Arab of noble descent, who in his early life was a scribe, and who rose by himself useful first to the ministers and to the favourite wife. By them he was promoted, and in time he brought their ruin. By her he was made hajib—lord chamberlain, prime minister, great domestic, alter ego, in short, of the puppet caliph—for Hishâm II. in all his long life was nothing else—and in due time he reduced the sultana to insignificance. The administration of Mahommeh ben Abdallah, who took the regency at eight, was a picaresque revolution, headed by Mahommed through God) and is generally known as Mansur (p.v.), is also counted among the glories of the caliphate of Cordova. It was the rule of a strong man who made, and kept under his own control, a janissary army of slaves from all nations, Christian mercenaries from the north, Berbers and negroes from Africa. With that host he made fifty invasions into the Christian territory. A more statesmanlike conqueror leading a people capable of real civilization would have made five, and his work would have lasted. Mansur made raids, and left his enemies in a position to regain all they had lost. It mattered little where he went, for the shining example of his brother, the monastery of Cardeña in Castile, took Leon, Pamplona and Barcelona; if at the end he left the roots of the Christian states firm in the soil, and to his son and successor as hajib only a mercenary army without patrioti sm or loyalty. In later times Christian ecclesiastical writers, finding it difficult to justify the unbroken prosperity of the wicked to an age which believed in the judgment of God and trial by combat, invented a final defeat for Mansur at Calatañazor. He died in 1002, undefeated, but racked by anxiety for the permanence of the prosperity of his house. His son Mozaffar, kept the authority as hajib, always in the name of Hishâm II., who was hidden away in a second palace suburb of Cordova, Zahira. But Mozaffar lasted for a short time, and then died, poisoned, as it was said, by his brother Abdurrahman, called San chol, the son of Mansur by one of the Christian ladies whom he extorted for his harem from the fears of the Christian princes. Abdurrahman San chol was vain and feather-headed. He extorted from the feeble caliph the title of successor, thereby deeply offending the princes of the Omayyad house and the populace of Cordova. He lost his hold on his slaves and mercenaries, whose chiefs had begun to think it would be more to their interest to divide the country among themselves. By the wise advice of a friend (the son of a woman, of the Omayyad family, who called himself Al Mahdi Billah (guided by God), and a street riot, upset the power of the hajib at Cordova while he was absent on a raid against Castile. His soldiers deserted him, and he was speedily slaughtered. Then in the twinkling of an eye the whole edifice went into ruin. The end of Hishâm II. is unknown, and the other princes perished in a frantic scramble for the throne in which they were the puppets of military adventurers. A score of shifting principalities, each ready to help the Christians to destroy the others, took the place of the caliphate. The fundamental difference between the Moslem, who knows only the despot and the Koran, and a Christian people who have the Church, a body of law and a Latin speech, was well seen in the contrast between the end of the greatness of Mansur, and the end of the weakness of his Christian contemporaries. The first left no trace. The second attained, after much fratricidal strife, to the foundation of a kingdom and of institutions. The interval between the death of Ramiro II. in 950 and the establishment of the kingdom of Castile by Fernando I. in 1035 is on the surface as anarchical as the Mahommedan confusion of any time.

The personages are not anywise heroic, even when like Alphonso V. (1099-1077) they were loyal to their duty. Sancho the Fat, and Bermudo II. the Gouty, with their shameless feuds in the presence of the common enemy, and their appeals to the caliph, were miserable enough. But the emancipation of the states was progress. Christians were given the towns and a class of burghers, endowed with rights and armed to defend them, was formed; while the council of the magnates was beginning to develop into a Cortes. The council over which Alphonso V. of Leon and his wife Geloria (i.e. Elvira) presided in 1026, conferred the great model charter of Leon, and passed laws for the whole kingdom. The monarchy became thoroughly hereditary, and one main source of anarchy was closed. By the beginning of the 11th century the leading place among the Christian kings had been taken by Sancho El Mayor (the Great) of Navarre. He was a straightforward man of Castile. Garcia was murdered by the sons of Count Vela of Alava whom he had despoiled, and Sancho took possession of Castile, giving the government of it to his son Fernando, (Ferdinand I.), with the title of king, and taking the name of "king of the Spains" for himself. It was the beginning of attempts, which continued to be made till for a century, to obtain the unity of the Christians by setting up an emperor, or king of kings, to whom the lesser crowns should be subject.

Ferdinand I., the son of Alphonso V., married a German princess, who was the best of women, and lived in peace with the new king, and lost his life in the battle of Tamaron, in a war which he had himself provoked. Fernando now united all the north-west of Spain into the kingdom of Castile and Leon with Gallicia. Navarre was left by Sancho to another son, Garcia, while the small Christian states of the central Pyrenees, Aragon and Sobrarbe with the Ribagorza went to his other sons, Ramiro Sanchez and Gonzalo. Fernando, as the elder, called himself emperor, and asserted a general superiority over his brothers. That he took his position of king of kings seriously would seem to be proved by the fact that when his brother Garcia attacked him in 1054, and was defeated and slain at Atapuerca, he did not annex Navarre, but left his nephew, Garcia's son, on the throne as vassal. The Council of Coyanza, now Valencia de Don Juan (1056), at which he confirmed the charters of Alphonso V., is a leading date in the constitutional history of Spain. When he had united his kingdom, he took the field against the Mahommedans; and the period of the great reconquest began. So far the Christians had not gone much beyond the limits of the territory left to them at the end of the 8th century. They had only developed and organized themselves within it. Under Fernando, they advanced to the banks of the Tagus in the south, and into Valencia on the south-east. They began to close round Toledo, the shield of Andalusia. The feeble Andalusian princes were terrified into paying tribute, and Fernando advanced to the very gates of Seville without finding an enemy to meet him in the field. His death in 1065 brought about a pause for a time. He left his three kingdoms to his three sons Sancho, Alphonso and Garcia. Alphonso, to whom Leon had fallen as his share, remained master after the murder of Sancho at Zamora, which he was endeavouring to take from his sister, and the imprisonment of Garcia of Gallicia. The reign of Alphonso VI., which lasted till 1104, is one of the fullest in the annals of Spain. He took up the work of his father, with less of the crusading spirit than was in Fernando, but with conspicuous ability. His marriage with Constance, daughter of Robert, duke of Burgundy, brought a powerful foreign influence into play in Castile. Constance favoured the monks of Cluny, and obtained her husband's favour for them. Under their leadership measures were taken to reform the Church, from which hitherto little had been expected save that it should be zealos and martial. The adoption of the Roman instead of the Gothic
The confusion was increased by the fact that Alfonso, Urraca's son by her first marriage with Raymond of Burgundy, was recognized as king in Galicia, was bred up there by the able bishop Diego Gelmirez, and took an active part in the feuds of his mother and step-father. The death of Urraca in 1126 allowed her son to reunite the dominions of his grandfather.

In the meantime his quarrels with Urraca had not deterred Alfonso, who is surnamed the Battler in Aragonese history, from taking Saragossa in 1118, and from defeating the Almoravides at the decisive battle of Cutanda in 1120. In 1125 he carried out a great raid through Mahomedan Spain, camping in its midst for months, and returning with many thousands of the Christian reyes, who, under the name of caballeros, had been added to his dominions. The new feud from the bigotry and negro brutality of the Almoravides. The failure of Alfonso's attempt to take Braga in 1134 was speedily followed by his death. He left his kingdom by will to the Knights of the Temple and the Hospital, but the barons of Aragon paid no attention to his wish, and drew his brother Ramiro, a monk, from his cell to continue the royal line. Ramiro, having been first ex-claustrated by the pope, married Agnes of Aquitaine, and on the birth of his daughter Petronilla affianced her to Ramon Berenguer (Raymond Berenger), count of Narbonne. His marriage, indeed, which was arranged with Aragon since the fratricidal murder of his king Sancho in 1076, preferred to remain independent under a new ruler of its choice. It was therefore a small state lying across the Pyrenees, dependent on France, and doomed inevitably to be partitioned between its great neighbours to north and south.

Alfonso VII, the son of Urraca, was, during the twenty years of the reign of his brother and his own in 1157, the dominating sovereign of Spain. In 1155 he was crowned at Leon, in the presence of the new king of Navarre, of the counts of Barcelona and Toulouse, and of other princes, Christian and Mahomedan, "Emperor in Spain, and king of the men of the two religions." In his character of emperor and king of the men of the two religions Alfonso VII. seems to have aimed not at expelling, but at reducing the Moors to subjection as vasal communities. He took Cordova and conquered as far as Almeria, to the coast of the Alboran. The End of the "Empire," The Union of Castile and Leon. Sancho, his eldest son, took the first and Fernando the second. The dream of the empire was speedily dissipated by the death of Sancho of Castile a year after his father; Portugal had already become a semi-independent state.

The complicated story of the Christian kingdoms of Spain during the next two generations can be best made intelligible by taking the king of Castile as the centre of the Alfonso VIII. of Castile, 1158-1214. War with the Almoravides. In 1148 the downfall of the Almoravides opened the way to the Almohades, or followers of the Mahdi, an even more bigoted religious sect than the other. Alphonso had conquered Cuenca, in the full country between Castile and Valencia, in 1177, with the help of the king of Aragon, also an Alphonso, the son of Petronilla and of Ramon Berenguer of Barcelona. With eminent good sense he rewarded his ally by resigning all claim to feudal superiority over Aragon.

1 Raymond du Puy, grand master of the Hospitalers, came to terms with Count Raymond in the matter of the bequest. (See SAINT JOHN OF JERUSALEM, KNIGHTS OF.)
At a later period the two kingdoms defined their respective spheres of influence by a treaty. Aragon was left free to conquer the Balearic Islands and Valencia, while Murcia and Andalusia were to fall to Castile. The Almohádes took the field against Alphonso in force, and as his fellow Christian sovereigns failed him in the hour of need, he was defeated at Alarcos. But this wave of the ebbing Moslem tide had less force than the Almorávide, and fell back both sooner and farther than its predecessor. Alphonso had leisure to punish his brother kings for deserting him, and to look to the organization of his kingdom.

It was a great epoch of the granting of charters, and of the advance of the towns. To this age also belongs the formation of the great monastic military orders of Calatrava, Santiago and Alcántara. They supplied the Crown with a strong force of well-disciplined and well-appointed cavalry. To tighten the bond with Leon, Alphonso of Castile married his daughter Berengaria to its king Alphonso (1188–1230), the son of his uncle Fernando. The marriage was dissolved by the pope as being within the prohibited degrees, but the son born of it was recognized as legitimate. Berengaria, a woman of very noble character and eminent ability, deserved a better husband than her cousin of Leon, who was nicknamed El Baboso—the Slobberer—and who appears to have been epileptic. In 1212 the king of Castile reaped the reward of long years of patience. The Almohádes threatened an invasion in force, and he organized a crusade against them. Aragon was represented by its king Peter II., Navarre by its king Sancho, and Portugal by a strong contingent of Templars and other knights. At the Navas de Tolosa, just south of the Sierra Morena, the Almohádes received the final overthrow which laid Mahommedan Spain at the feet of the Christians. Alphonso died in 1214. His son Enrique (Henry) was killed by the fall of a tile three years later; and Berengaria, to whom the crown came, sent to Leon for her son Fernando, and abdicated in his favour.

Fernando (Ferdinand III.) who was in all ways worthy of his mother, took up the crusading duty of a king of Castile, and continued the advance into Andalusia. The Almohádes were in swifter decline than the Almorávides. One of them, al-Mamun, even sought Fernando's help to regain his throne. Fernando and Muzio divided the kingdom of Granada. In 1230 the death of Alphonso of Leon opened the way to a final union of the crowns. The “Baboso” had, indeed, left his kingdom by will to his daughter by Teresa of Portugal, but Fernando was saved from the necessity of enforcing his rights by his mother. She persuaded Teresa and the infantes to resign their claims in return for pensions and lordships. Castile and Leon were united, never to be divided again. The work of the reconquest was now completed with swift steps. In 1236 Cordova was conquered, and Seville fell in 1248 with the help of a fleet from the Basque coast and of the Moorish king of Granada, who was Fernando's vassal, paying tribute and attending Cortes when summoned. Fernando died in May 1252. It will avoid repetition to note here that the Aragonese share of the reconquest was completed by James the Conqueror (1213–1276), the son of that king Peter who fought in the Navas de Tolosa. He conquered the Balearic Islands in 1229 and Valencia in 1238. In 1265 he entered Murcia, which, however, he agreed to occupy in the name of Castile. Mahommedan Spain was reduced to Granada and a line of ports round to Ceutí. The Christian sovereignty had long ceased, and an Arab Population of Spain after the Reconquest. But those remnants who had lived here all the centuries of Moorish occupation had nowhere to go, and they were welcomed to the towns which had charters—called in Aragon the Universidades—the nobles, the gentry and the Church. The Catalans attained emancipation from feudal subjection by a succession of savage peasant revolts in the 15th and 16th centuries. In Valencia emancipation was finally brought by a measure which in itself was cruel—the expulsion of the Moriscoes in the 17th century. The landlords were compelled to replace them by free tenants. The prevalence of prelial slavery in Aragon and Valencia can be largely explained by the number of Múdèjares, that is Mahommedans living under Christian rule, and of Moriscoes—converted Moriscos and Moors who had been Christianized by force. If now we look at the internal history of Spain from the conclusion of the period of the reconquest, which may be put in the middle of the 13th century, down to the union of the crowns of Castile and Aragon by Ferdinand and Isabel in 1482, it will be found to be occupied with two great processes. These two processes are firstly, the christianization of Spain, a very different thing from its reconquest from Moslem masters—and, secondly, not its unification, for that is hardly attained even now, but its progress towards unification.
When Fernando (Ferdinand III.), the conqueror of Andalucia, died in 1252, he left the kingdom to the king's eldest daughter by his first wife, or even by his second; the Jews and the Mahommedans formed a very large part of his subjects. We have no means of estimating their numbers, but there is much probability that they were not less than a third or a fourth of the whole population. The Jews, who had suffered cruelly from the brutal fanaticism of the Almohades, had done a great deal to forward the reconquest. They had aided the last general of the Almohades to take the town, and had been rewarded by the king, and the period which includes the reign of Ferdinand and lasts till the end of the 14th century was the golden age of their history in Spain. In 1301 the preaching of a priest of Seville, named Bartolome de Medina, kindled the last general uprising of the Jews, who were envied for their prosperity and hated because they were the king's tax collectors. But the history of the persecution and expulsion of the Jews is the same every-where, except in Spain. The towns of the Mudejares and Mozarabes is peculiarly Spanish. In the Christian advance they were from the beginning first subjected and then incorporated. As far north as Astorga there is still a population known as Maragatins and familiar to all Spain as carters and milkmen. This marked type of the Leonese of modern times represents a Berber colony cut off among the Christians, and christianized at an early date, who never ceased to keep their customs. They are only the most conspicuous example of a process which was common to all the Peninsula. As the Christians worked down to the south they found an existing Mahommedan population. To them the slavery of its严密, at least, have been dangerous, and would also have been offensive to the Christians, who were themselves fighting for emancipation. To northward the Moslems had been to a great extent until the 13th century, so that the king, the nobles, the Church and the military orders combined to give them protection. For them, as for the Jews, the 13th and 14th centuries were a golden age. By the end of the 14th century the Moslem population was forced to migrate, a forced conversion followed, which, with the expulsion, which came in the reign of Philip III. (1508-1621). But before the end was reached all had been persuaded or forced into Christianity, had ceased to be Mudejares, and had become Moriscos. In the majority of cases the conversion had occurred so long ago that the memory of the time when they were Mahommedans was lost, and they were treated as Spaniards. In expanding, The Mozarabes again—the Christians who had always lived under Mahommedan rule—were an element of importance in medieval Spain. They had learnt to write in Arabic. They shared the characteristics of Latin, or the corrupt dialect of Latin which they spoke. The conquest of Toledo by Alphonso VI. first brought the Christians into contact with a large body of these Arabized Spaniards, and their influence was considerable. By Alphonso they were favoured. He stamped his name on his coins in Arabic letters. It is said with probability that one of the early kings of Aragon, Peter I., could write Arabic. Some of the Mozarabes preserved their tongue even when the Christian kingdom was conformed Latin, or the corrupt dialect of Latin which they spoke. on the frontier should be, garrison. Hence they were not only encouraged but required to possess arms. This was the law that they served.

The Cáballos de Puerto. The law was complained of by the townsfolk, and their remedy was to have the privilege of making a cáballos de puerto, or a chartered company of seamen, who were to have the power to seize and sell any ship, and to make a "caballería" to live as and count themselves "cavaliers." Hence the establishment of the Cáballos de puerto, non-nobles living "noblely" with a right to wear the sword. The privilege survived the Cáballos de puerto and was often exercised by the charters, or where no privilege had been granted by the king. But it was subject to innumerable exceptions, and particular jurisdictions. There was no common tribunal. Nor was any material change introduced after the epoch of the reconquest. Alfonso X, El Sabio or Learned, made a fuero real, which was formed by combining the best parts of existing charters. It was accepted by towns and districts not already chartered, but by them only. The famous siete partidas (the seven divisions), drawn up about 1260, is often spoken of as a code of laws. It was never so treated till it was adopted by the Cortes of Castile in 1325, 1326, when the king of his great-grandson, Alfonso XI. Even then it was subject to the restriction that it was not to prevail against any fuero, or the fuero real. The Cortes might have been expected to forward the work, but they did not do so; it is possible that without public approval, which requires particular treatment, it may be noted that the Cortes was no more coherent, or fixed in constitution or working, and was no more national, than any other of the institutions of the times. Before the reign of Castile, Leon had indeed a common Cortes after 1301. Aragon never advanced so far. It, Catalonia and Valencia had each their Cortes, which met with a little sense of its own regularity, freedom, or any rule as to the constitution of a Cortes. The third estate secured representation in the Cortes of Leon (1188), and then in Castile and the Common Cortes. In the kingdom of Aragon the right was secured about the same time. The Cortes secured that no new action could be imposed save with the consent of the commons, and that therefore they must be represented. But no rule was ever made as to whom the king was bound to summon, nor even that the presence of the clergy and the nobles was necessary to constitute a true Cortes. It was never claimed by the Cortes that its consent was necessary to the making of laws. The Roman maxim that what the prince would have was not necessary did not seem to be much doubted that the king acting by himself was "the prince." The check which the justicia, or chief justice, of Aragon imposed on the king was supported by the force of nobles and cities, but it was an exception. The Spanish Cortes were representative of persons and procuradores, i.e., attorneys of the cities. There was no knight of the shire in any Spanish Cortes. The great cities in Castile and Leon succeeded finally in redressing this right of representation by a privilege of eighteen among them, with the good will of the king, who found it easier to coerce or bribe the procurators of eighteen towns than the representatives of a hundred and fifty. The legislative work of such bodies was necessarily small. Their practical power might be great when the king was weak and necessitous, but only then.

The Kings of Castile.

Alfonso X., 1221-1284, was an admirable writer, and a man of keen intellectual interest in science and law. As a ruler he was at once weak, unstable and obstinate. He wasted much time and great sums of money in endeavouring to secure his election as emperor—not in Spain, but in the Holy Roman Empire. He did indeed add the town of Cadiz to his possessions with the help of his vassal, the Moorish king of Granada, but his reign is filled with quarrels between himself and his nobles. The nobles of Castile and Leon were not feudal vassals, but great landowners claiming and exercising rights or jurisdiction on their estates. Their name of ricos hombres, which first appears in written documents of the 12th century, has been credited with a Teutonic origin, but it was in all probability nothing but a "romance" or Castilian translation of the seniores and senatores, potentienses and possessores of the Visigoth councils and code. They represented a nobility of wealth and not of blood. In the later times their possessions were divided among their sons. It was only at the end of the 13th century and later that they began to form mayoragos or entails, to preserve their name and family. It was then that segundones, or younger sons, began to be known in the social life of Spain. But whatever their position may have been legally, they were as grasping as any feudal nobility in Europe, and they were singularly destitute of any capacity for combined political action. In Aragon, indeed, the nobles did extort a promise from the king that they should not be put to death or deprived of their estates by his mere decision. In Castile they never went beyond begging or extorting grants of the crown lands, or pensions charged on the royal revenue. Alfonso X. ended his life in a civil war with his son Sancho, who claimed the succession in preference to the children of his elder brother, Fernando de la Cerda, and in virtue of a doctrine of which much was heard in the middle ages elsewhere than in Spain. He maintained that the younger son, being nearer to the father than the grandson, had a right to succeed in preference to the children of an elder brother who had died before the succession was open. Alfonso, after first accepting Sancho's claim, repudiated it, and made a will by which not only the left the crown of Castile to the eldest son of Fernando de la Cerda, but cut vassal kingdoms out of the southern parts of Spain for Sancho's younger brothers. The reign of Sancho IV., surnamed El Bravo, or the Fierce (1284-1296), was one constant struggle with the very nobles who had helped him against his father, with his younger brothers, and with the sons of Fernando de la Cerda. Murder and massacre were his familiar methods. He was succeeded by his infant son Fernando (Ferdinand IV.), whose long minority was an anarchy, tempered by the courage and the tact of his mother, Maria de Molina. Fernando, ungrateful to his mother and incapable as a king, died in 1312, leaving a son of less than a year old, Alfonso XI. (1312-1350). After another minority of confusion, Alfonso, surnamed "of the Rio Salado," from the great victory he won over an invading host from Africa, ruled with energy and real political capacity. He was indeed ferocious, but such actions as the murder of his great-uncle, Don Juan El Tuerto—the distorted in body and mind—did not seem to his subjects more than the exercise of "the prince" that of right to act for the good of the state legibus solutus which is inherent in sovereignty. But Alphonso did not use his freedom to act legibus solutus except against such hoary and incorrigible intriguers as Don Juan el Tuerto or the Caballero Diego Gil, whom he beheaded with seventeen of his men after promising them security for their lives. He did something to found the judicial and administrative unity of the country. His death at the age of thirty-eight, during the great plague, and while he was besieging Gibraltar, was a misfortune to Spain. His successor, Peter, surnamed the Cruel (1350-1368) was destined to show the Castilians exactly what the constant use by the princes of their reserved rights of the sovereignty authority could be made to mean, when they were exercised by a passionate man maddened by suspicion of all about him. Administering the civil side of his government through Jewish tax-gatherers and farmers of the taxes, and surrounded by the Mudéjar guard, who were the executors of his justice, his path is marked by one long succession of murders. With all his appearance of energy, he shrank from action at the critical moment of his wars out of utter want of trust in all about him. His expulsion by his brother, Henry of Trastámara, the eldest son of Leonor de Guzman, his restoration by the Black Prince (q.v.), his treachery.
to him, and his final defeat and murder at Montiel, are famous episodes. Henry of Trastamara, the beginner of the “new kings” (1356-1379), reigned by election. The nobles and the city of Seville, to whom he owed his success, had proportionate power. In his reign and those of his immediate successors the Cortes flourished, although it failed to establish checks on the absolute power of the king. Henry was on the whole a successful ruler. He forced his neighbours of Portugal to make peace, his fleet defeated an English squadron of Rochelle, and he restored internal order.

The civic hermandades, or brotherhoods, enforced respect from the nobles. John I. (1379-1396), Henry’s son and successor, had to contend with John of Gaunt, son of the Black Prince, who inherited the lordship of England. He had married the eldest daughter of Peter the Cruel, and claimed the crown of Castile in her name. John averted the danger by arranging a marriage between his son John and Constance, the eldest daughter of John of Gaunt, an alliance which united the two equally illegitimate lines representing Alphonso XI., and so closed the dispute as to the succession. He was less fortunate in his efforts to vindicate the rights of his wife Beatriz to the throne of Portugal. The defeat of the Castilians at the battle of Aljubarrota (1385) compelled the king to renounce his pretensions.

Henry II. (1390-1406). El Doliante (the sufferer) did something to establish order. He recovered all the immense grants of crown lands and rents, impounded by the nobles during his minority. The first years of the minority of his infant son, John II. (1406-1454), were by a rare exception peaceful. The young king’s uncle Ferdinand (called “of Antequera” because he was besieging that town, which he took from the Moors, when he heard in 1412 that he had been declared heir to the throne of Castile) was put to death in 1416. Henry IV. (1385-1398), John I. (1387-1398), and Martin I. (1395-1410). In so far as their influence was felt in the internal affairs of their Spanish kingdoms, they had a double task to perform. The first was to reunite the Balearic Islands and Roussillon, which James the Conqueror had left by will to a younger son, to the crown of Aragon. This was finally achieved, after a hideous story of fratricidal hatred and murder by poison, by Peter IV. Their second task was to reduce their turbulent barons, in Aragon, Catalonia and Valencia alike, to the position of obedient subjects. In this task also it was Peter IV. who achieved success. The barons of Aragon and Valencia had extorted from his weak father the charter known as the Union, which not only recognized their just right not to be punished in life or property, except by process of law, but explicitly authorized them to elect the justicia or the chief justice, whose decisions were to be independent of royal confirmation, and to take up arms whenever they considered themselves aggrieved. Such an instrument was of course incompatible with the monarchical or any other form of government. The object of the life of Peter IV. was to force the barons to surrender their charters. After years of struggle and preliminary failures, Peter IV. defeated the “Union” utterly at the decisive battle of Epila (1434). He was a typical king of the 15th century, immeasurably false, and unspeakably ferocious, but he was not a mere blood-thirsty sultan like his enemy, Peter the Cruel of Castile. When he won he took indeed a brutal vengeance on individuals, and

he extorted the surrender of the charter and destroyed it with his dagger in the presence of the Cortes at Saragossa. He cut his hand in his eagerness, and declared that the blood of a king should be shed for his brother. In the destruction of Ferdinand I. “of Antequera”—whence his popular nickname of Peter the Dagger (del Pumjalet). But his use of the victory was statesmanlike. He fully confirmed the right of the nobles to trial by law and security against arbitrary punishment; he left the franchises of the city untouched, and respected the independence of the justicia. The result of his victory was to give Aragon and his other dominions a measure of internal peace unknown in Castile. The reigns of his sons and successors, John and Martin, were insignificant and tranquil. The death of Martin without children in 1438 was a blow to the Castilians, for their hopes for their grandson, Juan, as successor to John of Castile, the eldest son of Ferdinand’s elder brother. But the countries were not ripe for union. Nevertheless the choice of Ferdinand was a step forward towards union.

From 1412 to 1479 the separation lasted with a growing approximation of the two states whose interests touched one another so closely. In Castile John II. (1406-1454), a man of amiable but indolent character and of literary tastes, was governed by his kinsman, Álvaro de Luna, and harassed by his nobles. His reign is full of contentions which were not wars for a principle, but were struggles for the control of the state. On the other hand, his own love of life he sacrificed his favourite at the instigation of his second wife, an act which, it is said, justly embittered his last days. Of his son, Henry IV. (1454-1474) it is enough to say that he was called “the Impotent,” and that there is every reason to believe that he deserved the description in all the senses of the word. His reign was an inferior copy of his father’s. As the legitimacy of his alleged daughter Juana was disputed, his sister Isabella claimed the succession, and married her cousin, Ferdinand of Aragon, son of John I., in 1469 in the Capuchins of S. Domingo de la Calzada and was anointed as queen “of Antequera” (1412-1416) was succeeded by Alphonso V. (1416-1458) the Magnanimous, whose brilliant life belongs to Italy. In Aragon he was represented by his brother John, who administered as lieutenant-general, and who reigned in his own right (1458-1479) even after Alphonso V. died without legitimate heirs, leaving Naples by will to a bastard son. John I., a man of indomitable energy and considerable capacity, spent most of his life in endeavouring to enforce his claims to the kingdom of Navarre as the husband and heir of its queen Blanche. His conflict with his son by this first marriage, Charles, prince of Viana, was settled in his favour by the death of the prince. Then he had to contend with a national revolt in Catalonia, which endeavoured to make itself independent under three successive foreign princes. In the end the pertinacity of John triumphed. At the age of over eighty, blind and unconquerable, he transmitted his kingdom to Ferdinand, his son by his second marriage, with Juana Enriquez, of the family of the hereditary admirals of Castile. Navarre went to a daughter, and Roussillon was somewhat fraudulently retained by Louis XI. as security for a debt. Ferdinand conquered the Spanish half of Navarre later, and recovered Roussillon from Charles VIII., the successor of Louis XI.

With the death of John II. of Aragon in 1479 the history of Spain enters on an entirely new period. Hitherto it has been the story of a national development. The process did not cease, but, during the reign of Isabella the Catholic (1474-1504) until the death of her husband Ferdinand in 1516, was carried,
not to completion, but to the stopping place at which it was destined to rest for two centuries. The voyage of Columbus in 1492, and the intervention of Ferdinand in the great conflict of France, the empire and the papacy for predominance in Italy, had, simultaneously, the effect of opening to her the world of conquest and adventure in America, and of committing her to incessant wars in the Italian Peninsula. The death of John, the only son of Ferdinand and Isabella, the worst misfortune which ever happened to Spain, opened the succession to all the crowns and coronets won by the Catholic sovereigns to Charles of Habsburg—the emperor Charles V. From that day Spain became a part—the leader, then the paymaster, then the dupe—of the international monarchical confederation called "the illustrious House of Austria." The Spaniard became the swordsman and executioner of the counter-Reformation, because the power of the House of Austria depended on the imposition of religious unity in Europe. The decision of Charles V., king of Spain and emperor, to leave the Netherlands to his son Philip II., committed the Spaniards to conflict on the sea with England, and to the insane attempt to secure a safe road for their armies across Europe from the shores of the Mediterranean to the North Sea. Thereby they threatened the very national existence of France. The arrangement was made possible only by the hopeless divisions of Germany, the blind pride of Spain, and the utter political incapacity of both. It forced every patriotic ruler of England to oppose Spain on the sea, and every statesmanlike master of France to ruin her power on the land. Meanwhile the Spaniards were endeavouring to check the advance of the Turks in the Mediterranean, and to exclude all Europe from the waters of the New World. In the intensity of their struggle with the Reformation they subjected education to a censorship which, in order to exclude all risk of heresy, stifled thought and reduced knowledge to the repetition of safe formulas. With their eyes on the ends of the earth, and a ring of enemies from Constantinople to the Antilles, the Spaniards fought, with steadily diminishing material resources, with a character and intellect which shrivelled by swift degrees. When nearly bled to death for the illustrious House of Austria, they were transferred to the House of Bourbon, which in its turn dragged them into conflict with Austria in Italy and England together. At the beginning of the 19th century, Spain had fallen into such a state of weakness that Napoleon could, with some considerable measure of excuse, look upon their country as a species of no-man's-land into which his troops had only to march on police duty to secure immediate obedience. The history of the 19th century is the liquidation of an enormous bankruptcy, and the completion of the circle which confines the Spaniard once more to the soil of the Peninsula.

Ferdinand and Isabella were proclaimed king and queen of Castile together, although the crown was hers alone, and although she never consented to part with her sovereign authority. In the purely internal affairs of Castile it was always she who decided on questions of administration. Some opposition was offered by a faction of the nobles who took up the claims of Henry's supposed daughter, commonly called Juana la Beltraneja, because her father was alleged to have been Don Beltran de la Cueva, who, however, fought for Isabella. Juana's party had the support of the king of Portugal, who arranged a marriage between her and his son. The defeat of the Portuguese at Toro made an early end of the war. The new sovereigns immediately began the work of the 15th century, the cities and obedience in the dominions of the Crown. The line of policy followed by the Catholic sovereigns was to keep the old forms, but to draw the substance of power to themselves. Thus, for instance, they organized a police to clear the country of brigands, and attached a special jurisdiction to it, but they gave it the old name of Hermandad and the very superficial appearance of a voluntary association of the cities and the gentry. It consisted of a force of well-appointed horsemen, in the proportion of one to every hundred families. Its merits as a police force have perhaps been exaggerated, and in the war with Granada its bands were used as soldiers. But an end was at least put to the existence of peñas bravas in the dominions of the crown of Castile. And this was the uniform model of their policy. The master-ships of the military orders of Calatrava, St. Iago and Alcántara were one by one annexed to the Crown. Their commanderies were used to pay, or pension, the servants of the sovereigns. No attack was made on the charters of the towns, but in Castile and Aragon alike royal officers were appointed to adjudicate on disputes within the corporations themselves, or between corporation and corporation. By them the old councils were rapidly reduced to a state of atrophy. The same course was followed with the Cortes. It continued to be summoned by the Catholic sovereigns and their successors of the Habsburg line, but it was needed only to grant money. The nobles and the clergy, who as exempt from taxation had no vote, became purely ornamental parts of the Cortes. The representatives of the third estate were confined by the indifference of the Castilians to eighteen townsmen, whose procurators were named by the councils either from among themselves in rotation, or from particular families. Moreover, they received pay from the Crown while the Cortes sat. For the work of legislation the Cortes was not needed, and never had been. It was not even summoned during the whole of the war with Granada. The Catholic sovereigns provided themselves with a revenue by the customary wholesale resumption of grants made during the reigns of John II. and Henry IV., and by the suppression or reduction of the pensions they had granted with profusion. The nobles, having been brought to obedience by a , were left in possession of their estates, their social rank and the obligation to render military service. They were summoned to the royal council, but only as ornamental members, the real authority and the exclusive right to vote being confined to the letrados, or lawyers, chosen by the Crown from the class of the burgheers.

The encouragement of industry was not wanting; the state undertook to develop the herds of merino sheep, by issuing prohibitions against inclosures, which proved the ruin of agriculture, and gave premiums for large merchant ships, which ruined the owners of small vessels and reduced the merchant navy of Spain. The land tax, already introduced by Charles III. into Portugal, was placed on everything. The weaver, the fuller, the armourer, the potter, the shoemaker were told exactly how to do their own work. All this did not bear its full fruit during the reign of the Catholic sovereigns, but by the end of the 16th century it had reduced Spain to a state of Byzantine regulation in which every kind of work had to be done under the eye and subject to the interference of a vast swarm of government officials, all ill paid, and often not paid, all therefore necessitous and corrupt. When the New World was opened, commerce with it was limited to Seville in order that the supervision of the state might be more easily exercised. The great resource of the treasury was the alcoholas or excises—taxes (farmed by contractors) of 5 or 10% on an article every time it was sold—on the ox when sold to the butcher, on the hide when sold to the tanner, on the dressed hide sold to the shoemaker and on his shoes. All this also did not bear its full fruit till later times, but by the 17th century it had made Spain one of the two "most beggarly nations in Europe"—the other being Portugal.

The policy of the Catholic sovereigns towards the Church was of essentially the same character as their treatment of the Jews. They did not set up a temporal government of their own. The first measures adopted by them in Castile, before the union with Aragon, was to stop the nomination of foreigners to Spanish benefices by the pope. But the most characteristic part of their ecclesiastical policy was the establishment of the Spanish Inquisition (q.v.). By the bull of Sixtus IV. of 1578 they obtained authority to appoint three inquisitors, whom they were empowered to remove or replace, and who were independent of, and superior to, the inquisitorial courts of the bishops.
The Spanish Inquisition was a department of the royal government, employed to enforce religious unity and obedience, because they were held to be indispensable in order to obtain national unity and to enforce the authority of the Crown. The Inquisition was established at first in Mahoma (in 1480) in the dominion of Castile only; but it was extended in 1486 to Catalonia and in 1487 to Aragon, in spite of strong protests. The first duties of the Inquisition were to deal with the converted Jews and Mahommedans, respectively known as Marranos and Moriscoes, and with others who still adhered to religions. The latter were dealt with by expulsion, which in the case of the Jews was enforced in 1492, and in the case of the subject Mahommedans in Mudejares in 1502. Both were industrious classes, and the loss of their services was disastrous to Spain—the first of a long series of similar measures which culminated in the final expulsion of the Moriscoes in 1610. The converted Jews, the Mahommedans produced greater difficulties. The Inquisition. Many of the higher ecclesiastics and of the nobility were of Jewish, or partially Jewish, descent. The landlords who found the Moriscoes useful tenants, and the commercial authorities of towns like Barcelona, who knew the value of the converted Jews, endeavoured to moderate the zeal of the inquisitors. But they were supported by the Crown, and there can be no question that the Holy Office was popular with the mass of the nation. It produced a wholesome flight of the converted Jews to France.

In social life the religious zeal favoured by the Inquisition led to such things as those public processions of flagellants which went on in Spain all the end of the 16th century. It aimed at preserving orthodoxy and developing saintliness on the medieval model. Of ordinary immorality it took little notice, and the triumph of its cause in the 16th and 17th centuries, while producing such types of eccentricity as that of San Juan de la Peña, in the province of Cuenca (Agreda), (q.v.) and the Venerable Virgin Luisa de Carvajal (q.v.), was accompanied by an extraordinary development of moral laxity. The Holy Office showed a steady zeal in extending its jurisdiction and by the end of the 17th century had provoked a strong reaction. The most honourable passage in its history is the part it took in forwarding the great, though temporary, reform of the monastic orders, which was a favourite object with Queen Isabella.

Between 1481 and 1492 the Catholic sovereigns completed the work of the reconquest by subjugating the one surviving Mahommedan state of Granada. Their task was made easier by the internal dissensions of the senority, which a few years previously had been united under the sway of the Moors, whose princes intrigued against one another, and were to the last ready to aid the Christians in the hope of obtaining a small fragment of territory for themselves. The surrender of Granada on the 2nd of January 1492 was partly secured by promises of toleration, which were soon violated. A revolt had to be suppressed in 1501. Having secured the unity of their territory in the Peninsula, the Catholic sovereigns were free to begin the work of expansion.

Discovery of America.

In 1492 Columbus (q.v.) sailed on his first voyage to the west. In 1493 Ferdinand secured the restoration of Rossillon from Charles the Bold of Burgundy by the fateful treaty of Aix-la-Chapelle, which he undertook to remain neutral during the king's expedition to Italy. The voyage of Columbus had unforeseen consequences which led to diplomatic difficulties with Portugal, and the treaty of Tordesillas in 1494, which defined the respective spheres of influence of the two powers in the New World and in Asia. In 1497 Ferdinand, with the support of his wife, entered on those wars of Italy in which the Spanish regular soldiers first gained their reputation, and which made Spain for a time the dominant power in the Italian peninsula (see ITALIAN PENINSULA, THE), which made Spain for a time the dominant power in the Italian peninsula (see ITALIAN PENINSULA, THE). In 1498, the marriage of Juana, called the Mad, with Philip of Habsburg, son of the emperor Maximilian (q.v.) brought a new dynasty to Spain. On the death of the queen in 1504 her son-in-law claimed the regency, and was supported by the Castilian nobles. His death in 1506 and the insanity of his widow left the Castilians no choice but to restore Ferdinand as regent. During the next ten years Ferdinand governed with the very able assistance of the archbishop of Toledo, Jimenes de Cisneros (q.v.). He annexed the southern part of Navarre, which was held by the representatives of his half-sister. The archbishop organized and directed the expedition which conquered Oran, Tripoli and other points on the African coast. Here beyond all doubt lay the proper field for the expansion of Spain. She was drawn from it on the death of Ferdinand in 1516. He was succeeded by his grandson Charles of Habsburg, and when Charles was elected to the empire in 1519 Spain was dragged into the wars and politics of central Europe.

Only the smaller part of the reign of Charles was spent in Spain. He came to it from Flanders, where he had received his education, unable to speak the language and surrounded by Flemish favourites. To him and them the country was only a source of supply from which money was to be obtained in order to bribe the German electors. The disregard which both showed for the interests of Spain and its constitutional rights led to the outbreak of the revolt of the Comuneros—"the Revolt of the Comuneros, 1519-20"—by which the provinces of Castile, into confinement in 1519 and 1520 after the departure of Charles for Flanders. The rising of the Comuneros has been often spoken of as a struggle for freedom. But it has a very dubious right to the name. In many places the movement was simply an excuse for a revival of private wars between wealthy noble families. In others it was a struggle to enforce the claims of particular towns. It hardly extended as a political movement beyond the two Castiles. If its leaders had acted together, in conjunction with the part played by the Comuneros could have imposed their own terms, for there was no royal army to oppose them. But they drifted into hostility with the nobles, and were defeated by them at Villalar. The movement then rapidly collapsed. Charles had no part in the suppression of the revolt. Throughout his reign he respected the claim of the Cortes that no new taxation should be raised without its consent, but as he had to deal only with the representatives of eighteen cities, who could generally be bribed, he rarely failed to secure what he demanded. The outbreak of the Comuneros in Castile coincided with the social and agrarian revolt in Valencia known as the Germania, or brotherhood, which was instigated by a local committee appointed by the insurgents. It was in no sense a movement for political rights, but an attack by the sailors, the workmen of the towns, and the Christian peasants on the landowners and their troops

Rising of the Germania in Valencia.

Spain and the European Policy of Charles V.
The revolt in the Low Countries was inevitably favoured by both France and England. Philip was consequently drawn into intervention in the religious wars of France and the Netherlands (q.v.) and into war with England, which culminated in the great Armada (q.v.) of 1588. His relations with England were further complicated by the extension of English maritime enterprise to the New World (see HAWKINS, JOHN; and DRAKE, FRANCIS). In the Mediterranean he was equally forced by his position to take a part in resisting the Turks (see MALTA; HISTORY; and LEPANTO, BATTLE OF). But the key to his whole policy must be sought in his relations to his Flemish subjects. With his absolutist tendencies he was bound to wish to govern them as he did Castile, and the principle of religious toleration, which was not understood by any prince in Europe with the exception of the prince of Orange, William the Silent (q.v.), was peculiarly impossible for him. His reign was therefore one long struggle with forces which he was unable to master.

The burden of the struggle fell with crushing effect on his Spanish dominions and particularly on Castile. Aragon, which was poor and tenacious of its rights, would give little; Catalonia and Valencia afforded small help. The Flemish revenue was destroyed by the revolt. The Italian states barely paid their expenses. Resources for the incessant wars of the reign had been sought in the taxation of Castile and the revenue from the mines of America. They were wholly inadequate, and the result of the attempt to dominate all western Europe was to produce bankruptcy and exhaustion. In his internal government Philip was fully despotic. He made no pretence of war in the Netherlands, and though he summoned them to vote new taxes he established the rule that the old were to be considered as granted for ever, and as constituting the fixed revenue of the Crown. The nobles were excluded from all share in the administration, which was in the hands of boards (juntas) of lawyers and men of the middle class. All business was conducted by correspondence, and with a final reference to the king, and the result was naturally endless delay.

The first years of the reign of Philip II. were occupied in concluding the last of his father's wars with France, to which was added a very unwelcome quarrel with the pope, arising out of his position as duke of Milan. He was unable to avoid sending an army under Alva against Paul IV., and was glad to avail himself of the services of Venice to patch up a peace. On the Flemish frontier, with the help of an English contingent and by the good generalship of Philibert of Savoy he defeated a French army at St Quentin on the 10th of August 1557, and again at Gravelines on the 13th of July 1558. But he did not follow up his successes, and the war was ended by the signing of the peace of Cateau-Cambrésis on the 2nd of April 1559. The exhaustion of his resources made peace necessary to him, and it was no less desirable to the French government. Philip's marriage with Elizabeth, the daughter of Henry II. and of Catherine de Medici, together with their common fear of the Reformation, bound him for a time to the French royal house. In August 1559 he returned to Spain, which he never left for the rest of his life. The outré of the Cortes, whether of Castile or of the other states, for relief from taxation was loud. In some cases the king went so far as to levy taxes in what he acknowledged was an illegal manner and excused under the plea of necessity. By 1567 the revolt in the Netherlands was insuppressible, and in 1568 Philip was absent with a picked army, and at the expense of Spain, to put it down. In the following year the tyranny of the Inquisition, encouraged by the king who desired to purge his kingdom of all taint of heterodoxy, led to the revolt of the Moriscos, which desolated Granada from 1568 to 1570, and ruined the province completely. The Moriscos had looked for help from the Turks, who were engaged in conquering Cyprus from Venice. The danger to Spain and to the Spanish possessions in Italy stimulated the king to join in the Holy League formed by the pope and Venice against the Turks; and Spanish ships and soldiers had a great share in the splendid victory at Lepanto. But the penury of the treasury made it impossible to maintain a permanent naval force to protect the coast against the Barbary pirates (q.v.). Andalusia, Murcia, Valencia, Catalonia and the Balearic Islands were subject to their raids throughout the whole of the 16th and 17th centuries. In 1581 Philip annexed Portugal, as heir to King Henry, the aged successor of Dom Sebastian. Philip endeavoured to placate the Portuguese by the fullest recognition of their constitutional rights, and in particular by favouring the fidalgos or gentry. The duke of Braganza, whose claims were better than Philip's, was bought off by immense grants. Spain seemed now to have reached a commanding height of power. But she was internally exhausted. Her real weakness, and the incompetence of her government, were shown when open war began with England in 1585. While a vast armament was being slowly collected for the invasion of England, Drake swept the West Indies, and in 1587 burnt a number of Spanish ships in their own harbour of Cadiz. The ruinous failure of the great Armada in 1588 demonstrated the incapacity of Spain to maintain her pretensions. In 1591 the support given by the Aragonese to Antonio Perez (q.v.) led to the invasion of their country by a Castilian army. The constitutional rights of Aragon were not entirely suppressed, but they were diminished, and the kingdom was reduced to a greater measure of submission. In his later years Philip added to all his other burdens a costly intervention in France to support the league and resist the succession of Henry IV. to the throne. He was compelled to acknowledge himself beaten in France before his death on the 13th of September 1598. He left the war-wrecked England and with the Netherlands as an inheritance to his son.

The period of one hundred and two years covered by the reigns of Philip III. (1598–1621), Philip IV. (1621–1665), and Charles II. (1665–1700) was one of decadence, ending in intellectual, moral and material degradation. The dynasty continued to make the maintenance of the rights and interests of the House of Austria its main object. Spain had the misfortune to be saved from timely defeat by the weakness of its neighbours. The policy of James I. of England (q.v.), the civil wars of Charles I. (q.v.), the assassination of Henry IV. of France, the troubles of the minority and reign of Louis XIII. (q.v.) and the Fronde (q.v.), preserved her from concerted and persistent foreign attack. After a futile attempt to injure England by giving support to the earl of Tyrone in Ireland (see TYRONE, EARLS OF) peace was made between the powers in 1604. In 1660 a twelve years' truce was made with the Dutch. But the temporary cessation of foreign wars brought no real peace to Spain. In 1610 fears of the help which the Moriscos might give to a Mahomedan attack from Africa combined with religious bigotry to cause their expulsion. The measure was thoroughly popular with the nation, but it was industrially more injurious than a foreign invasion need have been. The king was idle and pleasure-loving. He resigned the control of his government to the duke of Lerma (q.v.), one of the most worthless of all royal favourites. The expenses of the royal household increased fourfold, and most of the increase was absorbed by the favourite and his agents. The nobles, who had been kept at a distance by Philip II., swarmed round the new king, and began to secure pensions in the old style. The pillage was so shameless that public opinion was stirred to revolt. Some of the lesser sinners were forced to restitution, but others, notably the Duke of Lerma, were supplanted by his son, the duke of Uceda, a man as worthless as himself. In that year was taken the step which was destined to consummate the ruin of Spain. The Thirty Years' War began in Germany, and Spain was called upon to support the House of Austria.

The death of Philip III. on the 21st of March 1621 brought no real change. His son, Philip IV., was an able man, and even gave indications of a wish to qualify himself to discharge his duties as king. But he was young, pleasure-loving, and wanted the strength of will to make his good intentions effective.
For twenty years the administration was really directed by his favourite the count of Olivares (q.v.) and duke of San Lucar, known as the "Conde Duque," the count-duke. Olivares was far more able and honest than Lerma. But he could only keep his place by supplying his master with the means of dissipation and by conforming to his dynastic sentiments. The truce concluded in 1609 with Holland ended in 1621, and was not renewed. The commercial classes, particularly in Portugal, complained that it subjected them to Dutch competition. War was renewed, and the Dutch invaded Brazil. As their fleets made it dangerous to send troops by sea to Flanders, Spain had to secure a safe road overland. Therefore she endeavoured to obtain full control of the Valtellina, the valley leading from Lombardy to Tirol, and to throw a barrier to the German ecclesiastical states, which allowed a free passage to the Spanish troops. War with France ensued. The failure of the treaty of marriage with England (see Charles I. and Buckingham, First Duke of) led to war, for the English court was offended by the Spanish refusal to aid in the restoration of the count palatine, son-in-law of James I., to his dominions. In Flanders the town of Breda was taken after a famous siege. The French conducted their campaign badly. The Dutch were expelled from Bahia in Brazil, which they had seized. An English attack on Cadiz in 1625 was repulsed. His flatterers called the king Philip the Great. A few years later it began to be a standing jest that he was great in the sense that a pit is great: the more that is taken from it the greater it grows. By 1640 the feebleness of the monarchy was so notorious that it began to fall to pieces. In that year Portugal fell away without needing to strike a blow. Then followed the revolt of Naples (see Masaniello) and of the Catalans, who were bitterly angered by the excesses of the troops sent to operate against the French in Roussillon. They called in the French, and the Spanish government was compelled to neglect Portugal. Olivares, who was denounced by the nation as the cause of all its misfortunes, was dismissed, and the king made a fresh effort to rule for himself. But he soon fell back under the control of less capable favourites than Olivares. In 1643 the prestige of the Spanish infantry was ruined by the battle of Rocroy. At the peace of Münster, which ended the Thirty Years' War in 1648, Spain was cynically thrown over by the German Habsburgs for whom she had sacrificed so much. Aided by the disorders of the minority of Louis XIV., she struggled on till the peace of the Pyrenees in 1659, by which Roussillon was ceded to France. An attempt was now made to subdue Portugal, but the battle of Montesclaros in 1665 proved the futility of the effort. The news of the death of the king at the castle of Óbidos on 17th of September 1665, Catalonia was saved by the reaction produced in it by the excesses of the French troops, and in Naples the revolt had collapsed. But Portugal was lost for ever, and the final judgment on the time may be passed in the words of Olivares, who complained that he could find "no men" in Spain. He meant no men fit for high command. The intellect and character of the nation had been rendered childish.

During the whole of the reign of Charles II. (1665-1700), the son of the second marriage of Philip IV. with the Infanta Maria Madeleine of France, the monarchy was an inert mass, which Louis XIV. treated as raw material to be cut into at his discretion, and was saved from dismemberment only by the intervention of England and Holland. The wars of 1667-68, ended by the peace of Aix-la-Chapelle, those of 1672-78, ended by the peace of Nijmegen, those of 1683-84, ended by the peace of Ratisbon, and the war of the League of Augsburg, 1689-96, were some of them fought wholly, and all of them partly, because the French king wished to obtain one or another portion of the dominions of the Spanish Habsburgs. But Spain took a subordinate and often a merely passive part in these wars. The king was imbecile. During his minority the government was directed by his mother and her successive favourites, the German Jesuit Nithard and the Granadan adventurer Fernando de Valenzuela. In 1677 the king's bastard brother, the younger Don John of Austria, defeated the queen's faction, which was entirely Austrian in sentiment, and obtained power for a short time. By him the king was married in 1679 to Marie Louise of Orléans, in the interest of France. When she died in 1689, he was married by the Austrian party to Mariana of Neuburg. At last the French party, which hoped to save their monarchy from partition by securing the support of France, persuaded the dying king to leave his kingdom by will to the duke of Anjou, the grandson of Louis XIV., and of Maria Teresa, daughter of Philip IV. by his first marriage. On the death of Charles II., on the 1st of November 1700, the duke of Anjou was proclaimed king.

The Bourbon Dynasty.—The decision of Louis XIV. to accept the inheritance left to his grandson by Charles II. led to a final struggle between pretenders to the title of French King of War of Europe (see Spanish Succession, War of the) which was terminated in 1713 by the peace of Utrecht. The part taken by Spain in the actual struggle was mainly a passive one, and it ended for her with the loss of Gibraltar and the island of Minorca, which remained in the hands of England, and of all her dominions in Italy and Flanders. Another and a very serious consequence was that England secured the Asiento (q.v.), or contract, which gave her the monopoly of the slave trade with the Spanish colonies, as well as the right to establish "factories"—that is, commercial agencies—in several Central and South American ports, and to send one cargo of manufactured goods yearly in a ship of 500 tons to New Carthagena. In internal affairs the years of the war were of capital importance in Spanish history. The general political and administrative nulity of the Spaniards of this generation led to the assumption of all real power by the French or Italian servants and advisers of the king. Under their direction important financial and administrative reforms were begun. The opposition which these innovations produced encouraged the separation tendencies that made the loss of the southern Peninsula. Philip V. was forced to reduce Aragon, Catalonia and Valencia by arms. Barcelona was only taken in 1714, the year after the signing of the treaty of Utrecht. The local privileges of these once independent kingdoms, which had with rare exceptions been respected by the Austrian kings, were swept away. Their disappearance greatly promoted the work of national unification, and was a gain, since they had long ceased to serve any really useful purpose. The removal of internal custom-houses, and the opening of the trade with America, hitherto confined to Seville and to the dominions of the province of Castile, to all Spaniards, were considerable gains. The main agents in introducing and promoting these changes were the French ambassadors, a very able French treasury official—Jean Orry, seigneur de Vignory (1652-1719)—and the lady known as the princes des Ursins (q.v.), the chief lady-in-waiting. Her maiden name was Anne Marie de la Trémoille, and she was the widow of Flavio Orsini, duke of Bracciano. Until 1714 she was the power behind the throne in Spain. On the death of Philip V.'s first wife Maria Louisa Gabriella of Savoy, in 1714, the king was married at once to Elizabeth Farnese of Parma, who had been the mistress of the Duke of Anjou, and who, during her husband's minority, had used her influence to drag Spain into a series of adventures in order to obtain Italian dominations for her sons. Her first agent was the Italian prince Alberoni (q.v.), whose favour lasted from 1714 to 1719. Alberoni could not, and perhaps did not, sincerely wish to prevent the queen and king from plunging into an attempt to recover Sardinia and Sicily, which provoked the armed intervention of France and England and led to the destruction of the rising Spanish navy off Cape Passaro (see Torkington, George Byrne, Viscount). In 1731 Elizabeth secured the succession of her eldest son, Charles, afterwards Charles III. of Spain, to the duchy of Parma, by arrangement with England and the Empire. Apart from the Italian intrigues, the most important foreign affairs of the reign were connected with the relations of Spain with England. A feasible attempt to regain
Gibraltar was made in 1733, and a serious war was only averted by the resolute peace policy of Sir Robert Walpole. But in 1739 trade difficulties, which had arisen out of the Asiento in America, led to a great war with England, which became merged in the War of the Austrian Succession (q.v.). The king, who had become almost entirely mad at the end of his life, died on the 9th of July 1746. His successor, Ferdinand VI., the second son of Charles III., was a retiring and modest man, who adopted a policy of peace with England. His ministers, of whom the most notable were Zenon de Somadevilla, marquis of Ensenada, and Richard Wall, an Irish Jacobite, carried on the work of financial and administrative reform. The advance of the country in material prosperity was considerable. Foreign influences in thought and literature began to modify the opinions of Spaniards profoundly. The party known as the Regalistas, the lawyers who wished to vindicate the royal rights of the Crown, against the encroachments of the bishops and the Inquisition, gained the upper hand.

The new sovereign was one of the most sincere, and the most successful, of the "enlightened despots" of the 18th century. He had had a long apprenticeship in Naples, and was a man of forty-three when he came to Spain in 1759. Until his death on the 14th of December 1788 he was engaged in internal politics, in endeavouring to advance the material prosperity of Spain. His foreign policy was less wise. He had a deep dislike of England, and a strong desire to recover Minorca and Gibraltar, which she held. He had also a strong family feeling, which directed his motives into the "French Conduct" with his French cousins. He made war on England in 1761, with disastrous results to Spain, which for the time lost both Havana and Manila. In 1770 he came to the verge of war with England over the Falkland Islands. In 1778 he joined France in supporting the insurgent English colonists in America. The most statesmanlike of his foreign enterprises, the attempt to take the piratical city of Algiers in 1775 (see Barbary Pirates), was made with insufficient forces, was ill executed, and ended in defeat. Yet he was able to recover Minorca and Florida in the War of American Independence, and he finally extirpated piracy with Algiers which put a stop to piratical raids on the Spanish coast. The worst result for Spain of his foreign policy was that the example set by the United States excited a desire for independence in the Spanish colonies, and was the direct incitement to the rebellions at the beginning of the 19th century. The king's domestic policy, on the contrary, was almost wholly fruitful of good. Under his direction many useful public works were carried out—roads, bridges and large schemes of drainage. The first reforms undertaken had provoked a disturbance in Madrid directed against the king's favourite minister, the Sicilian marquis of Squillacci. Charles, who believed that the Jesuits had promoted the outbreak, and also that they had organized a murder plot against him, allowed his minister Aranda (q.v.), the correspondent of Voltaire, to expel the order in 1766, and he exerted his whole influence to secure its entire suppression. The new spirit was otherwise shown by the restrictions imposed on the numbers of the religious orders and on the Inquisition, which was reduced to practical subjection to the lay courts of law. Many of the king's industrial enterprises, such as the Bavarian colony, established by him on the southern slope of the Sierra Morena, passed away without leaving much trace. On the other hand, the suppression had a beneficial influence on the industrial expansion of Spain greatly increased. The population made a considerable advance, and the dense cloud of sloth and ignorance which had settled on the country in the 17th century was lifted. In this work Charles III. was assisted, in addition to Squillacci and Aranda, by Campanones (q.v.), who succeeded Aranda as minister of finance in 1787, and by Floridablanca (q.v.), who ruled the country in the spirit of enlightened bureaucracy.

Charles III. was succeeded in 1788 by his son Charles IV. The father, though "enlightened," had been a thorough despot; the son was sluggish and stupid to the verge of imbecility, but the despotism remained. The new king was much under the influence of his wife, Maria Luisa of Parma, a coarse, passionate and narrow-minded woman; but he continued to repose confidence in his father's ministers. Floridablanca was, however, unable to continue his earlier policy, in view of the contemporaneous outbreak of the Revolution in France. The revival of Spain depended on the restoration of her colonial and naval ascendancy at the expense of Great Britain, and for this the support of France was needed. But the "Family Compact," on which the French alliance depended, ceased to exist when Louis XVI. was deprived of power by his subjects. Of this conclusive evidence was given in 1791. Some English merchants had violated the shadowy claim of Spain to the whole west coast of America by founding a settlement at Nootka Sound. The Spanish government lodged a vigorous protest, but the French National Assembly refused to lend any assistance, and Floridablanca was forced to conclude a humiliating treaty and give up all hope of opposing the progress of Great Britain. This failure was attributed by the minister to the Revolution; Spain and the French Revolution.
supremacy which the Spanish government had been struggling for almost a century to overthrow. Under the circumstances the queen and Godoy hastened to follow the example set by Prussia, and concluded the treaty of Basel with France (1795). The terms were unexpectedly favourable, and so great was the joy excited in Madrid that popular acclamation greeted the bestowal upon Godoy of the title of "Prince of the Peace." But the moderation of the treaty was only a flimsy disguise of the disgrace that it involved. Spain found herself tied hand and foot to the French republic. Godoy had to satisfy his allies by the encouragement of reforms which both he and his mistress loved, and in 1798 the veil was removed by the conclusion of the Treaty of San Ildefonso. This was, for all practical purposes, the end of the "Family Compact" of 1761, but with terms far more disadvantageous to Spain. Each power was pledged to assist the other in case of war with twenty-five ships, 18,000 infantry and 6000 cavalry. The real object of the treaty, which was to involve Spain in the war against Great Britain, was cynically avowed in the 18th article, by which, during the present war, the Spanish obligations were only to apply to the quarrel between Great Britain and France. A scheme was prepared for a joint attack on the English coast, but it was foiled by the battle of Camperdown. The British, however, were not long in seeing the danger to which they were exposed, and the British fleet to retire to Cadiz. This defeat was the most disastrous because it deprived Spain of the revenues derived from her colonies. Great Britain seized the opportunity to punish Spain for its conduct in the American War by encouraging discontent in the Spanish colonies, and in the Peninsula itself both nobles and people were bitterly hostile to the queen and her favourite. It was in vain that Godoy sought to secure the friendship of the reforming party by giving office to two of its most prominent members, Jovellanos and Saavedra. Spanish pride and bigotry were offended by the French occupation of Rome and the erection of a republic in the place of the papal government. The treatment of the duke of Parma by the Directory was keenly resented by the queen. Godoy found himself between two parties, the Liberals and the Ultramontanes, who agreed only in hatred of himself. At the same time the Directory, whose mistrust was excited by his attitude in the question of Parma, insisted upon his dismissal. Charles IV. could not venture to refuse; the queen was alienated by Godoy's notorious infidelities; and in March 1798 he was compelled to resign his office. Godoy's office was entrusted to Saavedra, but the reformers did not obtain the advantages which they expected from the change. Jovellanos was compelled in August to retire on account of ill-health—the result, it was rumoured—of attempts on the part of his opponents to poison him. His place was taken by Caballero, an ardent opponent of reform, who restored all the abuses of the old bureaucratic administration and pampered to the bigoted prejudices of the clergy and the court. The only advantage which Spain enjoyed at this period was comparative independence of France. The military plans of the Directory were unsuccessful during the absence of their greatest general in Egypt, and the second coalition gained successes in 1799 which had seemed impossible since 1793. But the return of Bonaparte, followed as it was by the fall of the Directory and the establishment of the Consulate, commenced a new epoch for Spain. As soon as the First Consul had time to turn his attention to the Peninsula, he determined to restore Godoy, who had already regained the affection of the queen, and to make him the tool of his policy. Maria Luisa was easily gained over by playing on her devotion to the house of Parma, and on the 1st of October 1800 a secret treaty was concluded at San Ildefonso. Spain undertook to cede Louisiana and to aid France in all her wars, while Bonaparte promised to raise the duke of Parma to the rank of king and to increase his territories by the addition either of Tuscany or of the Roman legations. This was followed by Godoy's return to power, though he left the department of foreign affairs to a subordinate. Spain was now more servile to France than ever, and in 1801 was compelled to attack Portugal in the French interests. The Spanish invasion, commanded by Godoy in person, met with no resistance, and the prince ventured to conclude a peace on his own authority by which Portugal promised to observe a strict neutrality on condition that its territories were left undisturbed. The treaty was resented this show of independence, and compelled Charles IV. to refuse its ratification of the treaty. Portugal had to submit to far harsher terms, and could only purchase peace by the cession of territory in Guiana, by a disadvantageous treaty of commerce, and by payment of twenty-five million francs. In the preliminary treaty with Great Britain he ceded the Spanish colony of Trinidad without even consulting the court of Madrid, while he sold Louisiana to the United States in spite of his promise not to alienate it except to Spain. The Spanish army had already abandoned all connexion with the reforming party. The Spanish Church was once more placed in strict subjection to the Roman see, from which for a short time it had been freed. As soon as Bonaparte saw himself involved in a new war with England, he turned to Spain for assistance and exerted a new treaty (Oct. 9, 1803), which was still more burdensome than that of 1796. Spain had to pay a monthly subsidy of six million francs, and to enforce strict neutrality upon Portugal, this involving war with England. The last remnants of its maritime power were shattered in the battle of Cape Finisterre (Oct. 12, 1807), on the coast of Buenos Aires. The popular hatred of Godoy was roused by passion by these disasters, and Spain seemed to stand on the brink of revolution. At the head of the opposition was Ferdinand, the heir to the throne, as insignificant as his rival, but endowed with all good qualities by the credulous favour of the people. Napoleon was at this time eager to humble Great Britain by excluding it from all trade with Europe. The only country which had not accepted his "continental system" was Portugal, and he determined to reduce that kingdom by force. It was not difficult to bribe Godoy, who was conscious that his policy could not be maintained after the death of Charles IV. In October 1807 Spain accepted the treaty of Fontainebleau. (See Portugal: History.) The treaty was hardly concluded when a French army under Junot marched through Spain to Portugal, and the royal family of that country fled to Brazil. Ferdinand, whose wife had died in 1806, determined to imitate his rival by bidding for French support. He entered into secret relations with Eugène Beauharnais, Napoleon's envoy at Madrid, and went so far as to demand the hand of a Bonaparte princess. Godoy, who discovered the intrigue, induced Charles IV. to order Godoy's arrest (Oct. 1807, 1807); but Bonaparte, when he knew the attempt to dethrone his father and to murder his mother and Godoy, the prince indeed was soon released and solemnly pardoned; but, meanwhile, Napoleon had seized the opportunity afforded by the effect of this public scandal in lowering the prestige of the royal family to pour his troops into Spain, under pretext of reinforcing Junot's corps in Portugal. Even this excuse was soon dropped, and by January and February 1808 the French invasion had become clearly revealed as one of conquest. Charles IV. and his minister determined on flight. The news of this intention, however, excited a popular rising at Aranjuez, whether the king and queen had gone from Madrid. A raging mob surrounded the palace, clamouring for Godoy's head; and the favourite's life was only saved by Charles IV.'s announcement of his abdication in favour of Ferdinand (March 17).—Murat, however, who commanded the French, refused to be turned aside by this change of circumstances. He obtained from Charles IV. a declaration that his abdication had been involuntary, and occupied Madrid (March 23, 1808). Meanwhile Napoleon had advanced to Bayonne on the frontier, whither, at his orders, Murat despatched the old king and queen and their favourite Godoy. The emperor had already made up his mind to place one of his brothers on the Spanish throne; but in order to achieve this it was necessary to cajole the young king Ferdinand VII. and get him into his power. Ferdinand, instead of retiring to Andalusia and making himself the rallying point of national resistance, had gone to Madrid, where he was at the mercy of Murat's troops and whence he wrote grovelling letters to Napoleon. It was no difficult matter for the emperor's
envoy, General Savary, to lure him by specious promises to the frontier, and across it to Bayonne, where he was confronted with his parents and Godoy in a scene of pitiful degradation. Struck and otherwise insulted, he was forced to restore the crown to his father, who laid it at the feet of Napoleon. The old king and queen, pensioned by the French government, retired to Rome; and Ferdinand was kept for six years under strict military guard at Talleyrand's château of Val encay (see Ferdinand VII, King of Spain). On the 13th of May Murat announced to an improvized "junta of regency" at Madrid that Napoleon desired them to accept Joseph Bonaparte as their king.

But Spanish loyalty was too profound to be daunted even by the awe-inspiring power of the French emperor. For the first time Napoleon found himself confronted, not by terrified and selfish rulers, but by an infuriated people. The rising in Spain began the popular movement which ultimately proved fatal to his power.

At first he treated the novel phenomenon with contempt, and thought it sufficient to send his less prominent generals against the rebels. Madrid was easily taken, but the Spaniards showed great capacity for the guerrilla warfare in the provinces. The French were repulsed from Valencia; and Dupont, who had advanced into the heart of Andalusia, was compelled to retreat and ultimately to capitulate with all his forces at Baylen (July 10). The Spaniards now advanced upon Madrid and drove Joseph from the capital, which he had just entered. Unfortunately the insurgents were kept for six years in a military camp by Godoy's agents, the ministers, were swept aside by the popular revolt, and their place was taken by local juntas, or committees, and then by a central junta formed from among them, which ruled despotically in the name of the captive king. In a country divided by sectional jealousies it was impossible to expect a committee of thirty-four members to impose unity of action even in a common cause; and the Spanish rising, the first fierceness of which had carried all before it, lacked the organizing force which alone would have given it permanent success. As it was, Napoleon's arrival in Spain was enough to restore victory to the French. In less than a week the Spanish army was broken through and scattered, and Napoleon restored his brother in Madrid. Sir John Moore, who had advanced with an English army to the relief of the capital, retired when he found he was too late, and an obstinate battle, in which the gallant general lost his life, had to be fought before the troops could secure their embarcation at Corunna. Napoleon, thinking the work accomplished, had quitted the Peninsula, and Soult and Victor were left to complete the reduction of the provinces. The capture of Seville resulted in the dissolution of the central junta, and the Peninsula was generally restored to Ferdinand and thedbname of Godoy restored. Napoleon sent his agents, capabbed of Wellington in Portugal and by dissensions among the French. The marshals were jealous of each other, and Napoleon's plans were not approved by his brother. Joseph wished to restore peace and order among his subjects in the hope of ruling an independent nation, while Napoleon was determined to annex Spain to his own overgrown empire. So far did these disputes go that Joseph resigned his crown, and was with difficulty induced to resume it. Meanwhile, the dissolution of the central junta had given free play to the extreme reforming parties; on the 24th of September these met at Cadiz, which became the capital of what was left of independent Spain.

The Spanish Cortes had never been so entirely suspended as the states-general of France. Philip V., after suppressing the local institutions of the crown of Aragon, had given representation to some of the eastern cities in the general Cortes of Spain. This body had been summoned at the beginning of reigns to swear homage to the new king and his heir, or to confirm regulations made as to the succession. It sat in one house, and was composed of the nobles and churchmen who formed the great majority of procurators. By laws passed by the Cortes or its branches, though varying number of towns, and of representatives of "kingdoms." The Cortes of 1808 was constructed on these lines, but with a very important difference in the proportion of its elements. The third estate of the commons secured 183 representatives, who were sufficient to swamp the nobles and the clergy. No intelligent scheme under which the representatives were to be elected had been fixed. In theory the members of the third estate had been chosen by a process of double election. In fact, however, since much of the country was held by the French, they were often returned by such natives of the regions so occupied as happened to be present in Cadiz at the time. The real power fell to those of the delegates who were influenced by the new ideas. Unhappily, they had no experience of affairs; and they were perfectly ready to make a constitution for Spain on Jacobin lines, without the slightest regard to the real beliefs and interests of Spaniards. Out of these materials nothing could be expected to come except such a democratic constitution as might have been made by a Jacobin club in Paris. In a country noted for its fanatical loyalty to the Crown and the Church, the kingship was to be deprived of all power and influence, and the clergy to be excluded as such from all share in legislation. As though to deprive the Spanish Constitution of any chance of being made effective, the worst expedients dictated by the suspicious temper of the French convention of 1790 were adopted. Ministers were excluded from the chamber, thus rendering impossible any effective co-operation between the legislature and the executive; and, worst of all, a provision was introduced making members of the Cortes ineligible for re-election, an effective bar to the creation of a class of politicians possessing experience of affairs.

The Spanish Cortes were so broken to obedience, and the mainspring of them so intent on fighting the French, that the Cortes was not at the time resisted. The suppression of the Inquisition and the secularization of the church lands—measures which had already been taken by the government of the intruding French king Joseph at Madrid—passed together with much else. But even before the new constitution was published and sworn, on the 19th of March 1812, large numbers of Spaniards had made up their minds that after the invaders were driven out, the Cortes must be suppressed.

The liberation of Spain could hardly have been accomplished without the assistance of Great Britain. The story of the struggle, from the military point of view, is told in the article Peninsular War. In 1812 Wellington determined on a great effort. He secured his base of operations by the capture of Ciudad Rodrigo and Badajoz, and at Salamanca he completely routed the opposing army of Marmont. This victory enabled the English general to enter Madrid (Aug. 12), and Joseph retreated to Valencia. But further advance was prevented by the concentration of the French forces in the east, and Wellington found it advisable to retire for the third time to winter quarters on the Portuguese frontier. It was during this winter that Napoleon suffered his first and greatest reverse in the retreat from Moscow and the destruction of his grand army. This was the signal for the outbreak of the "war of liberation," in Germany, and French troops had to be withdrawn from Spain to central Europe. For the first time Wellington found himself opposed by fairly equal forces. In the spring of 1813 he advanced from Ciudad Rodrigo and defeated Jourdan at Vittoria, the battle which finally decided the Peninsular War. Joseph retired altogether from his kingdom, and Wellington, eager to take his part in the great European contest, sought his way through the Pyrenees into France. Napoleon, who had suffered a crushing defeat at Leipzig, hastened to recognize the impossibility of retaining Spain by releasing Ferdinand VII., who returned to Madrid in March 1814.

Before entering Spain Ferdinand had undertaken to maintain the constitution of 1812, and when on the 22nd of March 1814 he reached Figueras, he was met by a demand on the part of the Cortes that he must accept all the terms of the constitution as a condition of his recognition, and that he must give proof of the true temper of the nation. He now refused to recognize the constitution, and was supported in his refusal...
not only by the army and the Church, but by the masses. There can be no doubt that Ferdinand VII. could have ruled despotically if he had been able to govern well. But, although possessed of some sardonic humour and a large measure of cunning, he was base, and had no real capacity. He changed his ministers incessantly, and on mere caprice. Governed by a camarilla of low favourites, he was by nature cruel as well as cowardly. The government under him was thoroughly bad, and the persecution of the " Jacobins, " that is, a few suspected of Liberal sentiment, ferocious. Partial revolts took place, but were easily crushed. The case was that of a man, who overpowered him in 1820 was a military mutiny. During the war the American colonies had rebelled, and soldiers had been sent to suppress them. No progress had been made, the service was dreadfully costly in life, and it became intensely unpopular among the troops. Meanwhile the brutality of the king and his ministers had begun to produce a reaction. Not a few of the officers held Liberal opinions, and this was especially the case with those who had been prisoners in France during the war and had been inoculated with radical ideas. The man whom the most conspicuous was Colonel Rafael Riego (q.v.), worked on the discontent of the soldiers, and in January 1820 brought about a mutiny at Cadiz, which became a revolution. Until 1823 the king was a prisoner in the hands of a section of his subjects, who restored the constitution of 1812 and had the support of the army. The history of these three miserable years cannot be told except at impossible length. It was a mere anarchy. The Liberals were divided into sub-sections, distinguished from one another by a rising scale of violence. Any sign of moderation on the part of the ministers chosen from one of them was enough to secure him the name of " Serviles " from the others. The " Serviles " proper took up arms in the north. At last this state of affairs became intolerable to the French government of Louis XVIII. As early as 1820 the emperor Alexander I. of Russia had suggested a joint intervention of the powers of the Grand Alliance to restore order in the Peninsula, and had offered to place his own army at their disposal for the purpose.

The project had come to nothing owing to the opposition of the British government and the strenuous objection of Prince Metternich to a course which he had advised. The most of whom the Austrian force was sent Russian force through the Austrian dominions. In 1822 the question was again raised as the main subject of discussion at the congress assembled at Verona (see VERONA, Congress of). The French government now agreed to be allowed to march into Spain, as Austria had marched into Naples, as the mandatory of the powers, for the purpose of putting a stop to a state of things perilous alike to herself and to all Europe. In spite of the vigorous protest of Great Britain, which saw in this demand only a pretext for reviving the traditional Bourbon ambitions in the Peninsula, the mandate was granted by the majority of the powers; and on the 7th of April 1823, the duke of Angoulême, at the head of a powerful army, crossed the Bidassoa. The result was a startling proof of the flimsy structure of Spanish Liberalism. What the genius of Napoleon had failed to accomplish through years of titanic effort, Angoulême seemed to have achieved in a few weeks. But the difference of their task was fundamental. Napoleon had sought to impose upon Spain an alien dynasty; Angoulême came to restore the Spanish king " to his own. " The power of Napoleon had been wrecked on the resistance of the Spanish people; Angoulême had the active support of the masses and the tacit cooperation of the majority. The Cortes, carrying the king with it, fled to Cadiz, and after a siege, surrendered with no conditions save that of an amnesty, to which Ferdinand solemnly swore before he was sent over into the French lines. As was to be expected, an oath taken " under compulsion " by such a man was little binding; and the French troops were compelled to witness, with helpless indignation, the orgy of cruel reaction which immediately began under the protection of their bayonets.

The events of the three years from 1820-1823 were the beginning of a series of convulsions which lasted till 1840. On the one hand were the Spaniards who desired to assimilate their country to western Europe, and on the other those of them who adhered to the old order. The first won because the general trend of the world was in their favour, and because their opponents were blind, contemptuous, and divided among themselves.

If anything could have recalled the distracted country to harmony and order, it would have been the object-lesson presented by the loss of all its colonies on the continent of North America. The Spanish colonies emerged from the struggle of the French Empire and Spain independent during the death-struggle of the Spanish monarchy with Napoleon, and the recognition of their independence de jure was, for Great Britain at least, merely a question of time. A lively trade had grown up between Great Britain and the revolted colonies; but since this commerce, under the colonial laws of Spain, was technically illegitimate, it was at the mercy of the pirates, who preyed upon it under the aegis of the Spanish flag, without there being any possibility of claiming redress from the Spanish government. The decision of the powers at the congress of Verona to give a free hand to France in the matter of intervention in Spain, was a blow to the British government its opportunity. When the invasion of Spain was seen to be inevitable, Canning had informed the French government that Great Britain would not tolerate the subjugation of the Spanish colonies by foreign force. A disposition of the powers of the Grand Alliance to come to the aid of Spain in this matter was countered by the famous message of President Monroe (Dec. 2, 1823), laying the veto of the United States on any interference of concerted Europe in the affairs of the American continent. The empire of Brazil and the republics of Mexico and Colombia were recognized by Great Britain in the following year; the recognition of the other states was only postponed until they should have given proof of their stability. In announcing these facts to the House of Commons, George Canning, in a phrase that became famous, declared that he had " called a new world into existence to redress the balance of the old " and that " if France had Spain, it should at least be Spain without her colonies."

In Spain itself, tutored by misfortune, the efforts of the king's ministers, in the latter part of his reign, were directed to re-establishing in the finances and reviving agriculture and commerce. This period, called the Reactionary Period, is marked by APOSTOLICOS, was often in difficulty in the attitude of the extreme monarchists; of APOSTOLICOS, who found leaders in the king's brother Don Carlos and his wife Maria Francisca of Braganza. Any tendency to listen to liberal counsels was denounced by them as weakness and met by demands for the restoration of the Inquisition and by the organization of absolutist demonstrations, and even revolts, such as that which broke out in Catalonia in 1828, organized by the " supreme junta " set up at Manresa, with the object of freeing the king from " the disused Liberals who swayed him. " Yet the absolute monarchy would probably have lasted for long if a dispute as to the succession had not thrown one of the monarchical parties on the support of the Liberals. The king had no surviving children by his first three marriages. By his fourth marriage, on the 11th of December 1829, with Maria Christina of Naples he had two daughters.

According to the ancient law of Castile and Leon women could rule in their own right, as is shown by the examples of Urraca, Berengaria, and Isabella the Catholic. In Aragon they could transmit the right to a husband or son. Philip V. had introduced the Salic Law, which confirmed the succession to males. But his law had been revoked in the Cortes summoned in 1789 by Charles IV. The revocation had not however been promulgated. Under the influence of Maria Christina Ferdinand VII. formally promulgated it at the close of his life, after some hesitation, and amid many intrigues. When he died on the 29th of September 1833, his daughter Isabella II. was proclaimed queen, with her mother Maria Christina as regent.
The immediate result of the dead king's decision was to throw Spain back into a period of squalid anarchy. Maria Christina would have ruled despotically if she could, and began by announcing that material changes would not be made in the method of government. But the Conservatives preferred to support the late king's brother Don Carlos, and they had the active aid of the Basques, who feared for their local franchises, and of the mountaineers of Navarre, Aragon, Catalonia, and Valencia, who were either quite clerical, or who had become attached, during the French invasion and the troubles of the reign of Ferdinand, to a life of guerrilla adventure. Maria Christina had the support of the army, and the control of the machinery of government; while the mass of the people passively submitted to the powers that were, while as far as possible eluding their orders. The regency found that this was not enough to maintain the Spaniards to resist the active hostility of the Carlists and the intrigues of their clerical allies. She was eventually driven by the necessities of her position to submit to the establishment of parliamentary institutions. She advanced only when forced, first by the need for buying support, and then with the bayonet at her back. First the historic Cortes was summoned. Then in April 1834, under the influence of the minister Martinez de La Rosa, a charter (Estado Real) was issued establishing a Cortes in two Estamentos or Estates, one of senators (próceres) and one of deputies, but with no right save that of petition, and absolutely no power of legislation. This constitution was far from satisfying the advanced Liberals, and the supporters of Christina—known as Cristinos—broke into two sections, the Moderados, or Moderates, and Progressistas or Escaldados, the Progressists or Hot-heads. In August 1836 a military revolt at the palace of La Granja in the hills above Segovia drove the regent by sheer violence to accept a democratic constitution, based on that of 1812, which was issued in 1837. Meanwhile Crístinos and Carlistas, the successors of the "Liberales" and "Serviles," were fighting out their quarrel. In 1835 a vast conspiracy against the monarchy took place. In some cities, notably in Barcelona, it was accompanied by cruel massacres. Though the measure was in itself repugnant to Maria Christina, the pressing needs of her government compelled her to consent when Juan Alvarez y Mendizabal (1790–1853), a minister of Jewish descent, forced on her by Liberals, secularized the monastic lands and used them for a financial operation which brought some relief to the treasury.

The Carlist War lasted from the beginning of Isabella's reign till 1840. At first the Carlists were feeble, but they gathered strength by denying the legitimacy of the Crown. Their leaders, Tomas Zumalacarregui in Biscay and Navarre, and Ramon Cabrera in Valencia, were the ablest Spaniards of their time. The war was essentially a guerrillas struggle in which the mountaineers held their ground among the hills against the insufficient, ill-appointed, and mostly very ill-led armies of the government, but were unable to take the fortresses, or to establish themselves in central Spain south of the Ebro; though they made raids as far as Andalusia. At last, in August 1839, exhaustion brought the Basques to recognize the government of Queen Isabella by the "Estados Generales," or Cortes, which gave them a share of their privileges. The government was then able to expel Cabrera from Valencia and Catalonia. Great Britain and France gave some help to the young queen, and their intervention availed to bring a degree of humanity into the struggle.

Maria Christina, who detested the parliamentary institutions which she had been forced to accept, was always ready to nullify them by intrigue, and she was helped by the Moderados. In 1841 the regent and the Espartanos, or Moderados, made a law which deprived the towns of the right of electing their councils. It was resisted by the Liberals and provoked a military rising, headed by the most popular of the Críston generals, Baldomero Espartero. The queen regent having been compelled to sign a decree illegally revoking the law, resigned and left for France. Espartero was declared regent. He held office till 1843, during an agitated period, in which the Carlistas reappeared in the north, mutinies were common, and a barbarous attempt was made to kidnap the young queen in her palace on the night of the 7th of October 1843. It was only defeated by the hard fighting of eighteen of the palace guards at the head of the main staircase. In 1843 Espartero, a man of much personal courage and of fitful energy, but of no political capacity, was expelled by a military rising, promoted by a combination of discontented Liberals and the Moderates. The queen, though only thirteen years old, was declared of age.

The reign of Queen Isabella, from 1843 till her expulsion in 1868, was a prolongation of that of her mother's regency. It was a confused conflict between the constant attempt of the queen to control a parliament of her own choice, and the necessity of her having to submit to the interference of a Cortes, and the growing wish of the Spaniards to possess a parliamentary government, or at least the honest and capable government which they hoped that a parliament would give them. In 1845 the Moderates having deceived their Liberal allies, revised the constitution of 1837 and limited the freedom it gave. Their chief leader, General Ramon Narvaez, had for his guiding principle that government must be conducted by the stick and by hard hitting. In 1846 Europe was scandalized by the ignominious intrigues connected with the young queen's marriage. Louis Philippe, the king of a French prince wearing the crown of Spain, offered the young queen a chance of reviving the family alliance "Spanish marriages" which had, in the 18th century, bound Bourbon marriages to Spain to Bourbon France. The court of Madrid was rent by the intrigues of the French and the English factions; the former planning an alliance with a son of the French king, the latter favouring a prince of the house of Coburg. The episode of the Spanish marriages forms an important incident in the history of Europe; for it broke the entente cordiale between the two western Liberal powers and accelerated the downfall of the July monarchy in France. There is no doubt, in spite of the apologetics for his action published by Guizot, in his memoirs, that Louis Philippe made a deliberate attempt to overawe the British government; and, if the attempt issued in disaster to himself, this was due, not to the failure of his statecraft so much as to his neglect of the obvious factor of human nature. Palmerston, on behalf of Great Britain, had agreed to the principle that the queen should be married to one of her Bourbon cousins of the Spanish line, and that the younger sister should marry the duke of Montpensier, son of Louis Philippe, but not till the birth of a heir to the throne should have obviated the danger of a French prince wearing the crown of Spain. Louis Philippe, with the aid of the queen-mother, succeeded in forcing Isabella to accept the hand of Don Francisco d'Assis, her cousin, who was notoriously incapable of having heirs; and on the same day the younger sister was married to the duke of Montpensier. The queen's marriage was miserable; and she consoled herself in a way which at once made her court the scandal of Europe, and upset the French king's plans by providing the throne of Spain with healthy heirs of genuine Spanish blood. But incidentally the scandals of the palace had a large and unsavoury part in the political troubles of Spain. Narvaez and his influence were the foundation of the disturbances of 1848 and 1849 without serious disturbance, but his own unstable temper, the incessant intrigues of the palace, and the inability of the Spaniards to form lasting political parties made good government impossible. The leaders on all sides were of small capacity. In 1844 another series of outbreaks began which almost ended in a revolution. Liberals and discontented Moderates, supported as usual by troops led into mutiny by officers whose chief object was promotion, imposed some restraint on the queen. Another revision of the constitution was undertaken, though not carried out, and Espartero was brought from retirement to head a new government. But the coalition soon broke up. Espartero was overthrown by General Leopold O'Donnell, who in 1853 formed the Union-Liberal ministry which did at last give Spain
five years of fairly good government. A successful war in
Morocco in 1859 flattered the pride of the Spaniards, and
the country began to make real progress towards prosperity.
In 1863 the old scene of confusion was renewed. O'Donnell
was dismissed. For the next five years the political history of
Spain was the story of a blind attempt on the part of the
queen to rule despotically, by the help of reckless adventurers
of mean capacity, and by brute violence. The
opposition took the form of successive military
outbreaks accompanied by murder, and suppressed
by massacre. In 1868 the government of Queen Isabella
collected a better army than ever. She had even lost the mob
popularity which she had once gained by joining in a
jovial song. All men of political influence were either in open opposition or,
when they belonged to the Conservative parties, were holding
aloof in disgust at the predominance of the queen's favourites,
Gonzalez Brabo, a mere ruffian, and Marfori, her steward, whose
position in the palace was perfectly well known.
In September 1868 the squadron at Cadiz under the command
of Admiral Topete mutinied, and its action was the signal for a
General secession. One gallant fight was made for
the queen at the bridge of Alcolea in Andalusia by
General Patiño, who was mortally wounded, but it
was an exception. Gonzales Brabo deserted her in a
panic. She went into exile, and her reign ended. The
Revolution of 1868 was the first openly and avowedly directed
against the dynasty. It became a familiar saying that the
'spurious race of Bourbon' had disappeared for ever, and that the
country was called upon to make a new and a better government.
But the history of the six years from September 1868
to December 1874 proved that the political incapacity of the
Spaniards had not been cured. There was no definite force anywhere
in the hands of the military politicians, Francisco Serrano (q.v.),
and Juan Prim (q.v.), who kept order by means of the army.
A constituent Cortes was assembled in 1869, and decided in favour
of a monarchy. Serrano was declared regent until a king
could be found, and it proved no easy task to find
one. Ferdinand of Portugal declined. Montpensier
was supposed to be unwelcome to Napoleon,
and was opposed by Prim, who had also committed himself
to the prophecy that the Bourbons would never return to Spain. Attempts to find a candidate in the Italian family
failed at first. So did the first steps taken to find a king in
the house of Hohenzollern-Sigmaringen. When the desired
ruler was again sought in this family in 1870, the acceptance
of the offer by Prince Leopold proved the immediate cause of
the Franco-German War, in which Spain had a narrow
escape of being entangled. At last, in August of
Savoy 1870, Prince Amadeo of Savoy, second son of Victor
Emmanuel II., consented to become candidate. He
was elected on the 3rd of November. On the 27th
of December 1870, on the very day on which the new king
reached Cartagena, Prim was murdered by assassins who
were never discovered.
The nominal reign of Amadeo lasted till February 1873.
It was a scandalous episode. The Italian prince had put himself
into a thoroughly false position, in which the nearest
approach to friends he could find were intriguing politicians
who sought to use him as a tool, and where every man of honest
principles, royalist or republican, looked upon him as an in-
truder. The Carlists began to collect in the mountains. Republic-
Uan agitators went on in the towns. At last a dispute in
regard to the offering of the artillery gave the
opportunity of a massacre. The Carlists increased rapidly in numbers and were joined by many Royalists, who looked upon them as the last resource. Bands of ruffians
calling themselves 'volunteers of liberty' were found to defend
the Republic, and to terrorize society. A new Cortes was
collected and proved a mere collection of hysterical ranter.
Three presidents succeeded one another within a year, Pi y
Margall, Salmeron and Castelar. Ministries changed every few
days. As the Republic was to be federal when finally organized
many parts of Spain proceeded to act independently. One
party went beyond federalism and proposed to split Spain
into two republics. The Carlists, who were altogether
of free, even mutated, and deserts and resided, seized the important harbour of Cartha-
gen and the ships in it. The ships were taken out of their hands by the British and German squadrons. The spectacle
of anarchy, and the stoppage in payment of taxes frightened
the Republican deputies into some approach to sanity. Sal-
meron allowed General Pavia to restore order in Andalusia.
When he gave place to Castelar, the eloquent Republican
deputy, who was left uncheckered by the recent
'success,' Castelar's
threw all his most eagerly avowed principles to the
wind, raised a great conscription, and provided
the means of reducing Cartha gena and pushing the war against
the Carlists with vigour. When the Cortes met again in January
1874, the extreme parties voted against Castelar on the 3rd
of the month. Hereupon General Pavia, the governor of
Madrid, turned the Cortes into the streets, to the relief of all
sane men in the country. Serrano was appointed as head
of the executive, and was mainly employed during the year in
attempts to save Bilbao from falling into the hands of the Carlists.
It had now become clear that the restoration of the Bourbons
in the person of Don Alphonso, Isabella's son, was the only
way of securing a final settlement. His civilian
agents would have preferred to see him brought in
by a Cortes. But on the 20th of December 1874
Alphonso XII. was proclaimed to be proclaimed king at Murviedo by a brigade of troops, and the example
there set was followed everywhere. Don Alphonso XII. landed in
Barcelona on the 19th of January 1875.
The Resignation of Amadeo, 1874-1875. This,
the first act of Alphonso was a royal decree confirming the appointment of Canovas del Castillo as prime minister. A strong Conservative administra-
tion was formed, to which Canovas admitted some men of the old parties of Queen Isabella's reign side by side with men
who had played a part in the Revolution before they became
his active auxiliaries in the Alphonsoist propaganda in 1872
and 1873. This cabinet gave its chief attention for fifteen
months to the pacification of the Peninsula, adopting a Con-
servative and Catholic policy which contributed quite as much
as the great display of military resources to make the Pretender
lose adherents and prestige from the moment that his cousin
reached Madrid. The Church, the nobility and the middle
classes of the national character were very much pleased
with the Alphonsoist armies, led by Marshals Campos and Jovellar,
swept the Carlist bands from the right bank of the Ebro to
the Pyrenees, and took their last stronghold in the eastern prov-
ces, Cantavieja and Seo de Urgel. Not a few of the Carlist
leaders accepted bribes to go abroad, and others put their
swords at the disposal of the government for employment against
the Cuban rebels. Then all the forces of King Alphonso
under Marshal Quesada gradually closed round the remainder
of the Carlist army in Navarre and in the Basque Provinces at the beginning of 1876. The young king himself was present at the close of the campaign, which sent his rival a fugitive across the French frontier, with the few thousand followers who had clung to his cause to the very end.

Directly the Carlist War was over, the government used part of the large army at its disposal to reinforce the troops which had been fighting the Cuban insurgents since 1869.

The Cuban Insurrec-

The Cuban Insurrections. Marshal Jovellor was sent out to Havana as governor-

general, with Marshal Martinez Campos as commander-in-chief of the forces. In about eighteen months they managed to drive the rebels into the eastern districts of the island, Puerto Príncipe and Santiago de Cuba, and induced all but a few irreconcilable chiefs to accept a convention that became famous under the name of the peace treaty of Zanjón. Marshal Campos, who very soon succeeded Jovellor as governor-general of Cuba, for the first time held out to the loyalists of the island the prospect of reforms, fairer treatment at the hands of the mother country, a more liberal tariff to promote their trade, and self-government as the crowning stage of the new policy. He also agreed to respect the freedom of the maroons who had fled from their masters to join the Cubans during the ten years prior to 1868, and Spain very soon granting gradual emancipation to the remainders of the slaves who had stood by their owners. Marshal Campos was not allowed to carry out his liberal and conciliatory policy, which the reactionary party in the colony, el partido español, resented as much as their allies in the Peninsula.

Though much of his time and energies had been devoted to the re-establishment of peace at home and in the colonies from 1875 to 1880, Señor Canovas had displayed considerable activity and resolution in the re-organization of the monarchy. Until he felt sure of the early termination of the struggle with the pretender, he ruled in a dictatorial manner without the assistance of parliament. Royal decrees simply set aside most of the legislation and reforms of the Spanish Revolution. Universal suffrage alone was respected for a while and used as the means to call into existence the first Cortes of the Restoration in 1876. The electors proved, as usual, so docile, and they were so well handled by the authorities, that Canovas obtained a parliament with great majorities in both houses which voted a limited franchise to take the place of universal suffrage. Immediately afterwards they voted the constitution of 1876, which was virtually a sort of compromise between the constitution of 1845 in the reign of Isabella and the principles of the democratic constitution of the Revolution in 1869. For instance, liberty of conscience, established for the first time in 1860, was reduced to a minimum of toleration for Protestant worship, schools and cemeteries, but with a strict prohibition of propaganda and outward signs of faith. Trial by jury was abolished, on the plea that it had not worked properly. Liberty of associations and all public meetings and demonstrations were kept within narrow limits and under very close surveillance of the authorities. The municipal and provincial councils were kept in leash by intricate laws and regulations, much resembling those of France under the Second Empire. The political as well as the administrative life of the country was absolutely in the hands of the wire-pullers in Madrid; and their local agents, the governors, the mayors and the electoral potentates styled los Cacicues, were all creatures of the minister of the interior at the head of Castilian centralization. The constitution of 1876 had created a new senate, of which half the members were either nominees of the Crown or sat by right of office or birth, and the other half were elected by the provinces of the Peninsula and the colonies, the clergy, the universities and the learned societies and academies. The House of Deputies, composed of 46 members, was elected by the limited franchise system in Spain and by an even more restricted franchise in the colonies, five-sixths of the colonists being deprived of representation. From the beginning of the Restoration the great statesman, who was nicknamed at the time the Richelieu of Alphonso XII.'s reign, established a system of government which lasted for a quarter of a century. He encouraged the men of the Revolution who wanted to bow to accomplished facts and make the best of the restricted amount of liberty remaining, to start afresh in national politics as a Dynastic Liberal party. From the moment that such former revolutionists as Sagasta, Ulloa, Leon y Castillo, Camacho, Alonso Martinez and the marquis de la Vega de Armijo declared that they adhered to the Restoration, Canovas did not object to their saying in the same breath that they would enter the Cortes to defend as much as possible what they had achieved during the Revolution, and to protest and agitate, legally and pacifically, until they succeeded in re-establishing some day all that the first cabinet of Alphonso XII. had altered in the Constitution of 1869. The premier not only approved Sagasta's efforts to gather round him as many Liberals and Democrats as possible, but did not even oppose the return of Emilio Castelar and a few Republicans. He also countenanced the presence in the Cortes for the first time of 15 senators and 42 deputies to represent Cuba and Porto Rico, including a couple of home rulers. Thus Canovas meant to keep up the appearance of constitutional and parliamentary government with what most Spaniards considered a fair proportional representation of existing parties, except the Carlists and the most advanced Republicans, who only crept into the House of Deputies in some later parliaments. Canovas ruled his own coalition of Conservatives and Catholics with an iron hand, managing the affairs of Spain for six years with only two short interruptions, when he stood aside for a few months, just long enough to convince the king that the Conservative party could not retain its cohesion, even under such men as Marshals Jovellor and Campos, if he did not choose to support them.

In the early years of the Restoration the king and Canovas acted in concert in two most delicate matters. Alphonso XII. agreed with his chief counsellor as to the expediency of keeping military men away from active politics. Canovas boldly declared in the Cortes that the era of military pronunciamentos had been for ever closed by the Restoration, and the king reminded the generals more than once that he intended to be the head of the army. The king and his prime minister were equally agreed about the necessity of showing the Vatican and the Church sufficient signs of regard that would make it possible for them to cease with what most Spaniards considered a fair proportional representation of existing parties, except the Carlists and the most advanced Republicans, who only crept into the House of Deputies in some later parliaments. Canovas ruled his own coalition of Conservatives and Catholics with an iron hand, managing the affairs of Spain for six years with only two short interruptions, when he stood aside for a few months, just long enough to convince the king that the Conservative party could not retain its cohesion, even under such men as Marshals Jovellor and Campos, if he did not choose to support them.

going on almost continuously as long as the régime of moderate tariffs and commercial treaties lasted, i.e. until 1890.

In 1881 the Dynastic Liberals began to show impatience at being kept too long in the cold shade of opposition. Their chief, Sagasta, had found allies in several Conservative and Liberal generals—Campos, Jovellar, Lopez-Dominguez and Serrano—who had taken offence at the idea that Canovas wanted to monopolize power for his party. This party was said to be the dynastic and monarchical ballast, and in some sort the dynastic guarantees of liberalism in the eyes of the court. Canovas came to the conclusion that it was expedient for the Restoration to give a fair trial to the quondam revolutionists who coalesced under Sagasta in such conditions. He arranged with the king to meet a series of financial projects the acceptance of which by His Majesty would have implied a long tenure of office for the Conservatives, and so Alphonso XII. found a pretext to dissent from the views of his premier, who resigned on the spot, recommending the king to send for Sagasta. The Liberal administration knew that statesman formed lasted two years and some months. The policy of Sagasta in domestic affairs resembled that of Canovas. The Liberals had to act cautiously and slowly, because they perceived that any premature move towards reform or democratic legislation would not be welcome at court, and might displease the generals.

Sagasta and his colleagues therefore devoted their attention chiefly to the material interests of the country. They made several treaties of commerce with European and Spanish-American governments. They reformed the tariff in harmony with the treaties, and with a view to the reduction of the import duties by quinquennial stages to a fiscal maximum of 15% ad valorem. They undertook to carry out a general conversion of the consolidated external and internal debts by a considerable reduction of capital and interest, to which the bondholders assented. They consolidated the floating debt proper in the shape of a 4% stock redeemable in 40 years, of which £70,000,000 was issued in 1882 by Senor Camacho, the greatest Spanish financier of the century. Sagasta was not so fortunate in his dealings with the anti-dynastic parties, and the Republicans gave him much trouble in August 1885. The most irreconcilable Liberals knew that they could not expect much from popular risings in great towns or from the disaffected and anarchist peasantry in Andalusia, so they resorted to the old practice of barrack conspiracies, courting especially the non-commissioned officers and some ambitious subalterns. The chief of the exiles, Don Manuel Ruiz Zorilla, who had retired to Paris since the Restoration, organized a military conspiracy, which was sprung upon the Madrid government at Badajoz, at Seo de Urgel, and at Santo Domingo in the Ebro valley. This revolutionary outbreak was swiftly and severely repressed. It served, however, to weaken the prestige of Sagasta's administration just when a Dynastic Left was being formed by some discontented Liberals, headed by Marshal Serrano and his nephew, General Lopez-Dominguez. They were joined by many Democrats and Radicals, who seized this opportunity to break off all relations with Ruiz Zorilla and to adhere to the monarchy. After a while Sagasta resigned in order to let the king show the Dynastic Left that he had no objection to their attempting a mildly democratic policy, on condition that the Cortes should not be dissolved and that Sagasta and his Liberal majorities in both houses should grant their support to the cabinet considered over by Senor Posada Herrera, a former Conservative, of which the principal members were General Lopez-Dominguez and Señores Moret, Montero Rios and Becerra. The support of Sagasta did not last long, and he managed with skill to elbow the Dynastic Left out of office, and to convince all dissentients and free lances that there was neither room nor prospect for third parties in the state between the two great coalitions of Liberals and Conservatives under Sagasta and Canovas. When Posada Herrera resigned, the Liberals and Sagasta did not seem much distressed at the advent to power of Canovas in 1884, and soon
looked upon the rights of Spain over the Caroline Islands in the Pacific as so shadowy that he sent some German war-ships to take possession of a port in the largest island of the group.

The action of Germany caused great indignation in Spain, which led, in Madrid, to imposing demonstrations. The government got alarmed when the mob one night attacked the German embassy, tore the arms of the empire from the door of the consulate, and dragged the escutcheon to the Puerto del Sol, where it was burnt amid much uproar. The troops had to be called out to restore order. Alphonso alone remained cool, and would not listen to those who clamoured for a rupture with Germany. He decided to trust to diplomacy; and Spain made out such a good case for arbitration, on the ground of her ancient rights of discovery and early colonization, that the German emperor, who had no desire to imperil the dynasty and monarchy in Spain, agreed to submit the whole affair to the pope, who gave judgment in favour of Spain.

After his return to Madrid the king showed himself in public less than usual, but it was clear to all who came in contact with him that he was dying. Nevertheless, in Madrid, Canovas would not allow the press to say alud. Indeed, in the ten months before the death of Alphonso XII. the Conservative cabinet displayed unprecedented rigour against the newspapers of every shade. The Dynastic, Liberal and Independent press, the illustrated papers and the satirical weeklies fared no better than the Republicans, Socialists and Carlists, and in 60 days 1260 prosecutions were ordered against Madrid and provincial papers. At last, on the 24th of November 1885, the truth had to be admitted and on the morning of the 25th the end came.

It was no wonder that the death of a king who had shown so much capacity for rule, so much unselfish energy and courage, and so many amiable personal qualities, should have made Spaniards and foreigners extremely anxious about the prospects of the monarchy. Alphonso XII. left no male issue. He had two daughters, the princess of the Asturias, born in 1880, and the Infanta Maria Theresa, born in 1882. At the time of his death it had not been officially intimated that the queen was enceinte. The Official Gazette did not announce that fact until three months after the demise of the sovereign. On the 17th of May 1886, six months after the death of Alphonso XII., his posthumous son, Alphonso XIII., was born at the Royal Palace of Madrid. Six months before this event definitely settled the question of the succession to the throne, the royal family and its councillors assembled to take very important decisions. There could be no doubt that under the constitution of 1876 the widowed queen was entitled to the regency. Doña Maria Christina calmly presided over this solemn council, listening to the advice of Marshal Campos, always consulted in every great crisis; of Captain-General Pavia, who answered for the loyalty of the capital and of its garrison; of the duke de Sexto, the chief of the household; of Marshal Blanco, the chief of the military household; and of all the members of the cabinet and the presidents of the Senate and Congress assembled in the presence of the queen, the ex-queen Isabella, and the Infanta Isabella. All looked chiefly to Marshal Campos and Canovas del Castillo for statesmanlike and disinterested advice. The question was whether it would be expedient to continue the policy of the late king and of his last cabinet. Canovas assured the queen-regent that he was ready to undertake the task of protecting the new state of things if it was thought wise to continue the Conservativist policy of the late king, but in the circumstances created by his death, he must frankly say that he considered it advisable to send for Señor Sagasta and ask him to take the reins of government, with a view to inaugurate the regency under progressive and conciliatory policy.

Sagasta was summoned to El Pardo, and the result of his interview with the queen-regent, Canovas and the generals, was the understanding ever afterwards known as the pact of El Pardo, the corner-stone of the whole policy of the regency, and of the two great statesmen who so long led the great dynastic parties and the governments of Doña Christina. It was agreed that during the first years of the regency, Canovas and Sagasta would assist each other in defending the institutions and the dynasty. Sagasta made no secret of the fact that it was his intention to alter the laws and the constitution of the monarchy so as to make them very much resemble the constitution of the Revolution of 1868, but he undertook to carry out his reform policy by stages, and without making too many concessions to radicalism and democracy, so that Canovas and his Conservative and Catholic followers might bow to the necessities of modern times after a show of resistance and opposition. The generals assured the queen-regent and the leaders of the dynastic parties that the army might be counted upon to stand by any government which was sincerely determined to uphold the Restoration against Republicans and Carlists. Sagasta left the palace to form the first of several cabinets over which he presided continuously for five years. He took for colleagues some of the strongest and most popular statesmen of the Liberal party, virtually representing the three important groups of men of the Revolution united under his leadership—veteran Liberals like Camacho and Martínez, Carlists like Don Juan de la Cerda and Delgadillo; and Marshal Jovellor; and Democrats like Moncalvo, Monseñor Ríos and Admiral Beranger. The new cabinet convoked the Cortes elected under the administration of Canovas in 1884, and the Conservative majorities of both houses, at the request of Canovas, behaved very loyally, voting supplies and other bills necessary to enable the government to be carried on until another parliament could be elected in the following year, 1886.

Pending the dissolution and general election, Sagasta and his colleagues paid most attention to public peace and foreign affairs. A sharp look-out was kept on the doings of the Republicans, whose arch-agitator, Ruiz Zorilla, in Paris displayed unusual activity in his endeavours to persuade the Federals, the Intransigeants, and even the Opportunists of Democracy that the times were ripe for a venture. Ruiz Zorilla found no response from the Republican masses, who looked to Pi y Margall for their watchword, nor from the Republican middle classes, who shared the views of Salmeron, Azcarrate and Pedregal as to the inexpediency of revolutionary methods. Castiella, too, raised his eloquent protest against popular risings and barricaded conspiracies. The Carlists showed equal activity in propaganda and intrigues. Sagasta derived much benefit from the divisions which made democracy powerless; and he was able to cope with Carlists chiefly because the efforts of the pretender himself abroad, and of his partisans in Spain, were first restrained and then decisively paralysed by the influence of foreign courts and governments, above all by the direct interference of the Vatican in favour of the Spanish regency and of the successor of Alphonso XIII. The young and most impatient adherents of Carlism vainly pleaded that such an opportunity would not soon be found again, and threatened to take the law into their own hands and unfurl the flag of Dios, Patria, y Rey in northern and central Spain. Don Carlos once more showed his well-known lack of decision and dash, and the Carlist scare passed away. Pope Leo XIII. went even further in his patronage, for he consented to be the godfather of the posthumous son of Alphonso XII., and he never afterwards wavered in the steady sympathy he showed to Alphonso XIII. He was too well acquainted with the domestic politics of the Peninsula to suppose that Carlism could ever do more than disturb for a while the tranquillity of Spain. He did not wish to stake the interests of the Church on a cause which could only revive against her the old animosities of Spanish liberalism and democracy, so roughly displayed in the years 1876 and 1868. Doña Christina, apart from the dictates of gratitude towards the head of her Church for the kindness shown to her son and government, was a zealous Catholic. She proved all through her regency that she not only relied upon the support of the Vatican and of the prelates, but that she was determined to favour the Church
and the religious foundations in every possible way. Her purse was always open to assist convents, monasteries, and religious works and societies of all kinds, as long as they were under the management of the Church. She became regent when Spain had felt the consequences of the expulsion of the Jesuits and other religious orders from France after the famous Jules Ferry laws, which aimed at placing these orders more under state control, to which they declined to submit. They selected Spain as a field of Caste expatriates, and it was inferred that all the governments of the regency showed so much indulgence towards the Catholic revival thus started, that in less than a decade the kingdom was studied with more convents, monasteries, Jesuit colleges, Catholic schools, and foundations than had existed in the palmy days of the houses of Austria and Bourbon in the 17th and 18th centuries. A wave of Clericalism and ultra-Catholic influences swept over the land, affecting the middle classes, the universities and learned societies, and making itself very perceptible also among the governing classes and both dynastic parties, Liberals and Conservatives.

Next in importance, papal protection was the favourable attitude of all the European governments towards the queen-regent and, later, towards her son. The court and government of Germany vied with the Austrian and Italian royal families and governments in showing sympathy to the widow of Alphonso XII. Republican France and the tsar made as cordial demonstrations as Queen Victoria and her government, and Switzerland, Belgium, Holland and others followed suit. The Spanish foreign office received every assurance that friendly governments would watch over the Carlists and Republicans, to prevent them from using their territories as a basis for conspiracies against the peace of Spain. The statesmen of both dynastic parties, from the beginning of the regency, agreed to observe strict neutrality in European affairs, in order to avoid complications fraught with evil consequences for the monarchy and the dynasty in the unsettled state of the country. This neutrality was maintained until the close of the 19th century.

Sagasta conducted the first general election in 1886 much after the usual precedents. The Long Parliament of the regency was composed of considerable Liberal majorities in both houses, though Sagasta had allowed a larger share than Canovas was wont to do to the minorities, so much so that on the opposition benches the Republicans of various shades were represented by their most eminent leaders, the Carlists had a respectable group, and the Conservatives a strong muster, flanked by a group of dissidents. The first Cortes of the regency in five sessions did really good and substantial work. A civil code was carefully drawn up by Señor Alonso Martinez, in order to consolidate the very heterogeneous ancient legislation of the monarchy and the local laws of many provinces, especially Catalonia, Aragon, Valencia, Navarre, and the Basque territory. Trial by jury was re-established for most crimes and offences. The laws regulating the rights of association and public meeting, the liberty of the press, and other rights of the subject were reformed on liberal and more tolerant lines. Finance and trade received attention. Some commercial treaties and agreements were made, including one with Great Britain, which proved highly beneficial to home trade, and the tariff was altered, in spite of much resistance on the part of the Protectionists. In his progressive policy Sagasta was actively and usefully supported by the advice of the president of Republicans, Emilio Castelar, who recommended his partisans to vote with the Liberal party, because he confessed that bitter experience had taught him that liberties and rights were better attained and made stable by pacific evolution than by revolution. He laid most stress upon this axiom when, in September 1886, Ruiz Zorilla suddenly sprang upon Sagasta a military and revolutionary movement in the streets and barracks of Madrid. The military authorities acted with promptitude, the rebels being pursued, dispersed and arrested. General Marina and several other officers were condemned to death by court martial, but Queen Christina commuted the sentence into penal servitude, and the ministers of war and marine retired from the cabinet in consequence. Very shortly afterwards, another war minister, General Castillo, attempted to strike at the root of military insubordination, and simultaneously in every garrison of the kingdom the senior sergeants, more than 1000 in all, were given their discharge and ordered to start for their homes on the spot. The lesson produced a good result, as no trace of revolutionary work revealed itself in the ranks of Republicans and at any rate more was heard of it. As time wore on, Sagasta found it difficult to maintain discipline in the ranks of the Liberal party. He was obliged to reconstruct the cabinet several times in order to get rid of troublesome colleagues like General Cassola, who wanted to make himself a sort of military dictator, and Camacho, whose financial reforms and taxation schemes made him unpopular. He had more often to reorganize the government in order to find seats in the cabinet for ambitious and impatient worthies of the Liberal party—not always with success, as Señor Martos, president of the Congress, and the Democrats almost brought about a political crisis in 1889. Sagasta cleverly attempted to resign and stand aside, so that Señor Alfonso Martinez might vainly attempt to form an intermediary cabinet. Canovas, who was consulted by the queen when Alonso Martinez failed, faithfully carried out the pact of El Pardo and advised Her Majesty to send for Sagasta again, as he alone could carry out what remained to be done of the Liberal programme. Sagasta reconstructed his ministry for the last time, and announced his intention to make the re-establishment of universal suffrage the crowning act of the Liberal policy, knowing very well that he would thus rally round him all the Liberals, Democrats and Republicans of the last session of the Long Parliament. The Suffrage Bill was carried through the Senate and Congress in the spring of 1890 after protracted debates, in which the Conservatives and many military politicians who had previously been regarded as the allies of Sagasta did their best to obstruct the measure. Marshals Campos, Jovellar and Novaliches, and Generals Pavia, Primo de Rivera, Daban and others, were angry with Sagasta and the Liberals not only because they deemed their policy too democratic, but because they ventured to curb the insubordinate attitude of general officers, who shielded themselves behind the immunities of their senatorial position to write letters to the war minister on purely professional questions. Spanish generals of pronunciamiento fame thought it perfectly logical and natural that sergeants and subalterns should be shot or sent to penal servitude for acts of indiscretion, but if an insubordinate general was sent to a fortress under arrest for two months they publicly demonstrated their sympathy with the offender, made angry speeches against their hierarchical chief, the war minister, in the Senate, and dared to call upon the queen-regent to make representations, which unfortunately were listened to, according to the worst precedents of the Spanish monarchy. The increasing violence of the Conservative press and opposition, the divisions developing in the ranks of liberalism, and the restlessness of the agricultural protectionists led by Señor Gamazo, did not weigh so much in the balance at court against Sagasta as the aggressive attitude of the military politicians. Sagasta held on as long as was necessary to secure the promulgation of the universal suffrage law, but he noticed that the queen-regent, when he waited upon her for the despatch of public business, showed almost daily more impatience for a change of policy, until at last, in July 1890, she peremptorily told him that she had considered the time had come for calling the Conservatives and their military patrons to her councils. Sagasta loyally furnished the queen with a constitutional pretext for carrying out her desire, and tendered the resignation of the whole cabinet, so that Her Majesty might consult, as usual, the party leaders and generals on the grave question of the expediency of entrusting to new ministers or to the Liberals the mission of testing the new electoral system. Queen Christina on this occasion acted exactly as she henceforth did in all ministerial crises. She slowly consulted the magnates of all parties with apparent impartiality, and finally adopted the course
which it was an open secret she had decided upon in loco precedent beforehand.

Canovas gathered round him most of the prominent Conservative and Catholic statesmen. The first step of the new cabinet was calculated to satisfy the protectionist aspirations which had spread in the kingdom about the same time that most Continental countries were remodelling and raising their tariffs. The Madrid government used an authorization which Sagasta had allowed his Long Parliament to vote, to request Gamazo the Liberal representatives of agricultural interests, empowering the government to revise and increase all tariff duties not covered by the then existing treaties of commerce. This was the case with most of the products of agriculture and with live stock, so Canovas and his finance minister made, by royal decree, an enormous increase in the duties on these classes of imports, and particularly on breadstuffs. Then, in 1891, they denounced all the treaties of commerce which contained clauses stipulating most-favoured-nation treatment, and they prepared and put in force in February 1892 a protectionist tariff which completely reversed the moderate free-trade policy which had been so beneficial to the foreign commerce of Spain from 1868 to 1892. Not a few nations retaliated with higher duties upon Spanish exports, and France raised her wine duties to such an extent that the exports of wines to that country dropped from £12,500,000 before 1892 to £2,400,000 in 1893 and the following years. The effect of the protectionist policy was so disastrous that the prohibitionary clauses were soon sharply felt in Spain. Foreign exchanges rose, exports decreased, the railway traffic declined, and the commercial classes and consumers of foreign goods and products were loud in their protests. Industrial interests alone benefited, and imported more raw materials, chemicals, and coal and coke, which naturally influenced the exchanges adversely. Spain only attempted to make new treaties of commerce with Holland, Norway, Sweden, Denmark, and Switzerland. The Great Powers contented themselves with securing by agreements the same treatment for their commerce in Spain as that granted by those five treaties. The Protection of Madrid in 1893 wrecked a treaty of commerce with Germany in the Senate; and Spain subsequently persevered in her protectionist policy. During his two and a half years' stay in office Canovas had not so much trouble with the opposition as with the divisions which sprang up in the Conservative ranks, though he fancied that he had managed the general election in 1891 so as to secure the customary docile majorities. The split in the Conservative camp originated in the rivalry between the two principal lieutenants of Canovas, Romero Robledo and Francisco Silvella. The latter and a strong and influential body of Conservatives, chiefly young politicians, discontented from the easy-going views of Romero Robledo and Canovas on the expediency of reforms to correct the notorious and old-standing abuses and corruption of the municipalities, especially of Madrid. When Canovas found himself deserted on so delicate a matter by a numerous section of his party, he resigned, and advised the queen to send for Sagasta and the Liberals.

Sagasta took office very reluctantly, as he considered a change of policy premature. He conducted the general election with much regard for the wishes of the opposition, and though he had to have more than 170, the Conservatives getting nearly 100 and the Republicans 30. He had to settle some knotty questions, foremost a conflict with Morocco, which was the consequence of the aggression of the unruly Rif tribes upon the Spanish outposts around Melilla. Reinforcements were tardily sent out; and in a second attack by the Arabs the Spanish forces lost heavily, and their commander, General Margallo, was killed. Public opinion was instantly fired, and the press called so loudly for revenge that the government sent to Melilla no less a personage than Marshal Campos, at the head of 20 generals and 25,000 men. The sultan of Morocco lost no time in censoring the behaviour of the Rif tribes, and in promising that he would chastise them. Marshal Campos was sent to Fez to make a treaty, in which he obtained ample redress and the promise of an indemnity of £800,000, which Morocco punctually paid.

Colonial affairs gave Sagasta much to do. He had given seats in his cabinet to Señor Antonio Maura as colonial secretary and to Señor Gamazo, his brother-in-law, Ministry of Finance and minister. These two moderate Liberals acted in concert to grapple with colonial questions, which in 1894 had assumed a very serious aspect. Spain had received many ominous warnings. Marshal Campos, on returning from Cuba in 1879, had advocated some concessions to satisfy the legitimate aspirations of the majority of the colonists. In 1886, in the first parliament of the regency, Cuban autonomist deputies divided the house on a motion in favour of home rule and of an extension of the franchise in Cuba. This motion was negatived by all the Conservatives, by most of the Dynamic Liberals and by some of the Republicans. The majority of Spaniards were kept by the government and the press quite in the dark about the growth of disaffection in Cuba, so that they were loath to listen to the few men, soldiers and civilians, courageous enough to raise the note of alarm during the ten years before the final catastrophe. For no other reason did the minister for the colonies, Señor Maura, in 1894 fail to convince the Cortes, and even the Liberal party, that his very moderate Cuban Home Rule Bill was an indispensable and wise, though tardy, attempt to avert a conflict which many plain symptoms showed to be imminent in the West Indies. Maura was warmly supported in Congress by the Cuban home rulers and by some far-sighted Liberals and Republicans. Nevertheless, his bill did not find favour with the Conservatives or the majority of the Liberals, and Sagasta, trimming according to his invertebrate habit, found a pretext to get rid of Maura and Gamazo. In the place of Maura he found a more pliant minister for the colonies, Señor Abarzuza, who framed a Cuban Reform Bill so much short of what his predecessor had thought an irredicible minimum of concessions, that it was censured in Havana by all the colonial Liberals and home rulers, and by their representatives in Madrid. The latter at the last moment recorded their votes in favour of the Abarzuza Bill when they perceived that a strange sort of fourteen-hour presentiment was about to make all the Spanish parties vote this insufficient reform. Before it could be promulgated, the tidings came of a separatist rising in the old haunts of Creole disaffection near Santiago de Cuba. Sagasta sent about 12,000 men to reinforce the 15,000 soldiers in Cuba under General Callaga, and was preparing more when a characteristically Spanish ministerial crisis arose. The subalterns of the Madrid garrison took offence at some articles published by Radical newspapers; and they attacked the editorial office. Neither the minister nor the commanders of the garrison chose to punish the offenders, and sooner than endorse such want of discipline, Sagasta and the Liberal party once more made way for Canovas. A very few days after he assumed office Canovas received information concerning the spread of the rising in Cuba which induced him to send out Marshal Campos with 30,000 men. He allowed Marshal Campos much liberty of action, but dissented from his views on the expediency of allowing him to offer the loyalists of Cuba as much home rule as would not clash with the supremacy of Spain. The prime minister declared that the Cubans must submit first, and then the mother country would be generous.

Before a year had passed, in view of the signal failure of Marshal Campos, the Madrid government decided to send out General Weyler, who had made himself famous in the Philippines and at Barcelona for his stern and cruel procedure against disaffection of every kind. He showed the same merciless spirit in dealing with the Cubans; and he certainly cleared two-thirds of the island of Creole hands, and stamped out disaffection by rigorous military operations and by obliging all the non-combatants who sympathized with the rebels in arms to elect between joining them in the bush, General Weyler's Campaign. La Manigua, or residing within the Spanish lines. This system might probably have succeeded if the United States had not
confronted the sending of supplies of every kind to the rebels, and if American diplomacy had not again and again made representations against Weyler's ruthless policy. Canovas so fully comprehended the necessity of averting American intervention and of the American minister in Madrid, Hannis Taylor, and laid before the Cortes a bill introducing home rule in Cuba on a more liberal scale than Maura, Abarzuza and Sagasta had dared to suggest two years before. Canovas did not live to see his scheme put into practice, as he was assassinated by an anarchist at the hotel Santaga Maria de the Basque Provinces, on the 9th of August 1897. The queen-regent appointed General Azcarraga, the war minister, as successor to Canovas; and a few weeks later President McKinley sent General Woodford as representative of the United States at the court of Madrid. At the end of September 1897 the American minister placed on record, in a note handed by him at San Sebastian to the minister for foreign affairs, the duke of Teteu, a strongly-worded protest against the state of things in Cuba, and demanded in substance that a stop should be put to Weyler's proceedings, and some measures taken to pacify the island and prevent the prolongation of disturbances which interfered with American interests. Less than a fortnight after this note had been delivered, the Conservative cabinet resigned, and the queen-regent asked Sagasta to form a new administration. The Liberal government recalled Weyler, and sent out, as governor-general of Cuba, Marshal Blanco, a conciliatory and prudent officer, who agreed to carry out the home-rule policy which was concerted by Señor Moret and by Sagasta, with a view to obtain the goodwill of the president of the United States. If things had not already gone too far in Cuba, and if public opinion in the United States had not exercised insatiable pressure on both Congress and president, the Moret home-rule project would probably have sufficed to give the Cubans a fair amount of self-government. All through the winter of 1897-1898 the Madrid government took steps to propitiate the president and his government, even offering them a treaty of commerce which would have allowed American commerce to compete on equal terms with Spanish imports in the West Indies and defeat all European competition. But the blowing up of the American cruiser "Maine" in the port of Havana added fuel to the agitation in the United States against Spanish rule in Cuba. When Congress met in Washington the final crisis was reached on an intrenched American intervention. The European mediation, to the pope, to courts and governments. All, with the exception of Great Britain, showed sympathy for the queen-regent and her government, but none were disposed to go beyond purely platonic representations in Washington. At last, on the 20th of April 1898, when the Spanish government learned that the United States minister, General Woodford, had been instructed by telegraph to present an ultimatum demanding the cessation of hostilities in Cuba, with a view to prepare for the evacuation of the island by the Spanish forces, Sagasta decided to give General Woodford his passports and to break off official relations with the United States. It was an open secret that this grave decision was not taken at the cabinet council presided over by the queen without a solemn protest by Señor Moret and the ministers of war and marine that the resources of Spain were totally inadequate for a struggle with the United States. These protests were overruled by the majority of the ministers, who invoked dynastic and monarchical considerations in favour of a desperate stand, however hopeless, in defence of the last remnants of the colonial empire of Spain. Reckless as was the course adopted, it was in touch with the feelings of the majority of a nation which had been to the very end deceived by the government and by the press not only in regard to its own resources, but also in regard to those of the United States and of the colonists in arms in Cuba and in the Philippine Islands. The sequel is soon told. The Spanish fleet in the Far East was defeated in Manila Bay by Admiral Dewey. Admiral Cervera's squadron was destroyed outside the Bay of Santiago de Cuba by the American fleet under Admirals Sampson and Schley. All communication between Spain and her colonies was thus cut off. An American expedition landed near Santiago, and the Spanish garrison surrendered after a fortnight's show of resistance. Very shortly afterwards, at the end of July, Spain sued for peace through the mediation of French diplomacy, which did not obtain much from President McKinley. It was agreed that hostilities should cease on sea and land, but that Spain should evacuate Cuba and Porto Rico pending the negotiations for a peace treaty which were to begin in Paris at the end of September 1898. In the meantime Manila and its garrison had surrendered to the Americans. The agreement of the 9th August was signed by M. Cambon, the French ambassador in Washington, in the name of Spain, and the American minister in the New World must be considered at an end, and that the fate of the Philippines would be settled at the Paris negotiations. Unfortunately, Spain indulged in the illusion that America would perhaps respect her rights of sovereignty in the Philippine Islands, or pay a considerable sum for their cession and recognize the debts of Cuba and of the Philippines. The American commission, presided over by secretary Day in Paris, absolutely refused to admit the Spanish contention that the United States, for the new administration in Cuba and the Philippines should be saddled with several hundred millions of dollars of debts, contracted by the colonial treasuries and guaranteed by Spain, almost entirely to maintain Spanish rule against the will of the Cubans and Filipinos. Spain could not help assenting to a treaty by which she renounced unconditionally all her rights of sovereignty over Cuba and Porto Rico and ceded the Philippine and Sulu Islands and the largest of the Marianne Islands in consideration of the payment of four millions sterling by America. Thus ended a struggle which only left Spain the Carolines and a few other islands in the Pacific, which she exchanged for territory in Germany in 1899 for $2,000,000, and a couple of islands which were left out in the delimitation made by the Paris peace treaty of the 12th of December 1898, and for which America paid $2,000,000 in 1900.

The consequences of the war and of the loss of the colonies were very serious for Spanish finance. The national debt, which consisted before the war of $234,866,500 of external and internal consols and redeemable debts, and $4,230,000 of home floating debt, was increased by $16,710,000 of Cuban and Philippine debts, which the U.S. had guaranteed and, by $60,000,000 of former debts contracted at a high rate of interest, and with the national guarantee, to meet the expenses of the struggle with the colonies and of the war with the United States. These additional burdens rendered it necessary that taxation and the budget should be thoroughly reorganized. Sagasta and the Liberal party would gladly have undertaken the reorganization of Spain and her finances, but the issue of the war and the unavoidable peace treaty had so evidently damaged their popularity in the country and their credit at court, that the government seized the pretext of an adverse division in the Senate to resign. The Liberals left office after having done all that was morally and materially possible, considering the extremely difficult, indeed inextricable, situation in which they found the country in October 1897. The task of reorganization was confided by the queen-regent to Señor Silvela, who had been universally recognized as the leader of the Conservatives and Catholics after the death of Canovas del Castillo. Silvela endeavoured to unite in what he styled a Modern Conservative party the bulk of the followers of Canovas; the Ultramontanes, who were headed by General Polavieja and Señor Pidal; the Catalan Regionalists, whose leader, Duran y Lasa, became a cabinet minister; and his own most prominent of whom the most prominent were the home secretary, Señor Dato, and the talented and energetic finance minister, Señor Villaverde, upon whose shoulders rested the heaviest part of the task of the new cabinet. Silvela lacked the energy and decision which had been the characteristics of Canovas. He behaved constantly like a wary and cautious trimmer, avoiding all extreme measures, shaking off compromising allies like the Ultramontanes and the Regionalists, elbowing out of the cabinet
General Polavieja when he asked for too large credits for the army, taking charge of the ministry of marine to carry out reforms that no admiral would have ventured to make for fear of his own comrades, and at last dispensing with the services of the ablest man in the cabinet, the finance minister, Senor Villaverde, when the sweeping reforms and measures of taxation which he introduced raised a troublesome agitation among the taxpayers of all classes. Villaverde, however, had succeeded in less than eighteen months in giving a decisive and vigorous impulse to the reorganization of the budget, of taxation and of the home and colonial debts. He resolutely reformed all existing taxation, as well as the system of assessment and collection, and before he left office he was able to place on record an increase of close upon three millions sterling in the ordinary sources of revenue, and the abolition of the taxation of the unemployed, complete; in fact, he exacted even more sacrifices from the bondholders than from other taxpayers. The amortization of the home and colonial debts was suppressed, and the redeemable debts of both classes were converted into 4% internal consols. The interest on all colonial debts ceased to be paid in gold, and was paid only in pescetas, like the rest of the internal debts, and like the external debt held by Spaniards. Alone, the external debt held by foreigners continued to enjoy exemption from taxation, under the agreement made on the 28th of June 1882 between the Spanish government and the council of foreign bondholders, and its coupons were paid in gold. The Cortes authorized the government to negotiate with the foreign bondholders, with a view to cancelling that agreement. This, however, they declined to do, only assenting to a conversion of the 4% external debt into a 3 1/2% stock redeemable in sixty-one years.

After parting with Villaverde, Silvela met with many difficulties, and had much trouble in maintaining discipline in the heterogeneous ranks of the Conservative party. He had to proclaim not only such important provinces as Barcelona, Valencia and Bilbao, but even the capital of Spain itself, in order to check a widespread agitation which had assumed formidable proportions under the direction of the chambers of commerce, industry, navigation and agriculture, combined with about 300 middle-class corporations and associations, and supported by the majority of the gilds and syndicates of taxpayers in Madrid and the large towns. The drastic measures taken by the government against the National Union of Taxpayers, and against the newspapers which assisted it in advocating resistance to taxation until sweeping and proper retribution had been effected in the national expenditure, checked this campaign in favour of reform and retribution for a while. Silvela's position in the country had been much damaged by the very fact of his policy having fallen into the hands of what the nation expected in the shape of reform and retribution. At the eleventh hour he attempted to retrieve his mistake by vague promises of amendment, chiefly because all the opposition groups, above all Sagasta and the Liberals, announced their intention of adopting much the same programme as the National Union. The attempt was unsuccessful, and on the 6th of March 1901 a Liberal government, under the veteran Sagasta, was once more in office.

Conflicting Tendencies.

...
situation; and order was restored. The methods by which this result had been achieved were the subject of violent attacks on the government in the Cortes, and on the 13th of March Sagasta resigned, but only to resume office five days later. He now returned to the question of the religious orders, and on the 9th of April issued a decree proclaiming his intention of enforcing that of the 10th of July 1901. The attitude of the Church was practically one of defiance. The nuncio, indeed, announced that the papacy would be prepared to discuss the question of authorization, but only on condition that all demands for such authorization should be granted. To avoid a crisis at the time when the young king was about to come of age, the government yielded; and on the 10th of May Sagasta announced that a modus vivendi with the Vatican had been established.

King Alphonso XIII, whose enthronement took place with all the antique ceremonial on the 17th of May, was himself at the outset under clerical and reactionary influences, and his contemptuous treatment of ministers—who at the ceremonial functions were placed wholly in the background—seemed to argue an intention of ruling personally under the advice of the court camarilla. This impression, due doubtless to the king's extreme youth and inexperience, was in the end to renew the Liberal government still further at the time. Señor Antonio Maura y Montanes, who proved himself later a statesman of exceptional character, seduced to the Conservatives. On the 7th of November Sagasta himself resigned, resumed office temporarily on the 14th, and handed in his final resignation on the 3rd of December. On the 6th of December a Conservative cabinet was formed under Señor Silvela, Señor Villaverde, pledged to a policy of retraction, taking the portfolio of finance.

The death of Sagasta, on the 5th of January 1903, temporarily broke up the Liberal party, which could not agree on a leader; its counsels were directed for the time by a committee, consisting of Señores Montero Ríos and Moret, the marquis de la Vega de Armijo, Señor Salvador and Count Romanones. The Republicans, under Salmeron, also had their troubles, due to the growing influence of Socialism; and, finally, the Conservatives were distracted by the rivalries between Silvela, Villaverde and Maura. In the country, meanwhile, the unrest continued. At Barcelona the university had to be closed to stop the revolutionary agitation of the students in April there were serious riots at Salamanca, Barcelona, and Madrid. The result of the new elections to the Cortes, declared on the 26th of April, revealed tendencies unfavourable to the government and even to the dynasty; the large towns returned 34 Republicans. A ministerial crisis followed; Maura resigned; and though the elections to the senate resulted in a large Conservative majority, and though in the lower house a vote of confidence was carried by 183 to 81, Silvela himself resigned shortly afterwards. Señor Villaverde was now called upon to form a cabinet. His government, however, accomplished little but the suppression of renewed troubles at Barcelona. His programme included drastic proposals for financial reform, which necessarily precluded an adventurous policy abroad or any additional expenditure on armaments, principles which necessarily brought him into conflict with the military and naval interests. On the 3rd of December Villaverde was forced to resign, his successor being Señor Maura. Meanwhile, on the 24th of November, the Liberal party had been reconstructed, as the Democratic party, under Señor Montero Ríos.

Señor Maura, as was to be proved by his second administration, represented the spirit of compromise and of conservative reform. His position now was one of singular difficulty. Though a Catholic, he had to struggle against the clerical coterie that surrounded the king, and had not influence enough to prevent the appointment of Monsignor Nozalea, formerly archbishop of Manila and a prelate of notoriously reactionary views, to the important see of Valencia. His concessions to the demands of the ministers of war and marine for additional estimates for the army and navy exposed him to the attacks of Villaverde. In the Cortes fiercer criticism was provoked by the measure, laid by him before the Cortes on the 23rd of June, for the revision of the concordat with Rome, and more especially by the proposal to raise a loan at 4% to indemnify the religious orders for their estates confiscated during the Revolution. Violent scenes greeted the attempt of the government to procure the suspension of the parliamentary immunities of 140 deputies, accused or suspected of more or less treasonable practices, and when, on the 4th of October, the Cortes reopened after the summer recess, Señor Moret, resolutely seating in the lower house, opened an attack on the ministry for their attempted breach of its privileges. Furious debates followed on this, and on the subject of Maura's financial proposals, which were attacked by the Conservative Villaverde and the Liberal Moret with impartial heat. On the 14th of December Maura resigned an impossible task and King Alphonso made General Azcarraga head of a narrowly Clerical-Conservative cabinet.

The new ministry, confronted by a rapidly spreading revolution, was faced by a rising backed by royal censure and famine in Andalusia, survived scarcely a month. On the 26th of January 1905 Azcarraga resigned, and two days later Señor Villaverde once more became prime minister. He was in no hurry to summon the Cortes, partly because the elections to the provincial councils were due in March, and these had to be manipulated so as to ensure the return of a Senate of the right colour, partly because the convocation of the Cortes seemed at best a necessary evil. Already the discredit of parliamentary government was being evidenced in the increased personal power of the young king. Alphonso was now shaking himself loose from the influence of the reactionary court, and was beginning to display a disconcerting interest in affairs, information about which he was apt to seek at first hand. The resignation of the see of Valencia by Archbishop Nozalea was a symptom of the new spirit. This was none the less distasteful to the Republicans, who thundered against personal government, and to the Liberals, who clamoured for the Cortes and the budget. The Cortes met at last on the 14th of June, and the upshot justified Villaverde's reluctance to meet it. Attacked by Maura and Moret alike, the strange ministry (June) accused itself of acting through personal pique; on a motion of confidence, however, he was defeated by 204 votes to 54, and resigned. He died on the 15th of July following, within a few weeks of his former leader and colleague Silvela.

The Liberals now once more came into power under Señor E. Montero Ríos, Señor Moret having refused the premiership. The government programme, announced with a view to influencing the impending elections, included financial reform, reform of the customs, modification of the octrois, and the question of the concordat with Rome. The result of the elections was a degrading influence of the reactionary court, and was beginning to display a disconcerting interest in affairs, information about which he was apt to seek at first hand. premiership; he took over Señor Echarry's budget, while General Weyler was replaced at the war office by General Luque.

The great constitutional parties had broken up into quarrelling groups just at the time when, as it seemed, the parties of reaction were concentrating their forces. Not the least ominous symptom was the attitude of the officers, who, irritated by newspaper attacks on their conduct in Catalonia more especially, demanded that all crimes against the army should be tried by the councils of war. The prolonged controversies to which this gave rise were settled on the 18th of March by a compromise passed by the Cortes; under this act all cases of press attacks on officers were to be tried by the courts martial, while those against the army generally and the national flag were still to be reserved for the civil courts. The singular weakness of the government really rendered absurd the attempts of the Cortes to regulate the functions of the civil power would have led to its speedy downfall, but for the truce during the festivities connected with the marriage of the king with Princess Victoria Eugénie of Battenberg, which took place on the 31st of May.

The king's marriage was in many respects significant. In spite of the young queen's "conversion" and the singular distinction conferred on her by the papal gift of the golden rose, the "Protestant" alliance marked a further stage in Alphonso XIII.'s emancipation from the tutelage of the Clerical-Conservative court. In the Clerical-Conservative court was head of a cabinet with a frankly anti-clerical programme, including complete liberty of worship, the secularisation of education, and the drastic regulation of the right of association. The signature by the king of an ordinance giving legal validity to the civil marriages of Catholics aroused a furious agitation among the clergy, to which bounds were only set by the threat of the government to prosecute the bishop of Tuy and the chapter of Cordova. In the session 1906-1907 the most burning subject of debate was the new Associations Law drawn up by Señor Davila. Even in the Liberal ranks the question aroused furious differences of opinion; Señor Montero Ríos, the president of the senate, denounced the "infamous attacks on the church"; the government itself showed a wavering temper in entering on long and futile negotiations with the Vatican; while in January 1907 the cardinal archbishop of Toledo presented a united protest of the Spanish episcopate against the proposed law. This and other issues produced complete disunion in the Liberal party. Already, on the 27th of November, Lopez-Dominguez had resigned; his successor, Señor Menéndez, had brought forward the bill and been succeeded in his turn, on the 4th of December, by marquis de la Vega de Aranjuez. The question was now mooted in the cabinet of dropping the Associations Law; but on the 21st of January Señor Canalles, president of the lower house, who was credited with having inspired the bill, publicly declared that in that event he would cease to support the government. By the 24th the cabinet had resigned, and a Conservative government was in office under Señor Maura as premier. The administration of Señor Maura, which lasted till the 21st of October 1905 marks an important epoch in the history of modern Spain. The new premier was no mere party politician, but a statesman who saw the need of his country, on the one hand for effective government, on the other hand for education, so as to enable it ultimately to govern itself. Though a sincere Catholic, he was no Clerical, as was proved by his refusal to withdraw the ordinance on civil marriage. The main objects that he set before himself were, firstly, the maintenance of order; secondly, the reform of local government, so as to destroy the power of the Caequies and educate the people in their privileges and responsibilities. The dissolution of the Cortes produced a certain rearrangement of parties. The Liberal groups, as usual when in opposition, coalesced. The Republicans, on the other hand, split into sections; in Barcelona, Tarragona and Gerona there was a group of representatives demanding the abdication of the king. Señor Maura, however, was the rump of Solidarists, consisting of Separatists, Carlists and Socialists. The elections in April resulted in a sweeping Conservative victory—the government secured a majority in the lower house of 88 over all other groups combined. As for the "dynastic opposition," it was reduced to a rump of 66 members, a result so unsatisfactory from the point of view of the monarchy that the government offered to quash certain Conservative returns in order to provide it with more seats. The dynastic opposition, however, considered that it had been unfairly dealt with in the conduct of the elections; and though, out of consideration for the dynasty (an heir to the throne having been born on the 10th of May), they attended the opening of the Cortes on the 13th of May, the Liberals refused to take part in the session that followed, which lasted till the 29th of July. When, however, the Cortes reopened on the 10th of October, the dynastic opposition was once more in its place. It was now that Señor Maura brought in his Local Administration Bill, a measure containing 429 clauses, the main features of which were that it largely increased the responsibility of the local elected bodies, made it compulsory for every elector to vote, and did away with official interference at the polls. The bill met with strenuous opposition, and on the 23rd of December 1907 the Cortes adjourned without its having been advanced. At the close of the year an Anarchist outrage gave the excuse for the proclamation of martial law in Barcelona, and after the opening of the new session of the Cortes (January 23, 1908) a bill was introduced into the senate giving to the government the most drastic powers for the suppression of Anarchism. Its provisions practically amounted to a complete suspension of the guarantees for civil liberty, it met with the most strenuous opposition, and its final passing by the Senate (May 9) was followed by a serious crisis. Two months later (March 22-23) King Alphonso, with characteristic courage, had paid a surprise visit to Barcelona, and the general enthusiasm of his reception seemed to prove that the disaffection was less widespread or deep than had been supposed. In the circumstances, Señor Maura dropped the Suppression Bill, and the king issued an ordinance re-establishing constitutional guarantees in Catalonia. This good feeling was unfortunately not destined to be of long duration; and in the following year the struggle between the antagonistic forces in Spain once more produced a perilous crisis. The Local Administration Bill, after being debated for two sessions, passed the lower house on the 13th of February 1909, having at the last moment received the support of the Liberal Señor Moret, though the Radicals as a whole opposed it as gratifying to Señor Cambó, the Regionalist leader, and therefore as tending to disintegration. Though ruling in the spirit of an enlightened despotism rather than in that of a constitutional government, Señor Maura had succeeded in doing a notable work for Spain. It was inevitable that in doing so he should incur unpopularity in many quarters. His efforts to reconstruct the Spanish navy were attacked both by the apostles of retreatment and by those who saw in the shipbuilding con- tracted by a dubious favour of the foreigner; the Marine Industries Protection Act was denounced as favouring the large shipowners and exporters at the expense of the smaller men; the
Compulsory Education Act as "a criminal assault on the rights of the family." His ecclesiastical policy also exposed him to the fate of those who take the middle way; the Liberals denounced the minister of education, Don F. Rodriguez San Pedro, for making concessions to the teaching orders, while the archbishops of Burgos and Santiago de Compostella fulminated against the government for daring to tax the congregations. In his reforming work Señor Maura had an active and efficient lieutenant in the minister of the interior, Señor La Cierva. Under his auspices laws were passed reforming and strengthening the police force and establishing trial tribunals, regulating the work of women and children, introducing Sunday rest, early closing, and other reforms. In short, the government, whatever criticism might be levelled at its methods, had accomplished a notable work, and when on the 6th of June 1909 the Cortes adjourned, its position seemed to be assured.

Its downfall was ultimately due to the development of the crisis in Morocco. This is described elsewhere (see Morocco: History); here it is only proposed to outline the effects of its reaction upon the internal affairs of Spain.

The trouble originated in the attack upon the Moors by the Rif tribesmen upon the workmen engaged on the railway being built to connect Melilla with the mines in the hills, held by Spanish concessionaires. The necessity for strengthening the Spanish forces in Africa had for some time been apparent; but Señor Maura had not dared to face the Cortes with a demand for the necessary estimates, for which, now that the crisis had become acute, he had to rely on the authorization of the council of state. The spark was put to the powder by the action of the war minister, General Linares, in proposing to organize a new field force by calling out the Catalan reserves. This sum up to the memories of the useless miseries of former over-sea expeditions. On the 26th of July a general strike was proclaimed at Barcelona, and a movement directed at first against the "conscription" rapidly developed into a revolutionary attack on the established order in church and state.

Barcelona Rising of July 1909.

The city, a collaxis genitum, was seething with dangerous elements, its native proletariat being reinforced by emigrants returned embittered from failure in South America and a cosmopolitan company of refugees from justice in other lands. The mob, directed by the revolutionary leaders, took July the11th, seizing and occupying the banks and churches. From the city the revolutionary movement spread to the whole province. In Barcelona the rising was suppressed after three days' street fighting (July 27-29).

On the 28th martial law was proclaimed throughout Spain; and now began a military reign of terror, which lasted until the end of September. In the fortress of Monjuich in Barcelona were collected, not only rioters caught red-handed, but many others—notably journalists—whose opinions were obnoxious. The greatest sensation was caused by the arrest, on the 31st of August, of Señor Ferrer, a theoretical anarchist well known in many countries for his anti-clerical educational work and in Spain especially as the founder of the "lay schools." He was accused of being the chief instigator of the Barcelona rising, was tried by court martial (Oct. 11-13), and shot. This tragedy, which rightly or wrongly aroused the most widespread indignation throughout Europe, produced a ministerial crisis in Spain. The opening of the October session of the Cortes was signalized by a furious attack by Señor Moret on Señores Maura and La Cierva, who were accused of having sacrificed Ferrer to the resentment of their clerical followers. At the government itself lay the seeds weakened by the news of Marshal Marina's reverse in Morocco (Sept. 30); to this new attack it succumbed, Señor Maura resigning on the 21st of October 1909.

On the 22nd the formation of a new cabinet under Señor Moret was announced. It was from the first in a position of singular weakness, without a homogeneous majority on the uncertain support of the extreme Left and the Republicans. For three months it existed without daring to put forward a programme. It sent General Weyler to keep Barcelona in order, caused the release of most of the prisoners in Monjuich, reduced the forces in Morocco, reopened negotiations with Rome for a modification of the concordat, and on the 31st of December, the end of the financial year, was responsible for the issue of a royal decree stating that the budget would remain in force until the Cortes could pass a new one. But, meanwhile, the municipal elections, under the new Local Administration Law, had resulted in a triumph of the Liberals under Señor Maura. What was now considered the time ripe for a dissolution; the king, however, refused to consent, and on the 9th of February 1910 the ministry resigned. The new cabinet, with Señor Canalejas as president of the council, included members of the various Liberal and Radical groups: García Prieto (foreign affairs), Count Sagasta (interior), General Aznar (war), the Democrat Arias Miranda (navy), Cobian, a strong Catholic though a Liberal (finance), Ruiz Valarino, a Democrat (justice), Caldehon (public works) and Count Romanones, who advocated a liberal settlement with the Church (education).

The government was thus in a position vigorously to pursue its religious policy. On the 31st of May the official Gaceta published a decree setting forth the rules to which the religious associations would have to submit. It was pointed out that, in conformity with the decree of the 9th of April 1902, it had become necessary to coerce those congregations and associations which had not fulfilled the formalities prescribed by the law of 1887, and also those engaged in commerce and industry which had not taken out patents with a view to their taxation.

It further ordered that all foreign members of congregations were to register themselves at their respective consulates, in accordance with the decrees of 1901 and 1902. On the 11th of June a further and still more significant step was taken. A royal ordinance was issued repealing that signed by Canovas del Castillo (Oct. 23, 1876), immediately after the promulgation of the constitution of 1876, interpreting the 11th article of the constitution, by which the free exercise of all cults was guaranteed in Spain. The article in question forbade "external signs or public manifestations of all religious con- fessions with the exception of that of the state," which was defined by Canovas del Castillo as meaning "any emblem, attribute or lettering which appear on the exterior walls of dissident places of worship." In the speech from the throne at the opening of the new Cortes (June 16) the king declared that his government would "strive to give expression to the...
public aspirations for the reduction and control of the excessive number of orders and religious orders, without impairing their independence in spiritual matters," and in introducing a bill for the amendment of the law of 1887, Señor Canalejas declared that the government, "inspired by the universal spirit of liberty of conscience," had given to article xi. of the constitution "the full sense of its text." 71

"Liberty of conscience," a principle condemned by the Syllabus of 1864 and sneered at in the encyclical Pascendi gregis of 1905, was hardly a phrase calculated to conciliate the Spanish clergy, still less the Vatican. A cry went up that to allow dissident churches to announce their presence was to insult and persecute the Catholic Church;2 at Rome the decree was attacked as unconstitutional, and a breach of diplomatic propriety all the more reprehensible as negotiations for a revision of the concordat were actually pending. A violent clerical agitation, encouraged by the Vatican, was started, 72 Spanish archbishops and bishops presenting a joint protest to the government. Fuel was added to the fire by the introduction of a bill—known as the Cadenas bill—forbidding church settlements in Spain until the negotiations with the Vatican should have been completed. This was denounced at Rome as a unilateral assertion on the part of the Spanish government of an authority which, under the concordat, belonged to the Holy See as well. As a preliminary to negotiation, the government was required to rescind all the obnoxious measures. This demand broke the patience of the prime minister, and on the 30th of July Señor de Ojeda, Spanish ambassador at the Vatican, was instructed to hand in his papers. In Vatican circles dark hints began to be dropped of a possible approachment with Don Jaime, who had succeeded his father Don Carlos, on the 18th of July 1909, as the representative of Spanish legitimacy and Catholic orthodoxy. The pretender, indeed, disclaimed any intention of stirring up civil war in Spain; his mission would be to restore order when the country should have wearied of the republican régime whose speedy advent he foresaw. The fulfillment of the first part of this promise seemed to some to be brought a step nearer by the overthrow of the monarchy in Portugal on the 5th of October 1910. For Spain its immediate effect was to threaten a great increase of the difficulties of the government, by the immigration of the whole mass of religious congregations expelled from Portugal by one of the first acts of the new régime.

**COUNTS OF CASTILE**

The counts of Castile began, as a body, and not as a line of chiefs, in the reign of Alphonso the Chaste (789–842). They strove for independence from the first, and when one count had replaced several they achieved it.

<table>

<td>Murdered. Castile then passed to Garcia’s sister, the wife of Sancho el Mayor of Navarre.</td>
</tr>
</tbody>
</table>

**EARLY KINGS OF NAVARRE**

The early history of Navarre has been overlaid with fable, and with pure falsification, largely the work of the Benedictines of San Juan de la Peña near Huesca. Their object was to prove the foundation of their house by a king of Navarre, Aragon and Sobrarbe, in the 9th century. They were helped by the Apotheosis of the Aragonese, who wished to give their kingdom an antiquity equal to that of Leon. Hence much pure invention, bolstered up by forgery of charters, falsification of genuine ones, and construction of imaginary pedigrees.

**THE EARLY COUNTS OF BARCELONA**

In the last years of the 8th and beginning of the 9th century, Charlemagne and Louis the Pius began conquering the north-east of Spain, which the Arabs had occupied as early as 713. By 811 the Franks had conquered as far as Tortosa and Tarragona. The territory gained was called the Marca Hispanica, and was governed by counts of Roussillon, Ampurias, Besalú, Barcelona, Cerdaña, Pallars and Urgell. They became independent during the decadence of the Carolingians. The supremacy was acquired gradually by the
counts of Barcelona who became independent with Wilfred I. by 874. He and his immediate descendants gradually subdued the other counts. They suffered much from the inroads of Mansur in the 10th century, but on the decline of the caliphate, they took part in the general advance.

<table>

Aragon, from the union with the county of Barcelona, to the union with Castile:–

| Alphonso II. | 1162–1196 | Son and successor of Petronilla and Ramon Berenguer IV. Recovered the Provençal possessions of Ramon Berenguer II. |
| Peter II. | 1196–1213 | Son. Killed at Muret. |
| James I., “The Conqueror.” | 1213–1276 | Son. Conquered the Balearic Islands and Valencia. Left the islands to his son James, from whom the title passed in succession to Sancho (d. 1324), his eldest son, to Sancho’s nephew James (d. 1349), and to another James, his son (d. 1375): but the actual possession was recovered by the elder line before the extinction of the younger branch. |
| Peter III. | 1276–1285 | Eldest son. Conquered Sicily, claimed by right of his wife Constance, daughter of Manfred of Beneventum. |
| James II. | 1291–1327 | Second son of Peter III. He had succeeded to Sicily, but recognized his rights, which were then assumed by his brother Frederick, who founded the Aragonese line of kings of Sicily. |
| Alphonso IV. | 1327–1336 | Son of James I. |
| Peter IV. | 1336–1387 | Finally reannexed the Balearic Islands. |
| John I. | 1387–1395 | Son by the marriage of Peter IV. with his cousin Eleanor of the Sicilian line. |
| Martin | 1395–1410 | Younger brother of John I. His son Martin was chosen king of Sicily, but died in 1406. The male line of the kings of Aragon of the House of Barcelona ended with Martin. |
| Alphonso V. | 1416–1438 | Son. Spent most of his life in Italy, where he was King of Naples and Sicily. |
| John II. | 1438–1479 | Brother of Alphonso V., whom he succeeded in the Spanish possessions, and Sicily, but not in Naples. |
| Ferdinand II. | 1479–1516 | Son. His marriage with Isabella united the crowns. |
Navarre till the conquest of Ferdinand the Catholic: —

<table>
<thead>
<tr>
<th>Kings of United Spain (continued)</th>
</tr>
</thead>
</table>

| Garcia IV. | 1134-1150 | A descendant of Sancho el Mayor. Electcd by the Navarrese on the death of Alphonso of Aragon without issue. |
| Sancho VI., called "The Wise" | 1150-1194 | Son. Father of Berengaria, wife of Richard Cœur de Lion. |
| Sancho VII. | 1194-1234 | Son. Died without issue. Husband of Blanche, daughter of Sancho "The Wise." |
| Theobald II. | 1253-1270 | Daughter, wife of Philip IV. of France. Navarre was now absorbed in France, and so remained till 1288, when on the death of Charles IV. of France, the last of the house of Hugh Capet, it passed to his niece Jeanne, daughter of Louis X., and wife of Philip, count of Evreux. |
| Jeanne I. | 1274-1305 | Son. These two kings were much concerned with France, and little with Spain. |
| Jeanne II. | 1328-1349 | King of Navarre by right of his wife Blanche, daughter of Charles III. On his death Navarre was passed to his daughter by Blanche, Eleanor, widow of Gaston IV., count of Poitou. She died in the same year as her father, and Navarre passed to her grandson, Francis Phoebus. |
| Charles II., called "The Bad" | 1349-1387 | Died without issue, and was succeeded by his sister, the wife of Jean d'Albret. The Spanish part of Navarre was conquered by Ferdinand the Catholic in 1512. |
| Charles III., "The Noble" | 1387-1425 | |
| John I. of Aragon | 1425-1479 | |
| Francis Phoebus | 1479-1483 | |
| Catherine | 1483-1514 | |

BIBLIOGRAPHY.—(1) Sources: There are several published collections of sources for Spanish history. Of these the oldest is R. Belus, Rerum hispanicarum scriptores aliquot in bibliotheca Roberti Beli...3 vols. fol. (Frankfort, 1579-1581). In 1740-1752 was published at Madrid J. A. de Creu y Bertrand's Catalogo de documentos, &c. that have been made use of by other writers, and published in 65 vols. (Madrid 1842-1876). In 1851 the Royal Academy of History of Madrid began the publication of its Memorial historicos de España, a collection of documents, &c. See also Dionisio Hidalgo, Diccionario general de bibliografia espanola, 7 vols. (Madrid, 1862-1881). (2) Works: The standard general history of Spain written by a Spaniard is in 4 vols. by Charles d'Ailly, Historie des royes de Castille et de Leon: Fernandez I.-Alfonso VII. (Cambridge, 1860-1867; new ed., by Valera, 22 vols., Barcelona, 1888). It was written before the medieval period had been properly investigated, is wordy, and largely spoilt by displays of national vanity. A later and more critical writer of nearly the same period, Don Vincente de la Fuente, has published valuable Estudios criticos sobre la historia y el derecho de Aragon (1884-1886). No satisfactory general history of Spain has been written by a foreigner. The best is that of M. Romey, Histoire d'Espagne (1843). Don Rafael Altamirano published an Historia de España y de la civilizacion espanola (2 vols., Barcelona, 1900-1902), in which he sums up the results of later research. Among older writers Juan de Mariana, who ends with the Catholic sovereigns, professcdly took Livy as a model, and wrote a fine example of a rhetorical history published in Latin (1592-1609), and then in Spanish translated and largely re-written by himself. It was continued to 1600 by Minana. An English translation, with supplements, was published by Captain J. Stephens in 1699. The Anales de Aragon de Gerónimo Zurita (1610) are very far superior to the history of Mariana in method and research. The great school of Spanish historians died out with the other glories of the nation in the 17th century. The later periods have been indifferently treated by them, but Don Antonio Cánovas del Castillo published some very valuable studies on the Austrian dynasty under the title of Estudios del reinado de Felipe IV. (1886). The reader may also consult—for the earlier period—Florian de Ocampo and Ambrosio de Morales, whose combined works are known as the Crónica general de España, 7 vols. (Madrid 1816-1856), republished in 4 vols. (Madrid, 1791-1792). This was continued by Prudencio de Sandoval, bishop of Tuy and afterwards of Pamplona, under the title of Hist. de los reyes de Castilla y de Leon: Fernandez I.-Alfonso VII. Both ancient and later times are dealt with in the Historia general de España, escrita por individuos de la real academia de la historia (Madrid, 1802 sqq.)—a series of studies by different hands; that on the reign of Charles III., by Señor Manuel Danvila, is very valuable for the later 18th century. An account of the troubled years of the 19th century has been written by Don Antonia Piral, Historia contemporánea (1871-1879). The latest general history of Spain is Don Rafael Altamirano y Crece's Historia de España, 10 vols. (Madrid, 1912-1926). The standard authority for the Moorish side of Spanish history is the Histoire des Musulmans d'Espagne, 710-1110, by R. P. A. Dozy (4 vols., Leiden, 1861). It requires to be supplemented by Don Fauscal de Gayouin's translation of A Makkari's History of the Mahommedian Dynasties in Spain (1840-1843) and by Señor Francisco Colera's Decadencia y desaparición de los Almorávides en España (Saragossa, 1890) and Bernabé de Castro's críticos de historia arabe espanola (ibid., 1905). See also Stanley Lane Poole, The Moors in Spain ("Story of the Nations," Series, 1887) and S. P. Scott, Hist. of the Moorish Empire in Europe (3 vols., Philadelphia and London, 1904). Other English works include also the following: Vincent of Spanish history, are Martin A. S. Hume's Spain, its Greatness and Decay, 1470-1714 (Cambridge, 1898) and Modern Spain, 1728-1858 ("Story of the Nations," Series, 1899), and Butler Clarke's Modern Spain, 1812-1888 (Cambridge, 1906). Excellent summaries of Spanish history year by year are published in the Annual Register.

The Iberian Peninsula is not a linguistic unit. Not to speak of the Basque, which still forms an island of some importance in the north-west, three Romance languages share this extensive territory: (1) Portuguese-Galician, spoken in Portugal, Galicia, and a small portion of the province of Leon; (2) Castilian, covering about two-thirds of the Peninsula in the north, centre, and south; (3) Catalan, occupying a long strip of territory to the east and south-east.

These three varieties of the *Romana rustic* are marked off from one another more distinctly than is the case with, say, the Romance dialects of Italy; they do not interpenetrate one another, but where the one ends the other begins. It has only been possible to establish at the points of junction of two linguistic regions the existence of certain jargons in which certain forms of each language are intermingled; but these jargons, called into existence for the necessities of social relations by bilinguals, have an essentially individualistic and artificial character. The special development of the vulgar Latin tongue in Spain, and the formation of the three linguistic types just enumerated, were promoted by political circumstances. From the 9th century onwards Spain was slowly recaptured from the Mahomedans, and the Latin spoken by the Christians who had taken refuge on the slopes of the Pyrenees was gradually carried back to the centre and ultimately to the south of the Peninsula, whence it had been driven by the Arab invasion. Medieval Spain divides itself into three tongues—that of Castile (much the most considerable), that of Portugal, and that of Aragon. If a given province now speaks Catalan rather than Castilian, the explanation is to be sought simply and solely in the fact that it was conquered by a king of Aragon and peopled by his Catalan subjects.

1. Catalan.—This domain now embraces, on the mainland, the Spanish provinces of Gerona, Barcelona, Tarragona and Lérida (the old principality of Catalonia), and of Castellón de la Plana, Valencia and Alicante (the old kingdom of Valencia), and, in the Mediterranean, that of the Balearic Islands (the old kingdom of Majorca). Contrary to what its most characteristic features, belongs to the Romance of southern France and not to that of Spain; it is legitimate, therefore, to regard it as imported into Spain by those *Hispani* whom the Arab conquest had driven back beyond the mountains into Languedoc, and who in the 9th century regained the country of their origin; this conclusion is confirmed by the fact that the dialect is also that of two French provinces on the north of the Pyrenees—Roussillon and Cerdaigne. From the 9th to the 12th century Catalan spread farther and farther within the limits of Catalonia, properly so called; in 1215 it was brought to Majorca by Jaime el Conquistador, and in 1238 the same sovereign carried it to Valencia also. Even Murcia was peopled by Catalans in 1266, but this province really is part of the Castilian conquest, and accordingly the Castilian element took the upper hand and absorbed the dialect of the earlier colonists. The river Segura, which falls into the Mediterranean in the neighbourhood of Orihuela, a little to the north of Murcia, is as nearly as possible the southern boundary of the Catalan domain; westward the boundary coincides pretty exactly with the political frontier, the provinces of New Castile and Aragon not being at all encroached on. Catalan, which by the union of Aragon and the countship of Barcelona in 1137 became the official language of the Aragonese monarchy—although the kingdom of Aragon, consisting of the present provinces of Saragossa, Huesca and Teruel, has always been Castilian in speech—established a footing in Italy also, in all parts where the domination of the kings of Aragon extended, viz. in Sicily, Naples, Corsica and Sardinia, but it has not maintained itself here except in a single district of the last-named island (Alghero); everywhere else in Italy, where it was not spoken except by the conquerors, nor written except in the royal chancery, it has disappeared without leaving a trace.

In the 13th century the name given to the vulgar tongue of eastern Spain was *Catalanesc (Catalanissus)* or Catalá (*Cata-

Ilanus*)—the idiom of the Catalans.1 By Catalanesch or Catalá was understood, essentially, the spoken language and the language of prose, while that of poetry, with a large admixture of Provençal forms, was early called *Lenosii, Limosii* or language of Limousin—Catalan grammarians, and particularly the most celebrated of them, Ramon Vidal de Besalú, having adopted *Lenosii* as the generic name of the language of the troubadours. These grammarians carefully distinguish the vulgar speech, or *pla Catalá*, from the refined *irobar* idiom, which originally is a modified form of Provençal. Afterwards, and especially in these parts of the Catalan domain outside of Catalonia which did not acknowledge that they derived their language from that province, *Lenosii* received a more extensive signification, so as to mean the literary language in general, whether of verse or prose. To this hour, particularly in Valencia and the Balearics, *Lenosii* is employed to them, the on the one hand the old Catalan and on the other the very artificial and somewhat archaising idiom which is current in the *fochs floralis*; while the spoken dialect is called, according to the localities, *Vaileقيد* (in Valencia), *Majorequi* and *Minorqueii* (in Majorca and Minorca), or Catalá (in Catalonia); the form *Catalanesch* is obsolete.

The principal features which connect Catalan with the Romance of France and separate it from that of Spain are the following: (1) To take first its treatment of the final vowels—Catalan, like French and Provençal, having only oxytones and paroxytones, does not admit more than one syllable after the tonic accent: thus *anima* gives *armas* (cameras), *ardir* (viridus). All the proparoxytones of modern Catalan are of recent introduction and due to Castilian influence. Further, the only post-tonic Latin vowel preserved by the Catalan is, as in Gallo-Roman, *a : mare gives mar, gratu (s) gives grat, but anima gives arma;* and, when the word terminates in a group of consonants requiring a supporting vowel, that vowel is represented by an *e*: *abri(e)brem,* Cat. *abre* (Prov. and Fr. *abre,* but Cast. *arbol*); *pop(al)ius,* Cat. *poble* (Prov. *poble,* Fr. *peuple,* but Cast. *pueblo*); sometimes, when it is inserted between the two consonants instead of being made to follow them, the supporting vowel is represented by an *o*: *ascendal (sca ndalum), fribol* (frivolus), *cirel* (circulus). In some cases a post-tonic vowel other than *a* is preserved in Catalan, as, for example, when that vowel forms a diphthong with the tonic (*Deus, Deus,* Ebrus, Hebreus); or, again, it sometimes happens, when the tonic is followed by an *i* in hiatus, that the *i* persists (dilatuus, diluivium; servici, servi vium; labi, labium; cir, creus); but in many cases these ought to be regarded as learned forms, as is shown by the existence of parallel ones, such as servey, where the atomic *i* has been attracted by the tonic and forms a diphthong with it (servici, servi t; servey). What has just been said as to the treatment of the final vowels in Catalan must be understood as applying only to pure Catalan, unaltered by the predominance of the Castilian, for the actual language is no longer faithful to the principle we have laid down; it allows the final *o* atomic in a number of substantives and adjectives, and in the verb it now conjugates *cano, teno, sento*—a thing unknown in the ancient language. (2) As regards conjugation only two points need be noted here: (a) it employs the form known as the inchoative, that is to say, the lengthening of the radical of the present in verbs of this third conjugation to make them obey the same rules of the conjugation as the corresponding forms of major verbs; (b) the formation of a great number of past participles in which the termination is added, as in Provençal, not to the radical of the verb, but to that of the perfect: *tinsa* from *tinch,* *pogut* from *poch,* *conegut* from *conech,* while in Castilian *tendido* (formerly also *tenudo*), *podido, conocido,* are participles formed from the infinitive.

As for features common to Catalan and Spanish (Castilian and Portuguese) Romance, on the other hand, and which are unknown to French Romance, only one is of importance; the conservation, namely, of the Latin *u* with its original sound, while the same vowel has assumed in French and Provençal, 1 The origin of the name Catalans is unknown.
Tonic Vowels.—With regard to a, which is pronounced alike in open and in closed pronunciation, the Spanish pursue its pronunciation (i) closer to the French (é), than the Catalan (e) and the Old Catalan (é), nothing to remark. The Latin é, which is treated like é, gives, sometimes, before a, sometimes, before e. On this point Catalan is more hesitating than Provençal; it does not distinguish clearly the pronunciation of é to its pronunciation of a. Nevertheless, é to a only, yielding an open e, the é is often pronounced close, and the poets have no difficulty in making words in é close and in e open rhyme together, which is not the case in Provençal. The Latin é yields ie in Catalan as it does in French and occasionally in Provençal; sedet becomes seu (where u represents the final d), pedem makes peu, and egou; in some words where the tonic é is closed, a surd s becomes a syllabic s (e.g. Hériti, mis, médio, mis, mélus), and the same holds good for é in a similar situation (ciri, cirius, circues, cara, lérias, and the like) before a (examples, éxemplu, madrié for mentrei, genti for genti). I tonic é closes, before another tonic é, hiatus with another vowel, produce i (amitich, a micu, a vis, a vi). O tonic long and o short are represented by o close and o open (a qui, a qui, a qui, a qui). The latter is the process of hing, oxidized into u or ou or, such a treatment is as foreign to Catalan as the diphthongization of é into ie, just as é before a syllable in which é occurs is changed into i, so in the same circumstances é becomes ei, and its pronunciation is the same as that of the Catalan eni, or its transcription ieni. The cented vowel precedes a group of consonants like ci, ti, and like (autoi, ol Ci, essui, scopi). Latin u persists with the Latin pronunciation, and, as already said, does not take upon itself to replace é by i, so that Latin e becomes e (cosa, causa or, a, aurum); Old Catalan has kept the diphthong better, but possibly we should attribute the examples of au which are met with in texts of the eleventh century to the influence of Provençal. Latin au tends to become o (c, qua, quar). Atomic Vowels.—As for the Latin post-tonic vowels already spoken of, it remains to be noted that o is often represented in writing by e, especially before i, in Old Catalan, the substantives, adjectives and participles readily form their singular in a and their plural in es: arna, armes (a nima, a nima); bona, bonet (bona, bona s); amado, amades (a mata, a mata s). This e is neither open nor closed pronunciation. Latin eu becomes e (cosa, causa or, a, aurum); Old Catalan has kept the diphthong better, but possibly we should attribute the examples of au which are met with in texts of the eleventh century to the influence of Provençal. Latin au tends to become o (c, qua, quar). Atomic Vowels.—As for the Latin post-tonic vowels already spoken of, it remains to be noted that o is often represented in writing by e, especially before i, in Old Catalan, the substantives, adjectives and participles readily form their singular in a and their plural in es: arna, armes (a nima, a nima); bona, bonet (bona, bona s); amado, amades (a mata, a mata s). The Castilian influence substituted or, so that one now hears bravo instead of bravos, which has been assimilated to words in s (sé); from bosch we originally had the plural bosches, but now boscos; from tirist, tiristes, but now tiristos. For these last in \textit{in} there exists a plural formation which is more in accordance with the general Castilian phonetic and syntactic pattern, namely the \textit{en} (e.g., los, la) as is the case in the Castilian \textit{en} form (e.g., los, la). Consequently there are two possible forms, one with the \textit{en} and the other with the \textit{en}.

The Castilian influence says \textit{ets} (anciently \textit{est}), as also, in the plural, \textit{sem, seu}, instead of \textit{som, sou}, to be noted; \textit{tenere} has passed over to the conjugation in \textit{en} (\textit{tienda} = \textit{tened}), but it is at the same time true that in ordinary Castilian we also have \textit{tener} alongside of \textit{tener} the habitual form; \textit{diere} gives not \textit{dir} but \textit{diere}, which is more regular.

2. Castilian.—This name is the most convenient designation to apply to the linguistic domain which comprises the whole of central Spain and the vast regions of America and Asia colonized from the 16th century onwards by the Spaniards. We might also indeed call it the \textit{Spanish} domain, narrowing the essentially geographical meaning of the word \textit{Español} (derived, like the other old form \textit{Español}, from \textit{Hispania}), and using it in a purely political sense. But the first expression is to be preferred, all the more because it has been long in use, and even the inhabitants of the domain outside the two Castiles fully accept it and are indeed the first to call their language \textit{spanish}.

It is agreed on all hands that Castilian is one of the two branches of the vulgar Latin of Spain, Portuguese-Galician being the other; both idioms, now separated by very marked differences, can be traced back directly to one common source—the Hispanic Romance. One and the same vulgar tongue, diversely modified in the lapse of time, has produced Castilian and Portuguese as two varieties, while Castilian, the third language of the Peninsula, connects itself, as has already been pointed out, with the Gallo-Roman.

Within the Castilian domain, thus embracing all in Spain that is neither Portuguese nor Castilian, there exist linguistic varieties which could perhaps be an exaggeration to call dialects, considering the meaning ordinarily attached to that word, but which are none the less worthy of attention. Generally speaking, from various circumstances, and especially that of the reconquest, by which the already-formed idiom of the Christian conquerors and colonists was gradually conveyed from north to south, Castilian has maintained a uniformity of which the Romance languages afford no other example. We shall proceed in the first instance to examine the most salient features of the normal Castilian, spoken in the two Castiles, Castile, and the 

\textit{Castilla}, which corresponds to all hands that Castilian is one of the two branches of the vulgar Latin of Spain, Portuguese-Galician being the other; both idioms, now separated by very marked differences, can be traced back directly to one common source—the Hispanic Romance. the tendency of the modern language is, as in Catalan, to reduce \( h y \) to \( y \); thus one readily hears \( y e n o \) (\( p l e n u m \)). \( N \) moulé (\( r \)) corresponds to the Lat. \( n m \), \( n n \), and \( n t \) in common writing; \( y n \), \( y m \), \( y n \), \( m \). \( n o d u m \). Passing to the dentals, except as an initial, \( r \) in words that are popularly current and belong to the old stock of the language, can occur in any of the positions that it occupies in the Latin and Castilian; \( m \), \( c \), \( s \), in middle (\( m \) \), \( c \)\( a t a r \)\( e \), \( p \)\( u n c t u a t u r \)). It must be observed that the habitual mode of representing \( t \) in normal Castilian is by \( c \) (pron. \( i c \)), as in directo (\( d \)\( i \)\( c \)\( u t u m \)), pecho (\( p \)\( e c h \)\( o \)). In some cases \( t \) represents \( c \) as secondary forms of learned words; thus we have bendito, obtuso, seudo as secondary forms of the learned words bendicito, octavo, sancto, alongside of the old popular forms bendico, octavo, sancto. \( D \) corresponds in Castilian to Latin \( d \) wherever the latter represents \( t \) as secondary forms of learned words; thus we have saldi, pon\( e \), for salud, pond\( e \), from \( l u \) (\( p o n \)\( i t u r \)). Sometimes \( d \) takes the interdental sound of \( s \) (English \( b a \)), or is changed into \( l \); witness the two pronunciations of the names of the capital: \( M \)\( a\)\( d\)\(r\)\( i\) (\( a \)d\( e \)\( m\)\( o \)\( d \)\( i \)\( t \)\( u \)\( m \)) and \( M \)\( a\)\( d\)\( r\)\( i\) (\( a \)\( d \)\( e \)\( m\)\( o \)\( d \)\( i \)\( t \)\( u \)\( m \)).

The study of the spirants, \( c \), \( s \), \( z \), \( g \), \( j \), is made a very delicate one by the circumstance that the interdental pronunciation of \( c \), \( s \), on the one hand, and the guttural pronunciation of \( g \), \( j \), on the other, are of covered that at the better date, of a very fine distinction in the value of these letters before the 17th century. It is admitted, not without reason, that the spirants \( c \), \( s \), which at present represent but one interdental sound, \( s \), or one (between \( s \) and another thing), had down till about the middle of the 16th century the voiceless sound \( t s \) and the voiced sound \( d z \) respectively, and that in like manner the palatal spirants \( g \), \( j \), \( x \), before assuming the unvoiced nature of the guttural \( g \), were in the course of the 16th century (\( C h u c h \)\( u d \)). Having previously represented the voiceless sound of \( f \) (\( F r \)), the voiceless sound of \( y \) (\( F r \)), which is still found in Portuguese and in the Castilian dialects of the north-west, the substitu- tion of \( u \) for \( y \) in Portuguese, and the substitution of the voiceless spirants respectively did not certainly not take place simultaneously, but the modifications of the old orthographic, and afterwards the decision of the Royal Academy, which suppressed, \( t \) and \( z \), \( z \) and \( j \), \( g \) and \( s \), \( s \), \( s \), \( s \), make it impossible for us to follow, with the help of the written texts, the course of the transformation. \( S \) now has the voiceless sound of \( s \), and when it occurs, as in gasco, gas, falls away, especially before liquids: \( t o l s \) for \( t o l s \), \( l a \)\( m \)\( o \)\( s \)\( n s \)\( o \)\( s \)\( n s \)\( o \). The principal sources of \( g \) (\( g \))—Lat. \( j \) and \( g \) before \( e \) and \( i \) (\( y \)\( e \)\( j u \)\( o \)\( c \)\( u \)\( m \))—gent, \( g \)\( e \)\( n \)\( e \)\( t \)\( e \)\( m \)\( e \). Lat. initial \( s \) (\( s \)\( a \)\( p \)\( o \)\( n \)\( m \)); Lat. \( s \)\( e \)\( g \)\( o \)\( x \)\( u \)\( m \); \( s \)\( a \)\( p \)\( o \)\( m \); \( s \)\( a \)\( p \)\( o \)\( m \). The sources of \( z \) (\( z \)) are Lat. \( c \)\( e \), \( c \)\( e \), \( i l \), \( s \)\( i \)\( c \)\( e \)\( a \)\( l \)\( e \)\( x \)\( a \)\( l \), \( c \)\( a \)\( l \)\( e \)\( x \)\( a \)\( l \); \( c \)\( a \)\( l \)\( e \)\( x \)\( a \)\( l \); \( s \)\( i \)\( c \)\( e \)\( a \)\( l \); \( s \)\( i \)\( c \)\( e \)\( a \)\( l \). As regards the spirants \( f \) and \( v \), it is to be ob- served that \( f \) has in many instances been replaced by the aspirated \( h \) (\( u \)\( m \)\( e \)\( l \)\( s \)\( u \)) after silent), while in others no less common among the people the transformation has not taken place (\( f l i \)\( l u \)\( m \)\( a \)\( m \)\( u \); \( f l i \)\( l u \)\( m \)\( a \)\( m \)\( u \)). In some cases the \( f \) has been preserved in order to avoid confusion that might arise from identity of sound: the \( f \) in \( f i e l \) (\( f i d \)\( e \)\( l \)\( e \)\( s \)\( i \)) has been kept for the sake of distinction from \( b i i \)\( e \)\( i \)\( l \)\( e \)\( s \)\( i \)\( e \). As \( r \), for a \( m \), has in modern Castilian become completely Latin \( m \), the sonant explosive \( b \); Joseph Scaliger’s pun—\( b i e r e \)\( e \)\( s \)\( i \)\( v \)\( é \)\( r \)\( e \)\( r \)\( e \)—is applicable to the Castilians as well as to the Gascons. \( H \) is now nothing more than a graphic sign, except in Andalusia, where the aspirate sound represented by it comes very near \( n \).

The Words beginning in \( h u \), where the \( h \), not etymologically derived, marks the inseparable aspiration of the initial diphthong \( u e \), are readily pronounced \( g \)\( i \)\( e \) throughout almost the whole extent of the domain: \( g \)\( i \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \). This \( g \)\( i \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \)\( e \)\( x \)\( u \)\( e \)\( l \). A very marked feature is the habitual “moulure” of \( n \) and \( l \) as initial letters: \( l e \)\( e \)\( c \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \)\( e \)\( x \)\( e \)\( l \).
Galicia (the modern provinces of Pontevedra, La Coruña, Orense, and Lugo) and of a portion of the old kingdom of Leon (the territory of Viviro in the province of Leon). Portuguese, like Castilian, is a literary language, which for ages has served as the vehicle of the literature of the Portuguese nation con- nected with the beginning of the 12th century. Galician, on the other hand, which is known to have been spoken very early in the middle ages—for it was employed by Alfonso the Wise in a treaty with the Navarrese-Aragonese in 1077 in honour of the Virgin—died out proportionally as the monarchy of Castile and Leon, to which Galicia had been annexed, gathered force and unity in its southward conquest. At the present day Gallego, which is simply Portuguese variously modified and with a development in some respects arrested, is much less important than Catalan, not only because the Spanish writers who speak it (1,800,000) are fewer than the Catalans (3,500,000), but also because, its literary culture having been early abandoned in Galicia, it fell into the vegetative condition of a provincial patois. Speaking generally, Portuguese is further removed than Castilian from Latin; its development is more complete, and its actual forms are more worn out than those of the sister language, and hence it has, without reason, been compared to French, with which it has some very notable analogies. But, on the other hand, Portuguese has retained more exclusively Latin in its vocabulary, and, particularly in its conjugation, it has managed to preserve several features which give it, as compared with Castilian, a highly archaic air. Old Portuguese, and more especially the poetic language of the 13th century, which received its language of the troubadours, in whose poetry the earlier Portuguese poets found much of their inspiration, certain words and certain turns of expression which have left upon it indelible traces.

Vowels.—Lat. a, e, i, o, u, have not been diphthongized into ia, ui, ae, eu, au, o, in baker (baker), pode (pote). On the other hand, Portuguese has a large number of long vowels produced by the attraction of an i in hiatus or the addition of an explosive into i: rabiota (rabiotar), fraria (friar, friar), estatismo (estatismo), seremo (seremo). The nasal character of the feature in the "nasal vowels," which are formed by the Latin accented vowels followed by m, n, or nt, md: be (ne, grão grandes, be (bonum). These nasal vowels enter into combination with a final atomic vowel: irma (sarna nus); also amão (a mänt), seremo (smeremen), where the o is a degenerate representative of the Latin final vowel. In Old Portuguese the nasal vowel was marked by the nasal (m), but was expressed indifferently and without marking the etymology by m or n: bem (bene), tan (tum), disserem (disserem), seremo (smeremo). The Latin diphthong au is rendered in Portuguese by o, au, as in o, ao, o, o, as in o, ao, o, with regard to the atomic vowels, there is a tendency to reduce a into a vowel resembling the Fr. e, &quot;meut,&quot; to pronunciation as a, and to drop after a group of consonants (dent, dente).

Consonants.—Here the most remarkable feature, and that which most distinctly marks the wear and tear through which the language has passed is the disappearance of the median consonants l and n: corna (corona), luna (luna), for formerly poor pone (poner), corno (canonicus), tur (vire), dor, formerly door (dolorem), pago (palatum), saude (salutem), pego (pelegus). Lat. t passes regularly into r: caçada (c a b u l u s), fara (f a b a r e), erro (a b o r b e r e): but, on the other hand, Lat. t, initial e readily tends to become b: beziga (vesica), bodo (votum). Lat. initial f becomes h: facultate (f a c i u m), e, fado (f i u m). Lat. c before e and i is represented by either th in hard sounds, or by &quot;th&quot; in soft sounds. Lat. &quot;g between vowels is dropped before e and i: ler for leer (ler e ger, &quot;ber, dito (digittum); the same is the case with d, of course, in similar combinations.&quot; Lat. v becomes r or &quot;e&quot; in hard sounds, or &quot;r&quot; in soft sounds. Lat. j has assumed the sound of the French j. The Latin ch, fl, pl at the beginning of words are transformed in two ways in words of popular origin. Either the initial consonant is retained while the nasal is changed into a v: ver e (florem); or the group is changed in ch (= Fr. ch, Catal. x) through the intermediate sounds kh, fj, fn: chanar (clamare), chanar (clamare), Chanar (clamare). Within the word the same group and other groups also join the inner group to form a new consonant: l produce l mouillé (written lh, just as n mouillé is written nh, as in French): oveira (ovi eira), veio (veius); and sometimes 1 is substituted for c in the following groups: &quot;la&quot; (l a m a), &quot;ma&quot; (m a). Before e and i gives x (Fr. ch): boixa (basius), faxa (ascia). This group c is reduced to it: leco (lectum), pedio (pectus), note (notc), sometimes to u: doto (octus). Such words as fruto, reto, dito are modern derivatives from the learned forms fructo.

3. PORTUGUESE.—Portuguese-Galician constitutes the second branch of the Latin of Spain. In it we must distinguish—(1) Portuguese (Portugueses, perhaps a corruption of the old Portuges = Portugalensis), the language of the kingdom of Portugal and its colonies in Africa, Asia and America (Brazil); (2) Galician (Gallego), or the language of the old kingdom of Galicia (the modern provinces of Pontevedra, La Coruña, Orense, and Lugo) and of a portion of the old kingdom of Leon (the territory of Viviro in the province of Leon).

**SPAIN**

directo, recto. Lat. ct becomes ts: seis (s e x); or esc, x ( = Fr. ich, chi); sexo (s e x u m), huxo (l u x u m); or even ts: disse (d i x i).

Portuguese—Spanish—Galician are all regarded as dialects of a common type, and the 1st persons of the singular and plural in the present indicative, in es, edes, ed has lost the of the 10th century, and have now become as, eis, eis, through the intermediate forms aes, ees, ees. The form in edes has persisted only in those verbs where it was pronounced in the 10th century, as, for example, fain, amareis, and also in some doubt in the forms of the imperative, where the theme has been reduced to a secondary degree by the disappearance of a consonant and the contraction of verbs: ides, credes, ledes, &c.

Portuguese is the only Romance language which possesses a personal or conjugative infinitive: amar, amar-es, amar-mos, amar-dei, amar-em; e.g. antes de sair-mos, "before we go out." Porto, that Galician does not possess the personal in its original meaning, so that, for example, amora (a m e r a m) signifies not merely elsewhere "I would love," but also "I have loved before." In the personal the suffix of the 2nd pers. sing, in ades, edes, edes, lost the a in the 14th century, and has now become instead, eis, eis, through the intermediate forms aies, ees, ees. The form in as has persisted only in those verbs where it was pronounced in the 10th century, as, for example, fain, amareis, and also in some doubt in the forms of the imperative, where the theme has been reduced to a secondary degree by the disappearance of a consonant and the contraction of verbs: ides, credes, ledes, &c.

In the Portuguese the preposition a has the form of the corresponding verb, as seen in the infinitive: amar a sair, in the past participle: amado, and in the gerund: amado. In Galician the preposition a has the form of Greek ai, as in the infinitive: amar a sair, and in the past participle: amado. In Portuguese the preposition a has the form of the corresponding verb, as seen in the infinitive: amar a sair, in the past participle: amado, and in the gerund: amado. In Galician the preposition a has the form of Greek ai, as in the infinitive: amar a sair, and in the past participle: amado. In Portuguese the preposition a has the form of the corresponding verb, as seen in the infinitive: amar a sair, in the past participle: amado, and in the gerund: amado. In Galician the preposition a has the form of Greek ai, as in the infinitive: amar a sair, and in the past participle: amado.
in the church of Toledo on the feast of Epiphany. Manifestly an imitation of the Latin Iudi represented in France during the early years of the 12th century, the Spanish piece cannot have been composed much before 1150.

The national hero Rodrigo Díaz de Bivar (d. 1099), better known in history by the Arabic surname of the Cid, was celebrated in the vulgar tongue in two poems, neither of which has come down to us in its entirety. The more ancient canto, usually entitled Poema del Cid, since it was originally edited (1770) by Tomás Antonio Sánchez, relates in its first part the valiant deeds (gesta) of the Cid subsequent to his quarrel with Alphonso VI.; in the second, the capture of Valencia, the reconciliation of the hero with the king and the marriage of his daughters with the infantes of Carrión; and in the third the treason of the infantes, the vengeance of the Cid, and the second marriage of his daughters with the infantes of Navarre and Aragon. The narrative of the last years of the Cid, which closes the epic, is much curtailed. Whilst in the Poema the Cid appears as the loyal vassal, deplores the necessity of separating from his king, the Cid of the second poem, Crónica rimada del Cid, is almost a rebel and at least a refractory vassal who dares treat his sovereign as an equal. The portion of the Crónica which has been preserved deals in the main with the youth of Rodrigo; it contains the primitive version of his quarrel with the Count Gomez de Gormaz and the marriage of the slayer with Ximena, the Count’s daughter, and also a series of fabulous episodes, such as the Cid’s journey to France to fight with the twelve peers of Charlemagne, &c.

The Poema, which survives in a 14th-century manuscript, belongs to about the middle of the 12th century; the form under which the primitive text has reached us is at least two centuries later; but, on the other hand, several traditions collected by the author bear an incontestable stamp of antiquity. The versification of both poems is irregular. Normally this epic measure may be divided into two hemistichs of seven or eight syllables each; but here the lines sometimes fall short of this number and sometimes exceed it; the strophes follow the model of the laisses of the French chansons de geste—that is, they have a single assonance and vary greatly in extent.

A fragment of an epic poem on the infantes of Lara has been reconstructed from the Crónica general by Ramón Menéndez Pidal (1930). Of the very ancient original poem, all that remains is the canto of Roderick, or mythical heroes like Bernardo del Carpio, they have not survived. Still the frequent allusions in the chronicles to the narratives of the juglares suggest that Castillian heroic poetry was richer than the scarcity of the monuments now extant would lead us to believe. Fernán González, first independent count of Castile (10th century), has alone been celebrated in a poem composed (about 1250 or later) in single-rhyme quatrains.

With the heroic poetry which takes its themes from the national history and legend there grew up in the 12th and 13th centuries such Poems of religious and didactic poetry, the most eminent representative of which is Gonzalo de Berceo (1182–1245). This poet, born at Berceo (Logroño), composed several lives of Spanish saints, and other devotional poems, such as the Miracles and the Praises of the Virgin. Berceo calls his poems poésa, decir, dictado, indicating thereby that he intended them to be read and recited, not sung like the cantares. They are written in single-rhyme quatrains and in verses of twelve to fourteen syllables, according to the ending of the hemistich is masculine or feminine. In the same metre were composed the long canto of the Infantes of the Cid, on Alexander the Great, the other on Apollonius of Tyre—after Latin and French sources. The author of the first of these poems contrasts his system of versification, which he calls mester de clerética, with the mester de joglaría used in heroic poetry, and intended to be sung; and he declares that this single-rhyme quatrain (curso rimado por la cuaderna via) consists of counted syllables. The composer of Apolonio calls this same versification nueva mestria. The single-rhyme quatrain, introduced in imitation of the French poetry of the 12th century, became from the time of Berceo and the Alexandre and Apolonió the regular form in Castilian narrative and didactic poetry, and prevailed down to the close of the 14th century.

To the 13th century is assigned a Life of St Mary the Egyptian, translated from the French, perhaps through a Provencal version, and an Adoration of the Three Kings, in verses of eight or nine syllables rhyming in pairs (aa, bb, cc, &c.), as well as a fragment of a Debate between Soul and Body, in verses of six or seven syllables, evidently an imitation of one of the medieval Latin poems, entitled Rima amanti et caritatis. The oldest lyric in Castillian, La Razón feita d’amor, belongs to the same period and probably derives from a French source; it bears the name of Lope de Moros, who, however, seems to have been merely the copyst. Mention may here also be made of the cantigas (songs) of Alphonso the Learned in honour of the Virgin, although, being in the Galician dialect, these probably belong to the history of Portuguese literature.

The 14th century saw the birth of the most original medieval Spanish poet. Juan Ruiz, archpriest of Hita (near Guadalajara), has left us a poem of irregular composition, known as the Poema of the Troubadours (Dantes), which, while reproducing apophthegms and didactic verses from foreign sources, he frequently trusts to his own inspiration. Ruiz celebrates love and woman; his book is of buen amor, that is, he shows by his own experience and the example of those whom he follows how a man may become a successful lover. By way of precaution, the poet represents himself as one who has survived his illusions, and maintains that carnal love (loco amor) must finally give place to divine love; but this mask of devotion cannot disguise the real character of the work. The Rimado de palacio of Pero Lopez de Ayala, chancellor of Castile at the end of the 14th century, does not refer exclusively to court life; the author satirizes with great severity the vices of all classes of laymen and churchmen. Akin to this Rimado de palacio are the proverbios morales of the Jew Sem Tob of Carrión, dedicated to Peter the Cruel (1350 to 1360). The Poema de Alfonso Oñezo, by Rodrigo Yáñez, is a far-off echo of the epic poems, the laisses being superseded by octo-syllable lines with alternate rhymes. The General Dance of Death and a new version of the Debate between Soul and Body, both in eight-line strophes of arte mayor (verses of twelve syllables), and both imitated from French poems, is typical of this period; they both belong, however, to the 15th century.

The word “romance” not only signifies in Spain, as in other Romanic countries, the vulgar tongue, but also bears the special meaning of a short epic narrative poem (historic Romanes, ballad) or, at a later date, a short lyric poem. As regards the form, the “romance” (Spanish el romance, in contrast to French, &c., la romance) is a composition in long verses of sixteen syllables ending with one assonance; these verses are often wrongly divided into two short lines, the first of which, naturally, is rhymeless. This being the form of the romance verse, the Crónica rimada del Cid, and even the Poema (though in this case the influence of the French alexandrines is perceptible), might be considered as a series of romances; and in fact several of the old romances of the Cid, which form each an independent whole and were printed as separate poems in the 16th century, are partly to be found in the Crónica. Other romances, notably those dealing with the heroes of the Carolingian epic, so popular in Spain, or with the legendary figures which Spanish patriotism opposed to the French paladins—as, for example, Bernardo del Carpio, the rival and the conqueror of Roland in Castilian tradition—seem to be detached fragments of the cantares of the cantares and the romances, which had previously passed from mouth to mouth, began to be written down, and afterwards to be printed, at first on broadsheets (piesgos sueltos) and subsequently in collections (romanceros); these are either general collections, in which romances of very different date, character and subject are gathered together, or are collections restricted to a single episode or personage (for example, the Romancero...
del Cid). In such romanceros the epic verse is usually regarded as octosyllabic and is printed as such; occasionally certain editions divide the romance into strophes of four verses (cuartetas).

King Alphonso X. (d. 1284), under whose patronage were published the code entitled Las Siete partidas and several great scientific compilations (such as the Libros de astro- nomia and the Lapidario), was also the founder of Spanish historiography in the vulgar tongue; and the Castilian and the Latin narrative of Guido delle Colonne were both translated. Lopez de Ayala translated, or caused to be translated, Pierre Bersuire's French version of Livy, Boetius and various writings of Isidore of Seville and Boccaccio.

While the Carolingian cycle is mainly represented in Spain by assonanced romances, of which the oldest seem to be fragments of lost poems by the juglares, the British cycle (Lancelot, Tristram, Merlin, &c.) is represented almost exclusively by works in prose (see ROMANCE). These are the origin of the national, and the latter, as already as the first half of the 14th century at least; of that there is no doubt. And, even if there were not satisfactory testimony on this point, the prodigious development in Spanish literature of the caballerias, or "books of chivalry," cannot be accounted for on any other grounds than that they were derived from the romance of Breton origin, would be proof enough that at an early date the Spaniards were familiar with these romantic tales derived from France. The oldest work of the kind is El Cabal-lero Cifor, composed at the beginning of the 14th century, but the first book of real importance in the series of strictly Spanish caballerias is the Amadís de Gaula. Certain considerations lead one to seek for the unknown author of the first Amadís in Portugal, where the romances of the Round Table were more highly appreciated than in Spain, and where they have exercised a deeper influence on the national literature. To Garcí Rodríguez de Montalvo, however, falls the honour of having preserved the book by printing it; he made the mistake of diluting the original text and of adding a continuation, Las Sergas de Esplandían. Allied to Montalvo's Amadís with its supplementary Esp lanzón (1510) are the Don Florisando (1510) and the Lisuarte de Grecia (1514), the Amadís de Grecia (1514), the Don Florir el de Nicaragua (1532-1551), &c., which form what Cervantes called the "Amadís set." Parallel with the Amadises are the Palmerines, the most celebrated of which are Palmerin de Oliva (1511), and Palmerin de Inglaterra, which was first written in Portuguese by Moraes Cabral. None of those caballerias inspired by the Amadís were printed or even written before the 16th century, and they bear the stamp of that period; but they cannot be separated from their medieval model, the spirit of which they have preserved. Among the caballerías we may also class some narratives derived from the Carolingian epic—the Historia del emperador Carlomagno y de los deces pares, a very popular version still reprinted of the French romance of Fierabras, the Espazgo de caballeras, into which has passed a large part of Boiardo's Orlando innamorato, the Historia de la reina Sibilla, &c.

The first half of the 15th century, or what comes almost to the same thing, the reign of John II. of Castile (1407-1454), is characterized as regards his literature (1) by the development of a court poetry, artificial and pre- tentious; (2) by the influence of Italian literature on Castilian prose and poetry, the imitation of Boccaccio and Dante, especially of the latter, which introduced into Spain a liking for allegory; and (3) by the serious intercourse with antiquity. After the example of the Provençal troubadours whose literary doctrines had made their

Other Prose Works of 13th and 14th Centuries. The other productions of Castilian prose in the 13th and 14th centuries are for the most part didactic and sententious compositions, which, however, contain illustrations or tales of Eastern origin. The Spanish translation of Kalila and Dimna, made direct from an Arabic text, dates from the middle of the 13th century, and the romance of the Seven Sages (Sindibad), translated under the title of Libro de los engaños e asaya- mientos de las mugeres, is referred to 1533. From the second half of the 13th century the collections of aphorisms, díts, apólogues and moral tales become very numerous: first of all, versions of the Secretum secretorum, attributed in the middle ages to Aristotle, one of which is entitled Portait of the porridges, next the Proverbios buenos, the Bocados de oro or Libro de beniam, Rey de Persia and the Libro de los gatos, which is derived from the Narraciones of Odo of Cheriton. During the first half of the 14th century the nephew of Alphonso X., the infante Juan Manuel, wrote the various works which place him in the first rank of medieval Spanish prose writers. The best known is the collection of tales, many of them borrowed from Oriental sources, entitled El Conde Lucanor; but, besides this contribution to literature, he wrote graver and still more didactic treatises. The knowledge of antiquity, previously so vague, made remarkable progress in the 14th century. Curiosity was awakened concerning certain episodes of ancient history, such as the story of Telemachus, which of Theocritus and the Latin narrative of Guido delle Colonne were both translated. Lopez de Ayala translated, or caused to be translated, Pierre Bersuire's French version of Livy, Boetius and various writings of Isidore of Seville and Boccaccio.

While the Carolingian cycle is mainly represented in Spain by assonanced romances, of which the oldest seem to be fragments of lost poems by the juglares, the British cycle (Lancelot, Tristram, Merlin, &c.) is represented almost exclusively by works in prose (see ROMANCE). The first half of the 15th century, or what comes almost to the same thing, the reign of John II. of Castile (1407-1454), is characterized as regards his literature (1) by the development of a court poetry, artificial and pretentious; (2) by the influence of Italian literature on Castilian prose and poetry, the imitation of Boccaccio and Dante, especially of the latter, which introduced into Spain a liking for allegory; and (3) by the serious intercourse with antiquity. After the example of the Provençal troubadours whose literary doctrines had made their
way into Castile through Portugal and Catalonia, poetry was now styled the arte de trobar. The arte de trobar is strictly "court" poetry, which consists of short pieces in complicated measures—love plaints, debates, questions and repartees, motes with their glossas, burlesque and satirical songs—verse wholly "occasional" and deficient in charm when separated from its natural environment. In order to understand and appreciate these pieces they must be read in the collections made by the poets of the time, where each poem throws light on the others. The most celebrated cancionero of the 15th century is that compiled for the amusement of his sovereign by Juan Alfonso de Baena; it is, so to say, the official collection of the poetic court of John II, although it also contains pieces by poets of earlier dates. After Baena's collection may be mentioned the Cancionero de Stáiga, which contains the Castilian poems of the trovadores who followed Alphonso V. of Aragon to Naples. These cancioneros, consisting of the productions of a special group, were succeeded by collections of a more miscellaneous character in which versifiers of very different periods and localities are brought together, the pieces being classed simply according to their type. The earliest genuine Cancionero general (though it does not bear the title) is that compiled by Juan Fernández de Constantina, which appears to have been issued from the Valencia press at the beginning of the 16th century; the second, much better known, was published for the first time at Valencia in 1511 by Hernando del Castillo. The other poetic school of the 15th century, which claims to be specially related to the Italians, had as its leaders Juan de Mena, author of the Coronación and the Laberinto de fortuna, and the marquis of Santillana, Ilígo Lopez de Mendoza, who in his sonnets was, perhaps, the first to imitate the structure of the Italian hendecasyllabics. With those two chiefs, who may be designated poetas as distinguished from the decodores and the trovadores of the cancioneros, must be ranked Francisco Imperial, a Genoese by descent, who at a somewhat earlier date helped to acclimatize in Spain the forms of Italian poetry. The marquis of Santillana occupies a considerable place in the literature of the 15th century not only by reason of his poems, but through the support he afforded to all the writers of his time, and the impulse he gave to the study of antiquity and to the labours of translators. In the next generation the most prominent figures are Gonzalo de Berceo and Jorge Manrique, either of whom has produced a short poem which is a masterpiece. With the exception of the chronicles and some caballerías the prose of the 15th century contains little that is striking.

PROSE OF 15TH CENTURY.

A curious and amusing book, full of details about Spanish manners, is the Corbacho (1438) of the archpriest of Talavera, Alfonso Martinez de Toledo, chaplain to King John II.; the Corbacho belongs to the numerous family of satires against women, and this title, by which it is commonly known—borrowed from a work of Boccaccio's, with which it has otherwise nothing in common—indicates that he has not spared them.

The ancient liturgical Spanish theatre is known to us only by fragments of the play of the Magian Kings, already mentioned; but certain regulations given in the Siete partidas (compiled between 1252 and 1257) prove that such a theatre existed, and that at the great festivals, such as Christmas, Epiphany and Easter, dramatis personae were given in charge. These representations, originally a simple commentary on the liturgy, gradually adulterated with buffoonery, which frequently brought down the censure of the clergy. Alphonso X. even thought it necessary to forbid the "clerks" playing juegos de escarnios, and permitted in the sanctuary only dramas destined to commemorate the principal episodes of the life of Christ. Of all the Church festivals, the most popular in Spain was that of Corpus Christi, instituted by Urban IV. in 1264. At an early date the celebration of this festival was accompanied with dramatic performances intended to explain to the faithful the eucharistic mystery. These dramas, called autos sacramentales, acquired more and more importance; in the 17th century, with Calderon, they become grand allegorical pieces, regular theological dissertations in the form of dramas. To the auto sacramental corresponds the auto al nacimiento, or drama of the Nativity. In Spain, as elsewhere, the secular theatre is a product of the religious theatre. Expelled from the Church, the juegos de escarnios took possession of the public squares and there attained true development; ceasing to be a mere travesty of dogma, they developed into a drama whose movements are no longer determined by the liturgy, and whose actors are borrowed from real life in Spanish society. This new theatre begins towards the close of the 16th century, with the pastoral pieces of Juan del Encina, which, after Virgil's example, he calls eagogas. Genuine shepherds are the interlocutors of these bucolics, into which are also sometimes introduced students, and Lucas Fernández, a contemporary and pupil of Encina's, introduces gentlemen and soldiers. A book which, strictly speaking, does not belong to the theatre, the Tragicomedia de Aventuras (1597), of which as many as four may have been caused the new theatre, still rudimentary in the attempts of the school of Encina, to make a step onwards. This astonishing novel taught the Spaniards the art of dialogue, and for the first time exhibited persons of all classes of society (particularly the lowest) speaking in harmony with their natural surroundings. The progress caused by the Celestina may be estimated by means of the Collectado of Bartolomé de Torres Naharro, a collection of pieces represented at Rome in presence of Leo X. Torres Naharro is thought to have borrowed from France the division of the play into "days" (fornadas); shortly after Naharro we find the comedy of manners in Lope de Rueda, whose dramatic work is composed of regular comedies constructed on the model of Italian authors of the beginning of the 16th century, and also of little pieces intended for performance in the intervals between the larger plays (entremeses and pasos), some of which are models of sprightly wit. Some of Naharro's, and especially of Rueda's, pieces foreshadow the comedy of intrigue, which is emphatically the type of the classic stage. But to reach Lope de Vega, the Spanish stage had to be enlarged in relation to national history. A poet of Seville, Juan de la Cueva, first brought on the boards subjects such as the exploits of the Cid, Bernardo del Carpio, and the Comanche, which had previously been treated only in romances. To a poet called Berrio, of whose work nothing has been preserved, are attributed the comedias of Moors and Christians, in which were represented famous episodes of the age-long struggle against the infidel. And it was at this period (1582) that Cervantes experimented in the drama; in his Tratos de Argel he gives us a picture of galley-life, recollections of his long captivity in Algiers. There is no need to linger over the attempts at tragedy of the ancient type by Jerónimo Bermúdez, Cristóbal de Virués, Lupercio Leonardo de Argensola, &c., the only successful specimen of which is the Numancia de Cervantes; these works, mere exercises in style and versification, remained without influence on the development of the Spanish stage. The pre-classic period of this stage is, as regards dramatic form, one of indecision. Some write in prose, like Rueda; others, like Naharro, show a preference for the redondillas of popular poetry; and there are those again who, to elevate the style of the stage, versify in hendecasyllabics. Hesitation is also evident as to the mode of dividing the drama. At first a division into five acts, after the manner of the ancients, is adopted, and this is followed by Cervantes in his early pieces; then the famous Cueva reduced the five acts to four, and in this he is imitated by most poets till the close of the 16th century (Lope de Vega himself in his youth composed pieces in four acts). Francisco de Avendaño divided his Florisoce into three acts as early as 1551, but his example was not followed till about forty years later, when this division was generally adopted in all dramatic works—with the exception of short pieces like the loa (prologue), the entremeses, the paso, the baile (different kinds of entr'acte).
The golden age of Spanish literature belongs to the 16th and 17th centuries, extending approximately from 1550 to 1650.

Prior to the reign of the Catholic sovereigns there exists, strictly speaking, only a Castilian literature, largely influenced by imitation first of France and then of Italy; the union of the two crowns of Aragon and Castile, and afterwards the advent of the house of Austria and the king of Spain’s election as emperor, achieved the political unity of Spain and the unity of Spanish literature. After the death of Philip IV, (1665) the light went out; the nation, exhausted by wars and bad administration, produced nothing; its literary genius sank in the general decline, and Spain was destined ere long to fall again under the influence of France, to which she had submitted during the first period of the middle ages. In the 16th and 17th centuries the literature was eminently national.

Lyric poetry, especially that of the more ambitious order, is always inspired by the Italian masters. An irresistible tendency leads the Spanish poets to rhyme in hendecasyllables—as the marquis of Santillana had formerly done, though his attempts had fallen into oblivion—and to group their verses in tercets, octaves, sonnets and canciones (canzoni). Juan Boscán, Garcielo de la Vega and Diego Hurtado de Mendoza are the recognized chiefs of the school al lírico mode, and to them belongs the honour of having succeeded in Spanish these forms of verse, and of having enriched the poetic language of their country. The defects of Boscán and Mendoza (such as certain faults of rhythmic accentuation) were corrected by their disciples Gutierre de Cetina, Gregorio Silvestre, Hernando de Acaña, by the poets of the so-called school of Seville, headed by Fernando de Herrera and also by those of the rival school of Salamanca, rendered famous mainly by the inspired poetry of Luis Ponce de León. Against these innovators the poets, faithful to the old Castilian manner, the rhymers of redonillas and romances, held their own; under the direction of Cristóbal de Castillejo, they carried on a fierce war against the “Petrarachistas.” But by the last third of the 16th century the triumph of the new Italian school was assured, and no one any longer thought of reproaching it for its exotic flavour. Still at this period there was a schism between the higher poetry and the other varieties: in the former only the hendecasyllabic and the heptasyllabic (quebrado) were employed, while the popular poets, or those who affected a more familiar tone, preserved the national metres. Almost all the poets, however, of the 16th and 17th centuries tried their powers in both kinds of versification, using them in turn according to the nature of their subjects. Thus Lope de Vega, first of all, who wrote La Dragontea (1592), Hidalgo de Angélica (1602), La Jerusalem conquisada (1609), in Italian verses and in octaves, composed his long narrative poem on Isidore, the patron of Madrid (1599), in quintillas of octosyllabic verse, not to mention a great number of romances. As regards this last form, previously disdained by artistic poets, Lope de Vega gave it a prestige that brought it into favour at court. A host of poets were pleased to recast the old romances or to compose new ones. The 17th century. It may be said, is characterized by a superabundance of lyric poetry, to which the establishment of various literary academies contributed. Of this enormous mass of verse all sorts little still survives; the names of most of the versifiers must be omitted, and in addition to those already cited it will be sufficient to mention Gonzaga and Quevedo. Gonzaga is especially famous as the founder of the “cultist” school, as the introducer into Castilian poetry of a periphrastic style, characterized by sonorous diction and artificial arrangements of phrase. The Spaniards have given the name of culto to this eccentric style, with its system of inversions based on Latin syntax; but Gonzaga, a poet of really great powers, had begun better, and as often as he is contented with romances he finds true poetic accents, ingenious ideas and felicitous expressions. Quevedo, much greater in prose than in verse, displays real power only in satire, epigram and parody. There is in some of his serious pieces the stuff of a Juvenal, and his satiric and burlesque romances, of which several are written in slang (germanos), are in their way little masterpieces. Another commonplace of Spanish poetry is the period war epic poetry after the style of Tasso’s Gerusalemme. These interminable and prosaic compositions in octavos reales do not approach their model; none of them can even be compared in style, elevation of thought and beauty of imagery, to Camoens’s Lusíadas. They are in reality rhymed chronicles, and consequently, when the author happens to have taken part in the events he narrates, they have a genuine historical interest. Such is the case with Alonso de Ercilla’s Araucana, of which it may be said that it was written less with a pen than with a pike. In burlesque poetry the Spaniards have been more successful: La Galatea of Lope de Vega, and La Mosca de Villavicencio (d. 1698) are agreeable examples of witty invention.

The departments of imaginative literature in which the genius of the new Spanish nation revealed itself with most vigour and originality are the novela and the drama. By novela must be understood the novel of manners, called picareosa (from picaro, a rogue or “picaroon”) because of the social status of the heroes of those fictions; and this type of novel is a Spanish invention. The pastoral romance, on the other hand—the best-known examples of which are the Diana of Jorge de Montemayor, continued by Alonso Perez and Cervantes, and the Arcadia of Lope de Vega—as well as the novel of adventure began by Cervantes in his Novelas exemplares, and cultivated after him by a host of writers, is directly derived from Italy. The Arcadia of Sannazarro is the source of the Diana and of all its imitations, just as the Italian novellieri are the masters of most Spanish novelistas of the 17th century. The picaresque novel starts in the middle of the 16th century with the Vida de Lazarillo de Tormes, sus fortunas y adversidades; the impetus was given, and the success of Lazarillo was so great that imitators soon appeared. In 1596 Mateo Alemán published the first part of the adventures of another picaroon, Guzmán de Alfarache; before he could issue the sequel (1604) he was anticipated (1602) by an unscrupulous rival, whose continuation was on a lower plane. Quite unlike that of the Lazarillo, the style of Mateo Alemán is eloquent, full, with long and learned periods, sometimes diffuse. Nothing could be more extravagant and more obscure than the history of Justinia the beggar woman (La Picara Justinia) by Francisco Lopez de Ubeda (1605), which is generally (but perhaps wrongly) said to be a name assumed by the Dominican Andrés Pérez. A long series of similar tales continued to be published by writers of considerable merit (see PICARESQUE NOVEL).

By degrees the picaresque romance was combined with the novel of Italian origin and gave rise to a new type—half novel of manners, half romance of adventure—of which the characteristic example appears to be the Marcos de Obregón (1618) of Vicente Martínez Espinel, one of the best written works of the 17th century. To the same class belong almost all the novels of Alonso Jerónimo de Salas Barbadillo, Luiz Velaz de Guevara and Francisco Santis’s popular pictures of life in Madrid, Día y noche de Madrid (1661), Periquillo, el de las galineras, etc. On the other hand, the novels of Tirso de Molina (Los Cigarreros de Toledo, 1634), Perez de Montalbán (Para todos, 1632), Maria de Zayas (Novelas, 1635–1647), are more in the manner of the Novelas exemplares of Cervantes, and consequently of the Italian type. Among the so-called historical romances one only deserves to be mentioned—the Guerras civiles de Granada (1505-1604) by Ginés Pérez de Hita, which deals with the last years of the kingdom of Granada and the inscription of the Moors of Alpujarras in the time of Philip II. Don Quixote (1605–1615), the masterpiece of Cervantes, is too great a work to be treated with others; and, moreover, it does not fall strictly within the limits of any of the classes just mentioned. If it has to be defined, it may be described as the social romance of
16th and 17th century Spain. Cervantes undoubtedly owed much to his predecessors, notably to the few picarosque romancers who came before him, but he considerably enlarged the scope of the type and strengthened the framework of the story by a lofty moral idea. His main purpose was not so much to ridicule the books of chivalry, which were already out of fashion by his time, but to show by an example pushed to absurdity the danger of those prejudices of pure blood and noble race with which three-fourths of the nation were imbued, and which, by the scorn of all useful labour which they involved, were destined to bring Spain to ruin. The lesson is all the more effective, as Cervantes's fiscalon, although ridiculous, was not put beyond the pale of the reader's sympathy, and the author condemns only the exaggeration of the chivalrous spirit, and not true courage and devotion when these virtues have a serious object. What happened to Guaman de Alfarache happened to Don Quijote. In 1614 a sourious second part of the adventures of Don Quixote made its appearance; Cervantes was thus roused from inactivity, and the following year gave to the world the true second part, which instantly eclipsed Avellaneda's imitation.

The stage in the 17th century in some measure took the place of the romances of the previous age; it is, as it were, the medium of all the memories, all the passions, and all the aspirations of the Spanish people. Its style, being that of the popular poetry, made it accessible to the most illiterate classes, and gave it an immense range of subject. The Bible, the lives of the martyrs, national traditions, the chronicles of Castile and Aragon, foreign histories and comedies, even the representations of contemporary Spanish life, the escapades and nightly brawls of students, the gallanties of the Calle Mayor and the Prado of Madrid, balcony escaldades, sword-thrusts and dagger-stabs, duels and murders, fathers befooled, jealous ladies, pilfering and cowardly valets, inquisitive and sprightly waiting-maids, sly and tricky peasants, fresh country girls—all are turned to dramatic account. The enormous mass of plays with which the literature of this period is inundated may be divided into two great classes—secular and religious; the latter may be subdivided into (1) the liturgical play, i.e. the auto sacerdotal or al nacimiento, and (2) the comedia divina or the comedia de santos, which has no liturgical element, and differs from a secular play only in the fact that the subject is religious and frequently, as one of the names indicates, derived from the biography of a saint. In the secular drama, classification might be carried almost to any extent if the nature of the subject be taken as the criterion. It will be sufficient to distinguish the comedia (i.e. any tragic or comic piece in three acts) according to the social types brought on the stage, the equipment of the actors, and the artifices resorted to in the representation. We have here Guillermina de Castro, the author of las comedias de la carrera, a sort of operaetta thus named after the royal residence of La Zarzuele, where the kings of Spain had a theatre. As to the dramatic poets of the golden age, even more numerous than the lyric poets and the romancers, it is difficult to group them. All are more or less pupils or imitators of the great chief of the new school, Lope Felix de Vega Carpio; everything has ultimately to be brought back to him whom the Spaniards call the "monster of Nature." Among Lope's contemporaries only a few poets of Valencia—Gaspar Honorat de Aguilar (1567-1623), Francisco Tarrega, Guillen de Castro, the author of las comedias del Cid (from which Corneille derived his inspiration) formed a small school, as it were, somewhat less subject to the master than that of Madrid, which could only win the applause of the public by copying as exactly as possible the manner of the great initiator. Lope left his mark on all varieties of the comedia, but did not attain equal excellence in all. He was especially successful in the comedy of intrigue (enredo), of the capa y espada class, and in dramas whose subjects are derived from national history. His most uncontrollable merit is to be attributed to him, the given the Spanish stage a range and scope of which it had not been previously thought capable, and of having taught his contemporaries to invent dramatic situations and to carry on a plot. It is true he produced little that is perfect; his prodigious fecundity and facility allowed him no time to mature his work; he wrote negligently, considered the stage an inferior department, good for the vulgo, and consequently did not judge it worthy of the same esteem as lyric or narrative poetry modelled on the Italians. Lope's first pupils exaggerated some of his defects, but, at the same time, each, according to his own taste, widened the scope of the comedia. Antonio Mira de Amescua and Luis Velez de Guevara were successful, especially in tragic histories and comedias divinas. Gabriel Téllez, better known under the pseudonym of Tirso de Molina, one of the most flexible, ingenious and inventive of the dramatists, displayed no less talent in the comedy of contemporary manners than in historical drama. El Burlador de Sevilla (Don Juan) is reckoned his masterpiece; but he showed himself a much greater poet in El Vergonzoso en palacio, Don Gil de las Calzas Verdes and Marta la Piedades. Finally Juan Ruiz de Alarcón the most original of the Spanish dramatists, especially in the field of romantic comedies, did not fails to achieve the comedy of character in La Verdad sospechosa, closely followed by Corneille in his Menteur. Most of the remaining play-writers did little but increase the number of comedias; they added nothing to the real elements of the drama. The second epoch of the classical drama is represented mainly by Pedro Calderón de la Barca, the Spanish dramatist who has obtained most celebrity abroad, where his pieces have been much studied and admired (perhaps extravagantly). It is Calderón who first made honour, or more correctly the point of honor, an essential motive in the conduct of his personages (e.g. El Médico de mi mujer): it is he also who made the comedia de capa y espada uniform even to monotony, and gave the comic "part" of the gracioso (confidential valet of the caballero) a rigidity which it never previously possessed. There is depth and poetry in Calderón, but also vagueness and bad taste. His most philosophic drama, La Vida es sueño, is a bold and sublime idea, but indistinct and feebly worked out; his autos sacramentales give evidence of extensive theological knowledge and dexterity in dramatizing abstractions. Calderón was imitated, as Lope had been, by exaggerating his manner and perverting his excellences. Two contemporaries deserve to be cited, along with him—Francisco de Rojas Zorrilla, author of the fine historic play Del Rey abajo ninguna, and Augustín Moreto, author of some pleasant comedies. Among those who worked in a less ambitious vein, mention must be made of Luis Quiñones de Benavente, a skilful writer of entremeses.

A new manner of writing appears with the revival of learning, the purely objective style of the old chroniclers, accumulating one fact after another, without showing the logical connexion or expressing any opinion on men or things, began to be thought puerile. An attempt was made to treat the history of Spain; the history of Spain to be based, not on Tacitus, whose methods of narration were directly adopted. The 16th century, however, still presents certain chroniclers of the medieval type, with more erudition, precision and the promise of a critical faculty. La Crónica general de España, by Ambrosio de Morales; the Compendio historial of Estéban de Garibay; and the Historia general de las Indias occidentales, by Antonio de Herrera, are, so far as style is concerned, continuations of the last chronicles of Castile. Jerónimo de Zurita is emphatically a scholar; no one in the 16th century knew so well how to turn to account documents and records for the purpose of completing and correcting the narratives of the
ancient chronicles. His *Anales de la corona de Aragón* is a book of great value, though written in a laboured style. With Juan de Mariana history ceases to be a mere compilation of facts or a work of pure erudition, and becomes a work of art. The *Historia de España* by the celebrated Jesuit, first written in Latin (1592) in the interest especially of foreigners, was afterwards rendered by its author into excellent Castilian; as a general survey of its history, well planned, well written and well thought out, Spain possesses nothing that can be compared with it. Various works of less extent—accounts of more or less important episodes in the history of Spain—may take their place beside Mariana's great monument: for example, the *Guerra de Granada*, by Diego Hurtado de Mendoza (a history of the revolt of the Moors of the Alpujarras under Philip II.), written about 1570, immediately after the events, but not published till 1627; the narrative of the expedition of the Catalans in the Morea in the 14th century, by Francisco de Moncada (d. 1635); that of the revolt of the same Catalans during the reign of Philip IV., by Francisco Manuel de Mello, a Portuguese by birth; and that of the conquest of Mexico by Antonio de Solís. Each of these writers was more or less inspired by some Latin author, one preferring Livy, another Sallust, &c. Most of these imitations are somewhat stilted, and their artificiality in the long run proves as fatiguing as the heaviness of the medieval chronicles. On the other hand, the historians of the wars of Flanders, such as Carlos Coloma, Bernardino de Mendoza, Alonso Vazquez and Francisco Verdugo, are less refined, and for that very reason are more vivid and more capable of interesting us in the struggle of two races so foreign to each other and of such different genius. As for the accounts of the transatlantic discoveries and conquests, they are of two kinds—either (i) memoirs of the actors or witnesses of those great dramas, as, *e.g.* the *Historia verdadera de la conquista de la nueva España*, by Bernal Diaz del Castillo (1492–1581), one of the companions of Cortés, and the *Historia de las Indias*, by Bartolomé de las Casas, the apostle of the Indians; or (ii) professional writers, such as Francisco Lopez de Gómara, official historiographers who wrote in Spain on information sent to them from the newly-discovered lands. Letter writers, a rather numerous body in Spanish literature, are nearly related to the historians; in fact, letters written to be read by others than the persons addressed, or in any case revised afterwards, are only a method of writing history in a familiar style. Fernando del Pulgar appended to his *Clares varones* a series of letters on the affairs of his time; and in the 16th century Antonio de Guevara (d. 1544) collected, under the title of *Epistolas familiares*, his correspondence, with his contemporaries which throws a great light on the early part of the reign of Charles V., although it must be used with caution because of the numerous recasts it has undergone. A celebrated victim of Philip II., Antonio Perez (d. 1611), revenged himself on his master by relating in innumerable letters, addressed during his exile to his friends and protectors, all the incidents of his disgrace, and by selling to the ministers of France and England the secrets of the Spanish policy in which he had a hand; some of these letters are perfect specimens of urbane gallantry.

**Philosophy.** The philosophy is rather poorly represented in the 16th and 17th centuries in the literature of the vernacular. The greater number of the Spanish thinkers of this epoch, scholastic, Platonic, Aristotelian or independent—wrote in Latin. Ascetic and mystical authors alone made use of the vulgar tongue for the reader diffusion of their doctrine among the illettrate, from whose ranks many of their disciples were recruited. Luis de Grandá (1504–1588), Luis Ponce de León (1528–1590), Teresa de Jesús y Colombres (1515–1582), Pedro Malón de Chalde and John of the Cross are the brighter lights of this class of writers. Some of their books, like the *Guía de pecadores* of Luis de Grandá, the autobiography of St Theresa, and Malón de Chalde's *Conversion of the Magdalen* (1588), have obtained a lasting success beyond the limits of the Peninsula, and have influenced the development of mysticism in France. The Spanish mystics are not only remarkable for the depth or subtlety of their thoughts and the intensity of the divine love with which they are inspired; many of them are masters of style, and some, like St John of the Cross, have composed verses which rank with the most sublime in the language. A notable fact is that those who are regarded as illuminati profess the most practical ideas in the matter of morality. Nothing is more sensible, nothing less ecstatic, than the manual of domestic economy by Luis de León—*La Perfecta casada*. Lay moralists are numerous in the 16th and 17th centuries. Some write long and heavy treatises on the art of governing, the duties of rulers, and the responsibilities of States. Diego de la Saavedra Fajardo's *Idea de un príncipe cristiano*, Quevedo's *La Política de Dios y gobierno de Cristo*, give a correct idea of the ability which the Spaniards have displayed in this kind of didactic literature—ability of no high order, for the Spaniard, when he means to expound a doctrine, loses himself in distinctions and easily becomes diffuse, pedantic and obscure. But there is a kind of morality in which he indubitably excels, namely, in social satire, which, under all its forms—dialogue and dream in the style of Lucian, epistle after the manner of Juvenal, pamphlet, and so forth—are rich in pithy and amusing sentences. Juan de Valdés (d. 1541), the most celebrated of the Spanish Protestants, led the way with his *Dildago de Murecurio y Cardón*, where the great political and religious questions of the first half of the 16th century are discussed with admirable vigour and freedom. The most eminent author in the department of social satire, as in those of literary and political satire, is Quevedo. Nothing escapes his scrutinizing spirit and pitless irony. All the vices of contemporary society are remorselessly pilloried and cruelly dissected in his *Sueños* and other short works. While this great satirist, in philosophy a disciple of Seneca, imitates his master even in his diction, he is none the less one of the most vigorous and original writers of the 17th century. The only serious defect in his style is that it is too full, not of figures and epithets, but of thoughts. His phrases are of set purpose charged with a double meaning, and we are never sure on reading whether we have grasped all that the author meant to convey. *Conceptism* is the name that has been given to this refinement of thought, which was doomed in time to fall into ambiguity; it must not be confused with the *cultism* of Góngora, the artificial and in some sense purely courtly, and thus typical of the second half of the 16th century. This new school, of which Quevedo may be regarded as the founder, had its Boileau in the person of Baltasar Gracián, who published his *Agudeza y arte de ingenio* (1642), in which all the subtleties of conceptism are reduced to an exact code. Gracián, who had the gift of sententious moralizing rather than of satire, produced in his *Críticas* animated pictures of the society of his own day, while he also displayed much ingenuity in collections of political and moral aphorisms which have won him a great reputation abroad.

Spanish thought as well as public spirit and all other forms of national activity began to decline towards the close of the 17th century. The advent of the house of Bourbon, and the increasing invasion of French influence in the domain of politics as well as in literature and science, frustrated the efforts of a few writers who had remained faithful to the pure Spanish tradition. In the hands of the second-rate imitators of Calderón the stage sank lower and lower; lyric poetry, already compromised by the affected diction of Góngora, was abandoned to rhymer who tried to make up by extravagance of style for poverty of thought. The first symptoms, not of a revival, but of a certain resumption of intellectual production, appear in the department of linguistic study. In 1714 there was created, on the model of the French academies, La Real Academia Española, intended to maintain the purity of the language and to correct its abuses. This academy set itself at once to work, and in 1726 began the
publication of its dictionary in six folio volumes, the best title of this association to the gratitude of men of letters. The Gramática de la lengua castellana, drawn up by the academy, did not appear till 1771. For the new ideas which were introduced into Spain as the result of more intimate relations with France, and which were in many cases repugnant to a nation for two centuries accustomed to live a self-contained life, it was necessary that authoritative sanction should be found. Ignacio de Luzzán, well read in the literatures of Italy and France, a disciple of Boileau and the French rhetoricians, yet not without some originality of his own, undertook in his Política (1757) to expound to his fellow countrymen the rules of the new school, and, above all, the principle of the famous "unities" accepted by the French stage from Corneille's day onward. What Luzzán had done for letters, Benito Fejoo, a Benedictine of good sense and great learning, did for the sciences. His Teatro crítico and Cartas eruditas y curiosas, collections of dissertations in almost every department of human knowledge, introduced the Spaniards to the leading scientific discoveries of foreign countries, and helped to deliver them from many superstitions and absurd prejudices. The study of the ancient classics and the department of learned research in the domain of national histories and literatures had an eminent representative in Gregorio Mayán y Sicar (1699-1781), who worthily carried on the great traditions of the Renaissance; besides publishing good editions of old Spanish authors, he gave to the world in 1757 a Retórica which is still worth consulting, and a number of learned memoirs. What may be called the littérature d'égrémont did not recover much lost ground; it would seem as if the vein had been exhausted. Something of the old picaresque novel came to life again in the Pray Guerendi, the Jewish Lord, by the Englishman Estebanez (1808-14), a biographical romance which is also and above all—to the detriment, it is true, of the interest of the narrative—a satire on the follies of the preachers of the day. The lyric poetry of this period is colourless when compared with its variegated splendour in the preceding century. Nevertheless one or two poets can be named who possessed a refinement of taste, and whose collections of verse at least show respect for the language. At the head of the new school is Menéndez Valdés, and with him are associated Diego González (1733-1794), José Iglesias de la Casa (1748-1801), known by his Lettres, Chrestem, and some other volumes; a remarkable poet of the 18th century who produced odes and didactic poetry it is only necessary to mention Leandro Fernández de Moratín and Quintana, but the latter belongs rather to the 19th century, during the early part of which he published his most important works. The poverty of the period in lyric poetry is even exceeded by that of the stage. No kind of comedy or tragic drama arose to take the place of the ancient comedia, whose platitudes and absurdities of thought and expression had ended by disgust ing even the least exacting portion of the public. The attempt was indeed made to introduce the comedy and the tragedy of France, but the stiff and pedantic adaptations of such writers as the elder Moratín, Agustín de Montiano y Luyando (1607-1764), Tomás de Iriarte, García de la Huerta and the well-known economist Gaspar de Jovellanos failed to interest the great mass of playgoers. The only dramatist who was really successful in composing on the French pattern some pleasant comedies, which owe much of their charm to the great purity of the language in which they are written, is Leandro Fernández de Moratín. It has to be added that the soñet was cultivated in the 18th century by one writer of genuine talent, Ramón de la Cruz; nothing helps us better to an acquaintance with the curious Spanish society of the reign of Charles IV. than the interludes of this genial and light-hearted author, who was succeeded by Juan Ignacio González del Castillo.

The struggle of the War of Independence (1808-14), which was destined to have such important consequences in the 19th century of world politics, exerted no immediate influence on the literature of Spain. One might have expected as a consequence of the rising of the whole nation against Napoleon that Spanish writers would no longer seek their inspiration from France, and would resume the national traditions which had been broken at the end of the 18th century. But nothing of the sort occurred. Not only the afrancesados (as those were called who had accepted the new régime), but also the most ardent partisans of the patriotic cause, continued in literature to be the submissive disciples of France. Quintana, who in his odes preached to his compatriots the duty of resistance, has nothing of the innovator about him; by his education and by his literary doctrines he remains a man of the 18th century. The same may be said of Martínez de la Rosa, who, though less powerful and impressive, had a greater independence of spirit and a more highly trained and classical taste. And when romanticism begins to find its way into Spain and to enter into conflict with the spirit and habits of the 18th century, it is still to France that the poets and prose writers of the new school turn, much more than to England or to Germany. The first decidedly romantic poet of the generation which flourished about 1830 was the duke of Rivas; no one succeeded better in reconciling the genius of Spain and the tendencies of modern poetry; his poem El Moro expulsado and his drama La fama del santo belong as much to the old romances and old theatre of Spain as to the romantic spirit of 1830. On the other hand, Espronceda, who has sometimes been called the Spanish Musset, savours much less of the soil than the duke of Rivas; he is a cosmopolitan romantic of the school of Byron and the French imitators of Byron; an exclusively lyric poet, he did not live long enough to give full proof of his genius, but what he has left is often exquisite. Zorrilla has a more flexible and exuberant, but much more unequal, talent than Espronceda, and if the latter has written too little it cannot but be regretted that the former should have produced too much; nevertheless, a multitude of hasty performances, brought out before they had been matured, his Don Juan Tenorio, a new and fantastic version of the legend treated by Tirso de Molina and Molière, will remain as one of the most curious specimens of Spanish romanticism. In the dramatic literature of this period it is noticeable that the tragedy more than the comedy is modelled on the examples furnished by the French drama of the Restoration; thus, if we leave out of account the play by García Gutierrez, entitled El Troyador, which inspired Verdi's well-known opera, and the work of others, all the dramatic work belonging to this date recalls more or less the manner of the professional playwrights of the boulevard theatres, while on the other hand the comedy of manners still preserves a certain originality and a genuine local colour. Bretón de los Herreros, who wrote a hundred comedies or more, some of them of the first order in their kind, apart from the fact that their diction is of remarkable excellence, adheres with great fidelity to the tradition of the 17th century; he is the last of the dramatists who preserved the feeling of the ancient comedia. Mariano José de Larra, a prose writer of the highest talent, must be placed beside Espronceda, with whom he has several features in common. Caustic in temper, of a keenly observant spirit, remarkably sober and clear as a writer, he was specially successful in the political pamphlet, the article d'actualité, in which he ridicules without pity the vices and oddities of his contemporaries; his reputation is much more largely due to these letters than either to his plays or his novel El Doncel de Don Enrique el Doliente. With Larra must be associated two other humoristic writers. The first of these is Mesonero Romanos, whose Escenas matriaronas, although less literary value than Larra's, give pleasure by their good-natured gaiety and by the humorous details they furnish with regard to the contemporary society of Madrid. The other is Estebanez Calderon, who in his Escenas andaluzas sought to revive the manner of the satirical and picaresque writers of the 17th century; in a uselessly archaic language of his own, tesseled with fragments taken from Cervantes, Quevedo and others, he has delineated with a somewhat artificial grace various piquant scenes of Andalusian or Madrid life. The most prominent literary critics belonging to the first generation of the
century were Alberto Lista (1775-1848), whose critical doctrine may be described as a compromise between the ideas of French classicism and those of the romantic school, and Agustín Durán, who made it his special task to restore to honour the old literature of Castile, particularly its romances, which he had studied with ardour, and of which he published highly esteemed collections.

If the struggle between classicists and romanticists continued even after 1830, and continued to divide the literary world into two opposing camps, the new generation—that which occupied the scene from 1840 till about 1868—had other preoccupations. The triumph of the new ideas was assured; what was now being aimed at was the creation of a new literature which should be truly national and no longer a mere echo of that beyond the Pyrenees. To the question whether modern Spain has succeeded in calling into existence such a literature, we may well hesitate to give an affirmative answer. It is true that in every species of composition, the gravaest as well as the lightest, it can show works of genuine talent; but many of them are strikingly deficient in originality; all of them either bear unmistakable traces of imitation of foreign models, or show (more or less happily) the imprint of the older literature of the 17th century, to which the historical criticism of Durán and the labours of various other scholars had given a flavour of novelty.

Foreign influence is most clearly marked in the work of Ventura de la Vega (1807-1885), whose relationship to the younger Moratin, and therefore to Mollière, is indicated in a Teatro de Don Juan, a clever comedy (1846), a piece written after a long apprenticeship spent in translating French plays. Among those who endeavoured to revive the dramatic system established by Lope de Vega were Aureliano Fernández-Guerra y Orbe (1816-1894) and Francisco Sánchez de Castro (d. 1878); the former in Alonso Cano, and the latter in Hermanegildo, produced examples of ingenious reconstruction, which testified to their scholarship but failed to interest the public permanently. A fusion of early and later methods is discernible in the plays of Adelardo López de Ayala and Tamayo y Baus. Campomor was a dramatist whom, though curious as expressions of a subtle intelligence cast in the form of dialogue, do not lend themselves to presentation, and were probably not intended for the stage. Nuñez de Arce in El Has de leña produced an impressive drama, as well as several plays written in collaboration with Antonio de Hurtado, before he found his true vocation as a lyric poet. The successor of Tamayo y Baus in popular esteem must be sought in José Echegaray, whose earlier plays—such as La Esposa del vendedor and En el puño de la espada—are in the romantic style; in his later works he attempts the solution of social problems or the symbolic drama. Such pieces as El Gran Gelato (1841), El Hijo de Juan, and the remarkable El Hijo de la muerte (1849), are a piece of study of the younger Dumas and Ibsen. During the last few years his popularity has shown signs of waning, and the copious dramatist has translated from the Catalan at least one play by Angel Guimerá (b. 1847). To Echegaray's school belong Eugenio Sellés (b. 1844), author of El Nudo gordiano, El Cielo el vuelo and La Mujer de Lath, and Leopoldo Cano y Masas (b. 1844), whose best productions are La Mortispa, Gloria and La Fasionári, an admirable example of concise and pointed dialogue. Mention must also be made of José Felix y Codina (1843-1897), a Catalan who wrote two vigorous plays entitled La Dolores and Marte del Carmen; Joaquín Dicenta (b. 1860), whose Juan José showed daring talent; and especially Jacinto Benavente (b. 1866), a dramatist whose mordant vigour and knowledge of stage-effect is manifest in La Comida de las fieras and Rosas de oloño. In a lighter vein much success has attended the efforts of Miguel Echegaray (b. 1848), whose buoyant humour is in keeping with the national character of his seculpheral gloom, and Vital Aza (b. 1851) and Ricardo de la Vega (b. 1858) deserve the popularity which they have won, the first by El Señor Curro and the second by Peña la freschacana, excellent specimens of humorous contrivance. But the most promising writing for the Spanish stage at the present time are Serafín Alvarez Quintero (b. 1871) and his brother Joaquín (b. 1873) whose collaboration are due El Ofijo derecho and Abanicos y panderetes, scenes of brilliant fantasy which continue the tradition of witty observation begun by Lope de Rueda.

Rivas, Espronceda and Zorrilla owe more to foreign models than either Campomor or Nuñez de Arce. It is true that Campomor has been described, most frequently by foreign critics, as a disciple of Heine, and undoubtedly Campomor suggests to cosmopolitan readers something of Heine's concentrated pathos; but he has nothing of Heine's acrimony, and in fact continued in his own semi-philosophic fashion a national tradition of immemorial antiquity—the tradition of expressing lyrical emotion in four or eight lines which finds its most homely manifestation in the five volumes of Cantos populares españoles edited by Francisco Rodríguez Marín. No less national a poet was Nuñez de Arce, in whose verses, though the sentiment and reflection are often commonplace, the workmanship is of irreproachable finish. His best performance is Gritos del combate (1875), a series of impassioned exhortations to concord issued during the civil war which preceded the restoration of the Bourbon dynasty. An ineffectual politician, Nuñez de Arce failed in oratory, but produced a permanent political impression with a small volume of songs. He wrote much in the ensuing years, and though he never failed to show himself a true poet he never succeeded in repeating his first great triumph—perhaps because it needed a great national crisis to call forth his powers. He found an accomplished follower in Emilio Pérez Ferrari (b. 1856), whose La Voz de mis hermanos (1892) calls the dignity but not the impeccability of his model. Another pupil in the same school was José Velarde (d. 1892), whose best work is collected in Voces del alma, some numbers of which are indications of a dainty and interesting, if not virile, talent. Absorbed by commerce, Vicente Wenceslao Querol (d. 1889) could not afford to improvise in the exuberant manner of his countrymen, and is represented by a single volume of poems as remarkable for their self-restraint as for a deep tenderness which finds expression in the Cortas a Marta and in the poignant stanza A mi madre de mi hermano Adela. The temptation to sound the pathetic note so thrillingly in Querol's subordinate harmonies proved irresistible to Federico Balart (1831-1902), a critic and humorist of repuhte who late in life astonished and moved the public with a volume of verse entitled Dolores, a sequence of elegies which bear a slight formal resemblance to In Memoriam; but the writer's sincerity was doubtful, and in Horizontes the absence of genuine feeling degenerated into fluent fancy and agreeable prettiness. A more powerful and interesting personality was Joaquín María Bartrina (1850-1880), who endeavoured to transplant the pessimistic spirit of (b. 1892), whose success is antipathetic; he is wholly wanting in the stately impassability of his exemplar, and his form is defective; but he has force, sincerity and courage, and the best verses in Algo (1876) are not easily forgotten. The Andantes y allegros and Cremos y acuerdas of Manuel Reina (1836-1905) have a delightful Andalusian effusiveness and metrical elegance, which compensate for some monotony and shallowness of thought. Manuel del Palacio (1832-1907) combined imagination and wit with a technical skill equal to that of the French Parnassians; but he flattered away his various gifts, so that but a few sonnets survive out of his innumerable poems. More akin to the English "Lake poets" was Amós de Escalante y Prieto (1831-1902), better known by his pseudonym of "Juan Garca," whose faculty of poetic description, revealed only to the few who had read his verses in the edition privately circulated in 1890, is now generally recognized. The vein of religious sentiment which runs through Escalante's most characteristic lyrics was also worked by Luis Ramírez Martinez y Guertero (d. 1874), who, under the pseudonym of "Larmig," wrote verses impregnated with Christian devotion as well as with a sinister melancholy which finally led to his suicide. Softly and with a delicate interest in the younger poets are provincials by sympathy or residence, if not by birth. Salvador Rueda (b. 1857), in his
Aires españoles, represents the vivid colouring and resonant emphasis of Andalucía; Ramón Domingo Perés (b. 1863), a Cuban by birth but domiciled at Barcelona, strikes a Catalan note in Musgo (1902), and substitutes restraint and simplicity for the Castilian sonority and pathos; Vicente Medina (b. 1866) in Aires Murcianos and La Costumbre de la huerta reproduces with vivid intensity the atmosphere of the Murcian orchard-country; Juan Alcoy and Miguel Costa, both natives of Majorca, celebrate their island scenery with luminous picturesqueness of phrase. The roll of Spanish poets may close with the name of José María Gabrily y Galán (d. 1903), whose reputation depends chiefly on the verses entitled "El Amor," in Castellanas; Gabrily y Galán was extremely unequal, and his range of subjects was limited, but in El Amor he produced a poem which is unsurpassed in modern Spanish poetry. The facility with which verses of a kind can be written in Spanish has made Spain most of singing-birds; but the chief names have been already mentioned, and no others need be recorded here.

Since 1850 there has been a notable renaissance of the Spanish novel. Fernán Caballero is entitled to an honourable place in literary history as perhaps the first to revive thematic realism which was temporarily checked by the romantic movement. In all that concerns truth and art she is superior to the once popular Manuel Fernández y González (d. 1888), of whom it has been said that Spain should erect a statue to him and should burn his novels at the foot of it. A Spanish Dumas, he equals the French author in facility, invention and resource, and some of his tales—such as El Cocinero de su majestad, Los Minúsculos de las Alpujarras and Martín Gil—are written with an irresistible brío; but he was the victim of his own facility, grew more and more reckless in his methods of composition, and at last sank to the level of his imitators. Antonio de Trueba followed Fernán Caballero in observing local customs and in poetizing them with a sentimental grace of his own, which attracted local patriots and uncritical readers generally. He had no gift of delineating character, and his plots are feeble; but he was not wanting in literary charm, and he went his road of invention and resource, and some of his tales—such as El Cocinero de su majestad, Los Minúsculos de las Alpujarras and Martín Gil—are written with an irresistible brío; but he was the victim of his own facility, grew more and more reckless in his methods of composition, and at last sank to the level of his imitators. Pedro Antonio de Alarcón, is remembered chiefly as the author of El Sombrero de tres picos, a peculiarly Spanish tale of picaresque malice. Neither Trueba nor Alarcón could have developed into great artists; the first is too facile, the second is too rhetorical, and both are too haphazard in execution. Idealizing country life into a pale arcadian idyll, Trueba frowned upon one of his neighbours whose methods were eminently realistic. José María de Pereda is the founder of the modern school of realistic fiction in Spain, and the boldness of his experiment startled a generation of readers accustomed to Fernando de los Monegros and his contemporaries, and to Trueba’s deliberate conventionality. Moreover, Pereda’s reactionary political views—to frequently obstructed in his imaginative work—alienated from him the sympathy of the growing Liberal element in the country; but the power which stamps his Escenas montañesas was at once appreciated in the northern provinces, and by slow degrees he imposed himself upon the academic critics of Madrid. So long as Pereda deals with country folk, sailors, fishermen, aspects of sea and land, he deserves the highest praise, for he understands the poor, hiss upon the moor, and his characters are the spontaneous product of his imagination and the keenest appreciation of natural beauty. His hand was far less certain in describing townsmen; yet it is a mistake to class him as merely a successful landscape painter, for he created character, and continually revealed points of novelty in his descriptions of the common things of life. Pereda is realistic, and he is real. His rival, Juan Valera, is not, in the restricted sense of the word, realistic, but he is no less real in his own wider province; he has neither Pereda’s energy nor austerity of purpose, but has a more infallible tact, a larger experience of men and women, and his sceptical raillery is as effective a moral commentary on Pereda’s Christian spirit. In Valera’s Pepe Jiménez and Dona Lluïsa, and in Pereda’s Sotilisa, we have a trio of Spanish heroines who deserve our fame: Pereda’s is the more vigorous, full-blooded talent, as Valera’s is the more seductive and patrician; yet, much as they differ, both are essentially native in the quality of their genius, system and phrasing. Benito Pérez Galdós gave a new life to the historical novel in his huge series entitled Episodios nacionales, a name perhaps suggested by the Romances nationaux of Erckmann-Chatrian; but the subjects and sentiment of these forty volumes are intensely local. The colouring of the Episodios nacionales is so brilliant, their incident is so varied and so full of interest, their spirit so stirring and patriotic, that the born Spaniard easily forgives their frequent prolixity, their insistence on minute details, their loose construction and their uneven style. Their appeal is irresistible; there is no such unanimous approbation of the politico-religious novels such as Doña Perfecta, Gloria and Ledo Roch, each of which may be regarded as a roman à thèse. The quick response of Néstor Galdós to any external stimulus, his sensitive nerves to every set off by the literary atmosphere, made it inevitable that he should come under the influence of French naturalism, as he does in Lo Prohibido and in Realdad; but his conversion was temporary, and two forcible novels dealing with contemporary life—Fortunata y Jacinta and Angel Guerra—mark the third place in the development of a susceptible talent. The true leader of the naturalistic school in Spain is Armando Palacio Valdés, whose faculty of artistic selection was first displayed in El Señorío Octavio. Two subsequent works—María y María and La Hermana San Sulpicio—raised hopes that Spain had, in Palacio Valdés, a novelist of the first rank, but La Estampa and La Fe, two social studies which caused all the more sensation because they contained caricatures of well-known personages, the author followed the French current, ceased to be national and did not become cosmopolitan. His latest books are more original and interesting, though they scarcely fulfil his early promise. Another novelist who for a time divided honours with Palacio Valdés was the lady who publishes under her maiden name of Emilia Pardo Bazán. The powerful, repellent pictures of peasant life and the ethical daring of Los Peones de Utrera and La Madre Nacionales are set off by the dramatic passages of description; in later works the author chose less questionable subjects, and the local patriotism which inspires Insolación and De mi tierra is expressed in a style which secures Emilia Pardo Bazán a high place among her contemporaries. Leopoldo Alas (1851–1901), who used the pseudonym of “Clarín,” was better known as a ruthless critic than as a novelist; the interest of his shorter stories has evaporated, but his ambitious novel, La Regenta, lives as an original study of the relation between mysticism and passion. Jacinto Octavio Picón (b. 1852), who has deserted novel writing for criticism, displays much insight in Literatura, the story of a priest who has himself forced to lay down his orders; this work was naturally denounced by the clerical party, and orthodoxy declared equally against El Enemigo and Dulce y sabrosa; more impartial critics agree in admiring Picón’s power of awakening sympathy and interest, his gift of minute psychological analysis and his exquisite diction. No suspicion of heterodoxy attaches to Manuel Polo y Peyrón, the author of that charming story La Tía Levilier, to the Jesuit-Luis Coloma (b. 1851), who obtained a fleeting triumph with Pequeñeces, in which the writer satirized the fashionable of Los Peones de Utrera and La Madre Nacionales are set off by the dramatic passages of description; in later works the author chose less questionable subjects, and the local patriotism which inspires Insolación and De mi tierra is expressed in a style which secures Emilia Pardo Bazán a high place among her contemporaries. The tendency of Spanish historical students is rather to collect the raw material of history than to write history. Antonio Cánovas del Castillo was absorbed by politics to the loss of literature, for his Ensayo sobre la casa de Austria en España is ample in information and impartial in judgment; the composition is hasty and the style is often ponderous, but many passages denote a genuine literary faculty, which the author was perhaps less aware of himself than others. The History of the Visigodos, in which Aureliano Fernández-Guerra and Orbe collaborated with Eduardo de Hinojo, illuminates an obscure but important period. Francisco Cárdenas (1816-1898) in his Historia de la propiedad territorial en España did so far for Spain that Maine did for England. Eduardo Pérez Pujo1 (b. 1830) in his Historia de las instituciones de la España gorda (1896) supplements the work of Fernández-Guerra and Hinojo, the latter of whom has published a standard treatise entitled Historia del derecho romano. Joaquín Costa’s Estudios ibéricos (1891) and Calendario agrario en España (1898) have been praised by experts for their minute research and exact erudition; but his Poesia popular española y mitología y literatura celto-ibérica is, in which a most ingenious attempt is made to reconstitute the literary history of a remote period, appeals to a wider circle of educated readers. The monographs of Francisco Codera y Zaidín (b. 1836), of Cesáreo Fernández Duro (1830-1907), of Francisco Fernández y González (b. 1833), of Gumersindo Azcárate (b. 1840), and of many others, such as the Jesuit epigraphist Fidel Fita y Calomé, are valuable contributions to the still unwritten history of Spain, but are addressed chiefly to specialists and are not designed for the general reader. The History of España y de la civilización española, now in progress, Literary criticism in Spain, even more than elsewhere, is too often infected by intolerant party spirit. It was difficult for Leopoldo Alas (“Clarín”) to recognize any merit in the work of a reactionary writer, but his prejudice was too manifest to mislead, and his intelligent insight frequently led him to do justice in spite of his prepossession. In the opposite camp Antonio Valbuena, a humorist of the moldart type, has still more difficulty in doing justice to any writer who is an ache men, an American or a Liberal. Pascual de Gayangos y Arce and Manuel Millá y Fontanals escaped from the quarrels of contemporary schools by confusing their studies to the past, and Marcelino Menéndez y Pelayo has earned a European reputation in the same province of historical criticism. Among his followers who have attained distinction it must suffice to mention Ramón Menéndez Pidal (b. 1890), author of La Leyenda de los infants de Lara (1897), a brilliant piece of scientific, reconstructive criticism; Francisco Rodríguez Martín (b. 1853), who has published valuable studies on 16th and 17th century authors, and adds to his gifts a habit of the most refined and unambitious, archaic style; Emilio Cotarelo y Morí (b. 1858), who, besides interesting contributions to the history of the theatre, has written substantial monographs on Enrique de Villena, Villamediana, Tirso de Molina, Iriarte and Ramón de la Cruz; and Adolfo Bonilla y San Martín (b. 1875), whose elaborate biography of Juan Luis Vives, which is a capital chapter on the history of Spanish humanism, gives him a foremost place among the scholars of the younger generation.

Bibliography.—The basis of study is Nicolás Antonio’s Bibliotheca hispana vetus et Bibliotheca hispana nova, in the revised edition of Francisco Pérez Bayer (4 vols., Madrid, 1878). Supplemen
tary works of this are Alonso de Chaves’ El Camino de la perfección (A. Poesía española de libros raros y curiosos (4 vols., Madrid, 1863-1889), edited by M. R. Zarco del Valle and José Sancho Rayón; Pedro Salva y Mallén’s Catálogo de la biblioteca de Salva (2 vols., Valence, 1875); Gregorio Martínez Sierra’s Catálogo de otros libros (3 vols., Lisbon, 1828-1829); Lucas Lyman’s A Catalogue of the Portuguese Books bequeathed by George Ticknor to the Boston Public Library (Boston, 1870); Domingo García Peres, Catálogo de los autores portugueses que escribieron en castellano (Madrid, 1890), most solid works are F. J. Wolf, Studien zur Geschichte der spanischen und portugiesischen Nationalliteratur (Berlin, 1889), and M. Millá y Fontanals, De la historia de la literatura ibérica (Barcelona, 1894-1896). The most solid works are Cayetano Alberto de la Barrera and Lezcano, Catálogo bibliográfico y biográfico del teatro antiguo español (Madrid, 1860); A. Páez y Mélia, Catálogo de las piezas de teatro que se conservan en España (Madrid, 1883); José L. Mejía, Antología de los monografías (Madrid, 1899); C. Pérez Pastor, Nuevos datos acerca del hispanismo español en los siglos xvi y xvii. (Madrid, 1901); José Sánchez-Arjona, Noticias referentes a las anales del teatro en Sevilla (Seville, 1878); B. H. Butler, Clarke, Spanish drama in the 16th century (Madrid, 1902). 2. Catalan Literature.—Although the Catalan language is simply a branch of the southern Gallo-Roman, the literature, in its origin at least, should be considered as that of a district rather than as a national, and it is material to that of Provence. Indeed, until about the middle of the 13th century there existed in the Catalan districts no other literature than the Provencal, and the poets of north-eastern Spain used no other language than that of the troubadours.

Guillem de Bergadán, Uc de Mataplana, Ramón Vidal de Besalú, Guillem de Cervera, Serret de Gerona and other verse writers of still more recent date were all genuine Provencal poets, and in same sense as are those of Limousin, Quercy or Auvergne, since they wrote in the langue d'oc and made use of all the forms of poetry that were current in the north of the Pyrenees. "Dampier Vidal (end of the 12th century and beginning of 13th) was a grammarian as well as a poet; his Rasa de trobar became the code for the Catalan poetry written in Provençal, which he called Lemoci, a name still kept up in Spain to designate, not the literary idiom of the troubadours only, but also the local idiom—Catalan—which the Spaniards chose to consider as derived from the former. The influence of R. Vidal and other grammarians of his school, as well as that of the troubadours we have named, was enduring; and even after Catalan prose—an exact reflection of the spoken language of the south of France—flourished in the Pyrenees and gave evidence of its vitality in some considerable works, Catalan poetry remained faithful to the Provençal tradition. From the combination of spoken Catalan with the literary language of the troubadours there arose a sort of composite idiom, which has some analogy with the Franco-Italian current in certain parts of Italy in the middle ages, although in the case the elements of the mixture are more distinctly apparent than are the romance of France and the romance of Italy in the other. The poetical works of Raymond Lully or Ramón Lull are among the oldest examples of this Provençalised Catalan; one has only to read the fine piece entitled La Despà (312), or song of his stanzas on religious subjects, to apprehend at once the eminently composite nature of that language. Muntaner in like manner, whose prose is exactly that spoken by his contemporaries, becomes a troubadour when he writes in verse; his Serró on the conquest of Sardinia and Corsica (1325), introduced into his Chronicle of the kings of Aragon, exhibits linguistically the same mixed character as is found in Lully, or, we may venture to say, in all Catalan verse writers of the 14th century. These are not very numerous, nor are their works of any great merit. The majority of their compositions are in verse that no doubt existed in the Pyrenees, and which gave evidence of its vitality in modern works, and which could be read in octosyllabic verse in rhymed couplets. There exist poems of this class by Pere March, by a certain Torrella, by Bernat Metge (an author more celebrated for his prose), and by others whose names we do not know; among the works belonging to this last category special mention ought to be made of a version of the romance of the Seven Sages, a translation of a book on good breeding entitled Pascues, and certain tales where, by the choice of subjects, by various borrowings, and even occasionally by the wholesale introduction of pieces of French poetry, it is clearly evident that the author of Catalan influence, and which give evidence of the langue d'oc. Closely allied to the versos rimades is another analogical form of versification—that of the codolada, consisting of a series of verses of eight and four syllables, rhyming in pairs, still made use of in one portion of the Catalan domain (Majoreca).

The 15th century is the golden age of Catalan poetry. At the instigation and under the auspices of John I. (1387-1399) Martin I. (1395-1416); and Ferdinand I. (1410-1416), kings of Aragon, there was founded at Barcelona a consistency of the Las Saber, on the model of that of Toulouse, and this official protection accorded to poetry was the beginning of a new style much more emancipated from Provençal influence. It cannot be denied, indeed, that its forms are of foreign importation, that the Catalan verse writers accept the prescriptions of the Leys d'amor of Guillaume Moliner, and that the names which they gave to their codoladas (stanzas) are all borrowed from the same art de trobar of the Toulouse school; but their language begins to rid itself more and more of Provençalisms and tends to become the same as that of prose and of ordinary conversation.

With Pere and Jaume March, Jordi de Sant Pau, Johan de Masovelles, Francesch Ferrer, Pere Torroella, Pau de Bellviure, Antoni Vallmany, and, above all, the Valencian Auzias March, there developed a new school, which flourished till the end of the 15th century, and which, as regards the form of its versification, is distinguished by its almost exclusive employment of eight-verse codoladas of ten syllables, each with "crossed" or "chained" rhymes (coda crobada or escacenable), each composition ending with a tornada of four verses, in the first of which the "device" (diris or senyol) of the poet is given out, in the second they are repeated, or have only recently been extracted from the cancioners, where they had been collected in the 15th century. Auzias March alone, the most inspired, the most profound, but also the most obscure of the whole group, was printed in the 16th century; his cantis d'amor and cantis de mort contain the finest verses ever written in Catalan, but the poet fails to keep up to his own high level, and by his studied obscurity occasionally becomes unintelligible to such a degree that one of his editors accuses him of having written in Basque. Of a wholly different class, and in quite another spirit, is the Liber de les dones of Jaime Roldós (d. 1478), a Valencian also, like March; this long poem is a nova rimada, only comedies, that is to say, it is in quadrissyllabic instead of octosyllabic verse. A bitter and caustic satire upon women, it purports to be a true history—the history of the poet himself and of his three unhappy marriages in particular. Notwithstanding its author's allegations, however, the Liber de les dones is mostly fiction; but it derives a very piquant interest from its really authentic element, its vivid picture of the Valencian of the 15th century and the details of contemporary manners. After this bright period of efflorescence Catalan poetry rapidly faded, a decline due more to the force of circumstances than to any fault of the poets. The union of Aragon with Castile, and the resulting predominance of Castilian throughout Spain, inflicted a death-blow on Catalan literature, especially on its artistic poetry, a kind of composition more ready than any other to avail itself of the triumphant idiom which soon came to be regarded by men of letters as the only noble one, and alone fit to be the vehicle of elevated or refined thoughts. The fact that a Catalan, Juan Boscán, inaugurates in the Castilian language a new kind of poetry, and that the Castilians themselves regard him as the head of a school, is important and characteristic; the date of the publication of the works of Boscán (1543) marks the end of Catalan poetry.

The earliest prose works in Catalan are later than the poems of the oldest Catalan troubadours of the Provençal school; these prose writings date no further back than the close of the 13th century, but they have the advantage of being entirely original. Their language is the very language of the soil which we see appearing in charters from about the time of the accession of James I. (1213). This is true especially of the chronicles, a little less so of the other writings, which, like the poetry, do not escape the influence of the more polished dialect of the country to the north of the Pyrenees. Its chronicles are the best ornament of medieval Catalan prose. Four of them—that of James I., apparently reduced to writing a little after his death (1276) with the help of memoirs dictated by himself during his lifetime; that of Bernat Desclot, which deals chiefly with the reign of Pedro III. of Aragon (1276-1280); that of Ramon Muntaner (first half of the 14th century), relating at length the expedition of the Catalan company to the Morea and the conquest of Sardinia by James II.; finally that of Pedro IV., the Ceremonios (1355-1387), genuine commentaries of that austere monarch, arranged by certain officials of his court, notably by Bernat Descoell—these four works are distinguished alike by the artistic skill of their
narration and by the quality of their language; it would not be too much to liken these Catalan chroniclers, and Muntañer especially, to Villehardouin, Johnville and Froissart. The Doctor Illuminatus, Raymond Lully, whose acquaintance with Latin was very poor—his philosophical works were done into that language by his disciples—wrote in a somewhat Provençalized Catalan various moral and propagandist works—the romance Blanquerna in praise of the solitude life, the little Biblioteca Catalana de la Castilla, of which is introduced a "bestia" taken by the author from Kalilah and Dimnah, and the Libre del orde de cavalleria, a manual of the perfect knight, besides a variety of other treatises and opuscula of minor importance. The majority of the writings of Lully exist in two versions—one in the vernacular, which is his own, the other in Latin, originating with his disciples, who desired to give currency throughout Christendom to their master's teachings. Lully—who was very popular in the lay world, although the clergy had a low opinion of him and in the 15th century even set themselves to obtain a condemnation of his works by the Inquisition—had a rival in the person of Francesch Ximenez or Eximenez, a Franciscan, born in Gerona some time after 1350. His Crestià (printed in 1483) is a vast encyclopaedia of theology, morals and politics for the use of the laity, supplemented in various aspects by his three other works—Vida de Jesucrist, Libre del angels, and Libre de les dones; the last named, which is at once a book of devotion and a manual of domestic economy, contains a number of curious details as to a Catalan woman's manner of life and the luxury of the period. Lully and Eximenez are the only Catalan authors of the period whose written works in a vulgar tongue had the honour of being translated into French shortly after their appearance.

We have chiefly translators and historians in the 15th century. Antoni Canals, a Dominican, who belongs also to the previous century, translates into Catalan Valerius Maximus and a treatise of St Bernard; Bernat Metge, himself well versed in Italian literature, presents some of its great masters to his countrymen by translating the Griseldis of Petrarch, and also by composing Lo Sompni ("The Dream"), in which the influence of Dante, of Boccaccio, and, generally speaking, of the Italy of the 13th and 14th centuries is very perceptible. The Poès ans d'armes de Catalunya of Bernat Boades (d. 1444), a knightly chronicle brought to a close in 1429, reveals a spirit of research and a conscientiousness in the selection of materials which are truly remarkable for the age in which it was written. On the other hand, Pere Tomich, in his Històries et conquistes del reynalme d'Aragó (1448), carries us back too much to the manner of the medieval chroniclers; his credulity knows no bounds, while his style has altogether lost the naïve charm of that of Muntañer.

To the list of authors who represent the leading tendencies of the literature of the 15th century we must add the name of Johanot Martorell, a Valencian author of three-fourths of the celebrated romance, Tiran to blanch (finished in 1460 and printed in 1490), which the reader has nowadays some difficulty in regarding as that "treasury of content" which Cervantes will have it to be.

With the loss of political importance coincided that of literary independence in the Catalanoman countries. Catalan fell to the rank of a patois and was written less and less; lettered persons ceased to cultivate it, and the upper classes, especially in Valencia, owing to the proximity of Castile, soon succeeded to make no further use of the local speech except in familiar conversation. The 16th century, in fact, furnishes literary history with hardly more than a single poet at all worthy of the name—Pere Serraf, some of whose pieces, in the style of Anzias March, but less obscure, are graceful enough and deserve to live; his poems were printed at Barcelona in 1585. Prose is somewhat better represented, but scholars alone persisted in writing in Catalan—antiquaries and historians like Miquel Carbonell (d. 1517), compiler of the Chroniques de Espayna (printed 1547), Francesc Tarafa, author of the Croniques de les aventures de les armades catalanes, Anton Beuter and some others not so well known. In the 17th and 18th centuries the decadence became still more marked. A few scattered attempts to restore to Catalan, now more and more neglected by men of letters, some of its old life and brilliance failed miserably. Neither Hieronim Pujades, author of an unfinished Coromona universol del principat de Catalunya (Barcelona, 1699), nor even Vicent Garcia, rector of Vallfogona (1582–1623), a verse-writer by no means destitute of verve or humour, whose works were published in 1700 under the pen-name of La Armoni del Parnás, mes numerosa en les poesias varis del adiant del cel poético Dr Vicent Garcia, and whose literary talent and originality have been greatly exaggerated by the Catalanans of the present day, could induce his countrymen to cultivate the local idiom once more. Sermons, lives of saints, a few works of devotion, didactic treatises and the like are all that was written henceforth in Catalan till the beginning of the 19th century. Writers who were Catalan by birth had so completely unlearned their mother-tongue that it would have seemed to them quite inappropriate, and even ridiculous, to make use of it in serious works. Had Castile struck its roots in the eastern provinces of Spain, and so thoroughly had the work of assimilation been carried out to the advantage of the official language of the court and of the government.

In 1814 appeared the Gramatyc y apologia de la llengua Catalana of Joseph Pau Ballet y Torres, which may be considered as marking the origin of a genuine renaissance of the grammatical and literary study of Catalan. Although the author avows no object beyond the purely practical one of giving to strangers visiting Barcelona for commercial purposes some knowledge of the language, the enthusiasm with which he sings the praises of his mother-tongue, and his appended catalogue of works which have appeared in it since the time of James I, show that this was not his only aim. In point of fact the book, which is entitled to high consideration as being the first systematic Catalan grammar, written, too, in the despised idiom itself, had a great influence on the authors and literary men of the principality. Under the influence of the new doctrines of romanticism twenty years had not passed before a number of attempts in the way of restoring the old language had made their appearance, in the shape of various poetical works of very unequal merit. The Oda a la patria (1835) of Buenaventura Carlos Aribau is among the earliest if not actually the very first of these, and it is also one of the best; the modern Catalan school has produced few poems more inspired or more correct. Following in the steps of Aribau, Joaquim Rubio y Ors (Dr Gaster del Lllobregat), Antonio de Bofarull (Dr Cobledor de Moncada), and soon afterwards a number of other versifiers took up the lyre which it might have been feared was never to sound again since it fell from the hands of Anzias March. The movement was first to Catalonia into other provinces of the ancient kingdom of Aragon; the appeal of the Catalans of the principality was responded to at Valencia and in the Balearic Isles. Later, the example of Provence, of the felibrige of the south of France, accelerated still further this renaissance movement, which received official recognition in 1859 by the creation of the Jochs Florsals, in which prizes are given to the best competitors in poetry, of whom some succeed in obtaining the diploma de mestre en gai saber. It is of course impossible to foresee the future of this new Catalan literature—whether it is indeed destined for that brilliant career which the Catalans themselves anticipate. In spite of the unquestionable talent of poets like Mariano Aguilo (Majorca), Teodoro Llorente (b. 1836; Valencia), and more especially Jacinto Verdaguer (1845–1902), author of an epic poem Atlàntida and of the very fascinating Cantis mistichs, it is by no means certain that this renaissance of a provincial literature will be permanent now that the general tendency throughout Europe is towards unity and centralization in the matter of language. At all events it would be well if the language were something more fixed, and if its writers no longer hesitated between the pretensions of nationalism and the incorporating tendencies of vulgar colloquialism. Some improvement in this respect is discernible in the poems of Joan Maragall (b. 1860), the lyrical verse of

Revival of Catalan Language and Literature.
Apelles Mestre (b. 1854), the fiction of Narcís Oller and Santiago Rusiñol, as also in the dramas of Angel Guimerà, and if the process he continued there may be a future, as well as a past, for Catalan literature.

SPALATIN, GEORGE, the name taken by George Burkhardt (1484-1545), an important figure in the history of the Reformation, who was born on the 17th of January 1484, at Spalt (whence he assumed the name Spalatinus), near Nuremberg, where his father was a tanner. He went to Nuremberg for his education when he was thirteen years of age, and soon afterwards to the university of Erfurt, where he took his bachelor's degree in 1499. There he attracted the notice of Nikolaus Marshalsch, the most influential professor, who made Spalatin his amanuensis and took him to the new university of Wittenberg in 1501. During 1502 Spalatin returned to Erfurt by his Юрьец, was recommended to Conrad Mutianus, and was welcomed by the little band of German humanists of whom Mutianus was chief. His friend got him a post as teacher in the monastery at Georgenthal, and in 1508 he was ordained priest by Bishop Johann von Laasphe, who had ordained Luther. In 1509 Mutianus recommended him to Frederick III. the Wise, the elector of Saxony, who employed him to act as tutor to his nephew, the future elector, John Frederick. Spalatin speedily gained the confidence of the elector, who sent him to Wittenberg in 1511 to act as tutor to his nephews, and prepared for his canon's study. In 1513 Spalatin became tutor to the electors son. He was promoted to be court chaplain and secretary, and took charge of all the elector's private and public correspondence. His solid scholarship, and especially his unusual mastery of Greek, made him indispensable to the Saxon court. Spalatin had never cared for theology, and, although a priest and a preacher, had been a mere humanist. How he first became acquainted with Luther it is impossible to say—probably at Wittenberg; but the reformer from the first exercised a great power over him, and became his chief counsellor in all moral and religious matters. His letters to Luther have been lost, but Luther's answers remain, and are extremely interesting. There is scarcely any fact in the opening history of the Reformation which is not connected in some way with Spalatin's name. He read Luther's writings to the elector, and translated for his benefit those that in Latin into German. He accompanied Frederick to the Diet of Augsburg in 1518, and shared in the negotiations with the papal legates, Cardinal Cajetan and Karl von Miltitz. He was with the elector when Charles was chosen emperor and when he was crowned. He was with his master at the Diet of Worms. In short, he stood beside Frederick as his confidential adviser in all the troubled diplomacy of the earlier years of the Reformation. Spalatin would have dissuaded Luther again and again from publishing books or engaging in overt acts against the Papacy, but when the thing was done none was so ready to translate the book or to justify the act.

On the death of Frederick the Wise in 1525 Spalatin no longer lived at the Saxon court. But he attended the imperial diets, and was the constant and valued adviser of the elector after the death of John Frederick. He went into residence as canon at Altenburg, and incited the chapter to institute reforms somewhat unsuccessfully. He married in the same year. During the later portion of his life, from 1526 onwards, he was chiefly engaged in the visitation of churches and schools in electoral Saxony, reporting on the confiscation and application of ecclesiastical revenues, and he was asked to undertake the same work for Albertine Saxony. He was also permanent visitor of Wittenberg University. Shortly before his death he fell into a state of profound melancholy, and died on the 16th of January 1543, at Altenburg.

Spalatin left behind him a large number of literary remains, both published and unpublished. His original writings are almost all historical. Perhaps the most important of them are: Annales reformationis, edited by E. S. Cyprian (Leipzig, 1718); and "Das Leben und die Zeitgeschichte Friedrichs des Weisen," published in Georg Spalatin's Historischer Nachlass and Briefe, edited by C. G. Neudecker and L. Preller (Jena, 1854). A list of them may be found in A. Seelheim's Georg Spalatin als sächs. Historiograph (1876). There is no good life of Spalatin, nor can there be until his letters have been collected and edited. A work still to be done. There is an excellent article on Spalatin, however, by T. Kolde, in Herzog-Hauk, Realencyklopädie, Bd. xviii. (1906).

SPALATO, or SPALATRO (Serbo-Croatian Splitski or Split), an episcopal city, and the centre of an administrative district, in Dalmatia, Austria, and on the Adriatic Sea. Pop. (1900), of town and commune, 27,198; chiefly Serbo-Croatian, and almost exclusively Roman Catholic. Spalato is situated on the seaward side of a peninsula between the Gulf of Braza and the Gulf of Salona. Though not the capital, it is commercially the most important city in Dalmatia and carries on an extensive trade in wine and oil. It is a port of call for the Austrians Lloyd steamers, and communicates by rail with Sebenico, Knin and Sinj. Spalato has a striking sea-front, in which the leading feature is the ruined façade of the great palace of Diocletian, to which the city owes its origin. A large part of Spalato is actually within the limit of the palace; and many modern houses are built against its ancient walls and incorporate parts of them, not only on the inner but also on the outer side. This palace was erected between A.D. 290 and 310. In ground plan it is almost a square, with a quadrangular tower at each of the four corners. It covers 9½ acres. There were originally four principal gates, with four U-shaped streets meeting in the middle of the quadrangle. These streets are a sort of a Roman camp. The eastern gate, or Porta Aenea, is destroyed, but, though the side towers are gone, the western gate, or Porta Ferrea, and the main entrance of the building, the beautiful Porta Aurea, in the north front, are still in fairly good preservation. The streets are lined with massive arcades. The vestibule now forms the Piazza del Duomo or cathedral square; to the north-east of this lies the temple of Jupiter, or perhaps the mausoleum. This has long been the cathedral of St Žujuni or Domni, small and dark, but noteworthy for its finely carved choir stalls. To the southeast is the穿刺 chamber, which served originally as a kind of court chapel, and has long been transformed into a baptistery. A beautiful Romanesque campanile was added to the baptistery in the 14th and 15th centuries. Architecturally the most important of the many striking features of the palace is the arrangement in the vestibule by which the supporting arches spring directly from the capitals of the large granite Corinthian columns. This, as far as the known remains of ancient art are concerned, is the first instance of such a method.

The ruins of Salona or Solonae, lying about 4 m. north-east of the palace, were chiefly exhausted during a series of excavations in the middle of the quadrangle. John S. M. Research was carried on regularly from 1821 to 1827, and again from 1842 to 1843. It was afterwards resumed at intervals
SPALDING, W.—SPALLANZANI

592

until 1877, when the excavation committee was granted an annual subsidy by the Austrian government. Many discoveries were made, including the ruins of a theatre, amphitheatre, city walls and gates, baths, aqueducts, pagan and Christian cemeteries, basilicas and many fragments of houses and arches. Professor F. Builtow, who had charge of the work and of the museum at Spalato, reported in 1894 that the collection of minor objects comprised 2034 inscriptions, 387 sculptures, 176 architectural pieces, 1548 fragments or objects of terra-cotta and vases, 1243 objects of glass, 3184 of metal, 929 of bone, 1229 gems, 128 objects from prehistoric times, and 15,000 coins (Munro, p. 244). These are preserved in the museum. One vase, of Corinthian workmanship, dates from the 6th century B.C. and many of the early Christian relics are of unusual interest. The so-called "cyclopean" walls, mortarless, but constructed of neatly squared and fitted blocks, are probably of Roman workmanship. Jackson suggests that the Pharsa, like the long walls at Athens, they were intended to unite the city with its port.

Salona under the early Roman emperors was one of the chief ports of the Adriatic, on one of the most central sites in the Roman world. Made a Roman colony after its second capture by the Romans (78 B.C.), it appears as Colonia Martia Julia and Colonia Claudia Augusta Pia Veteranorum, and bears at different periods the titles of respublica, conventas, metropolis, praefectura and praetorium. Diocletian died in 315; and before long the city became an episcopal see, with St. Dalmio as its first bishop. The palace was transformed into an imperial cloth factory, and, as most of the workers were women, it became known during the 13th century as the gynaeicum. Salona was several times taken and retaken by the Goths and Huns before 609, when it was sacked and nearly destroyed by the Avars. Its inhabitants fled to the Dalmatian islands, but returned shortly afterwards to found a new city within the walls of the palace. Salona itself was not entirely deserted until the close of the 13th century. In 650 the papal legate, John of Raveuna, was created bishop of Spalato, as the new city was named. "Spalato," or "Spalatro" (a very old spelling), was long regarded as a corruption of Salonae Palatium; but is now (Fondi) Spalato. The plan of Spalato included Trogirum, and Aspalatham, used in the 10th century by Constantine Porphyrogenitus. Spalathon, Spalathron and Spalattrum are early variants. In a few years Spalato became an archbishopric, and its holders were metropolitanals of all Dalmatia until 1933. In 1105 Spalato became a vassal state of Hungary; in 1327 it revolted to Venice; in 1357 it returned to its allegiance. It was ruled by the Bosnian king, Tvrtko, from 1390 to 1391; and in 1402 the famous and powerful Bosnian prince, Hrvoe or Harvoye, received the dukedom of Spalato from Ladislaus of Naples, the claimant to the Hungarian throne. In 1413, after the death of the workers were won by boat, it became known as the sea-bus. It was then a large octagonal tower, the Torre d'Harvoye, still bears his name. Spalato received a Venetian garrison in 1420, and ceased to have an independent history. The castle and city walls, erected by the Venetians between 1645 and 1670, were dismantled after 1807.

See T. G. Jackson, Dalmatia, the Quarnero and Istria (Oxford, 1887); and E. A. Freeman, Subject and Neighbour Lands of Venice (London, 1881), for a general description of Spalato, its antiquities and the horrible and tragic stories of the persecutions that were practiced there. The site of Spalato is well described in R. Munro, Bosnia-Herzegovina and Dalmatia (London, 1900). There are two magnificently illustrated volumes which deal with Diocletian's palace: R. Adam, Ruins of the Palace of the Emperor Diocletian at Spalato, in Dalmatia (London, 1764), engravings by Bartolozzi; and L. J. Cassas and J. Lavalle, Voyage pittoresque et historique de l'Istrie (Paris, 1842). The Dalmatian chronicles, reproduced by G. Lucia in his De regno Dalmatiae et Croatiae (Amsterdam, 1666), include several which deal specially with Salona and Spalato. The most important is the Historia salomonarum pontificum et salaminiensis, by Thomas, archdeacon of Spalato (1200-1268).

SPALDING, WILLIAM (1800-1859), British author, was born in Aberdeen on the 22nd of May 1800. He was educated at the grammar school there and at Marischal College, and he went in 1830 to Edinburgh, where he was called to the bar in 1833. In that year he published a Letter on Shakespeare's Authorship of the two Noble Kinsmen (reprinted for the New Shakspeare Society in 1876), which attracted the notice of Jeffrey, who invited Spalding to contribute to the Edinburgh Review. He also spent some time in Italy, and in 1841 published Italy and the Italian Islands from the Earliest Ages to the Present Time. He occupied the chair of rhetoric in Edinburgh University from 1840 to 1845, when he was appointed professor of logic in the university of St. Andrews, a post which he held till his death on the 16th of November 1859.

Besides contributions to the Edinburgh Review, Blackwood's Magazine and the eighth edition of the Encyclopaedia Britannica, he was the author of a concise History of English Literature (1853).

SPALDING, a market town in the Holland or Spalding parliamentary division of Lincolnshire, England, on the river Welland, and on the Great Northern and Great Eastern railways, 93 m. N. from London. Pop. of urban district (1901), 9385. The town is the centre of a rich agricultural district. The parish church of St Mary and St Nicholas was built in 1284 and is of peculiar construction, having four aisles to the nave. It is mainly Decorated in style. The adjoining lady chapel (St Mary and St Thomas à Becket) was built in 1315; in 1388 it was appropriated for the grammar school endowed in 1568 by John Blanke and again in 1588 by John Gamlyn. A new grammar school was erected in 1881. There are several modern churches and chapels, a corn exchange, a Christian association and literary institute, and the Johnson hospital (1881, endowed). The existing high bridge over the Welland, constructed in 1858, took the place of a wooden bridge erected from the end of the 17th century; this last was built on the site of a Roman bridge, in two arches, and the foundations of the centre pier of which were disclosed when the wooden bridge was constructed. Trade is principally agricultural, and there is considerable water-traffic on the Welland.

Although there are no traces of settlement at Spalding (Spalunig) before late Saxon times there was probably a village here before Thorold the sheriff founded his cell of Crowland Abbey in 1051. In Domesday Book the manor is said to belong to Ivo de Taillebois, who possessed a market there worth 40s., six fairs and rent from salt-pans. The manor was afterwards granted to Angers, and later belonged to Spalding Priory, which retained it until at the suppression it passed to the Crown. Stephen made Spalding Priory free of toll, while John gave the monks forest rights. The town was governed by the prior's manorial court, and never became a parliamentary or municipal borough. The prior obtained the grant of the Friday market in 1242, and in the reign of Edward I. claimed from old fairs on the feast of St Nicholas and fifteen days following, and on the vigil and octave of St Cross. In more modern times Spalding was well known for the club known as the "Gentlemans' Wood" erected by subscription in the early 17th century; a week at a coffee-house in the town for the discussion of literary and antiquarian subjects, and numbered among its members Newton, Bentley, Addison, Pope and Gay.

SPALLANZANI, LAZARO (1770-1790), Italian man of science, was born at Scandiano in Modena on the 10th of January 1772, and was at first educated by his father, who was an advocate. At the age of fifteen he was sent to the Jesuit college at Reggio di Modena, and was pressed to enter that body. He went, however, to the university of Bologna, where his famous kinswoman, Laura Bassi, was professor of physics, and it is to her influence that his scientific impulse has been usually attributed. With her he studied natural philosophy and mathematics, and gave also great attention to languages, both ancient and modern, but soon abandoned the study of law, and afterwards took orders. His reputation soon widened, and in 1754 he became professor of logic, metaphysics and Greek in the university of Reggio, and in 1760 was translated to Modena, where he continued to teach with great assiduity and success, but devoted his whole leisure to natural science. He declined many offers from other Italian universities and from St Petersburg until 1768, when he accepted the invitation of Maria Theresa to the chair of natural philosophy in the university of Pavia, which was then being reorganized. He also became director of the museum, which he greatly
enriched by the collections of his many journeys along the shores of the Mediterranean. In 1785 he was invited to Padua, but to retain his services his sovereign doubled his salary and allowed him leave of absence for a visit to Turkey, where he remained nearly a year, and made many observations, among which may be noted those of a copper mine in Chalki and of an iron mine at Principi. His return home was almost a triumphal progress: at Vienna he was cordially received by Joseph II., and on reaching Pavia he was met with acclamations outside the city gates by the students of the university. During the following year his students exceeded five hundred. His integrity in the management of the museum was called in question, but a judicial examination finally cleared him of his imputations, even of his accusers. In 1788 he visited Vesuvius and the volcanoes of the Lipari Islands and Sicily, and embodied the results of his researches in a large work (Viaggi alle due Sicilie ed in alcune parti dell' Apenino), published four years later. He died from an apoplectic seizure on the 12th of February 1799, at Pavia.

His indefatigable exertions as a traveller, his skill and good fortune as a collector, his brilliance as a teacher and expositor, and his keenness as a controversialist no doubt did much largely in accounting for Spallanzani's exceptional fame among his contemporaries; yet greater qualities were by no means lacking. His life was one of incessant eager questioning of nature on all sides, and his many and varied works bear the stamp of a fresh and original genius, capable of stating and solving problems in all departments of science—at one time finding the true explanation of "ducks and drakes" (formerly attributed to the elasticity of water) and at another having founded modern dynamics and meteorology. His main discoveries, however, were in the field of physiology: he wrote valuable and suggestive papers on respiration, on the senses of bats, &c., while he made experiments (1766) to disprove the occurrence of spontaneous generation, showing in opposition to J. H. Needom (1713-1781) that animalcules did not develop in vegetable infusions which had been boiled and were kept in properly closed vessels. His great work, however, is the Dissertazioni de' fisiologia animale e vegetale (2 vols., 1786). Here he first interpreted the process of digestion, which he proved to be no mere mechanical process of trituration, but one of actual solution, taking place primarily in the stomach, by the action of the gastric juice. He also carried out important researches on fertilization in animals (1780).

SPAN (from O. Eng. spann, to bind, connect together; the word is of general occurrence in Teutonic languages, the ultimate origin being the root span-, to extend, stretch out, cf. Gr. σπαν, to draw out, Lat. spatium, space), a distance stretched, the space between terminal points. The word was formerly used as a measure of length =10-368 in., taken from the stretch of the fully opened hand from thumb to little finger. The tendency of the towns and castles was to grow by opening of an arched or arched opening, and also the width of a roof between the wall plates. A "span roof" is a roof having two sides inclining to a centre ridge, in contradistinction to a "shed roof" (see SHED).

SPANDAU, a town of Germany, in the Prussian province of Brandenburg, at the confluence of the Havel and Spree, 8 m. N.W. of Berlin, of which it is practically a suburb, on the main lines of railway to Hanover and Hamburg respectively. Pop. (1883), 31,466; (1895), 55,813; (1905), 70,295 (including a garrison of about 5000). The town round which the fortress was formerly built has been enhanced by an excellent railway service with Berlin and improved navigation on the Havel. The fortifications, which were strengthened after the war, 1870-71, for the protection of the arsenal, have been razed on the northern and eastern sides, and of its former defences none remain except the citadel and a line of works along a ridge of hills to the south of the town. The Julius tower in the citadel, which is surrounded by water, contains the Imperial war treasure (Reichskriegsschatz), —a sum of 60,000,000 gold, kept in readiness for any warlike emergency, and reserved from the indemnity paid by France after the war of 1870-71. Spandau contains four Protestant churches, a Roman Catholic church, a gymnasia and a school of musickery. Besides numerous barracks, there are various military establishments appropriate to an important garrison town; and its chief industries are connected with the preparation of munitions of war. The government factories for the manufacture of small arms, artillery, gunpowder, &c., cover upwards of 200 acres, and employ about 6000 workmen. The other industries are not very important; they comprise miscellaneous manufactures, fishing, boat-building, and some shipping on the Havel.

Spandau is one of the oldest places in the Altmark, and received civic rights in 1322. It afterwards became a favourite residence of the Hohenzollern electors of Brandenburg, and was fortified in 1577-1583. In 1635 it surrendered to the Swedes, and in 1806 to the French. A short investment in 1813 restored it to Prussia.

See Ziegler, Geschichte der Stadt Spandau, (1851); and Kunzeltümer, Ueberkunde Geschichte der Stadt und Festung Spandau (Spandau, 1847).

SPANDRIL, or SPANDREL, (formerly splausandr, a word of unknown origin), in architecture, the space between any arch or curved brace and the level label, beams, &c., over the same. The spandrils over doorways in Perpendicular work are generally richly decorated. At Magdalene College, Oxford, is one which is perforated, and has a most beautiful effect. The spandrils of doors is sometimes ornamented in the Decorated period, but seldom forms part of the composition of the doorway itself, being generally over the lunette or side-light.

SPANGENBERG, AUGUST GOTTLIEB (1704-1799), Count Zinzendorf's successor, and bishop of the Moravian Brethren, was born on the 15th of July 1704 at Klettenberg, on the south of the Harz Mountains, where his father, Georg Spangenberg, was court preacher and ecclesiastical inspector of the countship of Hohenstein. Left an orphan at the early age of thirteen, he was sent to the gymnasium at Ilefeld, and passed thence (1722), in poorest circumstances, to the university of Jena to study law. Professor Johann Franz Buddeus (1667-1729) received him into his family, and a "stipendium" was procured for him. He soon abandoned law for theology; took his degree in 1726, and began to give free lectures on theology. He also took an active part in a religious union of students, in the support of the free schools for poor children established by them in the suburbs of Jena, and in the training of teachers. In 1728 Count Zinzendorf visited Jena, and Spangenberg made his acquaintance; in 1730 he visited the Moravian colony at Herrnhut. A "collegium pastorale practicum" for the care of the sick and poor was in consequence founded by him at Jena, which the authorities at once broke up as a "Zinzendorfian institution. But Spangenberg's relations with the Moravians were confirmed by several visits to the colony, and the attainment of an unfavourable appeal to the lot alone prevented his appointment as chief elder of the community, March 1733. Meanwhile his free lectures in Jena met with much acceptance, and led to an invitation from Gottlieb Francke to the post of assistant professor of theology and superintendent of schools connected with his orphanage at Halle. He accepted the invitation, and entered on his duties in September 1732. But differences between the Pietists of Halle and himself soon became apparent. He found their religious life too formal, external and worldly; and they could not sanction his comparative indifference to doctrinal correctness and his incurable tendency to separation in church life. Spangenberg's participation in private observances of the Lord's Supper and his intimate connexion with Count Zinzendorf brought matters to a crisis. He was offered by the senate of the theological faculty of Halle the alternative of doing penance before God, submitting to his superiors, and separating himself from Zinzendorf, or leaving the matter to the decision of the king, unless he preferred to "leave Halle quietly." The case came before the king, and, on the 8th of April 1733, Spangenberg was conducted by the military outside the gates of Halle. At first he went to Jena, but Zinzendorf at once sought to secure him as a fellow labourer, though the count wished to obtain from him a declaration which would remove from the Pietists of Halle all blame with regard to the disruption. Spangenberg went to Herrnhut and found amongst the Moravians his life-work, having joined them at a moment when the stability of the society was threatened. He became its theologian, its
apologist, its statesman and corrector, through sixty long years of incessant labour.

For the first thirty years (1733–1762) his work was mainly devoted to the superintendence and organization of the extensive missionary enterprises of the body in Germany, England, Denmark, Holland, Surinam, Georgia and elsewhere. It was on an island off Savannah that Spangenberg startled John Wesley with his questions and profoundly influenced his future career.

One special endeavour of Spangenberg in Pennsylvania was to bring over the scattered Schwenkfeldians to his faith. In 1741–1742 he was in England collecting for his mission and obtaining the sanction of the archbishop of Canterbury. During the second half of this missionary period of his life he superintended as bishop the churches of Pennsylvania, defended the Moravian colonies against the Indians at the time of war between France and England, became the apologist of his body against the attacks of the Lutherans and the Pietists, and did much to moderate the mystical extravagances of Zinzendorf, with which his simple, practical and healthy nature was out of sympathy. The second thirty years of his work (1762–1792) were devoted to the consolidation of the German Moravian Church. Zinzendorf's death (1771) left room and need for his labours at home. At Herrnhut there were conflicting tendencies, doctrinal and practical extravagances, and the organization of the brethren was very defective. In 1777 Spangenberg was commissioned to draw up an idea fidei fratum, or compendium of the Christian faith of the United Brethren, which became the accepted declaration of the Moravian belief. As compared with Zinzendorf's own writings, this book exhibits the finer balance and greater moderation of Spangenberg's nature, while those offensive descriptions of the relation of the sinner to Christ in which the Moravians at first indulged are almost absent from it. In his last years Spangenberg devoted special attention to the education of the young, in which the Moravian instructions have since been so successful. He died at Berthaelsdorf, on the 18th of September 1792.

In addition to the Idea fidei fratum, Spangenberg wrote, besides other apologetic books, a Declaration über die seither gegen uns ausgegangen Beschuldigungen sonderlich die Person unseres Ordinarius (Zinzendorf) betreffend (Leipzig, 1751), an Apologetische Schlusschrift (1752), Leben des Grafen Zinzendorf (1772–1773); and his hymns are well known beyond the Moravian circle.

Spangernsbergs (Halle, 1884); Gerhard Reichel's article in Herzog-Hauck's Realencyclopaedie (ed. 1906), s.v. "Spangenberg," in the Allgemeine deutsche Biographie; also Moravian Brethren.

SPANISH-AMERICAN WAR OF 1898.

For the causes leading up to the war see Cuba and United States: History. On the 15th of February 1898 the U.S. battleship "Maine," which had been sent to Havana on the 25th of January, was destroyed in Havana harbour by an explosion, with a loss of 266 lives. An American board of inquiry, of which Captain W. T. Sampson was president, in which an extensive examination of the wreck, and repeated the navy department on the 21st of March that the explosion was caused by an exterior mine, the principal reason for this decision being the upheaval of the ship's bottom.¹ On the 20th of April President McKinley approved a resolution demanding the withdrawal of Spain from Cuba and setting noon of the 23rd of April as the latest date for a reply to the demand. Before this could be delivered by the American minister in Madrid, the Spanish government sent him his passports. On the 22nd the president declared a blockade of Cuban ports; on the 24th the Spanish government declared war; and on the 25th the United States Congress declared that war had existed since the 21st.

The American government had begun to prepare for war as early as January: ships on several foreign stations had been drawn nearer home, and those in Chinese waters were collected at Hong-Kong; the North Atlantic squadron, the only powerful one, had been sent from Hampton Roads into the waters of Florida for manoeuvres; after the destruction of the "Maine"—the chief part of the ships in the Atlantic were concentrated at Key West; the battleship "Oregón" was ordered east from the Pacific; $500,000 was voted (March 9) "for the national defence"; ships were taken to purchase auxiliary cruisers, yachts and tugs, which were rapidly equipped; large supplies of ammunition were ordered, and Key West became an active base of preparation; Captain Sampson, senior officer of the North Atlantic squadron, was appointed its commander-in-chief with rank of acting rear-admiral; and a "flying squadron" composed of the armed cruiser "Brooklyn" (flag), the battleships "Texas" and "Massachusetts," and the fast cruisers "Minneapolis" and "Columbia," with Commodore W. S. Schley in command, was stationed at Hampton Roads.

There was a great preponderance of large ships on the side of the United States; only in torpedo craft and small gunboats was Spain superior. The American ships were highly efficient; in Spain everything was unready; Admiral Cervera felt that to send a Spanish squadron across the Atlantic was to send it to destruction, and when he had collected his squadron (including two cruisers from Havana) at the Cape Verde Islands in March, he renewed his expostulations, in which he was supported by a council of war. But on the 24th of April he was peremptorily ordered to leave for Porto Rico, without definite instructions or plan of campaign.

The American flying squadron was held at Hampton Roads, so great was the fear of attack by Spanish ships; and armed auxiliaries and fast cruisers were employed in patrolling the coast east of New York; these could have rendered good service elsewhere, but would have been of no use in repelling an attack by Cervera's squadron had it come that way.

The joint resolution of Congress of the 20th of April had declared that the relinquishment by Spain of authority in Cuba was the object of American action; the struggle thus naturally centred about the island. All operations were thus near at hand. There was, the real objective in Cuba, being only about 100 m. from Key West. A political reason for confining action to the western Atlantic was that an immediate attack upon the coasts of Spain might have aroused the strongly pro-Spanish sympathy of continental Europe into greater activity. The regular United States army, the only available force until war was declared and a volunteer force was authorized, had been assembled at Tampa, Florida, New Orleans and Chickamauga, Georgia, but until the control of the sea was decided, the army could not prudently be moved across the Strait of Florida. Cervera's fleet was thus the real objective of the navy, and had to be settled with before any military action could be undertaken.

Rear-Admiral Sampson left Key West early on the 22nd, and began the blockade of Havana and the north coast of Cuba as far as Cardenas, 80 m. east, and Bahia Honda, 50 m. west. His North Atlantic squadron of 24 vessels of all kinds, of which the armoured cruiser "New York" (flag), the battleships "Iowa" and "Indiana," and the monitors "Puritan," "Terror" and "Amphitrite," were the most important, which included six torpedo-boats, was increased to 124 vessels by the 1st of July, chiefly by the addition of extemporized cruisers, converted yachts, etc. In the Pacific, the American squadron—the protected cruisers "Olympia" (flagship of Commodore George Dewey), "Baltimore," "Raleigh," and "Boston," the small unprotected cruiser "Concord," the gunboat "Petrel," the armed revenue cutter "Hugh M'Culloch," with a purchased collier "Nanshan," and a purchased supply ship "Zafiro"—left Hong-Kong at the request of the governor and went to Mirs Bay, some miles east

¹ The Spanish authorities made an examination, but did not inspect the interior, the chief diver reporting that "the bilge and keel of the vessel throughout its entire extent were buried in the mud, but did not appear to have suffered any damage." It has been suggested that the explosion was the work of Cuban sympathizers who thus planned to secure American assistance against Spain. It was not until 1910 that Congress made an appropriation (and an inadequate one then) for raising the "Maine."
on the Chinese coast. Ordered (April 25) to begin operations, particularly against the Spanish fleet, which he was directed to capture or destroy, Dewey left Mira Bay on the 27th, and arrived off Luzon, in the Philippines, on the 30th of April. The Spanish admiral Montojo anchored to the eastward of the spit on which are the village and arsenal of Cavite, in a general east and west line, keeping his broadside to the northward. His force consisted of the “Reina Cristina,” the “Caszilla” (an old wooden steamer which had to be towed); the “Isla de Cuba” and “Isla de Luzon” (protected cruisers of 1030 tons); the “Don Juan de Austria” and the “Don Antonio de Ulloa” (gunboats numbering 1150 tons), and the “Marcos del Duerro” (of 500 tons). There were six guns (5 breech-loaders) in battery at or near Cavite.

Dewey stood on during the night, and passed into the Bocca Grande (about 5 m. broad), paying no attention to rumours of torpedoes in a channel so broad and deep, and at midnight passed El Fraile (a large rock, 1/2 m. from the south side), from which two shots were fired at him, and he was also fired at by the “Cavite” and one of the city batteries. When he sighted the Spanish squadron to the southward he ordered his transports and the small ships, except the “Isabella” and “Instructores” to stand down in column with the “Olympia,” “Baltimore,” “Raleigh,” “Petrel,” “Concord” and “Boston” at 400-yd. intervals. When within 5000 yds. he ported his helm, and at 5.41 a.m. opened fire. He stood westwards along the Spanish line, using his port batteries, turned to starboard and stood back, gradually decreasing his distance to 3000 yds. At 7 o’clock the Spanish flagship attempted to come out and engage at short range, but was driven back by the American fire. The Spanish squadron was now in very bad plight, but the seriousness of its condition was not fully known to the American commander. At 7.45 Dewey withdrew, gave his men breakfast, and had a consultation of commanding officers. Before he re-engaged at 11.16 the “Cristina” and “Casilla” had broken into flames, so that the remainder of the action consisted in silencing the Cavite batteries and completing the destruction and demoralization of the smaller Spanish ships, which the “Petrel” was ordered in to burn. The victory was complete. All the Spanish ships were sunk or destroyed. The injury done the American ships was practically nil. The Spanish lost 187 killed and 214 wounded, out of a total of 1875. The Americans had 7 slightly wounded out of 1748 men in action. Dewey took possession of Cavite, paroled its garrison, and awaited the arrival of a land force to capture Manila.

The blockade of Havana had progressed without incident, beyond the capture of a number of Spanish steamers and sailing vessels, and the shelling of some new earthworks at Matanzas on the 27th of April; but on the 11th of May a small action was fought at Cardeñas, in which the Americans were repulsed and Ensign Worth Bagley, the first American officer to lose his life in the war, was killed. On the same day a partially successful attempt was made, under a heavy fire from the shore, to cut the cable between Cienfuegos and Havana.

Cervera had left the Cape Verde Islands on the 29th of April with four armed cruisers, the “Almirante Oquendo,” “Infanta Maria Teresa” and “Vizcaya” (sister ships of 7000 tons) and the “Cristóbal Colon” (same size; differently equipped) and three torpedo-boat destroyers—a type not then represented in the American navy—“Furor,” “Terror” and “Pluton.” On hearing (May 1) of Cervera’s departure, Sampson went east 1000 m. to San Juan, Porto Rico, with the armoured cruiser “New York,” the battleships “Iowa” and “Indiana,” the cruisers “Montgomery” and “Detroit,” and one torpedo-boat. In going east he calculated on using a speed of 10 knots, on getting to San Juan on the 8th, about the time the Spaniards would reach its longitude, and if they were not there, on returning off Havana before they could get to Havana harbour. He wished to prevent Cervera’s refitting at San Juan, from which place the American coast would be within easy reach, New York being only about 1400 m. away. But the speed of the American squadron fell short of Sampson’s expectation; he reached San Juan on the 12th, stood in to see if Cervera was in the harbour, and opened fire upon the fortifications. He did not press the attack since Cervera was not present, and at once started back for Havana without news of Cervera, who was then in fact off Martinique, with orders to go to San Juan. When he heard that Sampson was at San Juan, Cervera decided to come to Curacoa instead of San Juan, where the authorities allowed him to coal. He reached Santiago de Cuba early on the 19th without being sighted on route by any of the American scouts, though several were in the vicinity. Sampson thought the Spanish squadron might have returned to Spain. But he learned that the enemy had not turned back, on the night of the 19th, when a telegram from the navy department directed him to proceed with all despatch to Key West. He got there on the afternoon of the 18th, and found the flying squadron (”Brooklyn,” “Massachusetts,” “Texas,” and “Scorpion”) which left on the 13th from Curacoa under Commodore George C. Scribner by the navy department as the certain objective of the Spanish squadron. The battleship “Iowa,” the gunboat “Castine,” the torpedo-boat “Dupont” and the collier “Merrimac” sailed to join Schley on the 20th, and gave him a force sufficient to meet Cervera. Sampson was advised by the department (on the 20th) to “send by the Iowa” to Schley to proceed off Santiago de Cuba with his whole command, leaving one small vessel off Cienfuegos, but he directed Schley in an order of the 21st if he was satisfied that Cervera was not at Cienfuegos, to proceed with all despatch to Santiago, and if the Spanish squadron was there, to blockade it.

Commodore Schley arrived off Cienfuegos on the 22nd, and held to the opinion that Cervera was there until the 24th, when Commodore M’Calla of the “Marblehead” communicated with the insurgents some miles westwards, and learned the truth. Schley started that evening for Santiago, 300 m. distant, but on the afternoon of the 26th was 20 m. south of the port. Early on the 27th Schley received a despatch from the navy department suggesting that the Spanish squadron was in Santiago and bidding him see “that the enemy, if therein, does not leave without a decisive action.” Schley replied “... cannot remain off Santiago present state squadron coal account... much to be regretted cannot obey orders of department... forced to proceed for coal to Key West by way of Yucatan Passage,” in the controversy that arose out of these events Schley’s critics insisted that the “Iowa” and the “Massachusetts” had at this time enough coal to carry them three distances from Santiago to Key West.

Sampson with the “New York” had arrived early on the 28th of May off Key West. When Schley’s telegram, which had much disturbed the Washington officials, was forwarded to Sampson, he secured permission to go at once to Santiago with the “New York” and “Oregon” (which had arrived at Key West on the 26th of May in excellent condition after her voyage of nearly 16,000 m. from the Pacific) to turn back Schley’s heavier ships. Before he started he received a telegram from Schley stating that he would remain off Santiago. It is now known from the documents published by Admiral Cervera that the Spanish squadron, in the interval preceding the 26th, when Schley arrived in sight of the port, was on the point of leaving Santiago. On the morning of the 29th two Spanish cruisers were seen a short distance within the entrance, and on the 31st Schley, with the “Massachusetts,” “Iowa” and “New Orleans,” stood in and made an attack upon these and the batteries at long range (8500–11,000 yds.). On the 30th Sampson, leaving a squadron on the north side under Commodore Watson, stood for

1Three of the best were afterwards raised and repaired by American engineers.
2The “Buenaventura,” the first prize of the war, was taken by the gunboat “Nashville” off Key West on the 23rd of April.
Santiago at a speed of 13 knots. He arrived early on the 1st of June and work was at once begun on the preparations for sinking the collier "Merrimack" in the entrance channel, which was less than 200 ft. broad in parts available for ships. The preparations for a quick sinking were chiefly carried out by naval constructor Richard P. Hobson, who went in, in the early morning of the 3rd of June, with a crew of seven men. The steering-gear was disabled by a shell, and the ship drifted too far with the tide and was lost in part of the channel after it had sunk almost to the block of Cervera's squadron. Cervera sent word to Sampson that Hobson and his men, who had been captured, were unhurt. They were exchanged on the 7th of July.

On the 6th of June the batteries at the entrance were bombarded and their weakness was ascertained. Sampson thereupon, every evening, a battleship (relieved every two and a half hours) close in, with a searchlight turned on the channel, making it impossible, as 4:00 p.m., to approach the entrance.

Cervera afterwards said, for the Spanish squadron to escape by night. The port of Guantánamo, 40 m. east of Santiago, was occupied by the "San Joven" and in May 4,776 men and, on the 7th, a battalion of marines from the transport "Panther" landed there on the 10th, and the port was used thereafter as a base-and-coaling station. On the 14th the Spanish land forces retired after an expedition of the American marines, who remained in occupation until the 5th of August.

A blockade of San Juan, Porto Rico, by one or two fast ships was kept up on account of the presence there of the destroyer "Terror," but this vessel, coming out (June 22) with a gunboat to attack the auxiliary cruiser "St Paul," suffered severely that she could hardly return to port, and was thereafter unserviceable. When war was declared the total military forces of the United States consisted of 27,822 regulars and 114,602 militia. An act of the 22nd of April had authorized the president to call upon the states and Territories for men in proportion to their population, the regimental and company officers to be named by the governors of the states, the general and staff officers by the president. A first call was made for 125,000 men, and a month later a second call for 75,000. On the 26th of April large additions to the regular army were sanctioned for the war. The quotas were filled with extraordinary rapidity, and in May 4,776 had volunteered. The troops were concentrated chiefly at Chickamauga, Georgia, at Camp Alger, Virginia, and at Tampa, Florida.

Preparations for a Land Campaign. Major-General W. R. Shafter was in command. With the exception of unimportant small expeditions, everything was delayed until control of the sea was assured, though some thirty large steamers were held in readiness near Tampa. After the arrival of Cervera at Santiago, the blockade of his squadron and the request (June 7) of Admiral Sampson to send a land force for co-operation, the troops embarked on the 7th and 8th of June, but a start was not made until the 14th, owing to a false report that Spanish war-ships were in Nicholas Channel. On the 20th the fleet of 32 transports, under convoy, arrived off Santiago. The whole force consisted of about 17,000 officers and men, 16 light field-guns, a train of heavier pieces, and some 200 vehicles. General Shafter selected Daiquiri, about 18 m. east of Santiago, for the point of landing, and the harbour entrance (preferred by Sampson) was disregarded. The fleet furnished all its available boats, and on the 22nd-23rd the army was landed on a rough coast with scarcely any shelter from the sea; after the first day Siboney, 7 m. nearer Santiago, was used as well as Daiquiri. With the exception of three volunteer regiments (the 1st Volunteer Cavalry, known as the Rough Riders, of which Theodore Roosevelt was lieutenant-colonel; the 2nd Massachusetts and the 71st New York Volunteers), these troops were composed almost wholly of regulars, most of whom had served on the plains against the Indians. Soon afterwards more volunteers arrived.

No opposition was made to the landing and the small Spanish contingents at Daiquiri and Siboney were withdrawn without doing any damage to the equipment of the railway which ran from Santiago to the iron mines at these points. The American troops (commanded by Major-General Joseph Wheeler until the 29th, when General Shafter landed) pushed forward, a as soon as they landed, and found a small Spanish rearguard which was covering the concentration of outlying detachments on Santiago and which was entrenched 2 m. beyond Siboney, at Las Guáumas. Brigadier-General S. M. Young with 964 dismounted cavalry engaged and Rickenbacker's Legion in it. In which he lost 16 killed and 52 wounded, drove back the enemy, of whom 11 were killed or wounded. The advance was slow and a week elapsed before Shafter was ready to fight a battle in front of Santiago. Here the defenders, under General Arsenio Linares, held two positions, the hill of San Juan, barring the direct road to Santiago, and the village of El Caneý, to the northward of the American position at El Pozo. The plan of attack on the 1st of July was Shafter's, but owing to the illness of Shafter the actual command was exercised by the subordinate generals, Joseph Wheeler, H. W. Lawton and J. F. Kent. General Lawton's division was ordered to attack El Caneý, and thence move against the flank and rear of the defenders of San Juan, which would then be attacked in front by Kent and Wheeler from El Pozo. But Lawton for nine hours was checked by the garrison of El Caneý, in spite of his great superiority in numbers (4500 to 520); at 3 p.m. the final assault on El Caneý was successfully delivered by General A. R. Chaifee's brigade. Only about 100 of the Spanish garrison escaped to Santiago; about 320 were killed or wounded, including General Yarn del Rey, who, with a brother and two sons, was killed. In the meantime Wheeler and Kent engaged an equally stubborn force on the opposite San Juan hill, where, in the absence of the assistance of Lawton, the battle soon became a purely front-line fight, and the rifles of the firing line had to prepare the attack unaided. The strong position of the Spaniards, gallantly defended by about 700 men, held out until 12:30, when the whole line of the assailants suddenly advanced, without orders from or direction by superior authority, and carried the crest of the Spanish position. A notable part in the attack was taken by the 1st Volunteer Cavalry or "Rough Riders," commanded by Colonel Leonard Wood and Lieut.-Colonel Theodore Roosevelt. The Spaniards had no closed reserves, and their retreat was made under a devastating fire from the Americans on the captured hills. On the American side over 1500 men out of 15,000 engaged, including several of the senior officers, were killed or wounded; and in one of Kent's brigades three successive commanders were killed or wounded. On the Spanish side, out of the small numbers engaged, over 75% were out of action. Linares himself was severely wounded, and handed over the command to General José Toral. The Cubans on the American right failed to prevent General Escario from entering Santiago with reinforcements from the interior, and at the beginning of the investment General Toral's forces numbered about 10,000 men of the army and a naval contingent from the fleet.

Though victorious, the American army was in danger: after great fatigue under a tropical sun by day, the time spent at night from digging trenches was spent on a rain-soaked ground covered with thick vegetation; the soldiers' blankets and heavy clothing had been cast aside in the attack; and there was insufficient food, because it was difficult to haul supplies over the poor road from the base of supplies at Siboney. There was even discussion of retiring to a point nearer Siboney. Britsk firing was continued on the 2nd and 3rd of July, with a considerable number of casualties to the Americans. On the morning of the 3rd a demand was sent to the Spanish commander to surrender, with the alternative of a bombardment of the city to begin on the 4th. This in effect had already begun on the 1st, when Admiral Sampson fired a number of 8-in. shells from a point 3 m. east of the harbour entrance over the hills into the city, using a range of about 4,34 miles. The result of this and the threat of General Shafter was an exodus of many thousands of civilians towards El Caneý, where the American supplies were heavily taxed to support them.
On the morning of the 3rd of July Sampson, in his flagship the "New York," left the fleet to confer with General Shafter at Siboney with regard to combined operations at the harbour entrance. 1 At 9.31, when he had gone about 5 miles, the "Maria Teresa" was seen coming out. The ships in front of the port were the yachts "Gloucester," the battleships "Indiana," "Oregon," "Iowa," and "Texas," the armoured cruiser "Brooklyn" and yacht "Vixen," in the order named from east to west, making a semicircle about 8 m. in length. The "Massachusetts" and "Swarvance" were煤ing at Guantánamo. The "Iowa" hoisted the signal "Enemy coming out." All at once stood in toward the Spanish ships, which were made fast to the shore, with the order to shew their side. The "Maria Teresa" (flagship) was followed at 800-yd. intervals by the "Vizcaya," "Colon," and "Oquendo." They were firing vigorously, but most of their projectiles went far beyond the American ships. The "Brooklyn" (flag of Commodore Schley, the senior officer present) made a turn to starboard, which seems to have caused the "Texas" to stop and back, and to have given the "Colon" the opportunity of passing almost unscathed. The "Maria Teresa" and "Oquendo" had taken fire almost at once, and, as their water mains (outside the protective deck) were cut, they were unable to extinguish the flames; they were run ashore at 10.15 and 10.20 respectively, about 6 f. west of Santiago, burning fiercely. The "Vizcaya" and "Colon" were still standing westwards. Cervera's destroyers, the "Pluto" and the "Furor," had come out last, some distance behind the "Oquendo," and were received with a heavy fire from the "Indiana" and from the unarmoured "Gloucester," which engaged them at close quarters. They attempted to close, but were cut to pieces. The "New York," Sampson's flagship, had passed, and stood on signalling the "Iowa" and "Indiana" to go back and watch the port, lest an attack be made on the American transports. The torpedo-boat "Erie-
son" was ordered to rescue the men from the two Spanish ships ashore, and the flagship, with all the others, stood on in pursuit of the "Vizcaya" and "Colon." The "Vizcaya" hauled down her colours off Aserraderos, 15 nautical miles west of Santiago, and was there run ashore burning about 11.15 a.m. The "Iowa" was ordered to stop and rescue her men, and the "Oregon," "Brooklyn" and "Texas" (and behind them the flagship) settled down to the chase of the "Colon," some 6 m. ahead of the nearest American ship. She was, however, slackening her speed, and at 11.40 the "Oregon" opened with her 5-in. guns at a range of 1000 yards, as did also the "Brooklyn," with her 8-in. When the "Oregon" had fired five shells, the "Colon" hauled down her colours, and was beached at the mouth of the Rio Turquino, where in spite of endeavours to recover her, she became a total wreck. The whole Spanish fleet was destroyed; Admiral Cervera was taken prisoner; Captain Villamil, commanding the torpedo flotilla, went down with his ship; and Captain Lazaga of the "Oquendo" was drowned. Over 500 Spaniards were killed or wounded, and the survivors (except a few who escaped to Santiago) were prisoners. On the American side only one man was killed and ten were wounded, and no ship received serious injury.

After the naval victory combined operations were arranged for attacking the batteries of the harbour, but little more fighting occurred, and eventually a preliminary agreement was signed on the 15th, and the besiegers entered Santiago on the 17th. In accordance with the terms of the capitulation, all the Spanish forces in the division of Santiago de Cuba surrendered and were conveyed to Spain. The total number amounted to about 23,500, of whom some 10,500 were in the city of Santiago. The exposure of the campaign had begun to tell in the sickness of the Americans; yellow fever had broken out to some extent; and no less than 50% were attacked by the milder forms of malarial fever. The army, indeed, was so weakened by illness that the general officers united in urging its removal from Cuba. Major-General Nelson A. Miles, the provost-marshal, had arrived with reinforcements on the 12th of July, but the majority of these men were retained on board ship.

The fleet and the army gathered in Guantánamo Bay; and a new flying squadron, the "eastern squadron," was organized under Commodore John C. Watson, to proceed by way of the Mediterranean to the Philippines, threatening the Spanish coast, in order to meet a Spanish "reserve squadron," which had been formed towards the end of May, and which was to be sent on to the eastern coast of the United States, and thence to the South Sea, to reinforce the Philippines, and Terceira, and Cadiz, on the 16th of June, for the East. This squadron turned back on the 8th of July after hearing the news of the Spanish defeat at Santiago.

On the 7th of May a telegram had been received from Dewey at Manila: "I control bay completely, and can take city at any time, but I have not sufficient men to hold." The cruiser "Charleston" and the steamer "Peking," with ammunition, supplies and troops, were sent to him at once. Major-General Wesley Merritt, to whom was assigned the command of the Philippines, first requested a force of 14,000, and afterwards the size of the squadron was increased. On the 25th of May the first troops, 2491 in number, under Brigadier-General T. M. Anderson, sailed in three transports from San Francisco, touched at Honolulu, and were convoyed thence by the "Charleston." On the 20th of June possession was taken of the island of Guam, and on the 30th of June the ships arrived in Manila Bay. A second detachment of troops, 3386 in number, under Brigadier-General F. V. Greene arrived on the 17th of July; on the 25th of July General Merritt, who had been appointed governor-general, arrived; and on the 31st the five transports with which he had left San Francisco arrived with 4847 men, making nearly 11,000 men at Manila, with 5000 more on the way. General Merritt moved his forces from Cavite, and established an entrenched line within a thousand yards of the Spanish position at Manila, from which, on the night of the 31st of July, a heavy fire of musketry and artillery was opened, causing a loss to the Americans of 10 killed and 43 wounded, and for the next few days night-firing was frequent from the Spanish lines. On the 7th of August, a joint note from Dewey and Merritt, announcing that bombardment might begin at any time after forty-eight hours, and offering opportunity for the removal of non-combatants, was sent to the Spanish captain-general, Fermín Jaudenes, who replied that he was surrounded by the insurgents, 2 and that there was no place of refuge for the sick and for the women and children. A second joint note demanding surrender was declined by the Spanish commander, who offered to refer it to Madrid. This was refused, and preparations were made for an attack. There were 13,000 troops within the city fortifications, but with the strong fleet in front, and with the beleaguering force of Americans and insurgents ashore, resistance was hopeless. When the combined assault of army and navy was made on the 13th there was no resistance, the place was hoisted at 11 o'clock, within one and a half hours after the fleet opened fire, a formal capitulation being signed the next day, the 14th of August. The total loss of the Americans during the whole campaign was 20 killed, 105 wounded.

Immediately after the surrender of Santiago (July 17), preparations were made for the invasion of Porto Rico with 3500 troops which had been sent as reinforcements to Santiago, but had not landed. They were largely reinforced and left Guantánamo, under General Miles, on the 21st of July, conveyed by a strong squadron. 3 On the 10th of May, Emilio Aguinaldo, who had been at Hong Kong, had landed from one of the American vessels at Cavité, and on the 1st of July, when the American troops landed, had proclaimed himself president of the Philippine Republic. The political attitude which he assumed was not sanctioned by the American authorities. At the head of the insurgents he had instituted a close siege of Manila.

1 Shafter had urged that the squadron should enter the harbour and shell the city of Santiago; the Secretary of War, however, was unwilling to risk losing a ship in the well-mined harbour and wanted the army to move on the forts and give the American squadron an opportunity to drag the harbour for mines.
SPANISH BROOM—SPANISH REFORMED CHURCH

SPANISH BROOM, a handsome shrub with long switch-like green few-leaved or leafless branches and large yellow sweet-scented papilionaceous flowers. It is a member of the pea family (Leguminosae), and known botanically as Spartium junceum. It is found in America, especially in the western region and the Canary Islands, and is often cultivated. The whole plant, but especially the flower shoots and seeds (herba et semen genitica hispanica vel juncea), have a bitter taste and tonic and diuretic properties, and were formerly used medicinally. The fibres of the young stems were used in making nets, carpets, mats, baskets, &c.

SPANISH REFORMED CHURCH (Iglesia española reformada), a small community of Protestants in Spain organized on the model of the Anglican Church. This body of Spanish Episcopalians had its origin in a congregation which rose for the first time, in June 1871, in the secularized church of San Basilio at Seville, under the leadership of Francisco Palomares, a priest who had left the Roman communion. Before long it was joined by numbers of lay people and several clergymen, including Juan Cabrera, an ex-Roman priest, who had for some time been a Presbyterian minister. In June 1878 a memorial was presented to the Lambeth Conference by nine congregations in Spain and Portugal (see below) asking for the episcopate. The reply expressed the sympathy of the bishops, but only suggested that this could be obtained by the formation of an Episcopal Church of the United States to minister to the reformed congregations in Mexico, should be invited to visit them and ordain and confirm for them. Archbishop Tait wrote a formal letter to Bishop Riley to this effect, and the request was complied with. A second petition for the episcopate was sent to the Irish bishops in 1879, and early in 1881, at their request, Lord Plunket paid his first visit to the Spanish Reformed Church, though nothing immediately resulted from it. In 1880 the first "synod" of the Church was held, under the presidency of Bishop Riley; the principles of the church were then established. In 1899, Senor Cabrera was chosen bishop-elect, the preparation of a liturgy was begun, and nine Articles of Religion of the Church of England, with certain modifications, were formally adopted as a standard of doctrine. Archbishop Plunket continued his efforts on their behalf; and at length the Irish bishops, having again received from them a petition for a bishop, brought the matter before the Lambeth Conference of 1888. The conference deprecated "any action that does not regard primitive and established principles of jurisdiction and the interests of the whole Anglican communion." The archbishop interpreted this as a modified blessing for the church, but the Irish bishops understood it to have been declined to consecrate a bishop for them. Meanwhile the movement prospered, being largely helped with money from friends in England. The foundation-stone of a new church was laid in Madrid in 1891, on the site of the Quemadero, where the autos de fe were formerly held; and after considerable legal and other difficulties, religious toleration in Spain being still imperfect, it was dedicated and opened for service. At length, at the meeting of the Irish House of Bishops on the 21st of February 1894, a letter was read from the archbishop of Dublin and the bishops of Clonfert and Roscommon, stating that they (C. Melland), in which they declared their intention, unless for some protest were made by the bishops, or by the general synod, to consecrate bishops for the Reformed churches in Spain and Portugal, subject to certain conditions being fulfilled by those churches. The bishops resolved, nemine contradicente, although the bishops of Derry (W. Alexander, subsequently primate of Armagh) and Cork did not vote, that they would not regard such action as "an indefensible exercise of the powers entrusted to the episcopate," and the general synod passed a resolution leaving the matter in the hands of the bishops. Accordingly, on the 23rd of September 1894, the three bishops laid hands on Señor Cabrera. The matter occasioned no little stir in the English Church, more especially as the Old Catholic bishops (see OLD CATHOLICS) had recently refused to take any part in the matter. It called forth a letter of protest and repudiation from Lord Halifax, as president of the English Church Union, to Cardinal Manneschoel, archbishop of Toledo; and this in turn evoked a letter from Cardinal Vaughan, which was widely circulated in Spain.

The consecration of Bishop Cabrera certainly produced, from the point of view of Anglican churchmen, a somewhat anomalous state of things, and the action, or inaction, of the Irish bishops laid them open to criticism from many who were not unfriendly to such movements (see e.g. Bishop John Wordsworth, Ministry of Grace, pp. 175–177, London, 1901). Objection was made to the act as contrary to church order, and as unjustifiable in view of the nature of the Spanish Reformed Church itself. As regards the latter, it is true that the Prayer-book of the body (first
SPANISH SUCCESSION, WAR OF THE

made in 1881 and published in a revised form in 1886) cannot really justify the claim made on its behalf as a "revised Mozarabic rite"; it contains indeed many beautiful prayers from the Mozarabic and other offices, but its doctrinal teaching is more unambiguously "Protestant" than that of the English Prayer-book. The Church possessed in 1066 ten congregations with some dozen clergy.

**Lusitaniense Church.**—A similar movement began in Lisbon in 1087, owing to the work of a Spanish priest there, Señor Mora; and at first its success was even greater than the movement in Spain, in spite of the fact that Portuguese priests who left the Roman communion had either to leave Portugal or to become subjects of another power. In 1087 the adherents of this movement threw in their lot with their Spanish brethren, and when Bishop Riley visited them in 1089 the Lusitaniens organized themselves as the "Lusitaniense Church," and the Rev. T. Godfrey Pope, D.D. (d. 1092), the English chaplain at Lisbon, was subsequently chosen by them as president of the synod. A request made to the Irish bishops in 1097 for the consecration of Canon Pope as their bishop led to an examination of the Lusitaniense Prayer-book, which was found to be even more defective from the Anglican point of view than that of the Spanish Reformed Church. Consequently no action was taken. In 1096 the Church had only some 500 adherents with five clergy.

**SPANISH SUCCESSION, WAR OF THE,** the name given to the general European war which began in 1701 and ended with the Treaties of Utrecht and Rastatt in 1713-14. The war in its **ensemble** is the typical "war with limited aim," carried out by professional armies in the interests of sovereigns and their cabinets and except in the last stages of the war in northern France enlisting no more than the platonic sympathies of the various peoples whose rulers were at war. Nevertheless, its monotonous round of marches and sieges is now and then quickened by the genius of three great soldiers, Marlborough, Eugene and Villars, and Peterborough and Galway, Catlin and Vendôme, though less highly gifted, were men of unusual and conspicuous ability. As usual in these wars, manoeuvres, threats and feints played the principal part in field warfare. The soldiers of those days were too costly to be squandered on indecisive battles, and few generals of that time knew how to make a battle a means of definitively settling the quarrel or had the influence and force of character to extort from their sovereigns permission to play for high stakes. The tangible assets, at the conclusion of peace, were fortresses and provinces; and the effective seizure of fortresses and provinces, "here a little, there a little," was in most cases the principal object with which kings and princes made war. Nevertheless, at the time of the Spanish Succession War the generals had not yet wholly reconciled themselves to their new position of superior chess-players. Moreover, the object of the war, at least in the first part, was not to win the Spanish dominions to their own domains than to cripple the power of Louis XIV. The ambition of the **Grand Monarque** had stepped beyond these narrow limits, and by placing on the throne of Spain his grandson Philip he had brought into politics the fear not merely of a disturbance but of an entire overthrow of the "balance of power." Thus the instrument of his ambition, his magnificent army, was (above all for England) an object in itself and not merely an obstacle to the attainment of other objects. Many of the allies, however, had good reason to fear for their own positions, and the Spanish army, rooted in Spanish soil and surrounding the Spanish dominions, combined with at least the hope of acquiring a few material gains at small expense. On the side of the allies therefore, throughout the war, there was a perpetual struggle between offensive activity and defensive passivity, and within the category of "activity" two very different forms of offensive alternately prevailed, the decision of the main question by the sword and the seizure of a minor object by stratagem. Were it not for the existence of this struggle, indeed, the war would be devoid of interest. Later in the 18th century there was, as a rule, no such struggle, for the grander form of offensive died out completely, and the feebler form was easily reconciled with the requirements of passive defence. But in 1700 the true spirit of war—in a leader of the greatness of Marlborough at least—was not yet entirely smothered by chicane.

The action of Louis XIV. in the matter of the Spanish succession was foreseen, and William III. of England had devoted his last years to providing against the emergency by the formation of a coalition to deal with it, and the production of a claimant to the Spanish throne by the archduke Charles. The coalition naturally grew out of the War of the Austrian Succession, and consisted of Austria, some of the German states, Great Britain, Holland, Denmark and Portugal. On the other side Louis XIV. was supported by Spain—where Philip, recognized as heir by the dying Charles II., had been promptly installed—Bavaria and Cologne. A doubtful ally was the duke of Savoy, whose policy was to secure and aggrandise himself by adhering at each moment to the stronger party. The alliance of Louis with the discontented prince of Hungary and Transylvanian Rakoczy was rather an impediment to his enemy than a distinct asset, as a policy of inactivity on the part of the Hapsburgs could hardly prevent the French from founding a new empire out of Italy and the Netherlands.

The war began, to all intents and purposes, with the handing over of the fortresses in the Spanish Netherlands to the French in March 1701. England and Holland at once began their preparations, but neither state was able to put an army in the field in the year—England because her peace-time army was absolutely insignificant, and Holland because she dared not act alone. In Italy, however, the emperor took the initiative, and an Austrian army under Prince Eugene, intended to over-run the Spanish possessions in the Peninsula, assembled in Tiroil in the early summer, while the opposing army (French, Spanish and Piedmontese), commanded by Marshal Catlin, was slowly drawing together between the Chiese and the Adige. But supply difficulties hampered Eugene, and the French were able to occupy the strong positions of the Rivoli defile above Verona. There Catlin thought himself secure, as all the country to the east was Venetian and neutral. But Eugene, while making ostentatious preparations to enter Italy by the Adige or Lake Garda or the Brescia road, secretly reconnoitred passages over the mountains between Roveredo and the Vicenza district. On the 27th of May, taking infinite precautions as to secrecy, and requesting to himself no provision or opposition so long as his troops behaved well, Eugene began his march by paths that no army had used since Charles V.'s time, and on the 28th his army was on the plains. His first object was to cross the Adige without fighting, and also by ravaging the duke of Mantua's private estates (sparing the possessions of the common people) to induce that prince to change sides. Catlin was completely surprised, for he had counted upon Venetian neutrality, and when in the search for a passage over the lower Adige, Eugene's army spread to Legnaro and beyond, he made the mistake of supposing that the Austrians intended to resist.TN the end, however, the Spanish army had no idea, and the dispositions had, of course, been for the defence of the Rivoli approaches, but he now thinned out his line until it reached to the Po, and after five weeks' cautious manoeuvring on both sides, Eugene found an unguarded spot. With the usual precautions of secrecy (deceiving even his own army), he crossed the lower Adige in the night of the 8th-9th of July, and overpowered the small cavalry corps that alone was encountered at Carpi (July 9). Catlin at once concentrated his scattered army backwards on the Minco, while Eugene turned northward and regained touch with his old line of supply, Roveredo-Rivoli. For some time Eugene was in great difficulties for supplies, as the Venetians would not allow his barges to descend the Adige. At last, however, he made his preparations to cross the Minco close to Peschiera and well beyond Catlin's left, with the intention
of finding a new supply area about Brescia. This was executed on the 28th of July. Catinat by cavalry, though coming within sight of Eugene’s bridges, offering no opposition. It seems that the marshal was well content to find that his opponent had no intention of attacking the Spanish possessions in the Peninsula, at any rate Catinat fell back quietly to the Oglio. But his army resented his retreat before the much smaller force of the Austrians and, early in August, his rival Tessé reported this to Paris, whereupon Marshall Villery, a favourite of Louis, was sent to take command. The new commander was perhaps the least competent of all the French senior officers, and ere long he attacked Eugene in a well entrenched position at Chiari (Sept. 1), and was thoroughly defeated, with a loss, it is said, of 3000 to the Austrians’ 150. But the Austrians, in retreat, had exhausted the exhaustion of supplies compelled them to move, when Villery retreated to the Adda. Both Villery and Catinat (who had remained with him as second-in-command), warned the king of the duplicity of the duke of Savoy, who, for all the reckless bravery that he had displayed in attempting to storm his cousin’s entrenchments, was in reality already intending to change sides.

As yet there was no declaration of war by either party. Preparations were made by both sides during the year, most vigorously of all by Louis, who set on foot no less than 450,000 regulars, the 150,000 men under the direction of the dukes of Anjou and Bourbon having been taken at Bayonne in 1701. Marlborough, in charge of the Rhine forces, was expected to effect a junction at Tongres; but instead of this, although, he was in correspondence with the Austrians and being first in the field. But the début was disheartening, and in the winter a fresh mishap befell the French. Eugene, who had taken up his winter quarters in such a way as to play upon Villery’s fears of an invasion of Naples, surprised Cremona on the night of the 1st of February 1702, and, after a confused fight, drew off, taking with him Villery as a prisoner. The brave but incapable marshal was however little loss, and the French troops, many of them surprised in their beds, had yet managed to expel Eugene’s men. The rest of the French army, instead of marching to the guns in the 19th-century manner, retreated in the 18th-century way, and quietly resumed its winter quarters and its blockade of Mantua.

With the year 1702 the real struggle began. Villars and one or two others of Louis’s best counsellors urged the king to concentrate his attention on the Rhine and the Danube, where, they pointed out, was the centre of gravity of the coalition. This advice was disregarded, and with political aims, which it is hard to imagine, the largest French army was employed on the side of the Meuse, while the Rhine front was entrusted to smaller forces acting on the defensive. In Italy the balance of power required no less than a million and a quarter men, and the numbers were increased to 200,000. Vendôme, was sent to replace the captured Villery. In the Low Countries, Ginkel, Earl of Athlone, the interim commander of the allies (English, Dutch and minor German states), was at the outset outmanoeuvred by the French (Boufflers), and although, in fact, the material advantage was with the allies, who captured Kaiserswerth on the Rhine, the momentary threat of a French invasion had a lasting effect on the Dutch authorities, whose timidity thereafter repeatedly ruined the best-laid schemes of Marlborough, who was obliged to submit to their obstruction and their veto. This handicap, moreover, was not the only one under which Marlborough suffered. Unless it is realized and borne in mind that the great captain was struggling against factiousness and intrigue in England and from jealousies, faint-heartedness and disagreements amongst the states who lent their contingents to his miscellaneous army, the measure of his achievements in ten years seems small. But in fact it was marvellous. Under 18th-century conditions of warfare, and with an army so composed that probably no other man in Europe could have held it together at all, obstructed and thwarted at every turn, he yet brought Louis XIV. and France to the very edge of ruin. In this theatre of war the French, in concert with the garrisons of the Spanish Netherlands, had fortified a line of defense more than 70 m. long from Antwerp to Huy, as well as another line, longer but of only potential importance, from Antwerp along the Scheldt-Lys to Aire in France. Besides the “Lines of Brabant” Boufflers held all the Meuse fortresses below Huy except Maes-
SPANISH SUCCESSION, WAR OF THE

French operations, and only campaigns of the methodical and non-commital kind were planned for Italy1 and the Low Countries. Villeroi and Boufflers commanded the French in the Low Countries, Tallard in Lorraine, Villars in Alsace, and Vendôme in Italy. In the Netherlands the French field army was behind the lines of Brabant, the Spanish troops in the lines of Flanders (Antwerp-Ghent-Aire). Together the two considerably outnumbered Marlborough (90,000 against 59,000), but the duke managed to be first in the field. As early as February Rheinberg had been taken, and in May he followed up this success by the capture of Bonn, returning to the Meuse before Villeroi had assembled his army at Diest. Marlborough's plan was to break the immensely long line of defence of the French and Spaniards by the capture of Antwerp. One Dutch corps under Coehoorn was to assemble in the Suyss-Houth region, and another under Opdam at Bergen-op-Zoom and Marlborough, after manoeuvring Villeroi's field army out of the way, was to join them before the fortress. Marlborough executed his own share of the movement with his usual skill, he pushed back Villeroi towards the Mehaigne and at the right moment, giving them the slip, marched for Antwerp via Hasselt. Villeroi, soon discovering this, hastened thither as fast as possible, and the Dutch generals enabled him to emerge from the manoeuvre with a handsome victory, for Coehoorn (in order to fill his own pockets, it has been suggested) had departed on a raid into West Flanders and Opdam was too late. But he was caught between the Boufflers and the Spanish general Bedmar surprised him (June 30) and put his corps to flight before Marlborough could come to his assistance. In disgust the great captain then resigned himself to a war of small sieges on the Meuse. The campaign closed with the capture of Huy (Aug. 23) and Limbourg (Sept. 27). On the Rhine great projects were entertained by the French, nothing less than the capture of Vienna by a combined Franco-Bavarian-Hungarian army being intended. Villars began by capturing Kehl (March 10) under the very eyes of the margrave, who dared not risk a battle lest the Bavarians coming up hotly destroy his weakened army. The Bavarians had in fact no such intention. The elector, while carrying on a trilling war with a small imperial army under Count Stryrum, insisted that Villars should cross the Black Forest and join him, which Villars was unwilling to do thus early in the year, as two-thirds of his officers were as usual on leave or detached on recruiting duties. Courtier though he was, the marshal would not stir even in spite of the king's orders until he was ready. At the end of April, leaving Tallard alone to defend Alsace and Lorraine against the margrave, Villars plunged into the defiles of the Black Forest and on the 5th of May joined the elector at Ebingen. All seemed favourable for the advance on Vienna, but at the last moment the elector half repented of his alliance with the enemies of Germany and proposed instead a junction with Vendôme by way of Tirol. This proposal came to nothing, the Tiroles were soon roused to revolt by the misconduct of the ill-disciplined Bavarians, and Vendôme, who, like Luxembourg, was a giant in battle and a sluggard in camp, would not stir. The active Villars meantime was reduced to impotence and faced Stryrum in an entrenched camp at Dillingen on the Danube, neither side offering battle. Villars attempted a yeat to contain the margrave's army should it turn back upon him, and this, after an engagement at Munderkingen (July 31) induced the cautious Louis to return to the Rhine. Five weeks later, however, the margrave returned in full force, and moving by the right bank of the Danube reached Augsburg on the 6th of September. The elector, returning from his futile Tirol expedition, had already rejoined Villars at Dillingen, and the marshal persuaded him to attack Stryrum before the two imperial generals could join forces. The result was the battle of Hochstett2 (Sept. 20) in which the elector and Villars won a great victory, at a loss of only 1000 men to Styrum's 11,000. Rarely indeed had an 18th-century general so great an opportunity of finishing a war at one blow. But even Villars saw no better way for the victory than the unimpeded junction of his own army with Tallard's and winter quarters in Würtemberg, and the elector on the other hand was principally anxious to evict the margrave's army from his dominions. The question was referred to Versailles, and another month passed away in inactivity. Tallard remained on the Rhine, and Villars in disgust applied to be recalled. The margrave, entrenched as usual, kept the field for another month and then retired to the Lake of Constance, where, in a still unexhausted district, he spent the winter. The elector wintered in the Iller with the combined army. Tallard meanwhile invested Landau and defeated a detachment sent by Marlborough's distant army to relieve the place in the battle of Spire (Nov. 10), which was almost as costly to the allies as Hochstett. Landau surrendered on the 12th of November. Old Breisach, besieged by Vauban, capitulated on the 6th of September. Thus in Germany, though the grand advance on Vienna had come to nothing, the French had won two important victories and established an army in Bavaria. More than this, under the prevailing conditions of warfare, it was impossible to expect. In Italy, on the other hand, Vendôme, although no longer opposed by Eugene, achieved nothing. After a raid towards Trieste he was brought back hurriedly by the news that Victor Amadeus of Savoy had changed sides, and though he was victorious in a few skirmishes and re-established touch with France by capturing Asti, he failed to prevent the Imperialists, under Guido Starckemberg, 'from slipping past his position in Lombardy and joining the duke of Savoy in Piedmont.'

The campaign of 1704, though in the Low Countries and in Italy practically nothing was done, is memorable for what was probably the greatest strategical operation in the 18th century, Marlborough's march to the Danube. At the outset the elector and Marsin (Villars) were in the valley of Ebingen, between Ulm and Memmingen, Tallard between Straßburg and Landau, Villeroi as usual between the Brabant lines and the Meuse. Between Villeroi and Tallard there was a small force on the Moselle, intended to reinforce either. On the other side the Margrave Louis was in the Stockach-Engen region, with his own army and the relic of Stryrum's, but being responsible for guarding the whole of the Middle Rhine as well as for opposing the elector he was weak everywhere, and his defence of the Rhine was practically limited to holding the strongholds of Stollhofen, a defensive position near Bühl in Baden. With Breisach and Kehl to their right hands, the French were more or less closely in touch with their comrades in Bavaria, and Tallard conveyed a large body of recruits for Marsin's army through the Black Forest defiles. But in doing so he lost most of them by desertion, the margrave's army dogged his march, and in fact no regular line of communication was established. Thus the five armies (Marlborough's, Eugene's, Tallard's, Marsin's and the margrave's) engaged in this theatre of war, were moving and facing in all directions in turn in a most bewildering fashion. Marlborough's purpose at any rate was quite definite—to transfer a large corps from the Low Countries to Bavaria and there in concert with the allies in that quarter to crush the elector decisively. He took no one into his confidence. The timid Dutch were brought, not without difficulty, to assent to a Lower Rhine and Moselle campaign, of much the same sort as the Bonn expedition of 1703, but rather than be burdened with Dutch councillors he forwent the assistance of the Dutch troops. These were left under Overkirk to defend the Meuse, and English and English-paid troops alone took part in the great venture. Meanwhile Tallard and Marsin, united at the moment of handing over the recruits, had promptly separated again. Tallard, Villeroi and the Versailles strategists, 1 In this year began the Camisard insurrection, in the Cevennes, which necessitated the detachment of a considerable body of troops from Vendôme's army in Italy. Similarly both in 1702 and 1703 the Hungarian insurrection compelled the Viennese government to keep back the reinforcements of which Eugene stood in need.
2 Fought on the same battlefield as was Blenheim next year; the latter is consequently called by some the 'second battle of Hochstett.'
well aware that Marlborough was ascending the Rhine, thought that a diversion on the Moselle was intended, and the feeble warnings of Marsin, who half suspected the real purpose, were disregarded. Villeroi remained in Brabant for fear that Overkirk would take a few towns in his absence.

Oneлег／the army moved over the Rhine and the French should collect to prevent his crossing, instead of themselves passing over to join the elector and Marsin. Thus the expedition would reach the Necker mouth, without its true purpose being suspected, and once there Marlborough would vanish from the ken of the defenders of the Rhine, to reappear on the Danube where he was least expected. On the 15th of May the army crossed the Meuse at Ruremond, on the 23rd it reached Bonn, on the 29th Mainz. On the 1st of June the puzzled French noted preparations for bridging the Rhine at Philippsburg. But two days later the English had turned to their left into the valley of the Neckar. On the roth of June Prince Eugene and on the 13th the margrave appeared at the duke’s headquarters to concert operations. It was arranged that the margrave was to join Marlborough and that Eugene should command the Stolhohen and other forces on the Rhine, for Tallard, it seemed, was about to be joined by Villeroi and Marlborough knew that these marshals must be kept west of the Rhine for the six weeks he allowed himself for the Bavarian enterprise. The margrave’s army duly joined Marlborough’s on the 22nd of June at Ursprung, 12 m. north of Ulm, where the elector and Marsin were encamped. The endurance of Marlborough’s corps, as displayed in the long march from Ruremond, was not the least extraordinary feature of the operation. For 18th-century troops such performances were generally provoking and involved the ruin of the army that attempted it. But Prince Eugene, we are told, was astonished at the fine condition of the army. On the French side meantime all was perplexity, and it was not until a week after the margrave and Marlborough had united that a decision was arrived at by Louis XIV., in whose eyes the feeble corps of Eugene sheltered in the lines of Stolhohen constituted a grave menace for Alsace, as he had foresaw the main body from the Meuse had after its first hesitations followed up Marlborough, in readiness for the supposed Rhine and Moselle campaign, and was now about Landau. Tallard with the smaller half of the united armies was to advance by Breisach and to “try to capture Villingen.” Villeroi was to watch Eugene’s corps, or rather the Stolhohen-Bühl position, and the small Moselle corps was to remain west of the Rhine. This meant conceding both the initiative and the superiority in numbers to Marlborough.

The duke had now manoeuvred himself with brilliant success from the Rhine to the Danube and had secured every advantage to himself. His method of utilizing the advantage showed his mastery of the rules of the strict game that, with the instinct of a great captain, he had just set at nought. From before Ulm he sidled gradually along the north side of the Danube in the hope of finding an unguarded passage. He and the margrave exercised the general command on alternate days, and when on his own day he arrived opposite Donauwörth, knowing Louis’s caution, he thought that direct attack was better than another two days’ extension to the east. Moreover he needed a walled town to serve as a magazine for his troops and had secured Villingen for his officers over the river. In the late afternoon of the 21st the army was flung, regardless of losses, against the entrenched hill of the Schellenberg at Donauwörth, where the elector had posted a strong detachment. The attack cost 6000 men, but it was successful, and of the 12,000 Bavarians on the hill only 3000 returned to their main body, which had now moved from Ulm to Lauringen. Passing the river, the allied besieged and took the small fortress of Rain, and thence moved to the neighbourhood of Augsburg, thoroughly and deliberately devastating the countryside as to force the elector to make terms. The best that can be said of this barbarous

device, more or less legitimate in the days when the quarrel was the people’s as much as the prince’s, is that Louis XIV. had several times practised it. Its most effective condemnation is that military devastations, in these purely political contests, were entirely unprofitable. Louis had already found them so, and had given up the practice. In the present case the success of Wallenstein for the margrave the two great soldiers sympathies, while at the same time Marlborough’s own supplies ran short, his convoys were harassed and his reconnaissances impeded. The movements of the two armies were but trifling. Marlborough, though superior, was not decidedly superior, and his opponents, well entrenched near Augsburg, waited for Tallard and (in vain) for Villeroi. Marlborough marked time until Eugene should join him.

There were now five armies in the field, two allied and three French. The centre of gravity was therefore in Villeroi’s camp. If that marshal followed Tallard, even Eugene’s junction with Marlborough would not give the latter enough force. If Tallard alone joined the elector and Eugene Marlborough, the game was in the hands of the allies. But none of the possible combinations of two armies against one were attempted by either side. Eugene did not venture to leave Villeroi’s front to attack Tallard, who was marching by Kehl-Villingen-Ulm on Augsburg, but when he knew that Tallard was on the move he slipped away from Villeroi to join Marlborough. In turn, Tallard and the elector, aware of Eugene’s march, could have left Marlborough to his own devices, and combined against Eugene, and thus well content to join forces peaceably at Augsburg. Worst of all, Villeroi, in whose hands was the key of the situation, was the nearest to Versailles and the least capable of solving the knotty problem for himself. When the king bade him follow Tallard to Villingen he hesitated, and when he had made up his mind to try, Louis had changed his and ordered him to detain Eugene (who was already far away) in the Stolhohen lines. The last stage of the campaign was brief. Marlborough and Eugene had in mind a battle, Tallard and Marsin a war of manœuvre to occupy the few weeks now to be span out before winter quarters were due. The two allied armies met in the Danube valley on the 6th of August. If the enemy remained on the south side Eugene was to cross, if they recrossed to the north bank Marlborough was to follow suit. The margrave Louis of Baden had been sent off to besiege Ingolstadt as soon as Eugene had come within a safe distance. The 18th-century general relied far more on himself than on the small surplus of force that his army, in the conditions of that time, could have thought of having over its opponent. When therefore the French and Bavarians were reported opposite Eugene on the north side, Marlborough crossed at once, and when moving in the face of his siege and combined against Eugene, but they were well content to move forward. On the 2nd of August (see BLENHEIM) they attacked and practically destroyed the armies of Tallard, Marsin and the elector.

The campaign of 1705 was uneventful and of little profit to either side. Marlborough’s army had returned to the Lower Countries, engaging en route in a small campaign in the Luxemburg and Thionville region, which was defended with skill and success by Villars. Villeroi had also returned to Brabant and retaken Huy. With him was the now exiled elector of Bavaria. In Italy alone was there any serious encounter. Here Vendôme’s army and a fresh corps from France were engaged in the attempt to subdue Victor Amadeus and his new Austrian allies (Starhemberg’s, originally Eugene’s army), and they were...
so far successful that the duke implored the emperor to send a fresh army. Eugene commanded this army, opposed to which was a force under Vendôme's brother Philip, called the Grand Prior. This man, a lazy dilettante, let himself be surprised by Eugene's fierce attack on the line of the Aida. The day was restored however, and the Austrians beaten off, thanks to Vendôme's opportune arrival and dauntless courage (battle of Cassano, August 16). Nevertheless, the subjugation of Piedmont was put off until next year, by Louis's orders.

1706 was a bad year for the French. At the very outset of the campaign in the Netherlands, Villeroi, hearing that some of the allied contingents that composed Marlborough's army had refused to join, went forward from his new defensive lines along the Dyke and offered battle. Marlborough would probably have fought in any case, but being joined in time by the belated allied contingents, he was able (May 12) not only to win but also to profit by the glorious victory of Ramillies (q.v.) on the 17th of May. This was one of the few cases of thoroughly efficient and successful pursuit in the military history of the 17th and 18th centuries. The whole of Flanders and Brabant, except a few minor fortresses, fell into his hands within two weeks. These too fell one after the other in August and September, and the British cavalry crossed the French frontier itself. But on the Rhine the inactivity of Louis of Baden had allowed Villars to transfer the bulk of his army to the Netherlands. Vendôme, too, was sent to succeed Villeroi, and Marlborough made no further advance. Louis's two most brilliant commanders devoted themselves to organizing the defence of the French frontier, and did not venture to interrupt Marlborough's sieges.

In Italy the campaign had, as before, two branches, the contest for Piedmont and the contest between the French forces in Lombardy and the Austrian second army that sought to join Victor Amadeus and Starhemberg. The latter, repulsed by Vendôme at Cassano, had retired to Brescia and Lake Garda, Vendôme following up and wintering about Castiglione and Mantua, and in April 1706, profiting by Eugene's temporary absence, Vendôme attacked the Imperialists' camp of Montechiaro-Calcinato. His intention was by a night march to surprise the post of Ponte San Marco on their extreme left, but when day came he noticed that he could give battle to the enemy's left wing at Calcinato before their right from Montechiaro could intervene. His onset broke up the defence completely (battle of Calcinato, April 19), and he hustled the fragments of the Imperialist army back into the mountains, where Eugene had the greatest difficulty in rallying them. Until the middle of June Vendôme completely baffled all attempts of Eugene to slip past him into Piedmont. He was then, however, recalled to supersede Villeroi in Belgium, and his feeble successors entirely failed to rise to the occasion. Philip of Orleans, with Marsin and the duc de la Feuillade as his advisers, was besieging Turin, trying in vain to remedy the errors of the engineers and the constant repulse of small storming parties by a savage bombardment of the town itself. As soon as he knew of Vendôme's departure Prince Eugene emerged afresh from the mountains, and, outmanoeuvring the French in Lombardy without the least difficulty, hurried towards Turin. Victor Amadeus, leaving the defence to the Austrian and Piedmontese infantry, escaped through the besiegers' lines and joined his cousin with a large force of cavalry. On the 7th of September they attacked the French lines round Turin. Owing to the disagreements of their generals, the various corps of the defenders, though superior in total numbers, were beaten in detail by the well-concerted attacks of Eugene, Victor Amadeus and the Turin garrison. Marsin was killed, many of the boldest officers in the army lost heart, and Philip retreated ignominiously to Pinerolo. Although in the same week Lieut.-General Médavy-Grancey inflicted a severe defeat on
Changing Conditions of the War.

The operations is Lille. Marlborough's act the objects of the war only partially and by sheer endurance. But it is from this very point that the French operations cease (though only gradually it is true) to be the ill-defined and badly-joined patchwork of forays and cordons that they had hitherto been. In the place of Tullards, Marsins and Villeroys Louis made up his mind to put his Villars, Vendômes and Berwicks, and above all the approach of the allied armies roused in the French nation itself a spirit of national defence which bears at least a faint resemblance to the great uprisings of 1702 and 1870, and under the prevailing dynastic and professional conditions of warfare was indeed a startling phenomenon. For the gathering of this unexpected moral force 1707 afforded a year of respite. The emperor, desiring to occupy Naples and Lombardy with the least possible trouble, agreed to permit Médavy-Grancey to bring off all the Italian garrisons, and with these and the militia battalions of the Midi Marshal Tessé formed a strong army for the defence of the Alpine frontier. In Spain the campaign opened with the brilliant success of Berwick at Almanza. In Germany Villars not only pricked the bubble reputation of the lines of Stolhohen, but raided into Bavaria, penetrating as far as Blenheim battle-field before he gave up the attempt to rouse the Bavarians again. The Imperialists and Piedmontese in the south succeeded in turning the Alpine barrier, but they were brought to a complete standstill by Tessé's galling defence of Toulon (August) and having, like their predecessors in 1692, roused the peasantry against them they retired over the mountains. In Belgium the elector of Bavaria, who was viceroy there for King Philip, and was seconded by Vendôme, remained quiescent about Mons and Gemboux, while Marlborough, paralysed more completely than ever before by the Dutch, spent the summer inactive in camp on the Gheto.

The respite of 1707 had enabled Louis to gather his strength in Flanders. He ordered operations on the Rhine and in Dauphiné are of quite secondary importance, so much so that Eugene and the main Austrian army are always found in the Low Countries fighting side by side with the Anglo-allied army of Marlborough.

In 1708 Eugene foresaw this shift of the centre of gravity and arranged with Marlborough to transfer the army which was Campagne of 1708. Brabant, repaying thus the debt of 1704. Indeed the main army of the French was markedly superior in numbers to Marlborough's and hardly inferior to Marlborough's and Eugene's combined. Placing the elector of Bavaria, with Berwick to advise him, at the head of the small army of Alsace, he put his young grandson and heir, the duke of Burgundy, at the head of the great army which assembled at Valenciennes, and gave him Vendôme as mentor. But the prince was pious, mild-mannered, unambitious of military glory and also obstinate, and to unite him with the fiery, loose-living and daring Vendôme, was, as Saint-Simon says, "mixing fire and water." At the end of May operations began. Vendôme advanced to engage Marlborough before Eugene, whose purpose had become known, hoping by so doing to surprise him. As the French came on towards Brussels, Marlborough, who had concentrated at Halfell back by a forced march to Louvain. Vendôme having thus won the first move, there was a pause and then the French suddenly swung round to the west, and began to overrun Flanders, where their agents had already won over many of the officials who had been installed by the allies since 1706. Ghent and Bruges surrendered at once, and to regain for King Phillip all the country west of the Scheldt it only remained to take Oudenarde. On the day of the surrender of Ghent Marlborough was in pursuit, and one long forced march brought his army almost within striking distance of the receding enemy. But though Eugene himself had joined him, Eugene's army was still far behind, and the duke was stopped by demands for protection from the officials of Brussels. Vendôme soon moved on Oudenarde. But scarcely had he begun this investment when Marlborough was upon him. The duke discussed the situation with Eugene, who had placed himself under his friend's orders. Marlborough was half inclined—another general would have been resolved—to wait for Eugene's troops before giving battle, for he knew that Vendôme was no ordinary opponent, but Eugene counselled immediate action lest the French should escape, and relying on his own skill and on the well-known disunion in the French headquarters, Marlborough went forward. As he approached, the French gave up the siege of Oudenarde and took up a position at Gavre, 7 m. lower down the Scheldt, so as to be able to act towards either Ghent or Oudenarde. Marlborough's advanced guard, boldly handled by Cadogan, slipped in between Gavre and Oudenarde. At once the dissensions in the French headquarters became flagrant. Vendôme began to place part of the army in position along the river while the duke of Burgundy was posting the rest much farther back as another line of defence. Cadogan was thus able to destroy the few isolated troops on the river. Thereupon Vendôme proposed to the duke to advance and to destroy Cadogan before the main body of the allies came up, but the young prince's hesitations allowed the chance to pass. He then proposed a retreat on Ghent. It is too late," replied Vendôme, "and we will let the army that was brought up from Ostend by the duke hang. The allied main body, marching with all speed, crossed the Scheldt at all hazards and joined Cadogan. In the encounter-battle which followed (see OUDENARDE) Marlborough separated, cut off and destroyed the French right wing. The French retreated in disorder on Ghent (July 11) with a loss of 15,000 men. Nevertheless Oudenarde was in no way decisive, and for the rest of the campaign the two armies wandered to and fro in the usual way. Berwick, recalled from Alsace, manoeuvred about Douay, while Vendôme remained near Ghent, and between himself and Eugene's army devoted themselves to the siege of Lille. In this town, one of Vanban's masterpieces of fortification, the old Marshal Boufflers had undertaken the defence, and it offered a long and unusually gallant resistance to Eugene's army. Marlborough covered the siege. Vendôme manoeuvred gradually round and joined Berwick, but though 90,000 and later 120,000 strong, they did not attack him. Berwick was a new element of dissension in the distracted headquarters, and they limited their efforts first to attempting to intercept a huge convoy of artillery and stores that the allies brought up from Brussels for the siege, and secondly to destroy another convoy that was brought up from Ostend by the duke of York. Webb known to readers of Esmond. The futile attack upon the second convoy is known as the action of Wymeneld (Sept. 28). The only other incident of the campaign in the open was an unsuccessful raid on Brussels by a small corps under the elector of Bavaria from the Moselle via Namur.

On the 8th of December the brave old marshal surrendered, Eugene complimenting him by allowing him to dictate the terms of capitulation. Ghent and Bruges were taken by the allies without difficulty, and, to add to the disasters of Oudenarde and Ghent, a terrible winter almost completed the ruin of France. In despair Louis negotiated for peace, but the coalition offered such humiliating terms that not only the king, but—what in the 18th century was a rare and memorable thing—his people also, resolved to fight to the end. The ruinous winter gave force to the spirit of defence, for fear of starvation, inducing something akin to the courage of despair, brought tens of thousands of recruits to the colours.

Of the three invasions of France attempted in this memorable year two were insignificant. On the Rhine the elector of

1 The Margrave Louis of Baden had died during the winter of 1706-1707. He was succeeded by the incompetent margrave of Bayreuth, who was soon displaced. This general's successor was the elector of Hanover, afterwards King George I. of England.
Hanover (King George I.) was held in check by the d'Harcourt on the Lauter and finally retired to the lines of Stolhoven, while a smaller allied corps under the imperial general Count Mercy was defeated with heavy loss by Marlborough's second in command, Du Bourg, at Rumersheim in Upper Alsace (Aug. 26). On the Alpine frontier Berwick, abandoning the fashionable method of "lines," prepared a remarkable system of mobile defence pivoted on Briçonnet, on which Victor Amadeus's feeble attacks made no impression. These affairs were little more than diversions. The main, indeed the only, attack was Marlborough's and Eugene's, and the Malplaquet campaign is one of the few episodes of 18th century warfare that retain a living and passionate interest.

Long before this Marlborough had proposed to dash straight forward into France, masking the fortresses, but this scheme was too bold even for Eugene, who preferred to reduce the strong places before going on. Lille having been successfully besieged, Tournai was the next objective, and—while Villars and his lieutenants Montesquieu and Albergotti lay inactive in their entrenchments at Béthune, Douai and Denain on the Scheldt, training their thousands of recruits and suffering severely from the famine that followed upon this bad winter—the allies suddenly and secretly left their camps before Lille as if for an attack on the Douai lines (June 26-27). But before noon on the 27th they had invested Tournai. A few days afterwards their siege guns came up from Menin by water (down the Lys and up the Scheldt) and the siege was pressed with intense vigour. But it was the 3rd of September before the citadel capitulated. The allies then, treacherously, Flushing the French secretly and by degrees to the river Halne, beyond Villars's right. East of St Ghislain Villars's long lines of earthworks were but thinly held, and after a march of 50 m. in 36 hours through rain-sodden country, the allied advanced guard passed through them unopposed (Sept. 6th). Mons, too, was weakly held, and Marlborough hoped by the rapidity of his operations to take it before Villars could intercept him. Based on Mons and Brussels, he could then, leaving the maze of fortresses in the Arras-Valenciennes region to his right, push on (as eighty years afterwards Coburg attempted to push on) straight to the heart of France. But Villars also moved quickly, and his eager army was roused to enthusiasm by the arrival of Marshal Boulfiers, who, senior as he was to Villars, had come forward again at the moment of danger to serve as his second in command. Thinking that the allies were somewhat farther to the east than they were in fact, the French marshals marched secretly, screened by the broken and wooded ground to the south of the fortress, and occupied the gap of Aulnois-Malplaquet (Sept. 9), one of the two practicable passages, where he set to work feverishly to entrench himself. Marlborough at once realized what had happened, and giving up the idea of Mons he hurried his army to the south-east of the place. Preparing, as at Oudenarde, to attack as rapidly as his brigades came on the scene, he cannonaded the French working parties and drew the return fire of all Villars's guns. At this crisis the duke submitted the question of battle—unwillingly, as one may imagine—to a council of war, and Eugene himself was opposed to fighting an improvised battle when so much was at stake. Others thought the capture of the little fortress of St Ghislain was the best solution of the problem, and it was not until the 11th that the allies delivered their attack on the north thoroughly entrenched position of the French. The battle of Malplaquet (q.v.) was by far the most desperately contested of the war. In the end Bouffiers, who took command when Villars was wounded, acknowledged defeat and drew off in good order, the left to Valenciennes, the right to Bayav and Le Quesnoy. Eugene was wounded, and Marlborough, after the most terrible experience in any soldier's lifetime, had only enough energy remaining to take Mons before he retired into winter quarters. The loss of the French is given variously as 7,000 and 12,000. The allies sacrificed no less, probably more, than 20,000 men, and if the English and Austrian survivors could count themselves the bravest soldiers alive, one considerable part of the allied army at least, the Dutch contingent, was ruined for ever. Even at Fontenoy, thirty-six years later, the memory of Malplaquet made them faint-hearted. From his bed the wounded Villars wrote triumphantly to Louis: "If God gives us another defeat like this, your majesty's enemies will be defeated!"

In 1711 Villars lay entrenched behind a new series of lines, which he called Ne plus ultra and which extended from Valenciennes to the sea. Marlborough made no attempt to invade France from the side of Mons, for Villars at the head of the army which had been through the ordeal of Malplaquet was too terrible an opponent to pass by with impunity. In England, too, the anti-Marlborough party was gaining the upper hand in the queen's council. So Marlborough took no risks, and returning to the Lille side, captured Douai (June 26) and Béthune (Aug. 26). No attack was attempted upon the lines. In Dauphiné, Berwick again repulsed the Austrians and Piedmontese.

1711 was Marlborough's last campaign, and it was remarkable for the capture of the Ne plus ultra lines by manoeuvres that must be recorded as being the Ne plus ultra of the 18th-century way of making war by stratagem. In May the sudden death of the emperor completely altered the political outlook, for his successor Charles was the coalition's claimant to the throne of Spain, and those who were fighting for the "balance of power" could no more tolerate a new Charles V. than they could see Louis XIV. become a Charlemagne. Before the allies could agree upon any concerted action, Eugene's army had departed for Germany, and Marlborough alone was left to face Villars's great army. But in pursuance of the policy of passive endurance the marshal remained on the defensive behind the lines, and Marlborough determined to dislodge him. What force could not achieve, the duke trusted to obtain by ruse. The lines extended from the sea along the Canche, thence to Arras, and along the Sensée to Bouchain on the Scheldt. Marlborough held Lille, Tournai, Béthune and, in front of these places, Douai, while Villars's strong places, other than those in the lines, were Valenciennes, Condé, Le Quesnoy, &c. As the western part of the lines lay between the invaders' point of view because their capture could not lead to anything, Marlborough determined to pass the barrier between Arras and Bouchain. Here the front was difficult of access, because of the inundations and swamps of the Sensée valley, but two causeways crossed this valley at Arleux and Aubanchoeil-au-Bac respectively. On the 6th of July Marlborough, who had encamped in the plain of Lens, sent a detachment to capture Arleux. He then marched away to the west as if to attack the lines between Arras and the headwaters of the Canche. Villars followed suit, but left a corps behind, as Marboch at once, Eugene's army had departed for Germany, and the commander of the garrison then sent urgent messages to say that he could not hold out, and Marlborough sent off Cadogan to relieve him. Cadogan, the only officer in the army in the duke's confidence, moved slowly, and the garrison had to surrender (July 22). Villars raged the defences of Arleux. The plot of the comedy now thickened. Marlborough lost his usual serenity, and behaved in so eccentric a manner that his own army thought him mad. He sent off one part of his forces to Béthune, another back to Douai, and ordered the small remainder to attack the lines between the Canche and Arras, where, as every one knew, Villars's whole army was massed.

On the 24th of August he personally reconnoitred the lines with a large staff, and calmly gave his generals instructions for the lines to be stormed. But Cadogan was hastening to give the duke's real orders to the corps at Béthune and Douai. In the night of the 4th-5th of August the main army set out for Aubanchoeil-au-Bac, at the highest possible speed. The Scarpe was crossed, the Béthune column came in punctually, and the word was passed down the ranks that Cadogan had crossed the lines at Arleux. Thereupon the pursuit was given up, though the handful of the infantry fell out and scores died from exhaustion. Five hours ahead of the French
army and level in the race with Villars and the cavalry, the red-coats crossed the rivers at Arleux, while Marlborough and the horse hurried on to Aubanchoei-au-Bac, crossed there, and turned back along the Senéze to meet the French squadrons. The army reassembled between Aubanchoei-au-Bac and Cambrai, and its leader, declining Villars's offer of a battle in front of Cambrai, manoeuvred still farther to the east and invested Bouchain. The siege, covered by a strong "line of circumvallation" which Villars did not attempt to attack, ended with the surrender of the place on the 13th of September, and so terminated a series of manoeuvres which to the modern mind is so extraordinary as to be almost incredible. In December of this year, his party opponents in England being now triumphant, the man who so consummated a master both of the 18th-century and the Ramillies-Oudenarde methods of making war was dismissed the service in disgrace. From 1712 the British contingent, under the Duke of Ormonde, withdrew from the Low Countries, the discontent of the men at Marlborough's disgrace breaking out in open mutiny, and thus ignominiously ended the career of the army of Blenheim and Malplaquet. The coalition practically dissolved.

But Holland and Austria determined to make one last effort to impose their own terms on Louis. Eugene's army, which had been used in 1711 to influence the imperial election instead of to beat Villars, was brought back to the Low Countries. Reading the meaning of Marlborough's fall, he quietly made preparations to take over the various allied contingents into Imperial and Dutch pay. Thus when England seceded, Ormonde only marched away with some 12,000 sullen men, and over 100,000 remained with the prince.

Mistreatments at Versailles helped Eugene in his first operations, for three members of Louis's family died within a week and all was in confusion, not to speak of the terrible misery that prevailed in the country. But the old king's courage rose with the danger and he told Villars that if the army were beaten he would himself join it and share in its fate. Villars, though suffering still from his Malplaquet wound, took command on the 20th of April, and spent some time in the lines of the Dutch and the armies of the Duke of Ormonde's contingent withdrew. Eugene, apparently with the intention of regaining the Mons line of operations, as the defection of England had made further operations near the sea unprofitable, neglected to besiege, not only Arras, but Valenciennes and Condé as well, and, based temporarily on Douai and Marchiennes and Bouchain he took Le Quesnoy (July 4) and moved thence on to Landrecies, which was closely invested. Then followed the last serious fight of the war, the battle of Denain, which saved the French monarch and completed the dissolution of the coalition.

In order to protect his camps around Landrecies, Prince Eugene constructed the usual lines of circumvallation with such speed that Villars, on coming up, found that they were too formidable to attack. Next, in order to guard the movements of his convoys between Marchiennes-on-Scarpe and the front against attacks from Cambrai or Valenciennes, he hedged in the route on both sides with continuous lines of breastworks, to the defence of which he assigned his Dutch corps. Villars anxiously looked out for an opportunity of breaking these modern long walls. At Denain, the besiegers' route crossed the Scheldt. From this point to the town of Grand Wasen and other obstacles reinforced the defence, but the marshal was told by a country priest that the lines were assailable north of Denain, and resolved to attack them there. The enterprise, like Marlborough's forcing of the Ne plus ultra lines, involved an extraordinary combination of resolution and skill—i.e. force and fraud—for the point of attack was far away and the opposing army almost within cannon-shot. Some days were spent by Villars in deceiving Eugene and his own army as well, as to his real intentions, and by various feints Eugene was induced to mass his main body about Landrecies and Le Quesnoy on the south side of the Scheldt. Then on the night of the 23rd of July the French army moved off silently, with its bridging train in the vanguard and cavalry posted everywhere along its right flank to conceal the march. By 9 a.m. on the 24th Villars's army had completely deployed on the north bank of the Scheldt. Eugene himself saw them and galloped away to bring up his army from Landrecies. But, long before it arrived, Villars's troops, without wasting precious moments in formal propositions of the Dutch—spiritless since Malplaquet—were huddled into the narrow avenue between the two entrenchments and forced back on Denain. Their generals were taken. The broken mob of fugitives proved too heavy a load for the bridges at Denain, and many were drowned, while the rest, pinned against the bank of the now impassable river, tamely surrendered. Eugene arrived on the other bank with some brigades of the imperial infantry, but after losing heavily gave up the attempt to reopen the passage. Villars followed up his victory at once. Montesquieu captured Marchiennes and Abbergot St Amand, and in these places all Eugene's reserve stores and munitions and guns fell into the hands of the French.

On the 2nd of August Eugene broke up the siege of Landrecies and retreated by a roundabout route to Mons, while Villars's lieutenants retook Douai and Bouchain (September-October). Before the next campaign opened the treaty of Utrecht had been signed, and although the emperor continued the struggle alone for another year, the enfeebled combatants were content to accept Villars's captures of Landau (July 22, 1713) and Freiburg (Nov. 21) as decisive. The treaty of Kastatt, between Austria and France, was signed on the 7th of March 1714, Eugene and Villars being the negotiators.

Naval Operations, and Military Operations in Spain

The war of the Spanish succession affected all the nations of western, northern, and central Europe in a greater or less degree, but that part of it which was fought on the lands of Spain lay aside from the campaigns in Flanders, Germany and Italy.

The purely Spanish campaigns had a close connexion with the movements of the fleets, and the two may be conveniently taken together. The naval war was superficially somewhat wanting in interest. Louis XIV., having to support armies of unprecedented size to contend with the forces of the Grand Alliance, and having also to meet the immense cost of the support of his court and the construction of palaces, was compelled to neglect his navy. Except therefore in 1704 he made no attempt to resist the fleets of the allies in the war sea. The honour of the French flag was chiefly maintained by the privateers who showed high courage and much skill. Some of their enterprises were undertaken with well-appointed squadrons, and attained to the dignity of regular operations of war.

When the Grand Alliance was formed on the 7th of September 1701 a French naval force under M. de Chateaurœnault was in the West Indies. Its avowed purpose was to cover the arrival in Europe of the Spanish treasure ships. The secret intention of King Louis XIV. was that the treasure should be brought into a French port, and used by him for the general advantage of the nation, notwithstanding the terms of surrender of 1704. On the 20th of September for a fleet of 10 ships commanded by Admiral Benbow was sent to the West Indies to intercept Chateaurœnault, and carry out other attacks on the French and Spanish ships. Benbow, who was reinforced in the West Indies, did not intercept Chateaurœnault, and his cruise was rendered of no effect by the gross misconduct of most of his captains, who refused to support him in an action with a French squadron under M. Du Casse near St Martha on the 20th of August 1702 and subsequent days. He was himself mortally wounded, but lived long enough to bring his captains to court martial. Two of them were shot for cowardice. The treasure fleet went straight for Europe only to fall into the hands of the allies at Vigo. On the 1st of July 1702 a powerful combined fleet of 30 British sail-of-the-line under Sir George Rooke, and
20 Dutch under Admiral Allemende sailed from Spithead carrying 5000 troops. The general command was given to the duke of Ormonde. The purpose of this expedition was to occupy Cadiz and encourage a rising in Andalusia on behalf of the Habsburg candidate. It reached Cadiz on the 22nd of August, but the inhabitants and the garrison of 7000 men fought bravely. The head of the expedition quarrelled with one another and the soldiers aroused the bitter indignation of the inhabitants by plundering the small towns of Santa Maria and Rota. On the 30th of September the expedition sailed away. Information sent by the British minister at Lisbon that Chateaurenault had put into Vigo reached them at Lagos. The duke of Ormonde and his colleagues decided to attack the treasure fleet. On the 22nd of October they forced the boom laid by the enemy between the inner and outer harbours of Vigo, and the treasure fleet was destroyed, but the bullion had been landed.

During 1703 the "grand fleet" of the allies, i.e. their main force in European waters, entered the Mediterranean to carry help to the insurgent Protestants in the Cevennes, but effected nothing of importance. Portugal having now joined the Alliance, it was decided to make a serious effort in Spain. A combined fleet carrying 4000 Dutch and 8000 British troops, and conveying the archduke Charles, claimant of the Spanish throne, sailed from Spithead on the 11th of February 1704. Portugal undertook to provide 30,000 troops to co-operate with the British and Dutch who were landed at Lisbon on the 8th of March. The operations on land were for the most part languid. The duke of Berwick who commanded the Bourbon forces on the Spanish frontier formed a vigorous plan for the invasion of Portugal. One Spanish force under Don Francisco Ronquillo was to threaten Beira Alta at Almeida. He himself entered Beira Baixa by the north bank of the Tagus. The prince of Tzeczlaus was to have advanced from the south to meet Berwick at Villa Velha. But though Berwick achieved some success, and though both the Dutch general Fagel who operated on the north of the Tagus, and the British general, the duke of Schomberg, who was stationed on the south, proved indolent and incapable, the invasion failed. Ronquillo and Tzeczlaus failed to support Berwick, and the newly levied Spanish troops proved unsteady. Fagel was surprised and taken prisoner with 2000 men at Solreina Ferrosa, and some of the frontier posts remained in Berwick's hands when the heat from which the British and Dutch soldiers suffered severely suspended operations. At sea, however, a material success was gained. Sir George Rooke went on from Lisbon accompanied by Prince George of Hesse-Darmstadt, to Barcelona. The prince who had been governor of Catalonia, believed that he could bring about a rising in the province in favour of the Habsburg cause. As the fleet carried no considerable body of troops the fleets of Hesse-Darmstadt failed to persuade the Catalans to act. They were embarrassed by the knowledge that the count of Toulouse, a natural son of Louis XIV., the admiral of France, who had sailed from Brest on the 6th of May with 23 sail-of-the-line had entered the Mediterranean, and had reached Toulon in June. In expectation of an attack by the united fleets of Brest and Toulon, the allies fell back to the straits. Having obtained information that Gibraltar (g.v.) was not sufficiently garrisoned, they attacked and took it on the 3rd of August. On the 24th the count of Toulouse, came to the relief of the fortress with 50 sail-of-the-line, and 24 galleys. He engaged the allies, 62 British and Dutch line of battle ships in all, off Málaga. The engagement was a cannonade accompanied with great loss of life, but without manoeuvring on either side. The French retired to Toulon, and the allies remained in possession of Gibraltar. An attempt of the Spaniards to retake it, made at the end of 1704 and beginning of 1705 was baffled by the resolute defence of the prince of Hesse-Darmstadt, and the relief afforded to the garrison by the squadron of Sir John Leake, who was left on the coast of Portugal, when Sir George Rooke returned to England. The 6000 French forced the allies to make more serious efforts to push the war in Spain. The duke of Schomberg was removed from the command of the troops in Portugal and replaced by the earl of Galway, a French Huguenot exile. But the main attack was made, and the first successes were achieved on the east coast of Spala. On the 3rd of June 1705 Charles Mordaunt, earl of Peterborough, was sent with a commission to command both the fleet and the army, and to promote the interests of the Habsburg and Austrian party. He was joined by the archduke at Lisbon, and by the prince of Hesse-Darmstadt at Gibraltar. The truth in regard to the operations which followed has been very much obscured. Peterborough, a man of much erratic cleverness, but vain, spiritless and absolutely indifferent to truth, successfully represented himself as a species of hero of romance who won the most astonishing victories in spite of want of means, and of the ill will or incapacity of his colleagues. Critical investigation has destroyed much of the showy edifice of fiction he contrived to erect. The substantial facts are that after some operations on the coast of Valencia, which led to an insurrectionary movement in favour of the archduke, Barcelona was attacked and taken between the 13th of September and the 9th of October. The prince of Hesse-Darmstadt was killed during the siege. All the east of Spain, the former kingdom of Aragon, which was at all times restive under the supremacy of Castile, now pronounced more or less openly for the Austrian party. The fall of Barcelona gave a severe shock to the Bourbon king. He came in person with Marshal Tessé who had replaced the duke of Berwick, and endeavoured to retake the town early in April 1706. The ferocity with which Tessé treated the people of Aragon and Catalonia raised the country against the Austrians. The British relieved Barcelona on the 9th of May, and Philip V. was compelled to retreat across the Pyrenees to Perpignan. In the meantime the withdrawal of troops from the Portuguese frontier for service in Catalonia, had opened the way for an invasion of Castile by the allies, British, Portuguese and Dutch. They occupied Madrid on the 23rd of June 1706, and the queen who acted as regent in the absence of her husband retired to Burgos. But the success of the allies was merely apparent. The appearance in their midst of an invading army of Portuguese and British forces, had at first caused the Catalans to turn to the Bourbon cause. As in the later Peninsular War, guerrilero bands sprang up on all sides, and they found capable leaders in Vallejo and Bracamonte. The duke of Berwick, who was sent back to Spain, collected an army, and soon the allies, who were distressed by want of provisions and had health, were forced to evacuate Madrid. They moved on Guadalajara to meet the archduke who was advancing from the east. Berwick outmancœuvred them, and forced them to retreat on Valencia. In February 1707 they were reinforced by troops brought by the fleet and advanced in April. On the 25th of the month they were defeated by the French and Spanish troops under the Bourbon king, which was near the town of Valencia, and had pressed the country in the province of Alicante, with the loss of all their infantry.

From this date till 1710, the land war in Spain remained stationary. The Bourbon king was master of the greater part of Spain, including Aragon. His generals retook Lérida on the Catalan frontier, and on the Portuguese frontier at La Guadita near Badajoz, on the 7th of May 1709, a Spanish army under the Marques de Bay defeated an Anglo-Portuguese army under the earl of Galway. Yet the Austrian party held Catalonia and Valencia, and the financial distress of the Spanish government, aided by the disorganized state of the administration, rendered a vigorous offensive impossible. By 1710 the French king had been reduced to great distress, and was compelled to make at least a show of withdrawing his support from his grandson Philip V. The allies decided to advance from Catalonia, a course which was strongly urged by General Stanhope (afterwards Earl Stanhope), who commanded the British troops. He had served in subordinate rank from the beginning of the war, and had gained some reputation by the capture of Port Mahon in 1708. Stanhope's energy overcame the reluctance of the Imperialist general Guido Starhemberg, who commanded the German troops and the archduke in Spain, and the Bourbon king seemed to carry all before them. The Spaniards were defeated at Alménara on the 27th of July 1710, and before Saragossa on the 20th of
August. On the 21st of September the archduke entered Madrid. But the invasion of 1710 was a repetition of the invasion of 1706. The 23,000 men of the allies, reduced by a loss of 2000 in the actions at Almánara and Saragossa, by casualties in constant skirmishes with the guerrilleros, and by disease, were absolutely incapable of occupying the two Castilles. The Portuguese gave no help. The Spaniards were reorganized by the duke of Vendôme, who was lent to King Philip V. by his grandfather, and were joined by soldiers of the Irish brigade, and by some Frenchmen who were allowed, or secretly directed, to enter the Spanish service. The position of the allies at Madrid, which was deserted by all except the poorest of its inhabitants, became untenable. On the 6th of November they evacuated the town, and began their retreat to Catalonia. The archduke left the army with 7000 cavalry, and hurried back to Barcelona. The rest of the army marched in three detachments, the division being imposed on them by difficulty of finding food. General Starhemberg with the main body of 12,000 men, was a day’s march ahead of the British troops, 5000 men, under Stanhope. Such a disposition invited disaster in the presence of so capable a general as Vendôme. On the 9th of December he fell upon General Stanhope at Brihuega, and after hard fighting forced him to surrender. Starhemberg, who received tardy information of the peril of his colleague, marched back to support him, and fought a drawn battle at Villa Viciosa, on the 11th. The fruits of victory fell to the British, and the Imperial army was forced to continue its retreat, harassed at every step by the Spanish cavalry and irregulars. His army was reduced to 7000 men when he reached Barcelona.

The disastrous result of the campaign of 1710 proved to the Spaniards that, however strong their naval forces, they were unable to force the archduke on the Castilians by any effort the allies were prepared to make. They remained quiescent at Barcelona till they evacuated the country altogether on the Peace of Utrecht. The Catalans, therefore, deserted by their allies, continued to fight for their local franchises which had been declared forfeited by the French. The Bourbons of France was only subdued on the 12th of September 1714, after a siege of great length and extraordinary ferocity, by the united exertions of the French and Spanish troops under the command of the duke of Berwick.

The naval operations, apart from the transport and support of the troops in Spain, were more numerous than memorable. The overwhelming superiority of the allies alone enabled them to maintain the war in the Peninsula, but as they met no serious opposition except in 1704, there is nothing to record save their successive cruises. In 1707 a British and Dutch fleet under Sir Edward Vernon, after the capture of the Imperial galleys by Vauban, on the 3rd of November 1706, reduced the French port of Toulon. The action of the allied navy was in fact as decisive as the naval strength of Great Britain was to be in the later struggle with Napoleon. But it was less brilliant. The many expeditions sent to the West Indies rarely did more than plunder coast towns or plantations in the French islands. An exception was indeed provided by the British admiral Sir Charles Wager, who in May 1708 destroyed or captured a whole squadron of Spanish treasure ships near Cartagena in South America. The loss of the treasure was a heavy blow to the government of Philip V. and had much to do with reducing his military difficulties. The vicarage of Angol Berberia, which was only subdued on the 12th of September 1714, after a siege of great length and extraordinary ferocity, by the united exertions of the French and Spanish troops under the command of the duke of Berwick.

original historical research in the American field." In 1849
Sparks succeeded Edward Everett as president of Harvard. He
retired in 1853 on account of failing health, and devoted the
rest of his life to his private studies. For several years he was
a member of the Massachusetts board of education. He died on
the 14th of March, 1866, in Cambridge, Mass. This valuable
collection of manuscripts and papers went to Harvard; and his
private library and his maps were bought by Cornell University.
He was a pioneer in collecting, on a large scale, documentary
material on American history, and in this and in other ways
rendered valuable services to historical scholarship in the United
States.

Among Sparks's publications not already mentioned, are Memoirs of the Life and Times of John Ledyard (1829); The Diplomatic Correspondence of the American Revolution (12 vols., reprinted 1854); Life of Governor Morris, with Selections from his Correspondence and Miscellaneous Papers (3 vols., 1852); A Collection of the Familiar Letters and Miscellaneous Papers of Benjamin Franklin (1853); The Works of Benjamin Franklin; with Notes and A Life of the Author (10 vols., 1836–1840; reprinted 1830), a work second in
scope and importance to his Washington; Correspondence of the
American Revolution; being Letters of Eminent Men to George
Washington, from the Time of his taking Command of the Army to
the End of his Presidency (4 vols., 1853). He also edited the Library
of Eminent Men (12 vols., 1855–1859), in two series (10 and 15 vols., respectively,
1853–1858, 1844–1847), which included all the lives of the
latter, Allen, Benedict Arnold, Marquette, La Salle, Count Pulaski, John Ribault,
Charles Lee and John Ledyard, the last a reprint of his early work. In March 1860, an edition
of the Papers of James Madison (1860), and brought out
an American edition of William Smyth's Lectures on Modern History
(2 vols., 1841), which did much to stimulate historical study in the
United States.

See Herbert B. Adams, The Life and Writings of Jared Sparks (2 vols., Boston, 1893); also Brantz Mayer, Memoir of Jared Sparks (1841), published for the Maryland Historical Society; and George E. Ellis, Memoir of Jared Sparks (1866), reprinted from the Proceedings of the Massachusetts Historical Society for May 1868.

(W. L. C.)

SPARROW (O. Eng. spearse; Icl. spörr; O.H. Sparo), a
word perhaps (like the equivalent Latin passer) originally
meaning almost any small bird, but gradually restricted in
signification, and nowadays in common English applied to
only four kinds, which are further differentiated as hedge-
sparrow, house-sparrow, tree-sparrow and reed-sparrow—
the last being a bunting (q.v.)—though when used without a prefix
the second of these is usually intended.

1. The hedge-sparrow, called "dunnock" in many parts of
England, Acciator modularis of the sub-family Turdinae of the
thrushes (q.v.), is the little brown-backed bird with an iron-grey
head and neck that is to be seen in nearly every garden throughout
the country, unobtrusively and yet tamely seeking its food,
which consists almost wholly of insects, as it progresses over the
ground. It is a sparrow in which more than being accompanied by
a slight jerk or shuffle of the wings. Though on the continent
of Europe it regularly migrates, it is one of the few soft-billed
birds that reside throughout the year with us, and is one of the
earliest breeders—its well-known greenish-blue eggs, laid in
a warmly built nest, being recognized by hundreds as among the
surest signs of returning spring; but a second or even a third
brood is produced later. The cock has a sweet but rather feeble
song; and the species has long been accounted, though not
with accuracy, to be the most common dupe of the cuckoo.
Several other species are assigned to the genus Accisor; but all,
except the hedge-sparrow, are members of Emberizidae, a family
British hedge-sparrow, inhabit more or less rocky situations, and one,
A. collaris, or alphas, is a denizen of the higher mountain-
ranges of Europe, though it has several times strayed to England.

2. The house-sparrow, the Fringilla domestica of Linnaeus
and Passer domesticus of modern authors, is far too well known
to need any description of its appearance or habits, being found,
whether in country or town, more attached to human dwellings
than any other wild bird; nay, more than that, one may safely
assume that it is not known to thrive anywhere far away from the
human habitations, and of its migratory movements. It has
spread itself throughout the countries as northern Scandinavia
and many parts of the Russian Empire as new settlements are formed and land brought under
cultivation. Thus questions arise as to whether it should not be
considered a parasite throughout the greater portion of the
area it now occupies, and as to what may have been its native
country. Moreover, it has been introduced to a number of other
seats of civilization in the house-sparrow is not primarily
injurious to the agriculturist and horticulturist has long been
a matter of discussion, and so definite result that a fair judge
accepts has yet been reached. It is freely admitted that
the damage done to growing crops is often enormous, but as yet
the service frequently rendered by the destruction of insect-pests
cannot be calculated. In the south of Europe the house-sparrow
sits on annual measure replaced by two allied species, P. hispaniolenis
and P. italicus, whose habits are essentially identical with its own;
and it is doubtful whether the sparrow of India, P. indicus,
is specifically distinct; but Africa has several members of the
genus which are decidedly so.

3. The tree-sparrow, the Fringilla montana of Linnaeus
and Passer montanus of modern writers—both sexes of which
much resemble the male house-sparrow, but are easily distin-
guishable by the reddish-brown crown, the black patch on the
sides of the neck, and doubly-barred wings—is a much more
local species, in England generally frequenting the rows of pollard-
willows that line so many rivers and canals, in the holes of which
it breeds; but in some Eastern counties it is reported that it frequents
houses, even in towns, and so fills the place of the house-sparrow.
Its geographical distribution is extensive and marked by some curious characters, among which may
be mentioned that, being a great wanderer, it has effected settle-
ments even in such remote islands as the Farcroes and some of the
Outer Hebrides.

The genus Passer belongs to the Passerine family Fringillidae.
The American birds called "sparrows" have little in common
with the members of the genus Passer, and belong to the family
Emberizidae, which is also allied to the Fringillidae. (A. N.)

SPARTEM (Gr. Σπαρτη or Σαλαμίδων), an ancient city
in Greece, the capital of Laconia and the most powerful state of the
Peloponnese. The city lay at the northern end of the central
Laconian plain, on the right bank of the river Eurotas,
a little south of the point where it is joined by its largest tributary,
the Oenus (mod. Klefeina). The site is admirably fitted
by nature to guard the only routes by which an army can
penetrate Laconia from the land side, the Oenus and Eurotas
valleys leading from Arcadia, its northern neighbour, and the
Lagnosta Pass over Mt Taygetus connecting Laconia and Messenia.
At the same time its distance from the sea—Spartum
is 27 m. from its seaport, Gythium—made it invaluable to a
maritime attack.

I.—History

Prehistoric Period.—Tradition relates that Sparta was
founded by Lacedaemon, son of Zeus and Taygete, who
called the city after the name of his wife, the daughter of
Europa. But Amyclae and Therapae (Therapae) seem to
have been in early times of greater importance than Sparta,
the former a Minyan foundation a few miles to the south of
Sparta, the latter probably the Achaean capital of Laconia
and the seat of Menedes, Agamemnon's younger brother.
The city years after the Trojan War, according to the traditional chronology,
the Dorian migration took place. A band of Dorians
(q.v.) united with a body of Aetolians to cross the Corinthian
Gulf and invade the Peloponnese from the north-
west. The Aetolians settled in Elis, the Dorians
pushed up to the headwaters of the Alpheus, where
they divided into two forces, one of which under Cresphontes
invaded and later subdued Messenia, while the other, led by
the other, led by Menelaus, Agamemnon's younger brother,
advances; and Procles, made its way down the Eurotas
valley and gained Sparta, which became the Dorian capital

Dorian invasion.
of Laconia. In reality this Dorian immigration probably consisted of a series of inroads and settlements rather than a single great expedition, as depicted by legend, and was aided by the Mitylene elements in the population, owing to their dislike of the Achaean yoke. The newly founded state did not at once become powerful: it was weakened by internal dissension and lacked the stability of a united and well-organized community. The turning-point is marked by the legislation of Lycurgus (q.v.), who effected the unification of the state and instituted that training which was its distinguishing feature and the source of its greatness. Nowhere else in the Greek world was the plainness of the individual so thoroughly subordinated to the interest of the state. The whole education of the Spartan was designed to make him an efficient soldier. Obedience, endurance, military spirit—the three were the alma-mater constantly kept in view, and beside these all other ends took a secondary place. Never, perhaps, in the world’s history has a state so clearly set a definite ideal before itself or striven so consistently to reach it. But it was solely in this consistency and steadfastness that the greatness of Sparta lay. Her ideal was a narrow and unworthy one, and was pursued with a calculating selfishness and a total disregard for the rights of others, which robbed it of the moral worth it might otherwise have possessed. Nevertheless, it is not probable that without the training introduced by Lycurgus the Spartans would have so successfully secured the supremacy in Laconia, much less in the Peloponnesian, for they formed a small immigrant band face to face with a large and powerful Achaean and autochthonous population.

The Expansion of Sparta.—We cannot trace in detail the process by which Sparta subjugated the whole of Laconia, but apparently the first step, taken in the reign of Archelaus and Charillus, was to secure the upper Eurotas valley, conquering the border territory of Aegys. Archelaus’ son Teleclus is said to have taken Amycla, Pharis and Geronthrae, thus mastering the central Laconian plain and the eastern plateau which forms the southern boundary of the Arcadian and Messenian, by the subjugation of Helos the lower Eurotas plain under Spartan rule. About this time, probably, the Argives, whose territory included the whole east coast of the Peloponnesian and the island of Cythera (Herod. i. 82), were driven back, and the whole of Laconia was thus incorporated in the Spartan state. It was not long before a further extension took place. Under Alcamenes and Theopompus a war broke out between the Spartans and the Messenians, their neighbours on the west, which, after a struggle lasting for twenty years, left the inhabitants of the cities of Hermione and the Argives, who were forced to pay half the produce of the soil as tribute to their Spartan overlords. An attempt to throw off the yoke resulted in a second war, conducted by the Messenian hero Aristomenes (q.v.); but Spartan tenacity broke down the resistance of the insurgents, and Messenia was made Spartan territory, just as Laconia had been, its inhabitants being reduced to the status of helots, save those who, as perioeci, inhabited the towns on the sea-coast and a few settlements inland. This extension of Sparta’s territory was viewed with apprehension by her neighbours in Arcadia, and Argos had vigorously aided the Messenians in their two struggles, and help was also sent by the Sikyonians, Pisatans and Triphylians: only the Corinthians appear to have supported the Spartans, doubtless on account of their jealousy of their powerful neighbours, the Argives. At the close of the second Messenian War, i.e. by the war 631 at latest, no power could hope to cope with that of Sparta save Arcadia and Argos. Early in the 6th century the Spartan kings Leon and Agaècles made a vigorous attack on Tegea, the most powerful of the Arcadian cities, but it was not until the reign of Anaxandridas and Aristo, about the middle of the century, that the attack was successful and Tegea was forced to acknowledge Spartan overlordship, though retaining its independence. The final struggle for Peloponnesian supremacy was with Argos, which had at an early period been the most powerful state of the peninsula, and even now, though its territory had been curtailed, was a serious rival of Sparta. But Argos was now no longer at the height of its power: its league had begun to break up early in the 4th century, and it could not in the impending struggle count on the assistance of its 100 allies, and, to the latter victory and Messenia, since the latter had been crushed and robbed of its independence and the former had acknowledged Spartan supremacy. A victory won about 406 B.C., when the Lydian Empire fell before Cyrus of Persia, made the Spartans masters of the Cynuria, the borderland between Laconia and Argolis, for which there had been an age-long struggle. The final blow was struck by King Cleomenes I. (q.v.), who maimed for many years to come the Argive power and left Sparta without a rival in the Peloponnesian. In fact, by the middle of the 6th century, and increasing power down to the period of the Persian Wars, Sparta had come to be acknowledged as the leading state of Hellas and the champion of Hellenism. Croesus of Lydia had formed an alliance with her. Scythian envoys sought her aid to stem the invasion of Darius; to her the Greeks of Asia Minor appealed to withstand the Persian advance and to aid the Ionian revolt; Plataea asked for her protection; Megara acknowledged her supremacy; and at the time of the Persian invasion under Xerxes no state questioned her right to lead the Greek forces on land and sea. Of such a position Sparta proved herself worthy. The career of Lycurgus and his successor, though he was insufficiently active, nor could she ever rid herself of her narrowly Peloponnesian outlook sufficiently to throw herself heartily into the affairs of the greater Hellas that lay beyond the isthmus and across the sea. She was not a colonizing state, though the inhabitants of Tarentum, in southern Italy, and of Lyttus, in Crete, claimed her as their mother-city. Moreover, she had no share in the expansion of Greek commerce and Greek culture; and, though she bore the reputation of hating tyrants and putting them down where possible, there can be little doubt that this was done in the interests of oligarchy rather than of liberty. In the great states which arose after her, her hegemony formed her sole claim to lead the Greek race: that she should truly represent it was impossible.

Constitution.—Of the internal development of Sparta down to this time but little is recorded. This want of information was attributed by most of the Greeks to the stability of the Spartan constitution, which had lasted unchanged from the days of Lycurgus. But it is, in fact, due also to the absence of an historical literature at Sparta, to the small part played by written laws, which were, according to tradition, expressly preserved in oral tradition, in other states. A law which always characterizes an oligarchical rule. At the head of the state stood two hereditary kings, of the Agiad and Euryptyndid families, equal in authority, so that one could not act against the veto of his colleague, though the Agiad king received greater honour in virtue of the seniority of his family (Herod. vi. 51). This dual kingship, a phenomenon unique in Greek history, was explained in Sparta by the tradition that on Aristodemus’ death he had been succeeded by his twin sons, and that this joint rule had been perpetuated. Modern scholars have advanced various theories to account for the twin kingship. Some admit that it may have been explained as an attempt to avoid absolutism, and is paralleled by the analogous instance of the consuls at Rome. Others think that it points to a compromise arrived at to end the struggle between two families or communities, or that the two royal houses represent respectively the Spartan conquerors and their Achaean predecessors; those who hold this last view appeal to the words attributed by Herodotus (v. 72) to Cleomenes I.: “I am no Dorian, but an Achaean.” The duties of the kings were mainly religious, judicial and military. They were the chief priests of the state, and had to perform certain sacrifices and to maintain communication with the Delphian sanctuary, which always exercised great authority in Spartan politics. Their judicial functions had at the time when Herodotus wrote (about 430 B.C.) been restricted to cases dealing with heiresses, adoptions and the public roads: civil cases were decided by the ephebi,
criminal jurisdiction had passed to the council of elders and the ephors. It was in the military sphere that the powers of the kings were most unrestricted. Aristotle describes the kingship at Sparta as “a kind of unlimited and perpetual generalship” (Pol. iii. 1285a), while Isocrates refers to the Spartans as “subject to an oligarchy at home, to a kingship on campaign” (iii. 24). Here also, however, the royal prerogatives were curtailed in course of time: from the period of the Persian wars the king lost the right of declaring war on whom he pleased, he was accompanied by the field by two ephors, and he was overruled also by the ephors in the control of foreign policy. More and more, as time went on, the kings became mere figure-heads, except in their capacity as generals, and the real power was transferred to the ephors and to the gerousia (q.v.). The reason for this change lay partly in the fact that the ephors, chosen by popular election from the whole body of citizens, represented a democratic element in the constitution without violating those oligarchical methods which seemed necessary for its satisfactory administration; partly in the weakness of the kingship, the dual character of which inevitably gave rise to jealousy and discord between the two holders of the office, often resulting in a practical deadlock; partly in the loss of prestige suffered by the kingship, especially during the 5th century, owing to these quarrels, to the frequency with which kings ascended the throne as minors and a regency was necessary, and to the many cases in which a king was, rightly or wrongly, suspected of having accepted bribes from the enemies of the state and was condemned and banished. In the powers exercised by the assembly of the citizens or arepa (q.v.) we cannot trace any development, owing to the scantiness of our sources. The Spartan was essentially a soldier, trained to obedience and endurance: he became a politician only if chosen as ephor for a single year or elected a life member of the council after his sixty-sixth year had brought freedom from military service.

Shortly after birth the child was brought before the elders of the tribe, who decided whether it was to be reared: if defective or weakly, it was exposed in the so-called Training of Apollotae (al 'átheira, from átheores, hidden).

Thus was secured, as far as could be, the maintenance of a high standard of physical efficiency, and thus from the earliest years of the Spartan the absolute claim of the state to his life and service was indicated and enforced. Till their seventh year boys were educated at home: from that time their training was undertaken by the state and supervised by the maqubhlos, an official appointed for that purpose. This training consisted for the most part in physical exercises, such as dancing, gymnastics, ball-games, &c., with music and literature occupying a subordinate position. From the twentieth year began the Spartan’s liability to military service and his membership of one of the átheira or filáira (dining messes or clubs), composed of about fifteen members each, to one of which every citizen must belong. At thirty began the full citizen rights and duties. For the exercise of these three conditions were requisite: Spartan birth, the training prescribed by law, and participation in and contribution to one of the dining-clubs. Those who fulfilled these conditions were the ὕπολοι (peers), citizens in the fullest sense of the word, while those who failed were called ἄφροι (lesser men), and retained only the civil rights of citizenship.

Spartiates were absolutely debarred by law from trade or manufacture, which consequently rested in the hands of the perioeci (q.v.), and were forbidden to possess either gold or silver, the currency consisting of bars of iron: but there can be no doubt that this prohibition was evaded in various ways. Wealth was, in theory at least, derived entirely from landed property, and consisted in the annual return made by the helots (q.v.) who cultivated the plots of ground allotted to the Spartiates. But this attempt to equalize property proved a failure: from early times there were marked differences of wealth within the state, and these became even more serious after the law of Epitadeus, passed at some time after the Peloponnesian War, removed the legal prohibition of the gift or bequest of land. Later we find the soil coming more and more into the possession of large land-holders, and by the middle of the 3rd century B.C. nearly two-fifths of Laconia belonged to women. In hand with this process went a serious diminution in the number of full citizens, who had numbered 8000 at the beginning of the 5th century, but had sunk by Aristotle’s day to less than 1000, and had further decreased to 700 at the accession of Ages IV. in 244 B.C. The Spartans did what they could to remedy this by laws certain penalties were imposed upon those who remained unmarried or who married too late in life. But the decay was too deep-rooted to be eradicated by such means, and we shall see that at a late period in Sparta’s history an attempt was made without success to deal with the evil by much more drastic measures.

The 5th Century B.C.—The beginning of the 5th century saw Sparta at the height of her power, though her prestige must have suffered in the fruitless attempts made to impose upon Athens an oligarchical régime after the fall of the Peisistratid tyranny in 510. But after the Persian Wars the Spartan empire expired: Sparta felt that an effort was necessary to recover her former position, and Pausanias, the victor of Plataea, was sent out as admiral of the Greek fleet. But though he won considerable successes, his overbearing and despotic behaviour and the suspicion that he was intriguing with the Persian king alienated the sympathies of those under his command; he was recalled by the ephors, and his successor, Dorcis, was a weak man who allowed the transference of the hegemony from Sparta to Athens to take place without striking a blow (see DELIAN LEAGUE). By the withdrawal of Sparta and her Peloponnesian allies from the fleet the perils and the glories of the Persian War were left to Athens, who, though at the outset merely the leading state in a confederacy of free allies, soon began to make herself the mistress of an empire. Sparta took no steps at first to prevent this. Her interests and those of Athens did not directly clash, for Athens included in her empire only the islands of the Aegean and the towns on its north and east coasts, which lay outside the Spartan political horizon: with the Peloponnesian Athens did not meddle. Moreover, Sparta’s attention was at this time fully occupied by troubles nearer home—the plots of Pausanias not only with the Persian king but with the Laconian helots; the revolt of Tegea (c. 473 B.C.), rendered all the more formidable by the participation of Argos; the earthquake which in 464 devastated Sparta; and the rising of the Messenian helots, which immediately followed. But there was a growing estrangement from Athens, which ended at length in an open breach. The insulting dismissal of a large body of Athenian troops which had come, under Cimon, to aid the Spartans in the siege of the Messenian stronghold of Ithome, the consummation of the Attic democracy under Ephialtes and Pericles, the conclusion of an alliance between Athens and Persia at Nineveh (446), were the crisis which terminated in the Peloponnesian War of 431 B.C., and the final destruction of Sparta as an independent power.
and Argos, which also about this time became democratic, united with other causes to bring about a rupture between the Athenians and the Peloponnesian League. In this so-called first Peloponnesian War Sparta herself took but a small share beyond helping to inflict a defeat on the Athenians at Tanagra in 437 B.C. After this battle they concluded a truce, which gave the Athenians an opportunity of taking their revenge on the Boeotians at the battle of Oenophyta, of annexing to their empire Boeotia, Phocis and Locris, and of subjugating Aegina. In 429 the war was ended by a five years' truce, but after Athens had lost her mainland empire by the battle of Coronea and the revolt of Megara a thirty years' peace was concluded, probably in the winter 426-425 B.C. By this Athens was obliged to surrender Troezen, Achaea and the two Megarian ports, Nisaea and Pegae, but otherwise the status quo was maintained. A fresh struggle, the great Peloponnesian War (q.v.), broke out in 431 B.C. This may be to a certain extent regarded as a contest between Ionian and Doric; it may with greater truth be called a struggle between the democratic and oligarchic principles of government; but at bottom its cause was neither racial nor constitutional, but economic.

The maritime supremacy of Athens was used for commercial purposes, and important members of the Peloponnesian confederacy, whose wealth depended largely on their commerce, notably Corinth, Megara, Sicyon and Epidaurus, were being slowly but relentlessly crushed. Materially Sparta must have remained almost unaffected, but she was forced to take action by the pressure of her allies and by the necessities imposed by her position as head of the league. She did not, however, prosecute the war with any marked vigour; her operations were almost confined to an annual inroad into Attica, and when in 425 a body of Spartiates was captured by the Athenians at Pylos she was ready, and even anxious, to terminate the war on any reasonable conditions. That the terms of the Peace of Nicias, which in 421 concluded the first phase of the war, were rather in favour of Sparta than of Athens was due almost entirely to the energy and insight of an individual Spartan, Brasidas (q.v.), and the disastrous attempt of Athens to regain its lost land-empire. The final success of Sparta and the capture of Athens in 405 were bought about partly by the treachery of Alcibiades, who induced the state to send Gylippus to conduct the defence of Syracuse, to fortify Decelea in northern Attica, and to adopt a vigorous policy of aiding Athenian allies to revolt. The lack of funds which would have proved fatal to Spartan naval warfare was remedied by the intervention of Persia, which supplied large subsidies, and Spartan good fortune culminated in the possession at this time of an admiral of boundless vigour and considerable military ability, Lysander, to whom much of Sparta's success is attributable.

The 4th Century.—The fall of Athens left Sparta once again supreme in the Greek world and demonstrated clearly her total unfitness for rule. Everywhere democracy was replaced by a philo-Laconian oligarchy, usually consisting of ten men under a harmost or governor pledged to Spartan interests, and even in Laconia itself the narrow and selfish character of the Spartan rule led to a serious conspiracy. For a short time, indeed, under the energetic rule of Agesilaus, it seemed as if Sparta would pursue a Hellenic policy and carry on the war against Persia. But troubles soon broke out in Greece, Agesilaus was recalled from Asia Minor, and his schemes and successes were rendered fruitless. Further, the naval activity displayed by Sparta during the closing years of the Peloponnesian War abated when Persian subsidies were withdrawn, and the ambitious projects of Ly- sander led to his disgrace, which was followed by his death at Hallartus in 395. In the following year the Spartan navy under Peisander, Agesilaus' brother-in-law, was defeated off Cnidus by the Persian fleet under Conon and Pharnabazus, and for the future Sparta ceased to be a maritime power. In Greece itself meanwhile the opposition to Sparta was growing increasingly powerful, and, though at Coronea Agesilaus had slightly the better of the Boeotians and at Corinth the Spartans main- tained their position, yet they felt it necessary to rid themselves of Persian hostility and if possible use the Persian power to strengthen their own position at home: they therefore concluded with Artaxerxes II. the humiliating Peace of Antalcidas (387 B.C.), by which they surrendered to the Great King the Greek cities of the Asia Minor coast and of Cyprus, and stipulated for the independence of all other Greek cities. This last clause led to a long and desultory war with Thebes, which refused to acknowledge the independence of the Boeotian towns under its hegemony: the Cadmeia, the citadel of Thebes, was treacherously seized by Phoebidas in 382 and held by the Spartans until 379. Still more momentous was the Spartan action in crushing the Olynthiac Confederation (see OLYNTHIUS), which might have been able to stay the growth of Macedonian power. In 371 a fresh peace congress was summoned at Sparta to ratify the Peace of Callias. Again the Thebans refused to renounce their Boeotian hegemony, and the Spartan attempt to prevent them from taking the defeat of the Spartan army at the battle of Leuctra and the death of its leader, King Cleombrotus. The result of the battle was to transfer the Greek supremacy from Sparta to Thebes.

In the course of three expeditions to the Peloponnesus undertook by Epaminondas, the greatest soldier and statesman Thebes ever produced, Sparta was weakened by the loss of Messenia, which was restored to an independent position with the newly built Messene as its capital, and by the foundation of Megalopolis as the capital of the Arcadians. This move brought Macedon into the way into Laconia and devastated the whole of its southern portion; but the courage and coolness of Agesilaus saved Sparta itself from attack. On Epaminondas' fourth expedition Sparta was again within an ace of capture, but once more the danger was averted just in time; and though at Mantinea (362 B.C.) the Thebans, together with the Arcadians, Messenians and Argives, gained a victory over the combined Mantinian, Athenian and Spartan forces, yet the death of Epaminondas in the battle more than counterbalanced the Theban victory and led to the speedy break-up of their supremacy. But Sparta had neither the men nor the money to recover her lost position, and the continued existence on her borders of an independent Messenian and Arcadia kept her in constant fear for her own safety. She did, indeed, join with Athens and Achaea in 353 to prevent Philip of Macedon passing Thermopylae and entering Phocis, but beyond this she took no part in the struggle of Greece with the new power which had sprung up on her northern borders. No Spartiate fought on the field of Chaeronea. After the battle, however, she refused to submit voluntarily to Philip, and was forced to do so by the devastation of Laconia and the transfer of the Laconian cities to the neighbouring states of Argos, Arcadia and Messenia. During the absence of Alexander the Great in the East Agis III. revolted, but the rising was crushed by Anti- pater, and a similar attempt to throw off the Macedonian yoke made by Archidamus IV. in the troublous period which suc- ceeded Alexander's death was frustrated by Demetrius Polior- cetes in 294 B.C. Twenty-two years later the city was attacked by an immense force under Pyrrhus, but Spartan bravery had not died out and the formidable enemy was repulsed, even the women taking part in the defence of the city. About 244 an epi- theban army overran Laconia, wreaking irreparable harm and carrying off, it is said, 50,000 captives.

But the social evils within the state were even harder to combat than foes without. Avarice, luxury and the glaring inequality in the distribution of wealth, threatened to bring about the speedy fall of the state if no cure could be found. Agis IV. and Cleomenes III. (qq.v.) made an heroic and entirely disinterested attempt in the latter part of the 3rd century to improve the conditions by a redistribution of land, a widening of the citizen body, and a restoration of the old severe training and simple life. But the evil was too deep-seated to be remedied by these artificial means; Agis was assassinated, and the
reforms of Cleomenes seem to have had no permanent effect. The reign of Cleomenes is marked also by a determined effort to cope with the rising power of the Achaean League (p. x) and to recover for Sparta her long-lost supremacy in the Peloponnesian, and even throughout Greece. The battle of Sellasia (222 B.C.), in which Cleomenes was defeated by the Achaean and Antigonean Dossen of Macedonia, and the death of the king, which occurred shortly afterwards in Egypt, put an end to these hopes. The same reign saw also an important constitutional change, the substitution of a board of patroinai for the ephors, whose power had become almost despotic, and the curtailment of the functions exercised by the gerousia; these measures were, however, cancelled by Antigonean. It was not long afterwards that the dual kingship ceased and Sparta fell under the sway of a series of cruel and rapacious tyrants—Lycurgus, Machanidas, who was killed by Philopoemen, and Nabis, who, if we may trust the accounts given by Polybius and Livy, was little better than a bandit chieftain, holding Sparta by means of extreme cruelty and oppression, and using mercenary troops to a large extent in his wars.

The Intervention of Rome.—We must admit, however, that a vigorous struggle was maintained with the Achaean League and with Macedon until the Romans, after the conclusion of the war with Philip V., sent an army into Laconia under T. Quinctius Flaminius. Nabis was forced to capitulate, evacuating all his possessions outside Laconia, surrendering the Laconian seaports and his navy, and paying an indemnity of 500 talents (Livy xxxiv. 33-43). On the departure of the Romans he succeeded in recovering Gythium, in spite of an attempt to relieve it made by the Achaean under Philopoemen, but in an encounter he suffered a crushing defeat at the hands of that general, who for thirty days ravaged Laconia unopposed. Nabis was assassinated in 192, and Sparta was forced by Philopoemen to enrol itself as a member of the Achaean League (p. xii) under a phil-Achaean aristocracy. But this gave rise to chronic disorders and disputes, which led to armed intervention on the part of the Achaean, who compelled the Spartans to submit to the overthrow of their city walls, the dismissal of their mercenary troops, the recall of all exiles, the abandonment of the old Lycurcan constitution and the adoption of the Achaean laws and institutions (188 B.C.). Again and again the relations between the Spartans and the Achaean League formed the occasion of discussions in the Roman senate or of the despatch of Roman embassies to Greece, but no decisive intervention took place until a fresh disturbance about the position of Sparta in the league led to a decision of the Romans that Sparta, Corinth, Argos, Arcadian Orchomenus and Heraclae on Oeta should be severed from it. This resulted in an open breach between the league and Rome, and eventually, in 146 B.C., after the sack of Corinth, in the dissolution of the league and the annexation of Greece to the Roman province of Macedonia. For Sparta the long era of war and intestine struggle had ceased and one of peace and a revived prosperity took its place, as is witnessed by the numerous extant inscriptions belonging to this period. As an allied force it was not long afterwards appointed to be the chief custos of the Achaeans, and it was this state of things which compelled on occasions to make "voluntary" presents to Roman generals. Political ambition was restricted to the tenure of the municipal magistracies, culminating in the offices of nomophylax, epior and patronomus. Augustus showed marked favour to the city, Hadrian twice visited it during his journeys in the East and accepted the title of eponymous patronomus. The old warlike spirit found an outlet chiefly in the vigorous but peaceful contests held in the gymnasium, the ball-place, and the arena before the temple of Artemis Orthia; sometimes too it found a vent in actual campaigning, as when Spartans were enrolled for service against the Parthians by the emperors Lucius Verus, Septimius Severus and Caracalla. Laconia was subsequently overrun, like so much of the Roman Empire, by barbarian hordes.

Medieval Sparta.—In A.D. 396 Alaric destroyed the city and at a later period Laconia was invaded and settled by Slavonic tribes, especially the Melings and Euxrits, who in turn had to give way before the advance of the Byzantine power, though preserving a partial independence in the mountainous regions. The Franks on their arrival in the Morea found a fortified city named Lacedaemon occupying part of the site of ancient Sparta, and this continued to exist, though greatly depopulated, even after Guillaume de Villehardouin had in 1248-1249 founded the fortress and city of Misithra, or Mistra, on a spur of Taygetus some 3 m. north-west of Sparta. This passed shortly afterwards into the hands of the Byzantines, who retained it until the Turks under Mahomed II. captured it in 1460. In 1687 it came into the possession of the Venetians, from whom it was wrested in 1715 by the Turks. Thus for nearly six centuries it was Mistra and not Sparta which formed the centre and focus of Laconian history.

The Modern City.—In 1834, after the War of Independence had resulted in the liberation of Greece, the modern town of Sparta was built on part of the ancient site from the designs of Baron Jochmus, and Mistra decayed until now it is in ruins and almost deserted. Sparta is the capital of the prefecture (poyòs) of Lacedaemon and has a population, according to the census taken in 1907, of 4436: but with the exception of several silk factories there is but little industry, and the development of the city is hampered by the unhealthiness of its situation, its distance from the sea and the absence of railway communication with the rest of Greece. As a result of popular clamour, however, a survey for a railway was begun in 1907, an event of great importance for the prosperity of Sparta and of the whole Eurotas Plain.

II.—Archaeology

There is a well-known passage in Thucydides which runs thus: "Suppose the city of Sparta to be deserted, and nothing left but the temples and the ground-plan, distant ages would be very unwilling to believe that the powers of the Lacedaemonians was at all equal to their fame. . . . Their city is not built continuously, and has no splendid temples or other edifices; it rather resembles a group of villages, like the ancient towns of Hellas, and would therefore make a poor show" (i. 10, trans. Jowett). And the first feeling of most travellers who visit modern Sparta is one of disappointment with the ancient remains: it is rather the loneliness and grandeur of the situation and the fascination of Mistra, with its grass-grown streets, its decaying houses, its ruined fortress and its beautiful Byzantine churches, that remain as a lasting and cherished memory. Until 1905 the chief ancient buildings at Sparta were the theatre, of which, however, little shows above ground except portions of the retaining walls; the so-called Tomb of Leonidas, a quadrangular building, perhaps a temple, constructed of immense blocks of stone and containing two chambers; the foundation of an ancient bridge over the Eurotas; the ruins of a circular structure; some remains of late Roman fortifications; several brick buildings and mosaic pavements. To these must be added the inscriptions, sculptures and other objects collected in the local museum, founded by 1912, the ruins of a theatre, a gymnasium, and the remains of the ancient walls of houses or churches. Though excavations were carried on near Sparta, on the site of the Amyclaean in 1890 by Tsountas, and in 1904 by Furtwängler, and at the shrine of Menelaus in Therapne by Ross in 1833 and 1841, and by Kastriotis in 1880 and 1900, yet no organized work was tried in Sparta itself save the partial excavation of the "round building" undertaken in 1892 and 1893 by the American School at Athens; the structure has since been found to be a semicircular retaining-wall of good Hellinic work, though partly restored in Roman times.

In 1904 the British School at Athens began a thorough exploration of Laconia, and in the following year excavations were made at Thalamae, Geronthrae, and Angelona near Monemvasia, while several medieval fortresses were surveyed. In 1906 excavations began in Sparta itself with results of great value, which have been published in the British School Annual, vol. xii. sqq.
A small circus described by Leake, but subsequently almost lost to view, proved to be a theatre-like building constructed soon after a.d. 200 and the altar and in front of the temple of Artemis Orthia. Here musical and gymnastic contests took place as well as the famous flogging-ordeal (diamastia). The temple, which can be dated to the 2nd century B.C. rests on the foundation of an earlier temple of the 6th century, and close beside it were found the scanty remains of a yet earlier temple, dating from the 9th or even the 10th century. The votive offerings in clay, amber, bronze, ivory and lead found in great profusion within the precinct range from the 9th to the 4th century B.C. and supply invaluable evidence for early Spartan art; they prove that Sparta reached her zenith in the 7th and 6th century B.C. and had already begun in the 7th to build the temple of Athena "of the Brazen House" (Xυλαγωνοι) was located on the Acropolis immediately above the theatre, and though the actual temple is almost completely destroyed, fragments of the capitals show that it was Doric in style, and the site has produced the longest extant archaic inscription of Laconia, numerous bronze nails and plates and a considerable number of votive offerings, some of them of great interest. The Greek city-wall, built in successive stages from the 4th to the 2nd century, was traced for a great part of its circuit, which measured 48 stadia or about 6 m. (Polyb. i. 29). The late Roman wall enclosing the Acropolis in a circuit which probably dates from the years following the Gothic raid of a.d. 262, was also investigated. Besides the actual buildings discovered, a number of points were fixed which greatly facilitate the study of Spartan topography, based upon the description left us by Pausanias. Excavations carried on in 1910 showed that the town of the "Myenean" period which lay on the lower bank of the Eurotas a little to the south-east of Sparta was roughly triangular in shape, with its apex towards the north: its area is approximately equal to that of Sparta, but sedation and destruction have wrought havoc with its buildings and nothing is left save ruined foundations and broken remains.

SPARTACUS, leader in the Slave or Gladiatorial War against Rome (73-71 B.C.), a Thracian by birth. He served in the Roman army, but seems to have deserted, for we are told that he was taken prisoner and sold as a slave. Destined for the arena, he, with a band of his fellow-gladiators, broke out of a training school at Capua and took refuge on Mt Vesuvius (73). Here he maintained himself as a captain of gladiators, his lieutenants being two Celts named Cæsare and the praetor Quintius, whom he himself had been gladiators. A hastily collected force of 3000 men under C. Claudius Pulcher endeavoured to starve out the rebels, but the latter clambered down the precipices and put the Romans to flight. Swarms of hardy and desperate men now joined the rebels, and when the praetor Publius Varinius took the field against them he found them entrenched like a regular army on the plain. But they gave him the slip, and when he advanced to storm their lines they found them deserted. From Campania the rebels marched into Lucania, a country better suited for guerrilla warfare, but was defeated there and was forced to retreat and take refuge in a salt prison. The insurgents reoccupied Campania, and by the defeat of C. Thoranus, the quaestor of Varinius, obtained possession of nearly the whole of southern Italy. Nola and Nuceria in Campania, Thurii and Metapontum in Lucania were sacked. The senate at last despatched both consuls against the rebels (72). The German slaves under Crixus were defeated at Mt Garganus in Apulia by the praetor Q. Arrius. But Spartacus overthrew both consuls, one after the other, and then pressed towards the Alps, where he, Crassus, governor of Cisalpinia, Gaul, and the praetor Gnaeus Manlius, who attempted to stop him, were defeated at Mutina. Freedom was within sight, but with fatal infatuation the slaves refused to abandon Italy. Spartacus led them against Rome, but their hearts seem to have failed them; and instead of attacking the capital, he passed on again to Lucania. The conduct of the war was now entrusted to the praetor Marcus Licius Crassus.

In the next battle Spartacus was worsted and retreated towards the straits of Messina, intending to cross into Sicily, where he would have been welcomed by fresh hordes of natives, but the pirates who had agreed to transport his army proved faithless. Crassus ordered Millius to drive the rebels by a circuit and to the right across the peninsula, but Spartacus forced the lines and, once more Italy lay at his feet. Disunion, however, was at work in the rebel camp. The Gauls and Germans, who had withdrawn from the main body, were attacked and destroyed. Spartacus now took up a strong position in the mountainous country of Petelia (near Strongoli in Calabria) and inflicted a severe defeat on the vanguard of the pursuing army. But his men refused to retreat farther, and in a pitched battle which followed soon afterwards his army proved annihilated. Spartacus had stabbed his horse before the battle, fell sword in hand. A body of the rebels which had escaped from the field was met and cut to pieces at the foot of the Alps by Pompey (the Great), who was returning from Spain. Pompey claimed the credit of finishing the war, and received the honour of a triumph, while only a simple ovation was decreed to Crassus. Spartacus was a capable and energetic leader; he did his best to check the excesses of the lawless bands which he commanded, and treated his prisoners with humanity. His character has been misrepresented by Roman writers, whom his name inspired with terror down to the times of the empire. The story has to be pieced together from the vague and somewhat inconsequent accounts of Joseph of Ephesus (Crassus, 8-11; Pompey, 21), Appian (Bell. civ. i. 116-120), Florus, (ii. 8), Livy (Epid. 95-97), and the fragments of the *Histories* of Sallust, whose account seems to have been full and graphic.
SPARTANBURG, a city and the county-seat of Spartanburg county, South Carolina, U.S.A., about 94 m. N.W. of Columbia. Pop. (1890), 53,441 (1900), 11,395, of whom 42,696 were negroes; (1906, estimate), 14,905. Spartanburg is served by the Southern, the Charleston & Western Carolina (controlled by the Atlantic Coast line), the Glenn Springs, the Carolina, Clinchfield & Ohio, and Inter-urban (electric) railways. It is a thriving city in a cotton-growing and cotton-manufacturing region, about 800 ft. above the sea and 25 m. S.E. of the Blue Ridge. Spartanburg is the seat of Wofford College (Methodist Episcopal, South; founded in 1850 with a bequest of Benjamin Wofford, a local Methodist minister, and opened in 1854), which had, in 1908, 12 instructors and 286 students; also of Converse College (nonsectarian; for women), which was founded by D. E. Converse in 1885, opened in 1890, and in 1908 had 22 instructors and 355 students. An annual musical festival is held here under the auspices of the Converse College Choral Society. Four miles south of the city, at Cedar Spring, is the South Carolina Institution for the Education of the Deaf and Blind, founded in 1839 and taken over by the state in 1857. There are gold-mines near the city; and Spartanburg county produces large crops of cotton. Cotton mills are the basis of the city's prosperity, and it has also a large wholesale trade, iron-working establishments, and various manufactures. The value of its factory product was $2,127,702 in 1905, or 33.7% more than in 1900. Spartanburg was founded in 1787, and, although railway communication with Columbia and Charleston was opened in 1859, there was little growth until the establishment of a branch of cotton mills in the vicinity in 1850, when it was chartered as a city in this year.

SPEAKER, a title of the presiding officer in the legislatures of various countries. In the English parliament the lord chancellor acts as Speaker of the House of Lords, but should his office be in commission the Crown usually appoints a Speaker to supply his place, a case in point being that of Sir L. Shadwell, vice-chancellor, who in 1835 was appointed Speaker during the time the Great Seal was in commission. Unlike the House of Commons, the Speaker of the House of Lords need not necessarily be a member of the House; Brougham in 1830 sat on the wood stools as Speaker in his capacity of lord chancellor, being then plain Mr Brougham, his patent of nobility not having yet been made out. The House of Lords has also deputied Speakers who are appointed by commission. The duties of the Speaker of the House of Lords are defined by a standing order as follows: "The lord chancellor, when he speaks to the House, is always to speak uncovered, and is not to adjourn the House, or to do anything else as mouth of the House, without the consent of the Lords first had, except the ordinary thing about bills, which are of course, wherein the Lords may likewise overrule; as for preferring one bill before another, and such-like; and in case of difference among the Lords, it is to be put to the question; and if the lord chancellor will speak to anything particularly he is to go to his own place as a peer." The Speaker of the House of Lords, as compared with the Speaker of the House of Commons, is an official without power; even his seat, the woolsock, is technically outside the House. Contrary to the practice in the Commons, he acts as a strong party man, making speeches on behalf of government measures from his place as a peer. Proposals have from time to time been made for augmenting the powers of the Speaker of the House of Lords, but it has been repeatedly out that, as he is a minister of the Crown, and not chosen by the House itself, and moreover is often the member of the least experience in the House, it would be inexpedient that he should exercise the same powers as the Speaker of the Commons.

The Speaker of the House of Commons is always a member of that House, and though chosen by the members themselves (subject to the approval of the sovereign) from one of the great political parties, he never either votes (except in the case of a tie) or speaks in his capacity as a member during the time he holds office. His duty is to enforce the observance of the rules laid down for preserving order in the proceedings of the House; he puts every question and declares the determination thereon. As "mouth of the House" he communicates its resolutions to others, conveys its thanks, and expresses its censure, its reprimands or its admonitions. He issues warrants for executing the orders of the House, as the commitment of offenders, the issue of writs, the attendance of witnesses or prisoners in custody, &c. The symbol of his authority is the mace, which is borne before him by the serjeant-at-arms when he enters or leaves the House; he repose on the table when he is in the chair, and it accompanies him on all state occasions.

The Speaker takes precedence of all commoners in the kingdom both by ancient custom and by legislative declaration (1 Will. & Mary c. 21). His salary is £3,000 a year. It is usual to create a retiring Speaker a peer of the realm, generally with the rank of viscount. The office is of great antiquity, and in the various conflicts between the Commons and the Crown was one of considerable difficulty, especially when, as mouthpiece of the House, he had to read petitions or addresses or deliver in the presence of the sovereign speeches on their behalf. The first to whom the title was definitely given was Sir Thomas Hungerford (d. 1398).

A list of Speakers, most of whom are separately noticed, from 1600 is appended. The date of election is given in brackets:

- J. Croke (1601).
- Sir E. Phillips (1604).
- T. Crewe (1614).
- T. Richardson (1621).
- Sir T. Crewe (1624).
- Sir H. Finch (1626).
- J. Finch (1628).
- J. Glanville (1630).
- W. Lenthall (1640).
- H. Pelham (1647).
- F. Roux (1655).
- Sir T. Widdrington (1659).
- C. Chute (1659).
- Sir L. Long (1659).
- T. Bampfylde (1659).
- W. Say (1660).
- Sir H. Grimston (1666).
- Sir E. Tumour (1661).
- Sir J. Charlton (1673).
- E. Seymour (1673).
- Sir R. Sawyer (1679).
- Sir W. Gregory (1679).
- W. Williams (1680).
- Sir J. Trevor (1685).
- H. Powle (1686).
- P. Foley (1695).
- Sir T. Littleton (1698).
- R. Harley (1701).
- (Earl of Oxford).
- J. Smith (1708).
- Sir R. Onslow (1708).
- W. Bromley (1710).

* Speaker in more than one parliament.

The title of Speaker is also applied to the presiding officer of the various legislative assemblies in the British colonies, that of president being applied to the presiding officer of the upper houses, legislative councils as they are usually called. In Canada, however, the presiding officer both of the Senate and the House of Commons is termed Speaker. In the United States the Speaker of the House of Representatives is an officer of considerable power (see United States: Constitution and Government).

Authorities.—Stubbs, Constitutional History; J. A. Manning, Lives of the Speakers (1850); E. Lummis, The Speaker's Chair

1 Brother of Sir R. Crewe.
2 Speaker of the Lower Parliament.
3 Convicted of bribery and expelled, 1693.
4 First Speaker of the Commons of Great Britain.
5 nephew of Sir R. Onslow, Speaker in 1708 and great-great-grandson of R. Onslow, Speaker in the second parliament of Elizabetb. Arthur Onslow was the second Speaker to be elected five times; the first Speaker to be so elected was Thomas Chaucer in the reign of Henry V. Onslow also held the Speakership for the longest period (1727-1761).
6 Afterwards prime minister. Was first Speaker of the Commons of the United Kingdom.
7 First to be Speaker six times and seven times.
SPEAR—SPECIES

(1900); for the United States, J. Bryce, American Common-
wealth, M. P. Follett's The Speaker of the House of Representa-
tives (New York, 1896); H. B. Fuller, Speakers of the House
(Boston, 1999).

SPEAR (O. Eng. spe, O. H. Ger. speer, mod. Ger. speer, &c.,
cf. Lat. sparsus; probably related to "spar," "a beam," a weapon
of offence. Developed from a sharp-headed stake, the spear
may be reckoned, with the club, as among the oldest of weapons.
All the prehistoric races handled the spear; all savage folk thrust
with it or hurl it; civilized man still keeps it as the lance and the
boar-spear; indeed, the bayonet is a spear-head with the rifle for
a shaft.

The English before the Norman conquest were a spear-bearing
race. The freeman's six-foot ashen spear was always near his
hand; and its head is found beside the bones of every warrior.
The casting javelin was commoner than the bow. Norman
horsemen made the long lance, a dozen feet long, its pennon
flattening below the point, the knifely weapons. Throwing
spears became rare, the Black Prince's English knights wonder-
ing at the Spanish fashion of casting darts. In the 14th cen-
tury the vamplate came into use as a guard for the lance hand
above the grip. At this time also the coronel head was devised
for the better safeguard of the jousters, many of whom, how-
ever, preferred the blunted or "rebated" point. The next
step in development gave the shaft a swell towards the hand
on both sides of the grip, a swell exaggerated in the jousting
lance of the 16th century, which, fluted and hollowed, is found
weighing twenty pounds, with a girth of as much as 72 in.
At the end of the 17th century, the weight, as regards the grip
and, before the end of the 14th century, the weight of
the jousting lance called for the use of the lance-rest, a hook
or catch screwed to the right breast of the harness.

The Scots, always weaker than the English in archery,
favoured the long spear as the chief weapon of the infantry,
and from Falkirk onwards held their own in their "schildron" for-
mation against all cavalry, until riddled and disarrayed by the
arrow-flights. Their English enemy, when harquebusiers
began to "bust the archers, exchanged the old bills for those
18 and 20 ft. pikes which, bristled from the squares pro-
tecting the "shot." At the same time, the English horsemen
began to leave the lance for sword, pistol and musketeer.
During the civil wars in the 17th century every man on foot was
either pikeman or musketeer. After 1675 the long pike gave
way to the bayonet in its first shape of a dagger whose hill
could be struck into the muzzle of the musket, and, some four-
ten years later, the bayonet with a ring-catch gave the infantry-
man the last form of his pike. Sergeants, however, carried
through the 18th century a "halfbrot" (q.v.) which, in its degen-
erate form, became a short pike, and infantry officers it
sometimes carried with the spadroon. In 1716 certain dragoon regiments were given the lance which had been seen at work
in the hands of Poles and Cossacks; and the weapon is still part
of the service equipment although controversy is still hot over
its value in action, its supporters urging the demoralizing effect
of the lance against broken troops. Queen Victoria's navy
gave up, in favour of the cutlass bayonet, the pikes which were
once served out to repel attacks of boarders. At the present
day the High Sheriff's party of javelin-men are the only
Englishmen who march on foot with the ancient weapon. (See
further LANCE.)

SPECIES, a term, in its general and once familiar significance,
applied indiscriminately to animate and inanimate objects
and to abstract conceptions or ideas, as denoting a particular
phase, or sort, in which anything might appear. In logic it
came to be used as the translation of the Gr. εἶδος, and meant
a number of individuals having common characters peculiar
to them, and so forming a group which with other groups were
included in a higher group. The application of the term was
purely relative, for the higher group itself might be one of the
"species," or modes of a still higher group. In medicine it
was used for the constituents of a prescription. In algebra
it denoted the characters which represented quantities in an
equation.

Early writers on natural history used the term in its vague
logical sense without limiting it to a special category in the
hierarchy of classification. To John Ray, the famous English
naturalist, the credit is generally given of first making species
a definite term in zoology and botany, but Ray owed much of
his classification to Kaspar or Gaspard Bauhin (1550-1624),
professor of Greek and of Anatomy and Botany at Basel, and much
of his clear definition of terms to an unpublished MS. of Johann
Jung of Hamburg (1587-1657). Sir W. T. Thistlethwaite Dyer
(Edinburgh Review, 1902, p. 370) thinks that Ray's use of
the word may be traced to the last-mentioned authors. It is
clear, however, that through Ray's work in the 17th century
the common biological application of species became fixed
much in its modern form, as denoting a group of animals or
plants capable of interbreeding, and although not necessarily
quite identical, with marked common characters. Working
these lines, and attaching special importance to common
descent, naturalists applied the term with more and more
precision, until Linnaeus, in his Philosophia botanica, gave
the aphorism, "species tot sunt diversae, quot diversae formae
ab initio sunt creatae." Just so many species are to be
reckoned as there were forms created at the beginning.
Linnaeus' invention of binomial nomenclature for designating
species served systematic biology admirably, but at the same
time, by attaching preponderating importance to a particular
grade in classification, crystallized the doctrine of fixity.
The lower grades in classification such as sub-species and varieties
on the one hand, and the higher grades or genera and families,
were admitted to be human conceptions imposed on the living
world, but species were concrete, objective existences to be
discovered and named. G. L. L. Buffon and J. P. B. Lamarck
practically conceded the objective existence of species in arguing that they might be modified by
external conditions, and G. L. Cuvier proclaimed their fixity
without reserve. Charles Darwin found the conception of
species so definite and fixed that he chose for the title of his
great book (1859) the words On the Origin of Species by
Means of Natural Selection, although his exposition of evolu-
tion applied equally to every grade in classification. E. B.
Poulton, in an admirable discussion of contemporary views
regarding species (presidential address to the Entomological
Society of London 1904), has shown that Darwin did not believe
in the objective existence of species, not only because he was led
to discard the hypothesis of special creation as the explanation
of the polymorphism of life, but because in practice as a working
systematist he could neither find for himself nor ascertain from
other systematists any settled criteria by which a group of
species could be definitely separated into a genus, accepted as a
species, or regarded as a variety.

The vast advance in knowledge of the existing forms of living
things that has been acquired and recorded since 1859 has
accentuated the difficulty of finding any morphological criteria
for species. A few writers have insisted that they are discon-
tinuous, and that real gaps exist between them. Equally great
gaps, however, may exist between males and females, between
climatic phases or summer and winter forms. The attempt
to find a physiological criterion has similarly failed; many
forms that have hitherto been accepted as true species produce fertile hybrids (see HYBRIDISM). In the best practice
(see ZOOLOGICAL NOMENCLATURE) systematists no longer
regard species as more than as an artificial rank in classification,
to be applied chiefly for reasons of convenience, so that
the word is reverting to its older logical significance. The word
"species" now signifies a grade or rank in classification assigned
by systematists to an assemblage of organic forms which they
judge to be more closely interrelated by common descent than
they are related to forms judged to be outside the species, and
of which the known individuals, if they differ amongst them-
sewelves, differ less markedly than they do from those outside
the species, or, if differing markedly, are linked by intermediate
forms. It is to be noted that the individuals may themselves
be judged to fall into groups of minor rank, known as sub-species
SPECIFICATION—SPECTACLES

or local varieties, but such subordinate assemblages are elevated to specific rank, if they appear not to intergrade so as to form a linked species, whilst on the other hand assemblages judged to be species are merged, or degraded to sub-species, if they are found to intergrade by discoveries of linking forms. A species in short, is a subjective concept, and some writers, as for instance E. Ray Lankester, have urged that the word is so firmly associated with historical implications of fixture which are now incongruous with its application, that it ought to be discarded from scientific nomenclature.

In technical biology each species is designated by two words, one for the genus, printed with an initial capital, and one for the particular species, printed without an initial capital in Zoology, whilst in Botany the habit once common to both subjects is retained, and the specific name if derived from a proper name is printed with a capital. The initials, and may be followed by the name of the author who first described the species. Thus "Canis vulpes Linnaeus" is the specific designation of the common fox, Canis being the generic term common to dogs, wolves and so forth, and vulpes indicating the particular species, whilst the attached author's name indicates that Linnaeus first named the species in question.

(P. C. M.)

SPECIFICATION (from Med. Lat. speciatio, specificare, to enumerate or mention in detail), any detailed statement, especially one on which an estimate or plan is based, as the specification of a builder or architect (see Specification). In patent law a specification is a description of an invention. An application for a patent must be accompanied by a specification, either provisional or complete. If a complete specification does not accompany the application, it must be forwarded usually within six months of the date of application, otherwise the application is deemed to be abandoned. A provisional specification declares the nature of the invention in general terms, while a complete specification describes the invention in detail, and shows the manner in which it is to be carried out (see further Patents).

In the civil law (see Accession) specification was the working up of a thing into a new product; for example, the making of bread from grain. The effect of specification was that the original owner lost his title in favour of the creator of the new product, but had an action for the value of the materials.

SPECIFIC PERFORMANCE, an equitable doctrine under which a court of equity, in certain exceptional cases where the normal legal remedy, i.e. damages, would not be a sufficient compensation, orders from a defaulting party a specific or actual performance of the thing which he had contracted to do. The courts act on their own discretion in affording or refusing the relief, and usually exercise a general rule which refuses such relief where the common law remedy is adequate, where the court would be unable to superintend or enforce the execution of its judgment, where the plaintiff has himself acted inequitably, or where the enforcement of specific performance would be unreasonable. Specific performance is usually confined to executory agreements, such as a conveyance or a lease of land; it is not usually enforced in the cases of personal acts or in those of contracts for personal service. In the case of a contract for the sale of a chattel the courts will only order specific performance when the chattel is of peculiar value to the purchaser, is peculiar to be obtained elsewhere. The courts are guided considerably by precedent, and it is only by reference to a standard textbook that details can be obtained of the conditions and restrictions which hedge the jurisdiction of the courts. In Scots law specific performance, or "implement," is part of the ordinary jurisdiction of the courts.

SPECTACLES, the name given to flat glasses, prisms, spherical or cylindrical lenses, mechanically adjusted to the human eyes, so as to correct (or aid in the correction of) various defects of vision ("Pt. 103, "Spectacles). They are made usually of crown glass or rock crystal ("pebbles"). They are mounted in rigid steel wire or gold frames, with fastening-pieces over the ears; single or double eye-glasses, and hand-glasses, or lorgnettes, being varieties of form, according to the circumstances and the wearer's taste.

Preservers.—Preserves are used to conceal deformities or to protect the eyes in the many conditions where they cannot tolerate bright light, such as ulceration and inflammation of the cornea, certain diseases of the iris, ciliary body, choroid, and retina. They are made of bluish, "smoked," or almost black coloured glass, and are of very various shapes, according to the amount of obscuration necessary.

Prisms.—Prisms are of great value in cases of double vision due to a slight tendency to squinting, caused by weakness or over-action of the muscular apparatus of the eyeball. Prisms deflect rays of light towards their bases. Hence, if a prism be placed in front of the eye, so as to intercept a ray of light falling upon it will be bent inwards, and seem to come from a point farther out from the axis of vision. Conversely, if the base of the prism is turned towards the temple, the ray of light will seem to come from a point nearer the axis, and will induce the eye to turn inwards, to converge towards its fellow. In cases of myopia or short-sight owing to weakness of the internal recti muscles, the eyes in looking at a near object, instead of converging, tend to turn outwards, and so double vision results. If a suitable prism is placed in front of the eyes the double vision may be prevented. These prisms may be combined with concave lenses, which correct the myopia, or, since a concave lens may be considered as composed of two prisms united at their apices, the same effect may be obtained by making the distance between the centres of the concave lenses greater than that between the centres of the pupils. Again, to obviate the necessity for excessive convergence of the eyes so common in hypermetropia, the centre of the pupil should be placed outside the centre of the corrective convex lenses; these will then act as prisms with their bases inwards. Where, on the other hand, there is no tendency to squinting, care must be taken in selecting spectacles that the distances between the centres of the glasses and the centres of the pupils are quite equal, otherwise squinting, or at any rate great fatigue, of the eyes may be induced.

Spherical Lenses.—Biconvex, biconvex and concavo-convex (meniscus) lenses are employed in ophthalmic practice in the treatment of errors of refraction. Until recently these spherical lenses were numbered in terms of their focal length, the inch being used as the unit. Owing principally to differences in the length of the inch in various countries this method had great inconveniences, and now the unit is the refractive power of a lens whose focal length is one metre. This unit is called a "dioptric" (usually written "D"). A lens of two dioptrics strength has a refractive power of 2, and a focal-length of half a metre, and so on.

Concave Lenses are used in the treatment of myopia or short-sight. In this condition the eye is elongated from before backwards, so that the retina lies behind the principal focus. All objects, therefore, which lie beyond a certain point (the conjugate focus of the dioptric system of the eye, the far point) are indistinctly seen; rays from them have not the necessary divergence to be focused in the retina, but may obtain it by the interposition of suitable concave lenses. Concave lenses should never be used for work within the far point; but they may be used in all cases to improve distant vision, and in very short-sighted persons to remove the far point so as to enable fine work such as sewing or reading to be done at a convenient distance. The weakest pair of concave lenses with which one can read clearly test types at a distance of 18 ft. is the measure of the amount of myopia, and this fully correcting glass may be worn in the slimmer forms of short-sight. In higher degrees, where full correction might increase the myopia by inducing a strain of the accommodation, somewhat weaker glasses should be used for near work. In the highest degrees the complete correction may be employed, but lorgnettes are generally preferred, as Bow can be removed when the eyes become fatigued. It must be remembered that
short-sight tends to increase during the early, especially the school, years of life, and that hygienic treatment, good light, good type, and avoidance of stooping are important for its prevention.

Convex Lenses.—In hypermetropia the retina is in front of the principal focus of the eye. Hence in its condition of repose such an eye cannot distinctly see parallel rays from a distance and, still less, divergent rays from a near object. The defect may be overcome more or less completely by the use of the accommodation. In the smaller forms no inconvenience may result; but in higher degrees prolonged work is apt to give rise to aching and watering of the eyes, headache, inability to read or sew for any length of time, and even to double vision and internal strabismus. Such cases should be treated with convex lenses, which should be theoretically of such a strength as to fully correct for the hypermetropia. Practically it is desirable that a certain amount of hypermetropia remains latent, owing to spasm of the accommodation, which relaxes only gradually.

At first glasses may be given of such a strength as to relieve the troublesome symptoms; and the strength may be gradually increased till the total hypermetropia is corrected. Young adults with slighter forms of hypermetropia need glasses only for near work; elderly people should have one pair of weak glasses for distant and another stronger pair for near vision. These may be conveniently combined, as in Franklin glasses, where the upper half of the spectacle frame contains a weaker lens, and the lower half, through which the eye looks when reading, a stronger one.

Anisometropia.—It is difficult to lay down rules for the treatment of cases where the refraction of the two eyes is unequal. If only one eye is used, its anomaly should be alone corrected; where both are used and nearly of equal strength, correction of each often gives satisfactory results.

Presbyopia.—When distant vision remains unaltered, but, owing to gradual failure of the accommodative apparatus of the eye clear vision within 8 in. becomes impossible, convex lenses should be used for reading of such a strength as to enable the eye to see clearly about 8 in. distance. Presbyopia is arbitrarily said to commence at the age of forty, because it is then that the need of spectacles for reading is generally felt; but it appears later in myopia and earlier in hypermetropia. It advances with years, requiring from time to time spectacles of increasing strength.

Cylindrical Lenses.—In astigmatism, owing to differences in the refractive power of the various meridians of the eye, great defect of sight, frequently accompanied by severe headache, occurs. This condition may be cured completely, or greatly improved, by the use of lenses whose surfaces are not plane but of cylindrical. They may be used either alone or in combination with spherical lenses. The correction of astigmatism is in many cases a matter of considerable difficulty, but the results to vision almost always reward the trouble.

Convex spectacles were invented (see Light) towards the end of the 13th century, perhaps by Roger Bacon. Concave glasses were introduced soon afterwards. Sir G. B. Airy, the astronomer, about 1827, corrected his own astigmatism by means of a cylindrical lens. Periscopic glasses were introduced by Dr W. H. Wollaston.

SPECTROHELIOGRAPH, an instrument for photographing the sun with monochromatic light. In its simplest form it consists of a direct-vision spectroscope, having an adjustable slit (called "a camera slit"), instead of an eyepiece, in the focal plane of the observing telescope. This slit is set in such a position as to transmit a single line of the spectrum, e.g., the K line of calcium. Suppose a fixed image of the sun to be formed on the collimator slit of this spectroscope, and a photographic plate, with its plane parallel to the plane of the solar image, to be mounted almost in contact with the camera slit. The spectroscope is then moved parallel to itself, admitting to the collimator slit light from all parts of the sun's disk. Thus a monochromatic image, by the use of lenses whose surfaces are of successive images of the spectral line employed, will be built up on the plate. As the only light permitted to reach the plate is that of the calcium line, the resulting image will represent the distribution of calcium vapour in the sun's atmosphere. The calcium clouds or floculi thus recorded are invisible to the eye, and are not shown on direct solar photographs taken in the ordinary way.

The calculation of the brilliant reversals of the H and K lines to which they give rise, and the protection to the plate afforded by the diffuse dark bands in which these bright lines occur, are easily photographed with a spectrohelio-}

ograph of low dispersion. In the case of narrower lines, however, higher dispersion is required to prevent the light of the continuous spectrum on either side of the dark line from blotting out the monochromatic image. A spectrohelio-}

ograph which gives excellent results with the lines of calcium, hydrogen and iron is shown in the figure. This instrument, used since 1905 in conjunction with the Snow (horizontal) telescope of the Mount Wilson-Solar Observatory, was constructed in the observatory instrument shop in Pasadena.

It consists of a heavy cast-iron platform (a) mounted on four steel balls (b) which run in V guides of hardened steel. Most of the weight of the instrument is floated on mercury contained in the photographic plate-carrier (e) which forms part of the camera base. The platform carries the two slits, the collimator and camera objectives and the prism-train. An image of the sun, about 6-7 in. in diameter, is formed by the Snow telescope on the collimator slit (d). This slit, when used, is extended through the camera objectives and across such prominences of ordinary height as may happen to lie at the extremities of a vertical diameter. After passing through the collimator and camera objectives, the light is deviated through an angle of 63° 29′, which is constructed in the manner of a portrait lens in order to give a sharp field of sufficient diameter to include the entire solar image. In the Snow telescope the ratio of aperture to focal length was 1.25:1; in this spectrohelio-}
THE SUN, 7TH OCTOBER 1908. Showing right and left-hand Sun-spot vortices.
Spectroscopy (from Lat. spectrum, an appearance, and Gr. στρογγυλός, to see), that branch of physical science which has for its province the investigation of spectra, which may, for our present purpose, be regarded as the product of the resolution of composite luminous radiations into more homogeneous components. The instruments which effect such a resolution are called spectrometers.

The Five-foot Spectroheliograph of the Mount Wilson Solar Observatory (camera lens, camera slit and plate carrier in section).

1. Introductory.—The announcement of the first discoveries made through the application of spectroscopy, then called spectrum analysis, appealed to the imagination of the scientific world because it revealed a method of investigating the chemical nature of substances independently of their distances: a new science was thus created, inasmuch as chemical analysis could be applied to the sun and other stellar bodies. But the beautiful simplicity of the first experiments, pointing apparently to the conclusion that each element had its characteristic and invariable spectrum whether in the free state or when combined with other bodies, was soon found to be affected by complications which all the subsequent years of study have not completely resolved. Compound bodies, we now know, have their own spectra, and only when dissociation occurs can the compound show the rays characteristic of the element: this perhaps was to be expected, but it came as a surprise and was not readily believed, that elements, as a rule, possess more than one spectrum according to the physical conditions under which they become luminous. Spectrum analysis thus passed quickly out of the stage in which its main purpose was "analysis" and became our most delicate and powerful method of investigating molecular properties; the old name being no longer appropriate, we now speak of the science of "Spectroscopy." Within the limit of this article it is not possible to give a complete account of this most intricate branch of physics; the writer therefore confines himself to a summary of the problems which now engage scientific attention, referring the reader for details to H. Kayser's excellent and complete Handbuch der Spektroskopie.

2. Instrumental.—The spectroscope is an instrument which allows us to examine the vibrations sent out by a radiating source; it separates the component parts if they are homogeneous, i.e. of definite periodicity, and then also gives us the distribution of intensity along the homogeneous constituents. This resolution into simple periodic waves is arbitrary in the same sense as is the decomposition of forces along assumed

from a low level, and sometimes reach considerable elevations in the form of eruptive prominences.

In such an exploration of the sun's atmosphere it might be anticipated that definite currents, or some evidences of atmospheric circulation analogous to those familiar in terrestrial meteorology, would be discovered. Neither the forms nor the motions of the calcium flocculi revealed the existence of such currents, but in the higher region shown by the hydrogen photographs the distribution of the dark flocculi suggested the operation of definite forces, though their nature remained obscure until the spring of 1908. At that time monochromatic photographs of the sun were first made on Mount Wilson with the red (Ha) line of hydrogen, previous hydrogen photographs having been taken with Hβ, Hγ or Hδ in the blue or violet. On account of the relatively great strength of Ha at a considerable distance from the photosphere, the new photographs recorded flocculi at high levels previously unexplored. The forms of these flocculi show that all sun-spots are vertical in nature, and are probably analogous to terrestrial cyclones or tornadoes. Most of the solar vortices indicate clockwise rotation in the southern hemisphere and counter-clockwise rotation in the northern, as in the case of terrestrial cyclones. But frequent exceptions have been observed in which the direction of rotation is reversed. The study of these vortices has led to the discovery of a magnetic field in sun-spots, apparently caused by electric convection in the vortices.

It is evident that by the use of a spectroheliograph of sufficiently high dispersion, photographs may be taken of vapours in the sun represented by lines narrower than those of calcium and hydrogen. Such work has been in progress both at Mount Wilson and at Meudon, and the erection of a spectroheliograph of 75 ft. focal length on Mount Wilson was at the end of 1908 contemplated for an early date.

Descriptions of spectroheliographs by Hale, Deslandres, Newall and others, may be found in various papers in Astronomy and Astrophysics, Astrophysical Journal, Comptes rendus, Bulletin astronomique, and other periodicals.

(G. E. H.)
axes; but, in the same way also the results are correct if the resolution is treated as an analytical device and in the final result account is taken of all the overlapping components. Spectroscopes generally consist of three parts: (1) the collimator; (2) the analysing appliance; (3) the telescope. The slit of the collimator confines the light to a nearly linear source, the beam diverging from each point of the source being subsequently made parallel by means of a lens. The parallelism, which is required to avoid aberrations, otherwise introduced by the prism or grating, may often be omitted in instruments of small power. The lens may then be also dispensed with, and the whole collimator becomes unnecessary if the luminous source is narrow and at a great distance, as for instance in the case of the crescent of the sun near the second and third contact of a total solar eclipse. The telescope serves to examine the image of the slit and to measure the angular separation of the different slit images; when photographic methods are employed the telescope is replaced by a camera.

The analysing appliance constitutes the main feature of a spectroscope. It may consist of one of the following:

a. A prism or a train of prisms. These are employed in instruments of small power, especially when luminosity is a consideration. A. Michelson produced the successive retardations, which largely extended the slit, in order to secure increased resolving power, the size of the prisms, or their number, is unduly increased.

b. A grating. Through H. A. Rowland's efforts the construction of gratings has been improved to such an extent that their use is being universal whenever great power or accuracy is required. By introducing the concave grating which (see DIFFRACTION OF LIGHT, § 8) allows us to dispense with all lenses, Rowland produced a revolution in spectroscopic measurement. At present we have still to content ourselves with a much diminished intensity of light when working with gratings, but there is some hope that the efforts to concentrate the light into one spectrum will soon be successful.

c. An échelon grating. Imagine a horizontal section of a beam of light, and this section divided into a number of equal parts. Let somehow or other retardations be introduced so that the optical length of the successive parts increases by the same quantity \( n \lambda \), \( n \) being some number and \( \lambda \) the wave-length. If on emergence the different portions he brought together at the focus it is obvious that the optical action must be in every respect similar to that of a grating when the order of spectrum is considered. A. Michelson produced the successive retardations by inserting step-by-step plates of glass of equal thickness so that the different portions of the beam traversed thicknesses of glass equal to \( n \lambda, 2n \lambda, 3n \lambda, \ldots \). The optical effect as regards resolving power is the same as with a grating of \( N \) lines in the 4th order, but, nearly all the light not absorbed by the glass may be concentrated in one or two orders.

d. Some other appliance in which interference with long difference of path is made use of, such as the interferometer of Fabry and Perot, or Lummer's plate (see INTERFERENCE OF LIGHT).

The échelon and interferometer serve only a limited purpose, but must be called into action when the detailed structure of lines is to be examined. For the study of Zeeman effects (see MAGNETO-OPTICS) the échelon seems specially adapted, while the great pliability of Fabry and Perot's methods, allowing a clear interpretation of results, is likely to secure them permanently an established place in measurements of precision.

The power of a spectroscope to perform its main function, which is to separate vibrations of different but closely adjacent frequencies, is called its "resolving power." The limitation of power is introduced as in all optical instruments, by the finiteness of the length of a wave of light which causes the image of an indefinitely narrow slit to spread out over a finite width in the focal plane of the observing telescope. The so-called "diffraction" image of a homogeneously illuminated slit shows a central band limited on either side by a line along which the intensity is zero, and this band is accompanied by a number of fainter images corresponding to the diffraction of a star image in a telescope. Lord Rayleigh, to whom we owe the first general discussion of the theory of the spectroscope, found by observation that if two spectroscopic lines of frequencies \( n_1 \) and \( n_2 \) are observed in an instrument, they are just seen as two separate lines when the centre of the central diffraction band of one coincides with the first minimum intensity of the other. In that case the image of the double line shows a diminution of intensity along the centre, just sufficient to give a clear impression that we are not dealing with a single line, and the intensity by the middle is that of the point of maximum intensity. We may say therefore that the difference between the frequencies \( n_1 \) and \( n_2 \) of the two waves is such that in the combined image of the slit the intensity at the minimum between the two maxima falls to \( \cdot \cdot \cdot \cdot \cdot \cdot \cdot \cdot \), the lines are just resolved and \( n_1 - n_2 \) may then be called the resolving power. There is something arbitrary in this definition, but as the practical importance of the question lies in the comparison between instruments of different types, the exact standard adopted is of minor importance, the chief consideration being simplicity of application. Lord Rayleigh's expression for the resolving power was therefore as follows: if the width of the central maximum of the diffraction image of the slit is narrow compared with the width of the diffraction image, this condition is necessary if the full power of the instrument is to be called into action. Unfortunately considerations of luminous power compel the observer often to widen the slit much beyond the range within which the theoretical value of resolving power holds in practice. The extension of the investigation to wide slits was first made by the present writer in the article "Spectroscopy" in the 9th edition of the Encyclopaedia Britannica. Reconsideration of the subject led afterwards to modify his views to some extent, and he has since more fully discussed the question.

Basing the investigation on the same criterion of resolution as in the case of narrow slits, we postulate for both narrow and wide slits that two lines are resolved when the intensity of the combined image falls to a value of \( \cdot \cdot \cdot \cdot \cdot \cdot \cdot \cdot \) in the centre between the lines, the intensity at the maxima being unity. We must now however introduce a new criterion the "purity" and distinguish it from the resolving power: the purity is defined by \( n_1 (n_1 - n_2) \), where \( n_1 \) and \( n_2 \) are the frequencies of two lines such that they would just be resolved with the width of slit used. With an indefinitely narrow slit, the purity is equal to the resolving power. As purity and resolving power are essentially positive quantities, \( n_1 \) in the above expression must be the greater of the two frequencies. With wide slits the difference \( n_1 - n_2 \) depends on their width. If we write \( P = \beta R \) where \( P \) denotes the purity and \( R \) the resolving power, we may call \( \beta \) the "purity-factor." In the paper quoted the numerical values of \( \beta \) are given for different widths of slit, and a table shows to what extent the loss of purity due to a widening of the slit is accompanied by a gain in luminosity. The general results may be summarized as follows: if the width of the slit is equal to \( \frac{\lambda}{4D} \) (where \( \lambda \) is the wave-length concerned, \( D \) the diameter of the collimator lens, and \( f \) its focal length) practically full resolving power is obtained and a further narrowing of the slit would lead to loss of light without corresponding gain. We call a slit of this width a "normal slit." With a slit width equal to twice the normal one we lose 6% of resolution, but obtain twice the intensity of light. With a slit equal in width to eight times the normal one the purity is reduced to \( 0.45R \), so that we lose rather more than half the resolving power and increase the light 3:7 times. If we widen the slit still further rapid loss of purity results, with very little gain in light, the maximum luminosity being obtainable with an indefinitely wide slit being four times that obtained with the normal one. It follows that for observations in which light is a consideration spectrosopes should be used which give about twice the resolving power of that actually required; we may then use a slit having a width of nearly eight times that of the normal one.

---

Theoretical resolving power can only be obtained when the whole collimator is filled with light and further (as pointed out by Lord Rayleigh in the course of discussion during a meeting of the Optical Convention" in London, 1906) each portion of the collimator must be illuminated by each portion of the luminous source. These conditions may be generally satisfied by projecting the image of the source on a slit with a lens of sufficient aperture. When the slit is narrow light is lost through diffraction unless the angular aperture of this condensing lens, as viewed from the slit, is considerably greater than that of the collimator lens.

When spectrosopes are used for stellar purposes further considerations have to be taken account of in their construction; and these are discussed in a paper by H. F. Newall. A Spectroscopic Measurement and Standards of Wave-Length.—All spectroscopic measurement should be reduced to wave-lengths or wave-frequencies, by a process of interpolation between lines of wave-lengths of which are known with sufficient accuracy. The most convenient unit is that adopted by the International Union of Solar Research and is called an Ångström (Å); and it is equal to 10\(^{-10}\) cm. A. Perot and C. Fabry, employing their interferometer methods, have compared the wave-length of the red cadmium line with the standard metre in Paris and found it to be equal to 6438.4696 Å, the observations being taken on the 20th of June and on the 1st of July (see p. 565).

This number agrees surprisingly well with that determined in 1803 by Michelson, who found for the same line 6438.4700 Å. Perot’s number is now definitely adopted to define the Ångström, and need never be altered, for should at some future time further researches reveal a minute error, it will be only necessary to change slightly, the temperature or pressure of the air in which the wave-length is measured. A number of secondary standards separated by about 50 Å, and tertiary standards at intervals of from 5 to 10 Å have also been determined. By means of these, spectrosopes are enabled to enable by interpolation the wave-length of any line they may wish to determine. Interpolation is easy in the case of all observations taken with a grating. In the case of a prism some caution is necessary unless the standards used are very close together. The most convenient and accurate formula of interpolation seems to be that discovered by J. F. Hartmann. If \(D\) is the measured deviation of a ray, and \(D_0\), \(a\), \(c\) and \(a\) are four constants, the equation

\[
\lambda = \lambda_0 + \frac{\varepsilon}{(D-D_0)^n}
\]

seems to represent the connexion between deviation and wave-length with considerable accuracy for prisms constructed with the ordinary media.

The constant \(a\) has the same value \(\varepsilon\) for crown and flint glass, so that there are only three disposable constants left. In many cases it is sufficient to substitute unity for \(a\) and write

\[
\lambda = \lambda_0 + \frac{\varepsilon}{D-D_0}
\]

which gives a convenient formula, which in this form was first used by A. Cornu. If within the range 5100-3700 Å, the constants are determined once for all, the formula seems capable of giving by interpolation results accurate to 0.2 Å, but as a rule the range to which the formula is applied will be much less with a corresponding gain in the accuracy of the results.

Every observer should not only record the resolving power of the instrument he uses, but also the purity-factor as defined above. The resolving power in the case of gratings is simply \(mn\), where \(m\) is the order of spectrum used, and \(n\) the total number of lines ruled on the grating. In the case of prisms the resolving power is \(t (d/d\lambda)\), where \(t\) is the effective thickness of the medium traversed by the ray. If \(b\) and \(a\) are thicknesses traversed by the extreme rays, \(t=b-a\), and if, as usual in the case, the prism is filled right up to its refraction cap, \(b=\infty\), and \(t\) becomes equal to the greatest thickness of the medium which is made use of. When compound prisms are used in which, for the purpose of obtaining smaller deviation, one part of the compound acts in opposition to the other, the resolving power of the opposing portion must be deduced in calculating the power of the whole. Opticians should supply sufficient information of the dispersive properties of their materials to allow \(d\lambda/d\lambda\) to be calculated easily for different parts of the spectrum.

The determination of the purity-factor requires the measurement of the width of the slit. This is best obtained by optical means. The collimator of a spectroscope should be detached, or moved so as to admit of the introduction of an auxiliary slit at a distance from the collimator lens equal to its focal length. If a source of light be placed behind the auxiliary slit a parallel beam of light will pass within the collimator and fall on the slit the width of which is to be measured. With fairly homogeneous light the diffraction pattern may be observed at a distance, varying with the width of the slit from about the length of the collimator to one quarter of that length. From the measured distances of the diffraction bands the width of the slit may be easily deduced.

4. Methods of Observation and Range of Wave-Lengths.—Visual observation is limited to the range of frequencies to which our eyes are sensitive. Defining oscillation as is usual in spectroscopic measurement by wave-length, the visible spectrum is found to extend from about 7700 to 3900 Å. In importance to the discovery of radio-waves, the optical properties of the eye are of little consequence, and the photographic method is adopted. Wave-lengths which are to be measured are generally charted on to a photographic plate, and the charts are then measured with a microphotometer or some other instrument.

The vibrations of the ultra-red light which are just absorbed by the eye are of the order of 400 Å, and the most sensitive instruments enable oscillations of about 100 Å to be detected. If, however, one wants to detect oscillations of 20 Å, photographic methods are absolutely necessary. The range of wave-lengths observed with these methods extends from 0.2 Å (interstellar) to 400 Å (ultraviolet).

These methods have been adopted by spectroscopists for the measurement of wave-lengths of all kinds of radiation, and the photography of oscillations of various gases in the ultra-red region has been found to be of great value in the investigation of the structure of the atomic nucleus. The absorption spectra of the elements in the ultra-red region have been much studied, and some of these absorption spectra have been found to be of great importance in the study of the structure of the atomic nucleus.

It is clear that, while the photography of oscillations of the ultra-red region has been of great value in the investigation of the structure of the atomic nucleus, the photography of oscillations of the ultra-red region has been of great value in the study of the structure of the atomic nucleus.
observed up to the present are those recorded by H. Rubens and E. Aschkinass\(^1\) (1661 cms., or 610,000 Å).

5. Methods of Rendering Gases Luminous.—The extreme flexibility of the phenomena shown by radiating gases renders it a matter of great importance to examine them under all possible conditions of luminosity. Gases, like atmospheric air, hydrogen, carbon dioxide or carbon monoxide do not become luminous if they are placed in tubes, even when heated up far beyond white heat as in the electric furnace. This need not necessarily be interpreted as indicating the impossibility of rendering gases luminous by temperature only; for the transparency of the gas for luminous radiations may be such that the emission is too weak to be detected. When there is appreciable absorption as in the case of the vapours of chlorine, bromine, iodine, sulpher, selenium and arsenic, luminosity begins at a red heat. Thus G. Slaet\(^2\) examined the iodine and aromatic liquid, and the bright bands when in contact with a platinum spiral made white hot by an electric current, and J. Evershed\(^3\) has shown that in this and other cases the temperature at which emission becomes appreciable is about 700°. It is only recently that owing to the introduction of carbon tubes heated electrically the excitement of the luminous vibrations of molecules by temperature alone has become an effective method for the study of their spectra even in the case of metals. Hitherto we were entirely and still are generally confined to electrical excitation or to chemical action as in the case of flames.

In the ordinary laboratory the Bunsen flame has become universal, and a number of substances, such as the salts of the alkalis and alkaline earths, show characteristic spectra when suitably placed in it. More information may be gained with the help of the oxyhydrogen flame, which with its higher temperature has not been used as frequently as it might have been, but W. N. Hartley has employed it with great success, and in cyanide (a silicate of aluminium) has found a material which is invisible at the temperature of this flame, and is therefore suitable to the substance which it is desired to examine. An interesting and instructive manner of introducing salts into flames was discovered by A. Gouy, who forced the air before it entered the Bunsen burner, through a spray produce containing a salt in solution. By this method even such metals as iron and copper may be made to show some of their characteristic lines in the Bunsen burner. The spectra produced under these circumstances have been studied in detail by C. de Watteville.\(^4\)

Of more frequent use have been electric methods, owing to the greater intensity of the radiations which they yield. Especially valuable as a test of the carbon arc alone seems sufficient to give vibrations of the requisite power. The metals may be introduced into the arc in various ways, and in some cases where they can be obtained in sufficient quantity the metallic electrodes may be used in the place of carbon poles.

The usual method of obtaining spectra by the discharges from a Ruhmkorf coil or Wimshurst machine needs no description. The effects may be varied by altering the capacity and self-induction of the circuit which contains the spark gap. The insertion of self-induction has the advantage of avoiding the lines due. As the gas through which the spark is taken, but it introduces other changes in the nature of the spark, so that the results obtained with and without self-induction are not directly comparable. Count Gramont\(^5\) has been able to obtain spectroscopic evidence of the metallocioids in a mineral by employing powerful condensers and heating the electrodes in an oxyhydrogen flame when these (as is often the case) are not sufficiently conducting.

When the substance to be examined spectroscopically is in solution the spark may be taken from the solution, which must then be used as cathode of air. The condenser is in this case

\(^5\) Comptes rendus, vols. 121, 122, 124.

not necessary, in fact better results are obtained without it. Lecoq de Boisbaudran has applied this method with considerable success, and it is to be recommended whenever only small electric power is at the disposal of the observer. To diminish the resistance the current should pass through as small a layer of liquid as possible. It is convenient to place the liquid in a short tube, a platinum wire sealed in at the bottom by the theory by the current reaching to the level of the open end. If a thick-walled capillary tube is passed over the platinum tube and its length so adjusted that the liquid rises in it by capillary action just above the level of the tube, the spectrum may be examined directly, and the loss of light due to the passage through the partially wetted surface of the walls of the tube is avoided.

For the investigation of the spectra of gases at reduced pressures the so-called Flücker tubes (more generally but incorrectly called Géotubes) are in common use. When the pressure becomes very low, insufficient arises owing to the difficulty of establishing the discharge. In that case the method introduced by J. J. Thomson might with advantage be more frequently employed. Thomson\(^6\) places spherical bulbs inside thick spiral conductors through which the oscillating discharge of a powerful battery is led. The rapid variation in the intensity of the magnetic field causes a brilliant electrodeless discharge which is seen in the form of a ring passing near the inner walls of the bulb when the pressure is properly adjusted. A variety of methods to render gases luminous should be at the command of the investigator. For nearly all show some distinctive peculiarity and any new modification generally results in fresh facts being brought to light. Thus E. Goldstein\(^7\) was able to show that an increase in the current density is capable of destroying the well-known spectra of the alkali metals, replacing them by quite a new set of lines.

6. Theory of Radiation.—The general recognition of spectrum analysis as a method of physical and chemical research occurred simultaneously with the theoretical foundation of the connexion between radiation and absorption. Though the experimental and theoretical developments were not necessarily dependent on each other, and by far the larger development was concerned with the subject which we now term Spectroscopy could stand irrespective of Gustav Kirchhoff's thermodynamical investigations, there is no doubt that the latter was, historically speaking, the immediate cause of the feeling of confidence with which the new branch of science was received, for nothing impresses the scientific world more strongly than just that little touch of mystery which attaches to a mathematical investigation which can only be understood by the few, and is taken on trust by the many, provided that the author is a man who commands general confidence. While Balfour Stewart's work on the nature of the radiation, was further extended by Kirchhoff, who applied it (though not with mathematical rigour as is sometimes supposed) to the separate wave-lengths. All Kirchhoff's further conclusions are based on the assumption that the radiation transmitted through a partially transparent body can be expressed in terms of two independent factors (1) an absorption of the incident radiation, and (2) the radiation of the absorbing medium, which takes place equally in all directions. It is assumed further that the absorption is proportional to the incident radiation and (at any rate approximately) independent of the temperature, while the radiation is assumed to be a function of the temperature

SPECTROSCOPY

only and independent of the temperature of the enclosure. This division into absorption and radiation is to some extent artificial and will have to be revised when the phenomena of radiation are placed on a mechanical basis. For our present purpose it is only necessary to point out the difficulty involved in the assumption that the radiation of a body is independent of the temperature of the enclosure. The present writer drew attention to this difficulty as far back as 1881, when he pointed out that the different intensities of different spectral lines need not involve the consequence that in an enclosure of uniform temperature the energy is unequally partitioned between the corresponding degrees of freedom. When the molecule is losing energy the intensity of each kind of radiation depends principally on the rapidity with which it can be renewed by molecular impacts. The unequal intensities are therefore observable in the effectiveness of the channels through which energy is lost, and this need not be connected with the ultimate state of equilibrium when the body is kept at a uniform temperature. For our immediate purpose these considerations are of importance inasmuch as they bear on the question how far the spectra emitted by gases are thermal effects only. We generally observe spectra under conditions in which dissipation of energy takes place, and it is not obvious that we possess a definition of temperature which is strictly applicable to these cases. When, for instance, we observe the relation of the gas contained in a glass tube to the temperature at which it is kept, there is a tendency to lose sight of the fact that the radiation from excited molecules is independent of the temperature of the reaction vessel. The definition we should have no difficulty in proving that in a vacuum most of the molecular impacts are thermal. The authors of the definition would fail in the case of a spark discharge. Adopting the definition we should have no difficulty in proving that in a vacuum tube gas at such temperatures, but we are doubtful whether such a conclusion is very helpful towards the elucidation of our problem. Radiation is a molecular process, and we can speak of the radiation of a molecule but not of its temperature. When we are trying to bring radiation into connexion with temperature, we must therefore take a sufficiently large group of molecules and compare their average energies with the average radiation. The question arises whether in a vacuum discharge, in which only a comparatively small proportion of the molecules are affected, we are to take the average radiation of the affected portion or include the whole lot of molecules, which at any moment are not in the discharge. The two processes would lead to entirely different results. The problem, which, in the opinion of the present writer, is the one of interest and has more or less definitely been in the minds of those who have discussed the subject, is whether the type of wave sent out by a molecule only depends on the internal energy of that molecule, or on other considerations such as the mode of excitation. The average energy of a medium containing a mixture of dissimilar elements possesses in this respect only a very secondary interest.

We must now inquire a little more closely into the mechanical conception of radiation. According to present ideas the wave originates in a disturbance of electrons within the molecules. The electrons responsible for the radiation are probably few and not directly involved in the structure of the atom, which according to the view at present in favour, is itself made up of electrons. As there is undoubtedly a connexion between thermal motion and radiation, the energy of these electrons within the atom must be supposed to increase with temperature. But we know also that in the complete radiation of a white body the radiative energy increases with the fourth power of the absolute temperature. Hence a part of what must be included in thermal energy is not simply proportional to temperature as is commonly assumed. The energy of radiation resides in the medium and not in the molecule. Even at the highest temperatures at our command it is small compared with the energy of translatory motion, but as the temperature increases, it must ultimately gain the upper hand, and if there is anywhere such a temperature as that of several million degrees, the greater part of the total energy of a body will be outside the atom and molecular motion ultimately becomes negligible compared with it. But these speculations, interesting and important as they are, lead us away from our main subject.

Considering the great variety of spectra, which one and the same body may possess, the idea lies near that free electrons may temporarily attach themselves to a molecule or detach themselves from it, thereby altering the constitution of the vibrating system. This is most likely to occur in a discharge through a vacuum tube and it is just there that the greatest variety of spectra is observed.

It has been denied by some that pure thermal motion can ever give rise to line spectra, but that either chemical action or impact of electrons is necessary to excite the regular oscillations which give rise to line spectra. There is no doubt that the impact of electrons is likely to be effective in this respect, but it must be remembered that all bodies raised to a sufficient temperature are found to eject electrons, so that the presence of the free electrons is itself a consequence of temperature. The view that visible radiation must be attributed to the impact of such an electron on our present ideas is therefore quite consistent with the view that there is no essential difference between the excitation due to chemical or electrical action and that resulting from a sufficient increase of temperature.

Chemical action has frequently been suggested as being a necessary factor in the luminosity of flame, not only in the sense that it causes a sufficient rise of temperature but as furnishing some special and peculiar though undefined stimulus. An important experiment by C. Günther seems however to show that the radiation of metallic salts in a flame has an intensity characteristic of the substance and not belonging to it in virtue of its temperature. If a short length of platinum wire be inserted vertically into a lighted Bunsen burner the luminous line may be used as a slit and viewed directly through a prism. When now a small bead of sodium or lithium is placed in the flame the spectrum of the white hot platinum is traversed by the dark absorption of the D lines. This is consistent with Kirchhoff's law and shows that the sodium in a flame possesses the same relative radiation and absorption as sodium vapour heated thermally to the temperature of the flames. According to independent experiments by Paschen the radiation of the D line sent out by the sodium is of sufficient density is nearly equal to that of a black body at the same temperature. Other more recent experiments confirm the idea that the radiation of flames is mainly determined by their temperature.

The definition of temperature given above, though difficult in the case of a flame and perhaps still admissible in the case of an electric arc, becomes precarious when applied to the disruptive phenomena of a spark discharge. The only sense in which we might be justified in using the word temperature here is by taking account of the energy set free in each discharge and distributing it between the amount of matter to which the energy is supplied. In a flash of light in this case we might then calculate the maximum temperature to which the substance might be raised, if there were no loss by radiation or otherwise. But the molecules affected by a spark discharge are not in any sense in equilibrium as regards their partition of energy and the word "temperature" cannot therefore be applied to them in the ordinary sense. We might probably with advantage find some definition of what may be called "radiation temperature" based on the relation between radiation and absorption in Kirchhoff's sense, but further information based on experimental investigation is required.

3. Ibid. (1894), 51, p. 40.
radiations. A homogeneous oscillation is one which for all time is described by a circular function such as \(\sin(n \cdot t - \phi)\), where \(t\) being the time and \(\phi\) and \(n\) a constants. The qualification that the circular function must apply to all time is important, and unless it is recognized as a necessary condition of homogeneity, confusion in the more intricate problems or radiation becomes inevitable. Thus if a molecule were set into vibration at a specified time and oscillated according to the above equation during a finite period, it would not send out homogeneous vibrations. In interpreting the phenomena observed in a spectroscopy, it is necessary to remember that the instrument now as pointed out by Lord Rayleigh, is capable of homogeneity within the limits defined by its resolving power. A spectroscopy may be compared to a mechanical harmonic analyser which when fed with an irregular function of one variable represented by a curve supplies us with the sine curves into which the original function may be resolved. This analogy is useful because the application of Fourier's analysis to the optical theory of spectroscopies has been doubted, and it may be urged in answer to the objections raised that the instrument acts in all respects like a mechanical analyser, the applicability of which has never been called into question. The homogeneity of radiation is ultimately set by the so-called Doppler effect, which is the change of wave-length due to the translatory motion of the vibrating molecule from or towards the observer. If \(\lambda\) be the frequency of a homogeneous vibration sent out by a molecule at rest, the apparent frequency will be \(N = \frac{\lambda}{V}\), where \(V\) is the velocity of light and \(v\) is the velocity of the line of sight, taken as positive if the distance from the observer increases. If all molecules moved with the velocity of mean square, the line would be drawn out into a band having on the frequency scale a width \(2\Delta V\), where \(\Delta V\) is now the velocity of mean square, and the translatory motion of the luminous molecules is about the same as that at the ordinary temperature. In that case \(N = \frac{\lambda}{V}\) or the half width of the band measured in wave lengths would be \(\frac{3}{2} \times \lambda\); or, for the red line, the half width would be 0.044 A. Michelson, who has compared the theoretical widening with that found experimentally by means of his interferometer, had to use a somewhat more complicated expression for the comparison, as his visibility curve does not directly give intensities for particular frequencies but an integral depending on a range of frequency. He finds a remarkable agreement between the theoretical and experimental values, which it would be important to confirm with the more suitable instruments which are now at our disposal, as we might in this way get an estimate of the energy of translatory motion of the luminous molecules. If the motion were that of a body at white heat, or say a temperature of 1000\(^\circ\), the velocity of mean square would be 3900 metres per second and the apparent width of the band would be doubled. Michelson's experiments therefore argue in favour of the view that the luminescence in a vacuum tube is similar to that produced by phosphorescence where the translatory energy does not correspond to the oscillatory energy—but further experiments are desirable. The experimental verification of the change of wave-length due to a source moving in the line of sight has been realized in the laboratory by A. Bélopolsky and Prince Galitzin, who substituted for the source an image formed of a stationary object in a rapidly moving mirror.

The homogeneity of vibration may also be diminished by molecular impacts, but the number of shocks in a given time depends on pressure and we may therefore expect to diminish the width of a line by diminishing the pressure. It is not, however, obvious that the sudden change of direction in the translatory motion, which is commonly called a molecular shock, necessarily also affects the phase of vibration. Experiments which will be discussed in § 10 seem to show that there is a difference in this respect between the impacts of similar and those of dissimilar molecules. When the lines are obtained under circumstances which tend towards sharpness and homogeneity they are found to be less complicated structures, single lines breaking up into two or more components of varying intensities. One of the most interesting examples is that furnished by the green mercury line, which when examined by a powerful échelon spectrooscope splits up into a number of constituents which have been examined by several investigators. Six companions to the main lines are found with comparative ease and certainty and these have been carefully measured by Prince Galitzin, H. Stansfield and L. Janicki. According to Stansfield there are three companion lines on either side of a central line, which consists of two lines of unequal brightness.

**Distribution of Harmonics in Line Spectra.**—It is natural to consider the frequencies of vibrations of radiating molecules as analogous to the different notes sent out by an acoustical vibrater. The efforts which were consequently made in the early days of spectroscopy to discover some numerical relationship between the different wave lengths of the lines belonging to the same spectrum rather disregard the fact that even in acoustics the relationship of integer numbers holds only in special and very simple cases. Some corroboration of the simple law was apparently found by Johnstone Stoney, who first noted that the frequencies of three out of the four visible hydrogen lines are in the ratios 20 : 27 : 32. In other spectra such “harmonic” ratios were also discovered, but their search was abandoned when it was found that their number did not exceed that calculated by the laws of probability on the supposition of a chance distribution.

The next great step was made by J. J. Balmer, who showed that the four hydrogen lines in the visible part of the spectrum may be represented by the equation

\[ n = \frac{A}{(1 - \frac{4}{\lambda^2})} \]

where \(n\) is the reciprocal of the wave-length and therefore proportional to the wave frequency, and \(s\) successively takes the values 3, 4, 5, 6. Balmer's formula received a striking confirmation when it was found to include the ultra-violet lines which are disrupted by William Huggins in the photographic spectra of stars. The most complete hydrogen spectrum is that measured by Evershed in the flash spectrum observed during a total solar eclipse, and contains thirty-one lines, all of which agree with considerable accuracy with the formula, if the frequency number \(n\) is calculated correctly by reducing the wave-length to vacuo.

It is a characteristic of Balmer's formula that the frequency approaches a definite limit as \(s\) is increased, and it was soon discovered that in several other spectra besides hydrogen, series of lines could be found, which gradually come nearer and nearer to each other as they become fainter, and approach a definite limit. Such series ought all to be capable of being represented by a formula resembling that of Balmer, but so far the exact form of the series has not been established with certainty. The more important of the different forms suggested are as follow:

1. \(n = A + \frac{B}{s} + \frac{C}{s^2} + \frac{D}{s^3} + \frac{E}{s^4}\) (H. Kayser and C. Runge).
2. \(n = A - \frac{B}{s^2} + \frac{C}{s^4}\) (J. R. Rydberg).

branches must according to the above law correspond to the most refrangible of the doublets of the trunk, and if the components of the doublets have different intensities the stronger components must lie on different sides in the trunk and branch series. This is confirmed by observation. Rydberg discovered a second relationship, which, however, involving the assumed equation connecting the different lines, cannot be tested directly as long as these equations are only approximate. On the other hand the law, once shown to hold approximately, may be used to test the sufficiency of a particular form of equation. These forms all agree in making the frequency negative when $s$ falls below a certain value $s_r$. Rydberg's second law states that if the main branch series is taken, the numerical value of $p_{s_r}$ corresponding to $s_{s_r}$ is equal to the frequency of the least refrangible member of the trunk series.

The two laws are best understood by putting the equations in the form given them by Rydberg. For the trunk series we write

$$\frac{n}{N} = \left(\frac{1}{(r + \sigma)}\right)^{\frac{1}{2}} \left(\frac{1}{(r + \beta)}\right)^{\frac{1}{2}}$$

and for the main branch series

$$\frac{n^m}{N^m} = \left(\frac{1}{(r + \sigma)}\right)^{\frac{1}{2}} \left(\frac{1}{(r + \beta)}\right)^{\frac{1}{2}}$$

Here $\sigma$, $\beta$, and $N$ are constants, while $s$ as before is an integer number.

The difference between the frequencies of the roots ($s = \infty$) is given by

$$\Delta = \left|\left(\frac{1}{(r + \sigma)}\right)^{\frac{1}{2}} \left(\frac{1}{(r + \beta)}\right)^{\frac{1}{2}} - \left(\frac{1}{(r + \sigma)}\right)^{\frac{1}{2}} \left(\frac{1}{(r + \beta)}\right)^{\frac{1}{2}}\right|$$

This is the first law.

If further in the two equations we put $s = 1$, we obtain:

$$n_1 = n_{1m}$$

This is the second law.

As has already been mentioned, the law is only verified very roughly, if Rydberg's form of equation is taken as correctly representing the series. The fact that the addition of the term introduced by Ritz not only gives a more satisfactory representation of each series, but verifies the above relationship with a much closer degree of approximation, proves that Ritz's equation forms a marked step in the right direction. According to him, the following equations represent the connexion between the lines of the three related series.

**Trunk series:**

$$\frac{n}{N} = \left[\left(\frac{r + a + b + b/2}{\beta}\right)^{1/2} \left(\frac{\beta + a + b}{\beta}\right)^{1/2}\right]$$

**Main Branch Series:**

$$\frac{n^m}{N^m} = \left[\left(\frac{r + a + b + b/2}{\beta}\right)^{1/2} \left(\frac{\beta + a + b}{\beta}\right)^{1/2}\right]$$

**Side Branch Series:**

$$\frac{n_{1m}}{N_{1m}} = \left[\left(\frac{r + a + b + b/2}{\beta}\right)^{1/2} \left(\frac{\beta + a + b}{\beta}\right)^{1/2}\right]$$

Here $s, r$ stands for an integer number beginning with 1 for the trunk and 2 for the main Branch, and $r$ represents the succession of numbers 1, 2, 3, 5, &c. As Ritz points out, the first two equations appear only to be particular cases of the form

$$\frac{n}{N} = \left(\frac{r + a}{\beta}\right)^{1/2} \left(\frac{r + b}{\beta}\right)^{1/2}$$

in which $s$ and $r$ have the form given above. In the trunk series $s$ has the particular value 1, 5, and in the main branch series $s$ has the particular value 2, but we should expect a weaker set of lines to exist corresponding to the trunk series with $r = 2, 5$ or corresponding to the main branch series with $s = 3$, and in fact a whole succession of such series. Taking the Trunk and Main Branch Series, we find they depend altogether on the four constants: $a_1$, $b_1$, $a_2$, $b_2$, while $N$ is a universal constant identical with that deduced from the hydrogen series. As an example of the accuracy obtained we give in the following Table the figures for potassium.

The lines of the trunk series are double but for the sake of shortness the least refrangible component is here omitted.

**Spectrum of Potassium.**

SPECTROSCOPY

W. M. Hicks has modified Rydberg's equation in a way similar to that of Ritz as shown by (1) above. This form has the advantage that the constants of the equation when applied to the spectra of the alkali metals show marked regularities. The most extensive series which have been investigated are those due to sodium when it is observed as an absorption spectrum; R. W. Wood has in that case measured as many as 50 lines belonging to this spectrum.

The different series have certain characteristics which they seem to maintain wherever they have been obtained. Thus the trunk series consists of lines which are easily reversed while those of the side branch series are not. The lines of the trunk series appear at lower temperatures, which may account for the fact that these are sometimes observed as absorption lines. If we compare together the spectra of the alkali metals, we find that the doublets of the branch series separate more and make the wavelength-lengths. Roughly speaking the difference in frequency is proportional to the square of the atomic weight. Taking sodium and lithium we find in this way that the lithium lines ought to be double and separated by 7 Å. They have not, however, so far as we know, been resolved.

The roots of the three series have frequencies which diminish as the atomic weight increases, but not according to any simple law.

In the case of other metallic groups similar series have also been found, but while in the case of the alkali group nearly the whole spectrum is represented by the combined set of three series, such is not the case with metals which form a shell-like series, such as calcium, zinc, cadmium, and mercury, give the two branch series, and each series is repeated three times with constant difference of frequency. In these elements the doublets of the alkali series are therefore replaced by triplets, and the whole spectrum consists of series, but only the side branch series has been observed. In the spectrum of barium no series has yet been recognized. The spectrum of helium, however, has been carefully studied by Riecke and Paschen. All its lines arrange themselves in two families of series, in other words, the spectrum looks like that of the superposition of two spectra similar to those presented by the alkali metals. Each family consists of the trunk, main branch and side branch. The conclusion which was originally drawn from this fact that helium is a mixture of two gases has not been confirmed, as one of the spectra of oxygen is similarly constituted.

We must refer to Kayser and Rünges' Handbuch for further details, as well as for information on other spectra such as those of silver, thallium, indium, and manganese, in which series lines have been found.

Before leaving the subject, we return for a moment to the spectrum of hydrogen. In 1896, Professor E. C. Pickering discovered in the structure of the star ξ Puppis a series of lines which showed a remarkable similarity to that of hydrogen having the same root. Kayser on examining the spectrum recognized the fact that the two series were related to each other in a way similar to the hydrogen. This was subsequently confirmed. If we compare Balmer's formula with the general equation of the spectra of magnesium, calcium, zinc, magnesium, and mercury, we find that the former may be expressed as

\[ \frac{1}{\lambda} = n^2 - \frac{1}{4} \]

where \( n \) takes successively the values 1, 5, 2, 5, 3, 5. A knowledge of the constants now determines the trunk series, which should be

\[ \frac{1}{\lambda} = \frac{1}{(1^2 - \frac{1}{4})} \]

The least refrangible of the lines of this series should have a wavelength of 6567 Å, and a strong line of this wavelength and has been found in the spectra of stars which are made up of bright lines, as also in the spectra of some nebulae. It seems remarkable, however, that although we have in reproducing the laboratory the trunk and main branch of the hydrogen spectrum, if the spectra in question really belong to hydrogen.

Considering the complexity of the subject it is not surprising that the efforts to connect theoretically the possible periods of the atom considered as a vibrating system have met with no considerable success. Two methods of investigation are available. The one endeavours to determine the conditions, which are consistent with our knowledge of atomic constitution derived from experiment and the other that treated in this paper and is the basis of the trunk series of the actual atom. We might then hope to particularize or modify these conditions so as to put them into more complete agreement. An attempt in that direction has been made with partial success by J. H. Jeans, who showed that a shell-like constitution of the atom, the shells being electrically charged, would lead to systems of periods not unlike those of a series of lines such as is given by observation. The other method starts from the observed values of the periods, and establishes a differential equation from which the solutions may be deduced. This is done in the hope that some theoretical foundation may then be found for the equation. The pioneer in this direction is E. Riecke, who deduced a differential equation of the 10th order. Ritz in the paper already mentioned follows in the footsteps of Riecke and elaborates the argument. On the whole it seems probable that the system of moving electrons, which according to a modern theory constitute the atom, is not directly concerned in thermal radiation, which would rather be due to a few more loosely connected electrons hanging on to the atom.

This difficulty that the lines of spectrscopic lines seem to involve at least an equal number of electrons in each line is overcome by supposing the atom may present several positions of equilibrium to the electron, which it may occupy in turn. A collision may be able to throw the electrons from one of these positions to another. According to this view the different lines are given out by different molecules, and we should have to take averages over a number of molecules to obtain the complete spectrum just as we now take averages of energy to obtain the temperature. If it should be confirmed that the period called N in the above investigation is the same for all elements, it must be influenced by the atom, and the whole connected with the collision of the atom. At present the quantity of electricity it carries, and also its mass, may be determined, and we can therefore derive units of length and of mass from our electrical measurements. The quantity N may serve to fix the third fundamental unit. One further point deserves notice. Lord Rayleigh, who has also investigated vibrating systems giving series of lines approaching a definite limit of " root," remarks that by dynamical reasoning we are always led to equations giving the square of the period and not the period, while in the equation representing spectral series the simplest range must be to the first power of the period. No follows from Rydberg's second law if we put on a more accurate basis by Ritz that in one case at any rate a negative period has reality and must be interpreted just as if it were positive. This looks indeed as if the square of the period were the determining quantity.

9. Distribution of Frequencies in Band Spectra.—In many cases the spectra of molecules consist of lines so closely ruled together in groups as to give the appearance of continuous bands unless high resolving powers are employed. Such spectra seem to be characteristic of complex molecular structure, as they appear when compounds are formed in which the number of atoms is very high. It is a case of the absorption spectrum of a compound made of a very large number of atoms. It is possible that we examine the absorption spectrum of vodups such as iodine and bromine and other cases where we know that the molecule consists of more than one atom. The bands often appear in groups, and such spectra containing groups of bands when viewed through small spectrosopes sometimes give the appearance of the flutings of columns. Hence the name "fluted spectra," which is sometimes applied. Each band, as has been stated, is made up of lines indicating highly homogeneous vibrations. A systematic study of the distribution of frequencies in these bands was first made by H. Deslandres, who found that the successive differences in the frequencies formed an arithmetical progression.

If \( s \) represents the series of integer numbers the distribution of frequency may be represented as

\[ n = C + Bn^2 \]

where C and B are constants. The brightest line, for which \( s = 0 \), is called the "head" of the band; and as \( s \) increases the lines diminish in intensity. The band fades towards the red or violet according as A is positive or negative, and the appearance is sometimes complicated by the fact that several sets of lines start from identical or closely adjoining heads. The equation which expressed "Deslandres' law" was only given by its author as an approximate one. The careful measurements of Kayser and Rünges of the carbon bands show that the successive differences in the frequencies do

\[ \text{Proc. Roy. Soc. (1900), 83, p. 226 (abstract).} \]
\[ \text{Phil. Mag. (1901), 2, p. 421.} \]
\[ \text{Drude's Annalen (1900), 1, p. 399.} \]
\[ \text{Nature (1895), 51, p. 293-294.} \]
\[ \text{Phil. Mag. (1897), 44, p. 356.} \]
\[ \text{Comptes rendus (1885), 100, p. 1256.} \]
not quite keep up with the mathematical expression but tend to become more equal. The distances between the two first lines is \( A \), and is small compared with the frequency itself, which is \( B \).

If this is the case it is obvious that an equation of the form

\[
n = \frac{B}{s} + 3\frac{C}{s^2} + D
\]

does, for small values of \( s \), becomes identical with Deslandres’ equation, \( s \) representing a constant which is large compared with unity. If we wish to be more general, while still adhering to Deslandres’ law as a correct representation of the frequencies when \( s \) is small, we may write

\[
n = A - \frac{B}{s} + \frac{C}{s^2} + D
\]

where \( A \) is an additional constant.

We have now reduced the law for the bands to a form which we have found in a series of experiments, but with the important difference that while \( A \) in the case of line spectra is a small corrective term, it now forms the constant on which an essential factor in the appearance of the band depends. Halm,\(^1\) to whom we owe a careful comparison of the above equation with the observed frequencies in a great number of spectra, attached perhaps too much weight to the fact that it is capable of representing both line and band spectra. It is no doubt important to recognize that the two types of spectra seem to represent two extreme cases of one formula, the significant difference being that in the line spectrum the distance between lines diminishes as we recede from the head, while in the case of bands, at any rate those associated, on the one hand, with the other hand, no one pretends to have found the rigorous expression for the law, and the appropriate approximation may take quite different forms when constants which are large in one case are small in the other. It would therefore be incorrect to push this agreement against Ritz’s expression which is not applicable to bands.

A discussion of band spectra on a very broad basis was given by Thiele,\(^2\) who recommends a formula

\[
n = \frac{a}{s} + \frac{b}{s^2} + \frac{c}{s^3} + \ldots + \frac{d}{s^i} + \ldots + \frac{e}{s^j} + \ldots
\]

where \( s \) as before represents the integer numbers and the other quantities involved are constants. If \( r = \lambda \), we obtain Pickering’s equation, which is the one advocated by Halm. Equations of this form have received a striking observational verification in so far as they predict the general law but without the lines in the neighborhood of the points where \( s \) is increased indefinitely. This fact bridges over the distinction between the band and line spectra. The distance between the lines measured on the frequency scale does not, according to the equation, increase indefinitely from the head downwards, but has a maximum which, in Pickering’s form as written above, is reached when \( (s + \mu)^\alpha = \lambda \). This gives a real value for \( s \) only when \( a \) is positive. If \( a \) is negative the frequency passes through a minimum, and the maximum distance between lines occurs there. If we only assign positive values to \( n \) and \( a \), the band fades away from the head, the line at first increasing in distance. It appears to be a metaphysical question whether one can say that the lines of the so-called spectrum of cyanogen those tails can be observed. If a negative value of the frequency is admitted, more complicated effects may be predicted. A band might in that case fade away towards the head, and then return again from infinity with diminishing distances, the head and the tail pointing in the same direction; or with a different value of constants a band might fade away towards infinite frequencies, then return through the whole range of the spectrum to zero frequencies, and once more return with its tail near its head. The same band may therefore cross its own head on the return journey. If we adopt Thiele’s view that each band is accompanied by a second branch for which \( s \) has negative values the complication is still further increased, but there does not seem to be sufficient reason to adopt this view.

10. Effects of Varying Physical Conditions.—The same spectrum may show differences according to the physical conditions under which the body emitting the spectrum is placed.

The main effects we have to discuss are (1) a symmetrical widening, (2) a shift of wave-length, which when it accompanies expansion in both directions may appear as an asymmetrical widening, (3) a change in the relative intensities of the lines.

As typical examples illustrating the facts to be explained, the following may be mentioned. (a) When a sodium salt is placed in a Bunsen burner in sufficient quantity, the yellow lines are widened. When the amount of luminous matter is small the lines remain narrow. (b) If a spark be sent through a Plucker tube containing hydrogen the lines are widened when the pressure

\[627\text{is increased.} \]

(c) Under moderate pressures the lines of hydrogen may be widened by powerful sparks taken from a condenser.

(d) If a spark be taken from an electric condenser through air, both the lines of oxygen and nitrogen are wide compared with what they would be at low pressures. But a mixture of nitrogen and oxygen containing only little nitrogen will show the nitrogen lines narrow and similarly narrow oxygen lines may be obtained if the quantity of oxygen is reduced. (e) If a spark be taken from a solution of a salt, e.g. lithium, the relative intensities of the lines are different according as the solution is concentrated or dilute. (f) The relative intensity of lines in the spark taken from metallic poles may be altered by the insertion of greater or smaller capacities, similarly the relative intensities are different in arc and spark spectra.

Increased pressure nearly always diminishes the frequency of vibration, but this effect is generally of a smaller order of magnitude than the widening which takes place in the other cases. In investigating the effects of mixture on the widening of lines in absorption spectrum, R. W. Wood discovered some interesting effects. The cadmium line having a wave-length of about 2250\(\AA\) is quite striking; if mercury be added the broadening is more marked on the less refrangible side.

The discussion as to the causes of this widening has turned a good deal on the question whether it is primarily due to changes of density, pressure or temperature, but some confusion has been caused by the want of proper definition of terms. For the cause of this the writer of the present article is jointly with others at any rate partly responsible, and clearness of ideas can only be re-established by investigating the mechanical causes of the effect rather than by applying terms which refer to a different order of physical phenomena.

The facts, as quoted, point to the closeness of the packing of molecules as the factor which always accompanies and perhaps causes the widening of lines. But is this alone sufficient to justify us in assigning the widening to increased density? Increased density at the same temperature means in the first place a reduction of the average distance between the molecule, but it means also a reduction in the mean free path and an increase in the number of impacts. The question is: which of these three factors is significant in the explanation of the widening? If it is the average distance irrespective of length, the number of impacts we should be justified in ascribing the effect to density, but if it is the number of impacts it would be more reasonable to ascribe it to pressure. The question could not be settled by experiments made at the same temperature, and if the temperature is altered the question is complicated by the distinction which would probably have to be drawn between the number of collisions and their intensity. Experimentally we should be confined to a strict investigation of absorption spectra, because in the electric discharge temperature has no definite meaning, and variations of pressure and density are not easily measured.

Assuming for a moment the change to be one of density and leaving out of account the pressure shift, the cases (e) and (f) point to the fact that it is the closeness of packing of similar molecules which is effective, e.g. the number of oxygen molecules per cubic centimetre determines the width of the oxygen lines, though nitrogen molecules may be mixed with them without materially affecting the appearance. Experiment (c) is, however, generally taken to mean that this closeness of packing cannot be the sole determining cause, for it is argued that if a closed vacuum tube be altered, both wide and narrow the widening of the spectrum of discharge, density alone cannot account for the change. But this argument is not conclusive, for though the total number of hydrogen molecules is fixed when the gas is enclosed, yet the number of luminous molecules may vary with the condition. Those that are not luminous may, if they do not contain the same vibrating system, behave like inert molecules. When an electric current from a battery is sent through a tube containing hydrogen, increase of current simply means increase in the number of ions which take part

\(3\) Ibid. (1901), 14, p. 332.
in the discharge, except within the region of the cathode glow. Each molecule need not radiate with increased energy, but the more brilliant emission of light may be due to the greater number of particles forming similar vibrating systems.

When we compare together electric discharges the intensity of which is altered by varying the capacity, we are unable to form an opinion as to whether the effects observed are due to changes in the density of the luminous material or changes of temperature, but the experiments of Sir William and Lady Humphreys with the spectrum of calcium are significant in suggesting that it is really the density which is also the determining factor in cases where different concentrations and different spark discharges produce a change in the relative intensities of different lines.

The widening of lines does not lend itself easily to accurate measurements; more precise numerical data are obtainable by the study of the displacements consequent on increased density which were discovered and studied by W. J. Humphreys and J. F. Mohler. In the original experiments the pressures could only be increased to 15 atmospheres, but in a more recent work Humphreys and independently Duffield, were able to use pressures up to 100 atmospheres, and they have found that the change of frequency (\(dn/n\)) for a series of lines which behave similarly is approximately proportional to the frequency (\(n\)) so that we can take the fraction \(dn/n\) as a measure of the shift. It is found that the lines of the same element do not all show the same shift, thus the calcium line at 4233 is displaced by 0.4 Å by 100 atmospheres pressure, while the H and K lines are only displaced through about half that amount. Duffield finds that the iron lines divide themselves into three groups with pressure shifts which are approximately in the ratio 1:2:4. Curiously enough this is also approximately the ratio of the displacements found by Humphreys in the trunk series, the side branch and main branch in the order named, in cases where these displacements have been measured. It was believed that band spectra did not show any pressure shift, until A. Dufour discovered that the lines into which the band spectra of the fluorides of the alkaline earths earths may be resolved widen towards the red under increased pressure.

Let us now consider the causes which may affect the homogeneity of radiation. We have first the Doppler effect, which, according to this view the shifts would be similar if the increase of density were produced by the presence of molecules of a different kind from those whose lines are being examined. Though there is no absolutely conclusive evidence, no experiments hitherto have given any indication that the nature of the gas producing the pressure has any effect on the amount of shift. G. F. Fitzgerald suggested as an alternative explanation the change of inductive capacity of the medium due to increased density. J. Larmor developed the same idea, and arrived by a very simple method at an approximation estimate of the shift to be expected.

If the medium contains the vibration is divided into a sphere equal to \(k\) times the molecular vibration outside of which the effects of these molecules may be averaged up, so that its inductive capacity may be considered uniform and equal to \(K\), the frequency of the vibration is increased in the ratio of the square root of \(1 - k^{2}\) to its fundamental. Here \(n\) represents an integer which is \(\frac{1}{2}\) if the vibration is a simple doublet, but may be a higher or lower rational fraction of an integer, \(K\) has a value equal to unity, the pressure shift is \(\frac{1}{2} k^{2} n^{2} + \frac{1}{2} (K - 1)\), and it is significant that for different values of \(n\), the shifts should be in geometric ratio as stated above, the ratio occurring in the amounts observed with different line ratios would be the same. The question is complicated by the fact that in the cases which have been observed, the greater portion of the metallic vapour vibrates with a potential of 1/2000, and the result of the absorption is divided by \(1 - k^{2}\) to a 1/2000, which is a potential of 1/2000. The question is complicated by the fact that in the case of the two that have been observed, the greater portion of the metallic vapour vibrates with a potential of 1/2000, and the result of the absorption is divided by \(1 - k^{2}\) to a 1/2000, which is a potential of 1/2000.

The question is complicated by the fact that in the case of the two that have been observed, the greater portion of the metallic vapour vibrates with a potential of 1/2000, and the result of the absorption is divided by \(1 - k^{2}\) to a 1/2000, which is a potential of 1/2000.

\[ n \text{ represents an integer which is } \frac{1}{2} \text{ if the vibration is a simple doublet, but may be a higher or lower rational fraction of an integer, } K \text{ has a value equal to unity, the pressure shift is } \frac{1}{2} k^{2} n^{2} + \frac{1}{2} (K - 1), \text{ and it is significant that for different values of } n, \text{ the shifts should be in geometric ratio as stated above, the ratio occurring in the amounts observed with different line ratios would be the same.} \]

It is a potential of 1/2000.

\[ \text{The question is complicated by the fact that in the case of the two that have been observed, the greater portion of the metallic vapour vibrates with a potential of 1/2000, and the result of the absorption is divided by } 1 - k^{2} \text{ to a 1/2000, which is a potential of 1/2000.} \]

\[ \text{The question is complicated by the fact that in the case of the two that have been observed, the greater portion of the metallic vapour vibrates with a potential of 1/2000, and the result of the absorption is divided by } 1 - k^{2} \text{ to a 1/2000, which is a potential of 1/2000.} \]
11. Molecular Velocities.—A. Schuster and G. A. Hemsleach have measured the velocity with which the luminous molecules are projected from metallic poles when a strong spark is passed through the air interval which separates the poles. The method adopted consisted in photographing the spectrum on a film which was kept in rapid motion by being attached to the front of a rotating disk. The velocities ranged from about 400 to 1900 metres, the metals of small atomic weight giving as a rule the higher velocities. In the case of some metals, notably bismuth, the velocity measured was different for different lines, which seems intelligible only on the supposition that the metal vapour consists of different vibrating systems which can differ with different velocities. C. C. Schaeck subsequently conducted similar experiments, using a rotating mirror, and though he put a different interpretation on the effects, the main conclusions of Schuster and Hemsleach were not affected. These have further been confirmed and extended by the experiments of J. T. Royds made with the same rotating disk, but with improved optical appliances. The photographs taken by Royds show the separate oscillations of each spark discharge even when the circuit only contained the unavoidable capacity of the leads. It was found that during the successive electrical oscillations the metallic vapour projected from the poles was observed first near and farther away from the poles, thus giving a measure of the gradual diffusion of the metal. The subject wants further investigation, especially with a view to deciding the connexion between the molecular rush and the discharge. While some of the phenomena seem to indicate that the projection of metallic vapours into the centre of the spark is a process of molecular diffusion independent of the mechanism of the discharge, the different velocities obtained with bismuth, and the probability that the vibrating systems are not electrically neutral, seem to indicate that the projected metallic particles are electrified and play some part in the discharge.

12. The Zeeman Effect.—The change of frequency of oscillation of radiating molecules placed in a magnetic field, which was discovered by P. Zeeman, and the observed polarization of the components, are all beautifully explained by the theory of H. A. Lorentz, and leave no manner of doubt that the radiating centres are negative electrons. The fact that in certain simple cases where a line when looked at equatorially splits into a triplet, the ratio of the charge to the mass is found by Lorentz’s theory to be equal to that observed in the carrier of the kathode ray, shows that in these cases the electron moves as an independent body and is not linked in its motion to other electrons. On the other hand, most of the lines show a more complicated structure in the magnetic field, suggesting a system of electrons rather than a single free corpuscle. The question has been fully discussed by C. Runge in the second volume of Kayser’s Handbuch (see also Magnet-Optics), and we may therefore content ourselves with the mention of the law discovered by Th. Preston that all the lines of the same series show identical effects when measured on the frequency scale, and the fact recently announced by Runge that even in the more complicated cases mentioned some simple relation between the distances of the components exists. If \( a \) is the distance shown by the normal triplets the type of separation observed in the line \( D_1 \) shows distances from the central line equal to \( 0/3, 2/3, 5/3 \), while the type of \( D_2 \) gives \( 2/3, 4/3 \). In all observed cases the distances are multiples of some number which itself is a sub-multiple of \( a \). The component lines of a band spectrum do not as a rule give the Zeeman effect, and this seems to be connected with their freedom from pressure shifts, for when Dufour had shown that the bands of the fluoride of calcium were sensitive to the magnetic field, R. Rossi could show that they were also sensitive to pressure.

13. Identification of Spectra. —The interpretation of spectroscopic observation seemed very simple when Kirchhoff and Bunsen first announced their discovery, for according to their view every combination of an element showed the characteristic spectrum of its constituent atoms; it did not matter according to this view whether a salt, e.g. sodium chloride, introduced into a flame, was dissociated or not, as in either case the spectrum observed would be that of sodium. It was soon found, however, that compounds possess their own characteristic spectra, and that an element may give under special conditions of luminosity several different spectra. When we now speak of the identification of spectra we like to include, wherever possible, the identification of the particular compound which is luminous and even though we have only begun to make any progress in that direction—the differentiation between the molecular or electronic states which yield the different spectra of the same element.

One preliminary question must first be disposed of. The fact that the gases with which we are most familiar are not rendered luminous by being heated in a tube at a temperature well above a white heat has often been a stumbling block and raised the not unreasonable doubt whether approximately homogeneous oscillations could ever be obtained by a mere thermal process. The experiment proves only the transparency of the gases, and this is confirmed by the fact that bodies like bromine and iodine give on heating an emission spectrum corresponding to the absorption spectrum seen at ordinary temperatures. The subject, however, required further experimental investigation, which was supplied by Paschen. Paschen proved that the emission spectra of water vapour as observed in an oxyhydrogen flame and of carbon dioxide as observed in a hydrocarbon flame may be obtained by heating aqueous vapour and carbon dioxide respectively to a few hundred degrees above the freezing point. The same author proved that a sufficient thickness of layer raised the radiation to that of a black body in agreement with Kirchhoff’s law. The spectra experimented on by Paschen were band spectra, but as these split up into fine lines the possibility of homogeneous radiation in pure thermal oscillation may be considered as established. Paschen’s observations originated in the desire to decide the question raised by E. Pringsheim, who, by a series of experiments of undoubted merit, tried to establish that the emission of the fine spectra of the alkali metals was invariably associated with a reduction of the metallic oxide. Pringsheim seems, however, to have modified his view in so far as he now seems to consider that the spectra in question may be obtained also in other ways, and to attach importance to the process of reduction only in so far as it forms an effective inciter of the particular spectra. In spite of the fact that C. Fredenhagen has recently attempted to revive Pringsheim’s original views in a modified form—substituting oxidation for reduction—we may consider it as generally admitted that the origin of spectra lies with vibrating systems which are definite and not dependent on the method of incitement. These systems may only be semi-stable, but they must last a sufficient length of time to give a train of waves having a length corresponding to the observed homogeneity of the line.

In many cases there is a considerable difficulty in deciding whether a particular spectrum belongs to a compound body or to one of the elements composing the compound. Thus one of the most common spectra is that seen at the base of every candle and in every Bunsen burner. Everybody agrees that carbon is necessary for its appearance, but some believe it to be due to a hydrocarbon, others to carbon monoxide, and others to volatile carbon. There is a vast amount of literature on the subject, but in spite of the difficulty of conceiving a luminous carbon vapour at the temperature of an ordinary carbon flame, the evidence seems to show that no other element is necessary for its production as it is found in the spectrum of pure carbon tetrachloride and certainly in cases where chlorine is excluded. Another much disputed spectrum is that giving the bands which appear in the electric arc; it is most frequently ascribed to cyanogen, but occasionally also to carbon vapour. Compounds generally show spectra of resolvable bands, and
SPECTROSCOPY

If an elementary body shows a spectrum of the same type we are probably justified in assuming it to be due to a compound molecule. But that it may be given by the ordinary diatomic molecule is exemplified by oxygen, which gives in thick layers by absorption one of the typical sets of bands which were used by Deslandres and others to investigate the laws of distribution of frequencies. These bands appear in the solar spectrum as we observe it, but are due to absorption by the oxygen contained in the atmosphere.

If oxygen is rendered luminous by the electric discharge, a series of spectra may be made to appear. Under different conditions with the same gas a continuous spectrum most intense in the yellow and green, (b) the spectrum dividing itself into two families of series, (c) a spectrum of lines which appears when a strong spark passes through oxygen at atmospheric pressure, (d) a spectrum of bands seen in the kathode glow. We have therefore five distinct spectra of oxygen apart from the absorption spectra of ozone. To explain this great variability of spectroscopic effects we may either adopt the view that molecular aggregates of semi-stable nature may be found in vacuum tubes, or that a molecule may gain or lose one or more additional electrons and thus form new vibrating systems. It seemed that an importunity of the first could not account for the effect. What is to be obtained through the discovery of J. Stark, who examined the lines of the so-called “canal-rays” (Canalstrahlen). These rays are apparently the trajectories of positively charged particles having masses of the order of magnitude of the gaseous molecules. Stark discovered that in the case of the series of the spectrum of hydrogen and of other similar spectra the lines were displaced indicating high velocities; in other cases no displacements could be observed. The conclusion seemed natural that the spectra which showed the Doppler effect were due to vibratory systems which had an excess of positive charge. More detailed examinations of the “canal-rays” by J. Y. Thompson and others have shown however that they contain both neutral and charged molecules in a relative proportion which adjusts itself continuously, so that even neutral molecules may partake of the translatory motion which they gained while carrying a charge. No conclusion can therefore be drawn, as Stark has more recently pointed out, respecting the charge of the molecule which emits the observed spectrum. Nevertheless, the subject is well worth further investigation.

Previous to Stark’s investigation P. Lenard had concluded that the carriers of a motion of the lines of the flame spectra of the alkali metals are positively charged. He draws a distinction between the lines of the trunk series to which he assigns neutral, and the lines of carriers the two branch series of which are electrically charged. The numerical relations existing between the trunk series and the branch series make it somewhat difficult to believe that they belong to different vibrating systems. But while we should undoubtedly hesitate on this ground to adopt Fredenhagen’s view that the two branch series belong to the element itself and the trunk series to a process of oxidation, we cannot press the argument against the view of Lenard, because the addition or subtraction of an electron introduces two vibrating systems which are still connected with each other and some numerical relationship is probable. Whatever ideas we may form on this point, the observations of Stark and Siegl have shown that there is a Doppler effect, and therefore a positive charge, for one of the lines of the trunk series of potassium, and E. Dorn has found the Doppler effect with a number of lines of helium, which contain representatives of the trunk series as well as of other branch series. These facts do not countenance the view that there is an essential electric difference between the vibrating system of the three members of a family of series.

It is probable, however, that the above observations may help to clear up some difficulties in the phenomena presented by flames. While we have seen that the radiation of sodium vapour has an intensity considerably in excess of the radiation at the temperature of the flame, other flames not containing oxygen (e.g. the flames of chlorine in hydrogen) do not apparently emit the usual sodium radiation when a sodium salt is placed in them. In the light of our present knowledge we should look for the different behaviour in the peculiarity of the oxygen flame to ionize the metallic vapour.

14. Fluorescence and Phosphorescence.—When a simple periodic force acts on a system capable of oscillatory motion the ultimate forced vibration has a period equal to that of the impressed force, but the ultimate state is reached theoretically after an infinite time, and if meanwhile the vibrating system suffers any perturbations its free periods will at once assert themselves. Application of the reasoning to the case of a homogeneous radiation traversing an absorbing medium, we realize that the mutual disturbances of the molecules by collision or otherwise must bring in the free period of the molecule whatever the incident radiation may be. It is just in this degradation of the original period that (according to the present writer) the main phenomenon of absorption consists. With most bodies the incident light is absorbed by the body itself, but there are cases in which these intermediate stages can be observed and the body seems then to be luminous under the influence of the incident radiation. Such bodies are said to be fluorescent, the degradation of motion towards that determined by its temperature gives rise to the law of Stokes, the fluorescent light being in nearly all cases of lower frequency than the incident light. With absorbing gases we should expect the degradation to proceed more slowly than with liquids, and hence the discovery of E. Wiedemann and Schmidt that the vapours of sodium and potassium are fluorescent, important as it was from an experimental point of view, came as no surprise. It is not possible here to enter into a detailed description of the phenomena of fluorescence (q.v.), though their importance from a spectroscopic point of view has been materially increased through the recent researches of Wood on the fluorescence of sodium vapour. After Wood and Moore had confirmed and extended the observations of Wiedemann and Schmidt and showed that the vibrating system of the fluorescent light seems identical with that observed by absorption in the fluted band spectrum, Wood excited the fluorescence by homogeneous and dissonant light, and discovered that the fluorescence bands in the fluorescent light of the elements in this case appear to shift rapidly when the period of the incident vibration is altered, though the change may be small. The author, no doubt correctly, remarks that the shift does not indicate a change of frequency but a change of relative intensity, consisting of a great number of fine lines; when the maximum intensity of the distribution of light is altered, the appearance is that of a shift. It would probably not be difficult to imagine a mechanical system having a number of free periods which when set into motion by a forced vibration shows a corresponding effect. If the forced vibration is suddenly stopped, the free periods will appear but not necessarily with the same intensity when the period of the original forced vibration is altered. There cannot, however, be a question that, as R. W. Wood remarks, the careful investigation of these phenomena is likely to give us an insight into the mechanism of radiation.

Phosphorescence (q.v.) can only be here alluded to in order to draw attention to the phenomena studied by Sir William Crookes and others in vacuum tubes. When kathode rays strike certain substances, they emit a phosphorescent light, the spectroscopic investigation of which shows interesting effects which are important especially as indicating the influence of slight admixtures of impurities on the luminescence. It should be mentioned that the infra-red rays have a remarkable damping effect on the phenomena of phosphorescence, a fact which has

---

been made use of by Becquerel in his investigations of infra-red radiation.

15. Relationship between the Spectrum of an Element and that of its Compounds.—In the present state of our knowledge we cannot trace any definite relationship between the spectrum of a compound body and that of its elements, and it does not even seem certain that such a relationship exists, but there is often a similarity between different compounds of the same element. The spectra, for instance, of the oxides and haloid salts of the alkaline earths show great resemblance to each other, the bands being similar and similarly placed. As the atomic weight of the haloid increases the spectrum is displaced towards the red.

It is in the case of the absorption spectra of liquids that we can most often discover some connexion between vibrations of a complex system and that of the simpler system which form the complex. The phenomenon of this respect is the effect of a solvent on the absorption spectrum of a solution. A. Kundt,1 who initiated this line of investigation, came to the conclusion that the absorption spectra of certain organic substances like cyanin and fuchsine were displaced towards the red by the solvent, and that the displacement was the greater the greater the dispersive power of the solvent. This law cannot be maintained in its generality, but nevertheless highly dispersive substances like carbon bisulphide are always found to produce a greater shift than liquids of smaller dispersion like water and alcohol. In these cases the solvent seems to act like an addition to the mass of the vibrating system, the quasi-elastic forces remaining the same.

Dr. J. H. Gladstone,2 at an early period of spectroscopy, examined the absorption spectra of the solution of salts, each constituent of which was coloured. He concluded that generally but not invariably the following law held good: "When an acid and a base combine, each of which has a different influence on the rays of light, a solution of the resulting salt will transmit only those rays which are not absorbed by either, or, in other words, which are transmitted by both." He mentioned as an important instance the case of the ferrocyanide, which, when dissolved in oxalic acid, transmits the rays in great abundance, though the same rays are absorbed both by ferrocyanides and by ferric salts. Soret has confirmed, for the ultra-violet rays, Dr. Gladstone's conclusions with regard to the identity of the absorption spectra of different chromates. The chromates of sodium, potassium and ammonium, as well as the bichromates of potassium and ammonium, were found to give the same absorption spectrum. Nor is the effect of these chromates confined to the blocking out simply of one end of the spectrum, as in the visible part, but two distinct absorption bands are seen, which seem unaltered in position if one of the above-mentioned chromates is replaced by another. Chromic acid itself showed the bands, but less distinctly, and Soret does not consider the purity of the acid sufficiently proved to allow him to draw any certain conclusions from this observation.

In many of these cases the observed facts might perhaps be explained by dissociation, the undisassociated compound producing no marked effect on the spectra. In 1872 W. N. Hartley and A. K. Huntington examined by photographic methods the absorption spectra of a great number of organic compounds. The normal alcohols were found to be transparent to the ultra-violet rays, the normal fatty acids less so. In both cases an increased number of carbon atoms increases the absorption at the most refrangible end. The fact that benzene and its derivatives are remarkable for their powerful absorption of the most refrangible rays, and for some characteristic absorption bands appearing on dilution, led Hartley to a more extended examination of some of the more complicated organic substances. He determined that definite absorption bands are only produced by substances in which three pairs of carbon atoms are doubly linked together, as in the benzene ring. Subsequently 3 he subjected the ultra-violet absorption of the alkalioids to a careful investigation, and arrived at the conclusion that the spectra are sufficiently characteristic to offer a ready and valuable means of ascertaining the purity of the alkalioids and particularly of establishing their identity.

We may now turn to an important investigation of Sir William Abney and Colonel E. R. Festing, who examined the infra-red absorption of a number of substances. We may quote one of the principal conclusions at which they arrived:—

"An inspection of our maps will show that the radical of a body is represented by certain well-marked bands, some differing in position according as it is bonded with hydrogen, or a halogen, or with an organic oxygen compound. There seem to be characteristic bands, however, of any one series of radicals, and bands at 700 and about 1100, which would indicate what may be called the central haloid group, to which other radicals may be bonded. The central haloid group by itself gives a band between 700 and 1000. Certain radicals have a distinctive absorption about 700 together with others about 900, and if the first be visible it almost follows that the distinctive mark of the radical with which it is connected will be found. Thus in the ethyl series we find an absorption at 740, and a characteristic band, one edge of which is at 892 and the other at 920. If we find a body containing the 740 absorption and a band with the most refrangible edge commencing at 892, or with the least refrangible edge terming at 920, we may be pretty sure that we have an ethyl radical present. So with any of the aromatic groups; the crucial line is at 867. If we find both bands connected we may feel certain about the presence of benzene. There is also a derivative of benzene present. The benzyl group shows this remarkably well, since we see that phenyl is present, as is also methyl. It will be advantageous if the spectra of ammonia, alcohols, amine and amides be examined, and it might be possible to secure more characteristic bands for these. remarkable coincidences will at once become apparent, as also the different weighting of the molecule. The spectrum of nitrobenzene is almost with comparing with benzene and nitric acid. In our own hands there lingers no doubt as to the easy detection of any which we have examined, . . . and it seems highly probable by this delicate mode of analysis that the hypothetical position of any of the radicals which may be identified in the organic chemistry. The detection of the presence of chlorine or bromine or iodine in a compound is at present undecided, and it may be well that we may have to look for its effects in narrower parts of the spectrum. This, however, is not at present is in ethyl bromide, in which the radical band about 900 is curtailed in one wing. The difference between anil and iodine and bromide is not sufficiently marked to be of any value. 4"
telescope. The prisms are necessarily compound, and usually composed of flint and compensating prisms of crown, in cases where compound prisms are used, the angles must be accurately calculated. Amici in 1860 devised such an instrument; an improved form by Janssen was made up of two flint and three crown prisms, and was used by Sir Fulke Greville, whom Speed calls the “procureur of my pipe estate,” and through his patron’s interest he also received a “wailer’s room in the custom-house.” The results of the leisure thus secured to him appeared in 1611 in his Theatrum of the Empire of Great Britaine, a series of fifty-four maps of different parts of England, which had already appeared separately, and in which he was helped by Christopher Saxton, John Norden and William White. To each map descriptive matter was attached. In 1617 also he published his History of Great Britaine under the Conquests of the Romans ... to ... King James. Speed acknowledges his obligations to the chief antiquaries and historians of his day. Sir Robert Cotton lent him manuscripts and coins, and is said to have revised the proofs for him; in heraldry he acknowledges the help of William Smith (1550?-1618); and he had valuable help from John Barkham (1572-1642) and Sir Henry Spelman. Speed brought some historical skill to bear on the arrangement of his work, and although he repeated many of the errors of older chroniclers he added valuable material for the history of his country. He died in London on the 28th of July 1659.

Other maps of his, beside those in the Theatre, are in the British Museum. Another edition of the Theatre is Theatrum Magnae Britanniae Latine, reddidum a P. Holland (London, folio, 1616). He wrote Genealogies Recorded in Sacred Scriptures (1611), and a similar work, A Cloud of Witnesses (1616). These passed through numerous editions, and were frequently prefixed to copies of the Bible. An account of Speed’s descendants is to be found in Rev. J. Daubeney’s History of Southampton (1883), which was founded on MS. material left by John Speed (1700-1788).

SPEETON BEDS, in English geology, a series of clays well exposed at Speeton, near Filey on the Yorkshire coast. Peculiar interest attaches to these beds for they are the principal representatives in Britain of the marine phase of the Lower Cretaceous system. The Speeton Clays pass downwards without break into the underlying Kimeridge clays; they are capped by the Red Chalk, which may be regarded as the equivalent of the Upper Gault of southern England. These beds thus form a passage series between marine Jurassic strata and those belonging to early Cretaceous time, and in this way they correspond with the Purbeck-Wealden rocks, which form a connecting link between estuarine Jurassic and Cretaceous strata.

Above the dark, bituminous, nodular shales with Kimeridge fossils at the base of the Speeton Clay comes the zone of Belenmites lateralis (34 ft.), with Olocostephanus gravesiformis, O. rotula, and species of Hoplites and Oxyntenoceras; this is followed by the zone of Belenmites juculum, with B. crista tus, Olocostephanus (Astieria) ostleri, O. (Simbirskites) inermus and O. (S.) Spoonenesis in ascending order; Echinopatagium cordiformis, a species found in the typical Neocomian area, also occurs in this zone. The next higher zone is that of Belenmites brunnivicus (= semi- canaliculatus) (100 ft.), with B. Spoonenesis, Hoplites deshayesi, and Amaltheus bicirratus. The topmost zone is characterized by Belenmites minimus with Inoceramus concentricus and I. sulcatus; it consists of a few feet of mottled clays. It appears, therefore, that while the lower portions of the Speeton Clay are the equivalents of the Wealden and perhaps of the Purbeck beds, the higher portions are the equivalents of the Lower Greensand and part of the Gault. In Lincolnshire the upper Speeton clays are represented by Caundle Clay, the Tealby Lime-stone and Clay, and the lower Speeton by the Chassey Ironstone, Spilsby Sandstone and lower part of the Tealby clay. A similar faunal horizon is recognized in Heligoland and Russia.

SPEKE, HUGH (1866–c. 1742), English writer and agitator, was a son of George Speke (d. 1850) of White Lackington, Somerset. The older Speke was a member of the Green Ribbon Club, the great Whig organization which was founded in 1675, and was a supporter of the duke of Monmouth, voting for the Exclusion Bill in 1681. Educated at St John’s College, Oxford, Hugh Speke joined the Green Ribbon Club, and in 1863 he was put in prison for asserting that Arthur Capell, earl of Essex, another of Monmouth’s supporters, had been murdered by the friends of the duke of York. He was tried and sentenced to pay a fine, but he refused to find the money, and remained in prison for three years, being in custody during Monmouth’s rebellion, in consequence of which his brother Charles was hanged. At the time of his arrest, Hugh was serving in the Sudan, and from this he issued the Address to all the English Protestants in the Present Army, a manifesto written by the Whig divine Samuel Johnson (1649–1703), urging the soldiers to mutiny. In 1867 he was released, and in 1868 he served James II. as a spy in the camp of William of Orange. In December of this year a document, apparently official, was found by a London bookseller. This called upon the Protestants to disarm their Roman Catholic neighbours; it was freely circulated, and much damage was done to property in London before it was found that it was a forgery. It appears to have been the work of Speke, although this was not known until he, when he asserted his authorship in his Memoirs of the Most Remarkable Passages and Transactions of the Revolution. He afterwards issued these memoirs with modifications as The Secret History of the Happy Revolution in 1688 (1715). After compelling both Anne and George I. to reward his past services, Speke died in obscurity before 1725.

SPEKE, JOHN HANNING (1827–1864), English explorer, discoverer of the source of the Nile, was born on the 4th of May 1827 at Jordans near Ilminster, Somersetshire. On his father’s side he descended from the ancient Yorkshire family of Espec, a branch of which migrated to Somerset in the 15th century. His mother was a Miss Georgina Hanning, of Dillington Park, Somerset. Through his mother’s influence with the duke of Wellington he obtained a commission in the Indian Army, which he entered in 1844. He served in Sir Colin Campbell’s division in the Punjab campaigns, and acquired considerable repute both as a soldier and as a sportsman and naturalist. When on furlough Captain Speke had explored portions of the Himalayas, had crossed the frontier into Tibet and mapped part of its south-western districts; but his attention was at an early date turned to the great problems of African geography, and in 1854 he began his brief and brilliant African career by joining Captain (afterwards Sir) Richard Burton in an expedition into the Nyanza region, and of Somailand, the incidents of which are narrated in What led to the Discovery of the Source of the Nile (London, 1864). In April 1854 the expedition was attacked by Somalis near Berbera, one officer being killed, Burton slightly, and Speke severely wounded. Invalided home, Speke shortly afterwards volunteered for the Crimea and served during the war with a regiment of Turks. In 1856 he accepted an invitation from Burton to join an expedition to verify the reports as to the existence of great lakes in east central Africa, and especially to try and find Lake Nyassa. The route to Nyassa was closed by the Arabs, and the travellers left Zanzibar in June 1857 by a northerly route, which brought them by November to a place called Kazè in Unyanamwezi. Here they learnt from an Arab trader that further inland were three great lakes—and Speke leapt to the conclusion that the most northerly of the three would prove to be the source of the Nile. Continuing westward in January 1858 the travellers reached Lake Tanganyika, of which they made a partial exploration, Speke marking on his map the mountains which close off the lake to the north, “Mountains of the Moon.” By June they were back at Kazè, and here Speke induced his chief, who was ill, to allow him to attempt to reach the northern lake. Marching north at Monambo, in a prison Speke kept a printing-press, and along which he travelled till, on the 3rd of August, he saw it open up into the waters of a lake extending northward to the horizon. He no longer doubted that this lake—the Victoria Nyassa—was the source of the Nile. Returning to Kazè (August 25) he made known his discovery to Burton, who did not believe Speke’s theories. The explorers reached Zanzibar early in 1859, Speke hastened back to England in advance of his comrade, and at once made public his discoveries and conclusions. Despite the scepticism of his fellow traveller and many geographers, he secured the support of Sir Roderick Murchison, president of the Royal Geographical Society, under whose direction a new expedition, expressly intended to solve the Nile problem, was fitted out. Of this expedition Speke had the command, his only European companion being Captain (afterwards Colonel) J. A. Grant (q.v.). The expedition, over 200 men all told, started from Zanzibar in 1860, and reached Kazè on the 24th of January 1861. Despite illness and the hostility and extortions of the natives the Victoria Nyassa was again reached, at its south-west corner, in October 1861. Following the western shores of the lake Speke crossed the Kagera on the 16th of January 1862, and arrived at the capital of Uganda on the 19th of February following. Here he was detained by the king, Mtesa, for some months, but at last prevailed on the chief to furnish him with guides, and on the 28th of July Speke stood at the spot where the Nile issued from the lake. The great discovery was made, the problem which had baffled all previous efforts—over 2000 years—was solved. The troubles of the travellers were, however, by no means at an end; with difficulty they obtained permission to enter Unyoro, and with difficulty were allowed to leave, without being permitted to visit another large lake (the Albert Nyassa) of whose existence and connexion with the Nile they learned. As far as possible Speke and Grant followed the course of the Nile, and on the 3rd of December came in touch with the outside world once more, striking in 3° 10' 37" N. an outpost established at the request of John Petherick, British consul at Khartoum, who had been charged with a mission for the relief of the explorers. On the 15th of February 1863 they arrived at the town of Mount Elgon in Ethiopia; the expedition was concluded, and Speke and Grant parted. The honor of discovering the source of the Nile were claimed by the combined efforts of the two explorers, but Speke was eminently the more deserving. But as Speke had not been able to follow the Nile all the way from the Victoria Nyassa to Gondokoro, as the part played in the Nile régime by the Albert Nyassa was then unknown, Burton and others remained unconvinced, and Speke’s conclusions were criticized in The Nile Basin (1864), a joint production of Burton and James McQueen; it being argued in this work that Tanganyika was the true Nile source. It was arranged that Speke should meet Burton at the meeting of the geographical section of the British Association at Bath on the 10th of September and publicly debate the question of the Nile source. On the previous afternoon Speke was out partridge shooting at Box, near Bath. In getting over a low stone wall he laid down his gun at half cock. Drawing the weapon towards him by the muzzle one barrel exploded and entered his chest, inflicting a wound from which Speke died in a few minutes. A granite obelisk to his memory was erected by public subscription in Kensington Gardens.

SPELLING BEE, a match in which two sides contest in accuracy of spelling. The custom, an old one, was revived in the schools of the United States about the year 1873, and rapidly spread throughout the country.
throughout the country and to Great Britain, enjoying for a few years an extraordinary vogue, not only in schools, but in all classes and ages of society. In the United States inter-city and inter-state matches were not unknown. The holy books of the generally recognized rules a competitor who misspelled a word retired, and the match was won by the side having the greatest number of survivors at the close. The use of the word "bee" as an assemblage of persons for the purpose of joint work or play originated in America in colonial times, and was taken from the labour of the bees of a hive. Familiar examples of it are "husking-bee" and "quilling-bee," assemblages of villagers for the purpose of helping a neighbour with the husking of the corn or his wife with her quilting-making.

SPELLO (anc. Hispellum, q.n.), a town of Umbria, in the province of Perugia, from which it is 22 m. S.E. by rail, 1030 ft. above sea-level. Pop. (1901), 5571. It is picturesquely set on the slope of a mountain. The Cappella Baglioni in the church of S. Maria Maggiore contains some of Pinturicchio's finest frescoes (1501), "The Annunciation," "The Adoration" and "Christ in the Temple." The rich background with gold decoration in relief is characteristic. There is also a late altarpiece by Perugino (1521) and a fine early Renaissance canopy by Rocco da Vicenza (1515). In the sacristy is a crucifix in silver by the sculptor Paolo Vanni. In S. Andrea there is a large altarpiece by Pinturicchio (1508), upon which a letter from G. Baglioni to the artist is painted. See G. Urbini, in L'Arte (1897), ii. 357 sqq., (1898), iii. 16 sqq.

SPELMAN, SIR HENRY (c. 1564-1641), English antiquary, was the eldest son of Henry Spelman, of Congham, Norfolk, and the grandson of Sir John Spelman (c. 1495-1544), judge of the king's bench. Born probably in 1564, he was educated at Walsingham School, and proceeded in 1580 to Trinity College, Cambridge, where he took his degree in 1583. His father had died in 1581, and on Spelman devolved the management of the family estates. He became a member of Lincoln's Inn, but in 1590 he returned to Norfolk, where he married Eleanor L'Estrange. He became a guardian to his brother-in-law, Sir Hamon L'Estrange, on whose property at Husstanton he resided for some time. He occupied himself with the history and antiquities of his native county, writing an account of Norfolk for John Speed's Theatre of Great Britain. He belonged to the Society of Antiquaries, of which Sir Robert Cotton and William Camden were also members. The society gradually declined, and Spelman's efforts to revive it in 1614 were frustrated by James I. Having bought in 1594 the remainder of the two leases of two abbeys of which the Crown was the lessor, he became involved in long litigation over them, and a judgment given against him by Bacon makes it interesting to find Spelman subsequently among the petitioners who alleged corruption against the lord chancellor. His experience in this process no doubt combined with a scandal connected with a church and parsonage in the possession of his uncle Francis Sanders to occasion his pamphlet De non tenerandis ecclesiis (1615-1617), which induced many lay owners of ecclesiastical spoil to make restitution, and Spelman himself acted accordingly. This tract led up to his History and Fate of Abbeys (1626), which was the work in which his son-in-law, the Great Fire broke out. The book was supposed to have perished, but Bishop Gibson discovered part of it in the Bodleian Library. It was printed, not, however, under his editorship, in 1698, with the statement on the title-page that it was "wrote in 1632." Spelman had conceived the idea of a work on the foundations of English law, based on early charters and records, but finding that there were no adequate means of determining the exact meaning of the Anglo-Saxon and Latin law terms employed in the documents, he began to compile a glossary, the first volume of which, Archæologus in modum glossarii, was published at his own expense in 1636. He continued to work at the subject until 1638. A second volume, Glossarium archeologicum (1636), appeared after his death. His Codex legum veterum statutorum

regni Angliae, quaæ ab ingressu Gulielmi I usque ad annum annum Henry III, edita sunt was published by David Wilkins in his Lexgææ anglo-saxonice (1721). Spelman's most important work, Concaelia, decretali legis constituuntur, or arbiz brisauucii, is an attempt to place English church history on a basis of genuine documents. The first volume, which occupied him seven years, came down to 1666 and was published in 1636. A second volume was edited by Sir William Dugdale in 1644. Spelman entered parliament as member for Castle Rising in 1597, and in 1604 was high sheriff of his county. In 1612 he settled in London near his friend Sir Robert Cotton. In 1617 he served on a commission to inquire into disputed Irish estates, and later took part in three legal inquiries into the matter of estates. He died on board ship during a voyage to the admiralty courts. He was member of parliament for Worcester in 1625. In 1627 he became treasurer of the Guiana Company, and he was also an energetic member of the council for New England. His general services to the state were recognized in 1636 by a gift of money, and two years later by the offer of the masterships of Sutton's Hospital, Charterhouse. He died in London in October 1641, and was buried in Westminster Abbey. His later years had been spent in the house of his son-in-law, Sir Ralph Whitfield.

SPELEN, Thomas (1818-1883), inventor of a system of land nationalization, was born at Newcastle-on-Tyne on the 21st of June 1750, the son of a Scottish netmaker and shoemaker. A dispute in connexion with common land rights at Newcastle impelled him to the study of the land question. His scheme was not for land nationalization proper, but for the establishment of self-contained parochial communities, in which rent paid to the corporation, in which the absolute ownership of the land was vested, should be the only tax of any kind. His pamphlet, The Meridian Sun of Liberty, which was first hawked in Newcastle, appeared in London in 1793; it was reissued by Mr. H. M. Liddon under the title of The Nationalization of the Land in 1777 and 1882. Spence presently left Newcastle for London, where he kept a bookstall in High Holborn. In 1784 he spent six months in Newgate goal for the publication of a pamphlet distasteful to the authorities, and in 1801 he was sentenced to twelve months' imprisonment for seditious libel in connexion with his pamphlet entitled The Restorer of Society to its Natural State. He died in London on the 8th of September 1814. His admirers formed a "Society of Speenian Philanthropists," of which some account is given in Harriet Martineau's England During the Thirty Years' Peace.

See also Davenport, John, Life, Writings and Principles of Thomas Spence (London, 1836).

SPENCER, HERBERT (1820-1903), English philosopher, was born at Derby on the 27th of April 1820. His father, William George Spencer, was a schoolmaster, and his parents' religious convictions familiarized him with the doctrines of the
Methodists and Quakers. He declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and so was practically self-taught. During 1837–1846 he was employed as an engineer on the London & Birmingham railway; 1849–1851 as auditor of the Economist. From about this time to 1860 he contributed a large number of articles to the Westminster Review, which contain the first sketches of his philosophic doctrines. He also published two larger works, Social Statics in 1850, and Principles of Psychology in 1855. In 1860 he sent out the syllabus of his Synthetic Philosophy in ten volumes, and in spite of frequent ill health had the satisfaction of completing it in 1866 with the third volume of the Principles of Sociology. He died on the 8th of December 1903.

Herbert Spencer's significance in the history of English thought depends on his position as philosopher of the great scientific movement of the second half of the 19th century, and on the friendship and admiration with which he was regarded by men like Darwin, G. H. Lewes and Huxley. Spencer tries to express in a sweeping general formula the belief in progress which pervaded his age, and to erect it into the supreme law of the universe as a whole. His labours coincided in time with the great development of biology under the stimulus of the Darwinian theory, and the sympathizers with the new views, feeling the need of a comprehensive survey of the world as a whole, very widely accepted Spencer's philosophy at its own evaluation, both in England and, still more, in America. In spite of this, however, his heroic attempt at a synthesis of all scientific knowledge could not but fall short of its aim. Living at the commencement of an epoch of unparalleled scientific activity, Spencer could not possibly sum up and estimate its total production. To the specialists in sciences which were advancing rapidly and in divergent directions to results which often reacted on and transformed their initial assumptions, Spencer has often appeared too much of a philosopher and defective in specialist knowledge. To the technical philosophers, who strictly confine themselves to the logical side of the science, it is a misfortune that the master mind should not have been available to them. But his notions of what "evolution" is developed quite gradually. At first he seems to have meant by the word only the belief that progress is real, and that the existing order of nature is the result of a gradual process and not of a "special creation." In Social Statics (1850) he still regards the process teleologically, and argues after the fashion of Paley that "the greatest happiness is the purpose of creation" (ch. iii. § 1), and that to "gag the moral sentiment" is "to balk creative design" (ch. xxxii. § 7). But this phraseology soon disappears, without his considering how, in default of some sort of teleology in his estimate of the world's history as a process. In The Development Hypothesis (1852) he objects strongly to the incredibility of the special creation of the myriad forms of life, without, however, suggesting how development has been effected. In Progress, its Law and Cause (1857) he adopted Von Baer's law, that the development of the individual proceeds from the homogeneous to the heterogeneous. This is at once connected with the nebular hypothesis, and subsequently related to the "deduced" from the ultimate law of the "persistence of force," and finally supplemented by a counter-process of dissolution, all of which appears to Spencer only as "the addition of Von Baer's law to a number of ideas that were in harmony with it."

It is clear, however, that Spencer's ideas as to the nature of evolution were already partly definite when Darwin's Origin of Species (1859) revolutionized the subject of organic evolution by adding natural selection to the direct adaptation by use and disuse, and so suggesting an intelligible method of producing modifications in the forms of life. Spencer welcomed the Darwinian theory, and enriched it with the phrase "survival of the fittest"; but he did not give up the (Lamarckian) belief in the hereditary transmission of the modifications of organisms by the exercise of function. Shortly afterwards (1860) he sent out the prospectus of a systematic exposition of his Synthetic Philosophy, of which the first volume, First Principles, appeared in 1862. This work is divided into two parts; the first intended to show that while ultimate metaphysical questions are insoluble they compel to a recognition of an inscrutable Power behind phenomena which is called the Unknowable; the second devoted to the formulation and illustration of the Law of Evolution. In the first part Spencer's argument rests on Malthus's Law of Population and Hamilton's "philosophy of the conditioned" (and so ultimately on Kant), and tries to show that alike in scientific and religious thought the ultimate terms are "inconceivable" (not by him distinguished from "unimaginable"). In science, the more we know the more extensive "the contact with surrounding nescience." In religion the really vital and constant element is the sense of mystery. This is illustrated by the difficulties inherent in the conception of Cause, Space, Time, Matter, Motion, the Infinite, and the Absolute, and by the "relativity of knowledge," which precludes knowledge of the Unknowable, since "all thinking is relational.

Yet the Unknowable may exist, and we may even have an "indefinite knowledge" of it, positive, though vague and extralogical. Hence both science and religion must come to recognize as the "most certain of all facts that the Power which the Universe manifests to us is utterly inscrutable." Thus to be buried side by side in the Unknowable constitutes their final reconciliation, as it is the refutation of irreligion which consists of "a lurking doubt whether the Incomprehensible is really incomprehensible."

These are the practical foundations of Spencer's metaphysic of the Unknowable, to which he resorts in all the fundamental difficulties which he subsequently encounters. Whatever its affinities with that version of "faith" which regards it as antagonistic to knowledge, it can hardly be deemed philosophically satisfactory. A failure to solve the problems of metaphysics must always remain a failure, in spite of all protestations that it was inevitable; and it in no wise justifies an advance to so self-contradictory an asylum ignorantiae as the Unknowable. In the edition of his First Principles, published in 1900, Spencer adds a "postscript" which shows some consciousness of the unprofitableness of all discussion of the Unknowable, and finally contends that his account of the knowable in part ii. will stand even if part i. be rejected. Even this, however, understates the case, seeing that a really inscrutable Unknowable would destroy all confidence in the order of nature and render all knowledge entirely precarious.

In part ii. Spencer recognizes successively likenesses and unlikelinesses among phenomena (the effects of the Unknowable, which are segregated into manifestations, vivid (object, non-ego) or faint (subject, ego), and then into space and time, matter and motion and force, of which the last is symbolized for us by the expenditure of resistance, and is that out of which our ideas of matter and motion are built. Hence the Persistence of Force is the ultimate basis of knowledge. From it Spencer proceeds to deduce the indestructibility of matter and energy, the equivalence and transformation of forces, the necessity of a rhythm, of Evolution (i.e. integration of matter with concomitant dissipation of motion) and Dissolution, and finally reaches the statement of the Law of Evolution as "an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation." This process of evolution is due to the "instability of the homogeneous" and the "multiplication of effects" and their "segregation," continuing until it ceases in complete "equilibration."

Sooner
SPENCER, HERBERT

or later, however, the reverse process of Dissolution, with its absorption of motion and disintegration of matter, which indeed has always been going on to some extent, must prevail, and these oscillations of the cosmic process will continue without end.

It appears, therefore, that Spencer ultimately describes the Knowable in terms of the mechanical conceptions of matter and motion, and that this must give a materialistic colouring to his philosophy. There are, however, other flaws also in his procedure. The presence of Force, i.e. his version of the methodological assumption of constancy in the quantitative aspects of phenomena, seems a very unsuitable basis for a philosophy of progress. To such a philosophy a consideration of the conditions, if any, under which progress can be conceived as ultimately real, seems a necessary preliminary, which Spencer omits. He also assumes that "Evolution" is a real, nay, an ultimate law of nature, but his evidence only goes to show that it is a result, in some cases, of the complex interaction of laws, which, like Rhythm, Segregation, &c., are in their turn only tendencies, and may be, and often are, counteracted. By the afterthought of a "dissolution" process (2nd ed. of First Principles) Spencer in a way admits this, but introduces fresh difficulties as to its relation to "Evolution." If the two processes go on together both are tendencies, and whether there is on the whole progress or not will depend on their relative strength; neither can be universal, nor the "law" of cosmic existence unless its coexisting rival is regarded as essentially secondary. But if so it ceases to be available as evidence of a coming reversal of the dominant process. If, on the other hand, the processes are strictly alternative, a world which ex hypothesi exemplifies the one can never justify us in inferring the other. Spencer appeals alternately to the "instability of the homogeneous" and the impossibility of complete equilibration to keep up the cosmic see-saw, but he can do so only by confessing himself to a part of the universe. A world wholly homogeneous or equilibrated could no longer change, while so long as a part only is in process, the process cannot be represented as universal. Again, an infinite world cannot be wholly engaged either in evolution or in dissolution, so that it is really unmeaning to discuss the universality of the cosmic process until it is settled that we have a universe at all, capable of being considered as a whole. In the last resort, therefore, Spencer fails to deduce philosophically not only the necessity of progress, but also its compatibility with the evolution-dissolution oscillation, and even the general possibility of conceiving the world as a process. In other words, in spite of his intentions he does not succeed in giving a metaphysic of evolutionism.

In the Principles of Biology the most notable points are the doctrine of life, as the continuous adjustment of internal to external relations, and the consequent emphasis on the need of adapting the organism to its environment. This exaggerates the passivity of life, and does not sufficiently recognize that the higher organisms largely adjust external to internal relations and adapt their environment to their needs. His universal process of Evolution seems to give Spencer a criterion of "higher" and "lower" "progression" and "degeneration," independent of the accidents of actual history, and unattainable by strictly Darwinian methods. The higher (at least in times of "evolution") is the more complex and differentiated, whether it invariably survives or not. On the other hand, he advances too easily from the maxim that function is prior to, and makes, structure to the conclusion that the results of use and disuse are therefore immediately incarnated in structural adaptations capable of hereditary transmission. This inference has involved him in much controversy with the ultra-Darwinians of Weismann's school, who deny the possibility of the inheritance of acquired characteristics altogether. And though Spencer's general position—that it is absurd to suppose that organisms after being modified by their life should give birth to offspring showing a reverse process of modification—is more philosophic, yet it does not dispose of the facts which go to show that most of the evidence for the direct transmission of adaptations is illusory, and that beings are organised to minimize the effects of life on the reproductive tissues, so that the transmission of the effects of use and disuse, if it occurs, must be both difficult and rare—far more so than is convenient for Spencer's psychology.

In his Principles of Psychology Spencer advocates the genetic explanation of the phenomena of the adult human mind by reference to its infant and animal ancestry. On the fundamental question, however, of the psychophysical connection and the derivation of mind from matter, his utterances are neither clear nor consistent. On the one hand, his whole formulation of Evolution in mechanical terms urges him in the direction of materialism, and he attempts to compose the mind out of homogeneous units of consciousness (or "feeling") "similar in nature to those which we know as nervous shocks; each of which is the correlative of a rhythmical motion of a material unit or group of such units" (§ 62). On the other hand, when pressed by his disciple, Fiske (Outlines of Cosmic Philosophy ii. p. 444), he is ready to amend "nervous into psychical shocks," which is no doubt what he ought to have meant but could not say without ruining the illusory bridge between the psychical and the physiological which is suggested in the phrase "nervous shock." And he admits (§ 63) that if we were compelled to choose between translating mental phenomena into physical and its converse, the latter would be preferable, seeing that the ideas of matter and motion, merely symbolic of unknowable realities, are complex states of consciousness built out of units of feeling. But easiest of all is it to leave the relation of the unknowable to the mental and substitute for the unknowable "substance of Matter" (substance he thought of as the unknowable substrate of phenomena) to the Unknowable, as he finally does. To the theory of knowledge Spencer contributes a "transfigured realism," to mediate between realism and idealism, and the doctrine that "necessary truths," acquired in experience and congenitally transmitted, are a priori to the individual, though a posteriori to the race, to mediate between empiricism and apriorism. It has already been explained, however, that the biological foundations of the latter doctrine are questionable.

In the Principles of Sociology Spencer's most influential ideas have been that of the social organism, of the origination of religion out of the worship of ancestral ghosts, of the natural antagonism between nutrition and reproduction, industrialism and warfare. Politically, Spencer is an individualist of an extreme laissez faire type, and it is in his political attitude that the consequences of his pre-Darwinian conception of Evolution are most manifest. But for this he would hardly have established so absolute an antithesis between industrial and military competition, and have shown himself ready to recognize that the law of the struggle for existence, just because it is universal and equally (though differently) operative in every form of society, cannot be appealed to for guidance in deciding between the respective merits of an industrial or military and of an individualist or socialist organization of society.

In the Principles of Ethics Spencer, though relying mainly on the objective order of nature and the intrinsic consequences of actions for the guidance of conduct, conceives the ethical end in a manner intermediate between the hedonist and the evolutionist. The transition from the evolutionist criterion of survival—which in itself it is difficult to regard as anything but natural—to the criterion of happiness is effected by means of the psychological argument that pleasure promotes function and that living beings must, upon pain of extinction, sooner or later take pleasure in actions which are conducive to their survival. Hence pleasure is, on the whole, good, and asceticism reprehensible, although in man's case there has arisen (owing to the rapidity of evolution) a certain derangement and divergence between the pleasant and the salutary (§ 39). Nevertheless pleasure forms an "inexpeugable element " of the moral aim (§ 16). Conduct being the adjustment of acts to ends, and good conduct that which is conducive to the preservation of a pleasurable life in a society so adjusted that each attains his happiness without impeding that of others, life can be
SPENCER, 3rd EARL (1872–1845), English statesman, better known by the courtesy title of Lord Althorp, which he bore during his father’s lifetime, was the son of George John, 2nd Earl (1758–1834), grandson of John (1734–1873), created 1st Earl Spencer in 1765, and great-grandson of Charles Spencer, 3rd Earl of Sunderland. His father served in the ministries of Pitt, Fox and Grenville, and was first lord of the admiralty from 1794–1801; and from 1816 to 1819, when he was visiting the new Althorp library, inherited from the 3rd Earl of Sunderland, which he developed into the finest private library in Europe; his wife, the eldest daughter of the 1st Earl Lucan, was conspicuous in London society for her gaiety and brightness. Their eldest son, John Charles, was born at Spencer House, London, on the 30th of May 1782. In 1800 he took up his residence at Trinity College, Cambridge, and for some time applied himself energetically to mathematical studies; but he spent most of his time in hunting and racing. Almost immediately after taking his degree in 1802, he set out on a continental tour, which was cut short, after he had passed into the ranks in the chief cities in Italy, by the renewal of war. Through the influence of Pitt’s government he was returned to parliament for the borough of Okehampton in Devonshire in April 1804, and, although he vacated his seat in February 1806, to contest the university of Cambridge against Lord Henry Petty and Lord Palmerston (when he was hopelessly beaten), he was elected in the same month for St Albans, and appointed a lord of the treasury. At the general election in November 1806, he was elected for Northamptonshire, and he continued to sit for the constituency until he succeeded by the purchase of a seat in the Commons, with which the duke of York’s conduct at the Horse Guards led him to move a resolution of the House of Commons in 1809 for the duke’s removal from his post. For the next few years after this speech Lord Althorp occasionally spoke in debate and always on the side of Liberalism, but from 1813 to 1818 he was only rarely in the House of Commons. His absence was partly due to a feeling that it was hopeless to struggle against the will of the Tory ministry, but more particularly to his marriage on the 14th of April 1814, to Esther, only daughter of Richard Acklow of Woburn Abbey, Northamptonshire, who died in childbirth in 1815. In 1819, on his return to political life after her death, and for many years after that date he pressed upon the attention of the house the necessity of establishing a more efficient bankruptcy court, and of expediting the recovery of small debts; and he saw both these reforms accomplished before 1825. During the greater part of the reign of George IV. the Whigs lost their legitimate influence in the state from their want of cohesion, but this defect was soon remedied in 1830 when Lord Althorp was chosen their leader in the lower house, and his capacity for the post was proved by his persistence. When Lord Grey’s resignation was offered at the close of the year the chancellorship of the exchequer combined with the leadership of the House of Commons was entrusted to Lord Althorp, and to him more than to any other man, with the exception of the prime minister and the lord chancellor, may be attributed the success of the government measures. The budget, it is true, was a failure, but this misfortune was soon forgotten in the struggles over the Reform Bill. The consideration of the preliminaries of this measure was assigned to four ministers, two in the cabinet and two outside that body; but their proposed work, after careful examination, approved or rejected by Lord Grey and Lord Althorp before they were brought under the notice of the cabinet. When the Bill was ready for introduction to the House of Commons its principles were expounded by Lord John Russell; but from the commencement of the protracted discussion over its details he had the assistance of Lord Althorp, and after some
SPENCER, 5th EARL—SPENCER

weeks of incessant toil, which the physique of Lord John Russell could not sustain any longer, the whole responsibility was cast on Lord Althorp. To combat the objections of three such pertinacious opponents as Croker, Sugden and Wetherell required both skill and courage, and in Lord Althorp these qualities were found. On one evening he made as many as twenty speeches. The Reform Bill was carried at last, and popular interest was right in assigning to the leader of the house a credit only second to that earned by Lord John Russell. After the dissolution of 1833 the Whigs returned to power with augmented numbers; but differences soon showed themselves among both leaders and followers, and their majority crumbled away. Their position was strengthened for a time by triumphantly carrying a new poor law bill; and even their keenest critics would not allow that, had the Whig propositions on tithes and church rates been carried into effect, many years of passionate controversy would have been spared. The ministry of Lord Grey was shattered to pieces by difficulties over an Irish coercion bill. Although Lord Melbourne became premier (July 14, 1834), the fortunes of the ministry rested on Lord Althorp’s presence in the House of Commons.

The death of the 2nd Earl Spencer in November 1834, called his son to the upper house, and William IV. took advantage of this event to summon a Tory cabinet to his side. The new Lord Spencer abandoned the cares of office and returned to country life with unabated delight. Henceforth agriculture, not politics, was his principal interest. He was the first president of the Royal Agricultural Society (founded 1838), and a notable cattle-breeder. Often as he was urged by his political friends to come to their assistance, he rarely quitted the peaceful pleasures which he loved. He died at Wiseton on the 1st of October 1845, being succeeded as 4th Earl, in default of issue, by his brother Frederick (d. 1857). He had held, as a statesman, a remarkable position. The Whigs required, to carry the Reform Bill, a leader of unalloyed character, one to whom party spirit could not attach the suspicion of greed of office, and against Lord Althorp malevolence was powerless. No stronger proof of his pre-eminence could be given than the oft-quoted saying of Lord Hardinge that one of Croker’s ablest speeches was demolished by the simple statement of Lord Althorp that he had collected some figures which entirely refuted it, but had lost them. The trust which the house put in him then was never wanting.

SPENCER, JOHN POYNTEZ SPENCER, 5th EARL (1835–1910), English statesman, was the son of the 4th Earl and his first wife, a daughter of William Stephen Poynze, of Cowdray Park, Sussex. Born on the 27th of October 1835, and educated at Harrow and Trinity College, Cambridge, he was a member of parliament for a few months before he succeeded to the earldom in December 1857. His long career as a Liberal politician dates from his acceptance of the office of lord-lieutenant of Ireland under Gladstone in 1868, a post which he retained until 1874. When the Liberals returned to power in 1880 he was appointed lord president of the council, but in 1882 he entered upon a second term of office as lord-lieutenant of Ireland. The three years during which Earl Spencer now filled this position was a period of exceptional disorder in Ireland, marked by a long series of outrages and conspiracies associated with the "Invincibles," but the courage and firmness by which he then displayed won the admiration of all, and made his adoption of the policy of Home Rule in 1885 an event of considerable interest. In the short Liberal administration of 1886 he was lord-president of the council, and from 1892 to 1895 he was a very capable first lord of the admiralty; it is on record that Gladstone, on retiring in 1894, would have recommended the Queen, if she had consulted him, to summon Lord Spencer to the premiership. From 1902 to 1905 he was the Liberal leader in the House of Lords, and early in 1905, when a change of government was suggested, he brought some quarters that he would be the most suitable Liberal prime minister. But his health broke down just at this time, and he took no further part in political life, although he survived until the 13th of August 1910, when he died at Althorp. For forty-five years the earl was a Knight of the Garter; he was lord-lieutenant of Northamptonshire for upwards of thirty years, and he had a reputation as a keen and daring rider to hounds. The fine library, collected at Althorp by the 2nd earl, was sold by him for £250,000 to Mrs Rylands, the widow of a Manchester merchant, and was by her presented to the city of Manchester. Earl Spencer had two sons and three daughters, and is survived by his half-brother, Charles Robert Spencer (b. 1857), who became the 6th earl. As the Hon. Charles R. Spencer he was one of the parliamentary representatives for Northamptonshire from 1880 to 1895 and again from 1900 to 1905, and was vice-chamberlain of the royal household from 1892 to 1895. In 1905 he was appointed lord chamberlain, and in the same year he was raised to the peerage as Viscount Althorp.

SPENCER, WILLIAM ROBERT (1769–1834), English poet and wit, was the son of Lord Charles Spencer, second son of Charles Spencer, 3rd duke of Marlborough and 5th earl of Sunderland. He was educated at Harrow and Christ Church, Oxford, but left the university without taking a degree. Spencer’s wit made him a popular member of society, but he took no part in public life although he numbered among his friends leading statesmen like Pitt, Fox and Sheridan. He was an accomplished writer of “occasional” verse, which was warmly praised by Scott, by Christopher North and by Byron, who placed him in the same rank as Moore, Rogers and Campbell. In 1796 he published an English version of Bürger’s Leonore, and in 1802 he burlesqued German romance in his Urseline, which was produced on the stage at Drury Lane. Among his best-known pieces, which were published in a collection of his poems in 1811, were “Beth Gelter” and “Too Late I Stayed.” He died in poverty in Paris in 1834. In 1791 he married Susan, daughter of Count Jenison-Walworth, chamberlain to the elector palatine, by whom he had five sons and two daughters. One son, Aubrey George Spencer (1795–1872), became first bishop of Newfoundland in 1839, being afterwards translated to the See of Jamaica. Another son, George Trevor Spencer (1797–1860), was in 1857 consecrated second bishop of Madras. He published several books relating to missionary work in India; on his return to England in 1849 he was appointed assistant to the bishop of Bath and Wells, and in 1860 became chancellor of St Paul’s Cathedral. He married, in 1823, Harriet, daughter of Sir Benjamin Hobhouse and sister of Lord Broughton.

SPENCER, a township of Worcester county, Massachusetts, U.S.A., about 11 m. W. of Worcester. Pop. (1890), 8747; (1900, 7677, of whom children were foreign-born; (1910, U.S. census), 6740. Area, about 34½ sq. m. The township is served by the Boston & Albany railway and by inter-urban electric lines. The Richard Sugden Public Library, founded in 1880, had 12,000 volumes in 1908. Bemis Memorial Park and the Samuel Bemis Monument were dedicated in 1901 in honour of the first settler of Spencer. There are three other public parks. Among the township’s manufactures are boots and shoes, woolens, muslin underwear, wire, and wooden and paper boxes. Spencer was a part of the Leicester grant; was included in the "West Parish" in 1744, and was the "West Parish of Leicester" in 1744–1753; and in 1753 was incorporated as a township, under its present name. In one house in Spencer were born Elias Howe, jun., the inventor of the sewing-machine, and his uncle, William Howe, inventor of the "Howe truss" bridge (see BRIDGES), and Tyler Howe (1800–1880), inventor (in 1835) of the spring bed; in 1900 a memorial was dedicated to these three inventors.

SPENER, PHILIPP JAKOB (1635–1709), German theologian, was born on the 13th of January 1635, at Rappoltsweiler in Upper Alasce. After a brief stay in the grammar school of Comlart he went to Strassburg in 1651, where he devoted himself
to the study of philology, history and philosophy, and won his degree of master (1653) by a disputation against the philosophy of Hobbes. He then became private tutor to the princes Christian and Charles of the Palatinate, and lectured in the university on philology and history. From 1659 to 1662 he visited the universities of Basel, Tübingen and Geneva, and commenced the study of heraldry, which he pursued throughout his life. In Geneva especially his religious views and tendencies were turned in the direction of mysticism. He returned to Strassburg in 1663, where he was appointed preacher without previous training with the right of holding lectures. Three years afterwards he was invited to become the chief pastor in the Lutheran Church at Frankfort-on-Main. Here he published his two chief works, *Pia desideria* (1675) and *Allgemeine Gottesgelehrtheit* (1680), and began that form of pastoral work which resulted in the movement called Pietism. In 1686 he accepted the invitation to the first court chaplaincy at Dresden. But the elector John George III., at whose personal desire the post had been offered to him, was soon offended at the fearless consciencesiveness with which his chaplain sought to discharge his pastoral duties. He refused to resign his post, and the Saxon government hesitated to dismiss him. But in 1691 the Saxon representative at Berlin induced the court of Brandenburg to offer him the rectorship of St Nicholas in Berlin with the title of "Konsistorialrat." In Berlin Spener was held in high honour, though the tendencies of the court and the government officials were rather rationalistic than pietistic. The university of Halle was founded under his influence in 1694. All his life long Spener had been exposed to the attacks and abuse of the orthodox Lutheran theologians; with his years his opponents multiplied, and the movement which he had inaugurated presented increasingly more matter for controversy. In 1696 the theological faculty of Wittenberg formally laid to his charge 264 errors, and only his death on the 5th of February, 1705, released him from these fierce conflicts. His last important work was *Theologische Bedenken* (4 vols., 1700-1702), to which was added after his death *Letzte theologische Bedenken*, with a biography of Spener by C. H. von Canstein (1711).

Though Spener has been justly called "the father of Pietism," hardly any of the errors and none of the extravagances of the movement can be ascribed to him personally. So far was he from sharing them that Sp. Ritschel (Geschichte der Pietismus, ii. 169) maintains that "he was himself not a Pietist," as he did not advocate the quietistic, legalistic and semi-separatist practices of Pietism, though they were more or less involved in the positions he assumed or in the doctrine he advocated. The only two points on which he departed from the orthodox Lutheran faith of his day were the requirement of regeneration as the sine qua non of salvation and the antagonism to the Grotian version of the Jews and the fall of Papacy as the prelude of the triumph of the church. He did not, like the later Pietists, insist on the necessity of a conscious crisis of conversion, nor did he encourage a complete breach between the Christian and the secular life.

Spener was a voluminous writer. The list of his published works comprises 7 vols. folio, 63 quarto, 7 octavo, 41 duodecimo; a new edition of his chief writings was published by P. Grünberg in 1889. See W. Hossbach, *Philipp Jakob Spener und seine Zeit* (1828, 3rd ed., 1861); A. Ritschel, Geschichte der Pietismus, ii. (1884); E. Nitschke, *Ursprung und Wesen des Pietismus* (1884); P. Grünberg, *F. J. Spener* (3 vols., 1893-1906).

**SPENNYMOOR, a market town in the Bishop Auckland parliamentary division of Durham, England, 6 m. S. of the city of Durham, on a branch of the North Eastern railway, Pop. of urban district, which includes several neighbouring parishes (1901), 16,665. It is in the midst of a populous coal-mining district, and its growth is modern.**

**SPENS, THOMAS DE (c. 1415-1480), Scottish statesman and prelate, received his education at Edinburgh, and by his exceptional abilities attracted the notice of the advisers of the Scottish king, James II., who sent him on errands to England and to France. About 1450 he became bishop of Galloway; soon afterwards he was made keeper of the privy seal, and in 1459 he was chosen bishop of Aberdeen. Much of his time, however, was passed in journeys to France and to England, and in 1464 he and Alexander Stewart, duke of Albany, a son of James II., were captured at sea by some English sailors. Edward IV., to whom the bishop had previously revealed an assassination plot, set him at liberty, and he was partly responsible for the treaty of peace made about this time between the English king and James III. He also helped to bring about the meeting between Edward IV. and Louis XI. of France at Picquigny, and another treaty of peace between England and Scotland in 1474. Spens was a frequent attendant at the Scottish parliaments, and contributed very generously to the decoration of his cathedral at Aberdeen. He died in Edinburgh on the 14th of April 1480.**

**SPENDER, EDMUND (c. 1552-1590), English poet, author of the Faery Queen, was born in London about the year 1552. The received date of his birth rests on a passage in sonnet lx. of the Amoretti. He speaks there of having lived forty-one years; the Amoretti was published in 1595, and described on the title-page as "written not long since"; which would make the year of his birth 1552 or 1553. We know from the Prethalamien that London was his birthplace. This at least seems the most natural interpretation of the words—**

"Merry London, my most kindly nurse, That to me gave this life's first native source."

In the same poem he speaks of himself as taking his name from the house of his ancient family. Several of his pieces are addressed to the daughters of Sir John Spenser head of the Althorp family; and in *Colin Clout's Come Home Again* describes three of the ladies as—

"The honour of the noble family Of which I meanest boast myself to be."

Mr R. B. Knowles, however, is of the opinion (see the *Spending of the Money of Robert Nowell*, privately printed, 1877) that the poet's kinsmen must be sought among the humbler Spencers of north-east Lancashire. Robert Nowell, a London citizen, left a sum of money to be distributed in various charities, and in the account-books of his executors among the names of other beneficiaries has been discovered that of "Edmund Spensore, scholar of the Merchant Taylor School, at his going to Pembroke Hall in Cambridge." The date of this benefaction is the 28th of April 1590. As the poet is known to have been a sizar of Pembroke, the identification is beyond dispute. Till this discovery it was not known where Spenser received his school education. The speculations as to the poet's parentage, started by the Nowell MS., are naturally more uncertain. Mr Knowles found three Spensers in the books of the Merchant Taylors, and concluded that the poorest of them, John Spenser, a "free journeyman" in the "art or mystery of clothmaking," might have been the poet's father, but he afterwards abandoned this theory. Dr Grosart, however, adhered to it, and it is now pretty generally accepted. The connexion of Spenser with Lancashire is also supported by the Nowell MS.—several Spensers of that county appear among the "poor kinsfolk" who profited by Nowell's bounty. The name of the poet's mother was Elizabeth, and he notes as a happy coincidence that it was borne by the three women of most consequence to him—wife, queen and mother (Amoretti, lxvii.).

It is natural that a poet so steeped in poetry as Spenser should show his faculty at a very early age; and there is strong reason to believe that verses from his pen were published just as he left school at the age of sixteen or seventeen. Certain pieces, translations from Du Bellay and Petrarch, afterwards included in a volume of poems by Spenser published in 1591, are found in a miscellany, *Theatre for Welldings*, issued by a Flemish Protestant refugee, John van der Noodt, on the 25th of May 1566. The translations from Du Bellay appear in blank verse in the miscellany, and are rhymed in sonnet form in the later publication, but the distinction is substantially the same; the translations from Petrarch are republished with slight variations. Poets were so careless of their rights in those days and publishers took such liberties that we cannot draw for certain the conclusion that would be inevitable if the facts were of more
modern date; but the probabilities are that these passages in
Van der Noodt’s *Theatre*, although the editor makes no
acknowledgment, were contributed by the schoolboy Spenser. 1
As the exercises of a schoolboy writing before our poetic
diction was enriched by the great Elizabethans, they are remarkable
for a sustained command of expression which many schoolboys
might exhibit in translation now, but which was a rarer and more
significant accomplishment when Surrey and Sackville were
the highest models in post-Chaucerian English.

Little is known of Spenser’s Cambridge career, except that
he was a sizar of Pembroke Hall, took his bachelor’s degree in
1572, his master’s in 1576, and left Cambridge without having
obtained a degree. Dr. Grosart has pointed out that, to those
familiar with the fact that his health was not good—college allowances while
he was in residence being often paid—“Spenser aerograting.”

One of the felows of Pembroke strongly influenced his destiny.
This was Gabriel Harvey, a prominent figure in the university
life of the time, an enthusiastic educationist, vigorous, versatile,
not a little vain of his own culture and literary powers, which
had gained him a certain standing in London society. The
revival and advancement of English literature was a passion
of the time, and Harvey was fully possessed by it. His fancy for
reforming English verse by discarding rhyme and substituting
unrhyming lines, and his massive work in this direction, *The
Art of English Poesie*, has been introduced to the modern reader
by Thomas Nash, have caused him to be regarded as merely an
obstreperous and pragmatic pedant; but it is clear that Spenser,
who had sense enough not to be led astray by his eccentricities,
received active and generous help from him and probably not a
little literary stimulus. Harvey’s letters to Spenser 2 throw a
very kindly light on his character. During his residence at
the university the poet acquired a knowledge of Greek, and at
a later period offered to impart that language to a friend in Ireland
(see Ludowick Bryskeft, *Discourse of Civil Life*, London, 1606—
written twenty years previously). Spenser’s affinity with Plato
is apparent in his *The Art of English Poesie* and in the *Faerie
Queen*.

Three years after leaving Cambridge, in 1579, Spenser issued
his first volume of poetry, the *Shepherd’s Calendar*. Where and
how he spent the interval have formed subjects for elaborate
speculation. That most of it was spent in the study of his art
we may take for granted. That he lived for a time in the
“north parts” of England; that there or elsewhere he fell in
love with a lady whom he celebrates under the anagram of
“Rosalind,” and who was most likely Rose, a daughter of a
yeoman named Dyneley, near Clitheroe; that his friend Harvey
urged him to return south, and introduced him to Sidney; that Sidney took to him, discussed his poetry with him, introduced him at court, put him in the way of preferment—
are ascertained facts in his personal history. Dr Grosart con-
jectures with considerable plausibility that he was in Ireland
in 1577. The words “for long time far estranged” in E.K.’s
preface to the *Shepherd’s Calendar* point that way. Spenser
undoubtedly entered the service of the earl of Leicester either
in 1578 or a year earlier (Carew Papers).

The interest of the *Shepherd’s Calendar* is mainly personal to
Spenser. Its twelve poems continue to be read chiefly because
they were the first published essays of the author of the *Faery
Queen*, the poems in which he tried and disciplined his powers.
They mark no stage in the history of pastoral poetry. The title,
*Shepherd’s Calendar*, and the systematic arrangement of his poem, which
was translated into English in 1593 and frequently reprinted, is
attractive but hardly tells with the subject. It may have been an
afterthought. Spenser had too strong a genius not to make his
own individuality felt in any form that he attempted, and his
buoyant dexterity in handling various schemes of verse must always
afford delight to the connoisseur in such things. But a reader not
accustomed to his verse, or otherwise familiar with the artificial
elegiac, would find little to attract him in the *Shepherd’s
Calendar*. The poems need a special education; given this, they

1 The first versions of the *Visions* of Petrarch and Du Bellay
are reproduced by Dr Grosart in his *Complete Works of Spenser*,
vol. iv. (London, 1882). The translations of Petrarch are imitated
from Marot. Koeppel (*Englische Studien*, vol. xv.), questions whether
they are by Spenser (see also J. B. Fletcher, *Modern Language
Notes*, vol. xxii.).

2 Letter-book of Gabriel Harvey (Camden Society).
engaged in a fierce struggle for existence against the Catholic powers of the Continent. Of Lord Grey's character his secretary was an enthusiastic admirer, exhibiting him in the Faery Queen as Arthegal, the personification of justice; and we know exactly what were his own views of Irish policy, and how strongly he deprecated that Lord Grey was not permitted to carry them out. Spenser's View of the State of Ireland drawn up after fourteen years' experience, but first printed in 1633 by Sir James Ware, who complains of Spenser's work of art, and the�eloquence and inadequate knowledge (History of Ireland, appendix), is not the work of a gentle dreamer, but of an energetic and shrewd public official.

The View is not a descriptive work; there is nothing in the style to indicate that it was ever written by the hand of an excited imagination. It is an elaborate state paper, the exposition in the form of a dialogue a minutely considered plan for the pacification of Ireland, written out of zeal for the public service for the eyes of the government of the day. A very thoroughgoing plan it is. After passing in review the history and character of the Irish, their laws, customs, religion, habits of life, armour, dress, social institutions and finding "evil usages", in every department, he propounds his plan of "reformation. Reformation can be effected only by the sword, by the strong hand. The interlocutor in the dialogue holds up his hands in horror. Does he propose extermination? By no means; but he would give the sword to be wielded by another. The government and the clergy. The government had vacillated too long, and, fearing the cost of a thorough operation, had spent twice as much without in any way compelling the Irish to mend their ways. Ireland is a country of necessity and 1000 horse, disperse them in garrisons—a scheme of localities is submitted—give the Irish twenty days to come in; if they did not come in, give no quarter afterwards, but hunt them through the country in the winter time when the cover is thin; "if they be well followed one winter, ye shall have little work to do with them the next summer"; famine would complete the work of the sword; and in eighteen months' time peace would be restored and the ground cleared for plantation by English colonists. There must be no flinching in the execution of this plan—"no remorse or drawing back for the sake of any such ﬂuish object as must thronour follow, nor for compassion of their calamities, seeing that by no other means it is possible to recover them, and that these are not of will but of very urgent necessity." The government had got out of foolish compassion drawn back before when an opportunity of planting the Irish to the same extent as the last time was sacrificed because of famine; the gentle poet warns them earnestly against a repetition of the blunder.

such was Spenser's plan for the pacification of Ireland, pronounced not on his own authority, but as having support in "the consultations and actions of very wise governors and counsellors whom he had sometimes heard treat thereof." He knew that it was "bloody and cruel"; but he contended passionately that the land of England was not complete without the Protestant religion. The method was repugnant to the kindly nature of average Englishmen; from the time of Lord Grey no English authority had the heart to go through with it till another remorseless zealot appeared in the person of Cromwell. That Cromwell knew the true meaning of the Faerie Queen. He entered into the sympathies of the poet's character. The plan of Cromwell and business-like character of the View shows that the poet was no scribe, but received his reward for substantial political services. He ceased to be secretary to the lord-deputy when Lord Grey was recalled in 1582; but he continued in the public service, and in 1586 was promoted to the onerous position of clerk to the council of Munster.

Amidst all the distractions of his public life in Ireland Spenser kept up his interest in literature, and among proper subjects for reform included Irish poetry, of which he could judge only through the medium of translations. He allows it some merit—"a very good invention"—some mention in his Faerie Queen, but laments that it is "abused to the gracing of wickedness and vice." Meanwhile he seems to have proceeded steadily with the composition of the Faery Queen, translating his varied experience of men and affairs into the picturesque forms of his allegory, and expressing through them his conception of the immutable principles that ought to regulate human conduct.

He had, as we have seen, conceived a work of the kind and made a beginning before he left England. The conception must have been very much deepened and widened and in every way enriched by his intimate daily contact with the actual struggle of conflicting individuals and interests and policies in a great crisis. Some four or five years later, being asked in a mixed company of English officials in Ireland (as recorded in Lodowick Bryskett's Discourse of Civil Life) to give off-hand a short sketch of "the ethical part of moral philosophy" and the practical uses of the study, Spenser explained to these simple-minded men that the subject was too big and not for an impromptu exposition, but that he had in hand a work called the Faery Queen in which an ethical system would be exhibited in action. The respect paid by his official brethren to Spenser as a man, "not only perfect in the Greek tongue, but also very well read in philosophy, both moral and natural," is an interesting item in his biography. Some years later still, when Spenser was settled at Kilcolman Castle, Sir Walter Raleigh found him with three books of the Faery Queen completed, and urged him to come with them to London. London accordingly he revisited in 1590, after nine years' absence. There is a very pretty record of this visit in Colin Clout's Come Home Again, published in 1595, but written in 1591, immediately after his return to Kilcolman. The incidents of the visit, by that time matters of wishful memory, are imaged as a shepherd's excursion from his quiet pastoral life into the great world. Colin Clout calls round him once again the masked figures of the Shepherd's Calendar, and describes to them what he saw, how he fared, and whom he met at the court of Cynthia, and how, through the influence of "the Shepherd of the Ocean," he was admitted at timely hours to play on his oaten pipe in the great queen's presence.

How much is pure fiction and how much veiled fact in this picture cannot be distinguished, but it is undoubted that Spenser, though his chief patrons Leicester and Sidney were now dead, was very graciously received by the great world on his return to London. Not only did the queen grant him an audience, but many ladies of the court, several of whom he afterwards honoured with dedications, honoured him with their patronage. The first three books of the Faery Queen, which were entered at Stationers' Hall on the 1st of December 1590, were published in 1590, and he was proclaimed at once with remarkable unanimity by all the writers of the time as the first of living poets.

From the first week of its publication the literary world had continued unanimous about the Faery Queen, except on minor points. When romanticism was at its lowest ebb Pope read Spenser in his old age with as much delight as in his boyhood. Spenser proved himself of having the same intoxicating, venomous quality as the Blovant Beast, and he seems to have had in more than ordinary share the poet's sensitiveness to criticism; but the detection or indifference have generally been found among men who, like the lord high treasurer Burghley, have no liking for poetry of any kind. The secret of Spenser's enduring popularity with poets and lovers of poetry lies specially in this, that he excels in the poet's peculiar gift, the instant for verbal music. Shakespeare, or the author of the sonnet usually assigned to him, felt and expressed this when he drew the parallel between

music and sweet poetic sound. "Thou lovest to hear the sweet melodious sound That Phoebus' lute, the queen of music, makes; And I in deep delight am chiefly drowned Whene'er himself to singing he betakes."

This is a early word in criticism of Spenser, and it is the last word about his prime and unquestionable excellence—a word in which all critics must agree. Whether he had imagination in the highest degree, or only luxuriant fancy, and whether he could tell a story in the highest manner or only put together a richly varied series of picturesque incidents, are disputable points; but about the enchantment of his verse there can be no difference of opinion. It matters not that he has on his melodies often by archaic affectations and licences of diction; there, however, purchased, the marvellously rich music is. In judging of the structure of the Faery Queen we must always remember that, long and difficult as it is, what we read is a fragment, the design, and that the narrative is regulated by an allegorical purpose; but, however intricate, however confused, the reader may feel the power of the words as he passes from one incident to another. When accident is the succession of incidents, it is only at the call of duty that he is likely to occupy himself with such a study in reading Spenser.
SPENSER, EDMUND

The ethical value of the allegory has been very variously estimated. The world would probably never have divined that there was any allegory if he had not himself drawn attention to it in a prosaic dedication and in doggerel headings to the cantos. It was apparent to Sir Walter Raleigh that Spenser had descended to explain his ethical purpose in A Letter of the Author, addressed to Sir Walter and dated the 23rd of January 1589-1590; otherwise it would have been as problematical as the similar intention in the case of the King himself. The indentation was declared. It is almost to be regretted, as far as the allegory is concerned, that the friendly "E. K." was not employed to furnish a dedication more fitting to the Faerie Queene than to Spenser's Calendar. Undoubtedly the peculiar "poetic luxury" of the Faerie Queen can be enjoyed without any reference to the allegory; even Professor Dowden, the most eloquent champion of Spenser's claims as a "teacher," admits that it is a mistake to look for minute correspondence between outward symbol and underlying sense, and that the poet is least enjoyable where he is most ingenious. Still the allegory governs the structure of the poem, and Spenser himself attached great importance to it as determining his position among poets. The ethical purpose is distinctive of the poem as a whole; it was foremost in Spenser's mind when he conceived the scheme of the poem, and present with him as he built up and articulated the skeleton; it was in this respect that he claimed to have "passed over" his avowed models Ariosto and Tasso. If we wish to get an idea of Spenser's imaginative force and abundance, or to see how he conceives his creations as he saw them, we must not neglect the allegory. It is obvious from all that he says of his own work that in his eyes the ethical meaning not only heightened the interest of the marvelously rich pageant of heroes and heroines, enchanters and monsters, but was an essential part of the work, and a thing not to be removed from its place. For the right appreciation of many of the characters and incidents a knowledge of the allegory is indispensable. For example, there is an intimation that the Red Cross Knight looked to be merely disgusting but for its symbolic character; the iron Talus and his iron flail is a revolting and brutally cruel monster if he is not regarded as an image of the executioner of righteous law; the Blatant Beast, a purely grotesque and ridiculous monster to outward view, acquires a serious interest when he is known to be an impersonation of malignant detraction.

Notwithstanding its immense range, the Faerie Queen is profoundly national and Elizabethan, containing many more or less cryptic allusions to contemporary persons and interests. It has never been popular abroad, as is proved by the fact that there is no complete translation of it in any of the Continental languages. This is doubtless on account of a certain monotony in the subject-matter, which is only partially relieved by subtle variations. The same objection applies to the famous "Spenserian stanza" (see below) with its concluding Alexandrine. It was by no means a happy invention, but its infelicity is disguised by its author's marvellous skill in rhythm, and thus rendered imperceptible by his power of adaptation, till one day Spenser was criticized by Sidney, Ben Jonson, Daniel and others for the artificiality of his language, his "aged accents and untimely words," but Ben Jonson went further—"Spenser's stanza pleased him not, nor his manner." Milton, on the other hand, duly appreciated "our sage and serious poet," and he has been followed by a long line of distinguished judges. It was Charles Lamb who named Spenser "the poet's poet."

After the publication of the Faerie Queen Spenser seems to have remained in London for more than a year, to enjoy his triumph. It might be supposed, from what he makes the Shepherd say in his argument: "Commit to no country in Ireland, that Raleigh had encouraged him to expect some permanent provision in London. If he had any such hopes, they were disappointed. The thrifty queen granted him a pension of £50, which was paid in February 1591, but nothing further was done for him. Colin Clout's explanation that the selfish scrambling and intriguing of court life were not suited to a lowly shepherd swain, and that he returned to country life with relief, may be pastoral convention, or it may have been an expression of the poet's real feelings on his return to Kilcolman, although in fact there is no evidence that he had been as much scrambling for good things in Munster as in London. Certain it is that he did return to Kilcolman in the course of the year 1591, having probably first arranged for the publication of Daphnis and Complaints. Daphnis is a pastoral elegy on the death of the niece of the mistress of the roes. The fact implied in the dedication that he was not personally known to the lady has more than once provoked the solemn remark that the poet's grief was assumed. Of course it was assumed; and it is hardly less obvious that sincerity of personal emotion, so far from being a merit in the artificial form of pastoral poetry, the essence of which lies in its dreamy remoteness from real life, would be a blemish and a discord. Any suggestion of the poet's real personality breaks the charm; once raise the question of the poet's personal sincerity, and the pastoral poem may at once be thrown aside. The remark applies to all Spenser's minor poetry, including his love-songs; the reader who raises the question whether Spenser really loved his mistress may have a talent for disputation, but none for the full enjoyment of hyperbolical poetry. Complaints, also published in 1591, is a piece of "grotesque" poetry, written at different periods. The volume contained The Ruins of Time; The Tears of the Muses; Virgil's Great; Mother Hubbard's Tale; The Ruins of Rome; Muispotamos; Visions of the World's Vanity; Bellay's Visions; Petrarch's Visions. Some of these pieces are translations already alluded to and interesting as the exercises of one of our greatest masters of melodious verse; but two of them, The Tears of the Muses and Mother Hubbard's Tales, have greater intrinsic interest. The first is the complaint of the decay of learning alluded to in Midsummer Night's Dream, v. i. 47-49:

"The thrice three Muses mourning for the death

Of Learning late deceased in beggary."

The lament, at a time when the Elizabethan drama was "mewing its mighty youth," was not so nappy as some of Spenser's political prophecies in his View of Ireland; but it is idle work to try to trace the undercurrents and personal allusions in such an occasional pamphlet. Mother Hubbard's Tale, a fable in Chaucerian couples, shows a keenness of satiric force not to be paralleled in any other of Spenser's writings, and suggests that he left the court in a mood very different from Colin Clout's.

Spenser returned to London probably in 1595. He had married in the interval a lady whose Christian name was Elizabeth—Dr Grosart says Elizabeth Boyle. The marriage, celebrated on the 11th of June 1594, was followed by a rapid succession of publications. The first was a volume (entered at Stationers' Hall, on the 19th of November 1594; published 1595) containing the Amoretti, a series of exquisite sonnets commemorative of the moods and incidents of his courtship, and the magnificent Epithalamion, incomparably the finest of his love-poems. As in the case of the Complaints, the publisher for other reasons than his own, this volume was issued nominally without his authority. Colin Clout's Come Home Again was published in the same year, with a dedication to Sir Walter Raleigh, dated 1591. Early in 1596 the second three books of the Faerie Queen were entered in the register of Stationers' Hall, and in the course of the same year were published his Four Hymns, his Prothalamion, and his Astrophel, a pastoral lament for Sir Philip Sidney, which he dedicated to the countess of Essex.

That Spenser wrote more of the Faerie Queen during the last two years of his life, and that the MS. perished in the sack of Kilcolman Castle by the rebels, may plausibly be conjectured, but cannot be ascertained. During those years he would seem to have been largely occupied with political and personal cares. He describes himself in the Prothalamion as a disappointed suitor at court. He drew up his View of Ireland in 1596 when he was in London, and from various circumstances it is evident that he had hopes of some kind from the favour of Essex. The View, with its urgent entreaty that Essex should be sent to Ireland, was entered at Stationers' Hall in April 1598, but he did not obtain leave to publish it. Burghley, who had long stood in his way, died in August of that year, and next month Spenser, who seems to have returned to Ireland in 1597, was appointed sheriff of Cork. In October Tyrone's rebellion broke out, and Spenser's house was sacked and burned. The poet himself escaped, and in December was sent to London with despatches. Again he ventured to urge upon the queen his plan for the thorough "reformation" of Ireland. But his own
end was near. On the 16th of January 1599 he died at West-
minster, ruined in fortune, if not heart-broken, and was buried in
Westminster Abbey, near his master Chaucer. Ben Jonson
asserted that he perished for lack of bread, and that when the
earl of Essex, hearing of his distress, sent him "20 pieces," the
poet declined, saying that he had no time to spend them.
This report of his end is mentioned also by the author of The
Return from Parnassus, but, having regard to Spenser's position in
the world, it is inherently improbable. Still there is an ugly
possibility of its truth. The poet left three sons and a daughter.
A pedigree of the family appeared in the Gentleman's Magazine
for August 1842.

Editions by Todd (8 vols., 1805) and by A. B. Grosart (10 vols.,
1882-1884); the Aldine edition, with Life by Collier, and the Globe
edition, with Life by J. W. Hales; Dean Church's Spenser, in "English
Men of Letters" series; Craig's Spenser and his Poetry (1845); Mrs
C. M. Kirkland's Spenser and the Faery Queen (New York, 1847);

(New York, 1847); Kitchin and Mayhew's Spenser's Faery Queen,
bks. i.-ii., and Herford's Spenser's Shepherd's Calendar (Oxford,
Clarendon Press); Roden Noel's preface to the Spenser volume in
the Canterbury Poets; and F. I. Carpenter's Guide to the Study of
Spenser (Chicago, 1894).

SPENSER, JOHN (1559-1614), president of Corpus Christi
College, Oxford, was educated at Merchant Taylors' school,
London, and Oxford. After graduating he became Greek reader
in Corpus Christi College, and held that office for ten years,
resigning in 1588. He then left Oxford and held successively
the livings of Alveley, Essex (1589-1592), Ardleigh, Essex (1592-
1594), Faversham, Kent (1594-1599), and St Sepulchre's
London (1599-1614). He was also presented to the living of
Bignor, near Chichester, and in 1599 he was appointed president
of Corpus Christi College. After the death of his friend Richard Hooker he edited the first five books of Hooker's
Ecclesiastical Policie (London, 1604). The Introduction to that
work and A Sermon at Poole's Crosse on Essay V., 2, 3 (London,
1615) are his only published writings. He was, however, one
of the translators of the authorized version of the Bible, serving
on the New Testament committee.

SPENSERIAN STANZA, a form of verse which derives its
name from the fact that it was invented by the poet Edmund
Spenser, and first used in his Faery Queene in 1590. The origin
of this stanza has been matter for disagreement among critics
of prosody. Schiller has argued that it was adapted from the
old French ballade-stanza (see BALLADE). But it is much more
probable that it was of Italian origin, and that Spenser, who was
familiar with ottava rima as it had long been employed in Italy,
and was at that very time being used by the school of Tasso,
added a line between the Italian fourth and fifth, modified
slightly the arrangements of rhyme, and added a foot to the last
line, which became an Alexandrine. The form of the pure
Spenserian stanza can best be observed by the study of a speci-
men from the Faery Queene.

Into the loviest temple thus I came,
Which fuming all with frankincense I found,
And odours rising from the altar's flame.
Upon a hundred marble pillars round
The roof was reared from the ground.
All decked with crowns and chains and garlands gay,
And thousand precious gifts worth many a pound,
The which sad lovers for their vows did pay.
And all the ground was strow'd with flowers as fresh as May.

It is necessary to preserve in all respects the characteristics of
this strophe, and the number of regular sequences and identity
of rhymes must be followed. It is a curious fact that, in spite of
the very great beauty of this stanza and the popularity of
Spenser, it was hardly used during the course of the 17th century,
although Giles and Phineas Fletcher made for themselves adap-
tations of it, the former by omitting the eighth line, the latter by
omitting the sixth and eighth. In the middle of the 18th century
the study of Spenser led poets to revive the stanza which bears
his name. The initiators of this reform were Akenside, in The
Virtuoso (1737); Shenstone, in The Scholemistress (1742); and
1 See Conversations with Drummond, Shakespeare Society,
pp. 7, 12.

Thomson, in The Castle of Indolence (1748). Mrs Tighe (1772-
1810) used it for her once-famous epic of Psyche. It was a
favourite form at the time of the romantic revival, when it was
employed by Campbell, for his Gertrude of Wyoming (1809);
by Keats, in The Eve of St Agnes (1820); by Shelley, in The Revolt
of Islam (London and Columbia) (1818); by Mrs Heenan; by Reginald
Heber; but pre-eminentiy by Byron, in Childe Harold (1812-
1817). Thomas Cooper, the Chartist, wrote his Purgatory of
Suicides (1845) in Spenserian stanza, and Tennyson part of his
Lotus Eaters. By later poets it has been neglected, but Worsley
and Conington's translation of the Hliod (1865-1868) should
be mentioned. The Spenserian stanza is an exclusively English
form.

SPERANSKI, COUNT MIKHAIL MIKHAILOVICH (1772-
1839). Russian statesman, the son of a village priest, spent his
early days at the ecclesiastical seminary in St Petersburg, where
he rose to be professor of mathematics and physics. His brilliant
intellectual qualities attracted the attention of the government,
and he became secretary to Prince Kurakin. He soon became
known as the most competent of the imperial officials. The most
important phase of his career opened in 1806, when the emperor
Alexander I. took him with him to the conference of Erfurt
and put him into direct communication with Napoleon, who
described him as the "only clear head in Russia," and at the
instance of Alexander had many conversations with him on the
question of Russian administrative reform. The result of these
interviews was a series of projects of reform, including a consti-
tutional system based on a series of dumas, the cantonal (poslov)
electing the duma of the district, the dumas of the districts
electing that of the province or government, and these electing
the Duma of the empire. As mediating power between the
autocrat and the Duma there was to be a nominated council of
state. This plan, worked out by Speranski in 1809, was for
the most part stillborn, only the council of the empire coming
into existence in January 1810; but it none the less, to quote M.
Chesle,1 dominated the constitutional history of Russia in the
19th century and the early years of the 20th. The Duma of the
empire created in 1805 bears the name suggested by Speranski,
and the institution of local self-government (the zemstvo) in
1864 was one of the reforms proposed by him. Speranski's
labours also bore fruit in the constitutions granted by Alexander
to Finland and Poland.

From 1809 to 1812 Speranski was all-powerful in Russia, so
far as any minister of a sovereign so suspicious and so unstable
as Alexander could be so described. He replaced the earlier
favourites, members of the "unofficial committee," in the tsar's
confidence, becoming practically sole minister, all questions
being laid by him alone before the emperor and usually settled
at once by the two between them. Even the once all-powerful
war-minister Arakcheev was thrust into the background.
Speranski used his immense influence for no personal ends.
He was an idealist; but in this very fact lay the seeds of his-failure.
Alexander was also an idealist, but his ideals were apt to centre
in himself; his dislike and distrust of talents that overshadowed
his own were disarmed for a while by the singular charm of
Speranski's personality, but sooner or later he was bound to
discover that he himself was regarded as but the most potent
instrument for the attainment of that ideal end, a regenerated
Russia, which was his minister's sole preoccupation. In 1810
and the first half of 1811 Speranski was still in high favour,
and was the confidant of the emperor in that secret diplomacy
which preceded the breach of Russia with Napoleon.2 He had, however,
committed one serious mistake. An ardent freemason himself,
he conceived in 1809 the idea of reorganizing the order in Russia,
with the special object of using it to educate and elevate the
Orthodox clergy. The emperor agreed to the first steps being
taken, namely the suppression of the existing lodges; but he was
naturally suspicious of secret societies, even when ostensibly
admitted to their secrets, and Speranski's abortive plan only
resulted in adding the clergy to the number of his enemies.

SPERMACETI—SPEUSIPPUS

On the eve of the struggle with Napoleon, Alexander, conscious of his unpopularity, conceived the idea of making Speranski his scape-goat, and so conciliating Old Russian sentiment which would be the strongest support of the autocratic tsar against revolutionary France. Speranski's own indiscretions gave the final impulse. He was surrounded with spies who reported, none too accurately, the minister's somewhat sharp criticisms of the emperor's acts; he had even had the supreme presumption to advise Alexander not to take the chief command in the coming campaign. A number of persons in the entourage of the emperor, including the grand-duchess Catherine, Karamzin, Rostopchin and the Swedish general, Baron Armfield, intrigued to involve him in a charge of treason. 1 Alexander did not credit the charge, but he made Speranski responsible for the unpopularity incurred by himself in consequence of the hated reforms and the still more hated French policy, and on the 17th-29th of March 1812 dismissed him from office. Reinstated in the public service in 1816, he was appointed governor-general of Siberia, for which he drew up a new scheme of government, and in 1821 entered the council of state. Under Nicholas I, he was engaged in the codification of the Russian law (published in 1830 in 45 vols.), on which he also wrote some important commentaries.

See the biography (in Russian) by M. Korff (St Petersburg, 1861). On his public life and constitutional reforms see Théodore Schiemann, Geschichte Russlands unter Kaiser Nikolaus I., Bd. i. Kaiser Nikolaus I. Gesellsch. der preuss. Akad. d. Wiss. p. 75 (Berlin, 1904); Pierre Chasles, Le Parlement russe p. 10 (Paris, 1830); and the works of V. Vagin (St Petersburg, 1872 and Moscow, 1905). Count Nesselrode's letters to Speranski and many references are published in vol. iii. of the Lettres et papiers du comte de Nesselrode.

Spermaceti (from Lat. sperma, seed, and oculus, a whale), a wax found in the head cavities and blubber of the sperm-whale (Physeter macrocephalus), where it is dissolved in the sperm oil while the creature is living; it also occurs in other Cetaceae (see Whale Oils). At a temperature of about 6° C. the solid matter separates in a crystalline condition, and when purified by pressure and treatment with weak solution of caustic alkali it forms brilliant white crystalline scales or plates, hard, but unctuous to the touch, and destitute of taste or smell. It is quite insoluble in water, very slightly affected by boiling alcohol, but easily dissolved in ether, chloroform, and carbon bisulphide. Spermaceti consists principally of cetin or cetyl palmitate, C₁₈H₃₇CO₂C₁₈H₃₇. The substance is used in making candles of standard photometric value, in the dressing of fabrics, and in medicine and surgery, especially in cerates, bougies, ointments, and in cosmetic preparations.

Sperm-whale, or cachalot (Physeter macrocephalus), the largest representative of the toothed whales, its length and bulk being about equal to, or somewhat exceeding those of the Arctic right-whale, from which, however, it is very different in appearance and structure. The head is about one-third of the length of the body, very massive, high and truncated in front; and owing its size and form mainly to the accumulation of a peculiarly modified form of fatty tissue in the large hollow on the upper surface of the skull. The oil contained in cells in this cavity, when refined, yields spermaceti, and the thick covering of blubber, which everywhere envelopes the body, produces the valuable spermaceti of commerce. The single blowhole is a longitudinal slit, placed at the upper and anterior extremity of the head to the left side of the middle line. The opening of the mouth is on the under side of the head, considerably behind the end of the snout. The lower jaw is extremely narrow, and

1 See Schiemann, op. cit., i. 81.

has on each side from twenty to twenty-five stout conical teeth, which furnish ivory of good quality, though not in sufficient bulk for most of the purposes for which this article is required. The upper teeth are rudimentary and buried in the gum. The flipper is short, broad, and truncated, and the dorsal fin a mere low protuberance. The general colour of the surface is black above and grey below, the colours gradually shading into each other. The sperm-whale is one of the most widely distributed animals, being met with, usually in herds or "schools," in almost all tropical and subtropical seas and oceans. About the northern seas, a number having been killed around the Shetlands a few years ago. The food of sperm-whales consists mainly of squid and cuttlefish, but also comprises fish of considerable size. The substance called "ambergris," formerly used in medicine and now in perfumery, is a concretion formed in the intestine of this whale, and found floating on the surface of the sea. Its genuineness is proved by the presence of the horny beaks of the cuttles on which the whale feeds. The one representative of the genus Cogio is called the lesser or pigmy sperm-whale, being only from 9 ft. to 13 ft. long.

Spes, in Roman mythology, the personification of Hope. Originally a nature goddess (like Venus the garden goddess, with whom she was sometimes identified), she represented at first the hope of fruitful gardens and fields, then of abundant offspring, and lastly of prosperity to come and good fortune in general, being hence invoked on birthdays and at weddings. Of her numerous temples at Rome, the most ancient was appropriately in the forum olitorium (vegetable market), built during the first Punic war, and since that time twice burnt down by animals. The story of its dedication (August 1) corresponded with the birthday of Claudius, which explains the frequent occurrence of Spes on the coins of that emperor. Spes is represented as a beautiful maiden in a long light robe, lifting up her skirt with her left hand, and carrying in her right a bud already closed or about to open. Sometimes she wears a garland of flowers on her head, ears of corn and poppy-heads in her hand, symbolical of a prosperous harvest. Like Fortune, with whom she is often coupled in inscriptions on Roman tombstones, she was also represented with the cornu caperis (born of plenty).

See G. Wissowa, Religion und Kultur der Römer (1902), according to which Speas was originally a garden goddess, but simply the divinity to whom offerings were made for the fulfilment of human wishes.

SPESSART, a highland forest country of Germany, belonging mainly to the Bavarian province of Lower Franconia, but in the north to the Prussian province of Hesse Cassel, and it is bounded on the S. and W. by the Main, on the E. by the Sinn and on the N. by the Kinzig and Joss. The main ridge of the formation, consisting of gneiss, granite and red sandstone, runs from a point opposite Miltenberg, in a north-westerly direction to the source of the Kinzig near Schlüchtern—a distance of 45 m.—and attains its highest elevation in the Geiersberg (1910 ft.), which lies north of the Rohrbrunn pass, through which runs the main road from Aschaffenburg to Würzburg. The forest, with which it is densely covered, consists of oak, beech, ash and fir, and the scenery, especially on the main side, between Gemünden and Lohr, is impressive. The climate is incline in winter and oppressively hot in midsummer. The inhabitants are engaged chiefly in woodcutting, raft-making and quarrying, and most of the timber is floated down to Holland. Cobalt, silver, lead and copper are also worked, and the southern and western slopes yield wine of good quality. This beautiful tract of country until recent years was comparatively little known to the tourist, but a club (Spessart Klub) through the establishment of finger-posts and the issue of maps, has indicated the more interesting tours to be followed.

See Bücking, Der nordwestliche Spessart, geologisch aufgenommen (Berlin, 1893); Schöber, Führer durch den Spessart (Aschaffenburg, 1904); Wolf, Der Spessart, sein Wirtschaftsleben (ibid., 1905).

Speusippus (4th century B.C.), Greek philosopher, son of Eurymedon and Potone, sister of Plato, is supposed to have been born about 407 B.C. He was bred in the school of Isocrates;
but, when Plato returned to Athens about 387, yielded to his influence and became a member of the Academy. In 361, when Plato undertook his third and last journey to Sicily, Speusippus accompanied him. In 347 the dying philosopher nominated his nephew to succeed him as scholar, and the choice was ratified by the school. Speusippus held the office for eight years, and died in 347 at a paralytic seizure. According to some authorities he committed suicide. There is a story that his youth was riotous, until Plato's example led him to reform his ways. In later life he was conspicuously temperate and amiable. He was succeeded by Xenocrates.

Of Speusippus's many philosophical writings nothing survives except a fragment of a treatise On Pythagorean Numbers. Nor have secondary authorities preserved to us any general statement or prospectus of his system. Incidentally, however, we learn the following details. (A) In regard to his theory of being: (1) whereas Plato postulated as the basis of his system a cause which should be at once Unity, Good, and Mind, Speusippus distinguished Unity, the origin of things, from Good, their end, and both Unity and Good from controlling Mind or Reason; (2) whereas Plato recognized three kinds of numbers—firstly, ideal numbers, i.e. the "determinants" or ideas; secondly, mathematical numbers, the abstractions of mathematics; and thirdly sensible numbers, numbers embodied in things—Speusippus rejected the ideal numbers, and consequently the ideas; (3) Speusippus traced number, magnitude and soul each to a distinct principle of its own. (B) In regard to his theory of knowledge: (a) he held that a thing cannot be known apart from the knowledge of all things besides; for, that we may know what a thing is, we must know how it differs from other things, which other things must therefore be known; (b) accordingly, in the ten books of a work called "Oeos, he attempted a classification of plants and animals; (c) the results thus obtained he distinguished at once from "knowledge" (ετωτημα) and from "sensation" (αληθηνα), holding that "scientific observation" (πεποιημωνη αληθηνα) though it cannot attain to truth, may, nevertheless, in virtue of a certain acquired trait, frame "definitions" (ληγος). (C) In regard to his theory of ethics: (a) he denied that pleasure was a good, but seemingly was not prepared to account it an evil.

In default of direct evidence, it remains for us to compare these scattered notices of Speusippus's teaching with what we know of its original, the teaching of Plato, in the hope of obtaining at least a general notion, firstly, of Speusippus's system, and, secondly, of its relations to the systems of Plato, of contemporary Platonists, such as Aristotle, and of the later Academy.

It has been suggested elsewhere (see Socrates) that the crude and unqualified realism of Plato's early manhood gave place in later years to a theory of natural kinds founded on a "thoroughgoing idealism," and that in this way he was led to recognize and to value the classificatory sciences of zoology and botany. More exactly, it may be said that the Platonism of Plato's maturity included the following principal doctrines: (i) the supreme cause of all existence is the One, the Good, Mind, which evolves itself as the universe under certain eternal immutable forms called "ideas"; (ii) the ideas are apprehended by finite minds as particulars in space and time, and are then called "things"; (iii) consequently the particulars which have in a given idea at once their origin, their being, and their perfection may be regarded, for the purposes of scientific study, as members of a natural kind; (iv) the finite mind, though it cannot directly apprehend the idea, may, by the study of the particulars in which the idea is revealed, attain to an approximate notion of it.

Now when Speusippus (1) discriminated the One, the Good, and Mind, (2) denied the ideas, and (3) abandoned the attempt to unify the plurality of things, he explicitly rejected the theory of being expressed in (i) and (ii); and the rejection of the theory of being, i.e., of the conception of the One evolving itself as a principle of motion, is the butt of a modified theory of knowledge conveyed in (iii) and (iv). For, if the members of a natural kind had no common idea to unite them, scientific research, having nothing objective in view, could at best afford a λογος or definition of the appropriate particulars; and, as the discrimination of the One and the Good implied the progression of particulars towards perfection, such a λογος or definition could have only a temporary value. Hence, though, like Plato, Speusippus (4) studied the differences of natural products (5) with a view to classification, he did not agree with Plato in his conception of the significance of the results thus obtained; that is to say, while to Plato the definition derived from the study of the particulars included in a natural kind was an approximate definition of the idea in which the natural kind originated, to Speusippus the definition was a definition of the particulars studied, and, strictly speaking, of nothing else. Thus while Plato hoped to ascend through classificatory science to the knowledge of eternal and immutable laws of thought and being, Speusippus, abandoning ontological speculation, was content to regard classificatory science not as a means but as an end, and (6) to rest in the results of scientific observation. In a word, Speusippus turned from philosophy to science.

It may seem strange that, differing thus widely from his master, Speusippus should have regarded himself and should have been regarded by others as a Platonist, and still more strange that Plato should have chosen him to be his successor. It is to be observed, however, firstly, that the scientific element occupied a larger place in Plato's later system than is generally supposed, and, secondly, that other Academics who came into competition with Speusippus agreed with him in his rejection of Platonism. When Plato, an alert and capable representative of his ontological theory, might well choose to succeed him a favourite pupil whose scientific enthusiasm and attainment were beyond question; and Speusippus's rivals, having themselves abandoned the theory of ideas, would not be in a position to tax him with his philosophical apostasy.

In abandoning the theory of ideas—that is to say, the theory of figures and numbers, the possessions of universal mind, eternally existent out of space and time, which figures and numbers when they pass into space and time as the heritage of finite minds are regarded as things—Speusippus had the approval, as of the Platonists generally, so also of Aristotle. But, whereas the new scholarch, confining himself to the detailed examination of natural kinds, attempted no comprehensive explanation of the universe, Aristotle held that a theory of its origin, its motions, and its order was a necessary adjunct to the classificatory sciences; and in nearly all his references to Speusippus he insists upon this fundamental difference of procedure. Conceiving that the motions of the universe and its parts are due to the desire which it and they feel towards the supreme external mind and its several thoughts, so that the cosmical order planned by the divine mind is realized in the phenomenal universe, Aristotle thus secures the requisite unification, not indeed of mind and matter, for mind and matter are distinct, but of the governing mind, the prime unmoved movet, since it and its thoughts are one. Contrariwise, when Speusippus distinguishes One, Good, and Mind, so that Mind, not as yet endowed with an orderly scheme, adapts the initial One to particular Goods or ends, his theory of nature appears to his rival "episodic," i.e. to consist of a series of tableaux wanting in dramatic unity, so that it reminds him of Homer's line—ὁδικ αγαθων πολυμορφων ηεων αποκορονιαν. Speusippus and his contemporaries in the school exercised an important and far-reaching influence upon Academic doctrine. When they, the immediate successors of Plato, rejected their master's ontology and proposed to themselves as ends mere classificatory sciences which with him had been means, they banned their hope of philosophic certainty for the tentative and provisional results of scientific experience. Xenocrates indeed, identifying ideal and mathematical numbers, sought to

1 That Plato did not neglect, but rather encouraged, classificatory science is shown, not only by a well-known fragment of the comic of Arius Satyrus, which shows him employing the method of investigating, under the eye of Plato, the affinities of the common pumpkin, but also by the Timaeus, which, while it carefully discriminates science from ontology, plainly recognizes the importance of the study of natural kinds.
SPEY—SPHENE

shelter himself under the authority of Plato; but, as the Xeno-
cratean numbers, though professedly ideal as well as mathe-
matical, were in fact mathematical only, this return to the
Platonic terminology was no more than an empty form. It would
seem, then, that Academic scepticism began with those who
had been reared by Plato himself, having its origin in their acceptance
of the scientific element of his teaching apart from the ontology
which had been its basis. In this way, and, so far as the present
writer can see, in this way only, it is possible to stand this
extraordinary revolution which converted Platonomism, philo-
osophical and dogmatic, into Academicism, scientific and sceptical.
It is as the official representative of this scientific and sceptical
departure that Spesippus is entitled to a place in the history of
philosophy.

Bibliography.—J. G. F. Ravaillon, Spesippe de primis rerum
principiis placita (Paris, 1839); Chr. Aug. Brandis, Geschichte der
griechisch-römischen Philosophie (Berlin, 1853), vol. i. i; Zeller, Die
Philosophie d. Griechen (Leipzig, 1873), ii. 1; Mullach, Fragmenta

SPEY, a river in the Highlands of Scotland. It rises in Mt.
Clach-a-Cheannach in the north of Lochaber, in Inverness-
shire, at a height of 1409 ft. above the sea. A mile from its
source it forms the small Loch Spey, and 37 m. lower down it
expands into the larger Loch Inch. After crossing the boundary
of Elginshire, below Grantown, it pursues an extremely serpen-
tine course, as far as Craigellachie, where it begins to flow due
northwards, becoming wholly a Moray stream as it approaches
Fochabers, and falling by several mouths into the Moray Firth
at Kingston. Its total length is about 110 m. It is the most rapid
river in Scotland, and is neither impeded by artificial barriers
nor does its Speymouth in its lowest reaches reach a ship-building has
been intermittently carried on. The strength of its current is due
partly to its lofty origin, and partly to the volume of water con-
tributed by numberless affluent streams from the mountainous
regions of its birth. The more important tributaries are, on the left,
the Markie, Calder, Dulnain, Tulchan, Ballintomb and Rothes and,
on the right, the Mashie, Truim, Tromie, Feshie, Nethy, Avon,
Fiddich and Milben. Its area of drainage is 1300 sq. m. At
several points the stream attains a considerable width, as at
Alvie, where it is 130 ft. wide, and at Kingussie, where its width
is from 80 to 100 ft. From below Craigellachie, and especially
on the low-lying coast-land, pools or stretches of fair size become
frequent. For beauty of scenery Strathspye holds its own with
any of the great valleys of Scotland. As a salmon river the
Spey yields only to the Tay and Tweed. It passes many interest-
ing spots in its long career, such as Laggan; Cluny Castle, the
seat of Cluny MacPherson; Craig Dhu, the "black rock," and
Kingussie. It flows past the pine forests of Rothiemurchus;
Granton, the capital of Stratspye; Cromdale, where the clans-
men suffered defeat at the hands of William III.‘s troops in 1690;
Ballindalloch, with a splendid Scottish baronial castle, the seat
of the Macpherson-Grant; and Charlestown of Aberlour and its
fine cataract.

SPEZIA, a city of Liguria, Italy, in the province of Genoa,
56 m. S.E. of that town by rail, 49 ft. above sea-level. Pop.
(1906), 47,773 (town); 75,756 (commune); in 1861 only 11,556.
It is the chief naval harbour of Italy, having been adopted as
such in 1861. The Bay of Spezia is sheltered from all except
southerly winds, and on its western shore are numerous openings,
which afford perfectly safe anchorage in all weathers. The
entrance is protected by forts, while a submarine embankment,
2 m. long, renders it secure. The arsenal consists of three depart-
ments, the principal of which is 3932 ft. long, with an average
width of 2460 ft. The chief basin is 23 acres in extent, and the
second—connected with the first by a canal 97 ft. wide—36
acres. Both basins have an average depth of between 33 and
35 ft. The second basin gives access to the docks, of which there
are six; two 390 ft. long, two 420 ft. long, one 500 ft. long, and
one 650 ft. long. The establishment of San Vito is devoted
to the production of artillery; that of San Bartolomeo is
exclusively used for electrical works and the manufacture
of submarine weapons, especially torpedoes. The arsenal was
constructed by General Chiiodo (d. 1879), whose statue rises at
the entrance, and near it are the naval barracks and hospital.
Though the town itself, with the barracks and military hospital
as its principal buildings, presents little to attract the foreign
visitor, the beauty of the Gulf and of the neighbouring country
has brought Spezia into some repute as a winter resort, and it is
also visited in summer for sea-bathing. The walls and gates
of the old city are for the most part destroyed. The opening of a
canal across the Apenines (there is a branch leaving the coast
line at Vezzano, and joining the line from Sarzana to S. Stefano di
Magra), placed Spezia in communication with Parma and the
most fertile regions of the Po valley, and so stimulated commerce
that a new commercial port to the east of the city was built.
This harbour consists of a broad quay with 657 ft. of wharfage,
and of a mole 1339 ft. long with 984 ft. of wharfage. The basin
of the harbour is about 26 ft. deep. A branch railway connects
the wharves directly with the main line. Since the opening of
the new port the traffic has considerably increased, and it exports
oil, pig-iron, silver, flour, wine, marble and sandstone for
paving purposes, while it imports quantities of coal, iron, cereals,
phosphates, timber, pitch, petroleum, and mineral oils. The
import of coal in 1906 was 439,494 tons, being nearly double
the average for 1901–1905. The tonnage of vessels entered was over
600,000, an increase of about 25% on that of 1905. Several
important industrial establishments lie along the bay, including
large lead and silver works at Pertusa (see LERICI), submarine
works on a shipyard at Muggiano for the construction of
currents vessels up to 10,000 tons, a branch of the Vickers
Terne works for armours plate, several motorboat works, brick
and cement factories, &c. The city contains numerous modern
buildings, including schools, hospitals, and public institutions.

The origin of Spezia is doubtful; but it probably rose after
the destruction of Luna. Sold by one of the Fieschi in 1726 to
Genoa, the town was fortified by its new possessors and made
the seat of a governor of some importance. It became a city in the
16th century. The idea of making the Gulf of Spezia a great
naval centre was first broached by Napoleon I.

SPHAERISTERIUM (Gr. εφαρμισθείον, εφαίραι, ball), the
term in Classic architecture given to a large open space connected
with the Roman thermae, for exercise with balls after the bath had
been anointed; they were also provided in the Roman villas.

SPHENE, a mineral consisting of calcium titanio-silicate,
CaTiSiO₅, crystallizing in the monoclinic system. The crystals
vary considerably in habit, but are generally thin and wedge-
shaped; hence the name sphene, from the Greek εφαίρει (a wedge),
given by R. J. Hawt in 1801. The earlier name tatanite, given by
M. H. Klaproth in 1795, is also in common use. Twinning
on the ortho-pinacoid is not uncommon.

The colour is green, yellow, brown or black, and the lustre resinous to adamantine;
crystals are transparent to opaque.

The hardness is 43, and the specific gravity 3.5.

The refractive indices and the optic axial
angle vary considerably with the colour of
the light: the dispersion of the optic axes is
inclined, and the interference figure seen in
convergent light between crossed nicsols is
very characteristic of the mineral. Sphere
is sometimes cut as a gem-stone, though it is
rather too soft to stand much wear; owing to
its high dispersive power it gives
brilliant flashes of prismatic colours. As small embedded
crystals, sphene has a wide distribution as an accessory constituent of many kinds of igneous rocks (granite, syenite, trachyte, phonolite, &c.), and also of gneiss, schist and crystalline
limestone. Sharply-developed, transparent, pale green crystals
are frequently associated with adularia, asbestos and quartz
in the crystal-line crevices of the schists of the Swiss
and Tyrolean Alps. Large, rough and dark-coloured crystals
are found at Arendal and Kragerø in Norway, and in granular
limestone at Diana in New York and Eganville in Ontario.

A greyish, compact and impure variety of sphene, known as
SPHENODON—SPHERE

"leucowne," frequently occurs in basic igneous rocks as an alteration product of ilmenite and rutile. (L. J. S.)

SPHENODON, or Tuatara. Sphenodon s. Herteria (called by Gray after Hatter), with one species, S. punctatus, is the sole surviving member of the whole group of Rynchocephalia (q.v. under Reptiles, Fossil). It is one of the few reptiles inhabiting New Zealand; formerly common on the main islands, now restricted to some of the small, uninhabited islands. Plate 151 shows the region of protection of the government. The Maoris call it ruatara, tuatote, or tuatara, the meaning "having reptile." This creature represents an almost ideally generalized type of reptile. The total length of large males is more than two feet, but mature females are scarcely half this size. In general appearance they much resemble the Agamidae, especially Uromastix, or Physignathus, with the massive head, the chisel-shaped front teeth, short legs and erectile crest of cutaneous spines on the head and along the mid-line of the trunk and tail, whilst the rest of the dark olive-green skin is granular, with yellowish specks. But the Agamoid resemblance is only skin-deep, and only the tyro can confound them with any group of Lacertilia. At the same time it is probable that Sphenodon stands near the ancestral root of the Lacertilia, before these divided into gekcos, chameleons, and lizards proper. The development of this animal has been first studied by G. B. Howes, who quotes the literature bearing upon the whole subject. A good account of the habits of the tuatara has been given by Newman. They live upon animals, but these are only taken when alive and moving about, e. g. fish, worms, insects. Sluggish in their habits, they sleep during the greater part of the day in their self-dug burrows, and are very fond of lying in the warm sun and basking on a hillside. Each individual excavates its own hole, a tunnel leading into a roomy chamber, lined with grass and leaves; part of the habitation is shared socially by a family of pets, which is said to occupy usually the left side, whilst the tuatara itself lives a solitary life. The male croaks or grunts much during the pairing season; the hard-shelled, long-oval eggs, about 28 mm. long, are laid in holes in the sand, about ten in one nest, from November to January or February. They contain nearly ripe embryos in the following August, but they are not hatched until about thirteen months old; in the meantime they feed by a kind of hibernation, their heads being flattened and becoming blocked with proliferating epithelium, which is resolved shortly before hatching during the southern summer. In spite of their imposing, rather noble appearance, when, with their heads erect, they calmly look about with their large quiet eyes, they are dull creatures, but they bite furiously.

SPHERE (Gr. σφάγη, a ball or globe), in geometry, the solid or surface traced out by the revolution of a semicircle about its diameter; this is essentially Euclid's definition;1 in the modern geometry of surfaces, it is defined as the surface passing through a circle at infinity. Every point is equidistant from a fixed point within the surface; this point is the "centre," the constant distance the "radius," and any line through the centre and intersecting the sphere is a "diameter." All sections of the sphere are necessarily circles; if the cutting plane contains the centre, the section is said to be "meridional," the curve of intersection is a "great circle," and the solid cut off is a "hemisphere." If the plane does not contain the centre, the curve of intersection is a "small circle," and the solid cut off is a "segment." Great circles may also be defined as circles on a sphere which pass through the extremities of a diameter; they are familiar as the meridians and parallels of geographers. The plane sections of great circles are called "great circles." The shortest distance between two points on a sphere is the arc of the great circle containing the points. This proposition is the basis of the "great circle sailing" of navigators, and the arc of the great circle is called the "rhumbline" or "loxodromic curve." The determination of the shortest distance between two small circles on a sphere is given in the article VARIATIONS, CALCULUS OF. The extremities of the diameter perpendicular to a small circle are called the "poles" of that circle, and the distance from the pole to the circle, measured by the arc of the great circle through the pole, is the "polar distance." To live the ill-imposed problem is maximized by a small circle and the radii vectors from the centre of the sphere is a "spherical sector," and the solid contained between two spherical sectors standing on copolar small circles is a "spherical cone." A "spherical sector" and "spherical cone" may be also regarded as the solids of revolution of a circular sector about one of its bounding radii, and about any other line through the vertex respectively. The solid intercepted between two parallel planes is a "zone."

The geometry of the sphere was studied by the Greeks; Euclid, in book xii. of his Elements, discusses various properties of the sphere, and in book xiii. he shows how to inscribe the five regular polyhedra in and about a sphere, but the solid polyhedra are not mentioned. The volumes of spheres are in the triplicate ratio of their diameters, a theorem probably due to Eudoxus, no mention is made of its mensuration. This subject was investigated by Archimedes, who, by means of the method of exhaustion, determined the volume of a sphere. He showed that the surface of a segment is equal to the area of the circle whose radius equals the distance from the vertex to the base of the segment; that the surface of the entire sphere is equal to the curved surface of the circumscribing cylinder, and to four times the area of a great circle of the sphere; and that the volume is two-thirds that of the circumscribing cylinder. To Zenodorus (c. 200 B.C.), and a similar problem—to construct a segment equal in volume to a given segment, and in surface to another segment—was solved by the Arabian mathematician and astronomer, Al Kuhi.

In analytical geometry, the equation to the sphere takes the forms $x^2+y^2+z^2=a^2$, and $x=a, y=0, z=0$, the first applying to rectangular Cartesian co-ordinates, the second to polar, the origin being in both cases at the centre of the sphere. If the centre be $(a, b, c)$, the Cartesian equation becomes $(x-a)^2+(y-b)^2+(z-c)^2=a^2$; consequently the general equation is $x^2+y^2+z^2+2ax+2by+2cz+d=0$, and it is readily shown that the co-ordinates of the centre are $(-a, -b, -c)$, and the radius $A^2+B^2+C^2-D=a$.

A sphere can therefore be described so as to satisfy four given conditions, the systems of equations of condition are thus systems of circles. If $r$, $r_1$ be the radii of two spheres, $d$ the distance between the centres, and $\phi$ the angle at which they intersect, then $\sin^2 r = r_1^2 + d^2 - 2d \cos \phi$; hence the measurement of the sphere of angle $\phi$ is named the "power" of the two spheres, and it is important in the investigation of systems of spheres. If the sphere $r_1$ degenerate to a point, the function $2r_1 \cos \phi$ has the limit $d^{-\phi}$; the power of the circle $d$ is termed the "power of the sphere at the point," or "power of the point with respect to the sphere." Two spheres intersect in a plane, and the equation to a system of spheres which intersect in a plane is $x^2+y^2+z^2-2x1-x-2y1-y-2z1-z-2d1=0$, $A$ varies from sphere to sphere, and $D$ is constant for all the spheres, the plane $z1$ being the plane of intersection, and the axis of $x$ the line of centres. Corresponding to the radical centre of three circles, there exists a point such that the tangents from this point to the four spheres are equal, and that with this point as centre, and the length of the tangent as radius, a sphere may be described which

---

1The surfaces formed by revolving a circle about any chord also received attention at the hands of the Greeks. According to Heron and Solidus they were discussed under the name spire by Ptolemy (c. 200–100 B.C.), their sections were termed spiral sections, and were called spirae, and as the hippocede of Eudoxus. The surface and solid traces by the revolution of the lesser segment of a circle is termed a "spindle." An "anchor ring" or "toric" results when a circle revolves about an axis in its plane.
SPHERES, MUSIC OF THE—SPHERES OF INFLUENCE

cuts the four spheres at right angles; this “orthomtic” sphere corresponds to the orthogonal circle of a system of circles.

The discovery of triangles and circles drawn upon the surface of a sphere is all-important in the sciences of astronomy, geodesy and geography. In astronomy, we are principally concerned with the orientation of points on a sphere—the so-called celestial sphere— with regard to certain fixed points on the earth; this subject is treated in the article ASTRONOMY (Spherical).

In geodesy, and the cognate subject “figure of the earth,” the mathematical treatment is with regard to the determination of the area of triangles drawn on the surface of a sphere—the so-called “spherical triangles”; this is a branch of trigonometry, and is studied under the name of spherical trigonometry. In geography, the problem of representing the surface of a sphere on a plane is of fundamental importance; this subject is treated in the article MAP.

SPHERES, MUSIC OF THE, in Pythagorean philosophy, the harmony produced by the heavenly bodies in their orbits, inaudible to human ears. Pythagoras (cf. Arist. de Coelo, ii. 9) held that Pythagoras, and he was governed by fixed laws which could be expressed in numbers according to the laws which give the harmony of sounds (see Pythagoras, ad fin.). It is the theory to which Shakespeare alludes in The Merchant of Venice (Act. v. i. seq.: “such harmony is in immortal souls, but...we cannot hear it.”). According to Gompertz (Greek Thinkers, i. 118, Eng. trans.) “there was nothing fanciful in the Pythagorean doctrine except the belief that the differences of velocity in the movements of the stars were capable of producing a harmonious orchestration and not merely sounds of varying pitch.”

SPHERES OF INFLUENCE. “Spheres of influence,” “spheres of action,” “spheres of interest,” “zones of influence,” “field of operations,” “Machtspäre,” “Interessen-sphäre,” are phrases in international law which have come into use to describe regions as to which nations have agreed that one or more of them shall have exclusive liberty of action. These phrases became common after 1850, when the “scramble for Africa” began, to describe diplomatic arrangements with respect to it. Some definitions may be quoted—when secretary of state for the colonies, Lord Kautskoy, replying to a deputation in 1856, said: “Spheres of action ’ is a term I do not wish to define now; but it amounts to this: we should not allow the Portuguese, Germans, or any foreign nation or republic to settle down and annex the territory” (quoted in Kenean’s Compendium of Geography, i. 21). “The term ‘sphere of influence’ implies an engagement between two states that one of them will abstain from interfering or exercising influences within certain territories which, as between the contracting parties, are reserved for the operation of the other” (Ilibert, Government of India, 2nd ed., p. 370). “Unter ‘Intessen-sphäre’ oder ‘Machtspäre’ versteht man nämlich das auf Grund von Vereinbarungen unter den behördigen Kolonialstaaten abgegrenzte Gebiet, innerhalb dessen ein Staat ausschließlich herrschend ist, also koloniale Herrschaft durch Besitzergreifung oder Abschluss von Protektoratsverträgen zu begründen, oder doch einen für diese in diesem Gebiete vorhandenen Völkerzonen massgebenden politischen Einfluss auszuüben” (Stengel, Die deutschen Schutzgebiete, p. 18). “The term ‘sphere of influence or sphere of interest’ has been given an extended meaning by recent developments. Formerly it was used to signify a region wherein a nation, through its citizens, had acquired commercial or industrial interests without having asserted any political protectorate or suzerainty. To-day, as used in China and elsewhere, the term applies rather to the region pre-empted for further exploitation and possibly for political control” (Dr. Reinisch’s Politics, pp. 60, 61). “A portion of a non-Christian or uncivilized country which is the subject of diplomatic arrangements between European states, but has not yet developed into a protectorate” (Jenkin’s British Rule and Jurisdiction beyond the Seas). See also Hall, 6th ed., 120.

The reasons for making these arrangements are to be explained partly by reference to the history of international law as to occupation. The Roman jurists recognized certain “natural modes” of acquiring property, in particular traditio and occupatio. The doctrines which the Roman jurists had worked out to as acquisition of private property by occupation were applied to the appropriation by states or their subjects of vacant lands (res nullius), including lands in the possession of barbarous tribes. “Quod enim nullius est, id discur- ratione naturali occupandi conceditur” (Institutes, i. 1-12). The Roman law required the animus of occupation, dominii—there must be a sever for and on behalf of the owner. There must be acquisition, acquisition must be by actus personalis, &c. et alio modo. (Dig. 37. 7. 3.) Professing to act on these doctrines, and relying also on an assumed right on the part of Christian nations to subdue obdu- rate non-Christian communities, the navigators and explorers of the 15th and 16th centuries made exorbitant claims. Having occupied certain points on the coast-line, they claimed to have occupied a whole island or continent (De Martens i. 462). They made vast claims under Papal bulls; for example, under the bull of Nicholas V. of 1454, and the bull of Alexander VI. of 1494, which assigned to the Portuguese the empire of Guinea from land on the coast of the Africa; Cutille’s outside its possess- sions, or which being hitherto without such possessions shall acquire them, as well as the Power which assumes a protectorate, shall accompany the respective act with a notification thereof, addressed to the other Signatory Powers of the present act, in order to enable them, if need be, to make good any claim of their own.” To a similar effect wrote Lord Salisbury in 1887 with reference to the claims of Portugal in East Africa. “Great Britain considers that it has been admitted in principle by all the parties to the act of Berlin that a claim of sovereignty in Africa can only be maintained by real occupation of the territory claimed; and that the doctrine has been practically applied in the recent Zambezi delimitation (State Papers 79, p. 1063). No paper annexation of territory can pretend to validity as a bar to the enterprise of other nations.” At its session at Lausanne, in 1899, the Institut de Droit International adopted the following principles:

1. Article 1.—L’occupation d’un territoire à titre de souveraineté ne sera pas considérée comme effectuée que par l’appui des conditions suivantes: 1° La prise de possession d’un territoire enfermé dans certaines limites, faite au nom du gouvernement. 2° La notification officielle de la prise de possession. La prise de possession s’accomplit par l’établissement d’un pouvoir pub- lic, approuvé, pourvu de moyens suffisants pour maintenir l’ordre et pour assurer l’exercice régulier de son autorité dans les limites du territoire occupé. Ces moyens pourront être employés, à des fins de maintien des actes existants dans le territoire occupé, et la notification de la prise de possession, soit pour la publication dans la forme qui, dans chaque État, est en usage pour la notification des actes officiels, soit par la voie diplomatique. Elle contiendra la détermination approximative des limites du territoire occupé.” (Annaire x, 201).

This development of international law naturally led to arrangements as to “spheres of influence.” Nations which had not yet settled or occupied, or established protectorates, in regions con- tiguous to their existing possessions, were desirous to retain a
Spherical Harmonics

hold over the former, and proceeded to enter into treaties defining the spheres of influence.

The following are the chief treaties by which such spheres are defined:

Great Britain and Portugal as to Africa. August 20, 1890. November the 1st of that year. Great Britain and France as to Upper Niger. January 20, 1891; November 15, 1893, as to Lake Chad. Great Britain and France as to Siam, January 15, 1896. The two governments engage to one another "that neither of them will cede to any other nation in any case or under any pretext, advance their armed forces into the regions, &c. They also engage not to acquire within this region any special privilege or advantage which shall not be enjoyed equally and commonly open to Great Britain and France or their nationals and dependants. Great Britain and Italy as to Africa, April 15, 1891; May 5, 1894, as to region of the Gulf of Aden. Congo and Portugal as to "spheres de souveraineté et d'influence" in the region of Lunda. Great Britain, Belgium and Congo, May 12, 1894, as to the sphere of influence of the independent Congo State. Great Britain and Germany, July 2, 1890 and November 15, 1893, as to East and Central Africa. Great Britain and Russia as to the spheres of influence to the east of Lake Victoria in the region of the Pambis, March 11, 1895.

As an example of the promises or engagements in such treaties may be quoted that between Great Britain and Portugal of the 20th of August 1890. Portugal engages that the territory of which the limits are defined in article 3 shall not, without the consent of Great Britain, be transferred to any other power. In the treaty between the same powers of the 14th of November 1890 it is stipulated that neither power will make, tender, accept protectorates, or exercise any act of sovereignty, &c. Sometimes a treaty defining spheres of influence declares that such and such territory shall be neutral.

In the treaty of delimitation between France and Germany of the 15th of March 1894, the line of demarcation of the zones of influence of the two states in the region of Lake Chad is drawn, and they agree to exercise no political influence in such spheres. Each of the states agrees (art. 2) to acquire no territory, to conclude no treaties, to accept no rights of sovereignty, or protectorate, and not to gêner ou de contester l'influence de l'autre Puissance dans la zone qui lui est réservée.

Being the result of treaties, arrangements as to spheres of influence bind only the parties thereto. As Mr Olney, in his correspondence with Lord Salisbury in regard to Venezuela, remarked: "Arrangements as to spheres of influence are new departures, which certain great European Powers have found necessary and convenient in the course of their division among themselves of great tracts of the continent of Africa, and which find their sanction solely in their reciprocal obligations" (United States No. 2, 1896, p. 27).

Some treaties expressly declare that the arrangement shall not prejudice other powers (Stoerck, Recueil, xvi. p. 932). No doubt, however, the tendency is for spheres of influence to become protectorates. It may be mentioned that Germany and Holland have concluded a treaty (Dec. 21, 1897) by which the latter agrees to extradite German criminals in spheres of influence. By an agreement of the 12th of May 1894 between Great Britain and the Congo State, the former granted to the latter a lease of territories comprised within the sphere of influence laid down in the Anglo-German agreement of the rst of July 1890 (19 Herrert, p. 170).

Somewhat akin to the rights of a state in a sphere of influence are those possessory in Germany in the zone surrounding the protectorate of Kiaochow under the treaty of the 6th of March 1898, and the rights obtained under treaties with China that certain provinces shall not be alienated.

Somewhat similar arrangements as to ports of the sea are not unknown. Grotius in his Mare liberum says: "Ilud interim fatemur, potuisse inter gentes aligus convenire, ut capti in mariis hac vel illa parte, hujus aut illius republcae judicium subintret, atque ita ad commoditatem distinguendae jurisdictionis in mari fines describit, quod ipsos non quidem sibi legem ferentes obligat, aliis populos non item; neque locum cuius propriae facit, sed in personas contradontium jus constituit" (c. 3).

The best known example of a claim to a sphere of influence, which is not the result of any treaty, is the Monroe doctrine, first broached by President Monroe in 1823. The Romans had their equivalent to the Monroe doctrine; they forbade any Asiatic king entering Europe and conquering any part of it; the breach of this rule was their chief grievance against Mithridates (Montesquieu, De la Grandeur et de la décadence des romains (c. 6).

Claims somewhat similar to those relating to spheres of influence have been put forward as against the whole world, in virtue of the right of continuity or the doctrine of the hinterland. Sometimes it is called the "doctrine of contiguity," or "droit de vicinauté, de priorité, de préemption ou d'enclave." He who occupies a part of a well-defined close or fundus, a parcel of land with artificial or natural boundaries, which enables him to control the whole area, may be said to occupy it. He need not be present everywhere, or enter on every part of it: "Sufficit quamlibet partem ejus fundi introire, dum mente et cogitatione haec sit, uti totum fundum usque ad terminum velit possidere" (Dig. xli. 2. 3). In virtue of a supposed analogy to such occupation, it has been said that the occupation of the mouth of a river is constructive occupation of all its basin and tributaries, and that the occupation of part of a territory extends to all the country of which it forms physically a part. A state, having actually occupied the coast, may claim to reserve to itself the right of occupying from time to time territory lying inland (hinterland). In the discussions as to the western boundary of the state of Louisiana between the commissioners of the United States and Spain, as to Oregon, as to the claims of the Portuguese in East Africa, and as to the boundaries of Venezuela, the question of the extent of the rights of the discoverer and occupier came up. Portugal actually claimed all territory lying between her African possessions. It has been urged that the subsequent settlement within a reasonable time of the mouth of a river, particularly if none of its branches had been explored prior to such discovery, gave the right of occupation, and ultimately of sovereignty, to the whole country drained by such river and its several branches. Another form of the same doctrine is that the occupier of a part of the sea-coast thereby acquires rights "extending into the interior of the country to the sources of the rivers emptying within that coast, to all their branches, and the country they cover" (Twiss, Laws of Nations in Time of Peace, p. 170; Twiss, Oregon Question, p. 245; Bluntschi, s. 282; Phillimore, Commentaries, p. 236; Westlake, International Law, pt. i. p. 128). Lord Salisbury referred to "the modern doctrine of hinterland with its inevitable contradictions" (United States, No. 2, 1896, p. 12). Certainly it is inconsistent with the doctrine, more and more received in recent times, that effective possession is necessary to found a title to sovereignty or control. An extravagant claim of the early Portuguese and Spanish navigators to territory on which they had never set foot or eyes. The doctrine of the hinterland is likely to become less important, now that Africa has been parcelled out.

B. Moore, Digest of International Law (1906), i. 268.

Spherical Harmonics, in mathematics, certain functions of fundamental importance in the mathematical theories of gravitation, electricity, hydrodynamics, and in other branches of physics. The term "spherical harmonic" is due to Lord Kelvin, and is primarily employed to denote either a rational integral homogeneous function of three variables \( x, y, z \), which satisfies the differential equation

\[
\nabla^2 \psi + \frac{1}{x^2 + y^2 + z^2} \psi = 0.
\]

known as Laplace's equation, or a function which satisfies the differential equation, and becomes a rational integral homogeneous function when multiplied by a power of \((x^2+y^2+z^2)^n\).
Spherical Harmonics

Of all particular integrals of Laplace's equation, these are of the greatest importance in respect of their applications, and were the only ones considered by the earlier investigators; the solutions of potential problems in which the bounding surfaces are exactly or approximately spherical are usually expressed as series in these spherical harmonics. In the wider sense of the term, a spherical harmonic is any harmonic function of the variables which satisfies Laplace's equation, the degree of the function being not necessarily integral or real, and the functions are not necessarily rational in \(x, y, z\), or single-valued; when the term spherical harmonic is used in the narrower sense, the functions may, when necessary, be termed ordinary spherical harmonics. For the treatment of potential problems which relate to spaces bounded by special kinds of surfaces, solutions of Laplace's equation are required which are adapted to the particular boundaries, and various classes of such solutions have thus been introduced into analysis. Such functions are usually of a more complicated structure than ordinary spherical harmonics, although they possess analogous properties. As examples we may cite Bessel's functions in connexion with circular cylinders, Lamé's functions in connexion with ellipsoids, and toroidal functions for anchor rings. The theory of such functions may be regarded as embraced under the general term harmonic analysis. The present article contains an account of the principal properties of ordinary spherical harmonics, and some indications of the nature and properties of the more important of the other classes of functions which occur in harmonic analysis. Spherical and other harmonic functions are of additional importance in the fact that they are largely employed in the treatment of the partial differential equations of physics, other than Laplace's equation; as examples of this, we may refer to the equation \(\frac{\partial^4 u}{\partial x^4} + \frac{\partial^4 u}{\partial y^4} + \frac{\partial^4 u}{\partial z^4} = 0\), or \(\nabla^4 u = 0\), (1) is termed a solid spherical harmonic, or simply a spherical harmonic of degree \(n\). The degree \(n\) may be fractional or imaginary, but we are here concerned mainly with the case in which \(n\) is a positive or negative integer. If \(x, y, z\) be replaced by their values \(r \cos \phi, r \sin \phi, r \cos \theta\) in polar co-ordinates, a solid spherical harmonic takes the form \(T(\phi, \theta)\); the factor \(T(\phi, \theta)\) is called a surface harmonic of degree \(n\). If \(V_n\) denote a spherical harmonic of degree \(n\), it may be shown by differentiation that \(\nabla V_n = m(2n + m + 1)^{-1/2}V_n\), and thus as a particular case that \(\nabla V_n = 0\); we have thus the fundamental theorem that any spherical harmonic of degree \(n\), another of degree \(-n-1\) may be derived by \(V_n\) by \(\nabla V_n\). All spherical harmonics of negative integral degree are obtainable in this way from those of positive integral degree. This theorem is a particular case of the more general inversion theorem that if \(F(x, y, z)\) is any function which satisfies the equation (1), the function

\[ \frac{1}{F(x, y, z, z)} \]

also satisfies the equation.

The ordinary spherical harmonics of positive integral degree \(n\) are those which are rational integral functions of \(x, y, z\). The most general integral function of degree \(n\) in three letters contains \(\binom{n}{2}(n+2)\) coefficients; if the expression be substituted in (1), we have on equating the coefficients separately to zero \(\binom{n}{2}(n+2)\) relations to be satisfied; the most general spherical harmonic of the prescribed type therefore contains \(\binom{n}{2}(n+2) - \frac{3n(n-1)}{2} = \binom{n-1}{n}\), or \(n+1\) independent constants. There exist, therefore, \(n+1\) independent ordinary harmonics of degree \(n\); and corresponding to each of these there is a negative harmonic of degree \(-n-1\) obtained by dividing by \(\sin\theta\). The three independent harmonics of degree 1 are \(x, y, z\); the five of degree 2 are \(x^2 - y^2, x^2, y^2, xy, x, y\). Every harmonic of degree \(n\) is a linear function of \(n+1\) independent harmonics of the degree; we proceed, therefore, to find the latter.

2. Determination of Harmonics of given Degree.—It is clear that a function \(f(ax+by+cz)\) satisfies the equation (1), if \(a, b, c\) are constants which satisfy the condition \(a^2 + b^2 + c^2 = 0\); in particular the equation is satisfied by \((x+ix \cos a+iy \sin a)^n\). Taking \(n\) to be a positive integer, we proceed to expand this expression in a series of cosines and sines of multiples of \(a\); each term will then satisfy (1) separately. Denoting \(e^{it}\) by \(k\), and \(x+iy\) by \(l\), we have

\[ (x+ix \cos a+iy \sin a)^n = (x + 2l^n)^n \]

which may be written as \((2k)^n((2k)^n - r^n)\). On expansion by Taylor's theorem this becomes

\[ (2k)^n \sum_{r=0}^{n} \frac{1}{r!} \frac{\partial^n}{\partial x^n} (x-r)^n \]

the differentiation applying to \(x\) only as it occurs explicitly; the terms involving \(cos ma, sin ma\) in this expansion are

\[ \frac{1}{2^n} cos ma \left\{ \begin{array}{c} \left( \frac{2}{2n} \right)^n \cos (n-m) \right\} \]

\[ \frac{1}{2^n} \sin ma \left\{ \begin{array}{c} \left( \frac{2}{2n} \right)^n \sin (n-m) \right\} \]

where \(m = 1, 2, \ldots n\); and the term independent of \(a\) is

\[ \frac{1}{2^n} \sum_{r=0}^{n} \frac{1}{r!} \frac{\partial^n}{\partial x^n} (x-r)^n \]

On writing

\[ (x+iy)^n = \cos m(\cos a, \sin ma)^n, (x+iy)^n = \sin m(\cos a, \sin ma)^n \]

and observing that in the expansion of \((x+ix \cos a+iy \sin a)^n\) the expressions \(cos ma, sin ma\) can only occur in the combination \(\cos m(a-\omega), \sin m(a-\omega)\), we see that the relation

\[ \cos m(a-\omega) = \cos m(a-\omega) \]

must hold identically, and that the terms in the expansion reduce to

\[ \frac{1}{2^n} \sum_{r=0}^{n} \frac{1}{r!} \frac{\partial^n}{\partial x^n} (x-r)^n \]

We thus see that the spherical harmonics of degree \(n\) are of the form

\[ \sum_{r=0}^{n} \frac{1}{2^n} \sum_{m=-n}^{n} \cos m(\cos a, \sin ma)^n \]

where \(m\) denotes \(\cos \theta\); by giving the values \(0, 1, 2, \ldots n\) we thus obtain the \(2n+1\) functions required. On carrying out the differentiation we see that the required functions are of the form

\[ A(x+iy)^n = (x-iy)^n \]

writing \(P_n(x)\) we observe that \(P_n(x)\) is zeros all lying between \(\pm 1\); consequently the locus of points on a sphere \(r=a\), for which \(P_n(x)\) vanishes is \(n\) circles all parallel to the meridian plane; these circles divide the sphere into zones, thus \(P_n(x)\) is called the zonal surface harmonic of degree \(n\), and \(P_n(x)\) the solid zonal harmonics of degree \(n\) and \(-n-1\). The locus of points on a

3. Zonal, Tesselal and Sectorial Harmonics.—Of the system of \(2n+1\) harmonics of degree \(n\), only one is symmetrical about the \(z\) axis; this is

\[ \frac{1}{2^n} \sum_{m=-n}^{n} \frac{1}{2^n} \frac{1}{\sin \theta} \frac{\partial^n}{\partial x^n} (x-r)^n \]

writing

\[ P_n(x) \]

we observe that \(P_n(x)\) is zero at \(\pm n\) lying at \(\pm 1\), consequently the locus of points on a sphere \(r=a\), for which \(P_n(x)\) vanishes is \(n\) circles all parallel to the meridian plane; these circles divide the sphere into quadrilaterals or \(\theta\) surfaces, except when \(n=m\), in which case the surface is divided into sectors, and the harmonics are therefore called tesselal, except those for which \(m=n\), which are called sectorial. Denoting \(1-\mu^2\) by \(\mu^2\) by \(\mu^2\), the tesselal surface harmonics are \(\cos \sin \theta, \sin \phi, \sin \phi \cos \theta\), where \(m=1, 2, \ldots n-1\), and the sectorial harmonics are \(\cos \sin \theta, \cos \theta\). The functions

\[ P_n(x) \]

\(1\) denote the expressions
SPHERICAL HARMONICS

\[ P_n^m(\theta, \phi) = \frac{(-1)^m}{2^n n!} \frac{\partial}{\partial \theta} \left( \frac{\partial}{\partial \theta} P_n^m(\theta, \phi) \right) \]

where \( P_n^m(\theta, \phi) \) is a spherical harmonic of degree \( n \) and order \( m \).

5. Maxwell's Theory of Poles.—Before proceeding to obtain by means of (7), the expressions for the zonal, tesseral and sectoral harmonics, it is convenient to introduce the conception, due to Maxwell (see Electricity and Magnetism, vol. i. ch. ix.), of the poles of a spherical harmonic. Suppose a sphere of any radius drawn with its centre at any line whose direction-cosines are \( l, m, n \) drawn from the origin, is called an axis, and the point where this axis cuts the sphere is called the pole of the axis. Different axes will be denoted by suffixes attached to the direction-cosines; the cosine \((l\cdot x+m\cdot y+n\cdot z)/r\) of the angle between the radius vector \( r \) to a point \((x,y,z)\) and the axis \((l,m,n)\), will be denoted by \( \lambda \); the cosine of the angle between two axes \( l_1, m_1, n_1 \) and \( l_2, m_2, n_2 \) will be denoted by \( \mu \).

The operation

\[ \frac{\partial}{\partial \theta} \frac{\partial}{\partial \theta} \left( \frac{\partial}{\partial \theta} \frac{\partial}{\partial \theta} \right) \]

performed upon any function of \( x, y, z \), is spoken of as differentiation with respect to the axis \((l, m, n)\), and is denoted by \( \partial/\partial \theta \).

The potential function \( V_0=\varepsilon_0/r \) is defined to be the potential due to a singular point of degree zero at the origin; \( \varepsilon_0 \) is called the strength of the singular point. Let a singular point of degree zero, and strength \( \varepsilon_0 \), be on an axis \( h_1 \) at a distance \( \omega \) from the origin, and also suppose that the origin is a singular point of strength \(-\varepsilon_1\); let \( \varepsilon_1 \) be indefinitely increased, and \( \varepsilon_0 \) indefinitely diminished, but so that the product \( \varepsilon_0 \varepsilon_1 \) is finite and equal to \( \varepsilon_0 \); the origin is then said to be a singular point of the first degree, of strength \( \varepsilon_1 \), the axis being \( h_1 \). Such a singular point is frequently called a doublet. In a similar manner, by placing two singular points of degree, unity and strength, \( \varepsilon_1 \), \( -\varepsilon_1 \), at a distance \( s \) along an axis \( h_2 \) at and the origin respectively, when \( \varepsilon_1 \) is indefinitely increased, and \( -\varepsilon_1 \) diminished so that \( \varepsilon_1 \) is finite and \(-\varepsilon_1 \) we obtain a singular point of degree 2, strength \( \varepsilon_2 \) at the origin, the axes being \( h_1, h_2 \). Proceeding in this manner we arrive at the conception of a singular pole of any degree \( n \), of strength \( \varepsilon_1 \) at the origin, the singular point having any \( n \) given axes, \( h_1, h_2, \ldots, h_n \). If \( \varepsilon_{n-1} = \phi \) \((x, y, z)\), \( \varepsilon_1 \) is the potential due to a singular point at the origin, of degree \( n-1 \), and strength \( \varepsilon_n \), with axes \( h_1, h_2, \ldots, h_n \), the potential of a singular point of degree \( n \), the new axis of which is \( h_n \), is the limit of

\[ \varepsilon_{n-1} + \frac{\partial^2}{\partial x^2} \left( \varepsilon_{n-1} + \frac{\partial^2}{\partial x^2} \left( \varepsilon_{n-1} + \cdots \right) \right) \]

as \( \varepsilon_1 \) is increased indefinitely, and \( \varepsilon_0 \) diminished till it is zero.

6. Expression for a Harmonic with given Poles.—The result of performing the operations in (8) is that \( V_n \) is of the form

\[ Y_n = \left( \frac{2\pi}{n!} \right)^{1/2} \sum_{l=0}^{n} \frac{(-1)^l}{l!} \frac{\partial^l}{\partial x^l} \frac{\partial^l}{\partial y^l} \frac{\partial^l}{\partial z^l} X_n \]

where \( X_n \) is a surface harmonic of degree \( n \), and \( \mu = \mu_1, \ldots, \mu_n \) are the direction-cosines of the normals to the surfaces of zero potential, with \( \mu_0 = 1 \), and \( n = 2 \) is the number of the poles.

In order to express \( Y_n \) in terms of the positions of its poles, we apply the theorem (7) to the evaluation of \( V_n \) in (8). On putting

\[ f_{x,y,z}(x, y, z) = \Pi(l_1, m_1, y, z, x, n_1) \]

we have

\[ Y_n(\mu'\lambda'x') = \sum_{l=0}^{n} \frac{(-1)^l}{l!} \frac{\partial^l}{\partial x^l} \frac{\partial^l}{\partial y^l} \frac{\partial^l}{\partial z^l} X_n(\mu'\lambda'x') \]

and generally

\[ D_{n,l}(\mu'\lambda'x') = \sum_{l=0}^{n} \frac{(-1)^l}{l!} \frac{\partial^l}{\partial x^l} \frac{\partial^l}{\partial y^l} \frac{\partial^l}{\partial z^l} X_n(\mu'\lambda'x') \]

where \( D_{n,l} \) denotes a summation with respect to \( m \) from \( m=0 \) to \( m=n \), or \( m=n-1 \), according as \( n \) is even or odd. This is Maxwell's general expression (loc. cit.) for a surface harmonic with given poles.

If the poles on a sphere of radius \( r \) are denoted by \( A, B, C, \ldots \), we obtain from (9) the following expressions for the harmonics of the first four degrees:

\[ Y_1 = \cos PA, Y_2 = l(\cos PA \cos PB - \cos AB), Y_3 = l(15 \cos PA \cos PB \cos PC - \cos PA \cos PC \cos BC - \cos PB \cos PC \cos CA) \]

\[ Y_4 = (l(35 \cos PA \cos PB \cos PC \cos PD - 52 \cos PA \cos PB \cos PC \cos CD) + 2 \cos AB \cos CD) \]

7. Poles of Zonal, Tesseral and Sectoral Harmonics.—Let the axes of the harmonic coincide with the axes of \( z \); we have then by (8) the harmonic

\[ Y_n = \frac{(-1)^n}{n!} \frac{\partial^n}{\partial x^n} \frac{\partial^n}{\partial y^n} \frac{\partial^n}{\partial z^n} \]

as the strength of the singular point.
applied to the theorem (2) to evaluate this expression, we have
\[
\left(\frac{-1}{n^2}\left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2\right) = 2\pi^2 n^2 \mathbf{P}_n(x, y, z) = 2\pi^2 n^2 \mathbf{P}_n(x, y, z),
\]
the expression on the right is \(\mathbf{P}_n(x, y, z)\), the zonal surface harmonic; we therefore have
\[
P_n(x, y, z) = \frac{(-1)^{n+1} \pi}{n!} \left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2.
\]

The zonal harmonic has therefore all its poles coincident with the \(x\) axis. Next, suppose \(n = m\) axes coincide with the \(z\) axis, and that the remaining \(m\) axes are distributed symmetrically in the plane of \(x, y\) at intervals \(\gamma\); the direction cosines of one of them being \(\cos a, \sin a, 0\). We have
\[
\Pi_0 \{ e^{i\tau \gamma x} \left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2 \} = \frac{(-1)^{n+1} \pi}{n!} \left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2.
\]

Next, evaluate the second term of (1) to be done.

It is well known that if any non-conjugate pair of roots is taken, the corresponding factor, and therefore the pole, is imaginary. There is therefore only one system of real poles of a given harmonic, and its determination requires the solution of an equation of degree 2\(n\). This theorem is due to Sylvester (Phil. Mag. (1876), 5th series, vol. ii., p. 2. A Note on Spherical Harmonics, etc.).

9. Expression for the Zonal Harmonic with any Axis.—The zonal surface harmonic, whose axis is in the direction \(z = y = 0\), is
\[
P_n(x, y, z) = \frac{(-1)^{n+1} \pi}{n!} \left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2,
\]
which is real. It is obvious that if any non-conjugate pair of roots is taken, the corresponding factor, and therefore the pole, is imaginary. There is therefore only one system of real poles of a given harmonic, and its determination requires the solution of an equation of degree 2\(n\). This theorem is due to Sylvester (Phil. Mag. (1876), 5th series, vol. ii., p. 2. A Note on Spherical Harmonics, etc.).

Similarly the coefficient of \(e^{i\tau \gamma x} + e^{-i\tau \gamma x}\) in the expansion of \(e^{i\tau \gamma x} + e^{-i\tau \gamma x}\) in powers of \(e^{i\tau \gamma x} + e^{-i\tau \gamma x}\), this has been already found, thus the coefficient is
\[
P_n(x, y, z) = \frac{(-1)^{n+1} \pi}{n!} \left(\frac{\partial}{\partial x} + i\frac{\partial}{\partial y}\right)x^2 + y^2 - z^2.
\]

In this result, change \(x, y, z\) into
\[
\frac{\partial}{\partial \theta} \left\{ \frac{\partial}{\partial \phi} \right\} \theta, \phi.
\]
and let each side operate on $1/r$, then in virtue of (10), we have

$$(r')^* P_n(r') = P_n(r) = \frac{x^2 - y^2 + z^2}{r^2} = P_n(\cos \theta \cos \phi + \sin \theta \sin \phi \cos \phi)$$

$= P_n(\cos \theta) P_n(\cos \phi) + 2 \sum_{m}(n+m) \frac{(-1)^m}{n+m} \binom{n}{m} P_n(\cos \theta)[\cos \phi (6-\phi)]$ (11)

which is known as the addition theorem for the function $P_n$. It has incidentally been proved that

$$P_n(\cos \theta) = \frac{n(n+m)}{2 \sin \theta (n-m+1) \cos \theta - m} P_n(\cos \theta) + \cos \theta \sin \theta +$$

which is an expression for $P_n(\cos \theta)$ alternative to (4).

10. Legendre's Coefficients.—The reciprocal of the distance of a point $(r, \theta, \phi)$ from a point on the z-axis distant $r'$ from the origin is

$$(r^2 - 2rr' \mu + r'^2 \mu^2)^{-\frac{1}{2}}$$

and when $r > r'$, the expression can be expanded in a convergent series of powers of $r/r'$, and when $r < r'$ in a convergent series of powers of $r/r'$. We have, when $h(2\mu - h)^{-1}< 1$

$$(1 - 2h + h^2)^{\frac{1}{2}} = 1 + h(2\mu - h) + \frac{1}{2}h^2(2\mu - h)^2 + \frac{1}{2} \frac{1}{2} \sum_{n=1}^{\infty} \frac{1}{n} (2\mu - h)^n$$

and since the series is absolutely convergent, it may be rearranged as a series of powers of $h$, the coefficient of $h^n$ is found to be

$$\frac{1}{n(n-1)} (2\mu - h)^{n}$$

which is the expansion we have already expressed by $P_n(\mu)$; thus

$$(1 - 2h + h^2)^{\frac{1}{2}} = P_n(\mu) + hP_n(\mu) + \ldots = \mu P_n(\mu) + \ldots$$ (13)

the function $P_n(\mu)$ may thus be defined as the coefficient of $\mu^n$ in this expansion, and from this point of view is called the Legendre's coefficient or Legendre's function of degree $n$, and is identical with $h^n$ in the zonal harmonic. It may be shown that the expansion is valid for all real and complex values of $h$ and $\mu$, such that mod. $h$ is less than the smaller of the two numbers mod. ($\mu = \sqrt{\mu^2 - 1}$). We now see that

is expressible in the form

$$\sum_{r=0}^{\infty} \frac{n!}{r!} P_r(\mu)$$

when $r < r'$, or

$$\sum_{r=0}^{\infty} \frac{n!}{r!} P_r(\mu)$$

when $r' < r$; it follows that the two expressions $r^2 P_n(\mu), r^n P_n(\mu)$ are solutions of Laplace's equation.

The values of the first few Legendre's coefficients are

$P_0(\mu) = 1, P_1(\mu) = \mu, P_2(\mu) = \mu(2\mu - 3), P_3(\mu) = \mu(3\mu^2 - 10\mu + 3)$

$P_4(\mu) = \frac{1}{16}(23\mu^4 - 231\mu^2 + 295), P_5(\mu) = \frac{1}{16}(429\mu^5 - 693\mu^3)$

We find also

$$P_n(1) = 1, P_n(-1) = (-1)^n$$

$P_n(0) = 0$, or $(-1)^n P_n(1)$

according as $n$ is odd or even; these values may be at once obtained from the expansion (13), by putting $\mu = 1, 0, -1$.

11. Additional Expressions for Legendre's Coefficients.—The expression (3) for $P_n(\mu)$ may be written in the form

$$P_n(\mu) = \frac{(2n)!}{2^n n!} \frac{1}{(\mu^2 - 1)^{\frac{1}{2}}}$$

with the usual notation for hypergeometric series.

On writing this series in the reverse order

$$P_n(\mu) = \frac{(-1)^n}{2^n} \frac{n!}{(n+1)!} \frac{1}{(\mu^2 - 1)^{\frac{1}{2}}}$$

or

$$(-1)^n \frac{n!}{2^n \mu n - 1} \frac{1}{n-1} \frac{1}{(\mu^2 - 1)^{\frac{1}{2}}}$$

according as $n$ is even or odd.

From the identity

$$(1 - 2h \cos \theta + h^2)^{-\frac{1}{2}} = (1 - h^2 \cos \theta)^{-\frac{1}{2}}$$

we may show that

$$P_n(\cos \theta) = \frac{1}{2} \left( \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right)$$

where it is shown that

$$P_n(\cos \theta) = \frac{1}{2} \left[ \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right]$$

which is known as Rodrigue's formula, we may prove that

$$P_n(\cos \theta) = \frac{1}{2} \left[ \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right]$$

and

$$P_n(\cos \theta) = \frac{1}{2} \left[ \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right]$$

By (13), or by the formula

$$P_n(\mu) = \frac{1}{2} \frac{d}{d\mu} \left( \frac{\mu^n}{(\mu^2 - 1)^{\frac{1}{2}}} \right)$$

which is known as Rodrigue's formula, we may prove that

$$P_n(\cos \theta) = \frac{1}{2} \left[ \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right]$$

and

$$P_n(\cos \theta) = \frac{1}{2} \left[ \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} \frac{(n+2)!}{(n+1)!} \frac{1}{(\cos \theta)^{n+1}} \right]$$

By means of the identity

$$(1 - 2h\mu + h^2)^{-\frac{1}{2}} = (1 - h\mu)^{-\frac{1}{2}}$$

it may be shown that

$$P_n(\cos \theta) = \cos \theta P_n(\cos \theta)$$

and

$$(1 - 2h\mu + h^2)^{-\frac{1}{2}} = (1 - h\mu)^{-\frac{1}{2}}$$

Laplace's definite integral expression (6) may be transformed into the expression

$$\frac{1}{2} \int_{0}^{\pi} \frac{d\phi}{\sin \theta}$$

by means of the relation

$$(\mu + \sqrt{\mu^2 - 1} \cos \phi \phi = \sqrt{\mu^2 - 1} \cos \phi \phi = 1)$$

Two definite integral expressions for $P_n(\mu)$ given by Dirichlet have been put by Mellier into the forms

$$P_n(\cos \theta) = \int_{\theta}^{\pi} \cos \theta \frac{\cos (n+1) \phi}{\cos \phi} \cos \phi = \frac{1}{2} \int_{\theta}^{\pi} \cos \theta \frac{\sin (n+1) \phi}{\cos \phi} \cos \phi$$

When $n$ is large and $\theta$ is not nearly equal to $\phi$ or $\pi$, an approximate value of $P_n(\cos \theta)$ is $[\frac{1}{2\sin n \theta}] \sin (n+1) \theta + (n+1) \theta$

12. Relations between successive Legendre's Coefficients and their Derivatives.—If $(1 - 2h\mu + h^2)^{-\frac{1}{2}}$ is denoted by $u$, we find

$$(1 - 2h\mu + h^2)^{-\frac{1}{2}} (1) \mu = 0;$$

on substituting $\mu P_n$, for $u$, and equating to zero the coefficient of $h^n$, we obtain the relation

$$nP_n(2n-1)P_{n-1} + (n-1)P_{n-2} = 0.$$
Spherical Harmonics

On integrating the expression \( k \) times by parts, and remembering that \((\mu^2-1)I\) and its first \( n \) derivative all vanish when \( \mu = \pm 1 \), the theorem is established. This theorem derives additional importance from the fact that it may be shown that \( AP_\mu(\mu) \) is the only rational integral function of degree \( n \) which has this property; from this arises the importance of the functions \( P_\mu \) in the theory of quadratures.

The theorem which lies at the root of the applicability of the functions \( P_\mu \) to potential problems is that if \( n \) and \( n' \) are unequal integers

\[ \int_{-1}^{1} P_n(\mu)P_{n'}(\mu) d\mu = 0, \quad (19) \]

which may be stated by saying that the integral of the product of two Legendre's coefficients of different degree taken over the whole of a spherical surface with its centre at the origin is zero; this is the fundamental harmonic property of the functions. It is immediately deducible from (18), for if \( n' = n \), \( P_n(\mu) \) is a linear function of powers of \( \mu \), whose indices are all less than \( n \).

When \( n' = n \), the integral in (19) becomes

\[ \int_{-1}^{1} |P_n(\mu)|^2 d\mu; \]

evaluate this write it in the form

\[ \int_{-1}^{1} \left( \frac{1}{2n+1} \right)^{n} d\mu = 0, \quad (20) \]

14. Expansion of Functions in Series of Legendre's Coefficients. — If it be assumed that a function \( f(\mu) \) given by

\[ f(\mu) = \sum_{n=0}^{\infty} a_n P_n(\mu), \]

which on putting

\[ u = \frac{1}{2}(1-\mu), \]

hence

\[ \sum_{n=0}^{\infty} a_n \int_{-1}^{1} P_n(\mu) d\mu = \frac{2}{2n+1} \int_{-1}^{1} f(\mu) d\mu, \quad (21) \]

The proof of the possibility of this representation, including the investigation of sufficient conditions as to the nature of the function \( f(\mu) \), that the series may in general converge to the value of the function requires an investigation, for which we have not space, similar in character to the corresponding investigations for series of circular functions (see FOURIER's SERIES). A complete investigation of this matter is given by Hobson, Proc. Lond. Math. Soc., 2nd series, vol. 6, p. 388, and vol. 7, p. 24. See also Dini's Serie di Fourier.

The expansion may be applied to the determination at an external and an internal point of the potential due to a distribution of matter of surface density \( f(\mu) \) placed on a spherical surface \( r = a \). If

\[ V_1 = \sum_{n=0}^{\infty} a_n P_n(\mu), \quad V_2 = \sum_{n=0}^{\infty} a_n^2 P_n(\mu), \]

we see that \( V_1, V_2 \) have the characteristic properties of potential functions for the spaces internal to, and external to, the spherical surface respectively; moreover, the condition that \( V_1 \) is continuous with \( V_2 \) at the surface \( r = a \), is satisfied. The density of a surface distribution which produces these potentials is in accordance with a known theorem in the potential theory, given by

\[ \sigma = \frac{1}{4\pi} \left( \frac{\partial V_1}{\partial r} \frac{\partial V_2}{\partial r} \right) r = a, \]

hence

\[ \sigma = \frac{1}{4\pi} \left( \frac{\partial V_1}{\partial r} \frac{\partial V_2}{\partial r} \right) \frac{1}{(2n+1)} \]

are the required expression for the internal and external potentials due to the distribution of surface density \( f(\mu) \).

15. Integral Properties of Spherical Harmonics. — The fundamental property of spherical harmonics, of which property (19) is a particular case, is that if \( Y_\mu(x, y, z) \), \( Z_\mu(x, y, z) \) be two (ordinary) spherical harmonics, then

\[ \int_{-1}^{1} Y_\mu(x, y, z) Z_\mu(x, y, z) d\mu = 0, \quad (22) \]

when \( n' = n \) and \( n' \) are unequal, the integration being taken for every element \( d\mu \) of a spherical surface, of which the origin is the centre. Since \( \nabla^2 Y_\mu = 0, \nabla^2 Z_\mu = 0 \), we have

\[ \int_{0}^{2\pi} \int_{0}^{\pi} (\nabla \cdot \nabla') Y_\mu \nabla'' Z_\mu \sin \theta \sin \phi \sin \theta' \sin \phi' \sin \theta'' \sin \phi'' \sin \theta''' \sin \phi''' \sin \theta'''' \sin \phi'''' d\phi d\theta = 0, \]

by a well-known theorem in the integral calculus, the integral may be replaced by a surface integral over the spherical surface; we thus obtain

\[ \int_{0}^{2\pi} \int_{0}^{\pi} \left( \nabla \cdot \nabla' \right) Y_\mu \nabla'' Z_\mu \sin \theta \sin \phi \sin \theta' \sin \phi' \sin \theta'' \sin \phi'' \sin \theta'''' \sin \phi'''' d\phi d\theta = 0, \]

on using Euler's theorem for homogeneous functions, this becomes

\[ n' + n \int_{0}^{2\pi} \int_{0}^{\pi} Y_\mu \nabla'' Z_\mu \sin \theta \sin \phi \sin \theta' \sin \phi' \sin \theta'' \sin \phi'' \sin \theta'''' \sin \phi'''' d\phi d\theta = 0, \]

whence the theorem (22), which is due to Laplace, is proved.

The integral over a spherical surface of the product of a spherical harmonic of degree \( n \), and a zonal surface harmonic \( P_{m}(\mu) \), of the same pole, of which is at \((x', y', z') \) is given by

\[ \int_{0}^{2\pi} \int_{0}^{\pi} Y_\mu(x, y, z) P_{m}(\mu) d\phi d\theta = \frac{2\pi}{4\pi} \delta_{m,n} Y_\mu(x', y', z'), \quad (23) \]

This theorem may also be written

\[ \int_{0}^{2\pi} \int_{0}^{\pi} Y_\mu(x, y, z) P_{m}(\mu) d\phi d\theta = \frac{2\pi}{4\pi} \delta_{m,n} Y_\mu(x', y', z'), \quad (23) \]

To prove the theorem, we observe that \( V_\mu \) is of the form

\[ \frac{2\pi}{4\pi} \delta_{m,n} Y_\mu(x', y', z'), \quad (23) \]

to determine \( a_0 \) we observe that when \( m = 1 \),

\[ P_1(\mu) = 1, \quad P_1^*(\mu) = 0, \]

hence \( a_0 \) is equal to the value \( V_0(0) \) of \( V_\mu(\theta, \phi) \) at the pole \( \theta = 0 \) of \( P_1(\mu) \). Multiply by \( P_1(\mu) \) and integrate over the space of radius unity, we thus have

\[ \int_{0}^{2\pi} \int_{0}^{\pi} Y_\mu(\theta, \phi) P_1(\mu) d\phi d\theta = \frac{2\pi}{4\pi} \delta_{m,n} Y_\mu(x', y', z'), \quad (23) \]

if instead of taking \( m = 1 \) as the pole of \( P_1(\mu) \) we take any other point \((\mu', \phi') \) we obtain the theorem (23).

If \( f(x, y, z) \) is a function which is finite and continuous throughout the interior of a sphere of radius \( R \), it may be shown that

\[ \int_{0}^{2\pi} \int_{0}^{\pi} f(x, y, z) d\phi d\theta = 4\pi R^2 \int_{0}^{2\pi} \int_{0}^{\pi} \frac{1}{R} \frac{\partial f}{\partial r} \sin^{n-1} \theta \sin \phi d\theta d\phi, \]

where \( x, y, z \) are put equal to zero after the functions have been performed, the integral being taken over the surface of the sphere of radius \( R \) (see Hobson, "On the Evaluation of a certain Surface Integral," Proc. Lond. Math. Soc. vol. xxv).

The following case of this theorem should be remarked: If \( f(x, y, z) \) is homogeneous and of degree \( n \)

\[ \int_{0}^{2\pi} \int_{0}^{\pi} f(x, y, z) d\phi d\theta = 4\pi R^2 n! \int_{0}^{2\pi} \int_{0}^{\pi} \frac{1}{R} \frac{\partial f}{\partial r} \sin^{n-1} \theta \sin \phi d\theta d\phi, \]

if \( f(x, y, z) \) is a spherical harmonic, we obtain from this a theorem, due to Maxwell (Electricity, vol. i. ch. ix.),

\[ \int_{0}^{2\pi} \int_{0}^{\pi} f(x, y, z) d\phi d\theta = 4\pi R^2 n! \int_{0}^{2\pi} \int_{0}^{\pi} \frac{1}{R} \frac{\partial f}{\partial r} \sin^{n-1} \theta \sin \phi d\theta d\phi, \]
where $h_1, h_2, \ldots, h_n$ are the axes of $Y_n$. Two harmonics of the same degree are said to be conjugate, when the surface integral of their product vanishes; if $Y_n Z_n$ are two such harmonics, the addition of conjugacy is

$$Y_n \left( \frac{\partial}{\partial x} \phi + \frac{\partial}{\partial y} \phi \right) Z_n = 0.$$

Lord Kelvin has shown how to express the conditions that $2n+1$ harmonics of degree $n$ form a conjugate system (see B. A. Report, 1871).

16. Expansion of a Function in a Series of Spherical Harmonics.——

It can be shown that under certain restrictions as to the nature of a function $F(x, \phi)$ given arbitrarily over the surface of a sphere, the function can be represented by a series of spherical harmonics which converges in general uniformly. On this assumption we see that the terms of the series can be found by the use of the theorems (22), (23). Let $F(x, \phi)$ be represented by

$$Y_n \phi, \phi, \phi, \ldots + \frac{\partial}{\partial a} Y_n + Y \phi, \phi, \phi + \ldots \phi,$$

hence the series which represents $F(x, \phi)$ is

$$\sum \int_0^{2\pi} F(x, \phi) Y_n \phi, \phi, \phi + \ldots \phi$$

and determining the solid harmonics $Y_n, Y_n, \ldots$ and then letting $r = 1$, in the result.

Since $\delta y = 2(2n-2\pi+1)Y_n$, we have

$$\sum \int_0^{2\pi} F(x, \phi) Y_n \phi, \phi, \phi + \ldots \phi$$

is the last equation being

$$\sum \int_0^{2\pi} F(x, \phi) Y_n \phi, \phi, \phi + \ldots \phi$$

or $\sum \int_0^{2\pi} F(x, \phi) Y_n \phi, \phi, \phi + \ldots \phi$, if it is even, and

$$\sum \int_0^{2\pi} F(x, \phi) Y_n \phi, \phi, \phi + \ldots \phi,$$

is the normal form, where $Y_n$ satisfies the equation

$$\frac{d}{dx} \left( (1+\mu)^n \right) Y_n = 0.$$
From this form it can be shown that
\[ Q_n(\mu) = \frac{1}{\pi} P_n(\mu) \log \frac{\mu + 1}{\mu - 1} - W_n(\mu), \]
where \( W_n(\mu) \) is a rational integral function of degree \( n-1 \) in \( \mu; \)
it can be shown that this form is in agreement with the definition of \( Q_n(\mu) \) by series, for the case \( m = 1 \). In case \( m < 1 \) it is convenient to use the symbol \( Q_n(\mu) \) for
\[ \frac{1}{\pi} P_n(\mu) \log \frac{\mu + 1}{\mu - 1} - W_n(\mu), \]
which is real when \( \mu \) is real and between \( =1 \), the function \( Q_n(\mu) \) in this case is not the analytical continuation of the function \( Q_n(\mu) \) for \( m > 1 \), but differs from it by an imaginary multiple of \( P_n(\mu) \). It will be observed that \( Q_n(1), Q_n(-1) \) are infinite, and \( Q_n(\mu) =0 \). The function \( W_n(\mu) \) has been expressed by Christoffel in the form
\[ \frac{2n-1}{\pi} P_{n-1}(\mu) + (n-2) P_{n-2}(\mu) + \ldots, \]
and it can also be expressed in the form
\[ \frac{1}{\pi} P_n(\mu) P_{n-1}(\mu) + \frac{1}{\pi} P_n(\mu) P_{n-1}(\mu) + \ldots \]
It can easily be shown that the formula (28) is equivalent to
\[ Q_n(\mu) = \sqrt{2} \int_0^{\pi} \sin \theta d\theta \left\{ (\mu - 1) \int_0^{\pi} \frac{d\mu}{(\mu^2 - 1)^{2n}} \right\}, \]
which is analogous to Rodrigue's expression for \( P_n(\mu) \).
Another expression of a similar character is
\[ Q_n(\mu) = \frac{1}{2} \int_0^{\pi} \frac{\sin \theta}{(\mu^2 - 1)^n} d\theta, \]
which holds for all values of \( \mu \) which are not real and between \( =1 \).
From Neumann's integral can be deduced the formula
\[ Q_n(\mu) = \int_0^{\pi} \frac{d\phi}{\mu + \sqrt{\mu^2 - 1}} \cos \phi, \]
which holds for all values of \( \mu \) which are not real and between \( =1 \), provided the sign of \( \sqrt{\mu^2 - 1} \) is properly chosen; when \( \mu \) is real and greater than \( 1, \sqrt{\mu^2 - 1} \) has its positive value.
By means of the substitution,
\[ \mu = \sqrt{\mu^2 - 1} \cos \phi, \] 
the above integral becomes
\[ Q_n(\mu) = \int_0^{\pi} (n-1) \int_0^{\pi} \frac{d\phi}{(n^2 - 1)^n} \left\{ (\mu - 1) \int_0^{\pi} \frac{d\mu}{(\mu^2 - 1)^{2n}} \right\}, \]
This formula gives a simple means of calculating \( Q_n(\mu) \) for small values of \( n; \) thus
\[ Q_n(\mu) = \int_0^{\pi} d\phi = \frac{1}{2} \int_0^{\pi} \frac{d\phi}{(\mu^2 - 1)^n}, \]
\[ Q_n(\mu) = 2 \log \frac{\mu + 1}{\mu - 1}. \sinh 2 \theta = \mu. \frac{1}{2} \log \frac{\mu + 1}{\mu - 1}. \]
Neumann's integral affords a means of establishing a relation between successive Q functions, thus
\[ n Q_n = -2(\mu - 1) n Q_n + (n - 2) Q_{n-2} \]
\[ = \frac{1}{n} \int_0^{\pi} P_n(\mu) + (n-2) P_{n-2}(\mu) - (n-1) \mu P_{n-1}(\mu) d\mu \]
\[ = - \frac{1}{\mu} \int_0^{\pi} (n-1) \mu P_{n-1}(\mu) d\mu \]
Again, it may similarly be proved that
\[ \frac{dQ_n}{d\mu} = (2n+1) Q_n. \]
19. Legendre Associated Functions.—Returning to the equation
\[ (\mu - 1) \frac{d^2}{d\mu^2} - 2(m+1) \frac{d^2}{d\mu^2} + (m-n)(n+m+1) \sigma = 0, \]
If, in Legendre's equation, we differentiate \( m \) times, we find
\[ (1-\mu^2) \frac{d^m}{d\mu^m} - 2(m+1) \mu \frac{d^m}{d\mu^m} + (n-m)(n+m+1) \sigma = 0; \]
it follows that \( v = \frac{d^m}{d\mu^m} \) hence \( u_m = (\mu^2 - 1)^m \frac{d^m}{d\mu^m} \).
The complete solution of (26) is therefore
\[ u = (\mu - 1)^m \frac{d^m}{d\mu^m} + \mu \frac{d^m}{d\mu^m} \]
when \( \mu \) is real and lies between \( =1 \), the two functions
\[ (1-\mu^2) \frac{d^m}{d\mu^m} + (\mu - 1)^m \frac{d^m}{d\mu^m} \]
are called Legendre's associated functions of degree \( n \) and order \( m \), of the first and second kinds respectively. When \( \mu \) is not real and between \( =1 \), the same names are given to the two functions
\[ (\mu - 1)^m \frac{d^m}{d\mu^m} + (\mu - 1)^m \frac{d^m}{d\mu^m}; \]
in either case the functions may be denoted by \( P_n(\mu), Q_n(\mu) \).
It can be shown that, when \( \mu \) is real and between \( =1 \)
\[ P_n(\mu) = \frac{1}{2^n} (1+\mu) (1-\mu)^{-n} (1+\mu) = 0 \]
\[ (m-n)(n+m+1) P_n(\mu) = 0, \]
\[ (m-n)(n+m+1) P_n(\mu) = 0. \]
20. Bessel's Functions.—If we take for three orthogonal systems of surfaces a system of parallel planes, a system of co-axial circular cylinders perpendicular to the planes, and a system of planes through the axis of the cylinders, the parameters are \( z, \rho, \phi \), the cylindrical co-ordinates; in that case \( H_1 = 1, \) \( H_2 = i, \) \( H_3 = 1/\beta, \) and the equation (25) becomes
\[ \frac{d^2}{d \rho^2} + \frac{\partial^2}{\partial \phi^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} = 0. \]
To find the normal functions which satisfy this equation, we put \( V = Z R \Phi \), when \( Z \) is a function of \( z \) only, \( R \) of \( \rho \) only, and \( \Phi \) of \( \phi \), the equation then becomes
\[ \frac{d^2}{d \rho^2} + \frac{\partial^2}{\partial \phi^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} = 0. \]
That this may be satisfied we must have \( \frac{d^2}{d \rho^2} \) constant, say \( =k^2, \)
\[ \frac{d^2}{d \rho^2} \] constant, say \( =-m^2, \) and \( R, \) for which we write \( u, \) must satisfy the differential equation
\[ \frac{d^2}{d \rho^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} + \left( k^2 - \frac{m^2}{\rho^2} \right) u = 0, \]
that is, as usual, suggests that the normal forms are \( \cos k \phi, \) \( \sin k \phi, \) \( u(k \phi) \), where \( \phi(\rho) \) satisfies the equation
\[ \frac{d^2}{d \rho^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} + \left( 1 - \frac{m^2}{\rho^2} \right) u = 0. \]
This is known as Bessel's equation of order \( m \); the particular case
\[ \frac{d^2}{d \rho^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} + \left( k^2 - \frac{m^2}{\rho^2} \right) u = 0, \]
and similarly for \( m = 0, \) is known as Bessel's equation. If we solve the equation (29) in series, we find by the usual process that it is satisfied by the series
\[ \rho^n \left\{ 1 - \frac{\rho^2}{2.2.4.2} + \frac{\rho^4}{2.4.2.2} + \frac{\rho^4}{2.4.2.2} + \frac{\rho^4}{2.4.2.2} + \cdots \right\} \]
the expression
\[ \frac{\rho^n}{2 \pi^2 \Pi(m) \cdots} \] 
or
\[ \sum_{n=0}^{\infty} \frac{(-1)^n \rho^n}{2 \pi^2 \Pi(m+n) \cdots} \]
is denoted by \( J_\alpha(\rho) \) or \( J_\alpha(\rho) \).
When \( m = 0, \) the solution
\[ \frac{d^2}{d \rho^2} + \frac{\partial}{\partial \phi} \frac{\partial}{\partial \phi} + \frac{1}{2} \cdots \frac{1}{2} \cdots \]
of the equation (30) is denoted by \( J_\alpha(\rho) \) or \( J_\alpha(\rho) \).
The function $J_m(r)$ is called Bessel's function of order $m$, and $J_1(r)$ simply Bessel's function; the series are convergent for all finite values of $r$.

The equation (29) is unaltered by changing $m$ into $-m$, it follows that $J_{-m}(r)$ is a second solution of (29), thus in general

$$u = A J_m(r) + B J_{-m}(r)$$

is the complete primitive of (29). However, in the most important case, that in which $m$ is an integer, the solutions $J_m(r)$, $J_{-m}(r)$ are not distinct, for $J_{-m}(r)$ may be written in the form

$$(\frac{d}{dx})^{-m}\sum_{n=0}^{\infty} \frac{(-1)^n}{\Pi(n-m)\Pi(n)} x^{2n}$$

and may be denoted by $Y_m(x)$. This definition has the advantage of giving a meaning to $Y_m(r)$ in the case when $m$ is an integer, for it may be evaluated as a limiting form $o/o$, and the limit will satisfy the equation (29). The only failing case is when $m$ is half an odd integer; in that case we take $\cos (x^{m})$, $Y_m(x)$ as a second finite solution of the differential equation.

When $m$ is an integer, we have

$$Y_m(x) = (-1)^m \frac{d^m}{dx^m} \left( 1 - \frac{x^2}{2} \right)$$

on carrying out the differentiations, and proceeding to the limit

$$Y_m(x) = J_m(x) \log \frac{2}{x} + \frac{1}{x} \sum_{n=0}^{\infty} \frac{(-1)^n}{\Pi(n-m)\Pi(n)} x^{2n}$$

where $\Pi(n)$ denotes $\Pi(n-1)/\Pi(n)$.

Finally we have the second solution of (30) given by

$$Y_m(x) = J_m(x) \log \frac{2}{x} + \frac{1}{x} \sum_{n=0}^{\infty} \frac{(-1)^n}{\Pi(n-m)\Pi(n)} x^{2n}.$$

21. Relations between Bessel's Functions of Different Orders.—Since

$$e^{\cos \phi} \sin \phi = J_0(\rho \sin \phi)$$

satisfies Laplace's equation, it follows that

$$\cos \phi \sin \phi = J_0(\rho \sin \phi)$$

satisfies the differential equation

$$\frac{\partial^2 u}{\partial \phi^2} + \frac{1}{\sin \phi} \frac{\partial u}{\partial \phi} + u = 0.$$  \hspace{1cm} (31)

The linear character of this equation shows that if $u$ is any solution

$$u = C \cos \phi \sin \phi + D \cos \phi + E \sin \phi$$

or

$$u = C \cos \phi + D \sin \phi$$

thus we have

$$u_m = C \cos^{m+1} \phi + D \cos^m \phi$$

where $C$ is a constant. If $u_n = J_n(\rho \sin \phi)$, we have $u_{n+p} = J_{n+p}(\rho \sin \phi)$, and by comparing the coefficients of $\rho^{n+p}$, we find $C = (-2)^p$, hence

$$J_n(\rho \sin \phi) = (-2)^p \rho^{n+p} \frac{d^p}{d\rho^p} J_n(\rho \sin \phi),$$

and changing $m$ into $-m$, $p$, we have

$$J_{-m}(\rho \sin \phi) = (-2)^p \rho^{m-p} \frac{d^p}{d\rho^p} J_{-m}(\rho \sin \phi).$$

In a similar manner it can be proved that

$$J_m(\rho \sin \phi) = 2\pi \rho^m \frac{d^m}{d\rho^m} J_0(\rho \sin \phi).$$

From the definition of $Y_m(\rho)$, and applying the above analysis, we prove that

$$Y_{m+p}(\rho) = (-2)^p \rho^{m+p} \frac{d^p}{d\rho^p} Y_m(\rho),$$

and

$$Y_{m-p}(\rho) = 2\pi \rho^m \frac{d^m}{d\rho^m} Y_{-m}(\rho).$$

As particular cases of the above formulae, we find

$$J_0(\rho) = (-2)^0 \rho^0 \frac{d^0}{d\rho^0} Y_0(\rho),$$

$$J_1(\rho) = -\frac{d}{d\rho} Y_1(\rho),$$

$$Y_0(\rho) = (-2)^0 \rho^0 \frac{d^0}{d\rho^0} Y_0(\rho),$$

$$Y_1(\rho) = -\frac{d}{d\rho} Y_1(\rho).$$

22. Bessel's Functions as Coefficients in an Expansion.—It is clear that the coefficients $a_0 \sin \phi \cos \phi = a_0 \sin \phi \cos \phi$ satisfy the differential equation (31), hence if these exponentials be expanded in series of cosines and sines of multiples of $\phi$, the coefficients must be Bessel's functions, which it is easy to see are of the first kind. To expand $e^{i\phi}$, and the $e^{i\phi_0} = e^{i\phi} + \nabla e^{i\phi} \sin \phi$, then we have to expand $e^{i\phi}$ in powers of $t$. Multiplying this expansion together the absolute convergent series

$$e^{i\phi} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} t^n e^{i(\phi - n\phi_0)} \sum_{m=1}^{\infty} \frac{(-1)^m}{m!} t^m e^{i(\phi_0 + m\phi)} \quad \text{or} \quad J_m(\rho \sin \phi),$$

we obtain the coefficient for $m$ in the product

$$\frac{\rho^n}{2^n m!} \left( 1 - \frac{2.2m+2}{2.4m+2} + \frac{2.4m+2}{2.6m+2} - \cdots \right) \text{or} \quad J_m(\rho \sin \phi),$$

hence $e^{i\phi} = J_0(\rho \sin \phi) + J_1(\rho \sin \phi) + \cdots + J_m(\rho \sin \phi) + \cdots$ (32)

$$\text{bessel's functions were defined by schlomilch as the coefficients of the power of $t$ in the expansion of $e^{i\phi}$},$$

and many of the properties of the functions can be deduced from this expansion. By differentiating both sides of (32) with respect to $t$, and equating the coefficients of $t^n$ on both sides, we find the relation

$$J_m(\rho \sin \phi) + J_{m+1}(\rho \sin \phi) = 2m \rho J_m(\rho \sin \phi),$$

which connects three consecutive functions. Again, by differentiating both sides of (32) with respect to $t$, and equating the coefficients of corresponding terms, we find

$$\frac{d}{d\rho} J_m(\rho \sin \phi) = J_{m+1}(\rho \sin \phi) - J_{m-1}(\rho \sin \phi).$$

In (32), let $t = e^{i\phi}$, and equate the real and imaginary parts, we have then

$$\cos (\rho \sin \phi) = J_0(\rho \sin \phi) + 2J_2(\rho \sin \phi) \cos 3\phi + \cdots$$

$$\sin (\rho \sin \phi) = J_1(\rho \sin \phi) + 2J_3(\rho \sin \phi) \sin 3\phi + \cdots$$

we obtain expansions of $\cos (\rho \phi)$, $\sin (\rho \phi)$, by changing $\phi$ into $\phi/\phi$. On combining these expansions with Fourier's series, we find expressions for $J_m(\rho \sin \phi)$ as definite integrals, thus

$$J_m(\rho \sin \phi) = \frac{1}{\pi} \int_{0}^{\pi} \cos (\rho \sin \phi) \cos (m \phi) \sin \phi \sin (m \phi) \sin \phi$$

$$J_m(\rho \sin \phi) = \frac{1}{\pi} \int_{0}^{\pi} \sin (\rho \sin \phi) \sin (m \phi) \cos \phi$$

It can easily be deduced that when $m$ is any positive integer

$$J_m(\rho \sin \phi) = \frac{1}{\pi} \int_{0}^{\pi} \cos (m \phi) \sin (\rho \sin \phi) d\phi.$$

23. Bessel's Functions as Limits of Legendre's Functions.—The system of orthogonal surfaces whose parameters are cylindrical coordinates may be obtained by a limiting case of those whose parameters are polar co-ordinates, when the centre of the spheres moves off to an indefinite distance from the portion of space which is contemplated. It would therefore be expected that the normal forms $e^{i\phi} J_{n}(\rho \sin \phi)$ would be derivable as limits of $\cos (\rho \sin \phi)$, and we shall show that this is actually the case. If $O$ be the centre of the spheres, and take as new origin a point $C$ on the axis of $\phi$, such that $OC = a$; let $P$ be a point whose polar co-ordinates are $r$, $\phi$, $\phi$ referred to $O$ as origin, and cylindrical co-ordinates $\rho$, $\phi$, $\phi$ referred to $C$ as origin; we have

$$\rho = \rho \sin \theta, \quad \phi = \phi - \alpha, \quad \text{and} \quad \rho \cos \phi = \rho \sin \phi \cos \phi = \sin \theta \cos \theta$$

Now let $O$ move off to an infinite distance from $C$, so that $\alpha$ becomes
SPEHERICAL HARMONICS

568

infinite, and at the same time let \( n \) become infinite in such a way that \( n/m \) has a finite value \( \lambda \). Then

\[
L \sec \theta = L \left( \sec \frac{\theta}{2} \right)^{\lambda} = 1, \quad L \left( 1 + \frac{x}{a} \right)^{n} = e^{x},
\]

and it remains to find the limiting value of \( P_{n}(\cos \theta) \). From the series (15), it may be at once proved that

\[
P_{n}(\cos \theta) = 1 - \frac{(n+1)}{2!} \frac{\sin \theta}{\sin \frac{\theta}{2}} + \ldots + \frac{(-1)^{m} n! (n-m)! \sin^{2m} \theta}{(2m)! (2m)!} \left( \frac{x}{a} \right)^{m},
\]

where \( \delta \) is some number numerically less than unity and \( m \) is a fixed finite quantity sufficiently large; on proceeding to the limit, we have

\[
L \sec \theta = \left( \frac{\theta}{a} \right)^{\lambda} = 1 - \frac{\lambda a^{2}}{2!} \frac{\lambda a^{4}}{4!} \ldots - \frac{(-1)^{m} \lambda a^{2m}}{2m!} \left( \frac{x}{a} \right)^{m},
\]

where \( \delta \) is less than unity.

Hence

\[
L_{n} \sec \theta = \left( \frac{\theta}{a} \right)^{\lambda} = J_{0}(\lambda a).
\]

Again, since

\[
P_{n}(\cos \theta) = \sin^{2n} \theta \frac{\sin \theta}{d(\cos \theta)^{m}},
\]

we have

\[
L \sec \theta = \left( \frac{\theta}{a} \right)^{\lambda} \frac{d}{d(\theta^{2})} \left( \frac{\sin \theta}{\theta^{2}} \right)^{m} = \left( \frac{\lambda a^{2}}{2!} \frac{\lambda a^{4}}{4!} \ldots - \frac{(-1)^{m} \lambda a^{2m}}{2m!} \left( \frac{x}{a} \right)^{m} \right),
\]

hence

\[
L_{n} \sec \theta = \left( \frac{\theta}{a} \right)^{\lambda} = J_{0}(\lambda a).
\]

It may be shown that \( Y_{n}(\theta) \) is obtainable as the limit of \( Q_{n}(\cos \theta) \) the zonal harmonic of the second kind; and that

\[
Y_{n}(\theta) = L \sec \theta = J_{0}(\lambda a).
\]

24. Definite Integral Solutions of Bessel's Equation.—Bessel's equation of order \( m \), where \( m \) is unrestricted, is satisfied by the expression

\[
\int_{0}^{\pi} e^{i\varphi} (\cos \theta)^{-m+1} d\varphi,
\]

where the path of integration is either a curve which is closed on the Riemann's surface on which the integrand is represented, or is taken between limits, at each of which \( e^{i\varphi} (\cos \theta)^{-m+1} \) is zero. The equation is also satisfied by the expression

\[
\int_{0}^{\pi} e^{i\varphi} (\cos \theta)^{-m+1} d\varphi
\]

where the integral is taken along a closed path as before, or between limits at each of which \( e^{i\varphi} (\cos \theta)^{-m+1} \) vanishes.

The following definite integral expressions for Bessel's functions are derivable from these fundamental forms.

\[
J_{m}(\theta) = \frac{1}{\Pi} \left( \frac{\theta}{a} \right) \frac{1}{\Pi} \left( \frac{\theta}{a} \right) \left( \begin{array}{c}
1 + m - 1 \\end{array} \right) \left( \begin{array}{c}
1 + m - 1 \\end{array} \right)
\]

where the real parts of \( m + 1 \) are positive.

\[
Y_{m}(\theta) = \int_{0}^{\pi} \sin \theta d\theta \cos \theta \sin \theta \theta \phi
\]

where the real parts of \( m + 1 \) are positive; \( \phi \) is purely imaginary and positive the upper limit may be replaced by \( \infty \).

\[
J_{m}(\theta) = \int_{0}^{\pi} \sin \theta d\theta \cos \theta \sin \theta \theta \phi
\]

under the same restrictions as in the last case; if \( \phi \) is a negative imaginary number, we may put \( \infty \) for the upper limit.

If \( \phi \) is real and positive

\[
J_{m}(\theta) = \frac{1}{2} \int_{0}^{\pi} \cos \theta \phi \cos \theta \phi \phi \phi \phi
\]

\[
Y_{m}(\theta) = \int_{0}^{\pi} \cos \theta \phi \cos \theta \phi \phi \phi \phi
\]

25. Bessel's Functions with Imaginary Argument.—The functions with purely imaginary argument are of such importance in connexion with certain differential equations of physics that a special notation has been introduced for them. We denote the two solutions of the equation

\[
d^{2}u + \frac{1}{d} du + \frac{1}{d} du = 0,
\]

by \( J_{0}(\theta), K_{0}(\theta) \) when

\[
I_{0}(\theta) = I_{0}(\theta) = 1 + \frac{1}{2} + \frac{1}{2} + \ldots
\]

We may denote by \( I_{n}(\theta), K_{n}(\theta) \), where

\[
I_{n}(\theta) = \frac{1}{\theta} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi \phi
\]

\[
K_{n}(\theta) = \frac{1}{\theta} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi
\]

The particular integral \( K_{n}(\theta) \) is so chosen that it vanishes when \( \theta \) is real and infinite; it is also represented by

\[
\int_{0}^{\infty} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi \phi
\]

and by

\[
\int_{0}^{\infty} \frac{1}{\theta} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi
\]

The solutions of the equation

\[
d^{2}u + \frac{1}{d} du + \frac{1}{d} du = 0
\]

are denoted by \( I_{m}(\theta), K_{m}(\theta) \), where

\[
I_{m}(\theta) = \frac{1}{2} \int_{0}^{\infty} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi
\]

We find also

\[
K_{m}(\theta) = \frac{1}{2} \int_{0}^{\infty} \cos \theta \phi \sin \theta \phi \theta \phi \phi \phi
\]

where \( P \) and \( Q \) denote the series

\[
P_{1} = \frac{1}{1.2.3.4.5.6.7},
\]

\[
Q_{1} = \frac{1}{1.2.3.4.5.6.7},
\]

These series for \( P, Q \) are divergent unless \( m \) is half an odd integer, but it can be shown that they may be used for calculating the values of the function, as they have the property that if in the calculation we stop at any term, the error in the value of the function is less than the next term; thus in using the series for calculation, we must stop at a term which is small. In such series the remainder after \( n \) terms has a minimum for some value of \( n \), and for greater values of \( n \) increases beyond all limits; such series are called semi-convergent or asymptotic.

We have as particular cases of such series:

\[
J_{0}(\theta) = \frac{1}{2} \cos \theta \phi \phi \phi \phi
\]

under the same restrictions as in the last case; if \( \phi \) is a negative imaginary number, we may put \( \infty \) for the upper limit.

If \( \phi \) is real and positive

\[
J_{0}(\theta) = \frac{1}{2} \int_{0}^{\pi} \cos \theta \phi \cos \theta \phi \phi \phi \phi
\]

\[
Y_{0}(\theta) = \int_{0}^{\pi} \cos \theta \phi \cos \theta \phi \phi \phi \phi
\]

27. The Bessel's functions of degree half an odd integer are of special
SPHERICAL HARMONICS

659

importance in connection with the differential equations of physics.
The two equations
\[
\frac{\partial u}{\partial r} = k^2 r^2 u, \quad \frac{\partial u}{\partial \theta} = k^2 r^2 u.
\]
are reducible by means of the substitutions \( u = e^{\pm i\epsilon}, \quad u = e^{\pm \epsilon} \) to the form \( \psi_0 + \psi = 0 \).
If we suppose \( \psi \) to be a function of \( r \) only, this last differential equation takes the form
\[
\frac{d^2\psi}{dr^2} + 4\frac{1}{r}\frac{d\psi}{dr} + \alpha^2 \psi = 0,
\]
so that \( \psi \) has the values
\[
\sin r, \cos r
\]
in order to obtain more general solutions of the equation \( \psi_0 + \psi = 0 \), we may operate on
\[
\sin r, \cos r
\]
with the operator
\[
Y_\alpha \left( \frac{\partial}{\partial \alpha} \right),
\]
where \( Y_\alpha \) is any spherical solid harmonic of degree \( \alpha \). The result of the operation may be at once obtained by taking \( Y_\alpha \) for \( \psi_0 \) in the theorem (7'), thus we find as solutions, of \( \psi_0 + \psi = 0 \), the expressions
\[
Y_\alpha(x, y, z), \quad Y_\alpha(x, y, z) \frac{d^2}{dr^2} + \alpha^2 \psi = 0.
\]
By recurring to the definition of the function \( J_n(r) \), we see that
\[
J_n(r) = \sqrt{\frac{2n}{\pi}} \left\{ r - 2 + \frac{r^2}{3} - \frac{r^4}{5} + \cdots \right\} \sqrt{\frac{2}{\pi}} \sin r,
\]
thus
\[
J_n(r) = \sqrt{\frac{2n}{\pi}} \left\{ r - 2 + \frac{r^2}{3} - \frac{r^4}{5} + \cdots \right\} \sqrt{\frac{2}{\pi}} \sin r
\]
Using the relation between Bessel's functions whose orders differ by an integer, we have
\[
J_{n+1}(r) = (-2)^n \frac{d^n}{dr^n} \left( \frac{d}{dr} \right) J_n(r) = (-2)^n \sqrt{\frac{2n}{\pi}} \left\{ r - 2 + \frac{r^2}{3} - \frac{r^4}{5} + \cdots \right\} \sqrt{\frac{2}{\pi}} \sin r
\]
It may be shown at once that
\[
J_{n+1}(r) = \sqrt{\frac{2n+1}{\pi}} \left\{ r - 2 + \frac{r^2}{3} - \frac{r^4}{5} + \cdots \right\} \sqrt{\frac{2}{\pi}} \sin r
\]
is a second solution of Bessel's equation of order \( n+\frac{1}{2} \); thus the differential equation \( \psi_0 + \psi = 0 \) is satisfied by the expression
\[
Y_\alpha(x, y, z) \frac{d^2}{dr^2} + \alpha^2 \psi = 0,
\]
and by the corresponding expression with a second solution of Bessel's equation instead of \( J_n(x) \) if \( S_n(\mu, \phi) \) denotes a surface harmonic of degree \( n \), the expression
\[
S_n(\mu, \phi) \frac{d^2}{dr^2} + \alpha^2 \psi = 0,
\]
is a solution of the equation \( \psi_0 + \psi = 0 \).

28. The Zeros of Bessel's Functions.—The determination of the position of the zeros of the Bessel's functions, and the values of the argument at which they occur, have been investigated by Hurwitz (Math. Ann., vol. xxxii.), and more completely by H. M. Macdonald (Proc. Lond. Math. Soc. vol. xxxi., xxxii.). It has been shown that the zeros of \( J_n(x) \) are all real and associated with the singular point at infinity when \( n \) is real and \( > -1 \), and that all the real zeros of \( J_n(x) \) when \( n \) is real and \( < -1 \), and not an integer, are associated with the essential singularity at infinity. When \( n \) is a negative integer \( -m, J_n(x) \) has, in addition, \( 2m \) real zeros coincident at the origin. When \( n = -m - 1, m \) being a positive integer, and \( t > > 0 \), \( J_{n+1}(x) \) has a finite number \( 2m \) of zeros which are not associated with the essential singularity. If \( n \) is real, and starts with any positive value, the zeros nearest the origin approach it as \( n \) diminishes, two of them reaching it when \( n = -1 \), and two more reach it whenever \( n \) passes through a negative integral value; these zeros then become complex for values of \( n \) not integral. The zeros of \( J_n(x) \) are separated by those of \( J_{n+1}(x) \), one zero of the latter, and one only lies between two consecutive zeros of \( J_n(x) \).

When \( n \) is real and \( > -1 \), all the zeros of \( J_n(x) \) are given by a formula due to Stokes; the \( m^\text{th} \) positive zero in order of magnitude is given by
\[
a = \frac{\alpha^2}{8a} \left\{ 4\alpha^2 - 1 \right\} \left( \frac{8a^2 - 1}{3} \right)^{n/4},
\]
where \( a = \frac{\pi}{2} (2n + 4m - 1) \). It has been shown by Macdonald that the function \( K_n(x) \) has no real zeros unless \( n = 2k + 1 \) where \( k \) is even, when it has one real negative zero; and that \( K_n(x) \) has no purely imaginary zeros, and no zero whose real part is positive, other than those at infinity. When \( n > 2k + 1 \), \( K_n(x) \) has no zeros other than those at infinity, when \( 2n^2 + 1 \), it has one zero whose real part is negative, and when \( m + 1 > n \) \( m \) is an integer, there are \( m \) zeros whose real parts are negative. When \( n \) is an integer, \( K_n(x) \) has zeros with negative real parts.

29. Spherical Harmonics.—For potential problems in which the boundary is an ellipsoid of rotation, the co-ordinates to be used are \( r, \theta, \phi \) where in the case of a prolate spheroid
\[
x = c \sqrt{1+\cos^2 \theta} \sin \phi, \quad y = c \sqrt{1+\cos^2 \theta} \sin \phi, \quad z = c \cos \theta,
\]
the surfaces \( r = r_0, \quad \theta = \theta_0, \phi = \phi_0 \) are confocal prolate spheroids, confocal hyperboloids of revolution, and planes passing through the axis of revolution. We may suppose \( r \) to range from \( t \) to \( \infty \), \( \theta \) from 0 to \( \pi \), and \( \phi \) from 0 to \( 2\pi \), every point in space has then unique co-ordinates \( r, \theta, \phi \).

For oblate spheroids, the corresponding co-ordinates are \( r, \theta, \phi \) given by
\[
x = c \sqrt{1+\cos^2 \theta} \sin \phi, \quad y = c \sqrt{1+\cos^2 \theta} \sin \phi, \quad z = c \cos \theta,
\]
where \( 0 \leq \phi \leq \pi, \quad 0 \leq \theta \leq \pi, \quad 0 \leq \phi \leq 2\pi \); these may be obtained from those for the prolate spheroid by changing \( c \rightarrow -c \), and \( r \) to \( -r \).

Taking the case of the prolate spheroid, Laplace's equation becomes
\[
\frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) \psi + \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial}{\partial \theta} \right) \psi + \frac{\cos \phi}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial}{\partial \phi} \right) \psi = 0
\]
and it will be found that the normal solutions are
\[
P_n^m(r) \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial}{\partial \theta} \right) \psi + \frac{\cos \phi}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial}{\partial \phi} \right) \psi = 0 \quad \psi = 0,
\]
the functions \( P_n^m(r) \phi \) required for the potential problems, are associated Legendre's functions of degree \( n - \frac{1}{2} \) half an odd integer, of integral order \( m \), and of argument real and greater than unity; these are known as toroidal functions. For the space external to a boundary tore the function \( Q_n^m(r) \phi \) must be used, and for the internal space \( P_n^m(r) \phi \).
The following expressions may be given for the toroidal functions:

\[ P_{n+1}^{m}(\cosh \rho) = \frac{(-1)^{m}}{\pi} \int_{0}^{\infty} \cos m\phi \frac{\cosh \rho - \sinh \rho \cos \phi}{\pi(n-m)\phi} d\phi \]

\[ P_{n}^{m}(\cosh \rho) = \frac{2^{m}}{\pi(n-m)!} \int_{0}^{\infty} \frac{\cosh^{m-1}\rho \cosh \phi}{\cosh \rho - 2 \cosh \phi} d\phi \]

\[ Q_{n+1}^{m}(\cosh \rho) = -(\frac{1}{\pi})^{2} \frac{\sinh n \phi}{\sinh n \phi} \int_{0}^{\infty} \cosh \phi \left( \frac{\cosh \rho \cos \phi}{\sinh \rho \cos \phi} \right)^{n+1} d\phi \]

The relations between functions for three consecutive values of the degree or the order are:

\[ 2n \cosh \rho P_{n}^{m}(\cosh \rho) = (n + m - 1) P_{n+1}^{m}(\cosh \rho) - (n + m) P_{n-1}^{m}(\cosh \rho) = 0. \]

with relations identical in form for the functions \( Q_{n+1}^{m}(\cosh \rho) \). The function \( Q_{n+1}^{m}(\cosh \rho) \) is expressible in the form

\[ \frac{\sinh(n+1)\phi}{\sinh(n+1)\phi} F(s, n + 1, n + 1, e^{-\phi}), \]

which is useful for calculation of the function when \( n \) is not small. \( P_{n}^{m}(\cosh \rho) \) can also be expressed in terms of \( \cosh^{m} \) by a somewhat complicated formula.

31. Ellipsoidal Harmonics.—In order to treat potential problems in which the boundary surface is an ellipsoid, Lamé took as co-ordinates the parameters \( \mu, \nu \) of systems of confocal ellipsoids, hyperboloids of one sheet, and of two sheets; these co-ordinates are three roots of the equation

\[ x^{2} + \mu x^{2} + \nu x^{2} = 1, \quad (k > h); \]

we then find that

\[ x = \frac{\mu x^{2}}{kk}, \quad y = \sqrt{\mu^{2} x^{2} + \nu^{2} x^{2} + \mu^{2} x^{2} - \nu^{2} x^{2}}. \]

where

\[ \infty > \mu x^{2} > \nu x^{2} > k x^{2}, \quad h x^{2} > \mu x^{2} > 0, \]

We find from these values of \( x, y, z \)

\[ (dx)^{2} + (dy)^{2} + (dz)^{2} = \frac{(\mu - \mu^{2})(\mu - \nu^{2})(\mu^{2} - \nu^{2})(\mu - \mu^{2})(\mu^{2} - \nu^{2})(\mu^{2} - \nu^{2})}{(\mu^{2} - \nu^{2})^{2}}. \]

and on applying the general transformation of Laplace's equation that equation becomes

\[ (\mu^{2} - \nu^{2}) \frac{\partial^{2} V}{\partial x^{2}} + (\mu^{2} - \nu^{2}) \frac{\partial^{2} V}{\partial y^{2}} + (\mu^{2} - \nu^{2}) \frac{\partial^{2} V}{\partial z^{2}} = 0, \]

where \( \xi, \eta, \zeta \) are defined by the formulae

\[ \xi = \int_{0}^{\phi} \frac{d\phi}{\mu^{2} - \nu^{2}}, \quad \eta = \int_{0}^{\phi} \frac{d\phi}{\mu^{2} - \nu^{2}}, \quad \zeta = \int_{0}^{\phi} \frac{d\phi}{\mu^{2} - \nu^{2}}. \]

which are equivalent to

\[ \rho = x^{2} + \mu x^{2} + \nu x^{2} = \mu x^{2} + \nu x^{2} = k x^{2}, \quad k, k^{2}, k^{3} \]

It can now be shown that Laplace's equation is satisfied by the product \( E(\rho)E(\mu)E(\nu) \), where \( E(\rho) \) satisfies the differential equation

\[ \frac{d^{2}E(\rho)}{d\rho^{2}} - \left( \frac{n(n+1)}{\rho^{2}} - \frac{k^{2}}{\rho^{2}} - k^{2}\right) E(\rho) = 0; \]

and \( E(\mu), E(\nu) \) satisfy the equations

\[ \frac{d^{2}E(\mu)}{d\mu^{2}} + \left( \frac{n(n+1)}{\mu^{2}} + \frac{(\mu^{2} - k^{2})}{\mu^{2}} \right) E(\mu) = 0, \]

\[ \frac{d^{2}E(\nu)}{d\nu^{2}} + \left( \frac{n(n+1)}{\nu^{2}} + \frac{(\nu^{2} - k^{2})}{\nu^{2}} \right) E(\nu) = 0, \]

where \( n \) and \( \rho \) are arbitrary constants. On substituting the values of the parameters \( \xi, \eta, \zeta \) in terms of \( \rho, \mu, \nu \), we find that the equation satisfied by \( E(\rho) \) becomes

\[ (\rho^{2} - k^{2})(\mu^{2} - k^{2}) \frac{d^{2}E(\rho)}{d\rho^{2}} + \rho^{2}(\mu^{2} - k^{2}) \frac{dE(\rho)}{d\rho} + \rho^{2}(\nu^{2} - k^{2}) \frac{dE(\rho)}{d\rho} + (k^{2} + k^{2}) \rho = \frac{n(n+1)}{\rho^{2}}E(\rho) = 0, \]

and \( E(\mu), E(\nu) \) satisfy equations in \( \mu, \nu \) respectively of identically the same form; this equation is known as Lamé's equation.

If \( n \) be taken to be a positive integer, it can be shown that it is possible in \( 2n+1 \) ways so to determine \( \rho \) that the equation in \( E(\rho) \) is satisfied by an algebraical function of degree \( n \), rational in \( \rho, \sqrt{\rho^{2} - k^{2}}, \sqrt{\rho^{2} - k^{2}} \). The functions so determined are called Lamé's functions, and the \( 2n+1 \) functions of degree \( n \) are of one of the four forms:

\[ K(\rho) = a_{0} + a_{1}\rho^{2} + \ldots, \]

\[ L(\rho) = \sqrt{\rho^{2} - k^{2}}(a_{0} \rho^{2} + a_{1} \rho^{2} + \ldots), \]

\[ M(\rho) = \sqrt{\rho^{2} - k^{2}}(a_{0} \rho^{2} + a_{1} \rho^{2} + \ldots), \]

\[ N(\rho) = \sqrt{\rho^{2} - k^{2}}(\sqrt{\rho^{2} - k^{2}})^{2} \]

These are the four classes of Lamé's functions of degree \( n \); of the functions \( K \) there are \( 1 + n \), or \( \frac{1}{2}(n+1) \), according as \( n \) is even or odd; of each of the functions \( L, M, N \), there are \( n \), or \( \frac{1}{2}(n-1) \), and of the functions \( N \), there are \( n \), or \( \frac{1}{2}(n+1) \). The normal forms of solution of Lamé's equation, applicable to the space inside the ellipsoid, are the \( 2n+1 \) products \( E(\rho)E(\mu)E(\nu) \). It can be shown that the \( 2n+1 \) values of \( \rho \) are real and unequal.

It can be shown, that subject to certain restrictions, a function of \( \mu \) and \( \nu \), arbitrarily given over the surface of the ellipsoid \( \rho = r \), can be expressed as the sum of products of Lamé's functions of \( \mu \) and \( \nu \) in the form

\[ \sum c_{2n+1}(\rho)E(\mu)E(\nu) \]
The lower end of the screw and those of the table legs are finely tapered and terminate in hemispheres, so that each rests on a point. If the screw has two turns of the thread, the millimetre scale on the head of the screw is usually divided into 500 equal parts, so that differences of 0.001 millimetre may be measured without difficulty. A vertical scale fastened to the table indicates the number of whole turns of the screw and serves as an index for reading the divisions on the head. In order to measure the thickness of a plate the instrument is placed on a perfectly level plane surface and the screw turned until the point just touches; the reading is then noted when it does so is defined by a sudden diminution of resistance succeeded by a considerable increase. The divided head and scale are read; the screw is raised; the thin plate slipped under it; and the process is repeated. The difference between the two readings gives the required thickness. A contact lever, delicate level or electrical contact arrangement may be employed to indicate the moment of touching more precisely than is possible by the sense of touch. To measure the radius of a sphere — e.g. the curvature of a lens — the spherometer is levelled and read, then placed on the sphere, adjusted with the four points on the moving pressure, and read again. The difference gives the thickness of that portion of the sphere cut off by a plane passing through the three feet. Calling this distance A and the distance between the feet a, the radius R is given by the formula: \( R = \frac{a^2 + 3b^2}{6A} \).

**SPHERULITES** (Gr. σφαιριές, sphere, λίθος, stone), in petrology small rounded bodies which commonly occur in vitreous igneous rocks. They are often visible in specimens of obsidian, pitchstone and rhyolite as globules about the size of millet seed or rice grain, with a duller lustre than the surrounding glassy base of the rock, and when they are examined with a lens they prove to have a radiate fibrous structure. Under the microscope the spherulites are of circular outline and are composed of thin divergent fibres, which are crystalline and react on polarized light. Between crossed nics a black cross appears in the spherulite; its axes are usually perpendicular to one another and parallel to the crossed wires; as the stage is rotated the cross remains stationary; when there are four bright sectors this shows that the spherulite consists of radiate, doubly refracting fibres which have a straight extinction; the arms of the black cross correspond to those fibres which are extinguished. The aggregate is too fine grained for us to determine directly of what minerals it is composed.

Spherulites are common in acid glassy rocks like those above mentioned, but they occur also in basic glasses such as tachylite. Sometimes they compose the whole mass; more usually they are surrounded by a glassy or felsitic base. When obsidians are devitrified the spherulites are often traceable, though they may be more or less completely recrystallized or silicified. In the centre of a spherulite there may be a crystal (e.g. quartz or felspar) or sometimes a cavity. Occasionally spherulites have zones of different colours, and while most frequently spherical they may be polygonal, or irregular in outline. In some New Zealand rhyolites the spherulites send branching "cervicorn" processes (like stags' horns) outwards through the surrounding glass of the rock. The name axiolites is given to long, elliptical or band-like spherulites.

Occasionally spherulites are met with which are half an inch or more in diameter. If the rock be powdered and the fragments examined, it is found that from their composition they may be regarded as a mixture of quartz and acid felspar. Direct microscopic evidence as to the presence of these minerals is rarely obtainable. Some authors describe spherulites as consisting of felsite or microfelsite, which also is supposed to be a cryptocrystalline quartzofelspathic substance.
Very large and cavernous spherulites have been called *lithophysae*; they are found in obsidians at Lipari, the Yellowstone Park, &c. The characteristic radiate fibrous structure is usually conspicuous, but the fibres are interrupted by cavities which are often arranged so as to give the spherulite a resemblance to a rosebud with folded petals separated by arching interspaces. Some of these lithophysae are an inch or more in diameter. In the crystallization of a glass there must be contraction, and it is supposed that thus the concentric cavities arise. The steam and other vapours in the magma would fill these empty spaces and exert a powerful mineralizing action on the warm rock. The presence of garnet, tridymite, fayalite and other minerals, very abnormal in rhyolites in these cavities, in the lithophysae is suggestive. The former are usually broad and seem to belong to alkali felspar (sandine or anorthoclase) embedded in tridymite and glass; by analogy it is often inferred that the extremely tenuous fibres of ordinary spherulites have the same composition.

Artificial glass which has not the right composition, or is retained for too long a time in a furnace, sometimes crystallizes, and contains spherulites which may be as large as a marble. As the glass has little similarity in chemical composition to volcanic obsidians these spherulites when analysed throw little light on the mineral nature of spherulites in rocks. They show, however, a close resemblance to the radiating fibrous structure which is often broad and seems to be the same as in alkali felspar. The characteristic radiate fibrous structure tends to originate at certain centres and to radiate outwards, producing spherulitic structures. Many salts and organic substances exhibit the same tendency, yielding beautiful spherulitic crystallizations when melted and cooled rapidly on a microscopic slide.

There are many structures in rocks which are allied to spherulites and usually grouped with them, though probably they are not exactly of the same nature. Some are more vitreous, while others are more perfectly crystalline than the true spherulites. Of the former we mention the doubly refracting glassy spheruloids common in rhyolites and obsidians. They differ in no respect from the spherulites described above, but the centres of growth, which are so obvious in the latter, are indistinct in the former. They are portions of the glass which are in a state of compression or strain and hence no longer isotropic. In gelatin, celluloid and artificial glasses similar appearances are occasionally seen. Opal, especially the variety known as hyalite, exhibits the same phenomenon.

In the group of porphyries known as granophyres crystals of quartz and felspar are surrounded by a ground-mass which has a fibrous or radiating spherulitic structure. The fibres consist of quartz and felspar, usually in graphic intergrowth over considerable areas, and are often sufficient to be seen with the naked eye. Some of the former are perfectly crystalline; others are more or less vitreous, and have a black cross like that of the spherulites. They are portions of the glass which is in a state of compression or strain and hence no longer isotropic. In gelatin, celluloid and artificial glasses similar appearances are occasionally seen. Opal, especially the variety known as hyalite, exhibits the same phenomenon.

Sphinx (Gr. σφίγγας, to draw tight, squeeze), the Greek name for this creature with lion's body and human head. The Greek sphinx had wings and female bust, and the male sphinx of Egypt (wingless) is distinguished as "andro-sphinx" by Herodotus. The type perhaps originated in Egypt, where figures of gods with human bodies and animal heads and compound animal forms like the gyphon were numerous from very early times. The sphinx, however, is a perfectly clear and well-defined type there, and is usually represented. The most celebrated example is the Great Sphinx of Giza, 180 ft. long, a rock carved into this shape, and from its situation likely to be a work of the IVth Dynasty. The pattern of the wig-lappets has been quoted to prove that it dates from the XIIth Dynasty, but it is said that the peculiar disposition of the uraeus on its forehead agrees with that in the earliest sculptures. The face looks out eastward from the pyramid field over the Nile valley, and, according to the inscriptions of the XVIIIth Dynasty in the shrine between the paws, it represented the sun-god Harmachis. Sphinxes of granite, &c., occur of the XIIth Dynasty and later. A pair from Tauris are attributed by Flinders Petrie to Pepi I. of the Vth Dynasty. The heads of the sphinxes are royal portraits, and apparently they are intended to represent the monarch of the reigning Pharaoh. The king as a sphinx, in certain religious scenes, makes offerings to deities; and elsewhere he tears his enemies in pieces. In the Saite period accordingly the figure of the sphinx was used as a hieroglyph for *neb*, "master," "lord." Recumbent sphinxes were especially used in pairs to guard the approach to a temple, and it may be conjectured that the Great Sphinx was sculptured at Giza to guard the entrance of the Nile valley. The name of the sphinx in Egyptian was Hu.

The great temple avenues at Thebes are lined with recumbent rams, true sphinxes (a few late instances), and with the so-called criosphinxes or ram-sphinxes, having lion bodies and heads of rams. Two of the most striking examples of animal-sphinxes are the recumbentphinxes, one dedicated to Harmachis in the temple of Abu Simbel, and is occasionally found in sculptures representing the king as Horus, or Mont, the war-god. It is distinguishable from the gryphon only by the absence of wings.

(F. L. G.)

From Egypt the figure of the sphinx passed to Assyria, where it appears with a bearded male head on cylinders; the female sphinx, lying down and furnished with wings, is first found in the palace of Esar-haddon (7th cent. B.C.). Sphinxes have been found in Phoenicia, one at least being winged and another bearded. They are copies of the Egyptian, both in form and posture, wearing the peshet and the uraeus, but distinguished by having the Assyrian wings. The sphinx is common on Persian gems, and the representations are finely executed. On a Persian intaglio are two sphinxes face to face, each wearing a tiara and guarding a sacred plant which is seen between them; but the sphinx, whether of the Egyptian or the Assyrian type, is not found in Persian sculptures (Perrot and Chipiez, *History of Art in Persia*, Eng. trans., London, 1892). In Asia Minor the oldest examples are the "Hittite" sphinxes of Euyuk. They are Egyptian sphinxes treated in the Assyrian style. They are not recumbent, and the hair falling from the head is curled, not straight, as in the true Egyptian sphinx. An ancient female sphinx, but wingless, stands on the sacred road near Miletus. Sphinxes of the usual Greek type are represented seated on each side of two doorways in an ancient frieze found by Sir Charles Fellows at Xanthus in Lycia, and now in the British Museum. The same type appears on the early sculptures of the half-Greek, half-oriental temple at Assus. In the early art of Cyprus—the half-way house between Asia and Greece—sphinxes of this type are not uncommon. On the other hand, on a gem of Phoenician style found at Curium in Cyprus there appear two male (bearded) sphinxes, with the tree of life between them. With regard to Greece proper, in the third tomb on the acropolis of Mycenae were found six small golden sphinxes; they are bearded, but the sex is doubtful. The bust is not that of a woman, though the head and face are distinctly feminine. A shallow cap covers the head, and from the middle of it there is always a sort of tail or plume, blown back by the wind. It is curious that, though the sphinx (as also the gryphon) were thus common in the Mycenaean period, the words φίγγας and ραβδιοθήκη do not occur in Homer. Helbig suggested that the word ἱάων (dog), which is
**SPIDER-MONKEYS**

**SPIDERS**, the common English name of Arachnida (q.v.) of the order Araneae, resembling the Pedipalpi in many structural points, but differing from them as well as from all other Arachnida in retaining short abdominal appendages known from their silk-manipulating function as spinnerets or spinning mammillae, with which are associated silk glands. It is probably owing to the possession of such glands and the varied purposes for which the silk is used that spiders as a group far surpass the other orders of Arachnida, with the possible exception of the Acari (mites and ticks), in diversity of form and of size, in numbers of genera and species, in extent of geographical distribution, and in adaptation to varied habitats. Except in the extreme north and south, and on the tops of the highest mountains, where there is no insect life as food supply, spiders are found all over the world, even in isolated oceanic islands. They occur up mountain slopes as far as vegetation extends, in tropical valleys and forests, in open grassy plains, in sandy deserts, and even in fresh-water ponds and between tide-marks on the seashore. Some are nocturnal, some diurnal; some catch their prey by speed of foot, some by cunningly lying hid, some by means of silken nets. The phenomena known as "protective resemblance," or similarity to inanimate objects or vegetation, and the kindred phenomenon of "mimicry," or beneficial likeness to certain protected species of animals, are also common in the group. In these particulars, considered in their entirety, spiders show a marked contrast to other Arachnida, such as the scorpions, pedipalps, book-scorpions and so-called harvest spiders, which by comparison are remarkably uniform, within the limits of the orders, in structure, habits and other respects. Spiders, in short, must be regarded as the most highly organized and the most successful members of the class Arachnida.

Their success in the struggle for existence, as already indicated, must be assigned in a great measure to the possession of silk glands and to their power of manipulating the silk for a variety of purposes. Several facts point to the conclusion that the majority of this function was the formation of egg-sacs and cocoons by the female, for this is the only constant use for which the silk is employed, without exception, by all species. The second step in the evolution of spinning instincts was probably the making of a silk-enamelled chamber for the reception of the cocoon itself and for the protection of the mother while guarding it and her newly-hatched young. If an aperture for ingress and egress, for purposes of feeding, were left in the wall of such a chamber, there would arise in a rudimentary form what is known as the tubular nest or web; and the next important step was possibly the adoption of such a nest as a permanent abode for the spider. Some spiders, like the *Dresdaeae* and *Salticae*, have gone beyond this stage in architectural industry; but next to the cocoon this simple tubular retreat—whether spun in a crevice or burrow or simply attached to the lower side of a stone—is the most constant feature to be observed in the spinning habits of spiders.

From this starting-point the evolution of web-making seems to have proceeded along two main divergent lines. Along one line there was a gradual elaboration of the tube until it culminated, so far as structural complexity is concerned, in the so-called trap-door nests or burrows of various families; along the other line the retreats of the spiders are of the kind known as pholcoids, i.e. webs or sheet silk. In association with a new structure, the spire or net, or one or the other, the pholcoids were superseded by the latter.

Trap-door nests are made by spiders belonging to two widely different groups, namely the *Lycosidae* or wolf-spiders, to which the true tarantula (q.v.) belongs, and the Mygalomorphae, containing the species which construct the best-known types of this style of burrow. Although there is no direct genetic affinity between the spiders of these two groups, an interesting parallelism in their habits may be traced. In both there are species which form no nest or burrow, others which construct a simple silk-lined tunnel in the soil, and others which close the aperture of the burrow with a hinged door; while both share the habit of lining the burrow with silk to prevent the infall of loose sand or mould; and the species which make an open burrow close the aperture with a sheet of silk in the winter during
SPIDERS

hibernation and open it again in the spring. Possibly from this habit was developed the instinct to build a door with a movable hinge. In the trap-door species of _Lycesidae_, like, for instance, _Lycosa opifex_ of the Russian steppes, the hinge is weak and the lid of the burrow is kept normally shut by being very much thicker and heavier at its free margin opposite the hinge so that it readily falls by its own weight. In the burrows made by the Mygalomorphae, on the contrary, the hinge is strong and highly elastic, its component silken threads being laid on in such a way that the door shuts with a snap when the occupant has passed in or out. The lid is sometimes thin and wafer-like as in the burrow of the species of _Nemastia_, sometimes thick and cord-like as in that of the species of _Ctenio_ or _Pachyloemus_. Its upper side is always covered by the spider with pieces of the vegetation growing up through the burrow when the door is closed, the position of the burrow is completely concealed. If an attempt be made by any enemy to lift the lid, the spider seizes its inner side with his fangs and striking his claws into the walls of the burrow offers the greatest possible resistance to the efforts of the intruder. When on the watch for prey the spider slightly raises the lid and, peeping through the chink, darts like a flash upon any beetle or fly that unwittingly passes within reach. Quite commonly the burrow has a second passage running obliquely upwards from the main passage to the surface of the soil, and this subsidiary track may itself be shut off from the main branch by an inner door that has forced an entrance through the main door, the spider retreats behind the second, leaving the intruder to explore the seemingly empty burrow.

There is no doubt that the primary influence that has guided the evolution of the architecture of the burrowing spiders has been that great necessity for the preservation of life, avoidance of enemies and protection from adverse physical conditions like rain, cold or drought. And when we turn to the other line along which the web-building instinct has developed we find that the primary guiding influence has been that second great vital necessity, namely the necessity of getting food. Reference has already been made to the silken tubolar tent, or simple structure, with an orifice at one or both ends, as the possible origin of all snares, however complex they may be. Perhaps the most rudimentary form of snare arose from the spinning of threads round the mouth of the tube to hold it in place. Be that as it may, the snare in many instances, as in that of the _Agalenidae_ (Tegenaria, Agalena), a family closely allied to the _Lycesidae_, is a horizontal sheet of webbing, upon which the spider runs, continuous with the lower half of the aperture of the tube, of which it is simply an extension. A very similar sheet is spun by a species of _Linyphia_, one of the _Argyojopidae_, but in this case there is no tube connected with the web and the spider hangs suspended beneath the horizontal netting. Snares of another type consisting of a tangled mass of threads amongst which the spider picks their way with ease, but which are impassable to insects, are spun by members of the _Theridiidae_ and _Pholcidae_; but by common consent the so-called orbicular web, so characteristic of the _Argyojopidae_ but by no means confined to them, is regarded as manifesting the greatest perfection of instinct in snare-spinning. These webs, which are typically subicular in form, consist of a system of threads radiating from a common centre and crossed at intervals, and approximately at right angles, by a set of concentric lines, the whole being suspended in a triangular, quadrilateral or polygonal framework formed of so-called foundation lines, attached to the branches or leaves of trees or other firm objects in the neighbourhood. Passing back from the centre of the web to the underside of an adjoining leaf or some other sheltered spot runs a single thread, the trap line allowing passage to the spider to and from the sheltered spot and the snare itself. At whatever spot an insect becomes entangled in the frame, the vibration set up by its struggles is transmitted along the nearest radiating thread to the centre and thence up the trap line to the shelter where the occupant learns of the signal. No sooner is the signal perceived than the spider descends with all speed to the centre, and by feeling the ends of the radiating lines learns which is ashare and rapidly, without the possibility of mistake, makes its way to the entangled insect. The probable reason for the wall-lines being concentric is that lines passing over the radii as nearly as possible at right angles are the shortest that can be laid on; they therefore use up a smaller quantity of silk and take a shorter time to spin than threads crossing the radii in any other direction; and at the same time they afford them the greatest possible support compatible with delicacy and strength of construction. On account of its delicacy no web is more difficult to see than one of the orbicular type above described. Its whereabouts is thus, to a great extent, concealed both from enemies searching for spiders and from insects suitable for food; and its open meshwork of strong threads makes it much less liable to be beaten down by rain or torn to shreds by winds than if it were a flat sheet of closely woven silk. In constructing, therefore, a so-called orb-web of radiating and unconnected lines, it seems that a spider economizes both time and silk and in addition renders the whole web as strong and as serviceable and yet as delicate and invisible aspossible.

Perfect orbicular webs are made by many genera of _Argyojopidae_ (Zilla, Meta, Gasteracantha), the best-known example being that of the common garden spider of England, _Aranea or Epeira diademata_; but these webs are not associated with any tubular retreat except such as are made under an adjoining leaf or in some nook hard by. Some tropical members of the family belonging to the genus _Nephila_, however, spin a web which is intermediate in structure between that of _Aranea_ and the complete sheet-like web of _Agalena_. It covers an area of about one-third of a circle and its radiating threads diverge from the mouth of a funnel-shaped tube resembling in every respect the tube of the last-mentioned genus. Again some species of _Dictyna_, belonging to the _Amaurobididae_, also have a tubular retreat opening on to the surface of a snare in which a crude attempt at a radial and concentric arrangement of the threads is perceptible. The interest of these two types of web lies in the fact that they bridge over the structural gap between the simple sheet-web of _Agalena_ and the perfect orb-web of _Aranea_.

_Dictyna_ may be cited as an example of a group of spiders, sometimes called the Cribellata, which have certain spinning glands and appliances not possessed by others. These glands are represented externally by a special plate, the _cribellum_, which lies in front of the ordinary spinning mamilla, and by a comb of short bristles, the _calamistrum_, placed in the penultimate segment of the leg of the last pair. By means of the calamistrum the silk secreted by the cribellum is teased into a fine thread which is twisted round the main threads of the web, giving it a very characteristic woolly or flocculent appearance.

There are many species to which silk is put, besides those mentioned above. By trailing a thread behind them spiders are able to drop from any height to the ground and to retrace their steps with certainty to a particular spot. The possession of silk-glands has also profoundly influenced the geographical distribution of spiders and has enabled them to cross arms of the sea and establish themselves on isolated oceanic islands which most of the orders of Arachnida are unable to reach. This is effected by the so-called habit of "ballooning" practised by very young spiders, which float through the air, often at great altitudes, in the direction of the prevalent winds. It was formerly supposed that this custom was peculiar to a single species, which was called the "gossamer" spider from the fact that the floating webs, when brought to the earth by rain or intercepted by bushes and trees, cont the foliage or grass with a sheeting of gossamer-like silk; but the habit is now known to be practised by the newly-hatched young of a great variety of species belonging to several distinct families.

As a commercial product spider-silk has been found to be equal, if not superior, to the best silk spun by lepidopterous larvae; but the cannibalistic propensities of spiders, making it impossible to keep more than in a single receptacle, coupled with the difficulty of getting them to spin perfectly in any given space, have hitherto prevented the silk being used on any extensive scale for textile fabrics.
The methods of catching prey adopted by spiders are extremely varied. The nets or snares are highly efficient for this purpose. Amongst the threads, which entangle the wings and legs of insects, the spiders are perfectly at home and can pounce on the struggling victim at once if it be small and harmless or keep at a respectful distance, checking all efforts at escape, if it be poisonous or strong. If in the latter case the spider be afraid to come to close quarters, various devices for securing it are resorted to. The Theraididae eject on to the insect from their spinning mamiliae drops of liquid adhesive silk; the Argyropidae, steadying it with the tips of their long front legs, sweep additional strands of silk over it with the legs of the hinder pair; the Agelenidae, attaching a long thread to a point hard by, run round and round the victim in circles gradually widening beyond the scope of breaking loose. Two genera of Argyropidae (Hyptiotes and Thersidionomus) construct spring-nets out of their incomplete webs of the orbicular type. To the web is attached a trap-line which when drawn taut holds the snare stretched and tight, and when relaxed loosens the whole structure so that the threads fall together. When an insect strikes the web the spider looses his hold of the trap-line, thus enveloping the victim in a tangle of threads which would otherwise not come into contact with it. Spiders which spin no snare are dependent for capturing prey for the most part upon their quickness or powers of surprise. Many Theridiidae and Tetragnathidae, those of the web, are provided with stigmas and petals of flowers, which they closely match in colour, waiting to seize the insects which visit the blossoms for nectar. Examples of Selenops (Clubionidae) lie flat and absolutely still on the bark of trees, to which their coloration assimilates, and spring like a flash of light upon any insect that touches their legs; the Lycosidae dart swiftly upon their prey; and the Salticidae, which compared with other spiders have keen powers of vision, stealthily stalk it to within leaping distance, then, gathering their legs together, cover the intervening space with a spring and with uncircling him seize it and bury it in pop on its back. Others of the Theridiidae (Phygarrachne), which inhabits the Oriental region, adopts the clever device of spinning on the surface of a leaf a sheet of web resembling the fluid portions of a splash of bird’s dung, the more solid central portions being represented by the spider itself, which waits in the middle of the patch to seize the butterflies or other insects that habitually feed on birds’ excrement and are attracted to the patch mistaking it for their natural food.

The sexes of spiders are distinct. Except in the case of the water-spider (Argyroneta) the males are smaller, sometimes very much smaller, than the females, but have proportionately longer legs and smaller bodies. When adult the males may always be distinguished from the females by the presence of a pair of horn-like intromittent organs, one of which is lodged in the terminal segment of each palpus or appendage of the second pair. In its simplest form this is a hollow flap-shaped horny piece, consisting of a dilated basal portion and a terminal spinniform portion with an orifice at the apex; but its structure is frequently complicated by accessory processes and outgrowths which aid copulation and serve to protect the delicate point from injury. In the breeding season the male makes a nest of silk on or near web of web, and tends it up in these flasks by means of capillary attraction and carries it about until he falls in with a female. During pairing he thrusts the tips of these organs into the seminal vesicles of the female and the eggs are fertilized as they pass out of the oviduct. Cases of parthenogenetic reproduction, or reproduction without the intervention of the male, have been recorded in the case of two genera (Filistata and Tegenaria), and may be commoner than is usually supposed. All spiders are oviparous. The number of eggs produced at a time varies enormously according to the species, from about half a dozen, more or less, in some anti-mimicking Attidae or jumping spiders to many hundreds in the larger orbicular-webbed spiders of the family Argyropidae. The first act of the female after oviposition is to wrap her eggs in a casing of silk commonly called the cocoon. The cocoon varies greatly in size, shape and consistency according to the nature of the spider that makes it. Sometimes, as in Pisania, it is merely a thin network of silk just sufficient to hold the eggs together. More often it consists of a thick felting of silk, either spun in one continuous piece into a globular form, as in the Aracnidae, or composed of two plate-like pieces, an upper and a lower, united at the edges and lenticular in shape, as in some of the Lycosidae. Sometimes it is woolly and flocculent, sometimes smooth like parchment, and its shape depends in a large measure upon the habits of the female towards her offspring. As a rule terrestrial spiders guard the cocoon in the permanent burrow, as in the trap-door spiders, or in the silken retreat which acts as a temporary nursery, as in the Salticidae. Other species of wandering habits carry the cocoon about with them, sometimes attached to the spinnerets, as in the Lycosidae, sometimes tucked under the thorax, as in the large tropical horse-spider, Heteropoda regia, one of the Clubionidae. The females of some snare-spinning species, like the Philodidae, carry it in their jaws; but in the case of the Argyropidae the females usually leave the cocoon to its fate as soon as it is constructed, sometimes rolling it in a leaf, sometimes attaching it by a stalk to a branch. It is in this and related families that the greatest diversity in the colour and form of the cocoon is found. In these spiders, too, the newly-hatched young shift for themselves as soon as they emerge from the cocoon; in others that guard the cocoon the young stay for a longer or shorter time under their mother’s protection after the female has constructed her cocoon. She is usually accompanied by her mate, and her eggs being fertilized, the young will be carried about with her wherever she goes. There is no metamorphosis during growth such as occurs in some insects, the young being hatched with its full complement of appendages and only differing from its parents in characters of comparatively minor importance. Growth is accompanied by a succession of moults, the spider emerging from its old skins by means of a fracture which extends along the front and sides of the cephalothorax just beneath the edge of the carapace. It is only at the final moult that the sexual organs are mature, the two sexes being alike in the earlier stages of growth. Until maturity is reached the spider has the power to repair lost or damaged parts. If a limb be lost at an early stage it may be re-grown in perfection; but at later stages it is only imperfectly reproduced and is shorter and thinner than the other limbs. Rapidity of growth and longevity vary greatly according to circumstances and to the species. In northern and temperate latitudes where insects disappear in the winter, species of Argyropidae like Aranea diademata, live only for a single season. The young emerge from the cocoon in the early spring, grow through the summer, and reach maturity in the early autumn. The sexes then pair and perish. In some families of the family Lycosidae, other families (Lycosidae, Clubionidae) may live for a few seasons, hibernating in the soil or amongst dead leaves; and examples of the larger spiders (Aracnidae) have been kept alive in captivity for several years. Owing to the smaller size of the male and the greater voracity of the female, the male makes his advances to his mate at the risk of his life and is not infrequently killed and eaten by her either before or after pairing has been effected. Fully aware of the danger, he pays his addresses with extreme caution, frequently waiting for hours in her vicinity before venturing to come close to her. Moreover, the female of the vachonidae, one of the Mygalomorphae, taps the walls of the tabular web of the female before daring to bite a hole in it and descend into her burrow. Most curious of all is the courtship of the males of some species of Salticidae, or jumping spiders, which are decorated with plumes or coloured stripes or iridescent patches. These they display before her, poised and performing extraordinary antics in her presence exactly as cock birds behave towards their hens. Lastly, the males of some species of spiders differ from the females in possessing striulatory organs consisting of horny ridges and spikes and lodged either between the mandibles and palp as in some species allied to Linyphia, one of the Argyropidae, or between...
SPIDERS

the cephalo-thorax and abdomen as in Steatoda, one of the Theridiidae and Cambricdea, one of the Agelenidae. It is believed that the males of these species signal to their females by means of the sound these organs emit. The greatest disparity in size between the sexes is met with in the tropical genus Nephila, the females of which are gigantic representatives of the Araneidae. The male, however, is a veritable pigmy beside the female, and during copulation presents the appearance of a parasite attached to her abdomen. It has been suggested that the diminutive size of the male is of great advantage to him during courtship, because he is enabled to move easily thereby to escape from her clutches should she turn upon him with hostile intent.

All spiders possess a pair of poison-glands, one in each of the cheliceræ or mandibles and opening by means of a duct at the tip of the fang. The primary function of this poison is to kill the prey upon which they feed. Its action being very rapid upon insects. In a great majority of cases, however, it is comparatively innocuous to human beings, despite legends to the contrary that have arisen in connexion with certain species like the tarantula. The bite, however, of any spider, strong enough to pierce the skin, may give rise to a certain amount of local inflammation and pain depending principally upon the amount of poison injected. The bite, for example, of large species of the family Aviculariidæ, sometimes called Mygales, and sometimes, but erroneously, known as tarantulas, species which have fangs half an inch long and as sharp as needles and a considerable quantity of venom. Others again may be more painful, though thought the Araneus, provided the health of the patient be good. There is one possible exception, however, to the innocuous nature of the poison and this is supplied by the species of the genus Lathrodictus, one of the Theridiidae. There is no actual proof that this spider is more poisonous than others, but it is a significant fact that its species, inhabiting countries as widely separated as Chile, Madagascar, Australia, New Zealand and South Europe are held in great fear by the indigenous population, and many stories are current of serious or fatal results following their bites. Many of the species of these spiders, moreover, are very conspicuously coloured, being either wholly black or black relieved by fiery red spots, forcibly suggesting that they are waringly coloured. Some of the species of Aviculariidæ also appear to be waringly coloured with black or black and red, and their coloration is associated with the urticated nature of their bristles, which makes them highly unpalatable to vertebrate foes. So far as is known, however, only the large spiders belonging to this group possess this special means of defence, and in many other species this is accompanied by highly-developed stridulating organs resembling those of rattlesnakes and scorpions in form and function. Other spiders, belonging to the Argiopeidæ, are armed with sharp and strong abdominal spines, and these spiders are hard-shelled like beetles and are spotted with black on a reddish or yellow ground, their spines shining with steel-blue lustre. The majority of spiders, however, are soft-skinned and succulent, and are tasty morsels for insectivorous reptiles, birds and mammals. Hence as a very general rule the coloration makes for concealment under natural conditions of existence, and the instincts which lead to concealment are very highly developed. As instances of procryptic or cleative coloration may be mentioned that of the species of the genus Dolomenes, one of the Lycosidae, which lives amongst reeds and is marked with a pair of longitudinal yellow lines which harmonize with the upright stalks of the vegetation, and Lycosa picta, which lives on the sand, can scarcely be seen on account of its mottled pattern: Sparassus smaragdulus and the species of Pecucula, which are found amongst grass or low green herbage, are mostly green in colour, and Salticus scenicus is handed with white and black to match the grey tint of the rocks and stone walls on which it hunts its prey. Similar instances of protective coloration could be cited without end. Sometimes the shape of the spider combines with the colour to produce the same effect, as in the species of Uloborus, such as they hang in thin shabby-looking webs exactly resemble fragments of wind-blown rubbish. The success of procryptic coloration depends, however, very largely upon stillness, and the instinct to keep stationary without moving a limb is a marked characteristic of all spiders unless engaged in hunting or fleeing from imminent danger. The instinct reaches its highest development in the phenomenon miscalled "death feigning." Spiders of various families will, when alarmed, lie the prey upon their legs tucked up and allow themselves to be pushed and rolled, and handled in various ways without betraying that they are alive by the slightest movement. But it would be absurd to suppose that they are in reality pretending to be dead, because there is no reason to think they can have any knowledge of death. They are merely practising the inherited instinct to lie motionless, movement being the only indication of the presence of living prey known to many insectivorous animals. When concealment is no longer possible terrestrial species, like the Lycosidae, dart swiftly to the nearest shelter afforded by crevices in the soil, stones, fallen leaves or logs of wood, while those that live in bushes, like the Argiopeidæ, drop straight to the ground and lie hidden in the earth or in the fallen vegetation beneath.

The extent to which procryptic coloration and instincts favouring concealment are developed indicates that generation after generation spiders have been subjected to persecution from enemies. No doubt large numbers are devoured by insectivorous birds, mammals and reptiles, but the mortality due to them and other foes sinks into insignificance beside that caused by the persecution of hymenopterous insects of the families Ichneumonidæ and Pompilidæ, especially of the latter, many species of which systematically restack their burrows with other spiders withwherethey feed their young in the breeding season. It is no exaggeration to say that countless thousands of spiders of all families are annually destroyed by these insects, and there is no reason to doubt that destruction on at least as great a scale has been going on for centuries, too many even to guess at. Hence it is probable that no factor has had a greater influence than these wasps in moulding the protective instincts and habits of spiders. One interesting phenomenon in spider-life seems to be directly and certainly traceable to this influence, and that is mimicry of ants. In the two families of spiders, but particularly in those like the Clubionidæ and Salticidæ, which are terrestrial in habits, there are species which not only live amongst ants, but so closely resemble them in their shape, size, colour and actions that it requires a practised eye to distinguish the Arachnid from the insect. Now the Pompilidæ or mason wasps provision their cells with insects of many different kinds, as well as with spiders; but, of the hundreds of species these wasps that have been described from different parts of the world, only one is known to use ants for this purpose; and this species is not one of the Ichneumonidæ and Pompilidæ. On the other hand it has been specially recorded of two of the species of Pompilidæ that they have a great dislike and apparent fear of these little poisonous Hymenoptera. So, too, it does appear that ants are entirely immune to the attacks of Ichneumonidæ, which destroy hosts of other insects and of spiders by laying their eggs upon their bodies. But since ants are not persecuted by these two families of Hymenoptera, the greatest enemies spiders have to contend with, it is evident that mimicry of ants is of supreme advantage to spiders. Ants, however, are not the only animals mimicked by spiders. Some members of the Argiopeidæ (Cyclosa) are exactly like small snails; others (Cyclosura) resemble Cocinellidæ in principal and colour. Now, Cocinellidæ (ladybirds) are known to be highly distasteful to most insectivorous mammals and birds, and snails would be quite unfit food for the Pompilid or Ichneumonid larvae, so that the reason for the mimicry in these cases is also perfectly clear. The exact extent, however, to which each particular class of enemy has affected the protective habits and attributes of spiders is by no means always evident; and it is impossible to discuss the question in detail within the limits of a short article. But two instances of extreme deviation from the ordinary mode of life due, apparently, like ant-mimicry, solely to mimicry are worthy of consideration. Nephila, the so-called "spider wasp," has been cited as illustrations of the profound effect upon habit brought about by long-continued persecution from enemies of this kind.
This deviation is the adoption of an aquatic mode of life by the European fresh-water spider (Argyrotona) and by the marine spider Desis, which is found on the shores of the Indian and Pacific Oceans from Cape Colony to eastern Australia. Desis lives invariably between tide-marks upon the rocks and in crevices and coral reefs, and may be found at low tide either crawling about upon them or swimming in tidal pools and feeding upon small fish or crustaceans. As the tide rises the spiders take refuge in crevices and spin their retreat a sheet of silk, impervious to water, beneath which they lie in safety with a supply of air until the ebb exposes the site again to the sun. The fresh-water spider (Argyrotona) lives amongst the weeds of lakes and ponds and, like Desis, is quite at home beneath the water either swimming from spot to spot or crawling amongst the stems of aquatic plants. As a permanent home the spider makes beneath the surface a thimble-shaped web, with inverted mouth, anchoring it to the weeds. He then ascends to the surface, carries down a bubble of air and releases it inside the mouth of the thimble, thus replacing a certain amount of water. This action is repeated until the domicile is filled with air, when the spider takes possession of it. The spider owes its name Argyrotona or the silver swimmer to its silvery appearance as it swims about under water enveloped in air, and its power to retain an envelope of air on its sternum and abdomen depends upon the circumstance that these areas are beset with hairs which prevent the water reaching the integument; but the air retained by these hairs can be released when the spider wishes to fill its subaqueous home. A similar ability is possessed by Argyroneta as well as by flies or gnats, which it seizes from below as they light upon the surface of the water. In the breeding season the male spins a bell or thimble near that of the female and joins the two by means of a silken passage. The female attaches her eggs to the inner wall of her own home, and the young when large enough to shift for themselves have the bell-making instinct fully developed. Since the adoption of an aquatic mode of life by Desis and Argyrotona involves no increased facilities in getting food, and merely substitutes for ordinary terrestrial enemies fishes and crustaceans in the former case, and fishes, amphibians, and insectivorous water-insects in the latter, the supposition is justified that the change in environment is due to the unremitting persecution of Pompilidae and Ichneumonidae, which would not venture to pursue their prey beneath the water’s surface. The habits of certain other spiders suggest the origin of the perfect adaptation to aquatic conditions exhibited by Desis and Argyrotona. The nature of the integument and its hairy clothing in all spiders enables them to be plunged under water and withdrawn perfectly dry, and many species, even as large as the common English house-spider (Tegenaria), are so lightly built that they can run with speed over the surface of standing water, and this faculty has been perfected in genera like Pirata, Dolomedes and Trichoria, which are always found in the vicinity of lakes or on the edges of rivers and streams, readily taking to the water or running down the stems of water plants beneath its surface when pursued. Some species of Dolomedes, indeed, habitually construct a raft by spinning dead leaves together and float over the water upon it watching for an opportunity to dash upon any insect that alights upon its surface.

Oecophila, spiders date from the Carboniferous Period, Arthroplea and others from the coal beds of Europe and North America being closely allied to the existing genus Lithophanes. Remains of spiders from the Baltic amber beds of Oligocene age and from nearly coeval fluvialite or lacustrine deposits of North America belong to forms identical with or closely related to existing genera, thus proving the great antiquity of our present spider fauna. (R. I. P.)

SPELHAGEN, FRIEDRICH VON (1829— ), German novelist, was born at Magdeburg on the 24th of February 1829.

He was brought up at Stralsund, where his father was a 1835 appointed government architect; he attended the gymnasmum there, and studied law and surgery at the universities of Berlin, Bonn and Greifswald. On leaving the university he became a master in a gymnasium at Leipzig, but upon his father’s death in 1854 devoted himself entirely to writing. After publishing Klara Vere (1857) and Auf der Dünne (1858), he obtained a striking success with Problematische Naturen (1860—61), one of the best novels of its time; it was followed by Die von Hohenstein (1863), In Reih‘ und Glied (1866), Wynnmer und Fries (1869), Deutsche Pioniere (1870), Alzelt voran (1872), Sturm und Drang (1876), Plattland (1878), Quisisana (1880), Angeia (1881), Ein neuer Pharao (1885), Faustulus (1897) and Freigeboren (1900). Speilhagen’s best work was produced between the years 1860 and 1876; he wrote nothing after Sturm und Drang which can be compared with that powerful romance. His novels combine two elements of especial power, the masculine assertion of liberty which renders him the favourite of the intelligent and progressive citizen, and the ruthless war he wages against the self-indulgence of the age. His love of the sea, derived from an early residence at Stralsund, introduces an element of poetry into his novels which is somehow rare in German fiction. Spielhagen’s dramatic productions, Hans und Grete (1868) and Liebe für Liebe (1875), and others, cannot compare with his novels. From 1878—1884 he was editor of Westermann’s Monatshefte.

Spielhagen’s Sämtliche Werke were published in 1871 in sixteen volumes, in 1878 in fourteen volumes; his Sämtliche Romane in 1890 (22 vols.), and these were followed by a new series in 1902. See also Correspondenzblatt und Bibliographie, Finker und Erfinder (2 vols., 1890); also G. Karpedes, F. Spielhagen (1889), and H. and J. Hart, Kritische Waffengänge (1886).

SPIESS, CHRISTIAN HEINRICH (1755—1799), German writer of romances, was born at Freiberg in Saxony on the 4th of April 1755.

For a time he was an editor in 1785 controller on the estate of a certain Count König at Betzdauk in Bohemia, where he died, almost insane, the result of his weird fancies, on the 17th of August 1799.

Spies, in his Ritter, Räuber- und Geister-Romane, as they are called—stories of knights, robbers and ghosts of the “dark” ages—the idea of which he borrowed from Goethe’s Götzen von Berlichingen and Schiller’s Räuber and Geisterseher, was the founder of the German Schauerromen (shocker), a style of writing continued, though in a finer vein, by Karl Gottlob Cramer (1758—1817) and by Goethe’s brother-in-law, Christian August Vulpius. These stories, though appearing largely to the vulgar taste, made Spies one of the most widely read authors of his day. The most popular was a ghost story of the 13th century, Das Petermännchen (1793); among others were Der alte Totenruf (1792); Das Hexenhaus; Die Heimatviertel, and letzter Regen der Erd- Luft- Feuer- and Wasser-Geister (1798). Beside numerous comedies, Spies wrote, anticipating Schiller, a tragedy Maria Stuart (1784), which was in the same year performed at the court theatre in Vienna.

See Karl Goedeke, Grundriss, v. 906 sq.; Müller-Fraureuth, Die Ritter- und Räuberromane (Halle, 1894).

SPIKENARD, or NARD (O. Fr. spikenard, Lat. spica nardi, from spica, ear of corn, and Gr. νάρδος, Pers. nard, Skt. nalada, Indian spikenard, from Skt, nal, to smell), a celebrated perfume which seems to have formed one of the most desirable aromatic ingredients in the costly ungents used by the Romans and Eastern nations. The ointment prepared from it (“ointment of pistic nard”) is mentioned in the New Testament (Mark ivr. 3—5; John xii. 3—5) as being “very costly,” a pound of it being valued at more than 300 denarii (over £10). This appears to represent the prices then current for the best quality of nard, since Pliny (H.N. xii. 26) mentions that nard spikes reached as much as 100 denarii per lb, and, although he does not mention the price of nard ointment, he states (xii. 2) that the “unguentum cinnamonomum,” a similar preparation, ranged from 25 to 300 denarii according to its quality. Nard ointment was also varied considerably in price from its liability to substitution (Ibid. xii. 26, 27, xii. 2). The genuine ointment1

1 The meaning of the word “pistic” is uncertain, some rendering it “genuine,” others “liquid,” and others taking it for a local name.

2 The use of alabaster vessels for preserving these fragrant ungents was customary at a very early period. Theophrastus (c. 314 B.C.) states that vessels of lead and alabaster were best for the purpose, on account of their density and coolness, and their power
SPILLIKINS—SPINAL CORD

(Anagodium nardinum sive foliata) contained costus (the root of Sausamurca lappa), amomum (the fruits of Anomum cordemomum), balm (the oleoresin of Balsamodendron opobalsamum) and myrrh, with Indian nard (Ibid. xii. 3).

The exact botanical source of the true or Indian nard was long a matter of uncertainty, the descriptions given by ancient authors being vague, but it is now identified as Nardostachys jatamansi, a plant in the valerian order, the fibrous root-stocks or "spikes" of which are still collected in the mountains of Bhotan and Nepal. The name "spike" is applied apparently from its resemblance in shape to a spike or ear of bearded corn. The root is crowned by the bases of several stems, each about 2 in. or more in length and as thick as the finger. To these the fibrous tissue of former leaves adheres and gives them a peculiar bristly appearance. It is this portion that is chiefly collected.

Other and inferior varieties of nard are mentioned by Dioscorides and subsequent writers. Celtic nard, obtained from the Ligurian Alps and Istria, consisted of the roots of plants also belonging to the valerian order (Valeriana celitica and V. saxatilis). This was exported to the East and thence to Egypt, and was used in the preparation of baths. Mountain nard was collected in Cilicia and Syria, and is supposed to have consisted of the root of Valeriana tuberosa. The false nard of Dauphiné, used in later times, and still cultivated in Switzerland, is the root-stock of Altimus victoriolais. It presents a singular resemblance to the spikes of Indian nard, but is devoid of fragrance. It is remarkable that all the nards belong to the natural order Valerianaceae, the odour of which is the same irrespective of the species. That of Nardostachys jatamansi is intermediate between valerian and patchouli, although more agreeable than either.

The name "spikemond" has also been employed in later times to several plants. The spikemond of the United States is Aralida racemosa, and another species of the same genus, A. nudicaulis, or "wild saracapulla, is known as "wild spikemond." In the West Indies Hybistus suaimomunus is called "spikemond," and in Great Britain the name "ploughman's spikemond" is given to Irisu conus.

SPILLIKINS (M.D., spilleken, little pin), or JACKSTRAWS (originally "jerk-straws"), a game of some antiquity played with a set of slender sticks of wood, bone or ivory, from 3 to 6 in. long, generally carved to represent weapons and utensils of various kinds, which are thrown in a heap haphazard upon the table. The players then endeavour in turn to extricate from the heap, one at a time, as many straws as possible, without moving any except the one angled for. The player obtaining the highest number of straws wins. The game is called in French Jeu de paques and in German Federespiel.

SPINA (Lat. for a thorn, or prickle, also backbone, whence spine), in architecture, the term given to the low podium wall which divided the circus of the Romans and round which the chariots ran; at each end of it was the meto or goal. On coins, gems and bas-reliefs it is shown with numerous other features on it, such as obelisks (of which those from the spina of the Circus Maximus are now in the piazzas of the Lateran and del Popolo), small aedicula or pairs of columns carrying an entablature, altars, statues, trophies, &c.

SPINACH (Spinacca oleracea), an annual plant, a member of the natural order Chenopodiaceae, which has been long cultivated for the sake of its succulent leaves. It is probably of Persian origin, being introduced into Europe about the 15th century. It should be grown on good ground, well worked and well manured; and for the summer crops abundant watering will be necessary.

The first sowing of winter spinach should be made early in August, and another towards the end of that month, in some sheltered but not shaded situation, in rows 18 in. apart—the plants being thinned when about 6 in. high. By the beginning of winter the outer leaves will have become fit for use, and if the weather is mild successive gatherings may be obtained up to the beginning of May. The prickly-seeded and the Flanders are the best for winter; and these should be thinned out early in the autumn to about 2 in. apart, and later of resisting the penetration of the ointment into their substance. Phylla also recommends alabaster for ointment vases. For small quantities onyx vessels seem to have been used (Horace, Carm. iv. 12, lines 10, 17).

on to 6 in. The lettuce-leaved is a good succulent winter sort, but not quite so hardy. To afford a succession of summer spinach, the seeds should be sown about the middle of February, and again in March; after this period small quantities should be sown once a fortnight, as summer spinach lasts but a very short time. They are generally sown in shallow drills, between the lines of peas. If a plot of ground has to be wholly occupied, the rows should be about 1 ft. apart. The round-seeded is the best sort for summer use.

The Orach or Mountain Spinach (Atriplex hortensis), a member of the same order, is a tall-growing hardy annual, whose leaves, though not regarded, are used as a substitute for spinach, and to correct the acidity of sorrel. The white and the green are the most desirable varieties. The plant should be grown quickly in rich soil. It may be sown in rows 2 ft. apart, and about the same distance in the row, about March, and for succession again in June. If needful, water must be freely given, so as to maintain a rapid growth.

The New Zealand Spinach (Tetragonas expansus), natural order Ficoidese, is a half-hardy annual, native of New Zealand, sometimes used as a substitute for spinach during the summer months, but in every way inferior to it. The seeds should be sown in March, on a gentle hot-bed, having been previously steeped in water for several days, and the seedlings should be potted, and placed under a frame till the end of May, and should then be planted out in light rich soil. The young leaves are those which are gathered for use, a succession being produced during summer and autumn.

SPINAL CORD, in anatomy, that part of the central nervous system in man which lies in the spinal canal formed by the vertebrae, and reaches from the foramen magnum to the lower margin of the first lumbar vertebra. It is about 18 in. long, and only full grown between the upper two-thirds of the spinal canal. The cord is protected by the same three membranes which surround the brain. Outside is the dura mater, which differs from that of the brain in not forming a periosteum of the bones, in sending no processes inward, and in having no blood sinuses enclosed within its walls. In other regards the spinal dura mater is somewhat similar to the periosteum of the central layer of the dura mater of the skull. Inside the dura mater is the arachnoid, which is delicate and transparent, while between the two lies the sub-dural space, which reaches down to the second or third sacral vertebra. The pia mater is the innermost covering, and is closely applied to the surface of the cord into the substance of which it sends processes. Between it and the arachnoid is the sub-arachnoid space, which is much larger than the sub-dural and contains the cerebro-spinal fluid. Across this space, on each side of the cord, run a series of processes of the pia mater arranged like the teeth of a saw; by their apices they are attached to the dura mater, while their bases are continuous with the pia mater surrounding the cord. These ligaments, each consisting of twenty-one teeth, are the ligamenta denticulata, and by them the spinal cord is moored in the middle of the cerebro-spinal fluid.

The spinal cord itself is a cylinder slightly flattened from before backward. In the cervical region it is enlarged where the nerves forming the tracheal plexus come off, while opposite the lower thoracic vertebræ the lumbar enlargement marks the region whence the lumbo-sacral nerves are derived. The spinal drapery is removed by opening up the cylinder, the medullary cord is pointed and forms the conus medullaris, from the apex of which a glistening membranous thread runs down among the nerves which form the cauda equina, and, after blending with the terminations of the dural sheath, is attached to the back of the coccyx.

In a transverse section of the cord two median fissures are seen; the antero-median (see fig. 3, A) is wide, and reaches about a third of the way along the antero-posterior diameter of the cord; it is lined by the pia mater, which, at its orifice, is thickened to form a

RAW_TEXT_END
The posterior visceral or Clarke's column is also largely confined to the thoracic region, and lies in the mesial part of the posterior cord. It is the place to which the sensory fibres of the sympathetic system (sympathetic splanchnics) run. The white matter, as has been shown, surrounds the grey and crosses across the spinal cord line to form the white commissure, which lies in front of the grey. It is composed of white and medullated nerve fibres, which are arranged in definite tracts, although in a section of a healthy cord these tracts cannot be distinguished even with the microscope. They have been and are still being gradually mapped out by pathologists, physiologists, and embryologists.

On tracing a sensory nerve into the cord (fig. 3, P.R.) through the posterior nerve root it will be seen to lie quite close to the mesial side of the posterior horn of the cord and runs upwards. The next root higher up takes the same position and pushes the former one toward the middle line, so that the lower nerve fibres occupy an area close to the posterior-median fissure known as the tract of Gowers (fig. 3, G.T.), while the higher lie more externally in the tract of Burdach (B.T.). The greater part of each nerve sooner or later enters the grey matter and comes into close relation with the cells of Clarke's column, but some fibres run right up to the nucleus gracilis and cuneatus of the brain, while a few turn down and form a descending tract, which, in the upper part of the cord, is situated in the inner part of the tract of Burdach and is known as the commissural tract (C.T.), but lower down gradually shifts close to the posterior-median fissure and forms the oval area of Flechsig (fig. 3, O.A.). It will be obvious that both these tracts could not be seen in the same section, and that fig. 3 is only a diagrammatic outline of their position.

A few fibres of each sensory nerve ascend in a small area known as Lissauer's tract (fig. 3, L.T.) on the outer side of the posterior nerve roots, and eventually enter the substantia gelatinosa.

To the outer side of Lissauer's tract and lying close to the lateral surface of the cord is the direct cerebellar tract (fig. 3, D.C.T.), the fibres of which ascend from the cells of Clarke's column to the cerebellum. As Clarke's column is only well developed in the thoracic region this tract obviously cannot go much lower.

In front of the last and also to the lateral surface of the cord is another ascending tract, the tract of Gowers (fig. 3, G.T.), or, as it is sometimes called, the lateral sensory fasciculus. It probably begins in the cells of the posterior horn, and runs up to join the fillet and also to reach the cerebellum through the superior cerebellar polemune. The crossed pyramidal tract (fig. 3, C.P.T.) lies lateral to the direct cerebellar tract, between it and the posterior cornu. It is the great motor tract by which the fibres coming from the Rolandic area of the cerebral cortex are brought into touch with the motor cells in the anterior horn of the opposite side. This tract extends right down to the fourth sacral nerve.

In front of the crossed pyramidal tract is the lateral basis bundle (fig. 3, L.B.B.), which probably consists of association fibres linking up different segments of the cord.

The anterior basis bundle (fig. 3, A.B.B.) lies in front on the mesial side of the anterior horn and, through it pass the anterior nerve roots. Like the lateral bundle it consists chiefly of association fibres, but it is continued up into the medulla as the posterior longitudinal bundle to the optic nuclei.

The direct pyramidal tract (fig. 3, D.P.T.) is a small bundle of the motor fibres from the Rolandic area, which, instead of crossing to the other side at the decussation of the pyramids in the medulla, runs down by the side of the anterior-median fissure. Its fibres, however, keep on gradually crossing to the opposite side through the anterior white commissure of the cord, and by the time the mid-thoracic region is reached it has usually disappeared.

The roots of the spinal nerves in the upper part of the canal arise from the cord nearly opposite the point at which the vertebrae begins; but the farther one passes down the higher the origin of each root becomes above its point of emergence. Consequently the lumbar and sacral nerves run a long way down before they reach their enlargements on their spinal foramina and are enclosed in the dural and arachnoid sheaths to form a mass like a horse's tail, which is therefore known as the cauda equina. The relation between the origin of each nerve and the spinal processes of the vertebrae has been worked out by R. W. Reid (Journ. Anat. and Phys., xxxii. 341).

Embryology.—The early development of the neural tube from the ectoderm is outlined in the article on the Brain. When the neural groove becomes a tube it is oval in section with a very large laterally

SPINAL CORD

Comparative Anatomy.—In the Amphioxus there is little difference between the brain and the spinal cord; the latter is merely the longer length of the body and is of uniform calibre. It encloses a central canal from which a dorsal fissure extends to the surface of the cord and it is composed of nerve fibres and nerve cells; most of the latter being situated round the central canal. There are no corpuscles in the human embryo. Some very large multipolar ganglion cells are present, and there are also large fibres known as giant fibres, the function of which is not clear.

When the reptiles are reached the cord shows slight enlargements in the regions of the limbs and these become more marked in birds and mammals.

In the mammal region of the cord the dorsal columns diverge and open up the central canal, converting it into a diamond-shaped space which is only roofed over by the membranes of the cord, and is known as the sinus rhomboidalis.

In the lower vertebrates except the Anura (frogs and toads), the cord fills the whole length of the spinal canal, but in the higher mammals (Primates, Chiroptera and Insectivora) it grows less rapidly, and so the posterior part of the canal contains the cauda equina within its sheath of dura mater. In mammals below the anthropoid apes there are no direct pyramidal tracts in the cord, since the decussation of the pyramids in the medulla is complete. Moreover, the crossed tracts vary very much in their proportional size to the rest of the cord in different animals. In man, for example, they form 11·57% of the total cross area of the cord, in the cat 7·79%, in the rabbit 5·3%, in the guinea-pig 3·9% and in the mouse 1·1%.

The tract is described as lower motor and, in that lower vertebrae the motor fibres of the cord are not so completely gathered into definite tracts as they are in man.

A decided growth in height has lately been taken in the anterior part of the cord which in the lower vertebrae runs through the centre of the central canal of the cord, and takes its origin in the optic reflex cells in close relation to the posterior commissure of the brain. More posteriorly (caudally) it probably acquires a course through the lateral columns of the cord and is looked upon as a means by which the muscles can be made to actively respond to the stimulus of light. It is known as Reissner's fibre, and its morphology and physiology have been studied most carefully in cyclostomes and fishes. It is said to be present in the mouse, but hitherto no trace of it has been found in man. It was discovered in 1860, but for forty years has been looked upon as an artefact.

SURGERY OF THE SPINE AND SPINAL CORD

Fracture of the spine may occur from indirect violence, as when a man falls from a height upon his head, or in a sitting position; or it may result from direct violence, as when he is hanged, or as when he is run over by a loaded van, or in a fall from a height across a beam. The vertebral column on the fracture being displaced from those below it, the spinal cord is generally torn across, and the parts of the trunk, or the limbs, which are supplied by the spinal nerves passing out from the posterior part of the spinal cord, is injured. In the case of the spinal column the sole connexion with the brain, and at once deprived of sensation and of the power of voluntary movement. In some cases of fracture of the spine there is at the time marvellously little constitutional disturbance. The higher up the column that the fracture occurs the more quickly does death ensue. If the fracture is in the middle of the back the patient may linger for several weeks, but even if he is lying upon a water-bed, and even if every care is taken of him, inflammation of the bladder and intractable bed-sores are apt to make their appearance, and his existence becomes truly miserable. Operative surgery is unable to effect much in these cases on account of the spinal cord being generally torn across or hopelessly crushed.

Curvature of the spine may be due to deformity of the bodies of the vertebrae caused by irregular pressure, or to the disintegration of their anterior parts by tuberculous ulceration, known as Pott's disease or spinal caries. Thus the causes of spinal curvature are very different, and it is necessary that the actual condition be clearly recognized or treatment may prove harmful. Briefly, the curvature which is due to tuberculosis disease requires absolute and continuous rest; the other causes for well-regulated exercises.

Lateral or rotary curvature of the spine is a deformity which comes on during the developing period of life, before the bodies of the vertebrae are solidly formed. In young people who are

Fig. 5.—Schema of a Transverse Section through the Early Neural Tube (Young).

The left side of the section shows an earlier stage than the right side, of the canal and shoot out long processes—the axons. The permanent central canal of the cord was formerly said only to represent the ventral end of the large embryonic canal, the dorsal part being converted into a slit by the gradual closing in of its lateral walls, thus forming the postero-median fissure. A. Robinson, however, does not believe that the posterior fissure is any remnant of the central canal, and there are many points which bear out his contention (Studies in Anatomy, Owens College, 1891). The most modern view (1908) is that the fissure is formed partly by an infolding and partly from the original central canal. The antero-median fissure is caused by the ventral part of the cord growing on each side, but not in the mid-line where no germinal cells are.

The anterior nerve roots are formed by the axons of the neuroblasts in the developing anterior cornua, but the posterior grooves into the cord from the posterior root ganglia (see Nerve Spinal), and, as they grow, form the columns of Goll and Burdach. That part of the grey matter from which the ventral, anterior or motor nerve roots rise is known as the basal lamina of the cord, while the more dorsal part into which the posterior nerve roots enter is the alar lamina. These parts are important in comparing the morphology of the spinal cord with that of the brain.

In the embryo up to the fifth month there is little difference in the appearance of the grey and white matter of the cord, but at that time the fibres in the columns of Burdach acquire their medullary sheaths or white substance, while the grey matter is probably abstracted from the blood. Very soon after these the fibres myelinate and then, in the sixth month, the columns of Goll. Next follow the direct cerebellar tracts and, in the latter half of the eight month, the tracts of Goll mature, while the fibres of the pyramidal and Lissauier's tracts do not gain their medullary sheaths until just before or after birth. At first the spinal cord extends as far as the last metmesodermal somite, but neuroblasts are only formed as far as the first coccyeal somite, so that the cord that is non-nervous and degenerates later into the filum terminale. After the fourth month the nervous portion grows more slowly than the rest of the body and so the long cauda equina and filum terminale are produced. At birth the lower limit of the cord is opposite the third lumbar vertebra, but in post-natal development it recedes still farther to the lower level of the first.

For further details see Quain's Anatomy, vol. I. (London, 1908); J. P. McMurrich, Development of the Human Body (1906). Most modern descriptions are founded on the writings of W. His, references to which and to other literature will be found on p. 463 of McMurrich's book.
Inflammation having thus been set up, ulceration (caries) of the vertebra, or of several vertebrae, occurs, and if the case runs on unchecked extensive abscesses may form in the thigh, loin or groin. The trouble is often begun by a blow or by a sprain of the spine, which, by lowering the power of resistance of the delicate bone, prepares it for the bacillary invasion. The earliest symptoms are likely to be a dull aching in the back with stiffness of the spine. The child complains of being tired, and is anxious to lie down and be left quiet whilst his little companions are running about. If the disease is in the middle part of the spine, pains are complained of in the front of the chest-region, and in the chest-region; towards the base of the neck there have been no complaints of pain in the back. As the bodies of the vertebrae crumble away, the spine bends forwards under the influence of the weight of the head and of the upper part of the trunk, and a projection may appear in the middle line of the back. In the neck, and in the loin-region, the projection is rarely well marked, but in the chest-region a conspicuous boss may make its appearance—the “hump-back.” The projection is often spoken of as an angular curvature—a contradiction in terms, for a thing which is angular is not curved. When the deformity is great there may be a dislocation of the spinal cord with more or less paralysis in the parts below.

The treatment of tuberculous disease of the spine demands absolute and uninterrupted rest. The best thing is to put the patient flat on his back for as many months as may be found necessary, but not in a close bedroom. If he is compelled to lie in a bedroom the windows should be open night and day. If the patient is a child, he should be laid flat in a box-splint, or upon a thin horseshoe mattress, and should be carried out of doors every day—but always lying flat. When the pressure-symptoms, such as the pains in the legs, thighs or arms, the “belly-ache,” or the pains in the chest or neck have passed away, a firm leather splint may be moulded on to keep the spine in an upright position. Severe cases of kyphosis may require the use of a jacket splint, or a bandage, the use of which is contraindicated only in those cases of which the curvature is due to the presence of pus. If the disease is localized at the top of the spine the child should lie with the neck in an elevated position.

In cases of advanced tuberculous disease of the spine, in which the spinal cord is compressed within its bony canal either by the posterior parts of the vertebral bodies or by inflammatory products, or in which, after severe injury, the cord is pressed upon by a displaced piece of bone, the surgeon may think it expedient to open the spinal canal from behind, removing in the procedure the posterior arches (laminae) of the vertebrae. The operation is called by the hybrid word laminectomy. Sometimes in the case of tuberculous disease, where the propriety of resorting to the operation is being discussed, the symptoms of the compression begin to clear off and the child make the test of the operation. The test is that the line of morbid if we should wait patiently and give Nature a full chance of doing her work in her own way. The operative treatment of these cases is not highly satisfactory. Still, there are a certain small number of cases in which it has been given with success.

The treatment of spinal abscess has been greatly influenced by the Listerian method. The collection of broken-down tuberculous matter from the spinal canal is not commonly done in the usual sense, for it does not contain “pus” or “matter,” being, as it were, a desert of septate micro-organisms. A spinal abscess is therefore no longer drained: it is incised, scraped, washed out, and swabbed dry, the opening being then closed and protected. The abscess is thus very nearly effectually excluded from the cavity, and the patient is spared the depressing and tedious discharging of the cavity which so often followed the old methods of treatment. It must be clearly understood, however, that every spinal abscess does not undergo cure after being subjected to the evacuation and closure treatment mentioned

Growing rapidly, and whose muscular system is weak, the bad habit of standing, and throwing the weight of the body constantly on one leg, gives rise to a serious tilting of the trunk; or, if, when writing at a desk, they sit habitually in a twisted position, a lateral curvature of the spine is apt to take place. By constant indulgence in these bad habits the spinal column gets permanently set in a faulty position. Sometimes the tilting of the base of the trunk is due to a congenital or acquired difference in the length of the legs. In the concavity of the curve there is increased pressure, and, necessarily, diminished growth; in the convexity of the curve there is diminished pressure with increased growth. The patient's friends probably notice that one shoulder is higher than the other, or that “the hip is growing out,” and unless means are taken to alter the abnormal distribution of pressure, the condition becomes worse, until complete ossification checks the further progress of the deformity. The growth of the subject being completed, the deformity ceases to increase. And when the growth is completed and the bones are solid and misshapen the condition is quite incapable of improvement. The usual curvature is one in which there is a convexity of the spine in the chest-region towards the right, with the right shoulder higher than the left. Compensatory curves in the opposite direction form in the loins and neck. Along with the lateral bending of the spine a rotation of the bodies of the vertebrae towards the convexity of the curve takes place, the spurious processes turning towards the concavity of the curve. Since the line of the spurious processes of the vertebrae can be easily traced through the skin, their deviation may mislead the superficial observer as to the actual amount of the curvature.

To counteract this deformity in the earliest stages (and it is in the early stage that treatment effects most), the patient (generally a girl) should be encouraged to walk perfectly erect. Systematic exercises, to strengthen the muscles of the back, ought to be strictly and persistently carried out under the direction of a surgeon with the assistance of a skilled instructor of gymnastics. During the intervals of rest the child should lie upon her back on a firm board, and should avoid taking exercise which gives rise to weariness of the muscles; for whenever the muscles become wearied she will attempt to take up a position which throws the strain on to her ligamentous and bony structures. One of the best exercises is to lay the patient on her face, fix her feet, and encourage her to raise herself by using the muscles of the back. Whilst she hangs from a trapeze the weight of the lower limb and pelvis will help to straighten the spine as a whole, necessarily diminishing the increased pressure upon the cartilaginous bodies of the vertebrae towards the concavity, and increasing the pressure between the sides of the bodies towards the convexity. It is often a good thing to remove a girl with commencing lateral curvature from the sedentary life of school or town and to let her run wild in the country, exercising her muscles to the full.

If the deformity is due to inequality in the length of the legs, a high boot on the short leg may correct it. In some cases of lateral curvature a tilted seat is useful. Mechanical spinal supports are useless; to strengthen the muscles of the back, indeed, they are positively harmful, in that they add to the weight of the trunk and hinder needful muscular development. By kyphosis is meant an exaggerated degree of roundness of the shoulders. It can be effaced only by constant drillings and exercises whilst the spinal column is still plastic. When once the bones are solid no great improvement is possible. The deformity is sometimes due to short sight. It is well, therefore, to have the child’s vision duly tested.

Lordosis is an exaggeration of the normal concavity of the loin-region of the spine. It is most often met with in those cases in which from congenital displacement of the head of the thigh bone, or from old disease of the hip-joint, the subject has acquired the habit of throwing the shoulders back in order to preserve the balance.

Tuberculous disease of the spine (Potter’s disease), is the result of a deposit of tubercle-germs in the body of the vertebra.
above, but that the surgeon is sometimes compelled to use irrigation and drainage.

In 1897 Dr Calot of Berck-sur-Mer reintroduced the method of straightening out the hump of the back, so often left after disease of the spine, by straightening the ill-fitting table and dealing with the hump, under chloroform, with what is commonly known as "brute force." A considerable number of hump-backed children on the Continent as well as in England and America were thus dealt with, but in many of the reported cases, results have not been collected and published, would be found to justify the enthusiasm and publicity with which the method was inaugurated and its details were spread abroad. It is scarcely necessary to say that the forceful straightening of a spine which has developed a hump because tuberculous disease has wrecked the front of the vertebral segments is in no sense a curative operation. Diminishing the size of the processus spinosus, the tuberculous lesion is unquestionably eradicated, but indeed, it may increase the ulcerative process or determine a scattering of the germs of tubercle throughout the body. The operation has not been accepted by British and American surgeons. In the practice of the foreign surgeon death ensued in three cases out of thirteen that were operated on, and an English surgeon reported fourteen cases "in all of which the deformity had recurred although the spines had been fixed in plaster of Paris after the straightening."

Being deeply placed in the mass of the muscles of the back, and, moreover, being jealously locked within the bony canal of the vertebral column, the spinal marrow or spinal cord was, until the last few years, little known to be an important organ, much every ancient and enterprising surgeon. Still, like other tissues, it was liable to diseases and injuries. The exact situation of a tumour pressing upon the spinal cord can now be located with great precision by noting the areas of pain and numbness, and the height in the limbs or trunk to which loss of power of voluntary movement ascends, and by noting also whether these effects are symmetrical upon the two sides or appear more upon one side than on the other. By cutting away the portion of the bone that is in the way of progression of the surgical cure of various sorts have been successfully removed from the interior of the canal. Displaced fragments of bone in tuberculous affection of the spine, abscess-contents and inflammatory tissue have also been similarly dealt with. Sir William Mac eachen of Glasgow and Sir Victor Horsley of London have been pioneers in this development of surgery. In cases of fracture of the spine, with displacement of the vertebral column and compression of the spinal cord, surgeons have also been trying what relief can be afforded by the adoption of bold operative measures, but as in most of these cases of fracture-dislocation the spinal cord is torn right across or crushed beyond hope of repair, active measures cannot be undertaken with much prospect of success.

"Concussion of the Spine."—Occasionally one hears persons, whose professional education should have taught them better, speaking or writing of concussion of the spine as if that were in itself a disease. It is an expression which is not infrequently used in an equally comprehensive and incorrect way when the ill-informed person is speaking of the injuries, real or imaginary, of which an individual makes complaint after having met with a severe shock when travelling on a railway. One might as well speak of concussion of the skull to convey the idea of an injury to the brain as if the brain were but the bony envelope of the spinal cord, as the skull is of the brain. The violent shaking of the spinal cord and the spinal nerves in a serious accident may, however, be followed by some functional disturbance, which may be associated with pains in the back, by numbness and tingling in the limbs, or with muscular weakness. In some cases the disturbance is due to slight haemorrhages into the nerve sheaths, which may clear up with rest and quiet. But when the presence of these obscure symptoms, after a railway accident for instance, becomes the subject of an action-at-law, there is a great difference between the way in which they will not pass off until a case is settled in one way or the other. Not, perhaps, that the individual concerned is dishonest in his estimation of them, but because the anxiety of the overhanging lawsuit has so grievously disturbed his mind and altered his perspective that his sense of proportion is for a time in abeyance. After the action-at-law the symptoms may clear up with a rapidity which to some people appears surprising.

(E. O.)

PHYSIOLOGY OF THE SPINAL CORD

The name spinal cord, given by early morphologists to the nervous mass lying in the tubular chamber enclosed by the vertebral column, was doubtless given under the supposition that the organ so named could be treated as an entity. Scientifically, however, it cannot be so treated, either as regards its structure or its function. It is merely a part of that great nervous structure which throughout the length of the body forms the central meeting-place of the nerve-paths arriving from and issuing to all regions with which nerve fibres are in touch. To separate from the rest of this system the part which lies within the spine is an artificial and in many ways misleading provision. This artificial treatment is the outcome of crude ideas drawn from the study of merely the gross form of the bodily parts. But crude as the distinction is, its historic priority has influenced the study of the vertebrate nervous system, not only in regard to morphological description but also in regard to exposition of the functional reactions of the nervous system and even up to the present day. Hence it is still customary and artificial to deal with the general working of the nervous system into a separate group and describe that group by itself, simply because they occur in nervous arcs whose central courses in the great central nervous organ lie within that part of it extending along the spine. An additional inconvenience attaching to the mode of description of the nervous system customary in works on human anatomy, is that in such works the parts of the nervous arcs outside the central organ are described apart from it under the term peripheral nerves. This severs artificially structures which are functionally interrelated. The outline and description of the working of the nervous system is hampered by this unphilosophic subdivision of its structural parts.

To gain a broader and truer point of view as starting-point for understanding the working of the spinal cord one must prepare the exposition by a short reference to the general function of the nervous system in the bodily economy.

Relation to General Nervous System.—An animal of microscopic size may continue throughout its life to be constituted entirely by one single cell. Animals of larger bulk, although each begins its existence as a single cell, attain their development by the multiplication of the original single cell, so that from it there comes to be formed a coherent mass of cells very many millions in number. In these multicellular animals each of the constituent cells is a minute self-centred organism, individually born, leading its own life and destined for individual death. The corporate power of the complex animal is the sum of the powers of those manifold individual existences, its cells. In the complex animal the several organs, even the most homogeneous, such as muscles or glands, are each composed of many thousands of cells similarly specialized but living each per se. A property of the complex organism as such is the end result of the binding together of the units which compose the complex organism. Of the agencies which integrate the complex animal, one of the most potent is nervous action. A certain number of the unit cells composing the animal are specially differentiated from the rest to bind the whole together by nervous action. These specially differentiated cells are called "neuromes." They constitute living threads along which waves of physico-chemical disturbance are transmitted to act as releasing forces for the energy in distant cells, where they finally impinge.

It is characteristic of this nervous system, the system of neuromes, that, although ramifying far and wide through the body, it is a continuum from end to end. The peripheral nerves are formed of bundles of neuromes lying side by side, but these, although packed close together, are strictly isolated one from another as conductors and remain isolated throughout the whole length of the nerve. The points of functional nexus of the neuromes one with another are confined to one region only of the whole system. All their conductive connexions one with another take place solely in the central nervous mass which constitutes the so-called central nervous system, a nervous organ extending axially along the length of the body midway between the body's lateral halves. Thither the neuromes converge in vast numbers, those of each body segment converging to that fraction of the central organ which belongs to their body segment. The central nervous organ thus receiving these neuromes is, where it lies in the head, called
the brain, the rest of it is called in vertebrates the "spinal
cord," in vermes and arthropods the "nerve-cord." The
central organ not only receives neurones which converge to it
from outside, but many of its own neurones thrust out their
conductive arms from it as nerve fibres carrying nervous
influence outwards to regulate the activity of glands and muscles.
In the vertebrata the ingoing neurones for each segment and
similarly the out-going neurone fibres are collected into a seg-
mental nerve. To the spinal cord these are each attached by
two roots, one dorsal, consisting of the afferent fibres, the other
ventral, consisting of the efferent fibres.

The Reflex.—Analysis of function of this nervous system leads to
what is termed "the reflex" as the unit of its action. The
simplest complete reaction of the system is the afferent and
efferent response in which many reflexes which are extremely complex, being built up of
a number of simpler reflexes combined together. A reflex is
a reaction started by the environment acting as a stimulus upon
some nerve which communicates the excitement thus started in
itself to other nerves by means of its connexions with these
in the central nervous organ. The excitement so generated and
transmitted finally travels outward from the central organ
by one or more of the efferent nerves and through these reaches
muscles or glands producing in them its final effect. The
muscles and glands are from this point of view termed effect-
ors. The reaction is therefore referred to as the reflex act of the
central organ. The nerve structures along which it runs in its tra-
jectory are spoken of as a nervous arc. The whole purpose of
the central nervous organ is therefore to bring afferent neurones
into touch with efferent neurones. The whole purpose of
reflex arcs is to bind one part of the organism to another part
in such a way that what the environment is doing to the organism
at one place may appropriately call forth or restrain movement
or secretion in the muscles or glands possessed by the organism.

Receptor Cells.—There is one condition for the due perform-
asce of these reactions which is not provided by the nervous
system itself. The afferent neurones are not in most cases
so constituted as to be excitable themselves directly by the
environment—for instance, they cannot be stimulated by light.
Their amenability to the environment, their sensitization to
environmental agencies, is effected by special cells adjacent to
their peripheral ends. These cells from organs are called
receptors. They are delicately adapted to be stimulated by this
or that particular agent and are classifiable into various species,
such that each species is easily excited by a particular agent which is "adequate" for it, and is quite inexitable or only excitible with
difficulty by agencies of other kinds. Thus in the skin
somatosensory receptors are adapted for mechanical stimuli (touch)
and not for thermal stimuli, while others (cold spots, warm
spots) are adapted for thermal stimuli and not for mechanical.
As far as it is known each afferent neurone is connected with
receptors of one species only. The receptors thus confer upon
the reflex arcs selective excitability. Each arc is thus tuned to respond to certain stimuli, while other arcs not having that
kind of receptor do not respond. The receptors, therefore,
while increasing the responsiveness of the organism to the
environment, prevent confusion of reactions (inco-ordination)
by observing what stimuli are to be acted upon. The afferent
spinal reflex arc is therefore referred to as a reflex arc.

Proprioceptors.—The system of neurones is thus made acces-
sible to the play of the external world acting on the body. And
in addition to those receptors which are stimulated directly by
the external world, are others lying within the mass of the
organism itself, which are excitable by actions occurring in
the organism itself. These are called proprioceptors. They are
distributed preponderantly in the muscles and structures
functionally adjacent to muscle, such as joints, ligaments, fasciae,
&c. The reactions induced in such motor structures reflexly in
response to environmental stimuli tend therefore secondarily
to be followed and accompanied by reflex reactions initiated
from proprioceptors.

Conduction.—The process by which the excitement generated in
the afferent neurone travels along the reflex arc is known as
conduction. Conduction along afferent and efferent nerves
differs in some important respects from that obtaining in the
nerve centre, i.e. in the piece of the central nervous system
connecting the afferent nerve with the efferent nerve. In a nerve-
trunk the excited state set up in it by a stimulus travels along
its fibres as wave-like disturbance at a speed of about thirty-
three metres per second, and does not alter in intensity or speed
in its travel. A nerve-trunk when excited (artificially) at some
point along its length transmits the "impulse," i.e. the wave-
like excited state in both directions, i.e. both up and down each
fibre, from the point stimulated. This is true whether the fibre
is afferent or efferent. The speed of travel of the nervous
impulse along the nerve-trunk is practically the same whether
the state of excitation, i.e. nervous impulse, is weak or intense.
Thus, the nerve-trunk shows no adaptation, i.e. no change in
an effective even though weak stimulus and its response ceases
practically at once on cessation of the exciting stimulus. When
excited by repeated brief stimuli the rhythm of the response
corresponds closely with that of the stimuli, even when the
frequency of the latter is as high as 100 per second. With
momentary stimuli a response even so brief as 20 can be given by
the nerve-trunk. Finally, nerve-trunk conduction is singular-
ly resistant to fatigue, to impoverished blood supply, and
to many drugs which powerfully affect reflex actions.

In conduction through the central nervous system the travel
of nervous impulses exhibits departure from these features.
Its intensity is liable to be altered in transit. Its time of
transit, especially if it be weak, is much longer than for a similar length of nerve-trunk. Its direction of transmission becomes
polared, that is, confined to one direction along the nervous
path. The state of excitement engendered does not subside
immediately on cessation of the stimulus, and may outlast the
stimulus by many seconds. The rhythm of response to a
rhythmic stimulus does not change in correspondence with
change in the stimulus-rhythm. A response, however brief the
stimulus, is probably never shorter than 50 in duration.
There are not striking differences, and morphological study of the structural features of the central organ does not at present
suggest how they for the most part arise. It seems certain
however, that in the central organ it is that part which consists
of so-called grey matter which forms the place of their occurrence.
There the spread of the impulse from one nerve-fibre to others
seems clearly due to the fact that each afferent fibre breaks
up into branching threadlets which ramify in various directions
and terminate in close apposition with other neurones. There
has been much dispute as to whether the termination is one
of contiguity with the next neurone or of actual continuity
with it. The result of recent investigation seems to show that
in the vast majority of cases continuity and not actual homoge-
neous continuity is the rule in the spinal cord. The point
of nexus of one neurone with another is termed the synapse.
If synapsis occurs by contiguity and not homogeneous continuity,
it is fair to suppose that at it the transmission of nervous
impulses must be different from that observable in the homo-
eneous conducting threads of nerve fibres. The conduction
must traverse something of the nature of a membrane. To
the properties of synaptic membranes many of the features
of conduction of nervous impulses are due. For instance, the
feature of irreversible direction of conduction.

Reflex Reactions.—When the spinal cord is severed at any point
the reflex arcs of the portion of the body behind the transection
are quite cut off from the rest of the nervous system in front,
including the brain. The reflex reactions elicited from the
thus isolated region cannot therefore be modified by the action
of the higher nervous centres. It is important to see what
character these reflexes possess. The higher centres in the
brain exercise powers over the motor machinery of the body
and in doing so make use of the simpler nervous centres that
belong to the segments severally, that is the local nervous
centres existing for and in each body segment itself. In the
head the local centres are overlaid by higher centres which
cannot by any simple severance be separated from them. By
studying, therefore, the powers of the cord behind a complete
spinal transsection we can obtain in a comparatively simple way information as to the powers of the purely local or segmental reflex mechanisms.

The so-called "flexion-reflex" of the limb is one of the most accessible of the local reflex reactions which can thus be studied with isolated portion of the spinal cord at its central end.

Let it be supposed that the limb observed is the hind limb. The three main joints of the limb are the hip, the knee and the ankle. Each of these joints is provided with muscles which flex or bend it, and others which extend or straighten it. It is found that the reflex throws into contraction the flexor muscles of each of these joints. It matters little which of all the various afferent nerves of the limb is stimulated, whichever of these the afferent nerve may be, the centrifuged discharge from the cord goes to practically the same muscles, namely, always to the flexors of the joints.

The centrifuged discharge does not go to the extensor muscles of the limb. However strong the stimulus and however powerful the afferent nerve chosen the spinal centre does not discharge impulses into the extensor muscles, though these muscles receive motor nerves issuing from the very same region of the cord as that supplying motor nerves to the flexor muscles. Not only does the reflex action not discharge motor impulses into the nerves of the extensor muscles, but if the spinal cord happens to be discharging impulses into these nerves when the reflex is evoked this discharge is suppressed or diminished (inhibited). The result is that whereas the extensor muscles made to contract, but their antagonists, the extensors, are, if in contraction at the same time, thrown out of contraction, that is, relaxed. In this way the latter muscles are prevented from impeding the action of the contracting flexors. This inhibition occurs at the beginning of the reflex action which excites the muscles and continues so long as the flexion-reflex itself continues. It thus prevents other reflexes from upsetting for the time being the due action of the flexion-reflex, for it renders the muscles opposing that reflex less accessible to motor discharge through the spinal cord whatever the quarter whence incitation to that discharge may come.

A feature of this reflex is its graded intensity. A weak stimulus evokes in the flexor muscles a contraction which is weak and in the extensor muscles a relaxation which is slight. Not only is the contraction weak in the individual flexor muscles, but it is limited to fewer of them, and in large muscles seems to involve only limited portions of them.

The duration of the reflex similarly varies directly with the duration of the exciting stimulus applied to the afferent nerve. The time relations of electrical stimuli can be controlled by the experimenter. The result is that when the chest presses against the abdomen the reflex centre has at command a stimulus of extreme brevity, lasting only a few millionths of a second. With such stimulus a lower limit is soon found to the brevity of the reflex effect as expressed by muscles. It is found difficult to evoke with brief stimuli reflex contractions so brief as those evoked from the muscle by similar stimuli applied direct to the motor nerve of the muscle. There is reason to think that such stimuli applied to a nerve may evoke one single nerve-impulse. A single nerve impulse generated in a motor nerve causes in the muscle a brief contraction which is called a twitch, and lasts a tenth of a second. A single nerve impulse generated in an afferent nerve sometimes fails on arriving at the spinal centre to evoke any observable reflex effect at all, but if it is effective the muscle contraction tends to be longer than a "twitch," often much longer. It is therefore questioned whether the spinal centre when excited even most briefly ever discharges one single centrifugal impulse only; it seems usually to discharge a short series of such impulses.

Allied to this character is the tendency which even simple spinal reflexes exhibit to continue discharging for a not very long time after their exciting stimulus has ceased to be applied. This after-discharge following a strong stimulus may persist even for several seconds.

Refractory Phase.—Besides characters common to all or many spinal reflexes certain spinal reflexes have features peculiar to themselves or exhibited by them in degrees not obvious in other reflexes. One of these features is refractory phase. The scratch-reflex exemplifies this. In the dog, cat, and many other animals the hind limb often performs a rapid scratch movement, in all these cases applying to the skin of the shoulders or neck, as if to groom the hairy coat in that region. This movement is in the intact animal under control of the brain, and can be executed or desisted from at will. When certain of the higher centres in the brain have been destroyed, this scratching action occurs very readily and in, as it were, an uncontrolled way. When the spinal cord has been severed in the neck this scratching movement of the hind limb can be elicited with regularity as a spinal reflex by merely rubbing the skin of the side of the neck or shoulder, applying there a weak electric current to the skin. And this reflex the stimulus evokes alternating and interconnected with the hairs in the skin and these convey impulses to the spinal centres in the neck or shoulder segments, and in these turn discharge impulses into nerve fibres entirely intraspinal passing backward along the cord to reach motor centres in the hind limb region. These motor centres in turn discharge centrifugal impulses into the muscles of the hind limb of the same side of the body as the shoulder which is the seat of irritation. The motor discharge is peculiar in that it causes the muscles of the hind limb to contract rhythmically at a rate of about four contractions per second, and the discharge is peculiar further in that it excites the flexor muscles of the limb and thus the extensor muscles alternately so that at the hip for instance the limb is alternately flexed and extended, each single phase of the movement lasting about an eighth of a second. Now this rhythmic discharge remains the same in rate whether the exciting stimulus applied to the skin be continuous or one of many various rates of repetition. Evidently at some point in the reflex arc there is a mechanism which after reacting to the impulses reaching it remains for a certain brief part of a second unresponsive, and then becomes once more for a brief period responsive, and so on. And this phase of alternation of excitability and insensitivity repeats itself through the continuance of the reflex even when that endures for minutes. The phase of inexcitability is termed the refractory phase. It is important as an essential element in the co-ordination; without it the scratching movement would obviously not be obtained for alternation of flexion and extension is essential to the act. A similar element almost certainly forms part of the co-ordinating mechanism for many other cyclic reflexes, including those of the stepping of the limbs, the movement of the jaw in mastication, the action of the eyelids in blinking, and perhaps the respiratory movements of the chest and larynx.

Fatigue.—Nerve trunks do not easily tire out under stimulation even most prolonged. Reflex actions on the other hand relatively soon tire. Some are more resistant, however, than are others. The flexion-reflex may be continued for ten minutes at a time and the scratch-reflex can be maintained so long. As a reflex tires, the muscular contraction which it causes tends to become less intense and less steady. The relatively rapid onset of fatigue in reflexes is counterbalanced by speedy recovery in repose. A long flexion-reflex which has been made to disappear by the wrist, the fingers, or the hand, will recommence after 30 seconds' repose with almost the same vigour and steadiness as if it had not recently been tired out.

This character of reflexes is in accordance with their executing movements which for the most part are not under natural circumstances required to last long. Such movements are the taking of a step by a limb, the movement of the jaw in mastication, the descent of the diaphragm in breathing, the withdrawal of the foot or the pinion from a noxious stimulus or the movement of the eyelids to wash off a particle touching the cornea, the natural movements to which the artificially provoked reflexes seem to correspond do not demand prolonged motor activity, or when they do, demand it in rhythmic repetition with intervening pauses which allow repose.
Reflex Postures.—But there are certain reflexes which do persist for long periods at a stretch. These are reflex postures. The hind limbs of the “spinal” frog assume an attitude which is reflex, for it ceases on severance of the afferent spinal roots. This attitude is one of flexion at hip, knee and ankle, resembling the well-known natural posture of the frog as it squats when quiet in the tank. Similarly in the “spinal” dog or cat certain muscles exhibit a slight but persistent contraction. This is seen well in the extensor muscles of the knee. These tonic reflexes are related to attitudes. In the dog and cat they are exhibited by those muscles whose action antagonizes gravity in postures which are usual in the animal, thus the extensors of the knee and hip and shoulder and elbow are in tonic contraction when the limb is extended.

The reflex arcs concerned in reflex maintenance of this tonic contraction of muscles have been shown in several cases to arise within those muscles, and in those very muscles which themselves exhibit the tonic contraction. It is not, however, certain that all muscles exhibit a reflex tonus; for instance, it is not certain that in the dog the tail muscles exhibit such a tonus. And in those muscles which do exhibit the spinal reflex tonus attempts to obtain a similar uniling slight steady reflex contraction by artificial stimuli applied to receptive organs or nerves have failed.

The Spinal Reflex Arc of the Hind Limb.—When the skin of the limb is stimulated the flexion-reflex already described is evoked. The reflex is excited by nocuous stimuli such as a prick or squeeze applied to the skin anywhere in the limb, but most easily when applied to the foot. Electrical stimuli wherever applied evoke the same reflex. Similarly electrical stimuli applied to any afferent nerve of the limb evoke this reflex, whether the afferent nerve be from skin or from the muscles. Since the reflex always provokes excitation of the flexor muscles and inhibition of the extensor muscles, the result is that central stimulation of the afferent nerve of a flexor muscle excites its own muscle and inhibits its antagonist (reciprocal innervation), while similar stimulation of the afferent nerve of an extensor muscle inhibits its own muscle and excites its antagonist (reciprocal innervation). The reflex flexion of the ipsilateral hind limb is commonly accompanied by reflex extension of the opposite hind limb. If the reflex spreads to the forelimb, it produces extension of the same side forelimb with flexion of the crossed forelimb sometimes, but sometimes extension of both forelimbs.

In the dog and cat extension of the ipsilateral hind limb can, however, be excited by stimulation of the skin in three limited regions. One of these is the sole of the foot; smooth pressure between the pads excites a strong brief extension. This is called the extensor thrust. It is accompanied by a similar sudden brief extension of all three other limbs. This reflex may be related to the action of galloping, and the pressure which excites resembles that which the weight of the body bears on the pads against the ground.

The two other regions are the skin of the front of the groin supplied by the crural branch of the genito-crural nerve, and the skin just below and mesial to the buttock. These always excite the extensor muscles, not the flexors. They may be concerned with sexual acts.

Reflexes of the Fore Limb.—These resemble those obtainable from the hind limb. The ipsilateral reflex is flexion at shoulder, elbow and wrist. The contra lateral fore limb at the same time is extended at shoulder, elbow and wrist. When the reflex spreads to the hind limbs the hind limb of the same side is extended at hip, knee and ankle, that of the crossed side is sometimes flexed at hip, knee and ankle, but sometimes is instead extended at hip, knee and ankle. The reflex sometimes spreads to the neck, causing the head to be turned toward the fore limb, which is the seat of the stimulation.

The Scratch Reflex.—This has already been partly described above. The area from which it can be excited by appropriate stimulation is a large one, namely, a field of skin which is somewhat saddle-shaped having its greatest width transversely across the shoulders. It extends from close behind the pinna back to the join. The stimuli which are effective are rubbing the skin or lightly pricking it, or lightly pulling on the hairs: also faradisation by a needle electrode whose point is only just inserted among the hairs but not deeper than their roots. If the stimulus be applied to the right hand of the mid-line the right hind limb is flexed at hip and performs the rapid scratching movement described above, and the left hind limb is thrown into steady extension. And conversely, when the stimulus is to the left side of the mid-line.

Each of these reflexes is a co-ordinate reaction. It is seen, therefore, that through the medium of the spinal cord the body behind the head has at command a certain number of reflexes and that these of these manages the skeletal musculature in a co-ordinate way. It will also be clear from the facts mentioned above about these separate reflexes that the fields of muscles worked by these several reflexes is to a large extent common to them all. Thus the reflex excited from the skin of the right hind limb acts on the muscles of that limb and also on those of the three other limbs. So similarly the reflex excited from the left hind limb, and from each fore limb. Study of the inter-relationship between these reflexes shows that by means of the spinal cord not only is co-ordinate action of the muscles ensured for each reflex, but that also the separate reflexes are co-ordinated one with another.

When we examine the relationship holding between individual reflexes we find that some resemble one another in regard to their action upon a particular muscle or group of muscles. On the other hand, some act in opposite ways upon a particular muscle or muscle group. In order to follow the co-ordination effected by the spinal cord in corresponding reflexes together we have to turn to a certain feature in the scheme of construction of the nervous system. This feature is embodied in what is termed the principle of the common path.

Interaction between Reflexes.—At the commencement of every reflex arc is a receptive neurone extending from the receptive surface to the central nervous organ. This neurone forms the sole avenue which impulses generated at its receptive point can use whithersoever be their destination. This neurone is therefore a path exclusive to the impulses generated at its own receptive point, and other receptive points than its own cannot employ it. A single receptive point may play reflexly upon quite a number of different effector organs. It may be connected through its reflex path with many muscles and glands in many different regions. Yet all its reflex arcs spring from the one singe shank or stem, i.e. from the one afferent neurone which excites the receptive point at the periphery into the central nervous organ.

But at the termination of every reflex arc we find a final neurone, the ultimate conductive link to an effector organ, (muscle or gland). This last link in the chain, e.g. the motor neurone, differs obviously in one important respect from the first link of the chain. It does not subserve exclusively impulses generated at one single receptive source, but receives impulses from many receptive sources situate in many and various regions of the body. It is the sole path which all impulses, no matter whence they come, must travel if they are to act on the muscles or organs to which the arc leads.

Therefore, while the receptive neurone forms a private path exclusively serving impulses of one source only, the final or efferent neurone is, so to say, a public path, common to impulses arising at any of many sources of reception. A receptive field, e.g. an area of skin, is analysable into receptive points. One and the same effector organ stands in reflex connexion not only with many individual points, but even with many various receptive fields. Reflexes generated in manifold sense-organs can pour their influence into one and the same muscle. Thus a limb muscle is the terminus ad quem of many reflex arcs arising in many various parts of the body. Its motor nerve is a path common to all the reflex arcs which reach that muscle.

Reflex arcs show, therefore, the general features that the initial neurone of each is a private path exclusively belonging to a single receptive point (or small group of points); and that
finally the arcs embouch into a path leading to an effector organ; and that their final path is common to all receptive points wherever they may lie in the body, so long as they have connexion with the effector organ in question. Before finally converging upon the motor neurone the arcs converge to some degree. Their private paths embouch upon interspinal paths common in various degree to groups of private paths. The terminal path may, to distinguish it from internuncial common paths, be called the final common path. The motor nerve to a muscle is a collection of final common paths.

Certain consequences result from this arrangement. One of these is the preclusion of essential qualitative difference between nerve-impulses arising in different afferent nerves. If two conductors have a tract in common there can hardly be essential qualitative difference between their modes of charge; and if the final common paths must be capable of responding with different rhythms which different conductors impress upon it. It must be to a certain degree aperiodic. If its discharge be a rhythmic process, as from many considerations it appears to be, the frequency of its own rhythm must be capable of being at least as high as that of the highest frequency of any of the afferent arcs that play upon it; and it must be able also to reproduce the characters of the slowest.

A second consequence is that each receptor being dependent for final communication with its effector organ upon a path not exclusively its own but common in part with other receptors, such nexus necessitates successive and not simultaneous use of the common path by various receptors using it to different or opposed effect. When two receptors are stimulated simultaneously, each of the receptors tending to evoke reflex action that for its end-effect employs the same final common path but employs it in a different way from the other, one reflex appears without the other. The result is this reflex or that reflex, but not the two together.

In the simultaneous correlation of reflexes some reflexes combine harmoniously, being reactions that mutually reinforce. These may be termed allied arcs, and the neural arcs which they employ allied arcs. On the other hand, some reflexes, as mentioned above, are antagonistic one to another and incompatible. These do not mutually reinforce, but tend to each other in inhibitory relation. One of them inhibits the other, or a whole group of others. These reflexes may in regard to one another be termed antagonistic; and the reflex or group of reflexes which succeeds in inhibiting its opponents may be termed "prepotent" for the time being.

Allied Reflexes.—The action of the principle of the final common path is best explained in regard to "allied arcs" in the scratch-reflex as follows. If, while the scratch-reflex is being elicited from a skin point at the shoulder, a second point distant 10 mm. from the other point but also in the receptive field of skin, is stimulated, the stimulation at this second point favours the reaction from the first point. This is well seen when the stimulus at each point is of subminimal intensity. The two stimuli, though each unable separately to invoke the reflex, yet do so when applied both at the same time. This is not due to overlapping spread of the feeble currents about the stigmatic poles of the two circuits used. Weak cancelization of either of the motor effects is avoided. Moreover, it occurs when localized mechanical stimuli are used. It therefore seems that the arcs from the two points, e.g. Ra and R have such mutual relation that reaction of one of them reinforces reaction of the other, as judged by the effect on the final common path.

This reinforcement is really an instance of summation in the final common path. So also is the effect to which Exner has given the name of "bahnung," a phenomenon of frequent occurrence in reflex reactions. Suppose a stimulus (A) be applied which is too weak to elicit the reflex which were it stronger it could evoke. It is found that a second stimulus (B) also of itself too weak to evoke the reflex, will evoke the reflex if applied at a short interval after the application of (A). The two stimuli sum in their effect upon the final common path. The "receptive field" of a reflex is really the common area of commencement of a number of allied arcs. And reflexes whose arcs commence in receptive fields even widely apart may also have "allied" relation. In the bulbo-spinal dog stimulation of the outer digit of the hind foot will evoke reflex flexion of the leg, and stimulation of each of the other digits evokes practically the same reflex; and if stimulation of several of these points be simultaneously combined the same reflex as a result is obtained more readily than if one only of these points is stimulated. And to these stimulations may be added simultaneously stimulation of points in the crossed fore foot; stimulation there yields by itself flexion of the hind leg; and under the simultaneous stimulation of fore and hind foot the flexion of the leg goes on as before, though perhaps more readily; that is, the several individual reflexes harmonize in their influence upon the common final common path. The motor neurones of a muscle of the knee are the termiinus ad quem of reflex arcs arising in receptors not only of its own foot, but from the crossed fore foot and pinna and tail, also undoubtly from the otic labyrinth, olactory organs and eyes. Thus, if we take as a standpoint any motor nerve to a muscle it consists of a number of motor neurones which are more or less bound into a unit mechanism among the reflex actions of the organism a number can all be brought together as a group, because they all in their course converge together among this motor mechanism, this final common path, activate it, and are in harmonious mutual relation with regard to it. They are in regard to it what were termed above "allied" reflexes.

Antagonistic Reflexes.—But not all reflexes connected to one and the same common final path stand to one another in the relation of "allied reflexes." Suppose during the scratch-reflex a stimulus be applied to the foot not of the scratching side, but of the opposite side. The left leg, which is executing the scratch-reflex, is in response to stimulation of the left shoulder skin is cut short in its movement by the stimulation of the right foot, although the stimulus at the shoulder to provoke the scratch-reflex is maintained until the time the stimulus to the right foot will temporarily interrupt a scratch-reflex, or will cut it short or will delay its onset; which it does of these depends on the time-relations of the stimuli. The inhibition of the scratch-reflex occurs sometimes when the contraction of the muscles innervated by the reflex conflicting with it is very slight. There is interference between the two reflexes and the one is inhibited by the other. The final common path used by the left scratch-reflex is also common to the reflex elicitable from the right foot. This latter reflex evokes at the opposite (left) knee extension; in doing this it releases extensor neurones of the right side and steadily inhibits the flexor neurones. But the scratch-reflex causes rhythmic excitation of the flexor neurones. Therefore these flexor neurones in this conflict lie as a final common path under the influence of two antagonistic reflexes, one of which would excite them to rhythmic discharges four times a second, while the other would continually repress all discharge in them. There is here an antagonistic relation between reflexes embouching on one and the same final common path.

In all these forms of interference there is a competition, as it were, between the excitatory stimulus used for the one reflex and the excitatory stimulus for the other. Both stimuli are in progress together, and the one in taking effect precludes the other's taking effect as far as the final common path is concerned; and the precise form in which occurs depends greatly on
the time-relations of application of the two stimuli competing against each other.

Again, if, while stimulation of the skin of the shoulder is evoking the scratch-reflex, the skin of the hind foot of the same side is stimulated, the scratching may be arrested. Stimulation of the skin of the hind foot by any of various stimuli that have the character of threatening the part with damage causes the leg to be flexed, drawing the foot up by steady maintained contraction of the flexors of the ankle, knee and hip. In this reaction the reflex arc is (under schematic provisions similar to those mentioned in regard to the scratch reflex schema)

(i.) the receptive neurone, noci-ceptive, from the foot to the spinal segment, (ii.) the motor neurone to the flexor muscle, e.g. of hip (a short intra-spinal neurone); a Schalt-zelle (v. Monakow) is probably existent between (i.) and (ii.) but omitted for simplicity. Here, therefore, there is an arc which embouches into the same final common path, FC. The motor neurone FC is a path common to it and to the scratch-reflex arc; both these arcs employ the same effector organ, namely, the knee-flexor, and employ it by the common medium of the final path FC. But though the channels for both reflexes embouch upon the same final common path, the excitatory flexor effect specific to each differs strikingly in the two cases. In the scratch-reflex the flexor effect is an intermittent effect; in the noci-ceptive flexion-reflex the flexor effect is steady and maintained. The accompanying tracing shows the result of conflict between the two reflexes. The one reflex displaces the other at the common path. Compromise is not evident. The scratch-reflex is set aside by that of the noci-ceptive arc from the homonymous foot. The stimulation which previously sufficed to provoke the scratch-reflex is no longer effective, though it is continued all the time. But when the stimulation of the foot is discontinued the scratch-reflex returns. In that respect, although there is no enforced inactivity, there is an interference which is tantamount to, if not the same thing as, inhibition. Though there is no cessation of activity in the motor neurone, one form of activity that was being impressed upon it is cut short and another takes its place. A stimulation of the foot too weak to cause more than a minimal reflex will often suffice to completely interrupt, or cut short, or prevent onset of, the scratch-reflex.

The kernel of the interference between the homonymous flexion-reflex and the scratch-reflex is that both employ the same final common path FC to different effect—just as in the interference between the crossed extension-reflex and the scratch-reflex. Evidently, the homonymous flexion-reflex and the crossed extension-reflex both use the same final common path FC. And they use it to different effect. The motor neurone to the flexor of the knee being taken as a representative of the final common path, the homonymous flexion-reflex inhibits it from discharging. Hence if, while the direct flexion-reflex is in progress, the crossed foot is stimulated, the reflex of the knee-flexor is inhibited. The crossed extension-reflex therefore inhibits not only the scratch-reflex, but also the homonymous flexion-reflex.

Further, in all these interferences between reflexes the direction taken by the inhibition is reversible. Thus, the scratch-reflex is not only liable to be inhibited by, but is itself able to inhibit either the homonymous flexion-reflex or the crossed extension-reflex; the homonymous flexion-reflex is not only capable of being inhibited by the crossed extension-reflex, but conversely in its turn can inhibit the crossed extension-reflex. These interferences are therefore reversible in direction. Certain conditions determine which reflex among two or more competing ones shall obtain mastery over the final common path and thus obtain expression.

Therefore, in regard to the final common path FC, the reflexes that express themselves in it can be grouped into sets, namely, those which excite it in one way, those which excite it in another way, and those which inhibit it. The reflexes composing each of these sets stand in such relation to reflexes of the same set that they are with them "allied reflexes." But a reflex belonging to any one of these sets stands in such relation to a reflex belonging to one of the other sets that it is in regard to the latter an "antagonistic" reflex. This correlation of reflexes about the flexor neurone in the leg, so that some reflexes are mutually allied and some are mutually antagonistic in regard to that neurone, may serve as a paradigm of the correlation of reflexes about every final common path, e.g. about every motor nerve to skeletal muscle.

As to the intimate nature of the mechanism which thus, by summation or by interference, gives co-ordination where neurones converge upon a common path, it is difficult to surmise. In the central nervous system of vertebrates, afferent neurones A and B in their convergence toward and impingement upon another neurone Z, towards which they conduct, do not make any lateral connexion directly one with the other—at least, there seems no clear evidence that they do. It seems, then, that the only structural link between A and B is neurone Z itself. Z itself should therefore be the field of coalition of A and B if they transmit "allied" reflexes.

It was argued, from the morphology of the perikaryon, that it must form, in numerous cases, a nodal point in the conductive lines provided by the neurone. The work of Ramón-y-Cajal, van Gehuchten, v. Lenhossek and others, with the methods of Golgi and Ehrlich, establishes as a concept of the neurone in general that it is a conductive unit wherein a number of branches (dendrites) converge towards, meet and coalesce in a single out-going stem (axone). Through this tree-shaped structure the nervous impulses flow, like the water in a tree from roots to stem. The conduction does not normally run in the reverse direction. The place of junction of the dendrites with one another and with the axone is commonly the perikaryon. This last is therefore a nodal point in the conductive system. But it is a nodal point of particular quality. It is not a nodal point where lines meet to cross one another, nor one where one line splits into many. It is a nodal point where conductive lines run together into one which is the continuation of them all. It is a reduction point in the system of lines. The perikaryon with its convergent dendrites is therefore just such a structure as spatial summation and immediate induction would demand.

\[\text{SPINAL CORD} \quad 677\]
The neurone Z may well, therefore, be the field of coalition, and the organ where the summational and inductive processes occur. And the morphology of the neurone as a whole is seen to be just such as we should expect, arguing from the principle of the common path.

With the phenomenon of "interference" the question is more difficult. There it is not clear that the field of antagonism is within the neurone Z itself. The field may be synaptic. We have the demonstration by Verworn that the interference produced by A at Z for impulses from B is not accompanied by any obvious change in excitability of the axone of Z. Z, if itself the seat of inhibition, might have been expected to exhibit that inhibition throughout its extent. This, as tested by its axone, it does not. There exist, it is true, older experiments by Uspensky, Belmonto and Oddi, &c., according to which the threshold of direct excitability of the motor root is lowered by stimulation of the afferents. This points to an inhibition of the facilitation effect through the whole motor neurone, conversely to Verworn's demonstration for central inhibition. Verworn's experiment and its result is very clear. It leads us to search for some other mechanism common to A and B to which might be attributable their mutual influence on each other's reactions. But if we admit the conception, argued above, that at the nexus between A and Z, i.e. at synapse A Z, and similarly between B and Z, i.e. at synapse B Z, there exists a surface of separation, a membrane in the physical sense, a further consequence seems inevitable. Suppose a number of different neurones A, B, C, &c., each conducting through its own synapse upon a neurone Z. The synapses A Z, B Z, C Z, &c. are all surfaces or membranes into which Z enters as a factor common to them all. A change of state induced in neurone Z might be expected to affect the surface condition or membrane at all of the synapses, since the condition of Z is a factor common to all those membranes. Therefore a change of state (excitatory or inhibitory) induced in Z by any of the neurones A, B, C, &c., playing upon it would enter as a condition into the nervous transmission at the other synapses from the other afferential neurones. In harmony with this is the spread of refractory state in the neurones as mentioned above. A change in neurone Z induced by neurone A playing upon it, in that case seems to effect its point of nexus with the other neurones B, C, &c., also. It is conceivable that the phenomena of interference may be based in part at least on such a condition. The neurone threshold of Z for stimulation through B will be to some extent a function of events at synapses A Z.

Factors Determining the Sequence.—The formation of a common path from tributary converging afferent arcs is important because it gives a co-ordinating mechanism. There the dominium, immediate induction of other arcs, or sets of allied arcs, possessing this dominium, is subject to supercession by another afferent arc, or set of allied arcs, and the supercession normally occurs without intercurrent confusion. Whatever be the nature of the physiological process occurring between the competing reflexes for dominance over the common path, the issue of their competition namely, the determination of which one of the competing arcs shall for the time being reign over the common path, is largely conditioned by four factors. These are spinal induction, relative fatigue, relative intensity of stimulus, and the function of the spinal reflex itself.

1. The first of these occurs in two forms, one of which has already been considered, namely, immediate induction. It is a form of "bahnung." The stimulus which excites a reflex tends by central spread to facilitate and lower the threshold for reflexes, allied to that which it particularly excites. A constellation of reflexes thus tends to be formed which reinforce each other, so that the reflex is supported by allied accessory reflexes, or if the prepotent stimulus shifts, allied arcs are by the induction particularly prepared to be responsive to it or to a similar stimulus. The tendency in the competition between afferent arcs is to fortify the reflex just established, or, if transition occur, to favour transition to an allied reflex. Immediate induction seems to obtain with highest intensity at the outset of a reflex, or at least near its commencement. It does not appear to persist long.

The other form of spinal induction is what may be termed successive induction. It is in several ways the reverse of the preceding.

In peripheral inhibition, exemplified by the vagus action on the heart, the inhibitory effect is followed by a rebound after-effect opposite to the inhibitory (Gaskell). The same thing is obvious in various instances of the reciprocal inhibition of the spinal centres. Thus, if the crossed-extension reflex of the limb of the "spinal" dog be elicited at regular intervals, say once a minute, by a carefully adjusted electric stimulus of defined duration and intensity, the resulting reflex movements are repeated each time with much constancy of character, amplitude and duration. If in one of the intervals a strong, prolonged (e.g. 30") flexion-reflex is induced from the limb yielding the extensor-reflex movement, the latter reflex is found intensified after the intercurrent flexion-reflex. The intercalated flexion-reflex lowers the threshold for the aftercoming extension-reflexes, and especially increases their after-discharge. This effect may endure, progressively diminishing, through four or five minutes, as tested by the extensor reflexes at successive intervals. Now, as we have seen, during the flexion-reflex the extensor arcs were inhibited; after the flexion-reflex these are in this case evidently in a phase of exalted excitability. The phenomenon is not anything new, and may be described as the "spontaneous" appearance of the antagonistic reflex. Thus the flexion-reflex, if intense and prolonged, may, directly its own exciting stimulus is discontinued, be succeeded by a "spontaneous" reflex of extension, and this even when the animal is lying on its side and the limb horizontal— a pose that does not favour the tonus of the extensor muscles. Such a "spontaneous" reflex is the spinal counterpart of the visual "Lichtchof." To this spinal induction, as it may be termed, seems attributable a phenomenon commonly met in a flexion-reflex of high intensity when maintained by very prolonged extensor activity. The reflex flexion is then frequently broken at irregular intervals by sudden extension movements. It would seem, therefore, that some process in the flexion-reflex leads to exaltation of the activity of the arcs of the opposed extension-reflex. An electrical stimulation of the proximal end of the severed nerve of the extensor muscles of the knee (cat), though it does not, in the present writer's experience, directly excite contraction of the extensors of the knee is on cessation often immediately followed by contraction of them.

As examples of the rebound exaltation following on inhibition the following may also serve. The so-called "mark-time" reflex of the "spinal" dog is an alternating stepping movement of the hind limbs which occurs on holding the animal up so that its limbs hang pendent. It can be inhibited by stimulating the skin of the tail. On cessation of that stimulus the stepping movement sets in more vigorously and at quicker rate than before. The increase is chiefly in the amplitude of the movement, but the writer has also seen the rhythm quickened even by 30% of the frequency.

This after-increase might be explicable in either of two ways. It might be due to the mere renewal of the reflex centre, the reflex set being reinforced by all the afferent arcs of the reflexes. Its tendency in the competition between afferent arcs is to fortify the reflex just established, or, if transition occur, to favour
stimulus being stretch of the hip-flexors under gravity—is not followed by after-increase of the reflex.

Or the after-increase might result from the inhibition being followed by a rebound to superactivity. This latter seems to be the case. The after-increase occurs even when both hind limbs are passively lifted from below during the whole duration of the inhibitory stimulus applied to the tail. It is the depression of inhibition, and not the mere freedom from an exciting stimulus, that induces a later superactivity. And the reflex inhibition of the knee-extensor by stimulation of the central end of its own nerve is especially followed by marked rebound to superactivity of the extensor itself.

Again, the knee jerk, after being inhibited by stimulation of the hamstring nerve, returns, and is then more brisk than before the inhibition.

By virtue of this spinal contrast, therefore, the extension-reflex predisposes to and may actually induce a flexion-reflex, and conversely the flexion-reflex predisposes to and may actually induce an extension-reflex. This process is qualified to play a part in linking reflexes together in a co-ordinate sequence of successive combination. If a reflex arc A during its own activity temporarily checks that of an opposed reflex arc B, but as a subsequent result induces in arc B a phase of greater excitability and capacity for discharge, it predisposes the spinal organ for a second reflex opposite in character to its own in immediate succession to itself. The writer has elsewhere pointed out the peculiar prominence of "alternating reflexes" in propulsive locomotion of the quadrupeds. It is significant that they are usually cut short with ease by mere passive mechanical interruption of the alternating movement in progress. It seems that each step of the reflex movement tends to excite by spinal induction the step next succeeding itself.

Much of the reflex action of the limb that can be studied in the "spinal" dog bears the feature of adaptation to locomotion. This has been shown recently with particular clearness by the observations of Phillipson. In describing the extensor thrust of the limb the writer drew attention at the time to its significance for the function of the limb. Spinal induction obviously tends to connect this extensor-thrust flexion of the limb as an after-effect. In the stepping of the limb the flexion that raises the foot and carries it clear of the ground prepares the antagonistic arcs of extension, and, so to say, sensitizes them to respond later in their turn by the supporting and propulsive extension of the limb necessary for progression. In such reflex sequences an antecedent reflex would thus not only be the means of bringing about an ensuing stimulus for the next reflex, but would predispose the arc of the next reflex to react to the stimulus when it arrives, or even induce the reflex without external stimulus. The reflex "standing" of the "spinal" dog does go on even without an external skin stimulus: it will continue when the dog is held in the air. The cat walks well when anaesthetic in the soles of all four feet.

Each reflex movement must of itself generate stimuli to afferent apparatus in many parts and organs—muscles, joints, tendons &c. This probably reinforces the reflex in progress. The reflex obtainable by stimulation of the afferent nerve of the flexor muscles of the knee excites those muscles to contraction and inhibits their antagonistics: the reflex obtainable from the afferent nerve of the extensor muscles of the knee excites the flexors and inhibits their antagonistics.

Where a reflex by spinal induction tends to eventually bring about the opposed reflex, the process of spinal induction is therefore probably reinforced by the operation of any reflex generated in the movement. This would help to explain how it is that a reflex reaction, when once excited in a "spinal" animal, ceases on cessation of the stimulus as quickly as it generally does. Such a reaction must generate in its progress a number of further stimuli and throw up a shower of centripetal impulses from the moving muscles and joints into the spinal cord. Squeezing of muscles and stimulation of their sensory nerves, &c., elicits reflexes. The primary reflex movement might be expected, therefore, of itself to initiate further reflex movement, and that secondarily to initiate further still, and so on. Yet on cessation of the external stimulus to the foot in the flexion-reflex the whole reflex comes usually at once to an end. The scratch-reflex, even when violently provoked, ceases usually within two seconds of the discontinuance of the experimental stimulus that provoked it.

We have as yet no satisfactory explanation of this. But we remember that such reflexes are intercurrent reactions breaking in on a condition of neural equilibrium itself reflex. The successive induction will tend to induce a compensatory reflex, which brings which moving parts back again to the original position of equilibrium.

2. Another condition influencing the issue of competition between reflexes of different source for possession of one and the same final common path is fatigue. A spinal reflex under continuous excitation or frequent repetition becomes weaker, and may cease altogether. This decline is progressive, and takes place earlier in some kinds of reflexes than it does in others. In the "spinal" dog the scratch-reflex under ordinary circumstances tires much more rapidly than does the flexion-reflex.

A reflex as it tires shows other changes besides decline in amplitude of contraction. Thus in the flexion-reflex, the original steadiness of the contraction decreases; it becomes tremulous, and the tremor becomes progressively more marked and more irregular. The rhythm of the tremor in the writer's experiments has often been about 10 per second. Then phases of greater tremor tend to alternate with phases of improved contraction as indicated by some regain of original extent of flexion of limb and diminished tremor. Apart from these partial evanescent recoveries the decline is progressive. Later, the stimulation being maintained all the time, brief periods of something like complete intermission of the reflex appear, and even of a replacement of flexion by extension. These lapses are recovered from, but tend to recur more and more. Finally, an irregular phasic tremor of the muscles is all that remains. It is not the flexor muscles themselves which tire out, for these, when under fatigue of the flexion-reflex they contract no longer for that reflex, contract in response to the scratch-reflex which also employs them.

Similar results are furnished by the scratch-reflex, with certain differences in accord with the peculiar character of its individual charge. One of these latter is the feature that the individual beats of the scratch-reflex usually become slower and follow each other at slower frequency. Also the beats, instead of remaining fairly regular in amplitude and frequency, tend to succeed in somewhat regular groups. The beats may disappear altogether for a short time, and then for a short time reappear, the stimulus remaining all the while. Here, again, the phenomena are referable to the muscle, for when excited through other reflex channels, or through its motor nerve directly, the muscle shows its contraction well. Part of the decline of these reflexes under electrical stimulation in the "spinal" dog may be due to reduction of the intensity of the stimulus itself by physical polarization. That does not account in the main for the above described effects. The graphic record of fatigue of the flexion of the scratch-reflex obtained by continued mechanical stimulation does not appreciably differ from that yielded under electrical stimulation. The different speed of the decline due to fatigue proceeds characteristically in different kinds of reflex, and in the same kind of reflex under different physiological conditions, e.g., "spinal shock": this indicates its determination by other factors than electrical polarization. Polarization has in a number of cases been deferred as far as possible by using equalized alternate shocks applied in opposite directions through the same gilt needle; this precaution has not yielded results differing appreciably from those given by ordinary double shocks or by series of make or break shocks of the same direction. The slowing of the beat in fatigue is also against the explanation by an anaesthetic action, since merely weakening the stimulus does not lead to a slower beat.

When the scratch-reflex elicited from a spot of skin is fatigued,
the fatigue holds for that spot, but does not implicate the reflex as obtained from the surrounding skin. The reflex is, when tired out to stimuli at that spot, easily obtainable by stimulation two or more centimetres away. This is seen with either mechanical or electrical stimuli. When the spot stimulated second is close to the one tired out, the reflex shows some degree of fatigue, but not that degree obtaining for the original spot. This fatigue may be a local fatigue of the nerve-endings in the spot of skin stimulated, to which in experiments making use of electric stimuli some polarization may be added. Yet its local character does not at all necessarily implicate its reference to the skin. It may be the expression of a spatial arrangement in the central organ by which reflex arcs arising in adjacent receptors are partially confluent in their approach toward the final common path, and are the more confluent the closer together lie their points of origin in the receptive field. The resemblance between the distribution of the incidence of this fatigue and that of the spinal summation previously discussed argues that the seat of the fatigue is intraspinal and central more than peripheral and cutaneous; and that it affects the afferent part of the arc inside the spinal cord, probably at the first synapse. Thus, its incidence at the synapse R—a and at R—p would explain its restrictions, as far as we know them, in the scratch-reflex.

The local fatigue of a spinal reflex seems to be recovered from with remarkable speed, to judge by observations on the reflexes of the limbs of the "spinal" dog. A few seconds' remission of the stimulus suffices for marked though incomplete restoration of the response. An instance of this is seen in the return of a reflex even during the stimulation under which the waning and disappearance of the reflex occurred. The exciting stimulus has usually in such cases been of rather weak intensity. In the writer's experience these spinal reflexes fade out sooner under a weak stimulus than under a strong one. This seeming paradox indicates that under even feeble intensities of stimulation the threshold of the reaction gradually rises, and that it rises above the threshold value of the weaker stimulus before it reaches that of a stronger stimulus. The scratch-reflex which has ceased to be elicited by a weak stimulus is immediately evoked—often with no sign of fatigue in its motor response—by increasing the intensity of the stimulus applied at the same electrode. The occurrence of fatigue earlier under the weaker stimulus than under the stronger also shows that the fatigue consequent under the weaker stimulus may often be, relatively to the production of the natural discharge, greater than when a stronger stimulus is employed. This, which has been of frequent occurrence in the writer's observations on the leg of the "spinal" dog, if obtaining widely in reflex actions, has evident practical importance.

A remedy to avoid in some degree the local fatigue associated with excitation of the scratch-reflex from one single spot in the skin by taking advantage of the spatial summation of stimuli applied at different points in the receptive field. When this was done, a curious result met the writer. The provocation of the reflex has been made through ten separate points in the receptive field, the distance between each member of the series of points and the point next to it being about four centimetres. Each point is stimulated by a double-induction shock delivered twice a second. When this is done a series of scratch movements is elicited, and continues longer when the stimuli are applied at the same interval, not to succeeding series of skin points but to one point. Thus three or four hundred beats can be elicited in unbroken series. But the series tends somewhat abruptly to cease. If, then, in spite of the cessation of the response, the stimulation be continued without alteration during three or four minutes or more, the scratching movement breaks out again from time to time and gives another series of beats, perhaps longer than the first. These experiments indicate that physical polarization at the stigmatic electrode is not answerable for the fading out of the scratch-reflex. It shows also the complexity of the central mechanisms involved in the reflex. The phenomena recall Lombard's phases of briskness and fatigue in series of records obtained with the ergograph.

It is interesting to note certain differences between the cessation of a reflex under fatigue and under inhibition. The reflex ceasing under inhibition is seen to fade off without obvious change in the frequency of repetition of the beats, or in the duration of the individual beats. The reflex ceasing under fatigue is seen to show a slower rhythm and a sluggish course for the latter beats, especially for the terminal few. Among the causes of fatigue of a reflex action there are several suggesting that in it the command over the final common path exercised for the time being by the receptors and afferent path in action becomes less strong, less steady and less accurately adjusted. Under prolonged excitation their hold upon the final common path becomes loosened. This view is supported by the fact that its connexion with the final common path is then more easily cut short and ruptured by other rival arcs competing with it for the final common path in question. The scratch-reflex interrupts the flexion-reflex more readily when the latter is tided up than when it is fresh.

In the hind limb of the "spinal" dog the extensor-thrust is indelicate under the flexion-reflex. That is to say, when the flexion-reflex is evoked with fair or high intensity the writer has never succeeded in evoking the extensor-thrust, though the flexed posture of the limb is itself a favouring circumstance for the production of the thrust if the flexion be a passive one. But when the flexion-reflex is kept up by appropriate stimulation of a single point over a prolonged time, so that it shows fatigue, the extensor-thrust becomes again elicitable. Its elicitation is, then, not regular nor frequent, but it becomes obtainable, usually in quite feeble degree at first, later more powerfully.

In other words, it can dispossess the rival reflex from a common path when that rival is fatigued, though it cannot do so when the rival action is fresh and powerful.

Again, the crossed extension-reflex cannot inhibit the reflexion of the flexor-reflex under ordinary circumstances if the intensity of the stimulation of the competing arcs be approximately equal; but it can do so when the flexion-reflex is tired.

The waning of a reflex under long-continued excitation is one of the many phenomena that pass in physiology under the name of fatigue. It may be that in this case the so-called fatigue is really nothing but a negative induction. Its place of incidence may lie at the synapse. It seems a process elaborated and preserved in the selective evolution of the neural machinery. One obvious use attaching to it is the prevention of the too prolonged continuous use of a common path by any one receptor. It precludes one receptor from occupying for long periods an effector organ to the exclusion of all other receptors. It prevents long continuous possession of a common path by any one reflex of considerable intensity. It favours the receptors, taking turn after turn. It helps to ensure variety of reactions. The organism, to be successful in a million-sided environment, must in its reaction be many sided. Were it not for such so-called fatigue, an organism might, in regard to its receptivity, develop an eye, or an ear, or a mouth, or a hand or leg, but it would hardly develop the marvellous congeries of all those various sense-organs which it is actually found to possess.

The loosening of the hold upon the common path by so-called fatigue occurs also in paths other than those leading to muscle and effector organs. If instead of motor effects sensual are examined, analogous phenomena are observed. A visual image is more readily inhibited by a competing image in the same visual field when it has acted for some time than when it is first perceived (W. Macdonagh).

One point, on a priori grounds, is a natural corollary from the principle of the common path," as indicated by the experimental findings relative to the incidence of fatigue. The reflex arcs, each a chain of neurones, converge in their course so as to impinge upon and conjoin in links (neurones) common to whole varied groups—in other words, they conjoin to common paths. This arrangement culminates in the convergence of many disparate spinal arc to one spinal neurone. This neurone thus forms the instrument for many different reflex arcs and acts. It is responsive to them in various rhythm and in
various grades of intensity. In accordance with this, it seems from experimental evidence to be relatively indefatigable. It thus satisfies a demand that the principle of the common path must make regarding it.

3. In the transition from one reflex to another a final common path changes hands and passes from one master to another. A new set of afferent arcs becomes dominant on the supercession of one reflex by the next. Of all the conditions determining which one of competing reflexes shall for the time being reign over a final common path, the intensity of reaction of the afferent arc itself relatively to that of its rivals is probably the most powerful. An afferent arc that strongly stimulates is coeteris paribus more likely to capture the common path than is one excited feebly. A stimulus can only establish its reflex and inhibit an opposed one if it have intensity. This explains why, in order to produce examples of spinal inhibition, recourse has so frequently been made in past times to strong stimuli. A strong stimulus will inhibit a reflex in progress, although a weak one will fail. Thus in Goltz's inhibition of micturition in the "spinal" dog a foreseeable sequel of the tail will do it, but not, in the present writer's experience, a weak squeeze. So, likewise, any condition which raises the excitability and responsiveness of a nervous arc will give it power to inhibit other reflexes, just as it would if it were excited by a strong stimulus. This is much as in the heart of the Tunicate. There the prepotent spot whence starts the systole lies from time to time at one end and from time to time at the other. The prepotent point at one instant is not the prepotent point at another. The common path is from time to time displaced by local increase of excitability at the other under local distension of the blood-sinuses there.

In judging of intensity of stimulus the situation of the stimulus in the receptive field of the reflex has to be remembered. One and the same physical stimulus will be weak if applied near the edge of the field, though strong if applied to the focus of the field.

Crossed reflexes are usually less easy to provoke, less reliable of obtaining, and less intense than are direct reflexes. Consequently we find crossed reflexes usually more easily inhibited and replaced by direct reflexes than are these latter by those former. Thus the crossed stepping-reflex is easily replaced by the scratch-reflex, though its stimulus be continued all the time, and though the scratch-reflex itself is not a very potent reflex. But the reverse can occur with suitably adjusted intensity of stimuli.

Again, the flexion-reflex of the dog's leg is, when fully developed, accompanied by extension in the opposite leg. This crossed extensor movement, though often very vigorous, may be considered as an accident which usually and which characteristically of which the prominent part is flexion of the homonymous limb. When the flexion-reflex is elicitable poorly, as, for instance, in spinal shock or under fatigue or weak excitation, the crossed extension does not accompany the homonymous flexion and does not appear. But, where the flexion-reflex is well developed, if not merely one but both feet be stimulated simultaneously with stimuli of fairly equal intensity, steady flexion at knee, hip and ankle results in both limbs, and extension occurs in neither limb. The contralateral part of each reflex is inhibited by the homolateral flexion of each reflex. In other words, the more intense part of each reflex obtains possession of the final common paths at the expense of the less intense portion of the reflex. But if the intensity of the stimuli applied to the right and left feet be not closely enough balanced, the crossed extension of the reflex excited by the stronger stimulus is found to exclude even the homonymous flexion that the weaker stimulus should and would otherwise evoke from the leg to which it is applied.

It was pointed out above that in a number of cases the transference of control of the final common path FC from one afferent arc to another is reversible. The character of the transference can coeteris paribus be easily governed by making the stimulation of this receptor or that receptor the more intense.

A factor largely determining whether a reflex succeed another or not is therefore intensity of stimulus.

4. A fourth main determinant for the issue of the conflict between rival reflexes seems the functional species of the reflexes. Reflexes initiated from a species of receptor-apparatus that may be termed noci-ceptors appear to be particularly dominant the majority of the final common paths issuing from the spinal cord. In the simpler sensations we experience from various kinds of stimuli applied to our skin there can be distinguished those of touch, of cold, of warmth and of pain. The adequate stimuli for the first-mentioned three of these are certainly different; mechanical stimuli, applied above a certain speed, which deform beyond a certain degree the resting contour of the skin surface, seem to constitute adequate stimuli for touch. Similarly the cooling or raising of the local temperature, whether by thermal conduction, radiation, &c., are adequate for the cold and warmth sensations. The organs for these three sensations have by stigmatic stimuli been traced to separate and discrete tiny spots in the skin. In regard to skin-pain it is held by competent observers, notably by V. Frey and Kiesow, that skin-pain likewise is referable to certain specific nerve-endings. In evidence of this it is urged that mechanical stimuli applied at certain places excite sensations which from their very threshold upward possess unpleasantness, and as the intensity of the stimulus is increased, culminate in "physical pain." The sensation excited by a mechanical stimulus applied to a touch-spot does not evoke pain, however intensely applied, so long as the stimulation is confined to the touch-spot. The threshold value of mechanical stimuli for touch-spots is in general lower than it is for pain-spots; and conversely the threshold value of electrical stimuli for touch-spots is in general higher than it is for the spots yielding pain. Similarly it is said that stimulation of a cold spot or of a warm spot does not, however intense, evoke, so long as confined to them, sensations of painful quality. But pain can be excited not only by strong mechanical stimuli and by electrical stimuli, but by cold and by warmth, though the threshold value of these latter stimuli is higher for pain than for cold and warm spots. If these observations prove correct there exist, therefore, numerous specific cutaneous nerve-fibres evoking pain.

A difficulty here is that sensory nerve-endings are usually provided with sense organs which lower their threshold for stimuli of one particular kind while raising it for stimuli of all other kinds; but these pain-endings in the skin seem almost equally excited by stimuli of such different modes as mechanical, thermal conductive, thermal radiant, chemical and electrical. That is, they appear anodetic receptors. But it is to be remarked that these agents, regarded as excitants of skin-pain, have all a certain character in common, namely this, that they become adequate as excitants of pain when they are of such intensity as threatens damage to the skin. And we may note about these excitants that they are all able to excite nere when applied to naked nerve directly. Now there are certain skin surfaces from which, according to most observers, pain is the only species of sensation that can be evoked. This is alleged, for instance, of the surface of the cornea—a modified piece of skin. The histology of the cornea reveals in its epithelium nerve-endings of but one morphological kind; that is, the ending being of the non-fibrous kind; that is, not to be found among the epithelial cells. Similar nerve-endings exist also in the epidermis generally. It may therefore be that the nerve-endings subserving skin-pain are free naked nerve-endings, and the absence of any highly evolved specialized end-organ in connexion with them may explain their fairly equal amenability to an unusually wide range of different kinds of stimuli. Instead of but one kind of stimulus being their adequate excitant, they may be regarded as adapted to a whole group of excitants, a group of excitants which has in relation to the organism one feature common to all its components, namely, a nocive character.

With its liability to various kinds of mechanical, chemical, and other damage, in a world beset with dangers amidst which the individual and species have to win their way in the struggle for existence,
we may regard nocuous stimuli as part of a normal state of affairs. It does not seem improbable, therefore, that there should under selective adaptation attach to the skin a so-to-say specific sense of its own injuries. As psychical adjunct to the reactions of that apparatus we find a strong displeasurable effective quality in the sensations they evoke. This may perhaps be a means for branding upon memory, of however rudimentary kind, a feeling from past events that have been perilously critical for the existence of the individuals of the species. In other words, if we admit that damage to such an exposed sentient organ as the skin must in the evolutionary history of animal life have been sufficiently frequent in relation to its importance, then the existence of a specific set of nerves for skin-pain seems to offer no genetic difficulty, any more than does the clotting of blood or innate immunity to certain diseases. That these nerve-endings constitute a distinct species is argued by their all evoking not only the same species of sensation, but the same species of reflex movement as regards "purpose" intensity, resistance to "shock," &c. And their evolution may well have been unaccompanied by evolution of any specialized end-organ, since the naked free nerve-endings would better suit the wide and peculiar range of stimuli, reaction to which is in this case required. A low threshold was not required because the stimuli were all intense, intensity constituting their harmfulness; but response to a wide range of stimuli of different kinds was required, because harm might come in various forms. That responsive range is supplied by naked nerve itself, and would be cramped by the specialization of an end-organ. Hence these organ, properly so described.

It is those areas, stimulation of which, as judged by analogy, can excite pain most intensely, and it is those stimuli which, as judged by analogy, are most fitted to excite pain which, as a general rule, excite in the spinal animal—where pain is of course non-existent—the prepotent reflexes. If these are reactions to specific pain-nerves, this may be expressed by saying that the nervous arcs of pain-nerves, broadly speaking, dominate the spinal centres in peculiar degree. Physical pain is thus the psychical adjunct of an imperative protective reflex. It is preferable, however, since into the purely spinal and reflex aspect of the reaction of these nerves no sensation of any kind can be shown to enter, to avoid the term "pain-nerves." Remembering that the feature common to all this group of stimuli is that they threaten or actually commit damage to the tissue to which they are applied, a convenient term for application to them is nocuous. In that case what from the point of view of sense are cutaneous pain-nerves are from the point of view of reflex-action conveniently termed nocicceptive nerves.

In the competition between reflexes the nociceptive as a rule dominate with peculiar certainty and facility. This explains why such stimuli have been so much used to evoke reflexes in the spinal frog, and why, judging from them, such "fatality" belongs to spinal reflexes.

One and the same skin surface will in the hind limb of the spinal dog evoke one or other of two diametrically different reflexes according as the mechanical stimulus applied be of noxious quality or not, a harmful insult or a harmless touch. A needle-prick to the plants causes invariably the drawing up of the limb—the flexion-reflex. A harmless smooth contact, on the other hand, causes extension—the extensor-thrust above described. This flexion is therefore the true nociceptive response. The scratch-reflex—of which it is readily evoked by simple light irritation of the skin of the shoulder—is relatively mildly nocicceptive. When the scratch-reflex and the flexion-reflex are in competition for the final neurone common to them, the flexion-reflex more easily dispossesses the scratch-reflex from the final neurone than does the scratch-reflex the flexion-reflex. If both reflexes are fresh, and the stimuli used are such as, when employed separately, evoke their reflexes respectively with some intensity, in my experience it is the flexion-reflex that is usually prepotent. Yet if, while the flexion-reflex is being moderately evoked by an appropriate stimulus of weak intensity, a strong stimulus suitable for producing the scratch-reflex is applied, the steady flexion due to the flexion-reflex is replaced by the rhythmic scratching movement of the scratch-reflex, and this occurs though the stimulus for the flexion-reflex is maintained unaltered. When the stimulus producing the scratch is discontinued the flexion-reflex reappears as before. The flexion-reflex seems more easily to dispossess the scratch-reflex from the final common path than can the scratch-reflex dispossess the flexion-reflex. Yet the relation is reversible—by heightening the intensity of the stimulus for the scratch-reflex or lowering that of the stimulus for the flexion-reflex.

In decrebrate rigidity, where a tonic reflex is maintaining contraction in the extensor muscles of the knee, stimulation of the nocicceptive arcs of the limb easily breaks down that reflex. The nocicceptive reflex dominates the motor neurone previously held in activity by the postural reflex. And nocicceptive reflexes are relatively little depressed by "spinal shock."

Nociceptive arcs are, however, not the only spinal arcs which in the intact animal, considered from the point of view of sensation, evoke reactions rich in affectionate quality. Beside those receptors attuned to react to direct noxa, the skin has others, concerned likewise with functions of vital importance to the species and colligate with sensations similarly of intense affective quality; for instance, those concerned with sexual functions. In the male frog the sexual clasp is a spinal reflex. The cord may be divided both in front and behind the brachial region without interrupting the reflex. Experiment shows that from the spinal male at the breeding season, and also at other times, this reflex is elicited by any object that stimulates the sensitive remains of the sternal and adjacent region. In the intact animal, on the contrary, other objects than the female are, when applied to that region, at once rejected, even though they be wrapped in the fresh skin of the female frog and in other ways made to resemble the female. The development of the reflex is not prevented by removal of the testes, but removal of the seminal reservoirs is said to depress it, and their destruction, even by indifferent fluids, to extol it. If the skin of the sternal region and arms is removed the reflex does not occur. Severe mutilation of the limbs and internal organs does not inhibit the reflex, neither does stimulation of the cutaneous nerve central to that section. The reflex is, however, depressed or extinguished by strong chemical and pathic stimuli to the sternal skin, at least in many cases. The tortoise exhibits a similar sexual reflex of great spinal potency.

It would seem a general rule that reflexes arising in species of receptors which considered as sense-organs provoke strongly affective sensation caeteris paribus prevail over reflexes of other species when in competition with them for the use of the "final common path." Such reflexes override and set aside with peculiar facility reflexes belonging to the same or superficial sense-organs, &c. As the sensations evoked by these arcs, e.g. "pains," exclude and dominate concurrent sensations, so do the reflexes of these arcs prevail in the competition for possession of the common paths. They seem capable of preeminent intensity of action.

Of all reflexes it is the tonic reflexes, e.g. of ordinary posture, that are in the writer's experience the most easily interrupted by other reflexes. Even a weak stimulation of the nocicceptive arcs arising in the foot often suffices to lower or abolish the knee-jerk or the reflex extensor tonus of the elbow or knee. And various species of reflex are arranged, therefore, in the order of potency in regard to power to interrupt one another, the reflexes initiated in receptors which considered as sense-organs excite sensations of strong affective quality lie at the upper end of the scale, and the reflexes that are answerable for the postural tonus of skeletal muscles lie at the lower end of the scale. One great function of the tonic reflexes is to maintain habitual attitudes and postures. They form, therefore, a nervous background of active equilibrium. It is of obvious advantage that this equilibrium should be easily upset, so that the animal may respond agilely to the passing events that break upon it as intercurrent stimuli.

Results.—Intensity of stimulation, fatigue and freshness,
spinal induction, functional species of reflex, are all, therefore, physiological factors influencing the result of the interaction of reflex-arcs at a common path. It is noticeable that they all resolve themselves ultimately into intensity of reaction. Thus intensity of stimulus means activity interposed from reaction. Those species of reflex which are habitually prepotent in interaction with others are those which are habitually intense; those specially impotent in competition are those habitually feeble in intensity, e.g. skeletal muscular tone. The tonic reflexes of attitude are of habitually low intensity, easily interfered with and temporarily suppressed by intercurrent reflexes, these latter having higher intensity. But these latter suffer fatigue relatively early, whereas the tonic reflexes of posture can persist hour after hour with little or no signs of fatigue. Fatigue, therefore, in the long run advantageously redresses the limitedness of an otherwise unequal conflict. We can recondize it in another agency working toward that plastic alternation of activities which is characteristic of animal life and increases in it with ascent of the animal scale.

The high variability of reflex reactions from experiment to experiment, and from observation to observation, is admittedly one of the difficulties that has retarded knowledge of them. Their variability, though often attributed to general conditions of nutrition, or to local blood-supply, &c., seems far more often due to changes produced in the central nervous organ by its own conductive activity. The functional reactions of the organ are therefore, a function of time. This functional activity itself causes from moment to moment the temporary opening of some connexions and the closure of others. The chains of neurones, the conductive lines, have been, especially in recent years, by the methods of Golgi, Ehrlich, Apathy, Cajal and others, richly revealed to the microscope. Anatomical tracing of these may be likened, though more difficult to accomplish, to tracing the distribution of blood vessels after Harvey's discovery had given them meaning, but before the vasomotor mechanism was discovered. The blood vessels of an organ may be turgid at one time, contracted almost to obliteration at another. With the conductive network of the nervous system the temporal variations are even greater, for they extend to absolute withdrawal of nervous influence. Under reflex inhibition a skeletal muscle may relax to its post-mortem length, i.e. there may then be no longer evidence of even a tonic influence on it by its motor neurone. The direction of the stream of liberation of energy along the pattern of the nervous web varies from minute to minute.

The final common path is handed from some group of a plus class of afferent arcs to some group of a minus class, or of a rhythmic class, and then back to one of the functional groups again, and so on. The conductive web changes its functional pattern with certain limits to and fro. It changes its pattern at the entrances to common paths. The changes in its pattern occur there in virtue of interaction between rival reflexes, "interference." As a tap to a kaleidoscope, so a new stimulus that strikes the receptive surfaces causes in the central organ a shift of functional pattern at various synapses. The central organ is a vast network whose lines of conduction follow a certain scheme of pattern, but within that pattern the details of connexion are, at the entrance to each common path, mutable. The central conduction is subdivisible, with a loss of accurate position, where, from moment to moment, though the end-points of the system are fixed, the connexions between starting-points and terminal points are changed to suit passing requirements, as the functional points are shifted at a great railway junction. In order to realize the exchange at work, one must add to its purely spatial plan the temporal datum that within certain limits the connexions of the lines shift to and fro from minute to minute. An example is the "reciprocal innervation" of antagonistic muscles—when one muscle of the antagonistic couple is thrown into action the other is thrown out of action. This is only a widely spread case of the general rule that antagonistic reflexes interfere where they embouch upon the same common paths. And that general rule is part of the general principle of the mutual interaction of reflexes that impinge upon the same common path. Unlike reflexes have successive but not simultaneous use of the common paths; like reflexes mutually reinforce each other on their common path. Expressed teleologically, the common path, although economically subservient for many and various purposes, is adapted to serve but one purpose at a time. Hence it is a co-ordinating mechanism and prevents confusion by restricting the use of the organ, its minister, to but one action at a time.

In the case of simple antagonistic muscles, and in the instances of simple spinal reflexes, the shifts of conductive pattern due to interaction at the mouths of common paths are of but small extent. The co-ordination covers, for instance, one limb or a pair of limbs. But the same principle extended to the reaction of the great arcs arising in the projicent receptor organs of the head, e.g. the eye, which deal with wide tracts of musculature as a whole, operates with more multiplex shift of the common path. Releasing forces acting on the brain from moment to moment shut out from activity whole regions of the nervous system, as they conversely call vast other regions into play. The resultant singleness of action from moment to moment is a keystone in the construction of the individual whose unity it is the specific office of the nervous system to perfect. The interference of unlike reflexes and the alliance of like reflexes in their action upon their common paths seem to lie at the very root of the great psychical process of attention. The spinal cord is not only the spinal reflexes whose "centres" lie wholly within the cord itself; it supplies also conducting paths for nervous reactions initiated by impulses derived from afferent spinal nerve, but involving mechanisms situate altogether headward of the cord, that is to say, in the brain. Many of these reactions affect consciousness, occasioning sensations of various kinds. In regard to the part played by spinal conduction in subserving these sensal reactions a question of practical rather than theoretical importance has been as yet the chief aim of inquiry. The inquiry has been in fact whether the impulses concerned in evoking the various species of sensations contained in headward and lateral parts of the cord certain discrete paths occupying separable fractions of the cross-area of the cord, and if they are thus confined to discrete paths in what parts of the cross-area of the cord do these parts lie. This "localization" problem has as yet been almost the sole problem attacked, and therefore, despite its limited scope and interest, the results attained in it may be briefly mentioned here.

**Localization.**—The sensations usually grouped under the name of touch may with advantage, as shown by Head, be distinguished from the point of view of their practical elicitation into superficial and deep. The former of these are referable to stimulation of afferent fibres distributed actually to the skin, the latter to stimulation of deeper afferents subjacent to the skin. The touch-fibres belonging to the skin proper are further subdivisible, as Head has shown, into two kinds. One kind, the **protopathic**, yield sensations so suffused with disagreeable affective tone (skin-pain) that they may for the present purpose be considered pain-nerves, and the description of their spinal connexions be relegated to the paragraph dealing with the spinal path for pain. The other kind, the **epicritic**, are those which react to tangible stimulus lightly applied, such as stroking or warm objects. The latter, in contrast with the former, are distributed only along the nerve-fibres of the skin, the latter to stimulation of deeper afferents subjacent to the skin. The touch-fibres not classed as cutaneous, but probably largely muscular in the sense that they run to muscles and contain side by side the afferent fibres in question and the effenter nerve-fibres causing muscular contraction. Head has brought forward clear evidence that though the afferent fibres subserving the epicritic tactual sense of the skin and deep touch of subcutaneous origin run separate courses in the peripheral nerves, the spinal fibres constituting the intraspinal headward-running paths from these two kinds of peripheral touch-fibres, the epicritic and the deep, to the brain, lie together and are implicated together by injuries of the spinal cord. In this sense there is, therefore, in the cord a tactual path. The question...
is, therefore, what course does this path follow in the cord? In the first place it must be noted that the path contains a synapse for the peripheral neurone whether belonging to the epiphragmatic tactual group or to the deep tactual group ends in the cord, probably not far, i.e., not more than four or five segments, from the place of entrance. The rest of the headward path must therefore run through one secondary neurone at least, it may be through a series of such arranged as a headward running line of relays. It is, however, more probable that one long secondary neurone reaching the bulb covers the whole of the remaining spinal part of the trajectory. The part of the headward-running path formed by the intraspinal part of the peripheral neurone (primary afferent neurone) lies certainly in the dorsal column of the cord of the same lateral half as the side from which the neurone entered, i.e., in the right dorsal column if the neurone entered by a spinal root of the right side. The secondary neurone continuing the path lies, however, in the ventral column of the crossed half of the cord. The junction or synapse between the primary and secondary neurone lies, of course, in the grey matter of the spinal cord.

The spinal path of impulses which when they reach the brain occasion pain has been determined chiefly in regard to pain referred to the skin. The primary afferent neurones bringing these impulses to the cord are the protopathic of Head mentioned above. These, there is much evidence to show, terminate in the grey matter of the cord not far from their point of entrance into the cord; that is, they terminate intraspinal near their point of entrance than do the corresponding primary afferent neurones for touch. From the local spinal grey matter the pain-path is continued headward in the lateral white columns of the cord by secondary afferent neurones. These secondary afferent neurones run chiefly in the lateral column of the opposite half of the cord from that which the primary afferent neurones entered; but some run up the lateral column of the same side as that by which the primary neurones entered. The synapse between the primary afferent neurone and the secondary afferent neurone of this path lies probably in the grey matter covering the spinal tract of the grey column.

The spinal path taken by the impulses concerned with sensations of heat and cold seems to agree closely with that taken by the impulses subserving skin pain. The position of the nerve fibres belonging to the secondary afferent neurones of the pain and temperature path has been fairly successfully identified with that of the spinal tract called Gowers' tract. The uncrossed portion of the temperature path appears, however, to be relatively smaller as compared with its crossed portion than is that of pain.

There is much evidence that impulses contributory to "muscular sense" pass headward along the spinal cord and in their course remain for the most part uncrossed. This course would in so far agree with the course taken by the intraspinal continuations of the primary afferent neurones which form the long fibres of the dorsal columns. These are known to run to the bulb without transgressing the median plane at all. In addition to this uncrossed tract there is another, namely, that offered by the dorsal cerebellar tract, a tract of secondary neurones connected through the grey matter of the vasculare column of Clarke with primary afferent neurones of the ipsilateral side. Either or both of these uncrossed tracts may be the path taken by the impulses subserving muscular sense, and there is experimental evidence in favour of such a possibility, but the question cannot be considered as definitely answered at present.

Besides the paths followed by headward-running impulses the spinal cord contains paths for impulses passing along it backwards from the brain. These paths lie almost entirely in the ventrolateral columns of the cord. The fibres of which they are composed cross but little in the cord. Their sources are various, some come from the hind brain and some from the mid brain, and in the higher mammals, especially in man and in the anthropoid apes, a large tract of fibres in the lateral column (the crossed pyramidal tract) comes from the cortex of the neocorpus of the fore brain. This last tract is the main medium by which impulses initiated by electrical stimulation of the motor cortex reach the moto-neurones of the cord and through them influence the activity of the skeletal muscles. Of the function of the other tracts descending from the brain into the cord little is known except that medially or immediately they either inhibit or excite the spinal moto-neurones by various levels. How they harmonize one with another in their action or what their purpose in normal life may be is at present little more than conjecture. Such terms, therefore, as "paths for volition," &c., are at present too schematic in their basis to warrant their discussion here.

(C. S. S.)

**SPINEL**, a name now given to a group of minerals, of which the typical member is a magnesium aluminate, sometimes used as a gem-stone, to which the term "spinel" was originally restricted. The name comes from the French *spinelle* (diminutive of Lat. *spina*), perhaps suggested by the sharp angles of the crystals. All spinels crystallize in the cubic system, usually in the tetragonal, and often twinned as in the accompanying figure, which is a form so characteristic as to be called the "spinel twin." The hardness of spinel is about that of topaz (8) and its specific gravity near that of diamond. Professor A. H. Church gives the range in variously coloured spinels as 3.582 to 3.715. Pure spinel is colourless, but most varieties are coloured, with no doubt differences with iron and probably in some with chrom. The deep red spinel is known as "spinel-ruby," or "ruby-spinel," and has often been taken for true ruby, from which it is distinguished, however, by being singly refracting and therefore not dichroic, as well as by its inferior hardness and density. The "balas ruby" is a rose-red spinel, said to derive its name from Balkh, the capital of Badakshan (Balaxia), where it occurs with rubies, and was formerly worked, chiefly in the Shighman valley, in the upper Oxus basin. Rubicelle is a spinel in which the red colour results from the removal of the magnesium spinel it passes into violet. Stones of the colour of vinegar are called vineyard-spinel. When the colour is blue the mineral is known as sapphire-spinel, and when green as chloro-spinel.

The spinels used in jewelry are found mostly in gem-graves, where, however, the octahedral form is often well preserved. The chief localities are Ceylon, Siam and Upper Burma. In all these localities the spinels accompany the coloured corundums, and their close association with true rubies led Tavernier to call spinel "the mother of ruby." Formerly there was much confusion between the spinel minerals, and probably many stones described as monster rubies have been spinels. The great historic "ruby" set in the Maltese cross in front of the Imperial state crown of England is really a spinel. This fine stone was given to Edward the Black Prince by Pedro the Cruel, king of Castile, on the victory of Najera in 1367, and it was afterwards worn by Henry V. at the battle of Agincourt, where it narrowly escaped destruction. V. Ball described, in 1804, a spinel weighing 1333 carats, engraved with a Persian inscription, then in the possession of Lady Carew.

All the isomorphous minerals known as the group of spinellids, of which spinel is the type, crystallize in regular octahedra and have a composition conforming to the general formula \(R^2R'O_2\), \(R^3R'O_3\), or \(R'O_2\), where \(R^2\) and \(R^3\) are cations of comparable size and \(O_2\) or \(O_3\) are anions. Ordinary spinel is \(MgAl_2O_4\). A black opaque spinel in which \(Fe\) partly replaces \(Mg\) is known as pleonaste (*pleonasës*, abundant, from the number of faces on certain crystals) or ferric corundum, from the island of Ceylon, but sometimes written ceylanite. It occurs in greisen, often with cordierite, and is found also in the ejected blocks of Monte Somma, Vesuvius. Large crystals come also from Vanock and Amity, Orange county, New York, U.S.A. The black spinels are either iron or brown when viewed in thin sections by transmitted light. In some cases spinel is evidently a result of contact metamorphism, whilst in others it has crystallized out of a molten magma. Some spinels, such as the spinel found in the turquoises of Brazil, are formed in the earth's crust. Most spinels are of a brownish red, but some are a deep purple with a greenish cast, and others are a deep blue or black, as in the "black spinels" of Ceylon. A chrome-spinel with the formula (Mg,Fe)\(_2\)(Al,Fe,Cr)\(_2\)O\(_4\) is named picotite, after Picot de la Peyrrouse, who described it. Picotite occurs in the form of black grains and crystals in certain olivine rocks and in serpentines. A black iron-spinel (FeAl\(_2\)O\(_4\))...
found in the granulites of Saxony and Bohemia, is known as hercynite from the Hercynian Forest. A zinc-spinel (ZnAl₂O₄), occurring in talcose slate near Falun in Sweden, is named gahnite, after its discoverer J. G. Gahn; whilst it has also been termed automerite from Gr. αυτόματος, a devisor, in allusion to the occurrence of zinc in a manner wall of the unexpected. The group of spinel includes, as its extreme members, magnetic (Fe₂±Fe³⁺)O₄ and chromite (FeCr₂O₄) (w.v.).

SPINELLO ARETINO (c. 1330–c. 1410), Italian painter, the son of a Florentine named Luca, who had taken refuge in Arezzo in 1310 when exiled with the rest of the Ghibelline party, was born at Arezzo about 1330. Spinello was a pupil of Jacopo di Casentino, a follower of Giotto, and his own style was a sort of link between the school of Giotto and that of Siena. In the early part of his life he worked in Florence as an assistant to his master Jacopo while painting frescoes in the church of the Carmine and in Sta Maria Novella. Between 1360 and 1384 Spinello's wanderings includes, as its extreme members, magnetic (Fe₂±Fe³⁺)O₄ and chromite (FeCr₂O₄) (w.v.).

SPINELLID (F. spinell), spinn (to spin, cf. Ger. spinnen, &c., the Teut. root is *spen*, to draw out, cf. span, spider), the forming of threads by drawing out and twisting various fibres. There is ample evidence of the great antiquity and wide diffusion of the art of spinning, for spinning necessarily precedes weaving (q.v.) whenever short fibrous materials have to be made into threads, and weaving is one of the primal and most universal employments of mankind. Either remains of implements employed in spinning, or spun threads, are found wherever a prehistoric man make their appearance. The simple spinning apparatus which was used in the earliest ages continued to be used by civilized communities till comparatively recent times, and it may therefore be said that no art which has been so long and widely practised remained so unprogressive as that of spinning. On the other hand, since about the middle of the 18th century, when human ingenuity bent itself in earnest to improve the art, there have not been developed in the whole range of mechanical industries machines of greater variety, delicacy of action, and manifold productive capacity than those now in use for spinning.

The primitive thread-making implement consisted of a wooden spindle, from 9 to 15 in. long, which was rounded and tapered at both extremities, as in the accompanying figure. Near the top there was usually a notch in which the yarn was caught while undergoing the operation of twisting, and lower down a whorl, or whorle, composed of a perforated disk of clay, stone, wood, or other material was secured to give momentum and steadiness to a rotating spindle. Long fibres were commonly attached to a distaff of wood, which was held under the left arm of the operator, but short fibres were spun from carded rolls. After attaching some twisted fibres to the spindle, a rotatory motion was given to the latter either by rolling it by hand against one thigh, or by twirling it between the fingers and thumb of the right hand, after which the fibres were drawn out in a uniform strand by both hands and converted into yarn. When the thread was of sufficient length it was suspended by it until a full stretch had been drawn and twisted, after which that portion was wound upon the body of the spindle, and the operation continued until the spindle was filled. The quantity thus rolled up gives the name to a now definite measure of linen yarn, namely the "spindle," or 14,400 yards. Simple as was this primitive apparatus, a dexterous spinner could produce yarn of an evenness, strength and delicacy such as has scarcely been exceeded by elaborate modern appliances. The yarns for the gossamer-like Dacca muslins of India were so fine that a lb weight of cotton was spun into a thread nearly 253 m. long. This was accomplished with the aid of a bamboo spindle not much bigger than a darning needle, and which was lightly weighted with a pellet of clay. Since such a tender thread could not support even the weight of so slight a spindle, the apparatus was rotated upon a piece of hollow shell. The spindle as here described was, so far as is
known, the sole apparatus with which yarn was spun until comparatively recent times.

The changes in modern spinning have had for their object: (1) the providing of mechanical means to rotate the spindle, (2) an automatic method of drawing out the fibres, and (3) devices for working a large group of spindles together, at speeds before unattainable.

The first improvement consisted in cutting a ring groove in the wharve, mounting the spindle horizontally in a frame, and passing a band from a large wheel round the wharve. A rotatory motion was then given to the spindle by turning the wheel with the left hand. After attaching the filaments to the spindle they were attenuated with the right hand, and when fully twisted the thread was moved to form a right angle with the spindle and coiled upon it. Such a wheel has long been known in India, and from a drawing in a 14th-century manuscript in the British Museum it is obvious that it was not unknown, although far from being in general use, in Europe at that early date. It came ultimately to be known in England as the "bobbin wheel," and was in constant use down to the beginning of the 19th century for spinning coarse and fine yarns. But fine yarns received two spinnings; the first consisted in drawing out and slightly twisting the fibres into what is still known as a roving, and by the second spinning the roving was fully attenuated and twisted. In 1533, a citizen of Brunswick is said to have cranked the axis of the large wheel and added a treadle, by which the spinner was enabled to rotate her spindle with one foot and have both hands free to manipulate the fibres. A modification consisting in the use of a quadrant and a right-angled forked flyer, was introduced in the 18th century; several patents were taken out for improvements in spinning appliances; it is certain that many were known and used long before they were generally adopted. Thus the flyer, which twists yarn before winding it upon a bobbin, is shown in a drawing by Leonardo da Vinci, together with a device for moving the bobbin up and down the spindle so as to effect an even distribution of the yarn. During the 18th century a machine of the foregoing type was widely used, and came to be known as the Saxony wheel. It changed spinning from an intermittent to a continuous operation. The spindle had affixed upon its cap a flyer, whose forked legs were far enough apart to enclose a double-flanged spool, and at short intervals bent wires, known as the hek, were inserted in each leg for the purpose of guiding the thread evenly upon the spool. This spool was loosely threaded upon the spindle and one of its flanges was grooved to take a driving band from the large wheel, hence the spindle and the spool were separately driven, but the former at a higher speed than the latter. The twisted filaments were drawn through an eye in the flyer, led along one of its legs, and made fast to the spool. By operating the treadle the flyer twisted all the fibres about a common axis once for each revolution, and the spool wound up the length thus spun: the thread being slipped from tooth to tooth of the heck at regular intervals to direct it evenly across the spool. During the 17th century a second and similar spindle and flyer were added, and these left the spinner free to manipulate one thread with her right, and another with her left hand. It was in this condition that the most advanced form of yarn-making was carried on until a great series of inventions revolutionized spinning, and laid the foundations of the factory system which now prevails.

The remaining part of the problem which lay before inventors was to draw out masses of parallel fibrous material, and twist them into uniform strands by mechanical means. The first stage in the evolution of mechanical spinning was effected by the invention of Lewis Paul, of Birmingham, who obtained a patent in 1738, and who was assisted by John Wyatt. The essential features of this invention consisted in passing carded slivers between pairs of parallel rollers, each succeeding pair of which moved faster than the preceding pair, to attenuate the sliver to the required extent. From Paul's specification it would appear that he attempted to turn the rollers about their horizontal and vertical axes simultaneously, in order to draw out the fibres and twist them at one operation. But he also mentions a plan for which he procured a patent twenty years later, namely, the use of only one pair of rollers working in conjunction with a bobbin which drew off the thread faster than the rollers delivered the sliver, and coiled the thread about itself. The bobbin, therefore, attenuated, twisted and wound the material. Neither plan proved a commercial success. Thomas Hargreaves, of Preston and Bolton, to achieve what his predecessors vainly struggled for, obtained patents in 1760 and 1775, for a machine which was subsequently known as the water-twist frame by reason of water-power being applied to drive it. Arkwright's first machine did not contain any really new feature, for it consisted of Paul's drawing rollers, and the spindle, flyer and spool from the Saxony wheel, but the spindles and rollers were grouped in sets of four. Later the water-twist frame was changed into the "throttle" frame, which in turn has almost ceased to be used. In 1774, C. Danforth (1737-1876), an American spinner, invented a dead spindle, on the top of which he placed a hollow cap to serve as the winding point, and inside the cap he rotated a spool: a plan still used by worsted spinners. In 1728 Mr Thorpe, also an American, invented the ring spinning frame, whose principal feature consisted in the substitution for the flyer of a flanged annular ring, and a light C-shaped traveller. By means of the traveller a thread was held in the best position for winding upon a spool, as well as put under the necessary tension. Later inventors have so altered the construction of the ring, traveller and spindle that a speed of upwards of 11,000 revolutions per minute may be obtained. This represents the highest degree of continuous spinning.

Whilst endeavours were being made to perfect continuous spinning, attention was also directed to perfecting the intermittent process as represented by the bobbin wheel. Between the years 1764 and 1767, James Hargreaves, of Standhill, invented the spinning jenny, by the aid of which sixteen, or more, threads could be spun simultaneously by one person. All the spindles were placed vertically and rotated from a drum, but the rovings were mounted in a moviable carriage and passed between a clamp that opened and shut like a parallel rule. After securely clamping the rovings and attaching them to the spindles, the carriage was drawn out slowly by one hand and the spindles revolved by the other. The rovings were thus stretched to the proper degree of tenuity, and sufficiently twisted. This was followed by the inward run of the carriage, when the stretch of spun threads was wound upon the spindles, and the operation repeated. Hargreaves therefore returned to the first principles of spinning, namely, simultaneous drawing and twisting. But although the jenny gave a greatly increased output, it was ill adapted for fine spinning. During the years 1774 to 1779, Samuel Crompton of Bolton, combined in the mule, the drawing rollers of Paul with the stretching of Hargreaves. But his rollers did not fully attenuate the rovings before twisting them, as is the case with continuous spinning, neither was stretching alone relied upon. From its introduction this machine was able to spin finer and more elastic threads than any of its rivals, but for a time the preparation of suitable rovings was a source of great trouble. The immediate consequence of the decision of the court of King's Bench, in 1785, to throw open to the public Arkwright's preparatory machinery, was to enormously increase the usefulness of the mule. Since Crompton's time a host of inventors have laboured to render all parts of the mule thoroughly automatic; this has led to many changes and additions, but none of its essential features have been discarded. The inventions of Paul, Arkwright, Hargreaves and Crompton are at the foundations of all modern systems of spinning; details regarding them are given in the article on Cotton-spinning Machinery.

(T. W. F.)

SPINOLA, AMBROSE, MARQUIS DE LOS BALBases (1560-1630), Spanish general, was born in Genoa in 1569. He was the eldest son of Philip Spinola, marquis of Sesto and Benafro, and his wife Polcena, daughter of the prince of Salerno. The family of Spinola was of great antiquity, wealth and power in Genoa.
In the 16th century the republic was practically a protected state under the power of Spain, the Genoese being the bankers of the monarchy and having entire control of its finances. Several of the younger brothers of Ambrose Spinola sought their fortune in Spain, and one of them, Frederick, distinguished himself greatly as a soldier in Flanders. The eldest brother remained at home to marry and continue the family. In 1592 he was married to Joanna Bacciatdonna, daughter of the count of Galeratta. The houses of Spinola and Doria were rivals for authority within the republic. Ambrose Spinola continued the rivalry with the court of Turin, then the chief of the Dorian, which was not successful, and having lost a lawsuit into which he had entered to enforce a right of pre-emption of a palace belonging to the Salerno family which the Doria wished to purchase, he decided to withdraw from the city and advance the fortunes of his house by serving the Spanish monarchy in Flanders. In 1602 he and his brother Frederick entered into a contract with the Spanish government—a "condotta" on the old Italian model. It was a speculation on which Spinola risked the whole of the great fortune of his house. Ambrose Spinola undertook to raise 9000 men for land service, and Frederick to form a squadron of galleys for service on the English Channel. He himself was slain in an action with the Dutch on the 24th of May 1603. Ambrose Spinola marched overland to Flanders in 1602 with the men he had raised at his own expense. During the first months of his stay in Flanders the Spanish government played with schemes for employing him on an invasion of England, which came to nothing. At the close of the year he returned to Italy for more men. His actual experience as a soldier did not begin till as general, and at the age of thirty-four, he undertook to continue the siege of Ostend on the 29th of September 1603. The rutinious answers of the place fell into his hands on the 22nd of September 1604. The archduke Albert and the infanta Clara Eugenia, daughter of Philip II., who then governed Flanders and had set their hearts on taking Ostend, were delighted at his success, and it won him a high reputation among the soldiers of the time. On the close of the campaign he went to Spain to arrange with the court, which was then at Valladolid, for the continuance of the war. At Valladolid he insisted on being appointed commander-in-chief in Flanders. By the 9th of April he was back at Brussels, and share in the operations connected with the siege of the French Fortresses of the Netherlands. He had reached, at that time almost wholly of sieges, and Spinola made himself famous by the number of places he took in spite of the efforts of Maurice of Nassau to save them. In 1606 he again went to Spain. He was received with much outward honour, and entrusted with a very secret mission to secure the government of Flanders in case of the death of the archduke or his wife, but he could not obtain the grandeeship which he desired, and was compelled to pledge the whole of his fortune as security for the expenses of the war before the bankers would advance funds to the Spanish government. As he was never repaid, he was in the end utterly ruined. The Spanish government began now to have recourse to devices for keeping him away from Spain. Until the signing of the twelve years' truce in 1609 he continued in command in the field with general success. After it was signed he retained his post, and had among other duties to conduct the negotiations with France when the prince of Condé fled to Flanders with his wife in order to put her beyond the reach of the amorous admiration of Henry IV. of France. By 1611 Spinola's financial ruin was complete, but he obtained the desired "grandees." In 1614 he had some share in the operations connected with the settlement of Cleves and Julliers. On the outbreak of the Thirty Years' War he made a vigorous campaign in the lower Palatinate and was rewarded by the grade of captain-general. After the renewal of the war with Holland in 1621 he gained the most renowned victory of his career—the capture of Breda after a long siege (Aug. 28, 1624.—June 5, 1625) and in spite of the most strenuous efforts of the prince of Orange (Frederick Henry) to save it. The surrender of Breda is the subject of the great picture by Velasquez, known as "Las Lanzas"; the portrait of Spinola is from memory.

The taking of Breda was the culmination of Spinola's career. Utter want of money paralysed the Spanish government, and the new favourite, Olivares, was jealous of the general. Spinola could not prevent Frederick Henry of Nassau from taking Grol, a good set-off for Breda. In January 1628 he left for Spain, resolved not to resume the command in Flanders unless security was given him for the support of his army. At Madrid he had to endure much insolence from Olivares, who endeavoured to make him responsible for the loss of Grol. Spinola was resolved not to return to Spain. Meanwhile the Spanish government added a war over the succession to the crown of Mantua to its other burdens. Spinola was appointed as pleni-potentiary and general. He landed at Genoa on the 19th of September 1629. In Italy he was pursued by the enmity of Olivares, who caused him to be deprived of his powers as pleni-potentiary. Spinola's health broke down, and, having been robbed of his money, grudged the compensation he asked for his children and disgusted in the presence of the enemy, he died on the 25th of September 1630 at the siege of Cassino, not accepting the Council of Trent as authoritative or in accordance with the true faith of the Catholic Church. He was buried in the family vault of the Spinolas at Tursi, in the province of Calabria.

Don A. Rodriguez Villa has published a biography well supplied with original documents—Ambrosto Spinola, primer marques de los Balbases (Madrid, 1905).
SPINOZA

medieval thought, who aim at combining the traditional theology with ideas got from Aristotle and his Neoplatonic commentators. Latin, still the universal language of learning, formed no part of Jewish education; and Spinoza, after leaving the elements from a German master, resorted for further instruction to a physician named Franz van den Ende, who eked out an income by taking pupils. Van den Ende appears to have been distinctly a man of parts, though of a somewhat indiscreet and erratic character. He was eventually hanged in Paris as a conspirator in 1674. His enthusiasm for the natural sciences may have been the only ground for the reputation he had acquired of instilling atheistic notions into the minds of his pupils along with the Latin which he taught them. But it is said that later in his life he was by no means so learned and enigmatic as in many others at that time, a materialist, or at least a naturalistic, turn of mind; indeed, we should expect as much in a man of Van den Ende's somewhat rebellious temperament. We do not know whether his influence was brought to bear in this sense upon Spinoza; but it has been suggested that the writings of Bruno, whose spirit of enthusiastic naturalism and fervid revolt against the Church would be especially dear to a man of Van den Ende's leanings, may have been put into the pupil's hand by the master. Latin, at all events, Spinoza leaned on that in the early part of his life when the want of sufficient knowledge of a foreign language does not, of course, conform to classical canons.

A romance has woven itself round Spinoza's connexion with Van den Ende's household. The physician had an only daughter, Clara Maria by name, who, besides being proficient in music, understood Latin, it is said, so perfectly that she was able to teach her father's pupils in his absence. Spinoza, the story goes, fell in love with his fair instructor; but a fellow-student, called Kerkering, supplanted him in her mistress's affections by the help of a valuable necklace of pearls which he presented to the young lady. Chronology unfortunately forbids us to accept this little episode as true. Recent investigation has proved that, while the marriage with Kerkering, or rather Kerkkrink, is a fact, it did not take place till 1671, in which year the bride, as appears by the register, was twenty-seven years of age. She cannot, therefore, have been more than eleven, or twelve in 1656, the year in which Spinoza left Amsterdam; and as Kerkkrink was seven years younger than Spinoza, they cannot well have been simultaneous pupils of Van den Ende's and simultaneous suitors for his daughter's hand. But, though the details of the story thus fall to pieces, it is still possible that the legend of his making many visits to Amsterdam Spinoza, who was living within easy distance and paid visits to the city from time to time, may have kept up his connexion with Van den Ende, and that the attachment may have dated from this later period. This would at least be some explanation for the existence of the story; for Colerus expressly says that Spinoza "often confessed that he meant to marry her." But there is no mention of the Van den Endes in Spinoza's correspondence; and in the whole tenor of his life and character there is nothing on which to fasten the probability of a romantic attachment.

The mastery of Latin which he acquired from Van den Ende opened up to Spinoza the whole world of modern philosophy and science, both represented at that time by the writings of Descartes. He read him greedily, says Colerus, and afterwards often declared that he had all his philosophical knowledge from him. The impulse towards natural science which he had received from Van den Ende would be strengthened by the reading of Descartes; he gave over divinity, we are told, to devote himself entirely to these new studies. His inward break with Jewish orthodoxy dated, no doubt, further back—from his acquaintance with the philosophical theologians and commentators of the middle ages; but these new interests combined to estrange him still further from the traditions of the synagogue. He was seldom seen at its services—soon not at all. The jealousy of the heads of the synagogue was easily roused. An attempt seems to have been made to draw from him his real opinions on certain prominent points of divinity. Two so-called friends endeavoured, on the plea of doubts of their own, to lead him into a theological discussion; and, some of Spinoza's expressions being repeated to the Jewish authorities, he was summoned to appear before the Amsterdam council and to produce an adherent, and probably desirous at the same time to avoid public scandal, the chiefs of the community offered him a yearly pension of 1000 florins if he would outwardly conform and appear now and then in the synagogue. But such deliberate hypocrisy was abhorrent to Spinoza's nature. Threats were equally unavailing, and accordingly on the 27th of July 1656 Spinoza was solemnly cut off from the commonwealth of Israel. The curses pronounced against him may be read in most of the biographies. While negotiations were still pending, he had been imprisoned for a time in a city jail, and his brother-in-law had even been obliged to resign his position to those who thought to expedite matters with the dagger. Warned by this that Amsterdam was hardly a safe place of residence for him any longer, Spinoza had already left the city before the sentence of excommunication was pronounced. He did not go far, but took up his abode with a friend who lived some miles out on the Old Church road. His host belonged to the Collegiants or Rhijnburgers, a religious society which had sprung up among the proscribed Armenians of Holland. The pure morality and simple-minded piety of this community seem early to have attracted Spinoza, and the whole of his unavenged life was passed among them. Several of his friends were Collegiants, and Spinoza had become a member of their similarly minded community of the Mononites, in which the Collegiants were afterwards merged. In this quiet retreat Spinoza spent nearly five years. He drew up a protest against the decree of excommunication, but otherwise it left him unmoved. From this time forward he disused his Hebrew name of Baruch, adopting instead the Latin equivalent, Benedictus. Like every Jew, Spinoza had learned a handicraft; he was a grinder of lenses for optical instruments, and was thus enabled to earn an income sufficient for his modest wants. His skill, indeed, was such that lenses of his making were much sought after, and those found in his cabinet after his death fetched a high price. It was as an optician that he was first brought into connexion with Huygens and Leibnitz; and an optical Treatise on the Rainbow, written by him and long supposed to be lost, was discovered and reprinted by Dr van Vloten in 1862. He was also fond of drawing as an amusement in his leisure hours; and Colerus had seen a sketch-book full of such drawings representing persons of Spinoza's acquaintance, one of them being a likeness of himself in the character of Masaniello.

The three years which followed the excommunication must have been devoted to concentrated thought and study. Before their conclusion Spinoza had parted company from Descartes, and the leading positions of his own system were already clearly determined in his mind. A number of the younger men in Amsterdam—many of them students of medicine or medical practitioners—had also come to regard him as their intellectual leader. A kind of philosophical club had been formed, including among its members Simon de Vries, John Bresser, Louis Meyer, and others who appear in Spinoza's correspondence. Originally meeting in all probability for more thoroughgoing study of the Cartesian philosophy, they looked naturally to Spinoza for guidance, and by and by we find him communicating systematic drafts of his own views to the little band of friends and students. The manuscript was read aloud and discussed at their meetings, and any points remaining obscure were referred to Spinoza for further explanation. An interesting specimen of such difficulties propounded by Simon de Vries and resolved by Spinoza in accordance with his own principles, is preserved for us in Spinoza's correspondence. This Simon de Vries was a youth of generous impulses and of much promise. Being in good circumstances, he was anxious to show his gratitude to Spinoza by a gift of 2000 florins, which the philosopher half-jestingly excused himself from accepting. De Vries died young, and would have left his fortune to Spinoza; but the latter refused to stand in the way of his brother, the natural heir, to whom the property was accordingly left, with the condition that he should pay to Spinoza an annuity sufficient for his maintenance. The heir

offered to fix the amount at 500 florins, but Spinoza accepted only 300, a sum which was regularly paid till his death. The written communications of his own doctrine referred to above belong to a period after Spinoza had removed from the neighborhood of Amsterdam; but it has been conjectured that the chief points of the argument in geometrical form, is a forerunner of the Ethics, and was probably written somewhat later than the rest of the book. The term “Nature” is put more into the foreground in the Treatise, a point which might be urged as evidence of Bruno’s influence—the dialogues, moreover, being specially concerned to establish the unity, infinity and self-containedness of Nature; but the two opposed Cartesian attributes, thought and extension, and the absolutely infinite substance whose attributes they are—substance constituted by infinite thought and extension—are not opposed by them. The notion—of substance—is said to correspond exactly to “the essence of the only glorious and blessed God.” The earlier differs from the later exposition in allowing an objective causal relation between thought and extension, for which there is substituted in the Ethics the idea of a thoroughlygoing parallelism. The Short Treatise is of much interest to the student of Spinoza’s philosophical development, for it represents, as Martinu says, “the first landing-place of his mind in its independent advance.”

Although the systematic framework of the thought and the terminology used are both derived from the Cartesian philosophers, the intellectual milieu of the time, the early work enables us, better than the Ethics to realize that the inspiration and starting-point of his thinking is to be found in the religious speculations of his Jewish predecessors. The histories of philosophy may quite correctly describe his theory as the logical development of Descartes’s doctrines of the one Infinite and the two finite substances, but Spinoza himself was never a Cartesian. He brought his pantheism and his determinism with him to the study of Descartes from the mystical theologies of his race.

Early in 1661 Spinoza’s host removed to Rijnsburg near Leiden, the headquarters of the Collegiate brotherhood, and Spinoza removed with him. The house where they lived at Rijnsburg is still standing, and the road bears the name of Spinoza Lane. Very soon after his settlement in his new quarters he was sought out by Henry Oldenburg, the first secretary of the Royal Society. Oldenburg became Spinoza’s most regular correspondent—a third of the letters preserved to us are to or from him; and it appears from his first letter that their talk on this occasion was “on God, on infinite extension and thought, on the difference and the agreement of these attributes, on the nature of the union of the human soul with the body, as well as concerning the principles of the Cartesian and Baconian philosophies.” Spinoza must, therefore, have unbound himself pretty freely to his visitor on the main points of his system. Oldenburg, however, was a man of no speculative capacity, and, to judge from his subsequent correspondence, must have quite failed to grasp the real import and scope of the thoughts communicated to him. From one of Oldenburg’s letters it is learned that "intelligentia cernentiae" was probably Spinoza’s first occupation at Rijhsburg. The nature of the work also bears out the supposition that it was first undertaken. It is, in a manner, Spinoza’s “organon”—the doctrine of method which he would substitute for the corresponding doctrines of Bacon and Descartes as alone consonant with the thoughts which were shaping themselves or had shaped themselves in his mind. It is a theory of philosophical truth and error, involving an account of the course of philosophical inquiry and of the various methods of approach. It was apparently intended by the author as an analytical introduction to the constructive exposition of his system, which he presently essayed in the Ethics. But he must have found as he proceeded that the two treatises would cover to a large extent the same ground, the account of the true method merging almost inevitably in a statement of the truth reached by its means. The Improvement of the Understanding was therefore put aside unfinished, and was first published in the Opera posthuuma. Spinoza meanwhile concentrated his attention upon the Ethics, and we learn from the correspondence with his Amsterdam friends that a considerable part of book i. had been communicated to the philosophical club there before February 1663. It formed his main occupation for two or three years after this date. Though thus giving his friends freely of his best, Spinoza did not cast his thoughts broadcast upon any soil. He had a pupil living with him at Rijhsburg whose character seemed to him lacking in solidity and discretion. This pupil (probably Albert Burgh, who afterwards joined the Church of Rome and penned a foolishly insolent epistle to his former teacher) was the occasion of Spinoza’s first publication—the only publication indeed to which his name was attached. Not deeming it prudent to initiate the young man into his own system, he took for a textbook the second and third parts of Descartes’s Principia, which deal in the main with natural philosophy. As he proceeded he put Descartes’s matter in his own language and cast the whole argument into a geometric form. At the request of his friends he devoted a fortnight to applying the same method to the first or metaphysical part of Descartes’s philosophy, and the sketch was published in 1663, with an appendix entitled Cogitata metaphysica, still written from a Cartesian standpoint (defending, for example, the freedom of the will), but containing hints of his own doctrine. The book was revised by Dr Meyer for publication and furnished with a preface by the author. It is expressly stated that the author speaks throughout not in his own person but simply as the exponent of Descartes. A Dutch translation appeared in the following year. In 1663 Spinoza removed from Rijhsburg to Voorburg, a suburban village about 2 m. from the Hague. His reputation had continued to spread. From Rijhsburg he had paid frequent visits to the Hague, and it was probably the desire of Boyle, and acquainted with most of the leaders of science in England as well as with many on the Continent. He delighted to keep himself in this way au courant with the latest developments, and lost no opportunity of establishing relations with men of scientific reputa-

1 Various manuscript copies were apparently made of the treatise in question, but it was not printed, and dropped entirely out of knowledge till 1852, when Edward Böhrer of Halle lighted upon an abstract of it, attached to a copy of Colerus’s Life, and shortly afterwards upon a Dutch MS, purporting to be a translation of the treatise from the Latin original. This was published in 1682 by Van der Linden. A Dutch translation of Spinoza’s other works was of the Dutch translation has been discovered, which has been edited by Professor Schaarschmidt and translated into German. Another German version with introduction and notes has been published by Sigwart based on a comparison of the two Dutch MSS. A second English translation similarly equipped was published by A. Wolf in 1910.

2 The fact that Spinoza nowhere mentions Bruno would not imply, according to the literary habits of those days, that he was not acquainted with his speculations and even indebted to them. There is no mention, for example, of Hobbes throughout Spinoza’s political writings, and yet Hobbesian political thinking is seen in a letter, although the obligation of the Dutch to the English thinker lies on the surface. Accordingly, full weight must be allowed to the internal evidence brought forward by Sigwart, Avernaeus and others to prove Spinoza’s acquaintance, with Descartes. But the point remains quite doubtful and is in any case of little importance.

3 Heinrich Oldenburg (c. 1626-1678) was a native of Bremen, but had settled in England in the time of the Commonwealth. Though hardly a scientific man himself, he had a genuine interest in science, and must have possessed social gifts. He was the friend of
to be within reach of some of the friends he had made in these visits—among others the De Witts—that prompted his changed residence. He had worked in hand, moreover, which he wished in due time to publish; and in that connection the friendly patronage of the De Witts might be of essential service to him. The first years at Voorburg continued to be occupied by the composition of the Ethics, which was probably finished, however, by the summer of 1665. A journey made to Amsterdam in that year is conjectured to have had reference to its publication. But, finding that it would be impossible to keep the authorship secret, owing to the numerous hands through which parts of the book had already passed, Spinoza determined to keep his manuscript in his desk for the present. In September 1665 we find Colerus putting himself in close touch with him, and putting in order. The external side of religion—thought and speech in speculative matters—has to do with the thought and speech in the church. The aegis of religion, therefore, cannot be employed to cover with its authority any speculative doctrine; nor, on the other hand, can any speculative or scientific investigation be regarded as putting religion in jeopardy. Spinoza undertakes to prove his case by the instance of the Hebrew Scriptures. Scripture deals, he maintains, in none but the simplest precepts, nor does it aim at anything beyond the obedient mind; it tells nought of the divine nature but what men may profitably apply to their life. The great end of the treatise is devoted to working out this line of thought; and in so doing Spinoza consistently applies to the interpretation of the Old Testament those canons of historical exegesis which are often regarded as of comparatively recent growth. The treatise thus constitutes the first document in the modern science of Biblical criticism. It was published in 1670, anonymously, printer and place of publication being likewise disguised (Hamburgi apud Heinricum Kinoz). The storm of opposition which it encountered showed that these precautions were not out of place. It was synchronically condemned along with Hobbes's Leviathan and other books as early as April 1671, and was consequently interdicted by the states-general of Holland in 1674; before long it was also placed on the Index by the Catholic authorities. But that it was widely read appears from its frequent reissue with false title-pages, representing it now as an historical work and again as a medical treatise. Controversialists also crowded into the lists against it. A translation into Dutch appears to have been proposed; but Spinoza, who foresaw that such a step would only increase the commotion which was so distasteful to him, steadily set his face against it. No Dutch translation appeared till 1663. The same year in which the Tractatus was published Spinoza removed from his suburban lodging at Voorburg into the Hague itself. He took rooms first on the Veerway with the widow Van de Velde, who in her youth had assisted Grotius to escape from his captivity at Loewenstein. This was the house afterwards occupied by Colerus, the worthy Lutheran minister who became Spinoza's biographer. But the widow insisted on boarding her lodger, and Spinoza presently found the expense too great for his slender purse. He accordingly removed to a house on the Paviljoen Gracht near at hand, occupied by a painter called Van der Spieck. Here he spent the remaining years of his life in the four small rooms in which he prized. Colerus gives particulars which enable us to realize the almost incredible simplicity and economy of his mode of life. He would say sometimes to the people of the house that he was like the serpent which forms a circle with its tail in its mouth, meaning thereby that he had nothing left at the year's end. His friends came to visit him in his lodgings, as well as others attracted by his reputation—Leibnitz among the rest—and were courteously entertained, but Spinoza preferred not to appear to them in his true condition. He spent the greater part of his time quietly in his own chamber, often baking his meals there and sometimes not leaving it for two or three days together when absorbed in his studies. On one occasion he did not leave the house for three months. "When he happened to be tired by having applied himself too much to his philosophical meditations, he would go downstairs to refresh himself, and discoursed with the Van der Spiecks about anything that might afford matter for an ordinary conversation, and even about trifles. He also took pleasure in smoking a pipe of tobacco; or, when he had a mind to divert himself somewhat of the humour, he looked for the pipe of tobacco to be oblique, and put the bowl and the stem together, or he threw some flies into the cobweb, and was so well pleased with the result of that battle that he would sometimes break into laughter" (Colerus). He also conversed at times on more serious topics with the simple people with whom he lodged, often, for example, talking over the sermon with them when they came from church. He occasionally went himself to hear the Lutheran pastor preach—the predecessor of Colerus—and would advise the Van der Spiecks not to miss any sermon of so excellent a preacher. The children, too, put in their habit of going often to church, and taught them to be obedient and dutiful in their parochial duties. A lady, who may have heard strange stories of her solitary lodger, came to him in some trouble to ask him whether he believed she could be saved in the religion she professed. "Your religion is a good one," said Spinoza; "you need not look for another, nor doubt that you will be saved in it, provided that, while you apply yourself to piety, you live at the same time a peaceable and quiet life." Only once, it is recorded, did Spinoza's admirable self-control give way, and that was when he received the news of the murder of the De Witts by a frantic mob in the Hague. As the year closed he feared the approach of the invasion of the Low Countries by Louis XIV. raised an irresistible clamour for a military leader and overthrew the republican constitution for which the De Witts had struggled. Join De Witt had been Spinoza's friend, and had bestowed a small pension upon him; he had Spinoza's full sympathy in his political aims. On receiving the news of the brutal murder of the two brothers, Spinoza burst into tears, and his indignation was so roused that he was bent upon publicly denouncing the crime upon the spot where it had been committed. But the timely caution of his colleagues prevented his issuing forth to almost certain death. Not long after Spinoza gave up his house in the Hague, the royal Viceroy in Ireland died, and Spinoza appears to have left for England in consequence of a visit which he paid to the French camp. He had been in correspondence with one Colonel Stoupe, a Swiss theologian and soldier, then serving with the prince of Condé, the commander of the French army at Utrecht. From him Spinoza received a communication enclosing a passport from the French commander, who wished to make his acquaintance and promised him a pension from the French king at the easy price of a dedication to his majesty. Spinoza went to Utrecht, but returned without seeing Condé, who had in the meantime been called elsewhere; the pension he civilly declined. There may have been nothing more in the visit than is contained in this narrative; but on his return Spinoza found that the populace of the Hague regarded him as no better than a spy. The town was full of angry murmur, and the landlord feared that the mob would storm his house and drag Spinoza out. Spinoza
quieted his fears as well as he could, assuring him that as soon as the crowd made any threatening movement he would go out to meet them, "though they should serve even as the pest of De Witts. I am a good republican, and have never had any aim but the honour and welfare of the state." Happily the danger passed off without calling for such an ordeal.

In 1673 Spinoza received an invitation from the elector palatine to quit his retirement and become professor of philosophy in the university of Heidelberg. The offer was couched in flattering terms, and conveyed an express assurance of "the largest freedom of speech in philosophy, which the prince is confident that you will not misuse to disturb the established religion." But Spinoza's experience of theological sensitiveness led him to doubt the possibility of keeping on friendly terms with the reformed religion, if he were placed in a public capacity. Moreover, he was not strong; he had had no experience of public teaching; and he foresaw that the duties of a chair would put an end to private research. For all these reasons he courteously declined the offer made to him. There is little more to tell of his life of solitary meditation. In 1675 we learn from his correspondence that he entered the idea of publishing the *Ethics*, and made a journey to Amsterdam to arrange matters with the printer. "But, whilst I was busy with this," he writes, "the report was spread everywhere that a certain book of mine had been burned by God in the market place, showing thereby that God is no God; and this report found credence with many. Whereupon certain theologians (themselves perhaps the authors of it) took occasion to complain of me to the prince and the magistrates; moreover, the stupid Cartesianists, because they are commonly supposed to side with me, desiring to free themselves from that suspicion, were diligent without ceasing in their excreations of my doctrines and writings, and are as diligent still." As the commotion seemed to grow worse instead of subsiding, Spinoza consigned the manuscript once more to his desk, from which it was not to issue till after his death. His last literary enterprise was the publishing of his *Political Theology*, and the publication of notes for a new edition of the *Tractatus theologico-politicus*, in which he hoped to remove some of the misunderstandings which the book had met with. The *Tractatus politicus* develops his philosophy of law and government on the lines indicated in his other works, and connects itself closely with the theory enunciated by Hobbes a generation before. Consumption had been making its insidious inroads upon Spinoza for many years, and early in 1677 he must have been conscious that he was seriously ill. On Saturday, the 24th of February, he sent to Amsterdam for his friend Dr Meyer. On the following day, the Van Speijks, having no thought of immediate danger, went to the afternoon service. When they came back Spinoza was no more; he had died about three in the afternoon with Meyer as the only witness of his last moments. Spinoza was buried on the 25th of February "in the new church upon the Spuy, being attended," Colerus tells us, "by many illustrious persons and followed by six coaches." He was little more than forty-four years of age.

Spinoza's effects were few and realized little more than was required for the payment of charges and outstanding debts. One and one-half hundred pounds was in the way of fortunes. Colerus says in his biography, "to perceive that it was the inventory of a true philosopher. It contains only some small books, some engravings, a few lenses and the instruments to polish them. His desk, containing his letters and his unpublished works, Spinoza had previously charged his landlord to convey to Jan Rieuwertz, a publisher in Amsterdam. This was done, and the *Opera postuma* appeared in the same year, without the author's name, but with his initials upon the title-page. They were furnished with a preface written in Dutch by Jari Jellis, a Mennonite friend of Spinoza's, and translated into Latin by Dr Meyer. Next year the book was proscribed in a year and a half from the date of its publication, and the law was made effective. The obloquy which thus gathered round Spinoza in the later years of his life remained settled upon his memory for a full hundred years after his death. Hume's casual allusion to "this famous and ridiculous hypothesis" is a fair specimen of the tone in which he is usually referred to; people talked about Spinoza, Lessing said, "as if he were a dead dog." The change of opinion in this respect may be dated from Lessing's famous conversation with Jacobi in 1780. Lessing, Goethe, Herder, Novalis and Schleiermacher, not to mention philosophers like Schelling and Hegel, united in recognizing the unique strength and sincerity of Spinoza's thought, and in setting him in his rightful place among the speculative leaders of mankind. Transfixed into their writings, his spirit has passed upon the world as an inspiration through the eighteenth and the nineteenth centuries, and it has also been widely influential beyond the schools. Instead of his atheism Hegel speaks of his acosmism, and Novalis dubbs him a God-intoxicated man. Schleiermacher's fine line, "he can only not be a philosopher," is better than saying "he was a lock of hair to the manes of the holy and excommunicated Spinoza." Spinoza's personal appearance is described by Colerus from the account given him by his manuscript people who knew him very familiarly. "He was of middle size, and had good features in his face, the skin somewhat dark, black curled hair, and the long eyebrows of the same colour, so that one might easily know from sight if he were the man from whom I had obtained the portrait. Schleiermacher also gives a similar description: "The celebrated Jew Spinoza had an olive complexion and something Spanish in his face." These characteristics are preserved in a portrait in oil in the Wolfenbüttel Museum, which was probably the original of the (very carelessly rendered) engraving prefixed to the *Opera posthuma* of 1677. This portrait was photographed for Dr Martineau's *Study of Spinoza*. In 1880 a statue was erected to Spinoza at the Hague by fresh letton subcommittee undertaken by Dr Van Voten and Professor J. P. N. Land for the Spinoza Memorial Committee formed in Holland to celebrate the bicentenary of the philosopher's death (1632-1832). The statue, dedicated 8 February 1882 and intended to recall the famous letter to the translator of Spinoza's *Ethics*, was not bought, supposed to be lost, was published anonymously in Dutch in 1687. The first collected edition of Spinoza's works was made by Paulus in 1802; there is another by Gröser (1830), and a third by Bouman (1843-1846). Of these, the last, in six volumes, pub- lished in 1860, *Ad Benedicti de Spinoza opera quae supersunt omnia supplementum*, is uniform with Bruder's edition, and contains the early treatise *De deo et homine*, the *Treatise on the Renunciation of the Will*, and several other works. The commentaries of the *Opera posthuma* included the *Ethics*, the *Tractatus politicus* and the *De intellectus emendatione* (the last two unfinished), a selection from Spinoza's correspondence, and the *Mysticum*; the *Tractatus theologico-politicus*, *De Bono*, supposed to be lost, was published anonymously in Dutch in 1687. The first collected edition of Spinoza's works was made by Paulus in 1802; there is another by Gröser (1830), and a third by Bouman (1843-1846). Of these, the last, in six volumes, pub- lished in 1860, *Ad Benedicti de Spinoza opera quae supersunt omnia supplementum*, is uniform with Bruder's edition, and contains the early treatise *De deo et homine*, the *Treatise on the Renunciation of the Will*, and several other works. The main authority for Spinoza's *life* is the sketch published in 1705, in Dutch, with a controversial sermon against Spinozism, by the Mennonite John de Vries. It was reprinted in 1799 by Pennington, and several times reprinted as well as translated into English and German. The English version, also dating from 1706, was reprinted by Sir Frederick Pollock at the end of his *Spinoza, his Life and Philosophy* (1880). This book, Dr Martineau's *Study of Spinoza* (1882) and Dr John Caird's *Spinoza* (1888), are all admirable pieces of work, and, as regards the philosophical estimate, complement one another. H. H. Joachim's *Study of the Ethics of Spinoza* (1901) and R. A. Duff's *Spinoza's Political and Ethical Philosophy* (1903) are important contributions of more recent date. Careful research by Professor Freudenthal, Dr W. Meyer and Dr K. O. Meinsma has brought to light much information on the life and times of Spinoza's life and increased our knowledge of his Jewish and Dutch environment. The earliest lives and all the available documents have been edited by G. R. H. Freudenthal in a single volume, *Die Leben*, published by A. Wolf in the "Life" prefixed to his translation of the *Short Treatise* (1910), and the greater part of it also in the second edition of Sir Frederick Pollock's *Spinoza* (1899).

**SPINY SQUIRREL**, a book-name for a group of African ground squirrels, characterized by the spiny nature of the fur of the more typical forms. They form the genus Xerus, which is split up into a number of subgenera: *Xerus rutilus* of Abyssinia and East Africa belonging to the typical group, while the striped
North African X. geltius represents the sub-genus *Atlantoxerus*. The more typical species are characterized by the coarse spiny hair, the small size, or even absence of the ears, and the long, nearly straight, claws. The skull is narrower and longer than in typical squirrels, and there are distinctive features in the cheek-teeth; but the more aberrant types come much closer to squirrels. Typical spiny squirrels differ from true squirrels in being completely terrestrial in their habits, and live either in clfts or holes of rocks, or in burrows which they dig themselves. (See Rodentia.)

**SPION KOP**, a mountain in Natal on the north side of the Tugela River, and 24 m. W.S.W. of Ladysmith. It is celebrated as the scene of a battle (Jan. 24, 1900) in the Transvaal War, in which the British forces under Sir Redvers Buller were defeated by the Boers (see Transvaal and Ladysmith). The Spion Kop incident led to much controversy; for an admirable elucidation of the facts see The Times History of the War in South Africa. The name itself (Dutch for "Look-out Hill") is fairly common as a place-name in South Africa.

**SPIRAL**, in mathematics, the locus of the extremity of a line (or radius vector) which varies in length as it revolves about a fixed point (or origin). Here we consider some of the more important plane spirals. Obviously such curves are conveniently expressed by polar equations, i.e. equations which directly state the position of each point of the curve in terms of the radius vector and the vector angle; another form is the "p, r" equation, wherein r is the radius vector of a point, and p the length of the perpendicular from the origin to the tangent at that point.

The equiangular or logarithmic spiral (fig. 1) is such that as the vector angle increases arithmetically, the radius vector increases geometrically; this definition leads to an equation of the form \( r = Ae^{k\theta} \), where \( e \) is the base of natural logarithms and A, B are constants. Another form is the "hyperbolic spiral" given by the equation \( r = a^p \); the only important are the Archimedean spiral, \( r = a\theta \); the hyperbolic or reciprocal spiral, \( r = a^{-p} \); and the litus, \( r = a^p \). The first-named was discovered by Conon, whose studies were completed by Archimedes. Its \( p, r \) equation is \( p = r^2 \sqrt{a^2 + r^2} \), and the angle between the radius vector and the tangent equals the vector angle. The second, called hyperbolic on account of the analogy of its equation (polar) to that (Cartesian) of a hyperbola between the asymptotes, is the inverse of the Archimedean.

The third, called hyperbolic on account of the analogy of its equation (polar) to that (Cartesian) of a hyperbola between the asymptotes, is the inverse of the Archimedean....

**SPIRE** (O. Eng. *spire*, a blade of grass, and so anything tapering to a point), the architectural term (Fr. *flèche*, Ital. *guglia*, Ger. *Spitze*) given to the lofty roofs in stone or wood covered with lead or slate, which crown the towers of cathedrals, churches, &c. In their origin, as in the church of Thaon in Normandy, they were four-sided, but became of slight elevation, but soon began to be features of great importance, but the square bases are generally of octagonal form, and equal in height sometimes to the towers themselves. The junction, however, of an octagonal spire and a square tower involved a distinct architectural problem, and its solutions in English, French and German spires are of infinite variety. One of the earliest treatments is that of the south-west wing of Chartres Cathedral, where, on the four projecting angles are lofty spire lights which, with others on the four faces and the octagonal spire itself, form a fine composition; at the abbey of St Denis the spire light at each angle was carried on three columns which filled both the triangular space at the angles and gave greater lightness to the structure; long vertical slots in the spire lights and the spire increased this effect, leading eventually to the introduction of tracery throughout the spire; the ultimate results of this we see in the face-work spires of Strassburg, Antwerp, St Stephen's at Vienna, Freiberg, Ulm and other examples, which in some cases must be looked upon as the "tours de force" of the masons employed. In England the spires were far less pretentious but of greater variety of form. The spire of the cathedral at Lincoln is a good example of the comparatively low elevation, of octagonal form with marked entasis, and is decorated with spire lights on each face and pinnacled turrets at the angles. Those which are peculiar to England are the broach-spires, in which the four angles of the tower are covered with a stone roof which penetrates the central, octagonal spire. In the best examples the spire comes down on the tower with dripping caves, and is carried on a corbel table, of which the finest solution is St Mary's at Stamford. The angles of the octagonal spire have a projecting moulding which is stopped by a head just above the corbel table, and at the corners of the tower all niches to which the broach-spires are continued. In England the spire lights are in three stages alternately in the front and diagonal faces. At St Mary, Kelton, and St Nicholas, Walcot, are similar designs. Seen, however, on the diagonal, the void space at the angles of these broach-spires is noticeable, so that an octagonal pinnacle was erected, of which the earliest example is that of the cathedral at Oxford, where the broach was of very low pitch. Of later date St Mary's, Wollaston, All Saints, Leighton Buzzard, and St Mary's, Witney, are good examples. As a rule the broach penetrates the octagonal spire about one-third of its height, or the third spire, which belongs to the peculiarly English form of spire. It should be noticed that the spire lights are sometimes divided into four parts, each being further enriched with crockets up each angle of the spire; the same is found in St Mary's, Whittlesea, Cambridgeshire. At St Michael's, Coventry, the lower part of the octagonal spire is made vertical with a battlemented cresting round it. In St Patrick's, Partridge, Yorkshire, the lower part of the spire, which otherwise is plain, is enclosed with an open gallery like the cresting of a crown. Sometimes the upper storey of the tower is made octagonal, and is set back so as to allow of a passage round with parapet or battlement, as at St Mary's, Bloxham, St Peter and St Paul, Seton, and St Mary, Castlelegate, York. The most important groupings are those which surmount the towers of the English cathedrals; at Lichfield square turrets of large size with richly crocketed pinnacles; at Peterborough, a peculiar but not happy arrangement where a lofty spire covers over the buttress between angle turret and spire; and at...

Fig. 3. Spire.
Salisbury an octagonal pinnacle at the angle and a triangular spire light against the spire. The happiest combination of all, however, is perhaps the spire of St Mary's, Oxford, with three ranges of angle niche-groups set one behind the other, forming with the centre spire a magnificent cluster of spires; the niche gables and pinnacles are all enriched with crockets and the ball flower in the arch mouldings.

Reference has already been made to two of the French spires, at Chartres and St Denis; there is nothing like the diversity of design in France, however, when compared with those in England, and there are but few on the crossing of nave and transept; the towers were built to receive them, as at Amiens, Rheims and Beauvais, but for some reason not carried above the roof, possibly from some doubt as to the expediency of raising stone lanterns and spires of great weight on the four piers of the crossing; on the other hand their places were taken by constructions in timber covered with lead, of immense height and fine design. There was a 13th-century flèche on the crossing of Notre-Dame, Paris, taken down soon after the beginning of the 19th century, of which the existing example by Viollet-le-Duc is a copy. The same fate befell that over the Sainte Chapelle, Paris, being reconstructed about 1850 by Lassus. The flèche at Amiens, though of late date (c. 1500), is still in good preservation, but a remarkable work; above the ridges of the roofs of nave and transept, and octagonal in plan, are two stages, the upper one set back to allow of a passage round, and, above the cresting of the latter, a lofty octagonal spire with spire lights at the base on each side, crockets up the angles, and other decorations in the lead work with which it is covered. Including the vane, from the ridge of roof the height is 182 ft. Of timber flèches covered with slates there are many examples in the north of France, those at Orbais (Marne) and the abbey at Eu (Seine Inférieure) being the best known. Returning to stone spires, those on the south front of St Stephen's, Calais (Alauna) are good examples with lofty octagonal turrets and pinnacles at west angle and spire light between, and among others are those of St Pierre at Caen, Senlis, Coutances, Bayeux, and many others in Calvados, and at Soissons, Noyon and Laon in Picardy. One of the most beautiful spires in France, though of late date, is that of the north-west tower to Chartres Cathedral. In the south of France, in the Charente and Périgord, the stone spire takes quite another form, being of much less height, of convex form, and studded with small scales, giving somewhat the appearance of a pine cone, with small pointed turrets and pinnacles at the angles of the tower. The west tower of Angoulême Cathedral, the central towers of Saints Le Palud, and Plassac in the Charente, and the tower of St Front, Périgueux, and Brantôme in Périgord, have all spires of this kind, of which a small example crowns the Lanterne des Morts at Cellefron. The German towers are generally covered with roofs only, of varied form, but at Ulm, Strassburg, Freiburg and Cologne is a remarkable series of traceried spires in stone, of great elaboration and showing great masonic ability, but wanting in repose and solidarity, and the same applies to the spire at Antwerp. In Spain there are not many examples of note, the spire at St Stephen's, Valencia, standing in its outline and want of height the influence of the Périgordian spires, and that at Salamanca the influence of those in the north of France.

Looking upon the spire as the crowning feature of a tower, those of the Renaissance period must be included here, though as a compromise they are often termed "steeples." Of these the finest and most varied are those by Wren in London, among which that of Bow Church and St Bride's, Fleet Street, are the best known, the former with two stages of lanterns with detached columns round, and the latter octagonal on plan with five stages, set one behind the other, with arches in centre of each face and pilasters at the angles. St Antholin, now destroyed, was the only example based on a Gothic prototype; it consisted of an octagonal spire with Renaissance spire lights and angle finials resting on the upper octagonal storeys of the tower. St Margaret Pattens somewhat resembles it, but the tower has a balustrade round and the angle pinnacles are in the form of obelisks, a favourite Renaissance interpretation of the Gothic spire, which is found in other churches, as in those of St Martins-in-the-Fields by Gibbs and St Giles-in-the-Fields by Wren. Hawksmoor apparently based his spire of St George's, Bloomsbury, which consists of a series of lofty steps, and is crowned with a statue of George I., on that of the mausoleum at Halicarnassus. In France, Italy and Spain, lanterns usually terminate the towers. The spire of the Sea at Saragossa in design somewhat resembles those of Wren, being one of the few examples worth noting. (R. P. S.)

Spires (Ger. Spirey or Spitey), a town and episcopal see of Germany, capital of the Bavarian palatinate, situated on the left bank of the Rhine, at the mouth of the Speyerbach, 16 m. S. of Mannheim by rail. Pop. (1895), 21,823. The principal streets are broad but irregular, and the general appearance of the town little corresponds to its high antiquity, owing to the fact that it was burnt by the English in 1814, and by Napoleon in 1796. The most important ancient building that survived the flames is the cathedral, a very large and imposing basilica of red sandstone, and one of the noblest examples of Romanesque architecture now extant. Beyond the general interest attaching to it as one of the old Romanesque churches of the Rhinelander, Spire Cathedral has a peculiar importance in the history of architecture as probably the earliest Romanesque basilica in which the nave as well as the side arcades was vaulted from the first (see Architecture: Romanesque in Germany). Built in 1030-1061 by Conrad II. and his son, although this church has had a chequered historic history, its disasters culminating in 1830, when the solomiers of Louis XIV. burned it to the bare walls, and scattered the ashes of the eight German emperors who had been interred in the king's choir. Restored in 1772-1784 and provided with a vestibule and façade, it was again desecrated by the French in 1794; but in 1846-1853 it was once more thoroughly restored and adorned in the interior with gorgeous frescoes at the expense of the king of Bavaria. The large cathedral bowl (Dompfaff) in front of the west façade formerly marked the boundary between the episcopal and municipal territories. Each new bishop on his election had to fill the bowl with wine, while the burgesses emptied it to his health. The heathen tower to the east of the church, on foundations supposed to be Roman, was probably part of the town-wall built in 1080 by Bishop Rodger. Of the Retscher, or imperial palace, so called because built after the model of the Hradchán at Prague, only a mouldering fragment of wall remains. It was in this palace that the famous Diet of Spire met in 1259, at which the Reformers first received the name of Protestants. The Altpörtel (alta portae), a fine old gateway of 1246, is a relic of the free imperial city. Among the modern buildings are several churches and schools, a museum and picture gallery, etc. St Michael's, although so very old, is still the city church, the only church in Spire, otherwise decorated with statues and paintings. Spire, as the capital of the county of Hesse-Spire, has never recovered from the injuries inflicted by the French in 1830. Its trade is insignificant, although it still has a free harbour on the Rhine. Its manufactures include cloth, paper, tobacco and cigars, sugar, sugar of lead, vinegar, beer and leather. Vines and tobacco are grown in the neighbourhood.

Spires, known to the Romans as Augusta Nemetum or Nemetica, and to the Gauls as Noviomagus, is one of the oldest towns on the Rhine. The modern name appears first under the form of Spira, about the 7th century. Captured by Julius Caesar in 47 B.C., it was repeatedly destroyed by the barbarian hordes in the first three centuries of the Christian era. The town had become an episcopal seat in the 4th century; but heathenism survived, and the present bishopric dates from 610. In 830 Spira became part of the Frankish Empire, the emperors having a "palatium" here; and it was especially favoured by the Salic imperial house. The contents between the bishops and the
citizens were as obstinate and severe as in any other city of Germany. The situation of the town opposite the mouths of several roads through the Rhine valley early fostered its trade; in 1294 it rose to be a free imperial city, although it owned no territory beyond its walls and had a population of less than 30,000. It enjoyed great renown as the seat of the imperial supreme court from 1527 till 1689; it was fifth among the free cities of the Rhine, and had a vote in the Upper Rhinen Diet. Numerous imperial diets assembled here. From 1801 till 1814 it was the capital of a department of France; but it was restored to Bavaria in the latter year. By the Peace of Spires in 1544 the Habsburgs renounced their claims to the crown of Sardinia.

SPIRITS. The original meaning of the word spirit (Lat. spiritus, Greek phorae) was wind, in motion, breath, the soul, and hence it came to denote that which gives life or vigour to the human body and other objects, and it is, therefore, synonymous with everything eminently pure, ethereal, refined or distilled. In popular chemical nomenclature the term “spirit” in its former sense is still occasionally encountered, for instance, “spirits of salts” for hydrochloric acid. The spirits of the British Pharmacopoeia (e.g. sp. aetheris nitrosi; sp. chloroformi; sp. camphorae) are solutions of various substances obtained either by distilling these with, or dissolving them in, the rectified spirit of the Pharmacopoeia, which latter is pure alcohol with 16% by volume of water.

In the modern sense, spirits may be broadly defined as the products resulting from the distillation of saccharine liquids which have undergone alcoholic fermentation. Spirits of wine means rectified spirit of a strength of 43 degrees over proof and upwards. By rectified spirit is meant spirit rectified at a licensed rectifier’s premises. Proof spirit, which is the standard spirit of the United States, is legally defined (58 Geo. III. c. 28) as a spirit which at 51° F. weighs exactly twelve-thirteenths of the weight of an equal volume of distilled water. The strength of proof spirit at 60° F.—the temperature now generally employed for official calculations—is now officially regarded as being equal to a spirit containing 57.06% by volume, or 49.24% by weight, of absolute alcohol. Spirit which possesses a greater or smaller alcoholic strength than proof is described as being so many degrees over or under proof, as the case may be. The strength is legally estimated by Sykes’s hydrometer, which was legalized in 1816 by 56 Geo. III. c. 40. The degrees “over” or “under” proof as ascertained by Sykes’s hydrometer are arbitrary percentages by volume of a standard spirit contained in the spirit under examination. This standard spirit is “proof spirit” at 60° F.—the temperature now generally employed for official calculations—is now officially regarded as being equal to a spirit containing 57.06% by volume, or 49.24% by weight, of absolute alcohol. Spirit of such a strength that 100 volumes of the same contain an amount of spirit equal to 175-25 volumes of the standard (proof) spirit. A spirit of 25 degrees under proof is one of which 100 volumes contain only as much alcohol as do 75 (i.e. 100-25) volumes of proof spirit. According to Netleton, “proof spirit” would appear to be the outcome of an attempt to produce a mixture of pure alcohol and water, containing equal weights of the constituents. The term “proof” probably originated from a rough test for spirits which was formerly employed, which consisted in moistening gunpowder with the spirit, and applying a light. If the gunpowder did not ignite, but the spirit merely burned away, the spirit was regarded as being under proof, i.e. it contained so much water that the gunpowder became moist and refused to deflagrate. The basis of the strength of other countries is almost invariably the unit volume of absolute alcohol, the hydrometers, or rather “alcoholometers”—such as those of Gay-Lussac and of J. G. Trâlles—employed indicating the exact quantity of alcohol in a mixture at a standard temperature, in percentages by volume. In the United States the term “proof” is also employed; American proof spirit being a spirit which contains 50% of alcohol by volume at 60° F. American “proof” spirit is, therefore, considerably weaker than British “proof.” Allowing for this difference and also for the fact that the American standard

1 For the sense of disembodied persons, see SPIRITUALISM.

FIG. 4.—Ancient form of Still, used in Tahiti.

gallon (which is really the old English wine-gallon) is equal to 0.833 of an imperial gallon, the American “proof” gallon roughly equals 0.73 of a British proof gallon.

SPIRITS. In the art of distillation, more particularly the preparation of distilled alcoholic fluids for beverage and medicinal purposes, is of very ancient origin. It is probable that the art of making spirits was well known many centuries before the advent of the Christian era. According to T. Fairley, the Chinese distilled liquor “sauchoo” was known long before the Christian era, and “arrack” was made in India at a date as remote as 800 B.C. Aristotle in his Meteorology (lib. ii. ch. ii.) says “Sea-water can be rendered potable by distillation: wine and other liquids can be submitted to the same process. After they have been converted into humid vapours they return to liquids.” There is, on the whole, little doubt that spirits were manufactured in Egypt, India, China, and the Far East generally, as far back as 2000 B.C. Figs. 1-4 (from Morewood’s Inebriating Liquors, published in 1838) show very ancient forms of stills in use in China, India, Tibet and Tahiti.

As far as can be ascertained the oldest reference to the preparation of a distilled spirituous liquor in the British Isles is contained in the “Mead Song” written by the Welsh bard, Taliesin, in the 6th century. He said “Mead distilled I praise, its eulogy is everywhere,” &c. (Fairley, The Ana-lyst, 1905, p. 300). The same authority points out that the knowledge of distillation in the British Isles was independent of the art of distillation from wine, seeing that distillation from grain was known in Ireland before the art of making wine came to Europe. An Irish legend states that St Patrick first taught the Irish the art of distillation; but, however that may be, it is certain that at the time of the first English invasion of Ireland (1170-72) the manufacture of a spirit distilled from grain (i.e. whisky) was known to the inhabitants of that country. It is probable that grain spirit was first prepared in the Far East, inasmuch as a spirit distilled from rice and other grains was made in India before the Christian era. The establishment of regular distilleries in England appears to date back to the reign of Henry VIII., and they are said to have been founded by Irish settlers who came over at that time. It is difficult to obtain exact data.
regarding the origin of the distilling industry in Scotland, but, as Fairley says, it is probable that distilling was carried on there almost as early as in Ireland. At the time of the Tudors Scotch whisky was held in great repute in England. The production of a spirit from wine (i.e. brandy) appears to have been known in the 9th century; but, according to Morewood, the first attempt at the distillation of wine in France is attributed to Arnaldus de Villa Nova, in the 13th century. As a manufacturing industry the distillation of brandy in France began in the 14th century. The history of the spirit industry in the United Kingdom is, as Nettleton has well pointed out, inseparably connected with matters of taxation. According to one writer, it was not until 1660 that an excise duty was first imposed on the consumption of spirit ("aqua vitae") in the United Kingdom, but it appears probable that the industry generally was taxed in one form or another in the reign of Elizabeth, when it first began to assume considerable importance. No record, however, of the quantity of spirit on which duty was charged is kept until 1684. In that year duty was paid on 527,492 gallons. At the end of the century the consumption reached 1,000,000 gallons, and in 1745 it had risen to a quantity equivalent to about 5,000,000 gallons at proof. Cromwell imposed a tax of 8d. per gallon, but the tax was soon increased to 2s. In 1751 a further increase of one shilling per gallon was imposed, and in 1766 this was further increased to 2s. After this various changes and complex methods of assessing the duty were introduced (see Nettleton, The Manufacture of Spirits, Marcus Ward, 1893) until, in more modern times, a more rational and uniform system was introduced.

**Conditions of Manufacture.**—The principal act now governing and regulating the manufacture of spirits and the working of distilleries in Great Britain is the Spirits Act of 1880. The provisions of this and of the other acts bearing on the subject are exceedingly numerous and complicated, and, therefore, only a few of the chief points can be set forth here, so that an adequate appreciation may be gained of the arduous and rigid conditions under which the spirit manufacturer is, in order to ensure the safeguarding of the revenue, constrained to carry out his operations. A distillery must not, without permission, be carried on at a greater distance than half a mile from a market town, nor may it be situated within a quarter of a mile from a rectifying establishment. A distiller must give notice of the erection of a new plant or apparatus, of the time of brewing, of the removing of sugar from store or of yeast from wort or wash, of the making of "bub" of the locking of the spirit receiver supply pipe, &c. He may use any material he pleases, provided that the gravity of the wort can be ascertained by the saccharometer, but he may not brew beer nor make cider, wine nor sweet wines. When the worts are collected in the wash-back (fermenting vessel) a declaration must be made at once, specifying the original gravity and the number of dry inches remaining in the back. At the end of every distilling period a return must be delivered showing (a) the quantity of brewing materials used, (b) the quantity of wort or wash attenuated and distilled, out of store, the number and size of vessels, the locking of the latter, and the painting of the pipes carrying various liquids in certain colours. The methods of assessing the duty are threefold, and whichever of these methods gives the highest return is the one adopted. The first is the "attenuation charge." This consists of levying the charge due on one gallon of proof spirit for every hundred gallons of worts collected and for every five degrees of attenuation observed, the latter being calculated by taking the difference between the highest specific gravity of the worts and the lowest gravity of the wash after complete fermentation. Secondly, there is the "low-wines charge," which is imposed upon the bulk-quantity at proof-strength of the low wines produced by the distillation of the wash; and lastly, the "feints and spirits charge." This is the method usually adopted, as it generally gives the highest results; it is assessed on the number of bulk gallons at proof of the spirits produced by the final distilling operations. The duty, which was fixed at 10s. per proof gallon in 1860, remained at that rate until 1890, when an addition of 6d. was made, but a further increase to the like amount made in 1894 was remitted in the next year owing to the unsatisfactory results obtained. The rate remained at 10s. 6d. until 1900 when it was raised to 11s., a further increase being made in 1906.

Legally, the word "spirit" implies spirit of any description, and all liquors, mixtures and compounds made with the same. In the same way plain spirit is any British spirit which has not been artificially flavoured, and to which no ingredient has been added subsequent to distillation.

The extremely severe and inelastic provisions of the act governing the manufacture of spirit in the United Kingdom have proved to be a very serious impediment to the development of the spirit industry on modern lines, and have placed the British manufacturer at a considerable disadvantage as compared with his foreign competitors. There is little doubt that the enormous revenue derived from the spirit industry could be adequately safeguarded in a manner more consistent with the development of the industry on sound commercial and technological lines than it is at present.

**Production and Consumption.**—The production of spirit in the United Kingdom amounted in 1907 to roughly 50,000,000 proof gallons, the consumption to a gallon per head of population. In the decade 1880-1890 the quantity of spirits distilled remained practically stationary at about 40,000,000 gallons, but during the ten years 1890-1900 there was a rapid increase, the maximum being attained in 1898, when nearly 64,000,000 gallons were produced. A point had then been reached at which the production had considerably outstripped the consumption, due in part to the desire of the spirit trade to meet the increased demand for "matured" spirits, and in part to the fact that an excessive amount of capital had, owing to depressed popularity of Scotch whisky, been attracted to the distilling industry. This over-production led to a vast increase in the quantity of spirit remaining in warehouse. In 1906 production and consumption were about equal, and the quantity of spirit in warehouse represented roughly a five years' supply.

The following figures regarding production, consumption, duty, &c, need no explanation:

The importation of foreign potable spirits into the United Kingdom has fallen off materially since 1870-1873, during which period it reached 15,000,000 proof gallons. This strength was largely due to the decreased consumption of brandy, and, to a smaller extent, to the diminishing importance of rum and other foreign spirits. The most remarkable change in this connexion is in the case of foreign methylated spirit. At one time (1891) the quantity of this article imported...
with regard to the materials employed in the manufacture of spirits in France, roughly 80-90% now consist of maize (and other starchy substances), beetroot and molasses whereas in 1840 nine-tenths of the alcohol produced was derived from the grape and other fruits. This change is due in part to the ravages of the oidium disease (1865-1873) and the phylloxera (1876-1890), which destroyed an immense number of vines, but chiefly to the increased demand for commercial spirit in the arts and manufactures, and also to the improved methods for obtaining a high-class spirit from practically any starchy or saccharine material.

In 1903 the number of alcohol units (the unit = 1,000 hectolitres of pure alcohol) distilled from maize and other starchy materials was 589, from molasses 516, from beetroot 1003, from wine, cider, les and fruits 499. In Germany roughly 75% of the spirit manufactured is derived from potatoes. In 1905 the total spirit distilled (2,977,000 hectolitres of pure alcohol), of which 2877 units were obtained from potatoes (18.5% from grain and 44.5 units from molasses and other material. In Russia spirits are distilled chiefly from potatoes and rye, in the United States from maize.

Manufacture.—The manufacture of spirits consists broadly in converting starchy or saccharine matter into alcohol, the latter product being subsequently separated, concentrated and rectified. When spirits are made from a purely saccharine material the process of conversion into alcohol is a relatively simple one, but where farinaceous raw products are employed it is primarily necessary to transform the starchy contained in them into sugar. The main varieties of spirits manufactured from sugar, or from sugar-containing materials, are:

- **Sugar-derived Spirits**
  - **Raw Material:** Cane sugar.
  - **Product:** Whisky, brandy.

- **Starch-derived Spirits**
  - **Raw Material:** Cereal grains: chiefly barley, rye, maize, wheat, maize.
  - **Product:** Whisky, brandy.

A. Spirits Derived from Saccharine Materials.—The manufacture of the five brandies, such as those of Cognac, is, as far as the processes involved are concerned, by no means a complex matter. The excellence of this class of spirit is due mainly to the character of the wine employed and to the great experience of the distillers in selecting and blending the raw materials and finished products. The character of the wine is, of course, chiefly due to the peculiar soil and climatic conditions, and in some degree to the methods of cultivation. The latter, it may be added, have since the reconstitution of the Charente vineyards subsequent to their partial destruction by the phylloxera (see Brandy) been much improved. In the pre-phylloxera days the vineyards were planted and cultivated in a very rough and ready fashion, without any attempt at regularity of planting. The result was that the wines spread practically unrestrained in every and any direction. In consequence there was a great irregularity of growth, feeble and hardy plants being found side by side, and the yield was poor. In vineyards constructed in the modern style the vines are planted in regular rows, and the bushes are, with a view to obtaining regular and rapid
ripening, methodically supported by wire. The wines produced by the Charente vineyards are of a light (white) character and possess no marked "bouquet," but they nevertheless produce a spirit of a peculiarly fine and delicate character. It is remarkable that the fuller and more aromatic wines of the Gironde and of Burgundy, for instance, are not so suitable for the manufacture of brandy as the relatively poor growths of the Charente. The apparatus employed for the distillation of the fine Cognac brandies is generally of a very simple pot-still type. Fig. 5 depicts the still-room of a Charente distillery of former times, and fig. 6 shows one of Messrs Martell's distilleries in Cognac, equipped on modern lines. It will be seen that, in principle, there is very little difference between

being called the "bonne chauffe" or "repasse." The first runnings—which vary in quality according to the quality of the wine, the manner of heating, &c.—are termed "produit de tête" or "têtes," and are separately collected and mixed with the "brouillis" of the following operation. The spirit which next comes over (starting at a strength of about 80% and running down to about 55%) is the "coeur," and as a whole, marks roughly 66 to 70% of absolute alcohol by volume. The residue in the still is then run down to water, and the spirit so obtained, which shows 20 to 25%, is called "seconde," and is either mixed with a fresh charge of wine or rectified separately, the stronger portion being mixed with the "brouillis," the weaker with a charge of wine (see BRANDY).

There are two main kinds of rum, namely, Jamaica rum and rum of the type prepared principally in Demerara and Trinidad (see RUM). There are two varieties of Jamaica rum (a) the common clear rum, and (b) flavoured, or "German" rum. (a) "Common clear" rum is prepared from a mixture of sugar-cane molasses, "skimmings" (the scum from the boiling cane juice) and "dunder," this last name being given to the spent lees from previous distillations. Previous to use the "skimmings" are subjected to acid fermentation either alone or in conjunction with "trash" (crushed cane). The work, which on the average contains about 10 to 15% of red sugar, forms very slowly owing to the fact that very little yeast—the latter being derived from the cane rind—is present. Roughly five to ten days are occupied by this operation. At first the fermentation is mainly alcoholic, but it rapidly assumes an acid character, owing to the presence of a great number of acidifying bacteria derived from the "dunder" and "skimmings." The distillation of the fermented wort is carried out in pot stills heated by fire or steam, either of a simple type or provided with rectifiers. In the former case two distillations are necessary, the first resulting in the production of a weak alcoholic liquid termed "low wines," the second, which consists in a rectification process producing "high wines" or strong rum. The other type of still is provided with two rectifiers, which are interposed between the still and the condensing worm. These are charged with low and high wines respectively. The first runnings of the still (25 to 40 o.p.) constitute the rum proper, the next fraction the high wines, and the final distillate the low wines. (b) Flavoured or "German" rum is prepared from the same materials as the "common clear" variety, with the addition of "acid" and "flavour." "Acid" is obtained by acidifying fermented cane juices by means of certain "trash" and refuse from the mash backs. "Flavour" is prepared in much the same way as "acid," except that "dunder" sediment is also added. The fermentation, which is to a very great extent bacterial, results in the formation of large quantities of acid, including much butyric acid and compound esters. The distillation of "flavoured" rum is carried out in much the same manner as that of the "common clear." The manufacture of "Demerara rum" is differentiated from that of the Jamaica varieties mainly by the fact that the fermentation in the former case is practically purely saccharomycetic (i.e. yeast), whereas in the latter case it is largely bacterial. For the distillation of the Demerara rums, which are much lighter in flavour than the Jamaica varieties, stills of the "patent" (see below) or rectifying type are frequently employed (see RUM and ARRACK).

For the manufacture of industrial spirit from saccharine materials see below, under Industrial Alcohol.

B. Spirits Derived from Starchy Materials.—The manufacture of spirit from saccharine materials is, as we have seen, a relatively simple operation, the sugar being transformed into alcohol by fermentation, and the latter then distilled off. To convert starchy matter into alcohol is a much more complicated matter. To the operations necessary for the transformation of sugar into spirit, must, in the case of starchy materials, be added that of converting the starch into sugar. This is accomplished either by the action of a diastatic ferment, such
as that present in malted grain (see Brewing) or secreted by certain living organisms, or by an acid such as sulphuric acid. The latter process is little employed at the present time. The materials employed by the distiller, and the methods of preparation and treatment to which they are subjected therein, and after entering the distillery, are in some respects similar, in others materially different, from those employed by the brewer. The materials most frequently employed are maize, rye, barley malt, raw barley, oats, wheat and potatoes. Comparing the main operations (apart from the actual process of distillation) of the brewer with those of the distiller, it is true that these are identical in the sense that they consist in the conversion of starch into sugar and of the latter into alcohol; but whereas the object of the brewer is to produce beer, of which alcohol forms only a relatively small proportion, the distiller, broadly speaking, desires to produce alcohol, and it is this fact which is responsible for the differences alluded to above.

Distillery Malting.—Where malt is employed as the main raw material, as, for instance, in the case of Scotch pot-still whiskies, and also, but to a minor degree, in Irish pot-still whiskies and patent-still whiskies, the process of preparation does not, except in some specific particulars, differ very widely from that used in making brewer's malt (see MALT). With regard to the barley employed for this purpose, certain qualities which are of the greatest importance to the brewer, such as the nature and a half to a full grain of the starch, are of little interest to the distiller, and providing that the grain is sound and that it contains a high percentage of starch and malts as well, it will pass muster as an average distillery material. It is usual to give barley intended for patent-still work a rather longer period in the steep and on the floors than in brewery malting, and it is well to treat the steep-water with some antiseptic, preferably lime, as the distiller has not the opportunity of lessening the dangers of bacterial infection at subsequent stages which is afforded to the brewer by the boiling and hopping of the wort. In distilleries where barley malt is not used as the main raw material, but mainly or chiefly as a diastatic agent (for instance, in potato and maize distilleries on the continent of Europe), the so-called "long" malt process is widely employed. This consists essentially in subjecting the grain first to a somewhat lengthy steep (until the increase in weight due to the absorbed water is about 40 to 45%), and secondly to a very prolonged "flooring" at a moderate temperature, great attention being paid to the conditions of ventilation and humidity. It was formerly believed that the germinating barley grain attains its maximum of diastatic power after a very short period, and that when the acropore is three-quarters "up" and the rootlets extend for the length of a grain, the grain is ready for removal from the floor. M. Delbruck, Hayduck and others have, however, shown that this is not the case, and the practical results obtained by adopting the twenty days' "flooring" period (and its attendant conditions) have amply confirmed the scientific researches on this subject.

Hayduck has shown that the relative diastatic strengths of "short" (seven to ten days) and "long" (twenty days) malt are, (1) for heavy barleys as 100: 128-3 (average), (2) for light barleys as 100: 160-5 (average). In contradistinction to the brewer (who can only use it on exceptional occasions and for special purposes), the distiller prefers, whenever this is feasible, to use green malt rather than kilned malt. One of the principal objects of kilning brewing malt is to restrict the diastatic power; but this is the very factor which the distiller desires to preserve, as the green malt possesses roughly twice the diastatic activity of high kilned malt. It is obvious that the distiller, who regards his malt merely as a starch-converting agent, will, *ceteris paribus*, use as little kilned malt as possible. The malt whisky distiller cannot, however, use green malt, as it relies to a great extent on the kilning process for the development of the peculiar flavour characteristic of the article he produces. Moreover, it is frequently difficult during hot weather to obtain a satisfactory green malt supply, especially as the latter will not bear carriage for any distance, and distillers who make pressed yeast (commonly called "German" yeast) find that a proportion of kilned malt is necessary for the satisfactory manufacture of this article. When the distiller is unable to use green malt he will, by preference, use a malt which has been kilned at as low a temperature as possible. Under these conditions the kilning is little more than a drying operation, and the temperature is rarely raised above 150° F.

Although green or low-dried barley malt is the saccharifying agent usually employed both in the United Kingdom and on the continent of Europe, malts prepared from other cereals are not infrequently employed for this purpose. According to Glaser and Moransky the relative starch-transforming capacities of the various malted grains, taking barley as the unit, are as follows:

<table>
<thead>
<tr>
<th>Malt</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barley</td>
<td>1-00</td>

<td>0-28</td>
</tr>
</tbody>
</table>

Oat malt, notwithstanding its low transforming power, possesses certain advantages, inasmuch as it is easily and rapidly prepared, it acts very quickly in the mash tun, and its diastatic power is well maintained during fermentation. Rye is best malted in conjunction with a little barley or oats, as it otherwise tends to superheat and to grow together in a tangled mass.

Distillery Mashing.—Distillery mashing, although outwardly very similar to the process employed in brewing, differs very widely in some important particulars. In brewing all the necessary fermentable matter is formed from the starch by the mashing operation. The wort so obtained is then hopped and sterilized. This method of working, however, cannot be adopted by the distiller. The brewer must have a certain proportion of dextrinized, non-fermentable carbohydrate matter in his wort; the distiller, on the contrary, desires to convert the starch as completely as possible into fermentable, that is, alcohol-yielding, material. This result is obtained in two ways: first, by mashing at low temperatures, thus restricting the action of the diastase less than is the case in the brewer's mash; and, secondly, by permitting the diastatic action to continue during the fermentation period. Low temperature mashing alone will not have the desired effect, for part of the dextrinous bodies resulting from diastatic starch-fermentation are not further degraded by diastase alone, but are rendered completely fermentable by the combined action of diastase and yeast. Hence the distiller is unable to boil, that is, to sterilize his wort, as he would thereby destroy the diastase entirely. In this he is at a serious disadvantage compared with the brewer, as an unsterilized wort is very liable to bacterial infection. The latter danger prevents the distiller from taking full advantage of the benefits of low-temperature mashing, and he is obliged to heat his mash to a temperature which will, at any rate, be a partial safeguard against the bacterial evil. The method employed varies according to the nature of the mash and the quality of the spirit that it is desired to obtain, but in principle it consists, or should consist, in bringing the mash as rapidly as possible to the temperature of maximum saccharification, keeping the whole at this point for some little time, then heating to the temperature of maximum liquefaction, and subsequently to as high a temperature as is consistent with the thickness of the mash and the preservation of sufficient diastase for the fermenting period.

The Fermenting Operations.—The conditions and methods of distillery fermentation vary considerably, and in some respects radically, from those employed in the brewery. In order to obtain the maximum alcohol yield the distiller is obliged to work with unsterilized wort, and at relatively high temperatures. The necessity for the former condition has already been explained, but the latter is due to the fact that the optimum working capacity of distillery yeast is reached at a temperature markedly above that most favourable to brewing types. Apart from this, if the distiller worked at brewing temperatures the
brewing yeasts would predominate, and these produce less alcohol than the distillery types. Thus at 75° F. (and above) distillery yeasts tend to predominate. The conditions of fermentation which are more or less forced upon the distiller are unfortunately also very favourable to the development of bacteria, and if special methods are not adopted to check their development, the result would seriously affect not only the quantity but also the quality of alcohol produced. The micro-organisms chiefly to be feared are those belonging to the class of fission fungi (sclizomycetes), such as the butyric, the lactic, the mannitic, and mucic fermenters.

Soured worts have been turned to practical distillers that in order to avoid irregular (bacterial) fermentations it is necessary either to let the wort "sour" naturally, or to add a small quantity of acid (formerly sulphuric acid was frequently employed) to it before pitching with yeast. The reason for this necessity was until recent times by no means clear. It has, however, now been demonstrated that a slightly acid wort is a favourable medium for the free development of the desirable types of distillery yeasts, but that the growth of brewery yeasts, and especially of bacteria, is very much restricted, if not entirely suppressed, in a "soured" wort. The acid which is the result of this decomposition of the sugar in the wort, by bacterial action, and according to the equation 
\[ \text{C}_6\text{H}_{12}\text{O}_6 = 2\text{C}_2\text{H}_5\text{O}_2 \]

For various reasons (one being that in order to restrict the lactic fermentation when sufficient acid has formed it is necessary to keep the sourred liquid to a higher temperature than is desirable in the case of the main wort) it is inexpedient to allow the souring process to take place in the main wort. It is usual to make a small mash, prepared on special lines, for the production of the "bubb" (German Hegefut), as the sourd wort is termed. This is allowed to the main wort. The beneficial effects of souring are not due to any specific action of the lactic bacteria, but purely to the lactic acid formed. It has been found that excellent and in some respects better-results can be obtained by the use of lactic acid as such in place of the old souring process. Some success has also attended the introduction of hydrofluoric acid and its salts as a substitute for lactic acid. Hydrofluoric acid is poisonous to bacteria in doses which do not affect distillery yeasts, and the latter can be cultivated in such a manner as to render them capable of withstanding as much as 0.2° of this acid. Bacteria, apparently, cannot be "acclimated" in this fashion. Worts treated with hydrofluoric acid produce practically no side fermentation, and it seems a fact that this substance stimulates diastatic action, and thus permits of the use of relatively low mashing temperatures.

The yeast employed in British and Irish pot-still and in some patent-still distilleries is still generally obtained from breweries, but it is now generally recognized that—at any rate for the production of industrial alcohol and for "plain" spirit—a special type of yeast such as the so-called "German" yeast, a good deal of which comes from Holland, but which is now also produced in the United Kingdom on a considerable scale, is desirable in the distillery. This variety of yeast, although closely allied botanically to that used in brewing (belonging as it does to the same class, namely Saccharomyces cerevisiae), is capable of effecting a far more rapid and far more complete fermentation than the latter. Probably the most widely known and best "pure-culture" distillery yeast is the one called "Species II," first produced in the laboratories of the Berlin Distillers' Association. The optimum working temperature of distillery yeast is at about 81-° F.; but it would be inexpedient to start the main fermentation at this temperature, as the subsequent rise may be as much as 36°. It is, therefore, usual to pitch at about 80° F., and then, by means of the attendant, to cool down very slowly until the temperature reaches 60° F. The temperature subsequently rises as fermentation goes on, but should not exceed 85° F. Pot-still whisky distillers frequently work at somewhat higher temperatures. Fermentation is carried on until practically all the saccharine matter is converted into alcohol; and when this is the case, the gravity of the mash is nearly equal to, or even a little below, that of water. In malt whisky distilleries the original gravity of the wort is usually from 1-050 to 1-060, occasionally lower, but in grain and potato distilleries the worts are often made up to a higher gravity. In German gravities as high as 1-11 are employed; but in that country "thick" mashes, owing to the method employed to raise the duty, are a matter of necessity rather than of choice.

It will be seen from the above that the employment of malt for the purpose of rendering starch soluble and fermentable leaves a good deal to be desired in regard to both the mashing and fermentation processes. The addition of a little more acid for this purpose is also attended by serious drawbacks inasmuch as a considerable proportion of the starch is converted into "reversion" products which are practically unfermentable and thus considerable caramelization is brought about by the action of the acid. In the case of the production of potable spirits such as whisky, where the alcohol yield is not the only object, and the conservation of a specific flavour is desired, it is doubtful whether any material improvement can be made in this connexion, as it seems probable that the outcome of the process may even be decided to some extent by the fact that the point of view in which the alcoholic yield alone are most desirable. For the production of industrial alcohol, however, and for the preparation of spirit intended to be used in compound potable spirits and liqueurs, these difficulties have now been surmounted. The older methods at the disposal of the distiller have of late years been enriched by the discovery that certain micro-organisms (or rather the enzymes contained in them) possess the power of converting starch into sugar, and also of splitting up saccharine materials into the ordinary products of alcoholic fermentation. It is possible to inoculate a sterilized wort with a pure culture of a micro-organism of this description and subsequently with a pure culture of yeast, and so avoid all undesirable features of the older processes.

Details concerning the practical application of this discovery will be found below under Industrial Alcohol.

**Distillation.**—The primary object of the distillation of all fermented liquids is that of separating, as far as possible, alcohol from the non-volatile constituents of the wash. In the second place the object of the distiller is to rectify and concentrate the dilute alcoholic liquid obtained by simple distillation. The degree and manner of rectification and concentration vary in accordance with the type of spirit to be produced, and it will be better therefore to discuss methods of distillation under the headings of the different types of spirit concerned.

1. Scotch Pot-still Whisky.—The raw material employed in the manufacture of Scotch pot-still whisky is practically without exception malted barley only. The malt is prepared in much the same way as brewery malt, except that it is generally cured (dried) with a peat, or mixed peat and coke, fire. It is to this peat drying that the so-called smoky flavour of most Scotch pot-still whisky is due. The malt is mashed in a mash-tun on lines similar to those obtaining in the brewery, except that the mashing heats are somewhat different. They should be so regulated as to obtain the maximum yield consistent with the preservation of the proper flavour. In order to obtain as high a yield as possible four separate mashes are as a rule made with the same lot of grist, the temperature of each successive mash being somewhat higher than that preceding it. The worts obtained from the first three mashes are united prior to
fermentation. The liquor from the last mash is used as mashing liquor for the next lot of malt. The general scheme of operations subsequent to mashing is illustrated by fig. 7, which depicts the process at one of Messrs Buchanan's distilleries.

After the work has been drawn off it is run through a refrigerator, and then passed to the wash backs. The latter are large wooden vessels corresponding to the fermenting backs of the brewer. Here the work is pitched with yeast, the fermentation starting as a rule at something over 70° F. The maximum temperature attained at some distilleries frequently exceeds 90° F., but in the opinion of the author this is excessive. Fermentation proceeds until the whole of the saccharine matter is converted into alcohol, and when this is the case the gravity of the fermented work—now termed wash—should be equal to, or a little lower than that of water. The wash from which it is drawn off is now collected in the wash charger, which is an intermediate vessel serving for the mixing of the contents of the different wash backs, and also for the purpose of enabling the revenue officer to ascertain the total volume and strength of the wash. In this way he obtains a check on the quantity and gravity of the work as taken prior to fermentation. From the wash charger the wash passes to the wash still, which is a copper vessel varying in size in Scotland from about 3000 to 8000 gallons. The usual size is about 5000 to 6000 gallons. This still is heated either by direct fire (as shown in the illustration), or frequently by means of a steam jacket or steam coil. The wash still is provided with rakes or chains actuated from outside for the purpose of preventing the solid contents of the wash from being charred. The whole of the spirit is drawn off in one fraction from this still, and is condensed by means of a copper coil cooled by running water. The distillate so obtained is termed "low wines," and the strength is generally about 50 p.p. The next stage in the process is the redistillation of the low wines. This takes place in the low wines still, which is a vessel similar to the wash still, but somewhat smaller. The distillate from the low wines still is collected in three separate fractions termed respectively and in the order of their collection, (a) foreshots, (b) clean spirit or whisky, (c) feints. The quantity of each of these three fractions is considerable, the second being the smallest. That portion of the first, which is still in the spirit being made, the quality of the material employed, and to other circumstances into which it is not necessary to enter. As a rule the foreshots will be run from the starting of the still down to 25 to 30 p.p. The clean spirit will be run from 30 to 35 p.p., and the feints will be run from 35 to 40 p.p., to proof, the remainder, namely the residual fraction, from proof down to water, being feints. In collecting the various fractions the distiller is mainly guided by the alcoholic strength of the spirit coming over, its flavoured, and by its behaviour on mixing with water. It is the object of the distiller to obtain a clean spirit or whisky which gives as little "blueing," that is opalescence, when mixed with water as possible. The foreshots and feints are run into the foents receiver, the whisky to the spirit receiver. The distiller is able to divert the spirit coming over into either of these receivers at will by means of a movable arm contained in the spirit safe. The spirit safe is a closed vessel containing two or three broad funnels each of which is connected with a pipe leading to a foents or spirit receiver as the case may be. The movable arm fixed on to the pipe leading from the condensing coil can be actuated from without by the distiller. In this way the distiller is able to regulate the distillation at will without having access to the spirit. The quality of the spirit coming over is judged by means of the appearance contained in the sampling safe. This is another closed vessel containing hydrometer jars fitted with hydrometers, and with a water supply. A small part of the spirit coming from the coil passes through this box into the hydrometer jars, where its strength is taken by means of the hydrometers and its behaviour towards water ascertained by mixing with a known volume of the same. The strength of the whisky collected varies at different distilleries, but it is generally from 25 to 30 p.p. The quantity and strength of the spirit are gauged in the spirit safe by the revenue officer, and the spirit is then run into casks and placed in store. The residue in the wash still is termed "pot ale" or "spent wash," the residue contained in the wash, and secondly to rectify it. Part of the volatile by-products pass out in the spent wash and spent lees; another part is eliminated by the modification which some of these products undergo during storage in the feints receiver.

2. Irish Pot-still Whisky.—Both as regards the raw material employed and the manner of manufacture, Irish pot-still whisky differs very appreciably from the Scotch variety. There are a few distillers who work with malted barley only, but the great majority employ a mixture of (generally) 25 to 50% of malted barley and 50 to 75% of a mixed grist of "raw" (i.e., unmalted) rye, wheat, barley and oats. The malt is not steeped. The distillation is carried out in a type of still radically different from the Scotch pot-still. The stills (of which there are generally three as against two in the Scotch process) are very large, ranging up to 20,000 gallons. A characteristic feature of the Irish pot-still is the great length and height of the "lyne-arm," i.e., the pipe connecting the still with the condensing coil. This lyne-arm generally runs up vertically from the still for a distance of 10 to 20 ft., then horizontally for another 30 or 40 ft., again vertically for 10 to 20 ft., and is then connected to the condenser. The horizontal portion of the lyne-arm lies in a shallow trough fitted with a water supply, and the temperature of the spirit vapours prior to their passing to the condenser may thus be regulated at will. According to the length and height of the lyne-arm and the temperature of the water jacket, more or less of the vapours condense and are carried back to the still by means of a pipe running back from the horizontal portion of the lyne-arm to the still. The return pipe is fitted with a cock, which enables the distiller to regulate the return flow. Occasionally there is a further return pipe for the condensing coil, but this is not usual. The result of this form of plant is that it is possible to work up far greater quantities of wash and
to obtain a much higher rectification in a single operation than is possible in the case of the Scotch pot-still.

A single type of Irish pot-still plant as employed at Messrs J. Jameson's, Dublin, is shown in fig. 8. It will be noticed that in this case there is no return pipe from the lyne-arm. The method of collecting the lyne is a somewhat complicated than that described under the Scotch variety. Three stills are employed and strong low wines and weak low wines, strong feints and weak feints are collected, and mixed in varying proportions according to the discretion of the distiller.

3. American Pot-still Whisky.—There are two main varieties of American pot-still whisky, namely, sour mash, in which maize is the predominant raw material, and Bourbon whisky, in which maize or Indian corn is the chief substance employed. There are different varieties of these whiskies.

"Sour mash" whisky is made by scalding the raw material with pot ale (i.e. the residue left in the stills from the previous operation), then cooling down to mashing temperature and saccharifying by means of malt. The distillation is sometimes carried out with naked fire, but more generally by means of steam which is passed into the wash (termed "beer" in America), either in a free state or by means of a coil, and then collecting the wash and running it rectifyingly by means of a second distillation (termed "doubleing"). "Sweet mash" whisky is made by mashing the raw material in the ordinary way by means of malt. The stills generally employed for making whisky by this process contain three compartments situated above one another and connected by means of a curve pipe. Live steam blown into the lower compartment causes the wash to boil. The vapours go up through the curved pipe into the next compartment and so cause the contents of the latter to boil. The vapour from the second compartment then passes up to the third in the same manner. The vapours from the third compartment pass into a vessel charged with low wines, and the vapours so obtained are finally condensed, forming whisky, or "high wines."

4. Patent-still Whisky.—Scottish and Irish patent-still or "grain" whiskies are manufactured usually with a mixed grist of raw and malted grain, and by means of an apparatus usually termed the "patent," but more properly called Coifey's still. For the manufacture of patent-still whisky a grist containing generally 75% or more of malted barley is employed. The balance consists of maize together with malted and unmalted rye, or rye or wheat and maize in various proportions. The distillation is divided into several operations, the individual stills being provided with a number of compartments to allow of the varying proportions of the mash being employed. The mashing takes place as a general rule in an ordinary mash-tun, and calls for no special mention. The fermentation is conducted in much the same way as at pot-still distilleries, except that at some patent-still distilleries where brewers' yeast is used, fermentation is conducted on somewhat different lines, the conditions being adjusted so as to suit the propagation of a healthy type of yeast of a particular variety. For fermentation of this description it is well recognized that the use of selected or pure yeast is necessary. The fermenting vessels, wash chargers, &c., are much the same as in the pot-still distillery, except that they are of much larger size. The "patent" still was invented by Aeneas Coiffy in the early part of the 19th century with a view of accomplishing in one operation that which necessitates several operations in the pot-still, of economizing time, fuel, and material, and also of obtaining at will a spirit of a higher purity than that which can be got by the pot-still. It is sometimes stated that the patent still does not produce whisky, but merely plain spirit or alcohol, but a matter of fact this is not the case. It can be so worked by selecting the materials and by running the still in a particular way as to produce an article which is most distinctly a patent spirit of the character of whisky. It can also be employed by altering the proportion of the materials and by running the stills differently to produce a spirit which may be used for purposes of mitcholation, or which may pass through the hands of the rectifier and emerge as plain spirit or alcohol pure and simple. It is, however, quite impossible to obtain from the Coiffy still a really plain or silent spirit such as that produced by some of the stills on the continent of Europe; in order to obtain this type of spirit, the product of the patent still is treated by the rectifier in a special rectifying still with charcoal and potash. In certain details the Coiffy still has been modified since it was devised by the inventor, but in principle it has been very little altered. Although it does not in some respects compare with some of the modern continental rectifying stills, it must be remembered that it is not made for the purpose of obtaining pure alcohol, and from this point of view it is a remarkable tribute to the ingenuity of Coiffy that he should at so early a date have designed so perfect an apparatus.

The still shown in fig. 9 is one of the type designed by Messrs Robert Willison of Alloa for Scotch grain whisky distilleries. The Coiffy still is a double still consisting of two adjacent columns, termed respectively the rectifier and analyzer. Both columns are subdivided into a number of chambers by perforated copper plates. The main structure is of wood firmly braced with iron. Each compartment communicates with the next by means of a drip pipe standing slightly above the level of the plate and passing downwards into a cup, which forms a water seal or joint. Each compartment is also fitted with a safety valve in case of the plates choking or of the condenser becoming clogged. The columns are filled with steam at a pressure of about 5 lb. The steam at the base of the analyser passes upwards through it, and then to the top of the column of the rectifier by means of the pipe B (termed the low-wines vapour pipe). The upper part of the rectifier. When both columns are filled with steam the wash is pumped up from the wash charger through the copper pipe A to near the top of the rectifier, which is then led through the columns from the top to the bottom of the rectifier forming a double bend in each compartment, and the wash (contained in the pipe) travels down in a zigzag course until it reaches the base of the rectifier at the point marked E. It then travels through the analyzer and on to the top of the analyser, where it emerges from the pipe and covers the plate of the top compartment. As there is an upward pressure of steam the wash is not able to pass through the perforations of the upper plate forming the base of the compartment, but collects until its level reaches the top of the first drop pipe. Through this it passes into the cup on the plate below and so on out to the next plate, drop pipe being trapped by the cups the steam cannot pass upwards through the former. In this way the wash passes from compartment to compartment to the analyser until it reaches the bottom, and then passes out by means of the spent wash siphon. The steam on its passage up through the analyser carries with it the alcoholic vapours and other volatile matters contained in the wash. The alcoholic vapours pass from the top of the analyser to the bottom of the rectifier, and then upwards through the latter from compartment to compartment, the beginning of the operating columns being cooled by the wash flowing down through the pipe A. This gradual cooling causes the less volatile constituents to condense and so to flow downwards through the plates and be trapped by the condenser or the rectifier. At a certain point in the upper part of the rectifier (marked S in the illustration) the bottom of the compartment in question is formed not of a perforated plate, but of a stout copper sheet braced by a collar, on which is fitted a plate which is designed to raise the level of the wash above the level of the former. This is termed the spirit plate. It is so placed that the alcoholic vapours condense either on or immediately above it. The alcohol passes out from the spirit plate chamber and flows down to the discharge pipe (or to the receivers as the case may be), and is then further cooled, in order to complete the condensation, by means of coils immersed in flowing water, as shown in the illustration. In order to render the condensation still more perfect the upper chambers of the rectifier are fitted with coils through which cold water is passed. The vapours condensed by this fall upon the spirit plate. The vapours which have an appreciably lower boiling-point than that of ethyl alcohol, such as the aldehydes, together with a large volume of carbonic acid gas derived from the wash, pass out of the top of the rectifier by means of the "incondensable gas" pipe E, and thence to the condenser. The condenser is a typical spiral condenser of the spirit type, and is designed generally about 64 o.p. The less volatile constituents of the wash, generally termed "fuel oil," which pass out of the base of the rectifier, are cooled and then returned to the oil vessel. After the apparatus has been worked for some time the fusel oil which floats in the layer on the top of the contents of the oil vessel is skimmed off. The water layer from the oil vessel, which still contains a little alcohol, is passed through the indirect still to remove this latter. By employing the cold wash to cool the alcoholic vapours much condensing water is saved as compared with the ordinary pot-still apparatus. Conversely, as the hot alcohol vapours heat the condenser to boiling point there is a great economy of coal as compared with the older process.

The distillation is controlled by an operator standing on the platform. The operator controls the still by means of the apparatus X to determine the quality and strength of the spirit of the wash. He is able, by regulating the quantity of steam admitted to the apparatus, by modifying the rate of pumping, and by running
SPIRITS

the spirit either to the spirit or to the feints receiver, as the case may be, to control the strength and quality of the product in much the same manner as does the pot-still distiller.

| parts of alcohol 0.5 parts and wood naphtha 5 parts, and they may also, under certain conditions and restrictions, employ pure alcohol. It is generally considered that the most satisfactory way of methylating or "denaturing" spirit intended for technical purposes is that which consists in adding one of the ingredients which would ordinarily be used in the course of manufacture, or some other ingredient which does not interfere with the manufacture of the specific article in question. In the year 1906 the total quantity of "industrial methylated spirit" employed in the United Kingdom was 2,041,373 proof gallons. The quantity of pure alcohol employed in the same year was 435,015 gallons; for the same period the total quantity of ordinary methylated spirit produced was 6,055,285 gallons. On the continent of Europe and in America alcohol is used in the industries to a greater extent than is the case in the United Kingdom.

The raw materials generally employed in making industrial alcohol are the sugar beet, and beet or cane molasses, potatoes, maize, rice and similar starchy materials. The manufacture of spirit for industrial purposes in many respects resembles the process for manufacturing potable spirit, but, broadly speaking, it may be said that the raw materials employed need not be of so high a class, and that the main object of the distiller in this case is to produce as high a yield of alcohol as possible. Taste and flavour are secondary considerations, although in the case of industrial alcohol employed for some purposes—for instance, for pharmaceutical preparations—a very fine spirit is required. When beets or molasses are employed for making alcohol, the process is a comparatively simple one. If beets are used the sugar is extracted from them in much the same way as is the case in the manufacture of sugar itself (see Sugar), although in recent years a process for steaming the beets under pressure in much the same way as in the preparation of potato mash has been employed. The sugar present in the beet and in molasses is not directly fermentable. It is generally rendered so by the addition of a small quantity of mineral acid. The saccharine solution is then pitched with yeast and fermented in the ordinary way. Potatoes, maize, rice and other starchy materials are generally treated under pressure with steam in a close vessel termed a converter. This method entirely disrupts the starch cells, and so renders the starch very readily convertible. When the pressure "cooking" is completed the mash is run out of the converter into the mash tun proper, where it is treated with a minimum quantity of malt at the most suitable temperature. The wort obtained is, after (as a rule) removing a part of the husks and skins by means of special machinery, pitched with yeast and fermented.

We have seen above in the paragraphs dealing with the general features of distillery operations that the method of converting starch into sugar by means of malt possesses very serious

---

**Industrial Alcohol.**—By industrial alcohol is understood spirit which is employed for other than potable purposes. Alcohol is largely employed in the industries and arts, and for domestic purposes. It is chiefly used for the manufacture of varnish, fine chemicals and dye-stuffs, for pharmaceutical purposes, and in the form of ordinary methylated spirit for lighting and heating. Ordinary methylated spirit for domestic purposes is prepared in the United Kingdom by adding 10 parts of wood naphtha and a small quantity of mineral naphtha to 90 parts of strong spirit. This spirit may be employed duty free for any purpose except that it may not be purifed in such a manner as to produce pure alcohol or a potable spirit. Up to the year 1906 British manufacturers were forced either to use this spirit or to pay the full duty if they wished to use any other variety. As a result of the recommendations of the industrial alcohol committee of 1904-1905 the Revenue Act of 1906 contained provisions modifying this undesirable state of affairs. Manufacturers may now use a special "industrial methylated spirit," which consists...
drawbacks. Of late years a process has been discovered whereby these disadvantages, as far as industrial spirit is concerned, are entirely overcome. It has been known for some time that certain micro-organisms (or rather the enzymes contained in them) possess the power of converting the starch directly into fermentable sugar, and further of splitting up the latter into the usual products of alcoholic fermentation. Among the organisms of this description first known may be mentioned the moulds, Aspergillus Oryzae and Eurotium Oryzae. Later A. L. C. Calmette discovered a mould to which he gave the name A. amylolyticus, which was employed by A. Collette and A. Boidin for producing alcohol on an industrial scale. Since then Boidin has discovered another mould to which he gave the name Mucor β, which possesses advantages over the other micro-organisms named insomuch as it works more rapidly and in a more concentrated wort. The amyl process, as this method of producing alcohol is termed, is now worked on a very large scale in many countries. The process consists in inoculating a sterile (mostly maize or rice) mash in a closed vessel with a very small quantity of the spores of the mould, passing filtered air through the liquid for a certain time, thus causing the material to develop very rapidly, and subsequently inducing fermentation by the addition of a pure yeast culture. The mould is of itself capable of fermenting the sugar produced, but it is found that the yeast acts more quickly, and will stand a greater percentage of alcohol, than the former. The whole process occupies about five days. The advantages accruing from operating, as is the case in the amyl process, with sterile worts are enormous, inasmuch as undesirable bacterial and side fermentations are impossible. The quality and yield of the alcohol is, owing to this fact, considerably improved. The fact that no malt is employed leads to a further very considerable economy. The general course of operations in the amyl process may be gathered from fig. 10. The maize or other raw material is steeped in the vessels AA with a sufficient quantity of dilute acid to convert the secondary into primary phosphates. When the steeping operations are complete the material passes into the converters BB. After conversion is completed the disintegrated material passes into the vessel C, and thence by means of the pipe D to the fermenting vessels E E E. After fermentation is completed the wash passes to the still F. It is impossible at present to employ the amyl process in its most satisfactory form in the United Kingdom owing to the fact that it is necessary in order to take full advantage of the process to employ a thick wort, i.e. one from which the husks have not been removed. The gravity of a wort of this description cannot be taken by the saccharimeter prescribed by the spirit Acts, but no doubt this difficulty will in time be overcome. The average yield by the amyl process is from one to one and a half gallons a cwt. of raw material more than is the caseier with the processes ordinarily employed in the United Kingdom.

Distillation of Industrial Alcohol.—A still intended for the distillation of industrial alcohol should be so devised as to yield a spirit of the greatest strength and purity in the most economical manner. Still are now constructed which yield in one operation a spirit containing up to 98% of absolute alcohol, and free from all but the merest traces of aldehyde, fusel oil, &c. (foreshots and tailings). An excellent still of this kind is that of R. Ilges. He takes advantage of the fact that if a liquid containing 15% of alcohol is boiled, the quantity of fusel oil in the vapour is equal to the amount in the remanent fluid, and that if the percentage of alcohol is less than 15% the amount of fusel oil in the vapour is greater than that in the liquid. It is therefore possible, by working on proper lines, to remove the whole of the fusel from the mash by a single operation. By subjecting the vapours so obtained to a carefully regulated distillation, the fusel oil condenses, together with the steam and a certain proportion of alcohol—in practice 15%. By further cooling the liquid so obtained the fusel separates out, and, being specifically lighter, rises to the surface of the watery spirit, and is then easily removed. This form of still is so arranged that any change from the correct temperature necessary for the adequate separation of the concentrated "feints" into two layers is automatically corrected by the admission of more or less cooling liquor over the refrigerating pipe coiled round the distilling column. The "foreshots" (aldehyde, &c.) are removed by submitting the alcoholic vapour passing through the main distillation apparatus to further purification. The Ilges apparatus yields three continuous streams of fine spirit, fusel oil, and foreshots respectively.

By-products of Fermentation and Distillation.—The main constituent of spirits is, of course, ethyl alcohol—spirit of wine—but all spirits contain small but varying quantities of by-products and it is by these that the character of a spirit is determined. The by-products are mainly formed during fermentation, but are also to a certain extent pre-existent in the raw materials, or may be formed during the operations preceding and succeeding fermentation. The nature of the by-products is complex, and varies sensibly according to the raw materials employed and the methods of malting, mashing, fermentation and distillation.

The by-products may be classified as follows: (a) higher alcohols—usually going under the name of fusel oil; (b) esters; (c) fatty acids; (d) fatty aldehydes and acetals; (e) furfuryl aldehyde; (f) terpene, terpene hydrate and ethereal oils; and (g) volatile butyric acid. The higher alcohols consist of mixtures of C₂H₅-OH of the formula C₄H₉-OH containing from 3 to 4 atoms of carbon in which, as a rule, amyl alcohol (C₄H₉-OH) predominates. The fusel oil of British pot-still spirits is chiefly composed of amyl and butyl alcohols, whereas in patent spirits propyl alcohol preponderates, that is, in the finished or fine spirit, since the fusel oil separated from patent spirit in the course of distillation consists mainly of amyl and butyl alcohols. Broadly speaking, the higher alcohols present in pot are of higher molecular weight than those in patent spirits. Potato fusel contains a high proportion of isobutyl alcohol, grain fusel of n-butyl alcohol. The acid present in spirits is chiefly acetic acid, but small quantities of propionic, isobutyric, butyric, and valeric acids are present in addition. The esters are formed by the interaction of alcohols and acids chiefly during the fermenting and distilling operations, consist almost entirely of fatty acid radicles in combination with ethyl and, to a minor extent, amyl alcohol. Ethyl acetate (acetic ester) is the main constituent of the esters, the others being mainly ethyl valerate, butyrate and propionate. Oenanthetic ether (ethyl palgalonate) is one of the characteristic esters of bracket. Purfuryl aldehyde (furfurol) is a characteristic product in pot-still spirits, although it occurs to a greater or less extent in patent spirits according to the degree of rectification. It is probable that the fusel is formed by the splitting up of a part of the pentoses contained in the wort. It was formerly thought that its occurrence in relatively large quantities in pot-still spirits was due to the charging effect of the action of the fire gases on the carbonaceous matter adhering to the bottom and sides of the still, but the author has shown that this is not the case, inasmuch as he has found that spirits distilled by means of a steam jacket instead of direct fire contain quite as much furfurol as those distilled in the old way. Terpene and terpene hydrate are characteristic constituents of grain fusel. Although the ethereal oils appear to play an important part in determining the character of a spirit, too little is at present known of their nature to warrant any closer description.

Effect of Maturing on the By-products.—That potable spirits (excepting, of course, pure alcohol) and wine are greatly improved by age is an undeniable fact, and one that has been recognized for many hundreds, and even thousands, of years. Thus, in the gospel of St Luke we have the statement "that no man having drunk old wine, straightway desireth new: for he saith,
The old is better.” And again in the Apocrypha, “New friends are like new wine: when it is old, thou shalt drink it with pleasure.” There is little doubt that the beneficial effect of age on the character of spirits is due to the changes effected in the character and quantity of the by-products, but the exact nature of these changes is by no means clear. Such improvement as takes place is apparently connected in some way with the free access of air to, or rather the satisfactory ventilation of, the containing vessel; for spirits preserved entirely in glass undergo relatively little change. While the cause in the latter instance is probably the same as in the former, it is evident that this does not affect the statement that the quality of agewines depends on the character of the spirit. Concerning the changes which take place during maturation, it was formerly believed that the higher alcohols decreased with age, and that the main reason of the improvement noticeable in mature spirits was due to this fact. The author has, however, shown conclusively that this is not the case, but that on the contrary the higher alcohols generally increase during maturation. This decrease is not absolute, but only relative, and may be due to the fact that the higher alcohols are less volatile than ethyl alcohol. There is a decided increase during maturation of both the volatile and non-volatile acid character of the spirit. Esters and aldehydes generally tend to increase, but not to so great an extent as was formerly believed to be the case. There is, however, a marked decrease in regard to furfurol. The type of cask exercises a marked influence on the course of maturation; and, as regards whisky, spirit stored in a sherry cask undoubtedly matures more quickly than that contained in a plain wood cask. The relative humidity of the cellar in which spirit is stored has a very great effect on the course of maturation. In a very damp cellar the spirit will lose alcohol very rapidly and as a result all those changes which are favoured by these conditions will take place with relative rapidity. On the other hand, in a very dry cellar the loss of alcohol is relatively smaller than that of water (cf. Schidrowitz and Kaye, Journ. Soc. Chem. Ind., June 1905).

Physiological Effects of Spirit By-products.—The nature of the physiological effects produced by the ingestion of spirits varies considerably, not only according to the class of spirit (i.e. whether whisky, brandy, rum, &c.) consumed, but also with its condition (i.e. whether new or old, and so on); and there is no doubt that the causation of these phenomena is intimately connected with the nature and quantity of the by-products, to which the various substances said to belong to the spirit are due. Commenting on a statement in Bailey’s Book of Sports to the effect that wine and brandy had a tendency to make a man fall on his side, whisky to make him fall forward, and cider and perry to make him fall on his back, Sir T. Laudon Brunton (Evidence, Spirits Committee, 1891) suggests that these statements—if correct—might indicate definite injury to various parts of the cerebellum. Thus, if the anterior part of the middle lobe of the cerebellum is injured, the animal tends to fall forward; when the posterior part is affected, the head is drawn backwards, &c. Brunton is inclined to believe that the varying action of different spirits may be due to the specific action of specific products on the separate nerve centres. Thus the cause of the epileptic convulsions produced by the injection of absinthe has been traced to the specific action of the chief flavouring agent of this liqueur.

In view of the doubt which modern research has thrown on the older theories, to the effect that the improved character of a mature, as compared with a new, spirit is due to the decrease in the quantity of the higher alcohols (i.e. the fusel oil), a discussion of the specific action and relative toxicity of these bodies may seem to become more especially as they occur in quantities which are apparently incapable of producing serious effects. As, however, there is considerable reason for believing that the higher alcohols do influence, at any rate, the flavour of the spirit a brief reference to their physiological action seems to the author not out of place. Broadly speaking, the toxicity of the fatty alcohols increases with their molecular weight. Dujar-din-Beaumetz and Audigé found that the lethal dose for dogs was 5-6 grammes per kilo-body-weight for ethyl (ordinary) alcohol; 375 grammes for propyl alcohol; 18 grammes for butyl; and 1-5 grammes for n-amyl alcohol. It is interesting to note that the experiments of these investigators were conducted chiefly with the pig, as the digestive organs of the latter animal are very similar to those of man, and also because the pig is apparently the only animal which willingly takes alcohol with its food. With regard to the action of spirits generally, the investigators named above found that the digestive organs of pigs fed for thirty months with pure alcohol alone were not affected, whereas the animals treated with similar quantities of imperfectly purified spirit (whether derived from the beet, the potato or from grain) suffocated considerably.

Of late years the attention of pharmacologists has been directed to furfurol especially, and the aldehydes generally, as being, at any rate in part, the cause of the unpleasant after or by-effects of certain spirits. Curci and others showed that furfurol in certain doses is poisonous to animals. Brunton and F. W. Tunnicliffe demonstrated a poisonous action of this substance upon man, and, comparing the after-effects upon animals of spirits containing, and freed from, aldehydes, found certain important physiological differences between them. I. Guareschi and others observed that samples of reputedly pure spirits contained small quantities of certain volatile bases of an alka! dolous nature. They apparently belong to the pyridine series, and have effects similar to those of strychnine. E. Bamberger and Einhorn discovered the presence of pyridine, dimethylpyridine and other bodies belonging to the same series, in commercial fusel oil. It is possible that the existence of these volatile bases in spirit may have given rise to the—on the face of it absurd—suggestion that tar bases have been used as adulterants of whisky. It appears likely that the formation of the bases in question is connected with the use of inferior or decaying grain or maize. Thus the spirit produced in Sweden in 1879 was particularly bad and had very curious effects, and it was found, on investigation by M. Huse, that it had actually been largely prepared from decomposing grain. Moreover, C. Lombrosi discovered an alka! dolous body in decayed maize, the action of which was not unlike that of strychnine. The quantities of these bases which have been found in spirits are very small, but it must be remembered that substances are known—such as abrine, for instance—which have marked effects in practically unweighable quantities. It is possible that these volatile bases may be responsible for some of the effects very similar to alka! dolous poisoning—produced by crude spirits such as Cape “smoke” and the cheap Portuguese liqueurs.

Having described the nature and effects of spirit by-products, and the changes occurring in them during storage, the question that arises is: How is the knowledge gained by scientific research in this direction applied in practice? It may be said that the old adage “prevention is better than cure” holds good in the spirit industry as elsewhere, and the distiller, therefore, tries as far as possible to avoid the formation of those by-products which are objectionable, or at any rate to remove them during the course of manufacture. These methods for obtaining a satisfactory potable spirit are so far, however, only successful up to a certain point, and the distiller is therefore bound to have recourse to prolonged storage or to one of the many artificial processes of purification and maturing, the majority of which have been devised—with varying success—during recent years. Referring, in the first place, to what may be called the natural or “preventive” methods for the production of a well-flavoured spirit, it is necessary (a) that the water supply (for steeping, mashing, &c.) be good; (b) that no mouldy or inferior barley be used; (c) that the use of pure water be kept up within reasonable limits; (d) that refrigerators be constructed so as to avoid bacterial infection; (e) that the “souring” of the wort be conducted on proper lines; (f) that a favourable and vigorous type of yeast be used; and (g) that stills, &c., be kept perfectly clean. Coming next to the methods ordinarily or frequently employed by distillers for eliminating the undesirable by-products, which, despite all care, are formed in the course of manufacture, the most important undoubtedly is purification by rational fractional distillation. By properly regulating the distilling heats, by
using a well-devised still, both in the first instance and also for rectifying, a product very free from fusel oil, and especially from fatty aldehydes and volatile ethers, may be obtained. The removal of acids—objectionable chiefly on account of the unpleasant decomposition products which they form in still—is carried out by neutralizing the still contents with an alkaline medium. The alkali so used also decomposes undesirable esters, and retains some of the aldehydes. For the elimination of fusel oil, treatment with charcoal is the most common method. Luck has suggested for this purpose the passing of the alcoholic vapours through petroleum, which is said to absorb the higher alcohols much more easily than it does ordinary spirit; and some distillers have successfully tried the method of V. Traube, which consists in introducing spirit with water into a current of various inorganic salts. This causes the formation of a supernatant layer, which is said to contain practically all the fusel oil as well as the greater part of the foreshot by-products, i.e. fatty aldehydes, &c.¹

Finally, there remain for consideration the artificial maturing processes. These are exceedingly numerous, but it may be said at once that the great majority of them are hardly to be taken seriously. Thus one inventor, acting upon the alleged fact that spirits are improved by lengthy journeys, suggests that a miniature railway, both numerous and augmented, including smoking action, be laid down in the distiller's warehouse. Of the methods worthy of consideration may be mentioned, first, those depending solely upon the action of currents of air, oxygen and ozone. They exist in numerous modifications, but the principle involved, broadly speaking, is to pass a current of hot or cold air or oxygen, or alternate currents of hot and cold air, or a current of ozonized air, through the liquid, with or without pressure, as the case may be. According to the patents of E. Mills and J. Barr, new whisky rapidly acquires the character of the mature sherry-cask stored spirit if the action of alternate hot and cold air is sufficiently prolonged. (a) to the liquid a little sherry and a minute trace of sulphuric acid, the latter being subsequently neutralized by lime. Secondly, there are the processes which make direct or indirect use of the electric current. Of the indirect methods in this class may be mentioned that of Hermite, which consists essentially in adding an electrolysed solution of common salt to the spirit, and subsequently redistilling. Thirdly, the processes which rely on accelerating natural cask action by artificially reproducing the conditions attendant on the latter in a purposely exaggerated or heightened form. One method strives to obtain this object by heating the spirit under pressure in an atmosphere of oxygen in a vessel provided with a quantity of oak shavings. This process certainly seems calculated to remove a portion of the by-products, for the "grog" obtained in A. H. Allen's experiments by steaming the staves of an old whisky cask contained appreciably more fusel oil and esters than common whisky. Fourthly, we have the methods chiefly dependent on the action of cold. R. P. Picket, by cooling a new brandy to −30°C, is said to have obtained a liquid which had apparently acquired the properties of a twelve-year-old spirit. R. C. Scott's process consists in energetically treating spirit which has been chilled down to 0°C with dry filtered air, and the operation is so conducted, it is said, that there is no loss of alcohol or of the important aromatic esters. According to the published data, the quantity of the fusel oil is materially reduced by this method, and the quality of the spirit much improved. None of the above processes has apparently (although in practice they may give satisfactory results) been devised with a view to effecting the direct removal of those specific substances (furfurol, other aldehydes and volatile bases) which latter research has shown to be present to a greater extent in new or inferior spirits than in the matured or superior article, and to some of which, at any rate, owing to their acknowledged toxicity in very small quantities, it is more than reasonable (as Lader and Brunton and Tunnichie have pointed out) to suppose that at least a part of the evil effects by drinking new or inferior spirit may be ascribed. In this connexion a patent taken out by J. T. Hewitt is of interest, inasmuch as it deals with the problem of spirit purification on seemingly rational scientific lines. This patent takes advantage of the fact that furfurol and similar aldehydes can be removed from spirits by distillation with phenyl-hydrazine-sulphonate of soda, which salt forms non-volatile products with the substance in question. (P. S.)

SPIRITUALISM, a term used by philosophical writers to denote the opposite of materialism, and also used in a narrower sense to describe the belief that the spiritual world manifests itself by producing in the physical world effects inexplicable by the known laws of nature. The theory is in a state of active development, and will be here discussed. The belief in such occasional manifestations has probably existed as long as the belief in the existence of spirits apart from human bodies (see ANIMISM; MAGIC, &c.), and a complete examination into it would involve a discussion of the religions of all ages and nations. In 1848, however, a peculiar form of it, believed to be based on abundant experimental evidence, arose in America and spread there with great rapidity, and thence over the civilized world. To this movement, which has been called "modern spiritualism," the present article is mainly devoted.

The movement began in a single family. In 1848 a Mr and Mrs J. D. Fox and their two daughters, at Hydesville (Wayne county), New York, were much disturbed by unexplained knockings. At length Kate Fox (b. 1839) discovered that the cause of the sounds was intelligent and would make raps as requested, and, communication being established, the raper professed to be the spirit of a murdered pedlar. An investigation into the matter was thought to show that none of the Fox family was concerned in producing the rappings; but the evidence that they were not concerned is insufficient, although similar noises had been noticed in the house by them in the absence of any explanation. It was almost immediately afterwards, at Rochester, where Kate and her sister Margaret (1836–1893) went to live with a married sister (Mrs Fish) that modern spiritualism assumed its present form, and that communication was, as it was believed, established with lost relatives and deceased eminent men. The presence of certain "mediums" was required to form the link between the worlds of the living and of the dead, and Kate Fox and her sister were the first mediums. Spiritualists do not as yet claim to know what special qualities in mediums enable spirits thus to make use of them. The earliest communications were carried on by means of the "raps"—as they are called—of Mrs Fox, and were, as Sir William Crookes calls them, "percussive sounds." It was agreed that one raps should mean "no" and three "yes," while more complicated messages were—and are—obtained in other ways, such as calling over or pointing to letters of the alphabet, when raps occur at the required letters.

The idea of communicating with the departed was naturally attractive even to the merely curious, still more to those who were mourning for lost friends, and most of all to those who believed that this was the commencement of a new revelation. The first two causes have attracted many inquirers; but it is the last that has chiefly brought modern spiritualism its religious aspect. Many came to witness the new wonder, and the excitement and interest spread rapidly. It should be noted that expectations favourable to the new idea had already been created by the interest in mesmerism and the phenomena of hypnotic trance (see HYPNOTISM), widely diffused at this time both in America and Europe. It was believed that information about other worlds and from higher intelligences could be obtained from persons in the sleep-waking state. Andrew Jackson Davis (q.v.) was in America the most prominent example of such persons; his work, The Principles of Nature, Her Divine Revelations (New York, 1847), was alleged to have been dictated in "clairvoyant trance, and before 1848 his followers were expecting a new religious revelation. Many reputed "clairvoysants" developed into mediums (q.v.). The "spiritualistic" movement spread like an epidemic. "Spirit circles" were soon formed in many families. There is very little evidence to show that mediumship
SPIRITUALISM

arose anywhere spontaneously; but those who sat with the Foxes were often found to become mediums themselves and then in their turn develop mediums in others. The mere reading of accounts of séances developed the peculiar susceptibility in some persons, while others, who became mediums ultimately, did so only after prolonged and patient waiting.

There seems to have been little practical interest in spiritualism in England till 1832, when its first development took the form of a mania for table-turning (q.v.). This seems to have prevailed all over Europe in 1853. In England it was greatly stimulated by the visit of Mrs Hayden, a professional medium from Boston, in the winter of 1852–1853. Daniel Dunglass Home, the next medium of importance who appeared in London, came over from America in 1853, and it is probable the chief mediums for physical phenomena known in England came from the United States. It was at Keighley in Yorkshire—where also the first English periodical, the Yorkshire Spiritual Telegraph, was published in 1853 and onwards—that spiritualism as a religious movement first made any mark in England; but this movement, though it spread rather widely, cannot be said to have attained at any time very vigorous proportions. It had taken more hold in its original home in the United States of America, and thence it has spread in some degree to most Christian countries. Nowhere, however, has there been more religious organization in connection with it, and there is a sort of religious atmosphere characteristic of the movement which seems to have declined rather than increased.

In the present article it is impossible to give an exhaustive catalogue of the phenomena and modes of communication of modern spiritualism. The greater part of the phenomena may be divided into two classes. To the first belong what may be called the physical phenomena (q.v.) of spiritualism—those, namely, which, if correctly observed and due neither to conscious or unconscious trickery nor to hallucination or illusion on the part of the observers, exhibit a force acting in the physical world hitherto unknown to science. The earliest of these phenomena was the rapping, first heard in the hands already spoken of and other sounds occurring without apparent physical cause, and the similarly mysterious movements of furniture and other objects; and these were shortly followed by the ringing of bells and playing of musical instruments. Later followed the appearance of lights; quasi-human voices; musical sounds, produced, it is said, without instruments; the "materialization" or presence in material form of what seemed to be human hands and faces, and ultimately of complete figures, alleged to be not those of any person present, and sometimes claimed by witnesses as deceased relatives; "psychography"—the automatic writing and drawing—asserted to be done without human intervention; "spirit-photography," or the appearance on photographic plates of human and other forms when no counterpart was visible before the camera to any but specially endowed seers; unfastening of cords and bonds; elongation of the medium's body; handling of red-hot coals; and the apparent passage of solids through solids without disintegration.

The second class of phenomena, which we may call the automatic, consists in table-tilting and turning with contact; writing, drawing, &c., through the medium's hand; convulsive movements in secondary dressing; entrancement, trance-speaking, and personation by the medium of deceased persons attributed to temporary "possession" (q.v.); seeing spirits and visions and hearing phantom voices. This class bears affinity to some of the phenomena of hypnotism and of certain nervous complaints, to certain epidemics of the middles ages, and to phenomena that have occurred at some religious revivals.

In a third class must be placed the cure of disease by healing mediums. This branch of medical psychology, and cannot well be studied apart from hypnotic treatment of disease, from the now well-recognized power of suggestion (q.v.), from "faith cures," "mind cures," "Christian Science," and cures connected with other forms of religious belief (see FAITH-HEALING).

Phenomena falling into the automatic class are much the most common. The investigation of Carpenter on unconscious cerebration and of Faraday on unconscious muscular action showed early in the movement that it was not necessary to look outside the medium's own personality for the explanation of even these two kinds of phenomena. It was thought at one time that unconscious movements would not be conveyed through table-tilting, automatic writing and trance-speaking—provided the matter communicated was not beyond the range of the medium's own knowledge or powers. And the whole subject of the action of the subconscious personality—the "subliminal self"—has since been more fully worked out by psychologists and notably by F. W. H. Myers. No one conversant with the facts now doubts that what looks like possession or inspiration by an external intelligence may generally be accounted for by subconscious mentation, so that in all cases where no material effects are produced except such as can be attributed to the mind, the use of the term "telepathy" is unjustified. In the phenomena of the medium, the evidence for a supernatural interpretation must depend on the content of the communication. Spiritualists maintain that true information is received, which is probably unknown to the medium or other persons present, or which at least is expressed in a manner obviously beyond their powers; and they attribute this to extra-corporal intelligences. Others, while not going so far as this, admit that the content of the communications does occasionally exceed the medium's knowledge and affords evidence of telepathic communication (see TELEPATHY) between living persons. Probably most persons who have studied the subject would not be inclined to go this length; and there is some evidence, notably in connexion with the trances of an American medium, Mrs Piper, which has convinced some good observers that the hypothesis of occasional communication from deceased persons must be seriously entertained.

Recently the Society of Psychical Research has obtained from various persons automatic script affording important new material for investigation and which prima facie supports the spiritualistic hypothesis. Whether or not further study of the scripts of these writers confirms this hypothesis, it cannot fail to throw light on the nature of the intelligence in connexion with these phenomena. Many volumes containing accounts of such phenomena have been printed, and appeal is often made to the mass of evidence so accumulated. "No physical science can array a tithe of the mass of evidence by which spiritualism" is "supported," says Serjeant Cox. But the graphs which should contain, besides the normal sitter, representations of deceased friends. For an account of these see Proceedings of the Society for Psychical Research, vii. 268.

1 See uncritical consideration of the spiritualistic séance at which took place at Tedworth in 1891 (see Glenvill's Sadduceus Triumphant) and at Slawensick in 1806 (see Kerner's Sekhert von Preorst), and others too numerous to mention.

3 There have been several professional photographers (all detected in fraud sooner or later) who made it their business to take photo-
SPIRITUALISM

707

majority of these accounts have scarcely any scientific value. Spiritualists have, as a rule, sought to convince not by testimony but by ocular demonstration. Yet, if there is not a mass of scientific evidence, there are a number of witnesses—among them distinguished men of science and others of undoubted intelligence—who have convinced themselves by observation that phenomena occur which cannot be explained by known causes; and this fact must carry weight, even without careful records, when the witnesses are otherwise known to be competent and trustworthy observers.

Among proposed "normal explanations" of these phenomena that of hallucination (e.g.), including illusion as to what is seen almost amounting to hallucination, deserves careful consideration. Sensory hallucination of several persons together who are not in a hypnotic state is, however, a rare phenomena outside the séance room and must not therefore be lightly assumed within it; nor is it in most cases a plausible explanation where there is general agreement not only of all the witnesses but of more than one sense as to what is perceived, as distinguished from what is inferred. Nevertheless something of the kind seems occasionally to have happened, especially at some of the séances with Home.1

What may broadly be called "conjuring" is a much more probable explanation of the majority of the phenomena; and in the vast majority of cases the witnesses do not seem to have duly appreciated the possibilities of conjuring, and have consequently rather taken precautions to exclude it nor allowed for the accidental circumstances which may on any particular occasion favour special tricks or illusions. The experiments of S. J. Davey and R. Hodgson should be studied in this connexion.2 At a spiritualistic séance the medium has the privilege of failing whenever he pleases and there is seldom any settled programme—circumstances very favourable to deception. As it was put by Mr. Stainton Moses, a leading spiritualist and himself a medium, who wrote under the nom de plume of "M.A. (Oxen.)": "In 99 out of every 100 cases people do not get what they want or expect. Test after test, cunningly devised, on which the investigator has set his mind, is put aside, and another substituted."3 In other words, the evidence is rarely strictly experimental, and this not only gives facilities for fraud, but makes it necessary to allow a large margin for accidents, mistakes and mal-observation. It may be urged that if none of the phenomena is genuine we have to assume a large amount of apparently aimless trickery in non-professional media. But it must be borne in mind that the excellent moral character in the medium is no guarantee against trickery, unless it can be proved that he was in no abnormal mental condition when the phenomena occurred; and extraordinary deceptions are known to have been carried on by hysterical patients and others with no apparent motive.

One of the possibilities to be allowed for is that of exceptional muscular endowment or anatomical peculiarity in the medium. For instance, it is not very uncommon to find persons who can make loud sounds by partially dislocating and restoring the toe, knee, or other joints, and some experiments made with the Fox girls in 1851 supported the view that they made raps by this method.

Besides the general arguments for supposing that the physical phenomena of spiritualism may be due to conjuring, there are two special reasons which gain in force as time goes on. (1) Almost every medium who has been prominently before the public has at some time or other been detected in fraud, or what cannot be distinguished from fraud except on some violently improbable hypothesis; and (2) although it is easy to devise experiments of various kinds which, by eliminating the necessity for continuous observation on the part of the investigator, would place certain phenomena above the suspicion of conjuring, there is no good evidence that such experiments have ever succeeded.

Nevertheless there does exist evidence for the genuineness of the physical phenomena which deserves consideration. Count Agéor de Gasparin, in his Tables tournantes (Paris, 1854), gives an account of what seem to have been careful experiments, though they are hardly described in sufficient detail to enable us to form an independent judgment. They convinced him that by some unknown force tables could be got to move without contact. The experiments were conducted with his own family and friends without professional mediums, and in some of them he was assisted by M. Thury, professor of physics at Geneva, who was also convinced of the operation of an unknown force.4 The minutes of the sub-committee No. 1 of the committee of the Dialectical Society (op. cit., pp. 373-391) report that tables moved without contact, whilst all the persons present knelt on chairs (the backs of which were turned to the table) with their hands on the backs. The report, however, would be of greater value if the names of the medium and of the working members of the committee were given—we only know that of Serjeant Cox—and if they had written independent accounts of what they witnessed. Sir William Crookes has published accounts of some experiments on physical phenomena, and it appears that the Séance-Pensées, have left him convinced of the genuineness of the wide range of physical phenomena which occurred through Home's mediumship.5 Of considerable interest again are the experiences of Mr. Stainton Moses between 1870 and 1880, of which the best account has been compiled from contemporary records by F. W. H. Myers in two papers published in the Proceedings of the Society for Psychical Research.6 More recently several men of science, including Sir Oliver Lodge in England, Professor Charles Richet in France, and Professors Schiaparelli and Morrell in Italy, have convinced themselves of the supernormal character of some of the phenomena described. The experiments which have left them convinced of the genuineness of the wide range of physical phenomena which have occurred in the presence of a Neapolitan medium, Eusapia Palladino, though it is known that she frequently practises deception,7 M. Joseph Maxwell, of Bordeaux, has published accounts of raps and movements of objects without contact, witnessed with private and other mediums, which he appears to have observed with care, though he does not describe the conditions sufficiently for others to form any independent judgment about them.

The interest in spiritualism, apart from scientific curiosity and mere love of the marvellous, is partly due to the belief that trustworthy information and personal anecdotes of events in the past can be obtained through mediums—to the same impulse in fact which has in all ages attracted inquirers to fortune-tellers. The more thoughtful spiritualists, however, are chiefly interested in the assurance of life and progress after death, and the moral and religious teaching, which they obtain through automatic writing and trance-speaking. It was discovered very early in the movement that the accuracy of these communications could not always be relied on; but it is maintained by spiritualists that by the intelligent exercise of the reason it is possible to judge whether the communicating intelligence is trustworthy, and whether the phenomena are genuine.8

great for anything like a universal spiritualistic creed to have been arrived at. In France the doctrine of successive reincarnations with intervals of spirit life promulgated by Allan Kardec (L. H. D. Rivail) forms prominent element of spiritualistic belief. This view has, however, made but little way in England and America, where the opinions of the great majority of spiritualists vary from orthodox Christianity to Unitarianism of an extreme kind. Probably it would be impossible to unite spiritualists in any creed, which, besides the generally accepted belief in God and immortality, should postulate more than the progress of the spirit after death. In a part of the dead to communicate with the living by means of mediums.

Spiritualism has been accused of a tendency to produce individuals who, but spiritualistic sittings carried on by private persons do not appear to be harmful provided those who find in themselves "mediumistic" powers do not lose their self-control and exercise these powers when they do not desire to do so, or against their better judgment. Public sittings are apt to be means of obtaining money by false pretences, and the great scandal of spiritualism is undoubtedly the encouragement it gives to the immoral trade of fraudulent mediumship.

BIBLIOGRAPHY.—In addition to the works already mentioned, the student will find a wealth of information under the following: F. Podmore, Modern Spiritualism (2 vols., London, 1902), and The Newer Spiritualism (1910); F. W. H. Myers, Human Personality and Its Survival of Bodily Death (2 vols., 1903); E. C. Worthington, Classification of the Various Aspects of the History of Spiritualism (Boston, 1875); A. T. Stewart, The Development of the Movement in America (J. E. Edmonds and G. T. Dexter, Spiritualism (1853-1855); R. Hare, Experimental Investigations of the Spiritual Manifestations (New York, 1856); Allan Kardec, Livre des esprits (1st ed., 1853); Mrs De Morgan, From Spirit (London, 1863), with preface by Professor De Morgan; Alfred Russel Wallace, Miracles and Modern Spiritualism (1876); W. Stainton Moses (M.A. (Oxon.)), Spirit Identity and Spirit Teaching; Zöllner, Wissenschaftliche Abhandlungen (the part relating to spiritualism has been translated into English under the title Transcendental Physics by C. C. Massey); Report of the Se scept Commission on Spiritualism (Philadelphia, 1887); Professor Th. Flourney, Des Indes à la Plénière Mars (Geneva, 1900; there is an English translation published in London); Proceedings of the Society for Psychical Research, passim. A succinct account of typical frauds of spiritualism is contained in D. D. Home's Lights and Shadows of Spiritualism (2nd ed., 1877-1878), and also in Hereward Carrington's The Physical Phenomena of Spiritualism, Fraudulent and Genuine (Boston 1907).

SPIT, a rotating bar for roasting meat, game or poultry. A spit usually has one or more prongs to which the meat is fixed; in the case of beef spit it is on the ends of iron rods. The usual form of spit was fixed on hooks or upper rachets on the fire-dogs; at one end of the bar is a grooved wheel for a chain connected with a smoke-jack in the chimney, or some similar contrivance for turning the spit so that every surface of the meat is exposed to the fire in turn. The jack was sometimes turned by a boy or a small dog trained for the purpose, the boy and the dog were equally known as turn-spits. The spits, when not in use, were placed in a spit-rack over the fireplace. These primitive arrangements eventually gave place to a combined spit and mechanical roasting-jack, which was fixed to a small crane projecting from the mantelpiece. The jack, which was largely of brass, rotated when wound up, and the meat was hung below it immediately in front of the fire, and the gravy and dripping were caught in a large shallow metal pan with a high screen to prevent the diffusion of heat. The almost universal employment in England of closed kitchens has thrown all forms of spits and jacks into disuse, but in old-fashioned kitchens they are still sometimes seen. The more ancient forms of roasting apparatus are now much sought after by collectors.

SPITALFIELDS, a district of London, England, in the western part of the metropolis. Borough of Stepney. The name is derived from the fact that the land belonged to a priory of St Mary Spital, founded in 1197. Excavations have revealed a Roman burial-place her. The name is well known in connexion with the silk industry established here by French refugees after the revocation of the Edict of Nantes, in 1685.

SPITHEAD, a strait of the English Channel, between the mainland (the coast of Hampshire, England) and the north-eastern coast of the Isle of Wight, forming the eastern entrance to Southampton Water, the Solent being the western. Its length is about 12 mi., and its general breadth about 4 mi., though the distance between Ryde and Girkicker Point is almost exactly 3 mi. The Spit Sand, extending south-east from this promontory, gives name to the strait. On the north side opens the narrow entry to Portsmouth Harbour, with the towns of Portsmouth and Gosport east and west of it. On the south the coast of Wight rises sharply though to no great elevation; it is well wooded and studded with country residences. Here is also the favourite watering-place of Ryde. Spithead, which runs north and south, is 25 fathoms deep at high water springs. In the fortifications of Portsmouth Harbour, the principal station of the British navy. In this connexion the strait has been the scene of many splendid naval pageants, such as those attendant upon the jubilee in 1907, and the funeral in 1901 of Queen Victoria, and that which celebrated the coronation of King Edward VII. on the 16th of August 1902.

SPITI, an extensive minor division of Kangra district in the Punjab, India. Area, 2,155 sq. m., the population (1901) being only 3,232, all Buddhists. It consists of an outlying Tibetan valley among the external ranges of the Himalayas, containing the uppermost branch of the Indus. Its mean elevation is 7,600 ft. It borders many passes over 20,000 ft. and one in the outer Himalayas of 23,064 ft. in altitude. Spiti originally formed part of the kingdom of Ladakh, and came into the hands of the British in 1846. The river Spiti rises at the converging angle of the Kamzam and outer Himalayan ranges at a height of 20,073 ft., drains the whole valley of Spiti, and falls into the Sutlej after a course of 120 mi.

SPITBERGEN (the name being Dutch is incorrectly, though commonly, spelled Spitsbergen), an Arctic archipelago, almost midway between Greenland and Novaya Zemlya, in 60° 26' to 80° 30' N. and 10° 20' to 32° 40' E., comprising the five large islands of West Spitsbergen or New Friesland, North-East Land, Edge Island, Barents Island and Prince Charles Foreland, the Wiche Islands, and many small islands divided by straits from the main group. The chief island, West Spitsbergen, shaped like a wedge pointed towards the south and deepely indented on the west and north by long branching fjords, has an area of about 15,200 sq. m. At the north-west angle of the island is a region of bold peaks and large glaciers, in the midst of which is the fine Magdalen Bay. Farther south the great series of ridges and small glaciers of the "Ice-sheet" or "Icefields," which drain a high snowfield reaching east almost to Wood Bay and south to the head of Cross Bay. On the south-east it is drained by glaciers towards or into Dickson and Ekman bays. South of this snowfield comes the mountainous King James Land, consisting of an intricate network of craggy ridges with glaciers between. A deep north-and-south depression is occupied by Wijde and Dickson bays, the one opening on the north coast, the other a head-branch of the great Ice Fjord of the west coast, bordered on the west by a range of fine mountains, a spur of which separates the bays. East of this depression there is a plateau rising to nearly 5,000 ft. Its edge is eaten away into deep valleys, down which the ice-sheet of New Friesland sends glacier tongues into Wijde Bay. East of Dickson Bay the marginal valleys are larger, and no glaciers come far down them. The plateau between Dickson and Klaas Billen bays is cut up by deep valleys such as the Rendal, Skandal and Mimesdal (all well known to geologists); it contains no large glaciers. Farther east is found a glaciated area called Garwood Land by Sir Martin Conway. The neck of West Spitsbergen is bounded on the north by a line from near the head of Klaas Billen Bay to Wiche Bay, and on the south by the Sassendal and the depression leading to Agardh Bay. It is a complicated area of fine craggy ridges with beautiful glaciers between. Adventure Land lies south of the neck, and is bounded on the south by a line from the head of Van Keulen Bay to Whales Bay. It is an area of boggy valleys, rounded hills, and small glaciers,
and may be described as the temperate and fertile belt, and is the only part of the island where reindeer still linger in any number. Near the west coast it contains some fine peaks and large glaciers. It is penetrated by the longest green valleys in Spitsbergen, e.g. from Coles Bay, Advent Bay and Low Sound (the valley of the Shallow River). The southern division of the island is very low. There is a high snowfield along its east side, and ranges of peaks farther west. Two parallel ranges form the backbone of the island south of Horn Sound, the higher of them containing the famous Horn Sund Tind (4560 ft.). The long narrow island, Prince Charles Foreland, with lofty peaks, runs parallel to the west coast of West Spitsbergen, from which it is separated by a narrow strait. Its range of mountains is interrupted towards the southern end of the island by a flat plain of 50 sq. m. raised only a few feet above sea-level. There is a narrow depression a few miles farther north. The broad Stor (Great) Fjord, of Wybe Jans Hope, separates the main island from two others to the east—Edge Island (2500 sq. m.) and Barents Land (580 sq. m.). Formerly these were considered as one, until the narrow Freeman Strait which parts them was discovered. Neither Barents Land nor Edge Island carries ice-sheets, and both are practically devoid of glaciers down their western coasts, but have large glaciers reaching the sea on the east. To the north-east of West Spitsbergen, separated from it by Hinlopen Strait (7 to 60 m. in breadth) lies North-East Land, with an area of about 6,500 sq. m. Its western and northern coasts are indented by bays, and its eastern part is connected with a true ice-sheet, while the neighbouring Wiche Islands to the south-east bear no large glaciers at all. East by north from Cape Leight Smith, the easternmost promontory of North-East Land, rises White Island, covered with snow and ice, and rising to about 700 ft. It was discovered by Cornelis Giles or Gillis in 1707, and is alternatively named Giles Land. Numerous small islands lie around the larger: Danes and other islands off the north-west coast of West Spitsbergen, the Seven Islands, Outiger Reps, Broch, and Charles XII. Island on the north of North-East Land; Hinlopen Strait contains many islands, and the Ryk Yse Archipelago, Hope Island, and Walrus Island, and the Thousand Islands (about a hundred small rocks) lie to the east and south of Edge Island.

The nomenclature is in a state of hopeless confusion, the names given by the old explorers having been carelessly transferred from point to point, or capriciously set aside. The true names, English and Dutch, of the principal misnamed sites are here indicated in brackets after the current names: South Cape (Point Look-out), Torrel's Glacier (Slaalberg), Recherche Bay (Joseph's Bay, Schoonhoven), Van Cuclen Bay (Lord Ellesmere Sound, Sardammer Rivier), Van Muylen Bay (Low Sound, Klok Rivier), Coal Bay (adjoining Advent Bay), St John's Bay (Osburn's Inlet), English Bay (Cove Comfortlesse), Foreland Sound (Sir Thomas Smith Bay, Keerwyk), Cross Bay (Close Cove), the bay called Smrecrenburg (Fair Haven, Dutch Bay), Flat Hook (Fox Point), Biscay's Hook (Point Welcome), Redbeach (Broad Bay), Leifde Island (Wiche Sound), Green Hook (Castin's Point), Wijde Bay (Sir Thomas Smith Inlet), Verlegen Hook (Point Desire), Treurenberg Bay (Bear Bay), Agardh Bay (Foul Sound), Stor Fjord (Wybe Jans Water), North-East Land (Sir Thomas Smith Island), North Cape (Point Purchas). Stans Foreland is not, as is sometimes supposes, an alternative name of Edge Island, but the name of its south-eastern cape only.

Geology.—The backbone of the main island consists of an ancient mass of Devonian granite, gneisses and schists forming a mountain chain in the western region. Resting upon these ancient crystalline rocks, the precise age of which has not been definitely determined, the Palaeozoic strata are superimposed in nearly every one of the prominent periods of geological time. For the eastern part of the group these strata lie nearly horizontal; here and there they are pierced by intrusive igneous rocks. The oldest, and perhaps the most ancient, of these rock formations are those which occur in the region of Hornkla Hook, dolomites, limestones, slates and quartzites; Silurian rocks may possibly exist in the north-west; and Devonian gneisses with Pteraspis have been recorded in Liefey Bay. The Carboniferous period is represented by Culm-like rocks (classed by O. Heer as Unisen—Upper Devonian); upon these come limestones with Spiifer Marquis (Hinlopen Straits) and above these again are limestones with Cyathophyllum and Fuissulina; (Eisfjord, Bell Sound, Horn Sound, &c.). Permo-Carboniferous limestones and dolomites occur on the west coast and in King James Land. Black slaty shales with large ammonites in the Calcareae nodules and beds of black, bituminous limestone represent the Trias at Cape Thorodsen; and Rhacitic fossils are found in them. Those at the base of the strata are the strangest and thickest, while the limestone beds occurring at the southern end in King Charles Land are Neocomian rocks with interbedded basalts. Plant-bearing lower Cretaceous strata have been recorded, and lower Eocene beds are freely occupied by the ammonites, the magnolia leaves and others; beds of London Clay age occur in Kol-y, Miocene Sandstones and clay with lignite beds, some 2800 ft. thick, occupy the west coast about Ice Fjord, Bell Sound, Advent Bay, &c. In this period these islands were probably all united, and covered a much greater area and were covered with extensive peat bogs, on the edges of which the marsh cypress flowered, dropping its leaves and blossoms into the marshes. *Sequoa*, poplars, birches, planes long remained practically unknown. While thick and underwood freely developed under their shadow, and thousands of insects swarmed in the thicket. Subsidence followed in late Tertiary times, to be succeeded by a new and last great period of elevation, during which the valleys and basins were formed by the erosion from such as those seen on Prince Charles Foreland, and possibly resubmergence may be again in progress. In comparatively recent geological times this, the main island, was over most of its area by a great ice-cap, and an extensive ice-sheet extended out to the west from the eastern region. This was then withdrawn from the west towards the east, the western region being thus cut up into deep valleys and more or less rugged mountains. Farther east the mountains are more rounded, but still high. From the plateau to the place of one of its easternmost peaks may be measured a passage which permits vessels to approach the western coast even under the most unfavourable conditions of ice in the arctic regions. Drift-wood from lower latitudes, glass floats of the Norwegian busses, and other evidence have established the extremity of Spitsbergen. On the other hand a cold current charged with ice descends from higher latitudes along the eastern coasts, rendering approach extremely difficult. On this account these shores long remained practically unknown.

Owing to the warm drift the climate of Spitsbergen is less severe than in the corresponding latitudes of Greenland and Smith Sound. Bear, however, notwithstanding its monotonous character, is rarely found in such lower temperature. The isotherm of 23° F., which crosses the middle of Eastern Sibereia, touches its southern extremity, and only the north-east coasts of Spitsbergen have an average yearly temperature so low. Cape Colbeck Bay (64° 51' N.) to 16° 7' N. or as low as the temperature is 16° (January 14-1°, July 39-3°). Even in the coldest months of the winter a thaw may set in for a few days; but, on the other hand, snow sometimes falls in July and August in this part of the coast. Icebergs are frequently seen, and sometimes float at a considerable distance from the shore, or drift close to it, and, in company with ice and snow, and interspersed with water and disappears in places, and scurry grass and the polar willow open their buds. By the end of June the thermometer has ceased to sink below the freezing-point at night; July, August and September are the best months. In September, however, autumn sets in on shore, and by the end of the month the pack-ice rapidly freezes into one solid mass. In Treurenberg Bay an annual precipitation of 64 in. has been observed.

Fauna and Flora.—The Greenland whale has completely disappeared in consequence of the great havoc made by the early whalers. According to Scoresby, not more than 5 or 6 of these animals have been killed between 1749 and 1755. A great diminution, in the same way, is to be observed in the numbers of other creatures which were the object of hunters. A reckless extermination of seals was carried on. Walruses are now only common in the waters of West Spitsbergen. Birds, also, have rapidly diminished in numbers. The fulmar petrel meets ships approaching Spitsbergen far away from the coasts. It makes colonies on the cliffs, as also do the glaucous gull and the rhodon. At the mouth of the rivers, where the ivory gulls, auk and kaittiukwa gulls breed on the cliffs, while geese, loons and snipe frequent the lagoons and small fresh-water ponds. The eider duck breeds along the south coast, and is seen in pairs. Salt marsh birds, such as the snipe and curlew, and the dunlin, and four others (the falcon, snowy owl, swan and skua) come occasionally. Of land mammals, besides the polar bear, the reindeer and arctic fox have been greatly reduced; the reindeer, in fact, are approaching extinction, whereas for several years consecutively
before 1868 from 1500 to 2000 were killed by hunters in a few weeks of summer. There are twenty-three species of fishes, but no reptiles. Insects are few. Arachnids, and especially Pantopods, on the other hand, are very common. Molluscs are also numerous. At some places the shores are so narrow that the large ships appear in great abundance. Of Crustaceans fully 100 species have been recognized in the waters of the archipelago.

The flora is, of course, peculiar. There is the only tree, the polar willow, which is to be seen. A few tiny bushes and grasses have developed in parts that are larger than a man's finger-nail; and the only bushes are the crowberry and cloudberry. But at the foot of the warmer cliffs some moss has been formed notwithstanding the slowness of putrefaction, and, in contrast with the brownish lichens that cover the hills, grows a carpet of mosses of the brightest green, variegated with the golden-yellow flowers of the ranunculus, the large-leaved swirv grass, several saxifraga, fox-tail grass, &c., with a few large flowers, Polygona and other meadow flowers, and the drearier yellow polypodium, yellow grasses, &c., are found. Even on the higher slopes, 1500 ft. above the sea, the poppy is occasionally met with. In all over 130 species of flowering plants have been found. Mosses, mostly European acquaintances, cover all places where peat has accumulated. The slopes of the crags and the blocks of stone on the beach are sometimes entirely covered with a luxuriant moss and lichen vegetation, among the last being the so-called "famine bread" (Umbilicaria arctica), which has maintained the life of many arctic travellers. Although limited in number, the flora is suggestive in its distribution. The vegetation of the south has a decidedly Lappish or European alpine character, and on the north coast it is decidedly arctic, and recalls that of Melville Island. Many flowering plants which are common in north-west Spitsbergen are absent from the east coast, whereas various species of lichens are found only in the north. On the other hand, one moss (Potnia hyperborea) and one lichen (Usnea melaxantha) are found there which are of American origin and grow both in North America and on the Cordilleras. Algae are also more numerous on the north coast. Like the common (Protococcus niveus), which fill all pools and are the chief food of many birds, being familiar in Europe. 

History.—Spitsbergen has never been permanently inhabited, although there are instances of hunters wintering on the island under stress of circumstances, and several scientific expeditions have done so. A Russian trader named Starashchikow visited the island in 1609, during the winter, after spending the summer season to the north, and in 1641, after discovering the island, reached Spitsbergen in June. Heer, a Danish trader, in 1610, visited the coast of Spitsbergen, and in 1611, Henry Hudson, a Dutch trader, visited the coast of the Spitsbergen whaling industry, which was to grow to such importance, was established in 1611. Very shortly the Dutch began to take a share in this, and there were frequent collisions between the whalers of the two nationalities, while in 1615 the Danes attempted to claim this part of "Greenland," as Spitsbergen was for a long time called to both England and France, and the boundary was settled in 1660. In 1660, the British gained a footing on the island, and in 1661, the Dutch began to take a share in the trade. The Danes and the English were the most successful, and in 1661, the Danes attempted to claim this part of "Greenland," as Spitsbergen was for a long time called to both England and France, and the boundary was settled in 1660. In 1660, the British gained a footing on the island, and in 1661, the Dutch began to take a share in the trade. The Danes and the English were the most successful, and in 1661, the Danes attempted to claim this part of "Greenland," as Spitsbergen was for a long time called to both England and France, and the boundary was settled in 1660. In 1660, the British gained a footing on the island, and in 1661, the Dutch began to take a share in the trade.
In 1882 the Swedish geologists, A. G. Nathorst and G. de Geer made a journey which furnished interesting data about the geology and flora of the islands. In the same year a Swedish meteorological station was established at Cape Thordsen for carrying on the observations desired by the International polar committee. During the last decade of the 19th century Spitsbergen attracted not only a number of scientists but also sportsmen and tourists. Such expeditions as those of Gustaf Norden skjöld in 1890 and the important circumnavigation by Nathorst in 1898, during which the Wicke Islands and White Islands were carefully explored, confined their attentions almost entirely to the coasts. In 1892 M. C. Rabot made the first serious attempt to penetrate the interior from the head of Ice Fjord, exploring a part of the Sassenland; and in 1896 Sir Martin Conway led an expedition which crossed the island for the first time, and surveyed the region between Ice Fjord and Bell Sound on the east coast. In 1897 Conway and Mr E. J. Garwood surveyed the glaciated area north of Ice Fjord to about 78° 16' N., and climbed Horn Sund Tind. In the same year Herr André made his fatal balloon ascent from Dannes Island with the intention of floating over the Pole. In 1896 a weekly service of Norwegian tourist steamers was established in summer, and a small inn was built at Advent Bay in Ice Fjord, and though this was afterwards closed, the west coast continued to be frequently visited by tourist steamers during the height of summer. In 1898, 1899 and 1906 the prince of Monaco made scientific investigations of the archipelago. During these and other Russian expeditions undertook the measurement of an arc of the meridian, the results of which were accompanied by valuable physiographical, meteorological, botanical and other observations. Dr W. S. Bruce made a complete survey and scientific investigations of Prince Charles Foreland. In 1900 coal began to be worked on Advent Bay, a seam 10 ft. thick being found below 40 ft. of fossil ice and 20 ft. of rock. This development and other considerations led to some discussion between the powers interested as to the territorial sovereignty over the archipelago, a question which though approached before (as in 1870) had never been brought to a settlement.

Bibliography.—On a land visited by so many scientific observers the literature is naturally voluminous. The chief source of scientific papers is the publications of the Swedish Vetenskaps Akademi. Sir W. Martin Conway narrates his expedition in the First Crossing of Spitsbergen (London, 1897); and in No Mon’s Land (Cambridge, 1906) he details the history of the Archipelago down to 1894, tabulates the principal voyages and incidents thereafter until 1902, and gives a complete full bibliography for the history and geography of Spitsbergen from the earliest time down to 1902. The various observations of the Swedish expedition for the measurement of an arc of the meridian together with the material from Messrs.Seeing, and J. B. Gladwin’s papers in Missions scientifiques pour la mesure d’un arc de méridien au Spitzberg... (Stockholm, 1903-1906), and those of the Russian expedition under the same title in 1904, seq. (st. Petersburg).

SPITTA, Friedrich (1854–1924), German Protestant theologian, was born at Wittlingen on the 10th of January 1854. His father, Karl Johann Philipp (1810-1859), well known as a hymn-writer (see Lyra domestica, 1st series, London, 1859; 2nd series, 1864), was superintendent at Burgdorf near Hanover. Friedrich studied at Göttingen and Erlangen, and in course of time became (1877) professor ordinarius and university preacher at Strassburg. In 1896 he became joint-editor with J. Smend of the Monatschrift für Gottesdienst und kirchliche Kunst, and he is widely known as the author of a work on the Acts of the Apostles (Die Apostelgeschichte, ihre Quellen und deren geschichtlicher Wert (1891). His other works include: Der Knebe Jesus, eine biblische Geschichte und ihre apokryphischen Entstehungen (1883), Die Offenbarung des Johannes (1880), Zur Reform des evang. Kultus (1891), and Zur Geschichte und Literatur des Urchristentums (3 vols., 1893-1901).

Spleen (Gr. σφέννα), a vascular organ situated on the left side of the abdomen (see DEXTROGLANDS). It was supposed in olden times to be the seat of ill-humour and melancholy, whereas the liver was called “to nourish the spleen,” to be out of temper, sly, morose, “spleenetic.”

Spitzberg Pass, one of the passes across the main chain of the Alps from Switzerland to Italy (from 1512 to 1797, however, Chiavenna belonged to the Grisons). The route quits that of the Albulag Pass (q.v.) at Thüssis, passes first through the celebrated gorge of the Vie Mala, then through the Schams basin and past Andere, beyond which the Rofna gorge gives access to the village of Spilgen (from which the pass takes its name) in the upper reach of the main or Hinter branch of the Rhine (q.v.). Leaving to the west the road over the San Bernardino Pass, 7670 ft. (by which the St Gotthard railway line is joined at Biasca, the route lying entirely through Swiss territory) the Splugen road (constructed in 1823) mounts south to the pass (6946 ft.), which forms the political frontier. On the other side the road avoids the old path through the dreaded Car-dinello gorge (here passed Macdonald’s army in December, 1800) in order to descend by zigzags to Yianazzio. Thence past Campo Dolomites and Gallivaggio the descent is made to the ancient town of Chiavenna at the junction of the road from the upper Engadine over the Maloja Pass, and 17 m. by rail above Colico, at the northern end of the lake of Como. The distance by road from Spilgen village (16 m. above Andere) to Chia-venna is 25 m. The diligences take 5½ hours from Spilgen village (4 hours above Thüssis) to Chiavenna. But by the proposal to pierce a railway tunnel of about 16 m. in length from Andere to Gallivaggio, it was calculated that the Splugen line would become the shortest route from southern Germany to Milan, while at Chiavenna it would receive the traffic from the upper Engadine.

SPODUMENE, a lithium-aluminium silicate, named by A. T. to the pyroxene group (see PYROXENE). It was named by B. J. d’Andrada e Silva, in 1800, from Gr. σπόδιος (ash-coloured), in allusion to its grey colour. Soon afterwards J. R. Haly termed it triphase, because it exhibited certain characteristics equally in three directions (τριφάσης, appearing three-fold). Spodumene crystallizes in the monoclinic system, the crystals having generally a prismatic habit and being often striated longitudinally. It has perfect prismatic cleavage, and imperfect cleavage parallel to the clinopinacoid, whilst a lamellar matrix may be developed by parting along the orthopinacoid. The hardness is 6½ to 7, and the specific gravity about 3:16. Though generally a dull mineral, some varieties of spodumene are so brightly coloured and transparent as to be valued as gem-stones. Such is the emerald-green hidenite (q.v.) and the lilac-coloured kunzite (q.v.), whilst a yellow or yellowish-green spodumene found as pebbles in the state of Minas Geraes, in Brazil, resembles, when cut, some kinds of chrysoberyl. Common spodumene is used as a source of lithium in chemical preparations.

Spodumene occurs in granite and crystalline schists. The original specimens came from the isle of U6 in Södermanland, Sweden, but the finest examples are found in the United States, especially in Massachusetts, where Goshen, Sterling and Chesterfield are well-known localities. Very fine specimens have been obtained from the Black Hills of S. Dakota. Some remarkable deposits containing spodumene were discovered many years ago at Branchville, Fairfield county, Connecticut, and the minerals which they yielded were exhaustively studied by Professor G. J. Brush and E. S. Dana. The spodumene occurred in large quantity, in a vein of albite-granite, associated with apatite, garnet, colbomite, pitchblende and other uranium minerals, together with several species of manganese phosphates, termed evespohorite, triplideite, dolomina, etc., and in the same deposit reddiegite, fafeldite and willowite. The spodumene, which has normally the formula LiAl(SiO3)2, becomes altered at Branchville to what has been called β-spodumene, which consists really of the mineral eucryptite (LiAlSiO4) and albite. Eucryptite was named by Brush and Dana from ευκρυπτος (concealed). Further alteration results in the formation of cymatolite, a mineral described by C. U. Shepard in 1867, but shown to be an intimate mechanical mixture of muscovite and albite. The final products of alteration of the spodumene may be muscovite, albite and microcline. The mineral discovered in 1871 in the mining district of Pay Hill at St Albans, and described by T. Thomson as kilfinite, appears to be an altered spodumene.

(F. W. R.*)
SPOHR, LUDWIG (1784–1859), German composer and violinist, was born at Brunswick on the 25th of April 1784. He spent his childhood at Seesen, where in 1798 he began to study the violin, and at six years old was able to take part in chamber-music. He had a few lessons in composition, but, as he himself tells us, he learnt more from studying the scores of Mozart. After playing a concerto of his own at a school concert with marked success, he was placed under Maucourt, the leader of the duke’s band; and in 1798 he started on an artistic tour. This proved a failure; but on his return to Brunswick the duke gave him an appointment in his band, and provided for his future education under Franz Eck, with whom he visited St Petersburg and other European capitals. His first violin concerto was printed in 1803. In that year Spohr returned to Brunswick and resumed his place in the duke’s band. A visit to Paris was prevented by the loss of his favourite violin—a magnificent Guarnierius, presented to him in Russia. After a series of concerts in Berlin, Leipzig, Dresden, and other German towns, his reputation gained for him in 1805 the appointment of leading violinist to the duke of Gothia. Soon after this he married his first wife, Dorette Scheidler, a celebrated harpist. At Gotha he composed his first opera, Die Prüfung, but did not succeed in producing it. Alruna was equally unfortunate, though Goethe approved of it at a trial rehearsal at Weimar in 1806. In this year Spohr heard that Talma was performing at Erfurt before Napoleon’s Congress of Princes, and failing to obtain admission to the theatre, bribed a horn-player to send him as his deputy; and, though he had never touched a horn in his life, he learned in a single day to play it well enough to pass muster in the evening and so to get a good view of Napoleon and the princes in a pocket mirror on his desk. Spohr’s third opera, Der Zweikampf mit der Geliebten, written in 1809, was successfully performed at Hamburg next year. In 1811 he produced his (first) Symphony in E flat, and in 1812 composed his first oratorio, Das jüngste Gericht. In writing this Spohr had used many pieces which he had produced in his first band, and the whole work, as is evident from the groups, was written as a concert piece, and is an interesting and characteristic instance of the constant study with which the contents of Marpurg’s Abhandlung von der Fuge. In 1812 Spohr visited Vienna, and was induced to accept the leadership of the orchestra at the Theater an der Wien. He then began his dramatic masterpiece, Faust, which he completed in 1813, though it was not performed until five years later. His strength and inventiveness as a composer were now fully developed, and enabled him to produce large works with astonishing rapidity. He resigned his appointment at Vienna in 1815, and soon afterwards made a tour in Italy, where he performed his eighth and finest violin concerto, the Scena cantante, with the motto esPressivo drammatico. The leading Italian critics called him “the finest singer on the violin that had ever been heard.” On Spohr’s return to Germany in 1817 he was appointed conductor of the opera at Frankfurt; and in 1818 he first produced his Faust. It was followed by Zemire und Azor, which, though by no means as fine as Faust, soon attained a much greater popularity. Faust suffered from its libretto, which is on quite a different plan from Goethe’s poem.

Spohr first visited England in 1820, and on the 6th of March played his Scena cantante with great success in London at the first Philharmonic concert. This, however, was the profusion in composition. His new symphony (Ne. 2 in D minor) and, instead of having it led by the first violinist and a maestro al cembalo, conducted it himself with a bőton; a great innovation in London at the time. Spohr had a triumphant success both as composer and as virtuoso; and on his side was delighted with the Philharmonic orchestra. At his farewell concert in London Mme Spohr played on the harp for the last time. The restrained attitudes of harp-playing were bad for her health; so in later concerts she played the pianoforte in duets with violin which her husband produced with his usual prompt facility. After a transitory visit to Paris, Spohr returned to Germany and settled for a time in Dresden, where German and Italian opera were flourishing side by side under the direction of Weber and Moschacchi. Spohr could not appreciate Weber’s genius; nevertheless Weber recommended him strongly to the elector of Hesse Cassel as Kapellmeister. Spohr entered upon his duties at Cassel on the 1st of January 1819, and soon afterwards began his sixth opera, Jessonda, which he produced in 1823. This work—which he himself regarded as one of his best—marks an important epoch in his operatic career. It was his first opera on Gluck’s lines, i.e. with accompanied recitative throughout in place of secco-recitative or spoken dialogue; and it was produced in the same year as Weber’s Euryanthe, a work marked by the same departure from German custom.

Spohr’s resources at Cassel enabled him to produce his new works on a grander scale and with more perfect detail than he could have attained in a less well-endowed post; and he never failed to use his privilege to the advantage of other eminent composers, though as a critic he was very difficult to please. Soon after his instalment Mendelssohn, then a boy of thirteen, visited Cassel; notwithstanding the disparity of their years, a firm friendship sprang up between the two, which ceased only with Mendelssohn’s death in 1847. Spohr’s next three operas, Der Berggeist (1823), Pietro von Abano (1827) and Der Alchemyst (1830), attained only fair temporary success. But at the Rhenish musical festival held at Düsseldorf in 1826, his oratorio Die letzten Dinge met with so enthusiastic a reception that it was repeated a few days later in aid of the Greek Insurgents, and became the most famous of his sacred compositions. It is known in English as The Last Judgment. In 1833 Spohr summed up another aspect of his career by publishing his Violin School, an admirable book for advanced students, which stands to the violin much as the combination of Cramer’s Studies with Clementi’s Gradus stands to the pianoforte. The year 1834 was saddened by the death of Spohr’s wife. In 1836 he married again. During 1833 he had been working at an oratorio—Des Heilands letzte Stunden, known in English as Calvary or The Crucifixion—which was produced at Cassel on Good Friday. In 1835 and 1836 Spohr returned to London, Fuji and Naples, with the support of Spohr’s own direction, with an effect which he afterwards always spoke of as the greatest triumph of his life. For the Norwich Festival of 1842 he composed The Fall of Babylon, which also was a perfect success, though the elector of Hesse-Cassel, unmoved by a petition from England almost amounting to a diplomatic representation, refused Spohr leave of absence to conduct it. His last opera, Die Kreuzfahrer, was produced at Cassel in 1845. Of his nine symphonies the finest, Die Weihe der Töne, was produced in 1832. His compositions for the violin include concertos, quartets, duets, and other concert pieces and solos, and among these a high place is taken by four double quartets, (i.e. octets for two antiphonal string-quartet groups), an art-form of his own invention. He was, indeed, keenly interested in experiments, notwithstanding his attachment to classical form; and the care with which he produced Wagner’s Fliegende Holländer and Tannhäuser at Cassel in 1842 and 1853, in spite of the elector’s opposition, shows that his failure to understand Beethoven lay deeper than pedantry. Spohr retained his appointment until 1857, when, very much against his wish, he was pensioned off. In the same year he broke his arm, but he was able to conduct Jessonda at Prague in 1857. This, however, was his last effort. He died at Cassel on the 10th of October 1859.

Spohr’s Selbstbiographie is a delightful document, revealing a character the generosity of which was conspicuous through all its complacent intellectual foibles. He was a born taste-maker, for he mastered the technique of his art safely and then applied his mastery to the expression of exactly those modes of thought which surprise no one who believes that each art-problem has one answer and that the critics know it. But he had a very genuine melodic invention, and his sense of beauty was such as to save the all-pervading mannerisms of his obsolete chromatic style could not quite destroy. He tried every experiment the copy-book optimism of his age could suggest; the subjects of his operas are all that is romantic and necromantic; he wrote almost as much “programme-music” as Berlioz; he invented

1 Not to be confused with The Last Judgment.
"double quartets," he wrote an Historical Symphony tracing the progress of music from Bach to his own day; and, lastly, his gift for orchestration was quite exceptional. Yet not one of his experiments shows any essential connexion between the new form and the old material which he has so skilfully packed into it. Nor is his treatment of his beloved classical forms any nearer to organic life. In conversation with Joachim he once in his last years expressed the ambition to write a set of string quartets "in the strict form with all the passages ending properly with shakes." This shows that all his work as a composer has failed to wean him from the conventions of virtuoso players, and it well illustrates the way in which "strict forms" desert their convenient functions to pose as classical ideas; for the"passage ending in a shake" is merely the easiest known way of finishing a section in concerto style, and is so far from being an essential feature in chamber-music that in the ten mature quartets of Mozart which Spohr undoubtedly regarded as his models it cannot be traced in more than twelve of the thirty-one movements in which it ought to occur.

The nearly level of Spohr's mastery prevents anything of his work from either rising to the height of Mendelssohn's masterpieces, or sinking to the weakness of Mendelssohn's failures. But where the true conditions of an art-form suit Spohr's training and temperament he is, at times, very nearly a great composer; and in the severely restricted medium of duets for two violins his work is an artistic tour de force, the neglect of which would be unfortunate in a wider field than that of mere violin-technique. His best work is not so great that we are obliged to live with it; but its merits demand that we should let it live.

**SPOIL-FIVE.** An old game of cards, probably imported from Ireland, where it is still very popular, though the original name, according to The Compleat Gambler, was "Five-cards." It may probably be identified with "Maw," a game of which James I. of England was very fond. A full pack of cards is used: about five players is the best number, each receiving five cards, dealt in pairs and triplets, the card that is left at the top of the pack being turned up for trumps. If the turn-up is an ace, the dealer must "rob," i.e. put out, face downwards, any card from his hand and take in the ace. The trump suit remains unaltered. "Robbing" must take place anywhere except the first player, the player on the dealer's left, leads. Similarly a player who holds the ace of trumps must rob, putting out any card and taking in the turn-up, but need not disclose the fact till it is his turn to play. A player who fails to rob cannot go out that hand. The card put out may not be seen. The player on the dealer's left leads. The highest card of the suit led—the value of the cards will be explained—or the highest trump, wins the trick. Players must follow suit to a lead of trumps, except in certain cases which will be mentioned. To a plain suit no one need follow except a player who holds no trumps; others may follow or trump as they please. If a player takes three tricks he wins the game. If no one succeeds there is a "spoil," and a fresh stake, smaller than the original one as a rule, is put into the pool for the next round. The order of the cards in plain suits may be remembered by "after the knave the highest in red and the lowest in black." In red suits the order is king, queen, knave, ten, &c., down to the ace, which is lowest: in black suits king, queen, knave, ace, &c., up to ten, which is lowest. But the ace of hearts, which is always a trump, is not reckoned in its own suit. In trumps the order is "below the king the lowest," as in plain suits. The order of red suits is five, knave, ace, of hearts, ace of trumps, king, queen, ten, &c.; in black suits five, knave, ace of hearts, ace of trumps, king, queen, two, three, &c., up to ten, which is the lowest. When trumps are led, the five and the knave of trumps and the ace of hearts need not be played. This is called "reneging," colloquially "renegging." The five may always reneg: if it is led, no card can reneg. The knave may reneg if the five is played, not led. Only the five can reneg to the knave led. The ace of hearts can reneg to any inferior card. If no trumps are led and the ace of hearts is led, a trump must be played if possible: if not, it is not necessary to play a heart. "Twenty-five" and "Forty-five" are varieties of "Spoil-five"; the game is played for either of these numbers; each trick counts five to the maker, and there is no "spoil," but the trick made by the highest trump out scores ten; if a player gets out before that trump is played, he wins the game all the same. The winning of all five tricks is called a "jink"; at "Spoil-five" a player who jinks, if jinking is agreed upon, receives an extra stake all round; but if, after winning three tricks, he elects to "jink" and fails to make a fifth, he loses all he can have won during the trick.

**SPOKANE,** a city and the county-seat of Spokane county, Washington, U.S.A., on both banks of the Spokane river, near the eastern boundary of the state, and about 242 m. E. of Seattle. Pop. (1890), 19,922; (1900), 36,848, of whom 7,833 were foreign-born, including 7,683 English Canadians, 1,326 Germans, and 1,168 Swedes; (1910 census) 104,402. Spokane is served by the Great Northern, the Oregon Railway & Navigation Co. (Union Pacific system), the Northern Pacific, the Idaho & Washington Northern, the Spokane, Portland & Seattle, and the Spokane & Inland Empire (electric) line connecting with the four d'Alène mining region, Idaho, and with Colfax, Washington and Moscow, Idaho. Among the principal buildings of the city are the Federal building, the county court-house, the city-hall, the post office, the Paulson building, the Columbia and Auditorium theatres, the Spokane club, the masonic temple, the Spokane-Review building, and a large Roman Catholic church. Spokane is the see of a Protestant Episcopal bishop. The city has a Carnegie library, and ten public parks aggregating 350 acres; the more important are Liberty Park (25 acres), Riverfront Park (8 acres), and Carlin Park (17 acres). Fort George Wright (established in 1895) is 3 m. west of Spokane on a tract of 1,022 acres given to the United States Government by the city, for that purpose, in 1894-1895. Spokane is the seat of Gonzaga College (Roman Catholic) for boys, founded in 1887 and incorporated in 1904; of Spokane College (1907; Lutheran); of Brunot Hall (Protestant Episcopal), for girls; the Academy of the Holy Names (Roman Catholic), for girls; and of other schools and academies. Among the city's charitable institutions are a home for the friendless (1890), the St John's orphanage (1890), St Luke's (1900) and the Marie Beard Deaconess (1896) hospitals, each having a training school for nurses, a Florence Crittenden home, and a House of the Good Shepherd. The Spokane river is a rapidly flowing stream with two falls (the upper of 60 and the lower of 70 ft.), within the city limits, providing an estimated energy of about 35,000 horse-power at low water. Of this energy, in 1908, about 17,000 horse-power was being utilized, chiefly for generating electricity (the motive power most used in the city's industries), as well as for lighting and transit purposes, while about 9,000 horse-power in electrical power was transmitted to the Coeur d'Alène mines. At Post Falls, Idaho, 20 m. east of Spokane, about 12,000 horse-power is developed, and at Nine Mile Bridge near Spokane, about 20,000 horse-power. Spokane's manufacturing interests have developed with remarkable rapidity. In 1900 there were 84 factories capitalized at $2,211,304, and their product was valued at $3,756,119. In 1905 there were 188 factories capitalized at $5,407,313 (44.5% increase), and the value of their products was $8,830,852 (153.1% increase). The city's principal manufactures in 1905 were: lumber and planing mill products ($2,040,059); flour and grist-mill products ($1,485,097); malt liquors ($670,274); foundry and machine-shop products ($479,959); and general merchandise products ($18,019). Spokane is an important ironing centre, is a natural supply point for the gold, silver and lead mining regions of northern and central Idaho, eastern Washington, and Oregon, and is a distributing point for the rich agricultural districts in this region.

The first permanent settlement on the site of Spokane was made in 1874 by James N. Glover, who bought from two trappers a tract of land here. The settlement was named Spokane Falls, in memory of the Spokane Indians, a tribe of
SPOLETO—SPON

Salishan stock, which formerly occupied the Spokane Valley; the word Spokan is said to mean "children of the sun." Spokane was incorporated as a town in 1887 and in the same year received its first city charter (amended in 1891). The city became the county-seat in 1882. The present name was adopted in 1890. The city was reached by the Northern Pacific railway in 1883, by the Union Pacific in 1889, and by the Great Northern in 1892. On the 4th of August 1880, thirty square miles of land (7,400 acres) were destroyed by fire, with a loss estimated at $5,000,000. Rebuilding was at once begun, and in about two years the city had been almost entirely reconstructed and greatly improved. In 1910 Spokane adopted a commission form of government.

SPOLETO (anc. Spoletium), a town and archiepiscopal see of the province of Perugia, Italy, 18 m. N.N.E. of Terni, and 88 m. N. by E. of Rome by rail. Pop. (1901), 5631 (town); 24,648 (commune). It is situated on a hill, so that the lowest part is about 1000, the highest 1485 ft. above sea-level, at the south end of the open valley of the Tiber, which it joins near Assisi. The principal industries are the collection and preparation of truffles and preserved foods, also tanning and the manufacture of earthenware. Spoleto is also the centre of an agricultural district, and contains a government experimental olive oil factory. There are few towns of Italy which possess so many Roman remains in good preservation under the medieval buildings, and few medieval towns with so picturesque an appearance. There are considerable remains of perhaps pre-Roman polygonal walls in one place, a piece of this walling has masonry of great blocks superposed, and in the walling of two of the Roman municipal magistrates (quaestorii). There are also a few traces of an inner enceinte of the Roman period. There are remains of a Roman theatre, over 370 ft. in diameter, and an amphitheatre 390 by 295 ft. A Roman bridge of three arches, 80 ft. long and 26 ft. high, exists at the lower (north) entrance to the town, under the modern road to Foligno, in the former bed of a torrent which has now changed its course. A Mithraeum was found outside this gate in 1878. The rock above the town was included within the polygonal walls: but Totila fortified, not this rock, but the amphitheatre, which remained the citadel until 1364, when Cardinal Albornoz destroyed it and erected the present Rocca, which was enlarged by Pope Nicholas V.; it is now a prison. The Porta della Fuga (the name alludes to the repulse of Hannibal) occupies the site of a Roman gate, but is itself medieval: while the medieval enceinte encloses a somewhat wider area than the ancient. The Piazza del Mercato represents the Roman forum; close by is a triumphal arch of Drusus and Germanicus, and a temple (?) into which is built the church of S. Ansano. A Roman house in the upper part of the town, with mosaic pavements, on the Via Provinciale to Vespasilla, with the mother of the emperor Vespasian. The Palazzo Municipale, close by, contains the archives and picture gallery. The cathedral of S. Maria Assunta, much modernized in 1644, occupies the site of a church of the Lombard dukes erected about 602. The present church was consecrated in 1198; the façade belongs to the middle of the 12th century. On the main entrance is a large mosaic of Christ enthroned, with the Virgin and St John, by the artist Solernus (1207). The Early Renaissance vestibule (after 1401) is fine. In the choir and on the half dome of the apse, are the finest frescoes of Fra Filippo Lippi (scenes from the life of the Virgin) completed after his death by Fra Diamante: his tomb, erected by Lorenzo de' Medici, with the epitaph by Politian, is on the left of the choir. The fine stalls and panelling in the winter choir date from 1548-1554. In and near the Piazza del Duomo are the unfinished Palazzo della Signoria, of the early 14th century, which contains the archaeological museum, the small Renaissance church of the Mannà d'Oro (1527), the façade of the Romanesque basilica of S. Eufemia (in the archbishop's palace) and the fine Early Renaissance Palazzo Arroni with its grattio frieze. The church of S. Pietro, outside the town on the road to Rome (wrongly supposed to have been the cathedral before 1067), was founded in A.D. 419 by Bishop Achilles. Its façade is remarkable for its richly sculptured decorations of grotesque figures and beasts, which are of two different dates, about 1000 and about 1200. S. Domenico is a fine example of later Italian Gothic with bands of different coloured stones. Both the church and its crypt contain 14th-century frescoes. The triple-apsed crypt of S. Gregorio probably dates from the 9th century: the upper church was consecrated in 1196 and the Romanesque work covered with stucco in the restoration of 1597. S. Nicolò is a beautiful example of Pointed Gothic. The basilica of S. Salvatore (Il Crocifisso) at the cemetery belongs to the 4th century A.D. The fine sculptures of the façade, with its beautiful windows, as also the octagonal dome, all belong to this period; Meliorantius, the sculptor of the portal of the cathedral (after 1155), took its inspiration hence. S. Ponziano, not far off, belongs to the 15th century, but its interior has been restored: the crypt contains frescoes of the 12th century. The city is still supplied with water by an aqueduct, to which belong the bridge called the Ponte delle Torri, crossing the ravine which divides the town from the Monte Luco (2723 ft.). The bridge is 253 ft. high and 755 ft. long and has ten arches: the ground plan is Roman; the stone piers are in the main later (the work is often attributed to Theodelapius, the third Lombard duke, in 604), while the pointed brick arches belong to a restoration of the 14th (?) century. The Monte Luco, which commands a splendid view, has several hermitages upon it.

The first mention of Spoleto in history is the notice of the foundation of a colony there in 241 B.C. (Liv. Epit. xx.; Vell. Pat. l. 14), and it was still according to Cicero (Pro Balb. 21)—"colonia latina in primis firma et illustris"—a Latin colony in 95 B.C. After the battle of Trasimenus (217 B.C.) Spoletium was attacked by Hannibal, who was repulsed by the inhabitants (Liv, xxii. 9). During the Second Punic War the city was a useful ally to Rome. It suffered greatly during the civil wars of Marius and Sulla. The latter, after his victory over Crassus, confiscated the territory of Spoleto (68 B.C.). From this time forth it was a municipium. Under the empire it again became a flourishing town, but is not often mentioned in history. It was situated on a branch of the Via Flaminia, which left the main road at Narnia and rejoined it at Forum Flaminii. An ancient road also ran hence to Nursia. Martial speaks of its wine. Aemilius, who had been proclaimed emperor by his soldiers in Moesia, was slain by them here on his way to Rome (A.D. 233), after a reign of three or four months. Rescripts of Constantine (326) and Julian (362) are dated from Spoleto. The foundation of the episcopal see dates from the 4th century. Owing to its elevated position it was an important stronghold during the Vandal and Gothic wars; its walls were dismantled on the occasion of its capture by Totila in 544. Under the Lombards Spoleto became the capital of an independent duchy (from 570), and its dukes ruled a considerable part of central Italy. Together with other fiefs, it was bequeathed to Pope Gregory VII. by the empress Matilda, but for some time struggled to maintain its independence. In 1155 it was destroyed by Frederick Barbarossa. In 1213 it was definitely occupied by Gregory IX. During the absence of the papal court in Avignon it was a prey to the struggles between Guelphs and Ghibellines, until in 1354 Cardinal Albornoz brought it once more under the authority of the Papal States. In 1850 it became capital of the French department of Trasimene. In 1860 it was taken by the Italian troops after a gallant defence. Giovanni Pontano, founder of the AccademiaPontaniana of Naples, was born here.

See A. Sansi, Degli Edifizi e dei frammenti storici dell'antichità di Spoleto (Foligno, 1869), and other works; G. Angelini Rota, Spoleto e dintorni (Spoleto, 1905); and various articles by G. Sordini, in Notizie degli Scavi (T. As.).

SPON, JACQUES (1647-1685), French doctor and archaeologist, was born at Lyons and died at Vevey. He is famed as a pioneer in the exploration of the monuments of Greece, traveling there in 1675-1676 with the Englishman (Sir) George Wheler
SPONGES

1650-1723), whose collection of antiquities was afterwards bequeathed to Oxford University. Spoon brought back many valuable treasures, coins, inscriptions and manuscripts, and in later years published various important works on archaeology, notably his "Voyage d'Italie, de Dalmatie, de Grèce et du Levant" (1678), and a "Histoire de la République de Genève" (1680).

SPONGES. The Sponges or Porifera form a somewhat isolated phylum (or principal subdivision) of the animal kingdom. This phylum includes an immense number of marine and fresh-water organisms, all of which agree amongst themselves in possessing a combination of important structural characters which is not found in any other animals. Though the phylum is a very large one yet almost the only examples with which the name "sponge" is popularly associated are the common bath sponges (species of the genera "Diplospongia," "Hymeniacidon," "Stylotus," etc.) among the most highly organized and least typical members of the group.

The history of the group begins with Aristotle, who recognized several different kinds of sponge, some of which were used by the Greek warriors for padding their helmets. Owing, however, to the permanently fixed character, irregular growth and feeble power of movement in the adult organism, it was not until the advent of microscopical research that it was definitely proved that the sponges are animals and not plants. Indeed our scientific knowledge of the group can scarcely be said to begin much before the middle of the 19th century, when the classical researches of Bowerbank, E. J. Gray, H. J. Carter and J. S. Bowerbank laid the foundations of modern spongology. It very soon became evident that the group is one which illustrates with remarkable clearness and beauty those laws of organic evolution which were beginning to attract so much attention from zoologists, a fact which found abundant recognition in Ernst Haeckel's epoch-making work on the Calcareaous Sponges published in 1872. This was followed by a series of remarkable researches by F. E. Schulze on the minute anatomy, histology and embryology of the group, which have served as a pattern to all subsequent investigations. In more recent years our knowledge of the sponges has advanced very rapidly, especially as the result of the great series of scientific exploring expeditions inaugurated by the voyage of H.M.S. "Challenger." The large collection made by the "Challenger" expedition alone, necessitated a complete reorganization of our systematic knowledge of the phylum, and afforded the foundation upon which our present system of classification has been built up. There is perhaps no great group of the animal kingdom in the study of which greater advance has been made in the last twenty years. It is impossible in the space at our disposal to do justice to the numerous valuable memoirs which have appeared during this period, but reference to the more important works of recent investigators will be found in the bibliography at the end of this article, while for a comprehensive account of the whole subject the reader should refer especially to Professor E. A. Minchin's article in Sir E. Ray Lankester's "Treatise on Zoology.

General Characters of the Phylum. — The sponges are all aquatic organisms, and for the most part marine. They vary in size from minute solitary individuals, scarcely visible to the naked eye, up to great compound masses several feet in circumference, and in form from almost complete shapelessness to the most exquisite and perfect symmetry. The indefiniteness of shape and size which characterizes the vast majority of the group is due to the power of budding, which is almost universal amongst them, whereby extremely complex colonies are built up in which it is usually impossible to determine the limits of the individual zooids or persons, while very frequently, by a process of integration, individuals of a higher order are produced which again form colonies by budding (fig. 2). The entire body of the sponge is penetrated by a more or less complicated canal-system, beginning with numerous inhalant pores, scattered over the general surface, or collected in special pore-areas, and ending in one or several larger apertures, the vents or oscula, situated usually on the uppermost portions of the sponge (fig. 8). If the living animal be kept under observation it will be seen that a stream of water is ejected with considerable force from the vents, carrying with it minute particles of organic matter. At the same time numerous smaller streams enter the canal system through the inhalant pores, bringing with them the minute particles of organic matter upon which the sponge feeds and the oxygen which it requires for respiration. This stream of water may be temporarily interrupted by the closure of the pores and vents, to be resumed apparently at will. It is maintained by the activity of certain cells, known as collared cells or chonocytes (fig. 35, g, fig. 36), which line the walls of the canal system either throughout their entire extent or in certain regions only. These cells bear an extraordinarily close resemblance to the chonoflagellate Protoprota or collared Monads. Each is provided with a flagellum—like appendage, and the movements of the latter drive the water out of the canal-system through the vents and thus keep up the circulation. In all but the simplest sponges the collared cells are confined to certain portions of the canal system known as flagellated chambers (fig. 9), the size, form and arrangement of which vary greatly in different types. That part of the canal-system which is not lined by collared cells is covered with a flattened pavement-epithelium (fig. 34, 1), and so also is the outer surface of the sponge. The space between the various branches of the canal-system is occupied by a gelatinous ground-substance, the mesoderm, which contains the pores or oscula and in which many protoplasmic cells are imbedded (fig. 34, 3, 4, 5; fig. 35, 6), and in which in most cases a well-developed skeleton is secreted by special cells known as scleroblasts. This skeleton (figs. 24-32, &c.) supports the extremely soft tissues of which the body is composed, and consists either of mineral spicules (carbonate of lime or silica) or of horny fibres (spongins), or of a combination of siliceous spicules with spongins. In many cases the proper skeleton is more or less completely replaced by sand.

The question as to how far the cell-layers of the sponge body correspond to the "germinal layers" usually recognizable in other animals is an extremely difficult one yet not yet by any means settled. It has until recently been generally supposed that the flattened epithelium which covers the outer surface of the sponge, together with part of that which lines the canal-system, is ectodermal, while the collared cells and the remainder of the flattened epithelium lining the canal-system are endodermal, and the term mesoderm has been frequently applied to the middle gelatinous layer. Recent embryological research, however, makes it certain that this view is entirely wrong; and now indeed the germ-layers of typical Metazoa can be identified at all in the Porifera. Embryological research, moreover, tends to show that the primitive gastric epithelia of the larvae are not completely enclosed in the flagellated chambers, but that an invasion of the dermal epithelium (composed of flat pavement-cells) is usual. Reproduction, by means of ova and spermatozoa, is probably universal throughout the group. The segmentation of the ovum gives rise to the free-swimming ciliated larva (figs. 38, 39) in the form of a hollow amphiblastula or of a solid "parenchymula." This larva becomes attached and, by means of a more or less complex metamorphosis, gives rise to the young sponge. During the metamorphosis the outer, ciliated or flagellated cells of the larva take up their position in the interior of the body and give rise to the collared cells of the adult; while the inner cells (of the parenchymula) migrate outwards and form the superficial epithelium, so that the position of the so-called "ectoderm" and "endoderm" is completely reversed in the adult as compared with the larva.

A sexual reproduction is effected by budding, and the buds may either remain attached to the parent and form colonies or become detached and form entirely separate individuals.

Types of Structure. — We may illustrate our account of the general characters of the group by a brief description of the anatomy of three widely divergent types, selected as being fairly representative of the entire group, viz. "Leucosolenia, Plakina" and "Eupongia.

Leucosolenia. — The genus Leucosolenia includes a number of calcareous sponges of very simple structure, and thus forms a suitable starting-point for our studies. Imagine a minute, thinned-out sac (fig. 1), attached at the lower end to some rock or seaweed, and enclosing a spacious cavity in its interior. This cavity is the digestive or excretory cavity, and it opens to the exterior
through a wide vent or osculum at the upper extremity of the sponge. The thin wall is also pierced by numerous small inhalant pores or protosomata. The inhalant pores, the gastric cavity and the vent constitute the canal-system, through which a stream of water can be kept flowing by the activity of the collared cells which line practically the whole of the gastric cavity. Each collared cell, derived from the collar of the type epitheliun, has a thick, plasmic collar, in the middle of which the whip-like flagellum projects into the water. They are placed close together, side by side, and thus form a continuous layer, extending almost up to the vent and interrupted only by the inhalant pores. The outer surface of the sponge is composed of a single layer of flattened pavement-epithelium or epidermis. Some of these cells, distinguished as porocytes, become perforated by the inhalant pores, around which their form contracts, and which are capable of opening and closing, and thus regulating the supply of water. Between the outer protective, dermal epithelium, and the inner gastric epithelium, consisting of collared cells, lies the mesogloea, a layer of gelatinous material containing cells of at least two kinds, amoebocytes and scleroplasts. The former closely resemble the amoeboid white blood corpuscles, or leucocytes, of higher animals, and have the power of wandering about from place to place in the sponge-system. They are able to serve food material and carry away waste products, and some of them undoubtedly give rise to the ova and spermatozoa. The scleroplasts have derived from the dermal epithelium which migrate inwards into the gelatinous ground-substance and there secrete the spicules of which the skeleton is composed. These spicules are composed of transparent crystalline carbonate of lime (calcite), and may be of three fundamental forms: tridrate, monoaxonic, and polyaxonic. It has been shown by E. A. Minchin, however, that the tridrate and quadridrate types are not simple spicules but spicule-systems, each formed of three or four primary spicules, originating from as many mother-cells and only secondarily united. In fig. 1 only tridrate spicules are represented, but very often all three kinds are present in the same sponge (cf. fig. 24). The tridrate spicules lie in the mesogloea with their three rays extended in a plane parallel to the surfaces of the sponge-wall, and form a kind of loose scaffolding upon which the soft tissues are supported. The quadridrate spicules resemble the tridrate in form and position, but a fourth ray is developed which projects towards the layer of collared cells into the gastric cavity, where it serves as a defence against internal parasites. The monoaxonic spicules have one end embedded in the mesogloea while the other project outwards and upwards and serves as a defence against external foes.

The genus *Olynthus* agree essentially in structure, yet exhibit very great diversity in external form. This is due to the habit of budding and colony formation. All start life after the metamorphosis of the larva in the simple sac-shaped condition, which becomes detached, and to which the name "Olynthus-type" is sometimes applied. This is indeed the simplest type of sponge organization known to us and we must look upon the Olynthus as representing a primary sponge-individual or "person." By a simple process of budding, in which the buds all remain united together by their bases, we get a branched colony in which the persons or zooids are still easily recognizable, each with its own vent or osculum. Very frequently, however, the zooids become elongated into slender cylindrical tubes which branch in an extremely complex manner and anastomose with one another in many places to form networks, in which it is no longer possible to recognize the individuality (fig. 2). This type is known as the "Clathrina" type of structure, and we may look upon a Clathrina colony as an individual of a higher order, which may assume a definite external form and even acquire a secondary bud-like opening, the osculum. Others are known as the secondary vent (pseudoculum), while the outer tubes of the colony may give rise to a protective skin (pseudoderm), perforated by secondary inhalant pores (pseudopores) which are obviously quite distinct from the primary inhalant pores or protosomata of the Olynthus.

Other types of colony-formation in the genus *Leucosolenia* will be discussed when we come to the sponges of the oxeate order. After the metamorphosis of the larva in certain species, and the little sponge consists of a cushion-shaped sac, attached below by a broad flattened base and remaining in such a rudimentary state. There is a large gastric cavity lined by pavement-epithelium and surrounded by a number of more or less spherical "flagellated chambers," lined by collared cells. These chambers open into the vent by means of short, semi-circular orifices and communicate with the exterior by smaller inhalant pores. The entire outer surface of the sponge is covered with pavement-epithelium and there is a well-developed mesogloea which may contain spicules. This Rhagon may be compared to an Olynthus which has become flattened out from above downwards and from which a number of small buds (the flagellated chambers) have been given off all round, except from the attached basal portion, so that the whole forms a small colony, in which the collared cells have become restricted to the buds. We may, therefore, perhaps, look upon the Rhagon as an individual or person of a higher order than the Olynthus. Like the Olynthus the Rhagon occurs as a transient stage in the development of certain sponges, but we do not know any non-calcareous sponges which remains in such a simple condition throughout the life. In *Plakina monophora*, for example, the entire wall of the colony becomes thrown into folds, the inner surface of which is formed of an exhalant canal-system in which the inhalant and exhalant canals is formed between the folds, through which the water has to pass on its way to and from the chambers. The inhalant canals lead down between the folds of the outer surface of the sponge. In *P. monophora* they are wide and ill defined. In another species, *Plakina diophora*, they become constricted to form perfectly definite, narrow canals, by the development of a thick layer of mesogloea (and pavement-epithelium) which covers the outer surface of the sponge in such a manner that the folded character is no longer visible externally. The external openings of the inhalant canals now form definite dorsal pores. In such a sponge as this the folded chamber-layer of the sponge-wall is sometimes called the chonosome, while the external layer of mesogloea and pavement-epithelium is called the ectosome. In a third species, *Plakina triloba*, further folding of the osculum and the development of lamellae "takes place and we thus get a still more complex canal-system. In *Plakina* the spicules are composed of colloidal silica. The fundamental spicule form is the simple spicule, consisting of four sharp-pointed rays diverging at equal angles from a central point (fig. 5, a-e). Modifications of this form occur in two directions: in the first place some of the rays, by the suppression of their tips, become shortened, and the entire linear suppression of rays, give rise to forms with three or even two rays only, triactis and diactis, the latter somewhat rounded off (fig. 5, f). The arrangement of the spicula is of a lamellar type (at the surface of the sponge). The other forms are similarly scattered without any sort of order throughout the mesogloea.

The "horny" sponges, to which belong all the finer bath sponges, is a typical example of the true "horny" sponges or *Eucetara*, characterized especially by the fact that the skeleton is not composed of spicules but of so-called horny fibres. A living

fundamental form of individual to which the name "Rhagon" is undoubtedly applied. The first stage is the same as after the metamorphosis of the larva in certain species, and the little sponge consists of a cushion-shaped sac, attached below by a broad flattened base and remaining in such a rudimentary state. There is a large gastric cavity lined by pavement-epithelium and surrounded by a number of more or less spherical "flagellated chambers," lined by collared cells. These chambers open into the vent by means of short, semi-circular orifices and communicate with the exterior by smaller inhalant pores. The entire outer surface of the sponge is covered with pavement-epithelium and there is a well-developed mesogloea which may contain spicules. This Rhagon may be compared to an Olynthus which has become flattened out from above downwards and from which a number of small buds (the flagellated chambers) have been given off all round, except from the attached basal portion, so that the whole forms a small colony, in which the collared cells have become restricted to the buds. We may, therefore, perhaps, look upon the Rhagon as an individual or person of a higher order than the Olynthus. Like the Olynthus the Rhagon occurs as a transient stage in the development of certain sponges, but we do not know any non-calcareous sponge which remains in such a simple condition throughout the life. In *Plakina monophora*, for example, the entire wall of the colony becomes thrown into folds, the inner surface of which is formed of an exhalant canal-system in which the inhalant and exhalant canals is formed between the folds, through which the water has to pass on its way to and from the chambers. The inhalant canals lead down between the folds of the outer surface of the sponge. In *P. monophora* they are wide and ill defined. In another species, *Plakina diophora*, they become constricted to form perfectly definite, narrow canals, by the development of a thick layer of mesogloea (and pavement-epithelium) which covers the outer surface of the sponge in such a manner that the folded character is no longer visible externally. The external openings of the inhalant canals now form definite dorsal pores. In such a sponge as this the folded chamber-layer of the sponge-wall is sometimes called the chonosome, while the external layer of mesogloea and pavement-epithelium is called the ectosome. In a third species, *Plakina triloba*, further folding of the osculum and the development of lamellae "takes place and we thus get a still more complex canal-system. In *Plakina* the spicules are composed of colloidal silica. The fundamental spicule form is the simple spicule, consisting of four sharp-pointed rays diverging at equal angles from a common centre (fig. 5, a-e). Modifications of this form occur in two directions: in the first place some of the tetracts, by the suppression of one ray, become triangular, and the entire linear suppression of rays, give rise to forms with three or even two rays only, triactis and diactis, the latter somewhat rounded off (fig. 5, f). The arrangement of the spicula is of a lamellar type (at the surface of the sponge). The other forms are similarly scattered without any sort of order throughout the mesogloea.

The "horny" sponges, to which belong all the finer bath sponges, is a typical example of the true "horny" sponges or *Eucetara*, characterized especially by the fact that the skeleton is not composed of spicules but of so-called horny fibres. A living

bath sponge appears as a dark-coloured, irregular or sometimes cup-shaped mass attached by the under surface to the sea-bottom. The outer surface is covered by a skin or dermal membrane, elevated in innumerable minute conuli by the growing apices of the primary skeleton fibres. This skin is pierced by a vast number of inhalant dermal pores of microscopic size, and by a much smaller number of comparatively large vents or oscula. When the sponge is removed from the water the soft tissues rapidly decay and leave behind only the elastic "horny" skeleton, which is what we usually speak of under the name "sponge." It consists of a very close network of spongin fibres (closely resembling silk in chemical composition), some of which, known as primaries, run towards the surface at fairly regular intervals, while others, known as secondary...
the property upon which the economic value of the bath sponge depends. In the living sponge the fibres are embedded in the mesogloea, where they are secreted by the mesogloial cells known as spongo-blasts, which are often found thickly clustering around them (fig. 7). The canal-system (figs. 6, 8) is very complex and shows but little indication of its origin from a folded rhizome. The inhalant pores lead each into a short, narrow, inhalant canal; these unite in roomy subdermal cavities lying in the ectosome, and from these in turn the main inhalant canals come off. The latter divide and subdivide, and thus ramify through the deeper parts of the sponge amongst the flagellated chambers, to each of which a small number of slender canaliculi are ultimately given off (fig. 6). The chambers themselves, lined by the usual collared cells, are small and approximately spherical, and each one discharges its water through a short and narrow exhalant canaliculus (fig. 6). The openings of the inhalant canaliculi into the chambers, of which there are several, correspond to the prosopyle of an Olynthus, while the single exhalant opening, or apophy, may possibly correspond to an Olynthus osculum.

Amongst the calcareous sponges, the species of Euplectella, Spongia, Phyllospongia, Tethya, all resemble one another, and the canaliculi unite together to form larger and larger canals which finally lead the stream of water to the vents on the surface of the sponge (fig. 8). The various parts of the canal-system, other than the chambers themselves, are lined by a flat pavement of gelatinous pavement epithelium, and the mesogloea, occupying all the spaces between the different parts of the canal-system, contains cells of various kinds, embedded in a very granular matrix.

Comparative Anatomy.

External Characters.—Amongst the simpler calcareous sponges, which are all of comparatively small size, the external form is usually symmetrical and is evidently a kind of outward expression of the arrangement of the canal-system. This is well seen in the simplest form of all, the sac-shaped Olynthus, and also in its simpler Syconoid and Leuconoid derivatives (described later on), which may be regarded either as individuals of a higher order or as colonies of Olynthus persons grouped around a central individual whose large gastric cavity opens to the exterior through the single osculum. In the more complex Leuconoids, however, the central parts of colony formation become very irregular and may give rise to great compound masses, with many vents. In these cases we may recognize the presence of individuals of three orders: (1) the primitive Olynthus persons, represented by the individual flagellated chambers; (2) the Leuconoid persons, indicated each by its osculum; and (3) the entire colony formed by the union of many such Leuconoid persons in an irregular manner. It is, however, very doubtful how far the flagellated chambers in such forms as this can be regarded as morphologically equivalent secondarily asyzygous individuals.

In the non-calcareous sponges we are always dealing with individuals of a high order, which usually form complex aggregations (colonies) of large size and very various shape. As a general rule the form of those non-calcareous sponges which grow in shallow water is extremely irregular and variable while at great ocean depths the shape is usually definite, constant and often exquisite. As a fact which may perhaps be accounted for in part by the absence of disturbing influences such as are met with in shallow water. In fact the most extraordinary external form yet discovered is that of Esperiops challengieri, discovered by the "Challenger" expedition in deep water off the Philip-

pine Islands (fig. 10), a form which reminds one strikingly of a number of flowers arranged in a raceme, except that the largest and oldest member of the compound colony is at the top of the stalk and the smallest at the bottom. In other deep-water species the external form may be explained as an adaptation to the special exigencies of the environment. Thus, for example, many species are provided with long stalks which lift up the body of the sponge out of the soft ooze in which it would otherwise be anchored, while the bottom of the stalk is frequently extended in root-like processes which serve to attach it to some solid object (e.g., Stylocordyla). In other cases the sponge supports itself on the surface of the ooze by long stiff processes, formed of bundles of spicules which radiate from the central, cap-shaped body; this is known as the "Crinorhiza form," and is met with in several distinct genera (fig. 11). Amongst the Hexactinellida, which are essentially a deep-water group, many very beautiful and special forms may be seen, known as the best known, perhaps, being the so-called Venus's flower basket (Euplectella, fig. 12). Flabellate (or fan-shaped) and cup-shaped forms are frequently met with even amongst shallow-water sponges, and in widely separated genera, such as Poterion (the great Neptune's cup sponge) and Reniera testudinaria. In Phyllospongia the flabellate and cup-shaped forms pass insensibly into one another, the cup being apparently merely a folded lamella. Slender branching forms are also not uncommon in shallow water, as seen in the common Chalina oculata of the British coast. Spherical forms, such as Tethya, likewise occur. By far the greater number of shallow-water sponges, however, are quite irregular in shape and either form crusts of varying thickness on the surface of rocks and sea-weed, or large and massive aggregations which may rise to a considerable height above the substratum. In the boring sponges (Family Clionidae) the sponge occupies an elaborate system of chambers and passages which it excavates for itself in the shells of Mollusca and other calcareous organisms. The common British Clytia celata begins as a tube.
life in this way, but soon outgrows the housing capacity of its host, whose shell then serves merely as a base of attachment for the large independent sponge-colony.

One of the most striking features of living sponges is their colour, which is often very brilliant. Yellow, red, orange, purple, brown, black, green and blue are all met with, in varying degrees of purity and intensity, amongst the commoner Non-calcarea; whilst the calcareous sponges are usually white. Theories have been advanced that the colour is more or less constant for each species, and may therefore afford a useful guide to specific identification. As a rule the colour is lost in spirit-preserved or dry specimens, but a noteworthy exception is found in the brilliant yellow of many of the Rhizomorphs of *Leucosolenia* by which the colour, though soluble in water, is permanent in dry specimens and in alcohol. The colouring matter is sometimes lodged in special pigment cells belonging to the sponge itself, and sometimes in symbiotic algae, with which the mesogloea is frequently filled.

Cana-system.—Whether we start with the primitive Olythus form of the Calcarea or with the advanced Syconid Rhizomorph of the Non-calcarea, it is evident that further advance in the complication of the canal-system is arrived at by either budding or folding, or by a combination of these processes. As, however, the canal-systems of the calcareous and of the main types of non-calcareous sponges have been evolved along perfectly independent lines it will be well to consider them separately.

In the genus *Leucosolenia* (Calcifera, Homocoea) the primitive Olythus form may, as we have already seen, give rise, by branching and anastomosing, to complex reticulate colonies of the Chlathrina type, in which a pseudoderm, pierced by inhalant pores, may cover over a system of inhalant and exhalant canals opening at the extremities of the colonics. These are formed by inhalant pores at the external circumference of the vent or pseudoculmata. In this remarkable modification the colonia, in which the Chlathrina colonies, lined by collared cells, widen out into large irregular spaces, while the inhalant and exhalant canals become constricted into narrow canals lined by collared cells on the outside. We have here a kind of inversion of the ordinary Chlathrina or canal-system, but a perfectly gradual transition from the ordinary to the inverted condition is seen as we pass from the exterior to the younger parts of the colony.

In *Leucosolenia* (Dendys) *tripodifera* (fig. 13) we find a totally different type of colony formation, which is of great importance as indicating in its canal-system the possible starting-point of a line of evolution which culminates in the highest Calcarea. Here a large central individual, whose spicate central cavity is lined by collared cells, gives off radial buds from all sides, which branch slightly and terminate in blind ends in contact with one another, so that the entire colony has an approximately even surface. The inhalant canals are represented by the interspaces between the radial tubes, between the blind extremities of which the water finds its way in from the outside. There is only a single vent, situated at the extremity of the central cavity. This cavity must be regarded as the original gastric cavity of a parent Olythus, from which the radial tubes have been produced by anastomosing.

We have next, amongst the Calcarea Heterocoea, the Syconid canal-system, and the transitional type from the foregoing in that the collared cells of the central gastric cavity are replaced by pavement epidermal. The radial canals form definiteflagellated chambers, pierced as before by numerous prosopyleis through which the water enters from the spaces between the chambers, while the original gastric cavity forms a central exhalant canal terminating in the single vent, a true osculum, corresponding to the osculum of an Olythus. In the simplest Syconid forms (*Sycetta*) the radial chambers remain perfectly straight and unbranched. They do not touch one another at all and there is no trace of an oscosome or dermal cortex, and hence there are no true inhalant canals, and the water circulates without interruption between the chambers.

In the genus *Sycon* (fig. 14) the walls of adjacent chambers come into contact with one another and fuse together and thus give rise to more or less well-defined inhalant "inter-canals." The chambers themselves may branch, and in some species of *Sycon* a thin, pore-bearing dermal membrane connects together their distal extremities and covers over the entrances to the inhalant canals. The canal-system now exhibits all the different parts found in the most highly-organized sponges: viz. dermal pores, inhalant canals, flagellated chambers, exhalant canal and osculum. In the genus *Granilla* and its allies (e.g. *G. cruciata*), the thin dermal membrane of *Sycon* is converted into a well-developed cortex, covering the extremities of the inhalant canals and the radial chambers, and sometimes containing a system of special cortical inhalant canals. We may now distinguish between an oscosome in the (dermal cortex) which contains no flagellate chambers, and a choanosome in which chambers are present. The next stage has probably been arrived at by a kind of folding of the choanosome, for we find the chambers arranged radially, not around the central gastric cavity but around diverticula of the latter which form special exhalant canals. In this condition, sometimes called the "systellic" type, is not characteristic of any particular genus or family, but occurs in a few isolated species, such as *Leucilla connectens* (fig. 16). A somewhat similar condition may be arrived at by branching of the radial flagellated chambers, as in *Heteropagia* (fig. 17). The next stage is marked by great reduction in the size of the chambers, which may become almost spherical, and by further folding of the choanosome, so that in a section of the sponge-wall we see the small chambers scattered irregularly in the mesogloea between the numerous branches of complicated inhalant and exhalant canals. Each
Sponges of osc., central transverse sg. tr., type Flagellated; beautiful ft. g.m., the Region Heteropegma, fundamental Lanuginella, which very elongated sometimes the number relatively is type sponge, system evolved exhalant canals into which the chambers open.

It is almost identical with one of the types commonly found in non-calcareous sponges (e.g. Plakina, fig. 4), but has of course been evolved independently. The various types of canal-system met with in the Calcarea are connected together by numerous intermediate forms, thus forming a very interesting evolutionary series, while both the Sylleibid and Leuconoid types appear to have been independently evolved several times, thus affording excellent examples of the phenomenon of convergence, a phenomenon which is very frequently met with amongst sponges.

Starting from the primitive Myxosponge ancestor, with large sac-shaped chambers, radially arranged, the Non-calcarea have apparently developed along four main lines, giving rise to the existing Myxospongida, the Hexactinellida (Triaxonida), the Tetraxonida and the Euceratosa. The Myxospongida have retained the large size of the chambers in certain forms (Halisarea, Bajalusa), but have lost this primitive character in the more advanced members of the group (Oscarella). The Hexactinellida have retained the large size and radial arrangement of the flagellated chambers throughout their entire series. The chamber layer, however, tends to become more or less folded (fig. 19), and always lies between two layers of loose trabecular tissue in which the canals are represented by irregular spaces. The Tetraxonida appear to have suffered reduction in the size of the flagellated chambers at a very early date, and it is of this group especially that the Rhagion type is characteristic (e.g. Plakina, fig. 4). The Euceratosa exhibit a beautiful series,
beginning with forms *(Aplysillidae)* having large sac-shaped chambers like those of Hexactinellids and ending with forms *(Spongiidae, Euspongia, figs. 6, 8, 9)* having small spherical chambers.

Along all four lines of descent it is probable that folding of the choanosome, or chamber-bearing layer of the sponge-wall, has played a very important part in the evolution of the canal-system. This folding is very clearly seen in the Hexactinellida and in such forms as *Osearella* (Myxospongida) and *Plakina* (Tetrasaxonia). By this process inhalant and exhalant canal-systems have been formed, and then the ends of the inhalant canals have in most cases been closed in by development of an ectosome, as in *Phakma triophora* and *Stelletta phris sensis* (fig. 20). In the majority of cases (e.g. *Tedania*).

To this type (fig. 4, f) the name "eurypylous" has been given, and we may include in it cases where there is only a single prosopyle, and perhaps even a short, narrow inhalant canal. In such forms the water is discharged from each chamber through a narrow exhalant canalculus (aphodus) peculiar to itself, and thence into wider canals. This is known as the "aphodal" type (e.g. *Corallium*, fig. 21). In the "dipodal" type there is a special inhalant canalculus (prosoplos) as well as a special aphodal to each chamber, with usually, at any rate, only a single prosopyle (e.g. *Corallium*, fig. 22). The progress from the eurypylous to the dipodal condition is accompanied by a corresponding increase in the development of the mesogloea, whereby the canals are greatly restricted in diameter, and at the same time the choanosome tends to lose its transparent gelatinous character and to become compact and granular.

With the growth of the sponges, we necessarily get a corresponding development of the proximal portion of the inhalant canal-system. At first the choanosome is merely a thin membrane, the dermal membrane, pierced by the inhalant pores, which are usually arranged in groups. Beneath the groups of pores (prosopyleaile areas) lie spacious subdermal cavities which form the commencement of the inhalant canal-system in the choanosome. In more advanced types the choanosome becomes greatly thickened and may become strengthened in a variety of ways to form a cortex. The inhalant pores no longer lead directly into the subdermal cavities, but first into a series of cavities lying in the cortex and known as chones, which may be separated from the underlying subdermal cavities (sub-cortical crypts) by definite sphincters (*Cydonium*, fig. 23).

The arrangement of the oscula and pores on the surface of the sponge varies greatly in different types, and sometimes plays a part in the most striking modifications of the external form. The oscula or vents are usually relatively large openings situated on the more prominent parts of the sponge, often on special elevations. Occasionally they are replaced by sieve-like oscular areas (e.g. *Geodia peromata*, a modification which doubtless serves to prevent foreign bodies from entering the wide exhalant canals. The inhalant pores may be irregularly scattered over the surface of the sponge or collected in more or less well-defined arealen areas. In cup-shaped sponges the pores are usually confined to the outer and the oscula to the inner surface. In flabellate sponges we find pores on one side and oscula on the other. In *Tetania actiniformis*, a deep-sea form, the pores are restricted to a narrow band surrounding the columnar body of the sponge just beneath the flattened top, while the oscula are on the way through the body, then they are kept from being choked up by the soft zoophy on which the sponge lies. In *Xestospongia*, a flattened discoid form, they are confined to narrow grooves on the upper surface, the chief of which run round the margin of the disk. In *Euplectella*, the pores are also confined to special grooves on the surface of the sponge, and in both these cases the grooves can apparently be opened and closed by special bands of muscle-fibres, and the supply of water thus regulated. In some species of *Larinaeula* we find the surface of the sponge covered with...
SPONGES

conspicuous projections of two kinds, some conical and bearing each a single vent, others truncated at the top and bearing the inhalant pores.

Skeleton.—The original ancestral form (Protospongia) from which all the Porifera are supposed to be descended, probably possessed no proper skeleton at all, and this condition has been retained in the existing Myxospongia, although these sponges have made considerable progress in the evolution of their canal-system. There appears to be little doubt that the Myxospongia are primitively devoid of skeleton, and in this respect they must be carefully distinguished from the genus Chondrosia, in which the skeleton has been secondarily suppressed, as well as from numerous and diverse species in which the proper skeleton has been more or less completely replaced by grains of sand or other foreign bodies. The Calcarea, Triaxonida, Tetraxonida and Euceratida, except in cases of extreme degeneration, all possess a well-developed proper skeleton. As this skeleton has been independently evolved in each of these great groups it is necessary to deal with it separately in each case.

Calcarea.—The skeleton in this group is composed of spicules of crystalline carbonate of lime (usually calcite), developed within special mother-cells or scleroblasts. Each spicule is enclosed in a delicate membranous spicule-sheath and contains an axial thread of organic matter. These main types of calcareous spicule are met with, triradiate, quadri-radiate and monaxon (fig. 24). The triradiates and quadri-radiates, however, are not simple spicules, but spicule-systems formed of three or four rays each originating independently from its own scleroblast (actinoblast) and all uniting together secondarily. There is reason to believe that this may also sometimes be the case with the monaxon or oxeate spicules. In the most primitive triradiate spicules all three rays lie in the same plane. Three chief varieties may be distinguished: (1) Regular (fig. 24, a), with all the rays and all the angles equal; (2) Sagittal (fig. 24, c, d, i, l, etc.), with two of the rays or two of the angles forming a pair, differentiated in some respect from the remaining ray or angle, the paired rays being termed "oral" and the odd ray "basal"; (3) Irregular (fig. 24, p), when conforming to neither of the above types. It has been proposed to draw a very sharp distinction between "equiangular" triradiates and "alate" forms (in which the angle between the oral rays differs from the paired angles), but it may be doubted whether such a distinction has any great value. The quadri-radiate (fig. 24, e, f, k, m) is formed by the addition of an "apical" or "gastral" ray to the three "facial" rays of the triradiate; this ray lies in a plane at right angles to that of the facial rays. The monaxon spicules (fig. 24, h, i, q, r, s) are straight or curved, and the two ends are usually more or less sharply differentiated from one another. In all these spicules the form and arrangement of the rays is usually clear, but in the sponge in such a manner that they are specially adapted for the work which they have to do. The arrangement of the spicules in the case of the genus Leucozoa has been dealt with above, and we must pass on at once to the Calcarea. In this group there is a well-marked evolutionary series no less remarkable than that of the canal-system. We may take as a convenient starting-point the genus Syceida, a typical Syconoid form, with the flagellated chambers radiating independently from the central gastric cavity. The wall of the gastric cavity is supported by a gastric skeleton of triradiate or quadri-radiate spicules. These may be sagittal, in which case the oral rays are turned towards the osculum while the basal ray is directed downwards. If there is an apical ray it projects into the gastric cavity. The walls of the radial chambers are supported by a special "tubal" skeleton (cf. fig. 14), consisting exclusively of

trippled spicules with their basal rays directed towards the distal end of each chamber. The oral rays are spread out at right angles to the length of the chamber, and as several spicules generally lie at the same level the tubar skeleton forms 3 series of more or less definite joints and is said to be "articulate." This type of skeleton is almost invariably associated with the Syconoid type of canal-system. In the genus Sycon itself we find the distal ends of the chambers specially protected by tufts of monaxon spicules (fig. 14), but the next great advance in the evolution of the skeleton is brought about by the development of a dermal cortex, in which a special dermal skeleton is developed. This is well seen in the genus Ute (fig. 15). After this the skeleton of the chamber layer in the sponge-wall begins to undergo modifications, some of which are obviously correlated with the gradual change of the canal-system from the Syconoid to the Leuconoid condition (cf. figs. 16 and 17). Finally all trace of the articulate tubar skeleton is lost, and we get a "parenchymal" skeleton of scattered radiate spicules in the chamber layer. The skeleton of the chamber layer, no matter what the type of canal-system, may be supplemented by large subdermal sagittal triradiates or subdermal quadri-radiates (fig. 17), whose basal or apical rays project inwards from the dermal cortex (Heteropidae and Amphoriscidae). Very generally a special "ocular" skeleton is developed in the form of a fringe of long monaxon spicules around the vent.

Various aberrant types of skeleton are met with in the group. In the genus Leucosia we find a partly fibrous skeleton, in which the fibres are composed of bundles of triradiates shaped like tuning-forks (fig. 24, q), and in Petrostoma the main skeleton is formed of calcareous spicules actually fused together. In Astrosclera (fig. 25) a very anomalous type of calcareous skeleton is found, consisting of spherical masses of aragonite, each originating in a special scleroblast and having a radiate structure, recalling that of a silicious
Sponges

The body of a sponge is closely packed together over large areas of the surface. These bodies are composed of colloidal silica deposited in concentric lamellae forming smaller axes of an organic substance which in life occupies the axial canal of the sponge. These axes are among the most characteristic of the sponge itself and are the basis of the classification of the sponge into the orders of the Hexactinellida. The hexactinellid type, characterized by the presence of three radii intersecting each other at right angles and thereby dividing into two rays or actines (fig. 26, c). According as one, two, three, or five of these actines are suppressed, we distinguish between pentact, tetract, diact, and monact spicules, and these may be further subdivided according to special modifications of the rays due to secondary branching, ornamentation by spines, or of concave, convex, or convexity of certain rays as compared with the remainder. Some of the most characteristic of these special types are illustrated in figs. 27 and 28. Two of them require special notice on account of their importance in the classification of the group. These are the hexaster and the amphidisc.

A hexaster (rosette) is a perfectly symmetrical hexact which actines branch out into secondary or terminal rays, in a star-like manner (fig. 30). Various sub-types are distinguished according to the character of the rays (floricate, plumicome, &c.). An amphidisc (fig. 27, d) is a diact spicule consisting of two opposite rays each of which terminates in a disk-like or spherical expansion surrounded by marginal teeth.

In some cases the spicules all remain disconnected from one another (Lysiscene condition), in others some of them may be united by silicious cement into a continuous framework (Dicyctinae condition), and the presence of these two types of arrangement was for a long time considered as indicating a primary subdivision of the Hexactinellida into Lysiscina and Dicyctina, but the latter view was abandoned by the term _fracture_ is applied to spicules which project freely from the surface of the sponge, and these are further distinguished as _basal_, _pleural_, or _marginal_, according to their position at the base of the sponge, on the sides, or around the margin of the osculum. The basal spicules frequently form a root-tube for attaching the sponge to the substratum (_Hyalonema, Exspereta_), and commonly have anchor-like distal extremities. They may be extremely long, as in the well-known "glass-ropes" of _Hyalonema_. In the remarkable genus _Monoraphis_ we find a single gigantic diact spicule, which may attain a length of two or three feet and the thickness of a lead pencil, transfixing the body of the sponge like a skewer from above downwards. A special dorsal skeleton is usually formed by a number of spicules distinguished as _dermal_, and a gastric skeleton may be similarly formed by special _gastric_ surrounding the central gastric cavity of the sponge. The dermal and gastric skeletons are formed of spicules, known as _pencrymmalia_, forming the most important part of the skeleton, supporting the chamber-layers and adjacent tissues. The distinction between large _megascles_ and small _microscles_ is perhaps less well marked in this group than in the _Tetragonida_.

Tetragonida.—Here, again, the spicules are composed of colloidal silica deposited around organic axial threads. The starting-point in the division of the very complex series of tetragon spicules is the primitive tetract or _caltrops_, characteristic of the most primitive members of the group (e.g. _Plakina_). This fundamental form (fig. 26, d) consists of four rays or actines of equal length, which meet one another at equal angles in the centre of the spicule, while their apices would occupy the four angles of a regular pyramid whose sides are four equilateral triangles. It is thus both _tetraactinellid_ (with four axes) and _tetragoneactinellid_ (with four rays). In _Plakina_ the spicules are all of about the same size, neither very large nor very small, but in higher forms we usually find a predominant formed megascles and others reduced to form microscles. The megascles play the principal part in building up the skeleton while the microscles are usually scattered through the mesogloea.

Triaene SERIES OF MEGASCLES.—When three rays (cladi) of the tetract resemble one another, while the fourth (shaft) differs in some respect the spicule is termed a triaene. The simplest form is the _plagioptia_ (fig. 29, 2), with three short simple cladi and an elongated shaft, the angles all remaining approximately equal. If the angles between the cladi and shaft become approximately right angles we have an _orthotriaene_. If the cladi pion forward, we have a _prototriaene_ (fig. 29, 6). If the cladi are turned backwards towards the shaft we have an _amatriaene_ (fig. 29, 5). If the cladi branch each into two we have a _dichotheia_ (fig. 29, 3). If the cladi are expanded laterally and fused together to form a plate, while the shaft is reduced, we have a _dischotheia_ (fig. 29, 4). The cladi may be reduced in size or even suppressed (fig. 29, 7, 8), leaving only the shaft, which may be either sharp at each end (oxtate) or sharp at the apex and rounded at the base (styline). The spicule has now become _monaxonid_ or _monaxonellid_ (i.e. with a single axis) and _monactinellid_ (with only a single ray), but this condition may also be arrived at in different ways, as we shall see directly.

The _tetracrepid desma_ (fig. 29, 9), characteristic of many Lithistids, has been derived from the primitive tetract by ramification of the ends of all the rays.

Monaxonid SERIES OF MEGASCLES.—We have already seen, in _Plakina_, how a diactinellid spicule may arise by suppression of two rays of the tetract (fig. 5). At first the two remaining axes...
are distinctly indicated by the presence of an angle in the middle of the ray (figs. 29, 10, 31), by straightening out of this angle we reach a monaxonid but diactinellid condition—the diactinellid oxate, with the organic centre of the spicule in the middle (fig. 29, 11). By rounding off of both ends this form passes into the strongylote (fig. 29, 12), then if both ends become enlarged into knobs it is said to be tylostyle (fig. 29, 13). If one end only is rounded off, it apparently usually takes place by suppression of one ray, while the other remains sharp, the spicule is termed stylostyle (fig. 29, 12). It is now monaxonid as well as monaxonid. If the blunt end of the style enlarges to form a knob we have the tylostyle (fig. 29, 13).

Acanthoxeates (fig. 29, 16), acanthohyles and acahotylyles (fig. 29, 14) are formed by the development of spicules on the surface of the spicule. The development of large recurved spines at the apex of a tylostyle gives us the cladostylole or granpel spicule (fig. 29, 15), which simulates an anatiaiene. By enlargement of the spiny base of an acanthohyle and suppression of the shaft we get forms which simulate astrose microsceleres and may be called pseudasters (fig. 29, 144, 145). Pseudasters also may be developed by shortening up of acanthoxeates, accompanied by enlargement of the spines (e.g. Spongillinae, fig. 29, 166). The exostyle appears to have been formed by enlargement of the outer end of a radially placed oxate at the surface of the sponge. By ramification of both ends of a diactinal megasclere we get the monaxonid desma (fig. 29, 20), characteristic of certain Lithistids and closely simulating the tetracrepid desma. By ramification of one end of a strongylote spicule we may get a cladostylole (fig. 29, 19).

**Diactinal Series of Microsceleres**—The starting-point of this series is the primitive angulate, diactinal oxate (fig. 29, 10). This has given rise to long hair-like forms or raphides (fig. 29, 28), short hair-like forms associated in bundles and called trichoderagnata (fig. 29, 34), and C- and S-shaped forms or sigmata (fig. 29, 30). From the sigmata may be initiated by the development of the triaenes. The cladis of these spicules are commonly extended in or beneath the ectosome and form a very efficient dental skeleton, while the shafts are directed centripetally through the choanosome. In the genus Discoridemia the discotreniae form a continuous dental armour of siliceous plates. When anatiraenes and protiateres are developed their cladi commonly project beyond the surface of the sponge and render it more or less strongly histic, thus forming a protection from the attacks of enemies. The shafts of the triaenes, though greatly reduced in Discoridemia, usually become very much hypertrophied and may be grouped together in bundles, often associated with oxate spicules. These spicules, or bundles of spicules, now form the principal part of the skeleton, and inasmuch as they radiate from the interior towards the surface of the sponge we distinguish this as the radiate type of skeleton. The skeleton of the vast majority of Tetraxonida is either actually radiate in structure or derived from the radiate type by further modification. In many Stellateididae, for example (fig. 31), we have a typical radiate skeleton in which a large number of the spicules retain the primitive tetracrepid form, though associated with oxates, while in Tetys the skeleton is arranged in a similar manner but only monaxonid spicules are present. From the radiate we pass to the reticulate type of
skeleton which characterizes the majority of the so-called Monaxononellida. This is derived from the former by the establishment of secondary spicule-bundles connecting the primary or radial bundles together, and the transition is usually accompanied by loss of the clad of the trianes and by the development of a massive irregular form on the part of the entire sponge. An intermediate condition is found in some of the massive species of Tetilla (e.g. T. limicola), in which the spicule-bundles are very well defined and form distinct primary fibres in the interior of the sponge, but no distinct secondary or connecting fibres are yet developed.

In the Sigmatomonaxonellida, derived from the Tetillidae, the reticulate type of skeleton is almost universal, and in this group an entirely new element is introduced into the skeleton with the development of a 'horny' cementing material (spongian) which unites the spicules together in the fibres. At first small in quantity (Remiera, fig. 32, A), the spongian cement gradually increases in proportion to the spicules until in many Chalininae (fig. 32, B, C) and Desmacididae the spicules become completely embedded in it, and the fibres may be formed chiefly of spongian, with only a core of spicules. The complete enclosure of the spicules by spongian at a very early stage cuts off their food supply and causes arrest of development. Finally, in some Chalininae (fig. 32, D) and Desmacididae the spicules entirely disappear from the interior of the fibre, and if at the same time they happen to be absent from the intervening mesogloea we get a skeleton composed exclusively of horny matter or spongian, to which the term pseudoceratose may be applied. In the sub-family Ectyoninae the skeleton becomes modified in an interesting manner by the development of 'echinating' spicules, usually acanthostyles or acanthorylstyles, whose bases are cemented on to the fibre by spongian while their apices project into the surrounding soft tissues. These doubtless serve to defend the most important internal organs of the sponge. In the echinating spicules may persist after the spicules have entirely disappeared from the interior of the strongly developed horny fibre. In the Axinellidae all the spicules in the fibres are typically more or less echinating in character and the fibres become plume-like.

Very frequently a special dermal skeleton is developed in the ecosphere altogether distinct from that formed by the clad of the trianes (when these are present). Thus in the Geodidae (fig. 23) the thick cortex is almost filled with densely packed sterratians. In many forms there is a dense layer of small radially arranged monaxonan spicules of the type which protect the surface and form an efficient protection. In the reticulate forms the ecosphere is usually a thin dermal membrane supported by a reticulate dermal skeleton of slightly different structure from the 'main' skeleton. In cases where a special stalk is developed this may be a dermal attachment and also find a special and appropriate skeleton in connexion therewith.

In the so-called Lithistidae alone amongst the Tetraaxonida do we find the spicules (desmas) united together by silica to form a coherent skeleton, sometimes of stony hardness, very different from the elastic, flexible skeleton resulting from the development of spongian, and analogous to the condition met with in the Dictyonine Hexactinellida.

The microscleres usually play quite a subordinate part in the formation of the skeleton, being scattered irregularly throughout the mesogloea, though sometimes (Geodia, Tethya) the asters may form a definite cortical layer.

Euceratose.—In the true horny sponges, if we neglect for the moment the presence of foreign bodies, we may say that the skeleton consists from the first exclusively of spongian, secreted (by special spongoblasts) in concentric layers to form very well-defined fibres.

In the two higher forms (Aplysilla, Dendrilla) this horny skeleton is dendritic in arrangement (fig. 33), composed of fibres which rise vertically upwards from the base of the sponge (where they may be expanded to form a horny basal cuticle which serves for attachment) and radiate towards the whole surface, where their apices push against the dermal membrane and cause it to project in the form of 'conuli.' No reticulation is formed in the simplest cases (Aplysilla, Dendrilla), but in Megalopasites secondary connecting fibres are established (in relation, doubtless, to the increasing in size and massive form of the sponge), and the skeleton thus simulates the pseudoceratose reticulate type of the Sigmatomonaxonellida. In Dendrilla we have, in addition to the dendritic skeleton, isolated "spicules" of spongian scattered irregularly through the mesogloea. The presence of these spicules, which are sometimes, though by no means always, hexactinellid in form, has given rise to much speculation as to their nature, and partly to the development of the "arenaceous" sponges also occur in other groups (e.g. Desmacididae). The culminating point in the development of the true horny skeleton is found in the Spongellidae (e.g. Euapogia), but even in the bath sponge (fig. 6) we commonly find sand grains or other foreign matter in the interior of the primary fibres. The value of the sponge for domestic purposes depends upon the softness and elasticity of the fibre, the closeness of the mesies, and the relative absence of sand.

Histology.

There are two primary tissue-forms in sponges, the flat pavement epithelium and the epithelium composed of choanocytes or collared cells. The former covers the whole of the external surface of the sponge and, except in the simpler Calcarea Homocella, it also lines a considerable portion of the canal-system. The latter lines prytically the whole of the primitive gastric cavity in the Calcarea Homocella, but in all higher types becomes restricted to well-defined "flagellated chambers." A gelatinous "mesogloea," which must be regarded primarily as an intercellular substance, appears between the primitive outer and inner layers of the sponge-wall. This contains primitive amoeboid wandering cells (archaeocytes),

Sponges

which give rise to the ova and spermatzoa, and also various other cells which are now generally believed to migrate into it from the primitive pavement epithelium (dermal epithelium) of the outer surface, such as spheroblasts, various connective tissue elements and contractile fibres.

Pavement Epithelium (fig. 34, 1).—This always consists of a single layer of polygonal cells, which are usually flat and very rarely (Oscarella) provided with cilia or flagella. They may be glandular and may secrete a definite cuticle (as in many Euceratosa). They may also be highly contractile.

Porocytes.—In certain Calcareous sponges (Leucosolenia) it has been shown (by E. A. Minchin) that the primitive inhalant pores (prosopyles) are formed as perforations in certain of the pavement epithelium cells, which acquire a tubular form and extend through the mesogloea from the dermal to the gastric surface. The outer portion of each porocyte forms a contractile diaphragm which doubtless regulates the admission of water to the gastric cavity. The porocytes are sometimes conspicuous on account of their highly granular character.

Scleroblasts.—We may distinguish three kinds of scleroblasts, according to the chemical character of the skeletal material which they secrete; these are calcoblasts, silicoblasts and spongoblasts. The calcoblasts and silicoblasts (fig. 35, h–n) form their respective spicules, at any rate in the first instance, as intra-syncytial (perhaps sometimes intra-syneutial) secretions, though we must suppose that in the case of large spicules the later stages in growth are accompanied by development of a definite collar or mother-cell, as in many spheroblasts in co-operation.

The spongoblasts (fig. 7) appear to co-operate with one another in the formation of the sponge film from the beginning. They are found only around the young, growing fibres, where they occur in large numbers, forming a single, or sheath of somewhat flattened cells, each placed at right angles to the surface of the fibre and with the nucleus in its broad distal end. The spongion is secreted in contact with the filament and is obviously intercellular in origin, and probably of the same nature as the cuticle which often occurs on the surface of the sponge.

Connective-tissue Elements.—The following are the chief forms assumed by the mesogloea according to the nature of its connective-tissue cells and intercellular substance. (a) Collenchesy, consisting of a clear gelatinous matrix with branching stellate collenchesytes (fig. 35, a) embedded in it; (b) Sarcomesch, in which the quantity of gelatinous matrix is more reduced and the connective-tissue cells are closely packed together; (c) Cystenchesy (fig. 7, Coll. fig. 35, c), consisting of close-packed, oval, vesicular cells with fluid contents and strands of protoplasm radiating from the nucleus to the periphery; (d) Chondrenchyme (fig. 35, b), somewhat resembling cartilage in form and with a very large amount of intercellular matrix.

The name desmacytes has been given to certain slender connective-tissue fibres (fig. 35, d) often united in dense bundles or layers, which occur especially in the ectosome of many Tetraxonda, giving rise to a fibrous cortex of leathery consistency.

Contractile Fibres.—Muscular fibres or myocytes (fig. 35, e) are of common occurrence, especially in relation to various parts of the canal-system, the diameter of which appears to be regulated by their agency. They may form definite sphincters around the vents or in other places (fig. 34, 2), or they may form transverse bands lying in the floor of pore-bearing grooves, by the contraction of which the lips of the groove are doubtless approximated and the incumbent stream of water shut off (Euppelia murrayi, Xenospongia flagelliformis).

Endothelial Cells.—In many sponges the developing embryos are enclosed in definite capsules composed of flattened polygonal cells, the whole being embedded in the mesogloea. The origin of the endothelial cells forming the capsule is doubtful. They sometimes aid in the nutrition of the developing embryo (e.g. in Stellospongia flagelliformis).

No nervous elements, nor sensory cells of any kind, have as yet been recognized with any degree of certainty in sponges, in spite of various heroic attempts to demonstrate their existence.

Collared Cells or Chasmocytes (fig. 35, g).—These are quite the most characteristic histological elements met with in sponges. Although exhibiting various minor differences in structure, and still more as regards size, they always show the same essential features. Each consists usually of an oval or rounded body (frequently appearing polygonal from the pressure of its fellows) surrounded by a more or less cylindrical or funnel-shaped collar, which surrounds a single long, whip-like flagellum projecting from the apex of the cell. The collar is a filmy, transparent extension of the cytoplasm (cell-protoplasm), which can be completely withdrawn. The flagellum may also be withdrawn, and preserved specimens neither collar nor flagellum is usually visible. The cell is usually broadest at the base and narrowed to form a neck or "collum," beneath the collar. The nucleus may be situated either at the base or at the apex of the cell-body or even between the two. The collar itself is often a more complicated structure than

One of the best-known cases is that of the calcareous genus Sycon (fig. 38). The fertilized ova develop into ciliated larvae within the parent sponge, embedded in the walls of the radial chambers, in their endothelial capsules. Each divides first into two, then into four, and then into eight equal and similar blastomeres by successive vertical clefts. The eight-celled stage (fig. 38, b, c) has the form of a somewhat flattened cushion, with an axial cavity which is the beginning of the blastocoele or segmentation cavity. A horizontal cleft now divides each blastomere into a somewhat smaller upper and a somewhat larger lower portion, and the sixteen blastomeres arrange themselves in the form of a hollow sphere surrounding the blastocoele. The smaller cells multiply rapidly and become columnar, while still remaining as a single layer. Each one presently acquires a flagellum ("cilium") at its outer end. The larger cells multiply more slowly and are characterized by their coarsely granular appearance. They are destined to give rise to the dermal layer and its derivatives (including archaeocytes?) and never become flagellated. The blastosphere or blastula (fig. 38, d, e) is now complete, the blastocoele being completely surrounded by a single layer of cells differentiated, however, into two groups, gastric and dermal. The large granula (dermal) cells now become invaginated, but this is only a temporary condition, probably to be explained as the mechanical result of the pressure of the spicules of the parent sponge. The beginning of "pseudogastrula" thus formed escapes by rapture

Reproduction. Reproduction in sponges may be effected in one of three ways: (1) The first is by vegetative budding, followed by separation of the buds and thus differing from the ordinary budding which leads merely to increase in the size of the sponge-colony. This process has been observed in many cases (e.g. Leucaulonema, Ocarella, Lophocalyx, Aplysilla). (2) The second way is by the formation of specialized reproductive bodies known as gemmules. This process is best known in the fresh-water sponges (Spongillinae), where it has been developed as a special means of tiding over unfavourable periods during which the parent sponge is liable to be destroyed by cold or drought. Each gemmule consists of an aggregation of amoeboid cells (statocytes) densely charged with nutrient granules and enclosed in a protective horny envelope which may be strengthened by a layer of special spicules. The ripe gemmule is very resistant to adverse conditions and is capable of remaining dormant for a lengthened period, and of developing into a new sponge on the return of favourable conditions. In temperate climates the gemmules remain dormant throughout the winter and develop in the spring, the development being very similar to that of an ordinary fertilized ovum except that it begins at the "morula" stage, with the numerous statocytes representing the blastomeres. (3) The third way is by the union of ova and spermatozoa to form zygotes, which undergo segmentation and develop into the adult through a more or less complex series of ontogenetic stages. Previous to fertilization the ovum undergoes a process of maturation accompanied by the extrusion of two polar bodies, as in higher animals. Very little is known about the actual process of fertilization, but it appears probable that this is effected in the inhalant canals of the parent sponge, where the ova have been observed suspended from the epithelial lining of the canals (e.g. in Aplysilla). After fertilization they appear, usually at any rate, to migrate back into the mesogloea, where they become surrounded by endothelial capsules and undergo segmentation. In Spongiopygium flagellophorus the cells of the capsule are of gigantic size and are attached to the superficial blastomeres of the developing embryo by protoplasmic processes, through which, no doubt, nutrition is passed from the parent to the embryo.

Embryology. The segmentation of the ovum appears to be in all cases complete or holoblastic, and the young sponge usually leaves the parent in the form of a free-swimming ciliated larva, which, after fixing itself to some object, undergoes a metamorphosis and then grows into the adult form. The details of development appear to differ widely in different species and various interpretations have been placed upon somewhat limited and discordant observations.

One of the best-known cases is that of the calcareous genus Sycon (fig. 38). The fertilized ova develop into ciliated larvae within the parent sponge, embedded in the walls of the radial chambers, in their endothelial capsules. Each divides first into two, then into four, and then into eight equal and similar blastomeres by successive vertical clefts. The eight-celled stage (fig. 38, b, c) has the form of a somewhat flattened cushion, with an axial cavity which is the beginning of the blastocoele or segmentation cavity. A horizontal cleft now divides each blastomere into a somewhat smaller upper and a somewhat larger lower portion, and the sixteen blastomeres arrange themselves in the form of a hollow sphere surrounding the blastocoele. The smaller cells multiply rapidly and become columnar, while still remaining as a single layer. Each one presently acquires a flagellum ("cilium") at its outer end. The larger cells multiply more slowly and are characterized by their coarsely granular appearance. They are destined to give rise to the dermal layer and its derivatives (including archaeocytes?) and never become flagellated. The blastosphere or blastula (fig. 38, d, e) is now complete, the blastocoele being completely surrounded by a single layer of cells differentiated, however, into two groups, gastric and dermal. The large granula (dermal) cells now become invaginated, but this is only a temporary condition, probably to be explained as the mechanical result of the pressure of the spicules of the parent sponge. The beginning of "pseudogastrula" thus formed escapes by rapture
of the parent tissues into a radial flagellated chamber and passes to the exterior with the outgoing stream of water. The invaginated dermal cells are pushed out again and the "amphiblastula" swims away (fig. 38, e). (Possibly the granular dermal cells, by proliferation, may form a solid mass blocking up the blastocoele completely, so that we have a solid embryo.) The larva now fixes itself by the anterior flagellated pole (which, according to Schulze, becomes permanently invaginated, thus giving rise to a true gastrula, fig. 38, f, g) and the dermal cells spread themselves out over the gastral cells, which they completely cover. The fixed larva ("pupa") consists of a solid mass of gastral cells enclosed in a single layer of now flattened dermal cells. Presently the gastral cavity appears (or reappears) in the middle, around which the gastral cells arrange themselves in a single layer. The young sponge elongates upwards, some of the dermal cells forming porocytes which become perforated by prosopyle, others migrate into the gelatinous mesogloea and form scleroblasts, from which spicules are secreted. The cells of the gastral layer acquire collars in addition to their flagella, an osculum is formed by perforation at the apex, and the young sponge begins to feed. It is now in the Olythus condition (fig. 38, h) and is exactly comparable to a simple Leucosolenia individual. As it grows older radial flagellated chambers are budded out around the central gastric cavity and the collared cells lining the latter are replaced by pavement-epithelium derived from the dermal layer.

An interesting account of the development of Leucosolenia (Clathrina) blanca has been given by E. A. Minchin. Segmentation is regular and complete, resulting in the formation of a hollow, ciliated, oval blastula (fig. 39, A), with a large blastocoel and a wall composed of a single layer of columnar flagellated cells and a pair of very large granular cells at the posterior pole. The latter are primitive archaeocytes and are destined to give rise to the amoebocytes and germ-cells of the adult. The flagellated cells will give rise to all the other cells of the adult, both dermal and gastric. The larva becomes free-swimming in this condition, and there and individual flagellated cells (destined to form the cells of the dermal layer) lose their flagella and, becoming amoeboid, migrate into the blastocoele, which presently becomes completely filled with such cells. The larva is thus converted into a solid "parenchymula," in which the archaeocytes remain unchanged in their original position at the posterior extremity. It now fixes itself and flattens out upon the substratum in the papula condition. During the metamorphosis which now ensues the majority of the cells of the inner mass (dermal cells) pass out to the exterior again between the flagellated cells (gastral cells), over which they spread themselves in the form of a dermal layer of flat cells. Some, however, remain in the inner mass as porocytes; the primitive archaeocytes have divided up into amoebocytes; and porocytes, amoebocytes, and the cells of the gastric layer are all crowded together in the interior, the last-mentioned cells are arranged vertically. A gastric cavity appears in the interior. The cells of the gastral layer arrange themselves around this cavity and develop their collar and haemal organs; the gastric cavity is lined by the porocytes, which presently separate and migrate outwardwards. Scleroblasts migrate inwards from the dermal layer and secrete spicules. An osculum and prosopyle are formed as in Sycon and the Olythus condition reached.

The development of sponges in general appears to be characterized by a remarkable want of uniformity in the arrangement of the different kinds of cells of which the larva is composed. Two, or possibly three, distinct primary flagellated cells, which will give rise to the collared cells of the adult, the non-flagellated (granular) cells, which will give rise to the dermal layer and its derivatives, and possibly the primitive archaeocytes (perhaps to be regarded as undifferentiated blastomeres). It may be considered doubtful, however, whether the primitive archaeocytes can in all cases be distinguished from the primitive dermal cells. The latter are in some cases (amphiblastula type) grouped at the posterior pole of the larva (Sycon), while in other cases (parenchymula type) they may pass inwards and completely fill the interior, blocking up the blastocoel and perhaps also freely projecting at the anterior end (Hyrtios). At the same time the derivative of the dermal cells pass to the outside and come to completely enclose the gastral cells, so that the two layers acquire their proper relative positions. The species are mainly divided into two main groups: (a) the Coelenterate "planula," with its ectoderm and endoderm, but it is very doubtful how far this comparison is valid, and in the present state of our knowledge it is perhaps better to avoid the use of the term collared larva altogether.

The idea naturally suggests itself that the two primary layers of the Sponge correspond to those of the Coelenterate, but in a reversed position, the inner layer of the one being the outer layer of the other, and vice versa, and this idea has found expression in the name Entosia which has been proposed for the group by Yves Delage, but which has not met with general acceptance.

Physiology.

Comparatively little is known of the physiology of sponges. The most obvious expression of the vital activity of the organism is the stream of water which flows through the dermal pores or ostia and out through the vents or oscula. That this stream is maintained by the undulatory movements of the flagella of the collared cells there can be no doubt, but the fact that the movements of the flagella of different cells are not co-ordinated, so that they do not act in unison, indicates that the mechanical problem involved is not so simple as is usually supposed. There can be no doubt that the incoming stream brings with it minute food-particles, consisting of fragments of organic matter, alive or dead, and also the oxygen required for purposes of respiration while the outgoing stream removes faecal products and waste matter (excreta). The rate of flow appears to be regulated by the opening and closing of the pores and vents, or of intermediate apertures such as the apertures of the latest openings or intermediate chambers. This opening and closing may be effected by the activity of muscular sphincters (fig. 34, 2) or, in the case of some prosopyle, by the contractility of the porocytes themselves.

The ingestion of the food particles is no doubt effected in large measure by the collared cells, which seem to feed much in the same manner as independent collared monads (Choanoflagellata). It seems not improbable that Sollas's membrane may be a temporary structure which assists in arresting food particles as they pass out into the gastric chambers. There is reason to believe also that amoebocytes (in this case therefore phagocytes) may capture minute organisms on their way through the canal system, and pass them on to the collared flagellate for digestion. Digestion, no doubt, is, at any rate chiefly, intracellular. The amoebocytes probably serve not only to ingest food themselves but also to receive surplus food from the collared cells and distribute it through the sponge (fig. 34, 5).

Nothing definite is known as to the function of excretion, but here, as in the case of nutrition, it seems likely that collared cells and amoebocytes are both concerned.

1 The position of the porocytes inside the collared cells appears at first sight very anomalous, but Minchin has shown that this condition is actually repeated in the adult sponge every time the gastric cavity is obliterated by contraction.
SPONGES

Sponges, as we have already seen possess no special nervous system and no special sense organs, and the power of response to stimuli appears to be very limited. Many sponges probably have the power of contracting as a whole, which may in some cases be due, in part at any rate, to the presence of bands of muscular fibres, and Sollas observed that irritation of the oscular margin is invariably followed after a short interval by a slow closure of the siphon. The power of movement in adult sponges is, however, chiefly confined to individual cells acting independently. The young larvae are often free-swimming, but are, like many other sponges, cemented in the Jurassic beds to foraminifera or flagella, whose movements must obviously be co-ordinated in order to ensure the progress of the entire organism in definite directions.

The rate of growth of sponges appears to be very rapid. A British species of Hymeniacidon is said to form a crust measuring a foot in diameter in so short a period as five months. With this rapidity of growth must be associated the fact that many sponges, marine as well as fresh-water, appear to be annual.

Distribution.

The vast majority of sponges are marine, only a single sub-family, the Spongillidae, having acquired the habit of living in fresh water. The Spongillidae are, however, very widely distributed, being found in lakes and rivers in all parts of the world. Marine sponges occur everywhere, from low-water mark to the greatest depths, but certain localities, such as the Gulf of Manaar, Port Phillip and Port Jackson, appear to be more rich than others both in individuals and species. The Heteroxenia are essentially a deep-water group and are therefore much more rarely met with than other forms. The Tetraxonia and Eucercotidae abound in shallow and in moderately deep water, and the Leucosoleniidae and the Grantidae are generally found at great depths. Both are dominant groups at the present day, represented by very large numbers of species and individuals. The Hexactinellida are comparatively rare and represented by very few species. They are characteristic of the littoral region, especially in sheltered situations amongst rocks and seaweed.

Most families and even genera of sponges enjoy a very wide geographical range, very many being cosmopolitan. Species are usually much more restricted in distribution, but even here there are some noteworthy exceptions, and future researches will probably show that many species from different localities which are at present regarded as distinct are connected by intermediate forms living in intermediate situations.

There appears to be a well-marked relation between temperature and the power of spong-secretion, and as a result we find that species of sponges occurring in tropical or sub-tropical regions, are comparatively warm waters. This fact brings about a striking contrast between the sponge-faunas of different latitudes.

Classification.

The classification of the Phylum Porifera, the characters of whichhave already been given, is as follows:-

Sub-phylum and Class Calcarea.—Sponges with a skeleton composed of carbonate of lime, commonly in the form of isolated spicules, and the sponge has a regular shape. Each spicule is a simple, unbranched and two-rayed (not more) skeleton (Sclerocalyptas) which is characterize by the shape in which it is enclosed. The skeleton is composed of three distinct orders:—

Order 1. Homocela.—Calcarea in which the skeletal cavity and its outgrowths are lined throughout by collared cells. This order is sometimes divided into sub-orders: Leucosoleniidae, Callymeniidae, and Chalinidae. The former is the simplest, and the latter is the most complex, of the three. The skeleton consists of an outer layer of spongy tissue, with a central axis of Calcarea rod-shaped, and a central axis of Calcarea cylindrical. The Calcarea are divided into two families:—

Order 2. Heterocela.—Calcarea in which the skeletal cavity is lined by a layer of collared cells. This order is divided into four families:—

Class Triaxonia (= Hexactinellida).—Sponges with a skeleton composed of siliceous spicules, either isolated or cemented together by siala, and either triaxonal or hexactinellid in form or both (i.e. triaxonal and hexactinellid). The Calyx in this case and the skeleton is formed of spongy tissue, and the skeleton is formed of a central axis of Calcarea cylindrical and a central axis of Calcarea rod-shaped. The Calyx is composed of three distinct orders:—

Order 1. Amphidiscophora.—Triaxonia with characteristic amphidisc sponges, but no hexactinellids, and with a root-tub of anchoring sponges. The family Hyalonematidae, including the well-known M. Berson, is the only family regularly recognized in this order.

Order 2. Hexasterophora.—Triaxonia whose most characteristic spicules are hexactinellid, and which belong to the families Eulipocystidae, Asconematidae, Rossellidae, Eutetridae, Melittionidae, Coscinoporidae, Tretodictyidae and Maaedrophoridae, and a number of extinct families such as the Venididae, the Veritididae so commonly met with in the Jurassic rocks. These are known as the Amphidiscophora. The Tetraxonida are a simple system, with small, more or less spherical flagellated chambers.

Class Tetraxonida.—Sponges with a skeleton composed of siliceous spicules, either isolated or cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). The Tetraxonida is a very diverse group, and it is not possible to give a complete list of the families, but the following are the most important:—

Order 1. Homostrophicidae.—Tetraxonida in which the microscleres are either isolated or cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). The Tetraxonida is a very diverse group, and it is not possible to give a complete list of the families, but the following are the most important:—

Order 2. Astrophyora.—Tetraxonida with triaxone microscleres, with and without sigmata. This order includes the families Pachastrellidae, Theinidae, Stellettidae, Geodideria.

Order 3. Sigmatophora.—Tetraxonida with triaxones, with sigmata for microscleres (when present), without asters. This order includes the families Tetractinidae and Spermatidae.

Grade (order) Lithistida.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 1. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 2. Astrophyora.—Tetraxonida in which the primitive tetraxonid and tetractinellid condition of the microscleres has been entirely lost through suppression of some of the spicules, so that none but monaxonellid microscleres remain. This order includes the families Tetractinidae and Spermatidae, and is the most important of the order. The Tetractinidae are divided into three sub-orders:—

Class Monaxonida.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 1. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 2. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 3. Sigmatophora.—Tetraxonida with triaxones, with sigmata for microscleres (when present), without asters. This order includes the families Tetractinidae and Spermatidae.

Grade (order) Lithistida.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 1. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 2. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 3. Sigmatophora.—Tetraxonida with triaxones, with sigmata for microscleres (when present), without asters. This order includes the families Tetractinidae and Spermatidae.

Grade (order) Lithistida.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 1. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 2. Astrophyora.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.

Order 3. Sigmatophora.—Tetraxonida with triaxones, with sigmata for microscleres (when present), without asters. This order includes the families Tetractinidae and Spermatidae.

Grade (order) Lithistida.—Tetraxonida in which the microscleres are cemented together, and either triaxonal and tetractinellid in form or both (i.e. triaxonal and tetractinellid). No desmas are developed.
SPONGES

which are, so far as we know, totally unrepresented at the present day.

It is quite remarkable and at present inexplicable spicule forms (fig. 29). In many of the more advanced Tetragonida, especially in the Chaetidae, the development of sponge cement also appears a new factor in the process of evolution. At first serving merely to glue the megascleres together into a continuous framework, it ultimately, in some extant genera, completely encloses the skeleton and gives rise to a purely "horny" skeleton in which all traces of spicules have been lost by degeneration. Thus we arrive at a "Pseudoceratose" condition (fig. 32, D) which must be carefully distinguished from the "condition of the skeleton, which has apparently branched off quite independently from Myxosponge ancestors. Here we have another typical example of that phenomenon of "convergence" which has rendered the classification of sponges so very difficult. In the Euceratid group of descent we start with forms (Aplysilla) with large sac-shaped chambers and altogether primitive canal system, accompanied by an arborescent horny skeleton (fig. 13) of the type of pycnocrustose Tetragonida. From this we ran trace the evolution gradually through the Spongillidae to the Spongiidae, the skeleton becoming reticulate and the canal system gradually more complex with accompanying reduction in size of the chambers. The bath sponge perhaps represents the culminating point in this direction. Thus it appears that both the horny type of skeleton and the siliceous spicular type have been twice independently produced in the evolution of the non-Calcarea. An analogous case of convergence is seen in the union of originally separate spicules into a coherent skeleton by means of cement of the same chemical composition as themselves. This has taken place independently in the groups (Petrostoma), the Dictyonyma, the Hexactinellida and the Lithistid Tetragonida.

Affinities of the Porifera.

Three main views have been put forward with regard to the position of the Sponges in the animal kingdom: (1) that they are colonies of Protozoa; (2) that they form a family of the Coelenterata; (3) that they are not Protozoa but have originated from Protozoan ancestors quite independently from other Metazoa (Enterozoa). The first of these views, associated especially with the names of James Clark and Saville Kent, is supported by the relative independence of the constituent cells in the sponge-body and by the extraordinary resemblance of the collared cells to the choanoflagellate or collared Monads. It is also supported by the existence of a remarkable colonial form of Choanoflagellate (Proterospongia) in which the collared Monads are partially embedded in the surface of a gelatinous matrix, in the interior of which amoeboid cells are found. A. A. Menchin has shown that even in the adult Leucosolenia (Clathrina) the collared cells and porocytes have the power of changing their relative positions, while migration of dermal and gastric cells and consequent inversion of the layers appears to be a common feature of the sponge larva at the time of metamorphosis. These facts are certainly suggestive of Protozoan colonies rather than of Metazoa. On the other hand it must not be forgotten that migratory amoebocytes (leucocytes) occur in probably all groups of Metazoa, while the degree of integration and the similarity of histology in Sponges are far greater than in any other Protozoan colonies known to us. It has been argued that the process of sexual reproduction by means of ova and spermatozoa is fatal to the Protozoan-colony theory, but this argument is completely disposed of by the discovery of spermatozoa and ova in the unicellular Sporoza. On the other hand the occurrence of collared cells has been held to distinguish the Sponges from all other Metazoa, and this argument has also been answered by the discovery of collared cells in the larva of Echinococcus (an Echinoderm) by H. Theil. It would, in short, be difficult to frame a definition of the Protozoa which should absolutely exclude the Sponges, while at the same time our conception of the nature of Protozoa will have to be profoundly modified if we are to admit the Sponges within the limits of that group.

The second view, that the Sponges constitute a subdivision of the Coelenterata, is maintained by some very eminent continental authors such as Ernst Haeckel and F. E. Schulze. This view is supported by the structure of the Olythus type, which, as we have seen, forms the starting-point of Spongidae. This larva has the appearance of a normal leucoselene, the gastrula layer as endoderm and the mesogloea with its contained cells as mesoderm, more highly developed

FIG. 41.—Spicules of Heteractinellida.

Phylogeny.

The most recent views as to the evolution and inter-relationships of the principal groups of sponges above enumerated may be conveniently expressed by the accompanying phylogenetic tree (fig. 42). Starting with the hypothetical Protozoon, as the ancestral form of the entire group, we see how two divergent lines of descent are very early established according to whether or not a calcareous skeleton is developed. The Calcarea are at first simple Olythus forms, Homoscolex, differing only from the Protolynthus in the presence of the calcareous spicules. From these are derived, by the process of budding, on the one hand reticulate forms (Clathrina) and on the other radiate forms (e.g., Leucosolenia tripodiform), and some of the latter (now probably extinct) form the starting point for the evolution of the Calcarea Heteroscolex, beginning with simple Spongellid forms and ending with complex Leucoscolex in which the original process of simple budding has been followed up by elaborate modifications of both skeleton and canal system.

Turning to the other main line of descent we find at once a conspicuous gap between the Protolynthus and the simplest known non-calcareous sponge; though the analogy of the Calcarea makes it easy to understand how the almost Spongellid canal system of the simplest Hexactinellida, or the primitive Agelas type of other groups, may have been derived from the Protolynthus ancestor in the first instance by simple budding. This line of descent may be regarded as continued straight on into the existing Myxospongida, with increase in the complexity of the canal system, due to folding of the chamber-bearing layer and the accompanying development of inhalent and exhalent canal systems, but without the development of any skeleton. The Triaxonida and Euceratida would seem to have branched off independently at a very early stage from the Myxosponge line, before the flagellated chambers had suffered that reduction in size which occurs in some existing Myxospongida and in all Tetragonida. In the Triaxonida the skeleton has played the principal part in the evolution of existing species, but the canal system too has undergone great modifications. The primitive triaxonid, tetractinellid siliceous spicules must have arisen quite independently, their fundamental form being totally different from that of the triaxonid hexactinellid type. The appearance of differentiated microscleres in this group introduced new possibilities of variation, of which full advantage has been taken, and we are confronted with a most interesting evolutionary series, terminating in many very

FIG. 42.—Phylogenetic Tree, showing the supposed relationships of the principal groups of sponges to one another.
Sponges

than in most Coelenterates. It is also supported by a consider-
able amount of agreement in the early stages of development, up to the formation of the ciliated larva. According to this view the Olynthus, or at any rate the imaginary "Protolunthus" is only a slightly modified gastrozoa, and the Sponges are therefore Entozoans without any coelom, or in other words Coel-en-
terata. The extraordinary histological differences between the Sponges and other Coelenterates (Cnidaria), combined with the highly characteristic canal system and the absence of tentacles, are, however, alone sufficient to throw grave doubts upon the probability of a close relationship between the two groups, and these doubts are greatly strengthened by recent embryological researches, which tend to show that the so-called ectoderm and endoderm are not homologous in the two cases.

There remains the third view, in accordance with which the Sponges are not Entozoans, but are highly modified Entozoans, a view which at present seems to have most in its favour. It is especially associated with the name of W. J. Sollas, who invented the term "Parazoan" for the group. In support of this view it may be pointed out that the tendency to form hollow, spherical colonies, resembling the blastostate stage in the development of Enterocozoa, is met with in very distinct groups of Protozoa (e.g. Volvox, Sphaerocozoa). This form of colony is obviously polyphyletic in origin. The fact that the segmentation of the ovum leads to such a form in both Sponges and Enterocozoa is therefore by no means conclusive evidence that Sponges and Enterocozoa have originated from the same Protozoan group. While, as has been repeatedly pointed out, the universal and characteristic collared cells of sponges point emphatically to a Chononflagellate ancestry, it is impos-
sible, in the present state of our knowledge, to indicate the par-
ticular Protozoan group which has given origin to the Enterocozoa. We may then consider the Metazoa, or many-celled animals, as a polyphyletic, or at any rate diphylectic group, including two perfectly distinct lines of descent from the ancestral Protozoan, the Sponge-line on the one hand, which leads to nothing higher than Sponges, which retain in many respects the characters of Protozoa, and the Enterocozoa line on the other, which leads through the Coelenterata to the Coelomata and so on to the highest divisions of the animal kingdom.

Economical.

All the bath sponges belong to the two genera Eupopsia, Brunn, and Hippopsangia, Schulze, subdivisions of the old genus Spongia, auctorum, distinguished from one another by the fact that in Hipposangia the body of the sponge is traversed by wide ramifying canals or vesibules, in addition to the proper canal system of the sponge. Species of these two genera occur in many parts of the world, probably wherever the temperature of the sea-water is sufficiently high and the depth and bottom suitable. It is only in a few localities, however, that they occur in sufficient numbers and of sufficiently good quality to render a sponge fishery practicable. The sponges of commerce are obtained chiefly from the Mediterranean, the coast of Florida and the Bahama Islands. From the Mediterranean three dis-
tinct species are obtained,—(1) Eupopsia officinalis, which includes the "fine sponges," with two chief varieties, mollissima (the Levantine sponges, very soft and often cup-shaped), and adriatica; (2) Eupopsia simoca, including the "hard" or Zimocca sponges; (3) Hippopsangia equina, the "common" or "horse" sponge.

Of the Florida sponges five principal kinds are recognized by the dealers,—(1) the sheep's wool sponge (Hipposangia gossypina)—this appears to be by far the most abundant in the market and also the most valuable; (2) the yellow sponge (Eupopsia agaricina), resembling the Zimocca sponge of the Mediterranean; (3) the grass sponges (including both Hip-

popsangia graminea and H. cerebriformis); (4) the violet sponge Hippopsangia maculata, which is not so common as the others; (5) the glove sponge (Eupopsia tubufifora), which is the least valuable. In the year 1909 the Florida sponges yielded 418,125 lb of sponges, valued at $67,685. The Bahama sponges appear to be very similar to those of Florida.

Both sponges occur in comparatively shallow water and are obtained by diving, by dredging, or by means of a Trident or long-handled fork. The preparation of the sponges for the market is extremely simple. The slimy soft tissues very soon begin to decay and run off when they are removed from the water; after this has gone on for some time the sponges are washed and beaten until the skeleton is clean, they are then threaded on string and dried. They are frequently "loaded" with foreign matter by the dealers in order to increase their weight; rock-salt, glucose, molasses, lead, gravel, sand and stones being used for the purpose. They are also often bleached by means of chemicals to give them a better colour, but though their appearance is thereby greatly improved, their durability is said to be impaired.

In spite of the undoubted rapidity with which sponges grow, as shown by the fact that on the coast of Florida marketable sponges are found commonly in places that had been stripped of saleable specimens in the preceding year, there appears to be considerable danger of injury to the sponge industry by over-

fishing and by the reckless destruction of young specimens, and it has been found necessary to introduce special legislation in America to counteract these evil tendencies. The question of the artificial propagation and cultivation of sponges has also been much discussed, but although some very interesting experiments have been made, they have not as yet led to any great practical results. As far back as 1862 Oscar Schmidt showed that "cuttings" of sponges will attach themselves and grow. This idea was followed out in the experiments of G. Bucchini on the Island of Lesina, from 1863-1872, but these experiments were brought to a close by the hostility of the native fishermen. Similar experiments have since been made on the Florida sponge-grounds. The possibility of rearing sponges in this way has thus been fully demonstrated, but whether the process can be done profitably is another question. According to the experience of G. Bucchini it appeared that they would take seven years for the cuttings to attain marketable size in the Mediterranean. The Florida experiments, on the other hand, indicate a much more rapid rate of growth, and it has been stated that under favourable conditions the cuttings will attain marketable size in about half the time as one year. It has been doubted, however, whether the total weight of sponges produced by cuttings would be greater than the weight of the sponges from which the cuttings were taken if these cuttings were allowed to continue their growth undisturbed. H. Y. Wilson has suggested that sponges may be artificially reared from the eggs of the bath sponge, like those of other sponges, develop into free-swimming ciliated larvae, and these might be made to attach themselves, like oyster-spats, to suitable objects, on which the young sponges could be cultivated under appropriate conditions. Detailed experiments are required to demonstrate the feasibility or otherwise of this interesting suggestion.

APIA SOURNETY—SPONTINI

(from Lat. sponsire, to promise), one who stands surety or another, especially in the rite of Christian baptism, a godfather. The person who performs the baptism, but in the custom of requiring an adult pagan who offered himself for the rite to be accompanied by a Christian known to the bishop, who vouch for the applicant and undertake his supervision, thus fulfilling the function performed in the Eleusian mysteries by the mystagogus. The Greek word for the person undertaking this function is ἄρθωμος, to which the Latin sussútor is equivalent. The word "sponsor" in this ecclesiastical sense occurs for the first time, but incidentally only, and as if it were already long familiar, in Tertullian's treatise On Baptism (vol. 18., 18), where, angling that in certain circumstances baptism may conveniently be postponed, especially in the case of little children, he asks, "For why is it necessary that the sponsors likewise should be thrust into danger, who both themselves by reason of mortality may fail to fulfil their promises, and may also be disappointed by the development of an evil disposition [in those for whom they become sponsors]?"
The sponsors here alluded to may have been in many cases the actual parents, and even in the 5th century it was not felt to be inappropriate that they should be so; Augustine, indeed, in one passage (op. cit. p. 138) says: "I was even very close to being the child's sponsor when, by the Junian prohibition of marriage between godparents and godchildren. On the other hand, the anciently allowable practice of parents becoming sponsors for their own children, though gradually becoming obsolete, seems to have lingered until the 9th century, when it was at last formally prohibited by the council of Mainz (813). For a long time there was no fixed rule as to the necessary or allowable number of sponsors and sometimes the number actually assumed was large. By the council of Trent, however, it was decided that one only, or at most three sponsorship was necessary, in addition to the mother.
The rubric of the Church of England according to which "there shall be for every male child to be baptized two godfathers and one godmother, and for every female one godfather and two godmothers," is not older than 1661; the sponsors are charged with the duty of instructing the child, and in due time presenting it for confirmation, and in the Catechism the child is taught to say that he received his name from his "godfathers and godmothers." At the Reformation the Lutheran churches retained godfathers and godmothers, but the Reformed churches reverted to what they believed to be the more primitive rite, that in ordinary circumstances this function should be undertaken by the child's proper parents. Most churches demand of sponsors that they be in full communion. In the Roman Catholic Church, priests, monks and nuns are disqualified from being sponsors, either because it might involve their entanglement in worldly affairs," or more probably because every relationship of fatherhood or motherhood is felt to be in their case inappropriate. The spiritual relationship established between the sponsor and the baptized, and the sponsors and the parents of the baptized, constitutes an impediment to marriage (see MARRIAGE: Canon Law).

SPONTINI, GASPARO LUIGI PACIFICO (1774-1851), Italian musical composer, was born on the 14th of November 1774 at Majolati (Ancona) in Italy. He was the son of a poor cobbler and was intended for the priesthood. His musical propensities however were not to be restrained, and he obtained lessons from Kapellmeister Quintilliani. In 1791 he went to the Conservatorio de' Turcini at Naples, where he was trained to write operatic music under Paisiello, Cimarosa and Fioravanti. His first opera, L'Eroismo ridicolo, was successfully produced in 1796, and by 1799 he had also acquired notation fairly well. After becoming court composer to King Ferdinand of Naples in this year an intrigue with a princess of the court compelled Spontini to leave Naples in 1800. For the next few years he wrote operas in Rome and Venice until 1803 when he settled in Paris, where his reception was anything but flattering. His comic opera Julie proved a failure; a successor, La Petite maison, was bussed. Undaunted by these misfortunes, he abandoned the light and somewhat frivolous style of his earlier works, and in Milos, a one-act opera produced in 1804, achieved a real success. Spontini henceforth aimed at a very high ideal, and during the remainder of his life strove so earnestly to reach it that he frequently remodelled his passages five or six times before permitting them to be performed in public, and wore his singers by introducing new improvements at every rehearsal. His first masterpiece was La Vestale, completed in 1805, but kept from the stage through the opposition of a jealous clique until the 15th of December 1807, when it was produced at the Académie, and at once took rank with the finest works of its class. Spontini had abandoned the porlando of Italian opera for a legato manner, but had increased the strength of the orchestra and introduced the big choral finale; Ferdinand Cortez, was received with equal enthusiasm in 1809; but another, Olympia, was much less warmly welcomed in 1819. Napoleon, whose approval of any work of art was at once a compliment to the artist and a serious imputation on the value of the work, professed immense admiration for Spontini's music.

Spontini had been appointed director of the Italian opera in 1810; but his quarrelsome and grasping disposition led to his summary dismissal two years later, and, though reinstated in 1814, he voluntarily resigned his post soon afterwards. He was in Paris until ill health compelled him to leave the capital. On the 28th of May 1820, five months after the failure of Olympia, he settled in Berlin by invitation of Frederick William III, commissioned to superintend all music performed at the Prussian court and compose two new grand operas, or three smaller ones, every three years. But he began by at once embroiling himself with the intendant, Count Brühl. Spontini's life in Berlin may be best described as a caseless struggle for precedence under circumstances which rendered its attainment impossible. Yet he did good work. Die Vestalin, Ferdinand Cortez and Olympia—the last two entirely remodelled—were produced with great success in 1821. A new opera, Neunmahal, founded on Moore's Lalla Rookh was performed in 1822, and another, entitled Alcide, in 1825; and in 1826 Spontini began the composition of Agnes von Hohen- sluften, a work planned on a grander scale than any of his
The former efforts. The first act was performed in 1827, and the complete work in three acts graced the marriage of Prince William in 1829. Though the German critics abused it bitterly, Agnes von Hohenstaufen is undoubtedly Spontini's greatest work. In breadth of conception and grandeur of style it exceeds both Die Vestal und Ferdinand Cortez, and its details are worked out with uniriting conscientiousness. Spontini himself, however, was utterly dissatisfied with it, and at once set to work upon an entire revision, so that on its re-presentation in 1837 many parts were scarcely recognizable by those who had heard the opera in its original form.

This was his last great work. He several times began to resolve his debt to Gluck, to Mozart, to Milon, and contemplated the treatment of many new subjects, such as Sappho, La Côte d'Accèlile, and other works of genius, through sheer envy of the laurels won by their composers. But the critics and reviewers of the period were so closely against him that it is difficult to know what to believe. After the death of Frederick William III. in 1840 Spontini's conduct became so violent and imperious that he was sentenced to five months' imprisonment for lèse-majesté. The sentence was remitted by Frederick William IV., but on the 2nd of April 1841, when he appeared at the conductor's desk to direct a performance of Don Juan, he was greeted with hisses and groans, and his orders to raise the curtain were ignored, so that he was compelled to leave the desk. The king dismissed him on the 25th of August, with power to retain his titles and live wherever he pleased in the enjoyment of his full salary. He elected to settle once more in Paris, after a short visit to Italy; but beyond conducting occasional performances of some of his own works he made but few attempts to keep his name before the public. In 1847 he revisited Berlin and was invited by the king to conduct some performances during the winter. In 1848 he became deaf. In 1850 he retired to his birthplace, Majolati, and died there on the 14th of January 1851, bequeathing all he possessed to the poor of his native town.

SPONTINO—SPOONBILL

SPONTOON (Fr. esponton, Ital. spontone, from Lat. punctum, point, pungere, to prick), a weapon carried by infantry officers in the 17th and early 18th centuries. It was a type of the partisan or halberd (g.z.), a shafted weapon with a special form of head.

SPOON (O. Eng. spéoun, a chip or splinter of wood, cf. Du. spaan, Ger. Spahn, in same sense, probably related to Gr. σφον, wedge), a table implement, bowl-shaped at the end, with a handle varying in length and size. From the derivation of the word the earliest northern European spoon would seem to have been a chip or splinter of wood; the Greek κοχλίας (Lat. cochlæus) points to the early and natural use of shells, such as are still used by primitive peoples. Examples are preserved of the various forms of spoons used by the ancient Egyptians of ivory, flint, slate and wood, many of them adorned with the symbols of their religion. The later forms of the Greeks and Romans were chiefly made of bronze and silver, and the handle usually takes the form of a spike or pointed stem. There are many examples in the British Museum from which the form of the various types can be ascertained, the chief points of difference being found in the junction of the bowl with the handle. Medieval spoons for domestic use were commonly made of horn or wood, but brass, pewter and "latten" spoons appear to have been common about the 15th century. The full descriptions and entries relating to silver spoons in the inventories of the royal and other households point to their special value and rarity. The earliest English reference appears to be in a will of 1250. In the wardrobe accounts of Edward I. for the year 1300 some gold and silver spoons marked with the fleur-de-lis, the Paris mark, are mentioned. One of the most interesting medieval spoons is the coronation spoon used in the anointing of the sovereign, an illustration of which is given under REGALIA. The sets of spoons popular as chrestening presents in Tudor times, the handles of which terminate in heads or busts of the apostles, are a special form to which antiquarian interest attaches (see APOTLE SPOONS). The earlier English spoon-handles terminate in an acorn, plain knob or a diamond; at the end of the 16th century the baluster and seal ending becomes common, the bowl being "fig-shaped." At the Restoration the handle becomes broad and flat, the bowl is broad and oval and the termination is cut into the shape known as the pied de biche, or hind's foot. In the first quarter of the 18th century the bowl becomes narrow and elliptical, with a tongue or a "rat's tail" down the back, and the handle is turned up at the end. The modern spoon, with the tip of the bowl narrower than the base and the rounded end of the handle turned down, came into use about 1760.

See C. J. Jackson, "The Spoon and its History," in Archaeologia (1892), vol. lili.; also Cripps, Old English Plate.

SPOONBILL. The bird now so called was formerly known in England as the Shovellar or Shovelor, while that which is perhaps the commonest species of the genus, the Shoveller, or Spoonbill, is the Shoveler (g.z.) of modern days—the exchange of names having been effected as already stated (loc. cit.) about 200 years ago, when the subject of the present notice—the Platalea leucorodia of Linnaeus as well as of recent writers—was doubtless far better known than now, since it evidently was, from ancient documents, the constant concomitant of Herons, and with them the law attempted to protect it. 1 J. E. Harting (Zeologist, 1886, pp. 61 seq.) has cited a case from the "Year Book" of 14 Hen. VIII. (1523), wherein the then bishop of London (Cuthbert Tunstall) maintained an action of trespass against the tenant of a close at Fulham for taking Herons and "Shovelars" that made their nests on the trees therein growing, and has also printed (Zeologist, 1877, pp. 425 seq.) an old document showing that "Shovelars' bred in certain woods in west Sussex in 1570. Nearly one hundred years later (1662) Sir Thomas Browne, in his "Account of Birds found in Norfolk" (Works, ed. Wilkin, iv. 315, 316), stated of the "Platae or Shovelard" that it formerly "built in the Hernerie at Claxton and Reedham, now at Trimley in Suffolk." This last is the latest known proof of the breeding of the species in England; but more recent evidence of a hitherto exceptional fact may be hoped for from tilled sources. That the Spoonbill was in the fullest sense of the word a "native" of England is thus incontestably shown; but for many years past it has only been a more or less regular visitant, though not seldom in considerable numbers, which would doubtless, if allowed, once more make their home there; but its conspicuous appearance renders it an easy mark for the greedy gunner and the contemplative collector. What may have been the case formerly is not known, except that, according to P. Belon, it nested in his time (1553) in the borders of Brittany and Poitou; but as regards north-western Europe it seems of late years to have bred only in Holland, and there it has been deprived by drainage of its favourite resorts, one after the other, so that it must shortly become merely a stranger, except in Spain or the basin of the Danube and other parts of south-eastern Europe.

The Spoonbill ranges over the greater part of middle and southern Asia, 2 and breeds abundantly in India, as well as on some of the islands in the Red Sea, and seems to be resident throughout Northern Africa. In Southern Africa its place is taken by an allied species with red legs, P. cristata ou teniersiris, 3

---

1 Nothing shows better the futility of the old statutes for the protection of birds than the fact that in 1534 the taking of the eggs of Herons, Spoonbills (Shovellers), Cranes, Bitterns and Bystards was allowed. In heavy prejudice, there was a tax of a penny upon each apparent bird in the breeding season. All of the species just named, except the Heron, have passed away, while there is strong reason to think that some at least might have survived had the principle of the Legal law (Deut. xxi. 20) been followed.

2 Ornithologists have been in doubt as to the recognition of two species from Japan described by Temminck and Schlegel under the names P. major and P. minor. It has been suggested that the former is only the young of P. leucorodia, and the latter the young of the Australian P. regia.
which also goes to Madagascar. Australia has two other species, P. regia or melanorhynchos, with black bill and feet, and P. flavipes, in which those parts are yellow. The very beautiful and wholly different P. ajaja is the Roseate Spoonbill of America, and is the only one found on that continent, the tropical or juxta-tropical parts of which it inhabits. The rich pink, deepening in some parts into crimson, of nearly all its plumage, together with the yellowish green of its bare head and its lake-coloured legs, sufficiently marks this bird; but all the other species are almost wholly clothed in pure white, though the English has, when adult, a fine buff pectoral band, and the spoon-shaped expanse of its bill is yellow, contrasting with the black of the gape and legs. Local names are legion, often also black.

In the breeding season, a pendent tuft of white plumes further ornament the head of both sexes, but is longest in the male. The young of the year have the primary quills dark-coloured.

The Spoonbills form a natural group, Platalea, allied to the Ibittidae, and somewhat more distantly to the Storks (see Stork). They breed in societies, not only of their own kind, but in company with Herons, either on trees or in reed-beds, making large nests in which are commonly laid four eggs—white, speckled, streaked or blotched, but never very closely, with lightly marked markings. The young are soon upstanding and covered with short plumage, and described, as for instance by P. L. Sclater and W. A. Forbes (Ibis, 1877, p. 412) and H. Seebom (Zoologist, 1880, p. 457), as specimens of another heron, B. Schlegel (Vogel, Nederland, taf. xvi.).

SPORADIES (Gr. ἄγγελος, from στέρω, to sow), the islands scattered about the Greek Archipelago, as distinguished from the Cyclades, which are grouped round Delos, and from the islands attached, as it were, to the mainlands of Europe and Asia. Ancient and modern writers differ as to the list of the Sporades (see Buck of Griechenland, ii. 348 seq.). The Doric Sporades—Skiathos, Skopelos, Thassos, Anapho, Astypalaia and Cos—were by some considered a southern cluster of the Cyclades. In modern times the name Sporades is more especially applied to two groups—the northern Sporades, which lie north-east of Negropont (Euboea), Skiatkos, Skopelos and Ikos being included in the department of Magnesia and Scyros in that of Euboea; and the southern Sporades, lying off the south-west of Asia Minor, being included in the Turkish vilayet of the "Islands of the White Sea." The northern, which have altogether an area of 180 sq. m. and a population of 12,350 (1898), comprise Skiathos, Skopelos, Thassos, like Pelagonisi, Giura, Pipari and Scyros (pop. 3512), with the adjacent islets. Skiathos is a beautifully wooded and picturesque island; the town stands on a declivity surrounding an excellent harbour. The larger island of Skopelos is also well wooded. Almost every householder in both islands is the owner, joint owner or skipper of a sailing ship. The southern Sporades are as follows: Icaria, Patmos, Leros, Calymnos, Astypalaia (Astypalai or Stampalai), Cos (Stanko), Nisyros, Tilos or Episcopi, Syme, Khalki, Rhodes, Crete and many smaller isles. Icaria (pop. about 5000) derives its name from the legend of Icarus. The forested slopes of its rugged mountains have been destroyed by the inhabitants for the manufacture of charcoal. Leros (pop. about 3000) was in ancient times a seat of the worship of Artemis. Calymnos (pop. about 7000) was once covered by forests—with Oxid, Άλα. ii. 81, "silvis umbrosa Calymne"), which have disappeared. Nisyros (pop. about 2500) possesses hot sulphur springs.

SPOROZOAI, a large and most important section of the Protozoa, all the members of which are exclusively parasitic in habitat. They are of extremely widespread occurrence; there is hardly one of the chief classes of animals which does not furnish hosts for these parasites, scarcely one of the common tissues or organs of the Metazoan body which may not be liable to infection. Sporozoa differ greatly as regards the effects which they produce upon their hosts. In many, perhaps in most, cases the general health of the infected animal seems to be unimpaired, even though the parasites may be fairly abundant. Some, however, give rise to dangerous or fatal diseases, while others may cause ravaging epidemics; instances of these are given under the various Orders.

Correlated with the mode of life are the two features characteristic of all Sporozoa: (a) They absorb only fluid nutriment, osmotically, and so lack any organs for ingesting and digesting solid food; and (b) they reproduce by sporulation, i.e., the formation of minute germes, which in most instances very numerous and are often enclosed in firm protective envelopes or cases, each case with its contents forming a spore. In addition, the great majority have also another method of reproduction, for increasing the number of the parasites in any individual host; this is by the fragmentation and subsequent reproduction, from the propagative or exogenous method (by means of the resistant spores), which serves for the infection of fresh hosts and secures the dissemination and survival of the species. Further, most if not all forms of Sporozoa undergo sexual conjugation at some period or other of the life-cycle.

Beyond this, however, it is impossible to generalize. In response to the exceeding diversity of habitat and of the conditions of life, the parasites exhibit manifold and widely-different types of form, organization and life-history. The recognition of this fact is expressed, at the present day, by the division of the Sporozoa into several well-defined orders, which are grouped in two main divisions, each containing more or less closely related forms. One of these consists of the Gregarines, Coccidia and Haemosporidia (qg.v.). The other comprises the Myxosporidia, Actinomyxidia, Sarcosporidia and Haplosporidia, the parasites included in the last named order being of comparatively simple structure, and probably near the base of this section. There are, in addition, various other forms (Sero- and Exo-sporidia), also primitive in character, but which are as yet too insufficiently known for it to be certain whether they are of distinct ordinal rank, or should be placed with the Myxosporidia.

The nomenclature assigned to these two principal divisions of the Sporozoa by different writers has varied according to the particular character on which they have primarily based the arrangement. Of late years, the terms Telosporidia and Neosporidia, proposed by F. Schaudinn (1900), have been most in favour. In the Telosporidia (comprising the Gregarines, Coccidia and Haemosporidia), sporulation does not begin until the close of the vegetative or trophic period, i.e. until growth has ceased; in the Neosporidia (including the remaining orders) growth and sporulation go on coincidently. Recently, however, considerable doubt has been thrown upon the general occurrence of this latter condition in certain Myxosporidia (Microsporidia); and the present writer adopts as preferable, therefore, the terms Ectosporia and Endosporia (qg.v.), invented by E. Metschnikoff and made use of by F. Mesnil (1899), which indicate a universal distinction between the two groups in their manner of sporulation. This distinction is probably the most fundamental one, and itself supports a conclusion which is, on other grounds, becoming more and more likely, namely, that these two divisions are not related phylogenetically, but have, on the contrary, a radically different origin. In other words, one finds the heading of either is included two entirely independent series of Protozoan parasites; the general resemblances which these exhibit are due to convergence brought about by their specialized mode of life.

The most recent and comprehensive account of the group is that by E. A. Minchin (in Lankester's Treatise on Zoology, pt. i., London, 1901), to which the present writer is much indebted; another useful treatise is that of F. Dolle, Die Protozoen als Parasiten u. Krankheitsverrerer (G. Fischer, Jena, 1901). Earlier accounts are those of A. E. S. Gerber, "Vergleichen der western Sporenentwicklung" (Jena, 1900); J. Wasilewski, Sporozaenwunde (Jena, 1866); Y. Delage and E. Hérouard in Traite de zoologie concretie, pt. i., Paris, 1896; E. R. Lankester, art. "Protozoa" in Encyc. Brit. 9th ed. (1886), and H. Mesnil, in Bonne's Klimate, art. "Ortungene des Tierreiches, i. i. (1882). There is a systematic enumeration of the group by A. Labbé in Das Tierreich, 5. (Berlin, 1899); and the classification and phylogeny are considered by E. Mesnil (Soc. Biol., vol. 73, Paris, 1899), and by H. Crawley in Amer. Nat. (1905), xxxix. 607.

(H. M. Wo.)
SPORT (a contracted or shortened form of "dispel" to amuse, divert oneself. O. Fr. se disperser or deporter, to leave off work, hence to play, Lat. dis-, away, and portare, to carry; the origin of the meaning lies in the notion of turning away from serious occupations, cf. " diversion "), play, amusement, entertainment or recreation. The term was applied in early times to all forms of out-of-door or manly recreations, such as shooting with bow, hunting and the like. Modern usage has given several meanings to " sport " and " sports." Generally speaking " sport " includes the out-of-door recreations, the " field-sports," such as fishing, shooting, fox-hunting, &c., connected with the killing or hunting of animals as opposed to organized " games," which are contests of skill or strength played according to rules. It also includes the special class of horse-racing, the votaries of which, and also of the prize-ring, have arrogated to themselves sometimes the name of " sportsman," applying that word even to those who follow racing simply as an occasion for betting. On the other hand, the plural " sports " is generally confined to athletic contests such as running, jumping, &c. (see ATHLETIC SPORTS and subsidiary articles).

In zoology and botany the word has a specific meaning of a sudden or singular variation from type, a " diversion " in a more etymological sense of the term.

SPORTS, THE BOOK OF, or more properly the Declaration of Sports, an order issued by James I. in 1617 on the recommendation of Thomas Morton, bishop of Chester, for use in Lancashire, where the king on his return from Scotland found a conflict on the Sunday between amusements of the Puritans and the gentry, many of whom were Roman Catholics. Permission was given for dancing, archery, leaping, vaulting and other harmless recreations, and of " having of May games, Whitsun ales and morris dances, and the setting up of May-poles and other sports therewith used, so as the same may be had in due and convenient time without impediment or neglect of divine service, and that women shall have leave to carry rushes to church for the decorating of it." On the other hand, " bear and bull-baiting, interludes, and (at all times in the mean sort of people by law prohibited) bowling " were simply as an occasion for betting. In 1618 James transmitted orders to the clergy of the whole of England to read the declaration from the pulpit; but so strong was the opposition that he prudently withdrew his command (Wilson, in Kennet, ii. 700; Fuller, Church History, v. 453). In 1633 Charles I. not only directed the republication of his father's declaration (Rushworth, i. 193) but insisted upon the reading of it by the clergy. Many of the clergy were punished for refusing to obey the injunction. With the fall of Laud all attempts to enforce it necessarily came to an end.

SPOTTISWOODE (SPOTSWOOD or SPOTTISWOOD), ALEXANDER (1676-1710), American colonial governor, was born, of an old Scotch family, in Tanger, Africa, in 1676. He served under Marlborough in the War of the Spanish Succession, and was wounded at Blenheim. He became lieutenant governor of Virginia in June 1710, when he was received with some enthusiasm, because he brought to the colony the privilege of habeas corpus; his term as governor closed in September 1722—probably because he meddled in ecclesiastical matters; but he remained in Virginia, living near his ironworks in Germanna, a settlement of Germans, on the Rapidan in Spottsylvania county (named in his honour) and he was deputy postmaster-general of the colonies from 1730 to 1739. He was the first representative of the British government in America who fully appreciated the value of the western territory. As governor he recommended the establishment of a Virginia company to carry on trade with the Indians, he urged upon the provincial government and also upon the British authorities the wisdom of constructing forts along the frontier, and he personally organized and conducted an exploring expedition (Aug. 17 to Sept. 20, 1716) into the Shenandoah Valley reaching the water-parting between the Atlantic and the Ohio river. These ambitious and expensive schemes, coupled with his haughty and overbearing conduct, involved him in a controversy with the rather niggardly House of Burgesses. He developed the iron industry of Virginia, promoted the religious education of the Indians and tried to advance the interests of education, and especially of the College of William and Mary. In 1740 he was commissioned major-general to conduct a military expedition against Cartagena, but died while attending to the embarkation, at Annapolis, Maryland, on the 7th of June 1740. His library he left to the College of William and Mary.

SPOTTISWOODE (SPOTSWOOD, SPOTTISWOOD or SPOTSWOOD), JOHN (1565-1639), archbishop of St Andrews and historian of Scotland, eldest son of John Spottiswood, minister of Calder and "superintendent of Lothian, was born in 1565. He was educated at Glasgow University (M.A. 1581), and succeeded his father in the parish of Calder in 1583. In 1601 he attended Ludowick, duke of Lennox, as his chaplain, in an embassy to the court of France, returning in 1603. He followed James to England on his accession, but was the same year nominated to the see of Glasgow, his consecration in London, however, not taking place until October 1610. Spottiswoode had originally become prominent as an ardent supporter of the strict Presbyterian party, but gradually came to see the inconveniences of "parity in the Church," attributed little importance to the existing matters of dispute, and thought that the interests of both church and state were best kept by compromise and in terms with the king. He was therefore ready to co-operate with James in curtailing the powers of the Kirk which encroached on the royal authority, and in assimilating the church of Scotland to that of England. On the 30th of May 1609 he became a member of the Scottish privy council. In 1610 he presided as moderator over the assembly in which presbytery was abolished, in 1615 he was made archbishop of St Andrews and primate of Scotland, and in 1618 procured the sanction of the privy council to the Five Articles of Perth with their ratification by parliament in 1621. In 1623 he crowned Charles I. at Holyrood. In 1635 he was appointed first lord chancellor of Scotland, an office which he retained till 1638. He was opposed to the new liturgy as inexpedient, but when he could not prevent its introduction he took part in enforcing it. He was a spectator of the riot of St Giles's, Edinburgh, on the 23rd of July 1637, endeavouring in vain to avoid disaster by concessions, and on the taking of the Covenant perceived that "now all that we have been doing these thirty years past is thrown down at once." He escaped to Newcastle, was deposed by the assembly on the 4th of December on a variety of ridiculous charges, and died in London on the 26th of November 1639, receiving burial in Westminster Abbey.

Spottiswoode published in 1620 Refutatio libelli de regimine ecclesiae scoticanae, an answer to a tract of Calderwood, who replied in the Vindiciae subjoined to his Altare damascenum, (1623). The only other writing published during his lifetime was the sermon he preached at the Perth assembly. His most considerable work was The History of the Church and State of Scotland (London, 1655, seq.). It displays considerable research and sagacity, and even when dealing with contemporary events gives a favourable impression, upon the whole, of the author's candour and truth. The opposite side can be studied in Calderwood's History.

Spottiswoode married Rachel, daughter of David Lindsay, bishop of Ross, and besides a daughter left two sons, Sir John Spottswoode of Dairies in Fife, and Sir Robert, president of the College of William and Mary. 1

1 To each of his comrades in this journey Spottswood presented a small golden horseshoe, lettered " Sic juvat transcendere montes."
the Court of Session, who was captured at the battle of Philiphaugh in 1645 and executed in 1646.

See the accounts prefixed to the first edition of Spottiswoode’s History of Scotland and to that published by the Spottiswoode Society in 1871; also David Calderwood’s Hist. of the Kirk of Scotland (1842–1849).

SPOTTISWOODE, WILLIAM (1825–1883), English mathematician and physicist, was born in London on the 11th of January 1825. His father, Andrew Spottiswoode, who was descended from an ancient Scottish family, represented Colchester in parliament for some years, and in 1831 became junior partner in the firm of Eyre & Spottiswoode, printers. William was educated at Laleham, Eton, Harrow and Balliol College, Oxford. His bent for science showed itself while he was still a schoolboy, and indeed his removal from Eton to Harrow is said to have been occasioned by an accidental explosion which occurred whilst he was performing an experiment for his own amusement. At Harrow he obtained in 1842 a Lyon scholarship, and at Oxford in 1845 a first-class in mathematics, in 1846 the junior and in 1847 the senior university mathematical scholarship. In 1846 he left Oxford to take his father’s place in the business, in which he was engaged until his death. In 1847 he issued five pamphlets entitled Meditations analytiques. This was his first publication of original mathematical work; and from this time scarcely a year passed in which he did not give to the world further mathematical researches. In 1856 Spottiswoode travelled in eastern Russia, and in 1857 was elected a Fellow of the Royal Society. In 1871 he undertook an expedition he has left an interesting record entitled A Taran-tasse Journey through Eastern Russia in the Autumn of 1856 (London, 1857). In 1870 he was elected president of the London Mathematical Society. In 1871 he began to turn his attention to experimental physics, his earlier researches bearing upon the polarization of light and his later work upon the electrical discharge in rarefied gases. He wrote a popular treatise upon the former subject for the “Nature” Series (1874). In 1878 he was elected president of the British Association, and in the same year president of the Royal Society, of which he had been a fellow since 1853. He died in London on 16th July 1883, and was buried in Westminster Abbey.

As a mathematician he occupied himself with many branches of his favourite science, more especially with higher algebra, including the theory of determinants, with the general calculus of symbols, and with the application of analysis to geometry and mechanics.

The following brief view of his mathematical work is quoted from the obituary notice which appeared in the Proceedings of the Royal Society (xxxviii. 34): “The interesting series of communications on the contact of curves and surfaces which are contained in the Philosophical Transactions of 1820 and subsequent years would alone account for the high rank he obtained as a mathematician. . . . The mastery which he had obtained over the mathematical symbols was so complete that he never shrunk from the use of expressions, however complicated—nay, the more complicated they were the more he seemed to revel in them—provided they did not sin against the ruling spirit of all his work—symmetry. To a mind imbued with the love of mathematical symmetry the study of determinants had naturally a peculiar attraction.”

In 1853 Mr Spottiswoode published in the form of a pamphlet an account of some elementary theorems on the subject. This having fallen out of print, permission was sought by the editor of Crete to reproduce it in the pages of that journal. Mr Spottiswoode granted the request and undertook to revise his work. The subject had, however, been so extensively developed in the interim that it proved necessary not only to revise but entirely to rewrite the work, which became a memoir of 116 pages. To this, the first elementary treatise on determinants, much of the rapid development of the subject is due. The effect of the study on Mr Spottiswoode’s own method was most pronounced; there is scarcely a page of his mathematical writings that does not bristle with determinants.”

His papers, numbering over two, were published principally in the Philosophical Transactions of the Royal Society of London, Quarterly Journal of Mathematics, Proceedings of the London Mathematical Society and Crée, and one or two in the Comptes rendus of the Paris Academy; but that arranged according to the several journals in which they originally appeared with short notes upon the less familiar memoirs, is given in Nature, xxvii. 599.

SPOTTISLYVANIA, a county of Virginia, U.S.A., so called after Alexander Spotswood (q.v.), lieutenant governor of Virginia in 1710–1722, who owned extensive estates and mines therein. It is bordered on the N. by the Rapidan and Rappahannock rivers and on the S. by the North Anna. It is celebrated as containing several of the most famous battlefields of the Civil War—Fredericksburg, Chancellorsville, the Wilderness, and particularly that of Spottsylvania Court House, where the armies of Grant and Lee came to nearly 200,000 men (May 31, 1863). The battles of Chancellorsville, Wilderness and Spottsylvania are described in the article WILDERNESS.

SPOUSE, (O. Fr. espous, mod. époux, espouse, épouse, Lat. sponsus, sponsa, a betrothed or promised man or woman, from spénderes, to promise), a husband or wife, properly one promised or betrothed to another in marriage.

SPRAT, THOMAS (1635–1713), English divine, was born at Beaminster, Dorsetshire, and educated at Wadham College, Oxford, where he held a fellowship (1657–1670). Having taken orders he became a preacher of Lincoln in 1660. In the preceding year he had gained a reputation by his poem To the Happy Memory of the most Renowned Prince Oliver, Lord Protector (London, 1659), and he was afterwards well known as a wit, preacher and man of letters. His chief prose works are the Observations upon Monsieur de Sorbier’s Voyage into England (London, 1663), a satirical reply to the strictures on Englishmen in Samuel de Sorbier’s book of that name, and a History of the Royal Society of London (London, 1667), which Sprat had helped to found. In 1669 he became canon of Westminster, and in 1670 rector of Uffington, Lincolnshire. He was chaplain to Charles II. in 1676, curate and lecturer at St Margaret’s, Westminster, in 1679, canon of Windsor in 1681, dean of Westminster in 1683 and bishop of Rochester in 1684. He was a member of James II.’s ecclesiastical commission, and in 1688 he read the Declaration of Indulgence to empty benches in Westminster Abbey. Although he opposed the motion of 1689 declaring the throne vacant, he assisted at the coronation of William and Mary. As dean of Westminster he directed Wren’s restoration of the abbey. He died on the 20th of May 1713.

SPRAT, a marine fish (Clupea sprattus), named “garvie” in Scotland, one of the smallest species of the genus Clupea or herrings, rarely exceeding 5 in. in length, but occuring in large shoals on the Atlantic coasts of Europe. Sprats are very often confused with young herrings, which they much resemble, but can always be distinguished by the following characters: they do not possess any teeth on the palate (vomer), like herrings; their gill-covers are smooth, without the radiating striae which are found in the shad and the pilchard; the anal fin consists of from seventeen to twenty rays, and the lateral line of forty-seven or forty-eight scales. The ventral fins are slightly anterior to the origin of the dorsal fin; and the spine consists of from forty-two to forty-nine vertebrae. The sprat spawns in the open sea from February to May, and the young are gathered in large shoals in the ripe condition. Its eggs are buoyant and pelagic and easily recognized. The sprat is one of the more important food-fishes on account of the immense numbers which are caught when the shoals approach the coasts. They are somewhat capricious, however, as regards the place and time of their appearance, the latter falling chiefly in the first half of winter. They are caught with the seine or with the bag-net in the tidalway. Large quantities are consumed fresh, but many are pickled or smoked and others prepared like anchovies. Frequently the captures are so large that the fish can be seen as a mass from the shore, lying on the surface of the water, and are only occasionally captured in the ripen condition.

SPRAT, THOMAS ABEL BRIGANCE (1851–1883), English vice-admiral, hydrographer and geologist, was born at East Teignmouth on the 11th of May 1851. He was the eldest son of Commander James Spratt, R.N., and entered the navy in 1872. He was attached to the surveying branch, and was engaged almost continuously until 1863 in surveying the Mediterranean. As commander of the “S spitfire” he rendered distinguished service in the Black Sea during the Crimean War, and was appointed C.B. in 1855. At an earlier date he was associated with Edward Forbes, then naturalist to the “Beacon,” and it was during the years 1866–1868 that they made observations on the bathymetrical distribution of marine life. To Forbes he was specially indebted for his interest in natural history and geology,
and together they published *Travels in Lycia*, &c. (1847). Spratt investigated the caves at Malta and obtained remains of the pigmy elephant (*Elephas melinus*), which was described by Dr. H. Falconer. He investigated the geology of several Greek islands, also the shores of Asia Minor, and made detailed observations on the Delta of the Nile. He was principally distinguished for his *Travels and Researches in Crete* (2 vols., 1863), in which he ably described the physical geography, geology, archaeology and natural history of the island. He was commissioner of fisheries from 1866 to 1873; and acting conservator of the Mersey from 1879 until the close of his life. He died at Tunbridge Wells on the 10th of March 1888.

**Spreckels, Claus** (1828-1908), American capitalist, was born in Lunsford, Hanover, in 1828. In 1846, to escape army service, he emigrated to the United States and became a grocer. In 1856 he removed from New York City to San Francisco, where he set up as a grocer, then a brewer, and, after a sugar refiner. He gradually obtained control of most of the sugar refineries on the Pacific coast; he was able to undersell his competitors because he bought his raw sugar in Hawaii, where he purchased large plantations and contracted for the produce of others. He built a large refinary in Hawaii, and his influence with the Hawaiian government was for a time paramount. By financing the Pacific Steamship Company he was able to reduce the freight charges on his sugar, and he also introduced various improvements in the methods of manufacture. It was he who built the railway from Salinas to San Francisco, by 1873, Teco & Spreckels, FP, first made a through line into San Francisco. Spreckels died in San Francisco on the 26th of December 1908. His eldest son, John Diedrich Spreckels (b. 1853), became proprietor of the *San Francisco Morning Call* and succeeded to his father's steamship interests; and another son, Rudolph Spreckels (1873-), became president of the First National Bank of San Francisco.

**Spree**, a river of Prussia, Germany, rising in the district of Upper Lusatia, in the kingdom of Saxony, close to the Bohemian frontier, and flowing nearly due north past Bautzen, Spremberg and Cottbus to Berlin; it is about 530 m. long, and is divided into two arms, which form a curve in a narrow space a few miles north of Berlin. The river Spree has a network of canals, and swings round in a big curve to the west forming the peculiar marshy region (30 m. long and 3 to 6 m. wide) known as the Spreewald. Having returned to its predominant direction, it turns W.N.W., and passing Fürstenwalde and Köpenick threads Berlin in several arms, and joins the Havel at Spandau. Its length is 227 m. of which 112 are navigable; the area of its drainage basin is 3660 sq. m. It is connected with the Oder by the Friedrich Wilhelm or Müllrose Canal made in 1863-1865, which is 17 m. long, and by the latter Spree Canal, made in 1877-1888, and with the Havel by the Berlin Spandau Navigation Canal, 3½ m. long, and by the Teltow Canal completed in 1905.

**Spreewald**, a district of Germany, in the Prussian province of Brandenburg, a marshy depression of the middle Spree valley, extending to some 106 sq. m., its length being 27 m. and its width varying from 1 to 7 m. It owes its marshy character to the river Spree, which above Lübben splits into a network of over two hundred arms, and in seasons of flood generally overflows considerable portions of the region. In the parts which are especially liable to inundation, as, for example, the villages of Lehe, Leipe and Burg, many of the homesteads are built each on a little self-contained island, approachable in summer only by boat, and in winter over the ice. In spite of its marshy character the Spreewald is in part cultivated, in part converted into pastureland, and almost everywhere, but more especially in the lower districts, wooded like a park, the predominant trees being willows. Fishing, cattle-breeding and the growing of vegetables, more particularly small picking cucumbers, are the chief occupations of the people, about 30,000 in all. In great part they are of Wendish blood, and though which major part have been Germanized, there is a small residue who have faithfully preserved their national speech, customs, and their own peculiar styles of dress. The attractive blending of wood and water makes the Spreewald in summer a resort of the people of the Prussian capital, but also in winter the district is largely visited by people bent on skating, sleighing and other winter pastimes. The chief town is Lübben, 43 m. south from Berlin on the railway to Görlitz. See W. von Schulenburg, *Wendische Volkssagen und Gebrauche aus dem Spreewald* (Leipzig, 1886); C. Wid, Der Spreewald und seine Bewohner (Cottbus, 1889); and Brandenburg, *Spreepfahlwertern* (Lübben, 1901).

**Spremberg**, a town of Germany, in the Prussian province of Brandenburg, situated partly on an island in the river Spree and partly on the west bank, 76 m. S.E. of Berlin by the railway to Berlin (Pop., 1903) 14,888. There are a Roman Catholic and two Evangelical churches; the school is a gymnasium for boys. The palace is an 11th century, a ducal chateau, built by a son of the elector John George about the end of the 16th century (now utilized as government offices), classical, technical and commercial schools and a hospital. It carries on considerable manufactures of woollen cloth.

**Sprengel, Kurt** (1766-1833), German botanist and physician, was born on the 3rd of August 1766 at Bodelkow in Pomernia. His uncle, Christian Konrad Sprengel (1752-1810), is remembered for his studies in the fertilization of flowers by the pollen. He reached the pinnacle of his fame some 20 years ahead of his time. His father, a clergyman, provided him with a thorough education of wide scope; and the boy at an early age distinguished himself as a linguist, not only in Latin and Greek, but also in Arabic. He appeared as an author at the age of fourteen, publishing a small work called *Aufsicht zur Botanik für Frauenzimmer* in 1786. In 1784 he began to study theology and medicine at the university of Halle, but soon relinquished the former. He graduated in medicine in 1787. In 1789 he was appointed extraordinary professor of medicine in his alma mater, and in 1795 was promoted to be ordinary professor of medicine. He devoted himself not only to investigations into the history of medicine; and he held a foremost rank as an original investigator both in medicine and botany. Among the more important of his many services to the latter science was the part he took in awakening and stimulating microscopic investigation into the anatomy of the tissues of the higher plants, though defective microscopic appliances rendered the conclusions arrived at by himself untrustworthy. He also made many improvements in the details of both the Linnaean and the "natural" systems of classification. He died of an apoplectic seizure at Halle on the 15th of March 1833.

Sprengel's more important works were: *Beiträge zur Geschichte des Pulses* (1757); *Galens Fieberslehre* (1788); *Apologie des Hippocrates* (1789); *Versuch einer pragmatischen Geschichte der Arzneikunde* (1792-1793); *Handbuch der Pathologie* (1795-1797); *Institutionen medicae* (6 vols., 1809-1816); *Geschichte der Medicin* (completed in 1820); *Antiquitatum botanicarum specimen* (1798); *Historia rei herbariae* (1807-1808); *Anleitung zur Kenntns der Gewächse* (1802-1804; and again 1817-1818); *Geschichte der Botanik* (1817-1818); *Von dem Bau und der Natur der Gewächse* (1812); *Flora halensis* (1806-1813; and in 1837); *Species unbedierfarum minus cognitae* (1818); *Neue Entdeckung im ganzen Umfang der Pflanzenkunde* (1820-1822). He edited an edition of Linnaeus's *Systema vegetabilium* in 1824 and of the *Genera plantarum* in 1830. A list of his botanical papers from 1798 onwards will be found in the Rheinische's *Kant'sche Pantograph*.

**Sprenger, Jakob** (fl. 1500), the Dominican inquisitor of Cologne, who with Heinrich Kratzer (institor) published *Malles malefiorum* or *Hexenhammer*, the standard textbook on witchcraft, especially in Germany. The book gives (1) evidences of witchcraft; (2) rules for discovering it; (3) proceedings for punishment.

**Sprengtpotten, Göran Magnus**, Count (1740-1810), Swedish and Russian politician, younger brother of Jakob Magnus Sprengtpotten, entered the army and rose to the rank of captain during the Seven Years' War. He assisted his brother in business affairs. In 1790 he made a colonel and brigadier in east Finland. Here he distinguished himself greatly as an organizer and administrator. The military school which he founded at Brahelinund subsequently became a state
Sprengtporten, J. M.—Springbuck

institution. Irritable and suspicious like his brother he also came to the conclusion that his services had not been adequately appreciated, and the flattering way in which he was welcomed by the Russian court during a visit to St Petersburg in 1779 still further incensed him against the purely imaginary ingratitude of his own sovereign. For the next two years he was in the French service, returning to Finland in 1781. It was now that he first conceived the plan of separating the grand duchy from Sweden and erecting it into an independent state under the protection of Russia. During the riksdag of 1786 he openly opposed Gustavus III., at the same time engaging in a secret and treasonable correspondence with the Russian ministers with the view of inducing them to assist the Finns by force of arms. In the following year, at the invitation of Catherine II., he formally entered the Russian service. When the Russo-Swedish War of 1788-90 began, Sprengtporten received the command of a Russian army corps directed against Finland. He took no direct part in the Anjala conspiracy (see Sweden: History), but urged Catherine to support it more energetically. His own negotiations with his fellow countrymen, especially after Gustavus III. had brought the Finlanders back to their allegiance, failed utterly. Nor was he able to serve Russia very effectually in the field for he was seriously wounded at the battle of Parasalmi (1790). At the end of the war, indeed, his position was somewhat precarious, as the High Court of Finland condemned him as a traitor, while Catherine regarded him as an incompetent intrigante who had not performed his promises. For the next five years, therefore (1791-98), he thought it expedient to quit Russia and live at Töplitz in Bohemia. He was re-employed by the emperor Paul who, in 1800, sent him to negotiate with Napoleon concerning the Maltese Order and the interchange of prisoners. After Paul's death Sprengtporten was again in disgrace for seven years, but was consulted in 1808 on the eve of the outbreak of hostilities with France. On the 1st of December 1808 he was appointed the first Russian governor-general of Finland with the title of count, but was so unpopular that he had to resign his post the following year. The last ten years of his life were spent in retirement.

See Finnska Tidskrift (Helsingfors, 1877-1890); and Svenska Letteratursällskapets i Finland förhandlingar (Helsingfors, 1887).

(R. N. B.)

Sprengtporten, Jakob Magnus (1727-1786), Swedish soldier and politician. In his twelfth year he chose the profession of arms, and served his country with distinction. The few and miserable triumphs of Sweden during the Seven Years' War were due almost entirely to young Sprengtporten, and he emerged from it with a lieutenant-colonelcy, a pension of £60, and the reputation of being the smartest officer in the service. Sprengtporten had a high value of distinction, and too heavily a consumer of "Hats" and "Caps" to belong to either. He regarded the monstrous system of misrule for which they were primarily responsible with indignation, made no secret of his sentiments, and soon gathered round him a band of young officers of strong royalist proclivities, whom he formed into a club, the so-called Svenska Botten (Sweden's groundwork). The club was suppressed by the dominant "Caps," who also sought to ruin Sprengtporten financially by inciting his tenants in Finland to bring actions against him for alleged extortion, not in the ordinary courts but in the riksdag itself, where Sprengtporten's political adversaries would be his judges. The enraged Finnish colonel thereupon approached Gustavus III. with the project of a revolution against their common enemies, the "Caps." It was to begin in Finland where Sprengtporten's regiment, the Nyland dragoons, was stationed. He undertook to seize the impregnable fortress of Sveaborg by a coup de main. The submission of the whole grand duchy would be the natural consequence of such a success, and, Finland once secured, Sprengtporten proposed at the head of his Finns to embark for Sweden, meet the king and his friends near Stockholm, and surprise the capital by a night attack. This plan, subsequently enlarged by a suggestion of a fellow plotter, J. K. Toll (q.v.), was warmly approved of by the king. On the 22nd of July 1772 Sprengtporten left Stockholm. On the 9th of August he reached Helsingfors. On the 16th he persuaded the fortress of Sveaborg to submit to him. Helsingfors followed the example of Sveaborg. A week later all Finland lay at the feet of the intrepid colonel of the Borgå dragoons. By the 23rd of August Sprengtporten was ready to re-embark for Stockholm with 700 men, but contrary winds kept him back, and in the meantime Gustavus III. himself had carried out his revolution unaided. On his return to Sweden, however, Sprengtporten was received with the greatest distinction and made a lieutenant-general and colonel of the guards. He was also appointed the president of a commission for strengthening the defences of Finland. But Sprengtporten was still dissatisfied. He could never forgive Gustavus for having forestalled the revolution, and his morbidly irritable and suspicious temper saw slights and insults in the most innocent concomitants. His first quarrel with Gustavus happened in 1774 when he refused to accept the post of commander-in-chief in Finland on the eve of threatened war with Russia. The king good-naturedly overlooked his outrageous insolence on this occasion, but the inevitable rupture was only postponed. A most trumpety affair brought matters to a head. Sprengtporten had insulted the guards by giving precedence over them at a court-martial to some officers of his own dragoons. The guards complained to the king, who, after consulting with the senate, mildly remonstrated with Sprengtporten by letter. Sprengtporten thereupon tendered his resignation as colonel of the guards, and at a later interview with Gustavus was so violent and insolent that anything like agreement between them became impossible. Sprengtporten was haunted by the fixed idea that the jeunesse dorée of the court was in league with his old enemies to traduce and supplant him, and not all the forbearance of the king could open his eyes. He received a pension of £2,400 a year on his retirement and was allowed an extraordinary privilege of a guard of honour as long as he lived. Nevertheless, to the end of his career, he continued to harass and annoy his long-suffering benefactor with fresh impertinences.

(R. N. B.)

Spring (from "to spring," "to leap or jump up," "burst out," O. Eng., springan, a common Teut. word, cf. Ger. springen, possibly allied to Gr. σκέπασμα, to move rapidly), primarily the act of springing or leaping. The word is hence applied in various senses: to the season of the year in which plant life begins to bud and shoot; to a source of water springing or welling up from below the surface of the earth and flowing away as a stream or standing in a pool (see Water Supply); or to an elastic or resilient body or contrivance for retaining a bent or for imparting mechanical power. The most common form in which springs in this last sense are made is that of a spiral coil of wire or narrow band of steel. There are many uses to which they are put, e.g. for communicating motion, as in a clock or watch (q.v.), or for relieving concussion, as in the case of carriages (q.v.).

Springbok, or Springbock (Antidorcas euchore), an aberrant South African gazelle inhabiting the country south of the Zambezi, but ranging north-westwards to Mossamedes. In the more settled parts of Cape Colony, the Transvaal and the Orange Free State it now only exists within the enclosures of the large farms, and can hardly be said to be any longer truly wild. Both sexes carry lyrate horns; the shoulder-height of an adult male is about 30 in., and an average pair of horns measures 14 in. along the curve; in the female the horns are more slender. The general colour above is reddish fawn, separated from the white of the under-parts by a dark band on the flanks. Along the middle of the hinder half of the back is a line of long erectile white hairs, forming the "fan," continued down over the rump; in repose this is concealed by the surrounding hair, but is conspicuously displayed when the animal takes the great leaps from which it derives its popular name. The period and migrations of springbuck are well known, and though the tracks are
small compared with those of about 1850, they still include very large herds. In 1896 there was a great trek, and about then in the north of Cape Colony a herd was seen which was estimated at 500,000 head.

SPRINGER, ANTON HENRICH (1825-1891), German writer, was born at Prague on the 13th of July 1825 and was educated at the university of his native city. Taking an interest in art, he visited Munich, Dresden and Berlin, and spent some months in Italy; afterwards he settled at Tübingen and in 1848 he returned to Prague and began to lecture at his own university on the history of the revolutionary epoch. The liberal tone of these lectures brought him into disfavour with the ruling authorities, and in 1849 he left Bohemia and passed some time in England, France and the Netherlands. In 1852 he settled at Bonn, where he lectured on art and became a professor in 1859; in 1872 he went to the university of Strassburg and in 1873 to Leipzig. As a journalist and a publicist Springer advocated the federal union of the states ruled by the Austrian emperor, and asserted the right of Prussia to the headship of Germany; during the Crimean War he favoured the emancipation of the small states in the south-east of Europe from Turkish suzerainty. After seven years of feeble health, he died at Leipzig on the 31st of May 1891.

SPRINGER is known as a writer both on history and on art. In the former connexion his most important work is his Geschichte Oesterreichs seit dem wiener Frieden (Leipzig, 1863-1865), which has been translated into English as Austria since the Peace of Vienna (1814-1815; London, 1867). His other historical works are: Geschichte des Revolutionssieges (Prague, 1849); Oesterreich nach der Revolution (Prague, 1850); Oesterreich, Preussen und Deutschland (Prague, 1851); Paris im xix. Jahrhundert (Leipzig, 1856); and Protokolle des Verfassungs-Ausschusses im oesterreichischen Reichstage 1848-1849 (Leipzig, 1885). His principal works on art are: Baukunst des christlichen Mittelalters (Bonn, 1854); the valuable Handbuch der Kunstgeschichte (7th ed., Leipzig, 1906), a revised edition of his Grundzüge der Kunstgeschichte (Leipzig, 1887-1888); Geschichte der bildenden Künste im xix. Jahrhundert (Leipzig, 1858); Bilder aus der neueren Kunstgeschichte (Bonn 1867, and again 1868); Religious Monuments of Europe and the United States (Leipzig, 1885); and Geschichte der Kunst in des xix. Jahrhundert (Leipzig 1880-1881). Springer wrote two biographies: Friedrich Christoph Dahlmann (Leipzig, 1870-1872), and Albrecht Dürer (Berlin, 1892); and was responsible for the German edition of Crowe and Cavalcawle's Lives of the Early Flemish Painters, which was published at Leipzig in 1875. His book of reminiscences, Aus meinem Leben (Berlin, 1892), containing contributions by G. Freytag and H. Jantischek, was edited by his son Jaro Springer (5, 1896), who is also known as a writer on art.

SPRINGER (Fr. rein), the term given in architecture to the stone from which an arch spring (see Arch); in some cases this is the stone resting on the impost or capital, the upper surface of which is a plane directed to the centre of the arch. In vaulting, however, where the lower stone of the arch or rib is laid in horizontal courses, so as to bond it well into the wall, constituting a system of construction known in France as the tas-de-charge, the springer may be considerably higher. The term is sometimes applied to the lowest stone of a gable.

SPRINGFIELD, the capital of Illinois, U.S.A., and the county-seat of Sangamon county, on the Sangamon river, in the central part of the state. Pop. (1890), 24,925; (1900), 34,159, of whom 40,543 (1890) and 49,490 (1900) of the population spoke English and 2,227 negroes; (1901 census) 51,678. Land area (1900), 7,07 sq. m., of which 3,37 sq. m. had been annexed since 1890. It is served by the Baltimore & Ohio South-Western, the Chicago & Alton, the Chicago, Peoria & St Louis, the Illinois Central, the Wabash, and the Cincinnati, Hamilton & Dayton railroads, and by inter-urban electric lines. The city has a park and a boulevard system; the principal parks are Washington, Lincoln, Reservoir and Mildred. The chief public building is the state capitol (built in 1866-1888 at a cost of about $5,000,000). The structure is of granite, with porches of granite and a dome 363 ft. high. It is the fifth state capitol, and the second erected in Springfield. Other prominent buildings are the Supreme Court building, the county court house (the old state capitol, finished in 1853), the city-hall, the state arsenal, the high school and the public library. In Oak Ridge cemetery, adjacent to the city, is the Lincoln monument, erected over Abraham Lincoln's grave with funds raised throughout the country by a Lincoln Monument Association. It was designed by Larkin G. Mead, and consists of a granite obelisk 121 ft. above the centre of a mausoleum, which is 119½ ft. long and 72 ft. wide, and in which there are six crypts for the burial of members of Lincoln's family, and a memorial hall, a museum of Lincolniana. Around the foot of the obelisk (besides a heroic statue of Lincoln) are four groups of figures in bronze, symbolizing the army and navy of the United States. The monument was completed and dedicated in 1874, was transferred to the state in 1895, and restored and in large part rebuilt in 1899-1901. Lincoln's home (erected in 1839 and bought by the state of Illinois in 1844) is in Springfield, and is well preserved by the state of Illinois.

In the city are the state library (1842), the state law library (1839), the Illinois historical library (1889), of which the State Historical Society (1903) is a department, and the Illinois Supreme Court library; several educational institutions, including Concordia-Seminar (Evangelical Lutheran), the Ursuline Academy (Roman Catholic), and the Academy of the Sacred Heart (Roman Catholic); the Springfield hospital (1897; Lutheran); and the St John's hospital (1875; under the Sisters of St Francis), two orphanages, two homes for aged and infirm, the permanent grounds of the State Fair (157 acres), and a state insane asylum (160 acres). Springfield is a trading and shipping centre for a prosperous agricultural region, and ships large quantities of bituminous coal from the immediate vicinity. The Wabash and the Chicago, Peoria & St Louis railways have large repair shops here. Among the manufactures are agricultural implements, watches and watch material—the Illinois Watch Company has a large factory here—lumber, flour, foundry and machine-shop products, automobiles, shoes and boilers. The total value of the factory product in 1903 was $5,976,637 (67½ % more than in 1900). The first settlement was made in 1818. In 1821 the place was chosen to be the county-seat of the newly created Sangamon county and was named Springfield. In 1823 it was platted, and was named Calhoun in honour of John C. Calhoun, but this name was not popular and the former name was soon restored. Springfield was incorporated as a town in 1832 and chartered as a city in 1840. In 1837 the state legislature passed a bill making Springfield the capital, and in December 1839 the legislature first met here.

SPRINGFIELD, a city and the county-seat of Hampden county, Massachusetts, U.S.A., about 99 m. W. by S. of Boston and 26 m. N. of Hartford, Connecticut, on the east bank of the Connecticut river. Pop. (1800), 2312; (1859), 11,766; (1890), 44,179; (1900), 62,950, of whom 14,381 were foreign-born (3462 Irish, 2474 French Canadians, 1144 English-Canadians, 1321 English), 33,710 were of foreign parentage (either parent foreign-born), and 1021 were negroes; (1910, census), 88,926. Springfield is served by the Springfield division of the New York & New England, the Hartford division of the New York, New Haven & Hartford, the Connecticut River division of the Boston & Maine, and the Athol division and the main line of the Boston & Albany railways, and by later-urban electric railways. The river is crossed here by four large bridges. The area of the city, which until 1852 was a township, is 38.53 sq. m. In its extreme eastern part is the small village of sixteen Acres; north-west of the main part of the city on the Connecticut river is another village, Brightwood (on the Boston & Maine railway) and on the Chicopee river, north-east of the business part of the city, is the village of Indian Orchard, served by the Athol division of the Boston & Albany railway.

The city contains many public and private buildings of architectural importance. Among these are some of the earlier works of H. H. Richardson, such as the Court House, the Union railway station (1880), the Church of the Unity on State Street, and the North Congregational Church. Among other buildings are: Christ Church (Protestant Episcopal) St Michael's Cathedral (Roman Catholic), the South Congregational Church, the Memorial Church, and the Church of the Sacred Heart; the Art Museum (1894-1896), which contains the George Walter Vincent Smith art collection and an art library; the Horace
Smith Hall of Sculpture; the Museum of Natural History (1808), organized in 1850; a group of municipal buildings, with a tower 270 ft. high and a large auditorium; a government building (1891) containing the post office and custom house, the Hampden County Hall of Records, the City Library with 175,000 volumes, and two branch libraries given by Andrew Carnegie; a state armory, and the business buildings of the Springfield Fire & Marine Insurance Company, the Union Trust Company, and the Institution for Savings. The Public Library, the Art Museum, and the Museum of Natural History are controlled by the City Library Association, organized in 1872. In 1873 are a government arsenal and armory. The arsenal was established by the Continental Congress during the War of Independence and began to be used as a repository for arms and ammunition about 1777. The armory, in the midst of a park on Armory Hill immediately east of the railway station, was established in 1794. Here the famous Springfield muskets used by the Federal forces during the Civil War were manufactured ($800,000 having been made during that struggle) and it is still the principal manufactory of small arms for the United States army. Springfield has a good system of parks (under a board of park commissioners) and public playgrounds. The public park extends 20 acres. Forest Park (464 acres), in the southern part of the city, is the largest and most attractive; it contains a good zoological collection, and in its ponds is one of the finest collections in America of lotus plants and Oriental aquatic flora; at its southern entrance is a monument to President McKinley by Philip Martiny. In Merrick Park, adjoining the City Library, there is St. Gaudens's famous statue of "The Puritan," commemorative of Deacon Samuel Chapin, one of the early settlers of the city. In Court Square are a statue of Miles Morgan (1616-1690), an early settler, by J. S. Hurlbut, and a monument in memory of the soldiers and sailors of the Civil War. In Carew Triangle in the northern part of the city is a monument in honour of soldiers of the Spanish-American War. In the suburbs of the city is Hampden Park, once a famous race track. There are two large cemeteries, in one of which are buried many of Springfield's famous men, including Samuel Bowles and J. G. Holland, whose grave is marked by a medallion by St. Gaudens. Among the hospitals are the Mercy Hospital (1806, under the Sisters of Divine Providence), the Wesson Memorial (formerly Hampden Homeopathic) Hospital (1900), the Overlook Hospital (1879), and the Springfield Hospital (1883). The Springfield public school system is excellent, and in addition to the regular high school there are a technical high school, a vocational school, and a kindergarten training school. Other schools in Springfield are: the training school of the International Young Men's Christian Association (1885); the American International College, established in Lowell (1885) as the French-American College for the education of French-Canadians, and now working among various immigrant races; and the MacDuffie school (1890) and the Elms (1886), both schools for girls.

Springfield is noted for the diversity of its industries. In 1903 the capital invested in manufacturing establishments was $24,081,090, and in the value of its factory products ($75,860,250, not including those of the U.S. Arsenal; 42.4% more than in 1900) Springfield ranked ninth among the cities of Massachusetts. The largest single item in point of value was the product ($3,033,088) of the slaughtering and meat-packing establishments. Other important products were foundry and machine-shop products ($1,749,654); paper goods ($1,487,427); not including envelopes, which had an additional value of almost $700,000); cars, automobiles, firearms (besides the Federal arsenal there is the Smith & Wesson revolver factory); and printing and publishing ($1,165,544).

The principal newspapers are the Springfield Republican (Independent; weekly, 1824; morning, 1844), one of the most able and influential journals in New England, which since its establishment by Samuel Bowles (q.v.) has been the property of the Bowles family; the Union (Republican; morning, evening, and weekly; 1864); the Daily News (Democratic; 1880); and the Springfield Homestead (tri-weekly; 1878). The New England Homestead (weekly; published by the Orange Judd Company), Farm and Home, a semi-monthly, and Good Housekeeping, a monthly (published by the Phelps Publishing Company), and the Kindergarten Review (monthly, published by the Milton-Bradley Company, who publish other educational matter) are important periodicals.

The city is governed by a mayor, a board of aldermen (one from each of eight wards) and a common council of eighteen members (two or three from each ward, according to population), elected in December and every other year. The city owns and operates the waterworks.

Springfield was founded in 1636 by a company of settlers from Roxbury led by William Pynchon (1590-1662). Pynchon, who had been one of the original patentees of the Massachusetts Bay Colony, was dissatisfied with the government of Roxbury, of which he had been a founder. On a trip to the Connecticut Valley he selected a spot for a new colony which should have a limited membership and in which his ideas as to government might be put into execution. Accompanied by a dozen families he removed thither early in 1636. The settlers found there a settlement of Agawam Indians (probably allied with the Pocomcon), and the settlement was at first known as Agawam. For some time the political affiliation was with the Connecticut river towns in Connecticut, but later the authority of the Massachusetts General Court was recognized. In 1640 the name was changed to Springfield, after the native place of William Pynchon in Essex, England. For several years Pynchon was the dominating influence in the colony, ruling it with the power of an autocrat. In 1650 he published a tract (The Meritorious Price of Our Redemption) in which he attacked the Calvinistic doctrine of the atonement, and which was burned on Boston Common by order of the General Court. He was removed from the magistracy and returned to England in 1652.

In King Philip's War Springfield was a centre of hostilities. In October 1675 a force of hostile Indians, joined by the hitherto friendly Agawams, surprised the settlers, killed some of them, drove the others into the three fortified houses, and burned the remaining buildings. They were preparing to storm the fortified houses when they were in turn attacked and driven off by a force of militia. Springfield was somewhat out of the track of operations of the warfare between the French and English in America, as it was later in the War of Independence; but men of Springfield served in all these conflicts. In 1777 the armory was established and the place became an important military supply dépôt for the Continental forces. In July of that year representatives of the New England States and New York met here in convention to consider plans of co-operation for meeting Burgoyne's invasion. During Shays's rebellion there was a riot here in September 1786, and on the 25th of January 1787 the insurgent forces under Daniel Shays attacked the arsenal, but were dispersed by the militia under Brigadier-General William Morgan (1737-1817). Springfield remained little more than a large country market town until the completion of the Boston & Albany railway in 1839. From that time its growth as a railway and manufacturing centre was marked. Springfield was a strong abolition centre before the Civil War, and from here active plans were put in operation for sending material aid in the form of men and arms to the "free state" party in Kansas. The city was chartered in 1852.

SPRINGFIELD, a city and the county-seat of Greene county, Missouri, U.S.A., in the S.W. part of the state, about 238 m. from St Louis. Pop. (1890), 21,850; (1900), 23,267, of whom 2268 were negroes and 1057 foreign-born; (1910, census), 35,201. It is served by the St Louis & San Francisco, the Missouri Pacific, and the Kansas City, Clinton & Springfield railways. The city is pleasantly situated on the Ozark Dome, about 1300 ft. above sea-level, is regularly laid out on an undulating site, and has
attractive residential districts. The principal building is that of the Federal government (1894), which is built of Indiana cut stone. Springfield is the seat of Loretto Academy, of a state normal school, and of Drury College (co-educational; founded in 1873 by Congregationalists, but now undenominational), which comprises, besides the college proper, an academy, a conservatory of music and a summer school, and which in 1908-1909 had 500 students. Near the city is the Academy of the Visitation under the Sisters of St Chantal. The municipal water-supply is drawn from springs 3 m. north of the centre of the city. There are four large private parks (340 acres) on the outskirts, and two municipal cemeteries—a Confederate cemetery, maintained by associations, the only distinctively Confederate burial ground in Missouri; and a National cemetery, maintained by the government. Among the chief commercial concerns of this region, which has large mining, fruit, grain, lumber and livestock interests. The jobbing trade is important. Springfield ranks fourth among the manufacturing cities of the state; in 1905 the value of its factory products was $5,309,315 (28.2% more than in 1900). Flour and grist mill products constituted in 1905 a third of the total; and carriages and wagons ranked next. The St Louis & San Francisco railroad has large shops here.

Springfield was settled in the years following 1829, and was laid out in 1833, though the public lands did not pass from the United States for sale until 1837. In 1838 and again in 1840 Springfield was incorporated as a town, and in 1847 was chartered as a city; though government lapsed during much of the time up to 1865, when prosperous conditions became settled. At the opening of the Civil War, Springfield was one of the most important strategic points west of the Mississippi river. In 1861-62 it was occupied or controlled a half dozen times in succession by the Confederate and the Union forces; the latter retaining control of it after the spring of 1862. In the battle of Wilson's Creek (August 10, 1861), fought about 10 m. south of the city, and of the bloodiest battles of the war, relatively to numbers engaged, a force of about 5,500 Union soldiers under General Nathaniel Lyon was defeated by about 10,000 Confederates under Generals Benjamin McCulloch (1811-1862) and Sterling Price. The other occupations and abandonments were unattended by serious conflicts in the immediate vicinity. In January 1863, after Springfield had been made an important Union supply post, it was attacked without success by a Confederate force of about 2,000 men under General J. S. Marmaduke. The year 1870 was marked by the arrival of the first railroad. In the same year Springfield was laid out and was incorporated as a town in 1879 and 1881. In 1887 Springfield was chartered as a city, of a higher class, and in 1887 it absorbed North Springfield. After 1902 the city's growth in population and in industries was very rapid.

SPRINGFIELD, a city and the county-seat of Clark county, Ohio, U.S.A., at the confluence of Mad river and Lagonda Creek, about 45 m. W.S.W. of Columbus. Pop. (1890), 31,805; (1900), 38,253, of whom 3,311 were foreign-born (including 1,337 German, 1,097 Irish and 428 English) and 4,253 were negroes; (1910, census), 45,921. Springfield is served by the Clevelands, Cincinnati, Chicago and St Louis; the Pittsburgh, Cincinnati, Chicago & St Louis; the Erie, and the Detroit, Toledo & Ironton railways, and by an extensive interurban electric system. The older portion of the city is in the narrow valley of Lagonda Creek, but from here the city has spread over the higher and more undulating surface farther back until it occupies an area of about 83 sq. m. Among the public buildings are the United States government building, the Clark county court house, the City building (the first of which is occupied by the city market), the Warder public library (established 1872), which in 1908 contained 25,000 volumes, the city hospital, and the city prison and work-house. On hills near the city border are the Ohio state homes for the Masons, the Independent Order of Oddfellows, and the Knights of Pythias. The city park contains more than 250 acres, and in 1908 the city adopted plans for an extensive park system. Ferncliff cemetery is a picturesque burial-ground. On a hill on the north side of the city is Wittenberg College (1843), which in 1909 had 33 instructors and 710 students. Springfield is in a productive farming region, and water power is provided by Lagonda Creek, so that manufactures closely related to agriculture have always been prominent. The value of the factory product in 1905 was $13,654,423, of which $4,051,167 was the value of agricultural implements, $2,074,403 of foundry and machine-shop products, and $1,925,244 of flour and grist-mill products. The municipality owns and operates the waterworks. Natural gas is piped from Fairfield county.

In 1799 Simon Kenton and a small party from Kentucky built a fort and four cabins near Mad river 3 or 4 m. beyond the present western limits of the city. Later in the same year James Demint built a cabin on a hill-side overlooking Lagonda Creek. In 1801 he engaged a surveyor to plat a town here and soon after this the site of the Kenton settlement was abandoned. The new town was near the border-line that had been fixed between the Whites and the Indians, and the latter threatened trouble until 1807, when in a council held on a large hill in the vicinity, at which Tecumseh was the principal speaker for the Indians, peace was more firmly established. In 1818, when Clark county was erected, Springfield was made the county-seat. It was incorporated as a town in 1827, and in 1850 it was chartered as a city.

See E. S. Todd, A Sociological Study of Clark County, Ohio (Springfield, 1904).

SPRING-GUN, a device formerly in use by poachers and trespassers. Wires were attached to the trigger of a gun in such a manner that any one stumbling over or treading on them would discharge it and wound himself. Since 1827 spring-guns and all man-traps are illegal in England, except within a house between sunset and sunrise as a protection against burglars. Spring-guns are sometimes used to trap wild animals or birds. Another (Achorutes socialis) may sometimes be found in abundance in the snow. Zoologically the springtails belong to the sub-order Collembola of the order Aptera (q.v.).

SPRING VALLEY, a city of Bureau county, Illinois, U.S.A., on the north bank of the Illinois River, in the northern part of the state, about 104 m. S.W. of Chicago. Pop. (1800), 3837; (1900), 6214 (2845 foreign-born); (1910) 7035. It is served by the Chicago, Burlington & Quincy, the Chicago, Rock Island & Pacific, the Chicago & North Western, and the Chicago, Ottawa & Peoria (electric) railways. Spring Valley is a shipping and distributing point for a large number of bituminous coals in its vicinity. It was chartered as a city in 1886.

SPRUCE, i.e. spruce-fir, a coniferous tree belonging to the genus Picea, of which there are several species, such as the Norway spruce, Picea excelsa; the black spruce, Picea nigra, &c. (see Fir). The name has a curious origin, which explains also the particular meaning of the adjective "spruce," neatly dressed, smart in appearance, fine. From a number of early quotations given by Skeat (Etym. Dict.) it is clear that "spruce" is a variant of "pruce," spike or thistle, used by the German Spruce, sprouts or young shoots (seen in "Spruiten-bier, spruce beer, made of the sprouts of this fir").
SPRUE—SPURGEON

SPRUE, a tropical disease, prevalent in India, China, Java, and the West Indies. It is described by Sir Patrick Manson as characterized by a peculiar, inflamed, superficially ulcerated, exceedingly sensitive condition of the mucous membranes of the tongue and mouth; great wasting and anaemia; and more or less diarrhoea, with pale and frothy fermenting stools. It is an obscure disorder, and the treatment recommended is rest and milk diet.

SPULLER, Eugène (1835-1896), French politician and writer, was born at Seurre (Côte d’Or) on the 8th of December 1835, his father being a German who had married and settled in France. After studying law at Dijon he went to Paris, where he was called to the bar, and entered into close relations with Gambetta, collaborating with him in 1856 in the foundation of the Revue politique. He had helped Emile Ollivier in his electoral campaign in Paris in 1863, but when in 1869 Ollivier was preparing to “rally” to the empire he supported the republican candidate. During the siege of Paris he escaped from the city with Gambetta, to act as his energetic lieutenant in the provinces. After the peace he edited his chief’s Parisian organ, the République française, until in 1876 he entered the Chamber of Deputies for the department of the Seine. He was minister of foreign affairs during part of the brief Gambetta administration, and subsequently one of the vice-presidents of the chamber, serving also on the budget commission and on a special industrial and agricultural inquiry. His Parisian constituents thought his policy too moderate on the clerical question, and he had to seek election in 1885 in the Côte d’Or, which in later years he represented in the Senate. He was minister of education, religion and the fine arts in the Rouvier cabinet of 1887, minister of foreign affairs under Tirard (1889-1890), and minister of education in 1894 in the Casimir-Périer cabinet. He died on the 28th of July 1896. His published works include some volumes of speeches and well-known studies of Ignatius Loyola (1876) and of Michelet (1876).

SPUR (A.S. spura, spora, related to spurman, spurman, to kick, spur; cf. M.H.G. sporn, mod. Ger. Sporn), an instrument attached to the heel of a rider’s boot for the purpose of goading the horse. The earliest form of the horseman’s spur armed the heel with a single prong. In England the rowel spur is shown upon the seal of Henry III., but it does not come into general use until the 14th century. In the 15th century spurs appear with very long shanks, to reach the horse’s flank below the outstanding bars. After this time, and until the beginning of the modern period of costume at the Restoration, they take many decorative forms, some of which remain in the great spurs worn by Mexican cavaliers. Gilded spurs were reckoned the badge of knighthood, and in the rare cases of ceremonious degradation they were hacked from the knight’s heels by the cook’s chopper. After the battle of Courtrai, in 1302, the victors hung up bushels of gilt spurs in the churches of Courtrai and Maastricht as trophies of what is still remembered by the Flemings as the Goudenstapeng. For another reason the English named the French rout beside Thérouanne as the Battle of Spurs.

In architecture, a spur (Fr. griffe, Ger. Knoll), is the ornament carved on the angles of the base of early columns; it consists of a projecting claw, which, emerging from the lower torus of the base, rests on the projecting angle of the square plinth. It is possibly to these that Pliny refers (Hist. Nat. xxvi. 42) when speaking of the lizard and frog carved on the bases (spiraes) of the columns of the temples of Jupiter and Juno in the Portico of Octavius; the earliest known example is that of Diocletian’s palace at Spalato. In Romanesque work the sensitive contours are often found on the bases in crypts where they assumed various conventional forms; being, however, close to the eye, the spur soon developed into an elaborate leaf ornament, which in French 13th-century work and in the early English period is of great beauty; sometimes the spur takes the form of a fabulous animal, such as a griffin.

SPURGEON, CHARLES HADDON (1834-1902), English Nonconformist divine, was born at Kelvedon, Essex, on the 19th of June 1834. He was the grandson of an Essex pastor, and son of John Spurgeon, Independent and of the Upper Street, Islington. He went to school at Colchester and Maidstone, and in 1849 he became usher at a school in Newmarket. He joined the Baptist communion in 1851, and his work at once attested his “conversion.” He began distributing tracts and visiting the poor, joined the lay preachers’ association, and gave his first sermon at Teversham, near Cambridge. In 1852 he became pastor of Waterbeach. He was strongly urged to enter Stepney (now Regent’s Park) College to prepare more fully for the ministry, but an appointment with Dr Joseph Angus, who had been a tuition, urged him to accept it. He was eventually ordained, and the contretemps as a divine warning against a college career. The lack of early systematic theological training certainly had a momentous effect upon his development. Broad in every other respect, he retained to the last the narrow Calvinism of the early 19th century. His powers as a boy preacher became widely known, and at the close of 1853 he was “called” to New Park Street Chapel, Southwark. In a very few months’ time the chapel was full to overflowing. Exeter Hall was used while a new chapel was being erected, but Exeter Hall could not contain Spurgeon’s audiences. In 1856 an enlarged chapel was opened and the curious smallness for the number of the congregation had been projected in Newington Causeway. The preacher had recourse to the Surrey Gardens music hall, where his congregation numbered from seven to ten thousand. At twenty-two he was the most popular preacher of his day. In 1857, on the day of national humiliation for the Indian Mutiny, he preached at the Crystal Palace to 24,000 people. The Metropolitan Tabernacle, with a platform for the preacher and accommodation for 6000 persons, was opened for service on the 23rd of March 1861. The cost was over £50,000, and the debt was entirely paid off before the close of the opening services, which lasted from May 1861 to June 1864. Spurgeon preached habitually at the Tabernacle on Sundays and Thursdays. He frequently spoke for nearly an hour, and invariably from heads and subheads jotted down upon half a sheet of letter paper. His Sunday sermons were taken down in shorthand, corrected by him on Monday, and sold by his publishers, Messrs Passmore & Alabaster, literally by tons. They have been extensively translated. Clear and forcible in style and arrangement, they are models of Puritan exposition and of appeal through the emotions to the individual conscience, illuminated by frequent flashes of spiritual and spiritual humor. In his method of employing illustration he is suggestive of Thomas Adams, Thomas Fuller, Richard Baxter, Thomas Manton and John Bunyan. Like them, too, he excelled in his vigorous command of the vernacular. Among more recent preachers he had most affinity with George Whitefield, Richard Cecil and Joseph Irons. Collected as The Tabernacle Pulpit, the sermons form some fifty volumes. Spurgeon’s lectures, aphorisms, talks, and “ Saplings for Sermons” were similarly stereotyped, corrected and circulated. He also edited a monthly magazine, The Sword and Trowel; an elaborate exposition of the Psalms, in seven volumes, called The Treasury of David (1870-1885); and a book of sayings called John Ploughman’s Talks or, Plain Advice for Plain People (1869), a kind of religious Poor Richard. In the summer of 1864 a sermon which he preached and printed on Baptismal Regeneration (a doctrine which he strenuously repudiated, maintaining that immersion was only an outward and visible sign of the inward conversion) led to a difference with the bulk of the Evangelical party, both Nonconformist and Anglican. Spurgeon maintained his ground, but in 1865 he withdrew from the Evangelical Alliance. Subsequently in 1887 his distrust of modern Biblical criticism led to his withdrawing from the Baptist Union. His powers of organization were strongly exhibited in the Pastors’ College, the Orphanage (at Stockwell), the Tabernacle Almshouses, the Colportage Association for selling religious books, and the gratuitous book fund which grew up under his care. He received large money testimonial
SPURN HEAD—SQUALL

(£4000 on his silver-wedding day and £5000 on his fiftieth birthday), which he handed over to these institutions. He died at Montcote on the 21st of January 1892, leaving a widow with twin sons (b. 1856). One of them, Rev. Thomas Spurgeon, after some years of pastorate in New Zealand, succeeded his father as minister of the Tabernacle, but resigned in 1908 and became president of the Pastors' College.

An Autobiography was compiled by his widow and his private secretary from his diary, sermons, records and letters (1897-1900).

SPURN HEAD, or SPURN POINT, a foreland of the North coast of England, in Yorkshire, projecting across the mouth of the Humber. Its length is nearly 4 m. from the village of Kilnsea, but its breadth seldom exceeds 300 yds., and it rises only a few feet above sea-level. It is formed of sand and shingle, the débris of the soft coast of Holderness to the north, from which it is estimated that six million tons of material are annually removed by southerly currents along the shore. Deep water is found close off the seaward side of Spurn Head, the formation of which appears to have taken place within historic times, even since about the close of the 16th century. There are two lighthouses and a lifeboat station on the head.

SPURZHEIM, JOHANN CHRISTOPH [KASPAR] (1776-1832), German phrenologist, was born near Treves on the 31st of December 1776. He made the acquaintance of F. J. Gall while studying medicine in Vienna, and for some years assisted him in spreading his phrenological doctrines, but in 1813 the two separated. Spurzheim lectured with considerable success in England and the United States when he died at Boston, Massachusetts, on the 10th of November 1832. His works include: Anatomie et physiologie du système nerveux (1810-1820); Observations sur la phrénologie (1816); The Physiognomical Systems of Drs. Gall and Spurzheim (1815), and Essai philosophique sur la nature de l'Homme (1820). (See PHRENOLOGY.)

SPY, a commune near Namur, Belgium. Here in 1886, in Biethe aux Roches cavern, Maximilien Lohest and Marcel de Puydt found two nearly perfect skeletons (man and woman) at the depth of 16 ft., with numerous implements of the Mousterian type. All the human remains are now in the Lohest Collection, Liége. The skulls were characterized by enormous brows, retracting forehead, massive jaw-bones, rudimentary chin and large posterior molars. The skeletons were further marked by a divergent curvature of the bones of the fore-arm; the tibia were shorter than in any other known race, and stouter than in most; the tibia and femur, being so articulated that to maintain equilibrium the head and body must have been thrown forward, as in the gait of the larger apes. These characteristics justify placing "the man of Spy in the lowest category... the dentition is inferior to that of the neolithic man in France... approximates near to the apes, although there is still, to use the language of Fraipont and Lohest, an abyss between the man of Spy and the highest ape" (E. D. Cope, "The Genealogy of Man" in The American Naturalist, April 1893, p. 334). With the skeletons were found bones of extinct mammals, the woolly rhinoceros (Rhinoceros tichorhinus), mammoth (Elephas primi-genius), and the cave-bear (Ursus spelaeus).

See also L'Homme contemporain du mammouth à Spy (Namur, 1887); G. de Mortillet, Le Préhistorique (1900).

SPY (from "to spy" or "espy"; O. Fr. espie, espier, to spy, watch; cf. Ger. spähen, Lat. spectare, to look; the Fr. term "espionage" is of course from the same source). In war—a person who, disguised or without bearing the distinguishing marks of belligerent forces, mixes with the enemy for the purpose of obtaining information useful to the army he is serving. As by the law of war a spy is liable, if caught, to the penalty of death, the Hague "Regulations respecting the Laws and Customs of War on Land" are very precise on the subject. A soldier not wearing a disguise is not a spy, though he may be found within the zone of the hostile army and though his object may be to obtain information; nor are soldiers or civilians spies who cross enemy lines openly carrying messages. This applies even to persons sent in balloons for the purpose of carrying despatches. In short, it is essential to the character of a spy that he should act clandestinely or on false pretences, that he should be caught within the zone of operations of the hostile belligerent forces, and that his object should be to obtain information for use against them (art. 29). The regulations also provide that he cannot be "punished" without previous trial (art. 30). Nor can he be treated as a spy if he is captured after he has rejoined his army. He must then be treated as an ordinary prisoner of war (art. 31).

The term "spy" is applied also to those who in time of peace secretly endeavour to obtain information concerning the forces, armaments, fortifications or defences of a country for the purpose of supplying it to another country. Every country has always endeavoured to guard jealously its military and naval secrets, and with this object denies admittance to fortified places or arsenals to those who cannot produce the proper credentials. Notwithstanding the utmost precautions, it is impossible to prevent some amount of leakage to countries which are prepared to pay for information otherwise unobtainable. Consequently, most countries have legislation dealing with "spying" in time of peace, and from the Old Testament to the present there have been frequent cases of spies and spysmanship.

SPYDING (art. 1720), a naval officer despatched on special service. In military use, "spying" (a shortened form of "spydrin") is used of any small detachment of men detailed for drill, fatigue or other duty.

SQUANDER (from skald or seal, a ninepin), an old English game in which disks are snapped or struck with the palm from the edge of a table or board at a mark at its centre. Its early prototype was shore-groat, called also shyp-groat or slide-thrift, which in the 18th century went under, the name of jervis or jervis. This last variation was played on a table marked with chalk into alleys divided into squares numbered from 1 to 9 or 10, the object being to send a halfpenny into a high-numbered space. If it went beyond nothing was scored. The highest aggregate of a certain number of plays won. The most scientific development of this class of games is the modern Slack-Jerd (q.v.).

SQUALL, the name given to any sudden increase of wind to gale force. Generally speaking a squall is understood to be of short duration, but the word "gust" would be used to indicate an increase of wind force of more transient character than a squall. Gusts may succeed one another several times within the compass of a minute. A squall may comprise a succession of gusts, with intervening partial lulls, and would last with varying intensity for some minutes at least. The distinction
between gusts and squalls is best illustrated by the traces of a Dines pressure-tube anemograph. The trace reproduced in fig. 1 for an ordinary steady wind shows that the force of the wind is constantly oscillating. The general appearance of the trace is a ribbon which has a breadth proportional to the mean wind velocity. The breadth of the ribbon is also dependent upon the nature of the reference; the better the exposure the narrower the ribbon; for an anemograph at a coast station the ribbon is wider for a shore wind than for a sea wind.

From the records obtained at Scilly and Holyhead, Dr G. C. Simpson concluded that a wind of mean hourly velocity was composed of alternations of gusts and lulls ranging on the average between limits \(-5\pm1.21\) and \(-10\pm6.81\). In other words, the average range of the ribbon is \(5\pm4.5\) for the two stations during the hour when the mean velocity is \(v\), and the extreme range within the same period is \(2\cdot0\pm6.81\). The differences of gust velocity at stations with different exposures may be illustrated by quoting the breadth of the ribbon for a 30 m wind at the following stations:

- Southport (Marshside) 10 m.
- Scilly 15 m.
- Shoeburyness 20 m. (from W.)
- Holyhead 15 m. (from E.N.E.)
- Pendennis Castle (Falmouth) 8 m. (from S.)
- Aberdeen 16 m. (from W.)
- Alnwick Castle 30 m. (from N.W.)
- Kew 30 m.

Fig. 2 represents a succession of squalls occurring in an ordinary gusty wind; the squalls succeed one another with fair regularity about every twenty minutes and last in full force for a few minutes.
succession of squalls of this kind is a common experience with westerly wind at Scilly, and the onset of squalls is generally associated with the veering of the wind to the north-west. Changes in wind velocity, either in the form of gusts or squalls, are generally associated with some change in direction of the wind, but the relation between the changes in gusts have not yet been studied.

A characteristic of squalls is the suddenness with which the increase of wind velocity occurs. At sea the ruffling of the surface can be seen travelling over the water, and the wind producing it and travelling with it strikes a sudden blow when it reaches a ship. If squalls are of sufficient violence to do damage to trees or buildings their progress can be traced in a like manner over the land.

These phenomena are exhibited in their most striking form in "line squalls." The characteristic feature of a line squall is that a number of places arranged, roughly speaking, in a straight or slightly curved line across the country experience a similar sequence of events at the same time, and the line of action sweeps across the country as a front advancing nearly uniformly throughout its length. This march of a linear front gives the impression of a wave or bore with an advancing front hundreds of miles long, sweeping over the country with a velocity that can be identified from the time of occurrence of the various changes at different places. The associated events are very well marked by those recorded for the line squall of the 2nd of August 1906 (fig. 3). They comprise a sudden increase of wind with a veer of direction of 45° to 90°, a sudden rise of pressure known in France as the crochet d'orage, and in Germany as the Gewitter Nase, a pronounced and permanent fall of temperature, and a shower of rain, hail or snow. While these various phenomena are indicated all along the advancing line their intensity may be very different at different points along it. The squall often exhibits greater violence in the middle portion, and it becomes more intense as the whole line advances. In the most fully developed portions the weather phenomena take the form of thunderstorms with violent wind and rain. The course of events in a typical line squall has been most carefully worked out by R. G. K. Lempfert in a paper on the "Line Squall" of the 8th of February 1906 (Quart. Journ. Roy. Met. Soc. vol. xxxii.). Fig. 4 (reproduced from the papers) shows the successive positions of the line of the front from which its rate of travel can be estimated. The line of advance of a line squall is generally from some point between south and north on the western side, the change of wind being from a warm southerly or westerly wind to a colder westerly or northerly one. So far as is known to the writer there is no case of a line squall exhibiting a backing wind. The date and direction of advance appear to be, generally speaking, those of the final wind, but in cases where the thunderstorms are developed there is a local violence of the wind bearing no relation to the isobaric distribution of the final wind.

Endeavours have been made to explain the phenomena of line squalls as due to vortex motion of particular character. The violent wind blowing out in front of the storm is part of the circulation of a vortex with horizontal axis. It supplies the air for the rainfall of the stations in front. Its place is taken by descending air at the back, which becomes in its turn the surface supply for stations farther in. But such an explanation seems in many ways incomplete. Although perhaps if the wind velocities in a vertical plane were plotted there might be some evidence of circulation in the mathematical sense by integrating round a closed curve, yet the idea of circulation in a vertical plane as suggesting the primary constitution of the phenomena is very inadequate. The change of air which takes place during the passage of the line squall is altogether different from that which we would get by passing the surface air through a complete vertical cycle and condensing a large quantity of water vapour on the way. If vertical circulation were complete the air would return to the surface warmed and dried. A few revolutions would produce a very considerable elevation of temperature. The air which remains after the passage of a line squall is, however, distinctly colder, of an entirely different kind from that which it replaces and, in those cases which have been investigated, can be traced back to a different point of the compass. Moreover, the smallness of vertical dimensions in the atmosphere as compared with the horizontal dimensions makes it difficult to allow that there is really room for an effective vortex with a horizontal axis. To carry air up 5 m. and bring it back again would practically deprive it of all its moisture and raise its temperature 7° F. Yet 5 m. would be a very small allowance for the horizontal spread of the phenomena of the squall.

The sudden replacement of warm air by cold with a change of wind seems much more likely to be associated with the flooding of the country by an advancing sweep of cold air. The pressure changes are continuous in the old layer and in the new layer, but discontinuous with varying degrees of discontinuity along the line of junction, where instability of the upper air may be set up. Fig. 5 shows the discontinuity of pressure in the example discussed by Mr Lempfert. It is clear that as the discontinuity of pressure becomes accentuated there arise
SQUALL

violent and destructive form is shown in the records for the 1st of June 1908. In the record at Kew the squall of wind which destroyed a number of the trees of Bush Avenue is shown as lasting for a very long period (fig. 6).

A line squall of historic interest is that which capsized H.M.S. "Eurydice" off the Isle of Wight on the 24th of March 1878. The occurrence is discussed by the Hon. Ralph Abercromby in 1884 (Quart. Journ. Roy. Met. Soc. x. 172) and previously by the Rev. Mr Clementhey (Symon's Met. Mag., April 1878). The shift of wind in this case appears to have been from west to north, and the change in the wind was accompanied by the transitions from fine blue sky to snow. The records at the seven observatories belonging to the Meteorological Council are reproduced in the Quarterly Weather Report, from which fig. 7 is taken.

Whatever explanation may be given of the cause and origin of the phenomena of line squalls, it must take account of the fact that a first squall is often succeeded by others of a similar character but often of less intensity than the first. After the sudden shift of wind, with accompanying weather changes, the conditions seem to revert more or less to the original state. The warm southerly wind reasserts itself, but is driven out again by another attack, and ultimately the cold wind holds the field. It is easy to suggest, but at present not easy to verify, the course of replacement of the warm wind. Upper air observations in such circumstances with kites or manned balloons are dangerous, both for the apparatus and the observer; but it may be possible to trace the actual course of events by the records of rounding balloons supplemented by observations of the motive balloon by means of theodolites.

Little has been said about the actual force of the wind in gusts or squalls, and in the present state of anemometry it is difficult to

Fig. 5.—Distribution of Pressure (Feb. 8, 1906). Isobars are shown for each 0·1 in.

in the localities on the line of advance very steep pressure gradients for which there are corresponding winds. The violent winds may therefore be attributed to the breakdown of the dynamical system under the stress of these local differences of pressure.

From this point of view the phenomena of the line squall are to be regarded as a development of the ordinary phenomena of the V-shaped depression. A sudden change of wind and a line of rain that pass over the country with the velocity of the same order as that of the following wind are quite common features of the S.W. quadrant of a cyclonic depression, and they, too, seem to point to the juxtaposition of currents of different temperature coming from different regions but forming adjacent components of supply for the depression.

Examples of all degrees between the comparatively unimportant rain line and the most violent tornado-like squall could be put side by side with cases in which the typical pressure, temperature and weather changes are accompanied by a sudden lull in the wind, as in the example quoted in the Life History of Surface Air Currents (M. O. publication, No. 174, 1906). An example of a line squall in its most

Fig. 6.—Records of wind velocity on June 1, 1908.

Fig. 7.—"Eurydice" Squall, from the Quarterly Weather Report.
regard the figures hitherto obtained as final; moreover, the large wind force in squills is probably subject to large local variations, the squill, the record of the squill of 1st June 1908 at Kew and Shepherd's Bush suggests that it may have been much stronger at Bushy, where the damage was done. The highest velocity in a gust hitherto recorded on instruments belonging to the Meteorological Office at Sandycombe Castle on the 15th of March 1905. Gale force is defined for the purposes of the meteorological office as that of a wind which has an average velocity during an hour of 38 m. per hour. According to Simpson's results at Scilly or Ladybird, where the measurements are taken, the average of the reckoning of gales would reach 44 m. per hour in the ordinary gusts, with occasional records of 51 m. per hour. Squills with velocity of reaching 75 m. per hour, and the rare wind of wind velocity which constitutes a squill may be anything between 40 m. an hour and upwards of 100 m. an hour. (W. N. S.)

SQUAW, the anglicized word for woman among the North American Indians; the Massachusetts Indian form is squa or squo, the Narraganset squaw, the Cree ciskaou, Delaware ochoue, kheoue, &c. It is also used in composition with names of animals to denote the female. SQUIRREL, support to be derived from the German word schieder, to push or shove forward with a sliding movement, the name for a projected kind of firearm that is flung out of a groove and breaks with a flash and a clatter. Hence, in the literary sense, a squib is a slight satirical composition put forth on an occasion; and it is intended that it should make a noise by its explosion, not by possession of any particular importance. Steele says, in the Tatler, that “squibs are those who in the common phrase of the world are call'd libellers, lampooners and pamphleteers,” showing that, at the beginning of the 18th century, the man who composed the satire, as well as the satire itself, was equally culpable. The word “squib” is of the same origin as these little literary fireworks flew from place to place, and he himself was a proficient in the making of noisy squibs. Perhaps the best type of a squib in English literature is Gray's Candidate, which was written and circulated among the electors in 1764, when Lord Sandwich was canvassing for the office of high-steward of the university of Cambridge. The object of this poem was, by ridicule and defamation, to injure Lord Sandwich's prospects of success. When once the election was over the verses served no further purpose, and they have survived simply in consequence of their fluent wit and of the reputation of the great poet who composed them. (See also LAMPOON.)

SQUILL, the name under which the bulbous root of Urginea Scilla is used in medicine. It belongs to the natural order Liliaceae. The name of "squill" is also applied by gardeners to the various species of Scilla. The medicinal squill is a native of the countries bordering the Mediterranean, and grows from the sea-level up to an elevation of 3000 ft. The bulbs are globular and of large size, often weighing more than 4 lb. Two varieties are met with, the one having white and the other pink scales. They are collected in August, when they are leafless, the membranous outer scales being removed and the fleshy portion cut transversely into slices and dried in the sun. These are then packed in casks for exportation. They are chiefly imported into the United Kingdom from Malta. When reduced to powder and exposed to the air the drug rapidly absorbs moisture and cakes together into a hard mass.

Squill has been used in medicine from a very early period. The ancient Greek physicians prescribed it with vinegar and honey almost in the same manner as it is used at present. The composition of the drug, first efficiently studied by Merck in 1875, is very complex. The chief constituent is scillitoxin, a bitter and intensely irritating principle. A somewhat similar substance, scillitoxin, is also physiologically active. The bitter glucoside, scilline, or scillarin, is unimportant. The bulb also contains mucilage, and a considerable quantity of an irritant resin. It has been shown that a definite action on the heart is not obtainable unless a large dose of squill be given, and that the action is curative. The irritation on the genito-urinary tract, a bronchial and a renal irritant. The two latter properties constitute it a powerful expectorant and a fairly active diuretic. The drug must not be given alone, owing to its toxic effects. The bitter is given as a diuretic in cardiac cases in the form of a pill containing one grain each of mercury, digitals and squill. Combined with a sedative, such as opium, it may be given in chronic bronchitis. It must not be given in acute bronchitis, for it is only aggravates, nor in phthisis, which is invariably accompanied by a hyperventilatory state of the alimentary tract. For similar reasons squill should not be given in any form of Bright's disease. The textbook prohibition against its use in acuteBright's disease should certainly be extended to chronic nephritis in all its forms. The use of this irritating drug, while still extensive, is yearly diminishing. It does not always relieve cysts in which it may not otherwise be achieved at loss cost to the secreting surfaces of the patient.

An allied species, Urginea indica, is used in India in the same manner as the European species. The true squills are represented in Great Britain by two species, Scilla autumnalis and S. serosa. The former has a racemose inflorescence and leaves appearing in autumn after the flowers; the latter has the flowers arranged in a corymbose manner, leaves appearing in spring, and is confined to the sea-coast. Several species are cultivated in gardens, S. bifolia and S. stibrica being remarkable for their beautiful blue flowers, which are produced in early spring; Chinese squill is S. chinensis, a half-hardy species; Roman squill is a popular name for species of Belolavialis, a genus now generally included in Hyacinthus; striped squill is Psachkina scilloides, a lilaceous plant, not an herb.

SQUINCH, possibly a corruption of sconce (French equivalents are pendentive, trompe), the term in architecture applied to a corbeling out by means of arched rings in stone thrown across the angles of a square tower, to carry an octagonal spire or a dome. The earliest examples are found in the palaces of Serbittan and Firuzabad constructed by the Sassanid dynasty (A.D. 350-450), and in the mosque at Damascus, where it takes the form of a niche. In early French Romanesque work a small niche with additional rings above is employed; a greater importance is sometimes given by small shafts at the sides, of which there are examples in the Cloisters churches of Egypt, and in France in the cathedral at Le Puy and the church of St Martin at Dijon. (See PENDENTIVE.)

SQUINT (possibly connected with Swed. stinka, to flinch, O. Eng. swiccan, avoid), properly an adjective meaning looking different ways, hence oblique, indirect vision, particularly a strabismus, an affection of the eyes consisting in non-coincidence of the optic axes (see EYE, § Diseases; and Vision). In architecture squint is used of a slit or opening usually on one or both sides of the chancel arch, giving a view of the altar from the transept or aisles; it is also styled" hagioscope." (q.v.)

SQUIRE, an abbreviated form of "esquire" (q.v.), originally with the same meaning of an attendant on a knight. In this form, however, the word has developed certain special connotations. Thus in England it is used partly as a courtesy title, partly as a description of the chief landed proprietor, usually the lord of the manor, in a parish the lesser proprietors being "gentlemen" or yeomen. In some parts also it is not uncommon for the title of "squire" to be given to small freeholders of the yeoman class, known in Ireland half-contemptuously as "squires." In the United States the title has also survived and is applied to justices of the peace, or judges of lower dignitaries in country districts and towns. In another sense "squire" has survived in its sense of "attendant," "to square" being used so early as Chaucer's day as synonymous with "to wait upon." A "squire of dames" is thus a man very attentive to women and much in their company. Footpads and highwaymen were termed sometimes "squires of the pad" as well as "gentlemen of the road.

SQUIRREL (Fr. écureuil), properly the name of the well-known red, bushy-tailed British arboreal mammal, Sciurus vulgaris, typifying the genus Sciurus and the family Sciuridae, but in a wider sense embracing all the rodents included in this
and a few nearly allied genera. For the characteristics of the family Sciuridae and the different squirrel-like genera by which it is represented, see Rodentia.

What may be called typical, that is to say arboreal, squirrels are found throughout the greater part of the tropical and temperate regions of both hemispheres, although they are absent both from Madagascar and Australasia. The species are both largest and most numerous in the tropics, and reach their greatest development in the Malay countries. Squirrels vary in size from animals no larger than a mouse, such as *Nanomys socius* or Borneo, or *N. minitus* of West Africa, to others as large as a cat, such as the black and yellow *Rattus bicolor* of Burma and the Malay area. The larger species, as might be expected from their heavier build, are somewhat less strictly arboreal in their habits than the smaller ones. The common squirrel, whose habits are too well known to need special description, ranges over the whole of Europe and Northern Asia, from Ireland to Japan, and from Lapland to North Italy; but specimens from different parts of this wide range differ so much in colour as to constitute distinct races. Thus, while the squirrels of north and west Europe are of the bright red colour of the British animal, those of the mountainous regions of southern Europe are of a deep blackish grey; while those from Siberia are a clear pale grey colour, with scarcely a tinge of rufous. There is also a great seasonal change in appearance and colour in this squirrel, owing to the ears losing their tufts of hair and to the bleaching of the tail. The pairing time of the squirrel is from February to April; and after a period of gestation of about thirty days the female brings forth from three to nine young. In addition to all sorts of vegetables and fruits, the squirrel is exceedingly fond of animal food, greedily devouring mice, small birds and eggs. The squirrels of the typical genus *Sciurus* are unknown in Africa south of the Sahara, but otherwise have a distribution co-extensive with the rest of the family.

Although the English squirrel is a beautiful little animal, it is surpassed by many of the tropical members of the group, and especially by those of the Malay countries, where nearly all the species are brilliantly marked, and many are ornamented
taken to quarter itself in the immediate neighbourhood of human habitations. It has been generally supposed that there is only one palm-squirrel throughout India, but there are really two distinct types, each with local modifications. The first or typical palm-squirrel, *Panamibius palmatus*, inhabits Madras, has but three light stripes on the back, and shows a rufous band on the under-side of the base of the tail. In Pennant's palm-squirrel, *P. pennanti*, on the other hand, there is a pair of faint additional lateral white stripes, making five in all, and the under-surface of the tail is uniformly whitish olive. As this species has been obtained in Surat and the Punjab, it is believed to be the northern type. One Oriental species (*Sciurus caniceps*) presents almost the only known instance among mammals of the assumption during the breeding season of a distinctly ornamental coat, corresponding to the breeding plumage of birds. For the greater part of the year the animal is of a uniform grey colour, but about December its back becomes a brilliant orange-yellow, which lasts until about March, when it is again replaced by grey. The squirrel shown in the illustration is a native of Burma and Tenasserim, and is closely allied to *S. caniceps*, but goes through no seasonal change of colour. Another Burmese squirrel, *S. haringtoni*, differs as regards colour in a remarkable manner from all other known members of the group. It is a medium-sized species of a pale creamy buff colour above, lighter beneath, and with a whitish tail, while it is further characterized by the absence of the first upper premolar, which shows that it is not an albino or pale variety. Two examples were obtained by Captain H. H. Harington, of one of the Punjabi regiments, on the banks of the upper Chindwin river. It may be added that generic subdivisions of the squirrels are based mainly on the characters of the skull and teeth. That they are essential is evident from the circumstance that the African spiny squirrels *Xerus* (see Spiny Squirrel) come between *Sciurus* and some of the other African genera.

**SQUIRREL MONKEY**, the English name of a small golden-haired South American monkey, commonly known as *Chrysotrichia sciuica*, and also applied to the two other members of the same genus, whose collective range extends from Costa Rica to Bolivia and Brazil. It has, however, been proposed to transfer the name *Chrysotrichia* to the marmosets of the genus *Hepale*, to which it is stated to have been originally applied, and to replace it by *Scimiri*. The squirrel-monkeys were formerly classed with the douroucoulis (see Douroucoulis), but, on account of their brain-structure, they have been transferred to the Cebinae (see Capuchin-Monkey), from the other members of which they differ by their practically non-prehensile tails and smaller size, while they are further distinguished by their comparatively large eyes and the backward prolongation of the hinder part of the head. They are exceedingly primitive little monkeys. (See Primates.)

**SRINAGAR**, capital of the state of Kashmir, in Northern India, 5250 ft. above sea-level, on both banks of the river Jhelum, which winds through the city with an average width of 80 yds. and is crossed by seven wooden bridges. The houses occupy a length of about 3 m. and a breadth of about 1½ m. on either side of the river; but the greater part of the city lies on the right bank. No two buildings are alike. The curious grouping of the houses, the frail tenements of the poor, the substantial mansions of the wealthy, the curious carving of some, the balconies of others, the irregular embankment and the mountains in the background, form a quaint and picturesque spectacle. Area, 3705 acres. Pop. (1901), 122,618. The city is exposed to both fire and flood. In 1893 six of the seven bridges were swept away, and great damage was again caused in 1903. A regular water-supply has been provided. The artisans of Srinagar enjoy a high reputation. Unfortunately, the historic industry of shawl-weaving is now practically extinct. The loss of the French market after the war of 1870 was followed by a line of 1877-1879, which drove many of the weavers into the Punjab, and the survivors have taken to the manufacture of carpets. Other industries are paper, leather, papier

The Burmese Red-bellied Squirrel (*Sciurus pygerythus*).
mâché, silver and copper ware, wood-carving and boat-making. The three chief routes of communication with India are: (1) along the Jhelum valley to Murree and Rawalpindi, which has been opened throughout for wheeled traffic (105 m.); (2) over the Bânhâl pass (9,000 ft. above the sea) to Jammu (163 m.); (3) over the Pir Panjâl pass (11,400 ft.) to Gujrat (180 m.).

See Sir Walter R. Lawrence, The Valley of Kashmir (1893); M. A. Stein, Chronicle of the Kings of Kashmir (1900).

SRIRANGAM, or SERENGHAM, a town of British India, in Trichinopoly district, Madras presidency, 2 m. N. of Trichinopoly city. Pop. (1901), 23,030. It stands on an island of the same name, formed by the bifurcation of the river Cauvery and by the channel of the Coleroon. The town is celebrated for its great temple, dedicated to Vishnu, composed of seven square enclosures, one within another, and 359.50 ft. distant from each other. Each enclosure has four gates with high towers, placed one in the centre of each side opposite to the four cardinal points. The successively widening enclosures and the greater elaboration of the outer as compared with the inner buildings mark the progress of the shrine in fame and wealth. The outer wall of the temple is not less than 4 m. in circumference. Not far distant is the smaller but more beautiful Jambukeswaram, a temple dedicated to Siva. From 1751 to 1755 the island and its pagodas were the object of frequent contests between the French and the English.

STAAI, MARGUERITE JEANNE CORDIER DELAUNAY, Baronne de (1684-1759), French author, was born in Paris on the 30th of August 1684. Her father was a painter named Cordier. A woman of great taste, she have conceived a great love for the art of literature, and by marrying a man of wealth, she was able to lead a life of ease which she used to pass in the society of her many friends. She translated into French nearly all the works of Seneca, Plutarch, and others, and her literary labours were rewarded by the praise of Voltaire, Diderot, and other French critics.

Her life was one of great happiness, and she was surrounded by a court of close friends who were attached to her. She was a great patron of the arts, and her house was the centre of literary and musical society. She was a great admirer of the classics, and her translations of Greek and Latin authors were highly esteemed.

She died in Paris on the 7th of December 1759, and her tomb is at the pantheon of the city.

See M. Ruggiero, Scavi di Stabia del 1749 al 1762 (Naples, 1801); J. Beloch, Campanien, 2nd ed. p. 428 sqq. (Breslau, 1890). (T.A.S.)

STABLE, a building in which horses are kept, including the stall in which they stand, furnished with manger and rack, the room in which the harness is kept and attended to, the loft in which the hay and corn are stored, and other accessory rooms, &c. (See Horse.) This is the current usage, but the word was formerly applied, as was the Latin stabulum, i.e. standing place (from stare, to stand), to a stall or enclosure for all kinds of domestic animals, cows, sheep, &c. The adjective "stable," meaning firmly established, comes directly from Latin stabilitas, also from stare, to stand.

STADE, BERNHARD (1848-1906), German Protestant theologian, was born on the 11th of May 1848, at Arnsstadt, in Thuringia. He studied at Leipzig and Berlin, and in course of time became (1873) professor ordinarius at Giessen. Once a member of Franz Delitzsch's class, he became a convinced adherent of the newest critical school. In 1881 he founded the Stadische historische Wochenschrift, which he continued to edit; and his critical history of Israel (Geschichte des Volks Israel, 2 vols., 1887-1888; vol. ii. in conjunction with Oscar Holtzmann) has made him very widely known. With C. Siegfried he has revised and edited the Hebrew lexicon, Hebr. Wörterbuch zum Altten Testament (1892-1893). Stade's other works include Über die alttestamentlichen Vorstellungen vom Zustand nach dem Tode (1877), Lehrbuch der hebr. Grammatik (vol. i., 1879), Ausgewählte akadimische Reden und Abhandlungen (1899), and Biblische Theologie des Alten Testaments (1905, &c.). He died on the 6th of December 1906.

See O. Pfeiderer, Development of Theology (1890).
STADE, a town of Germany in the Prussian province of Hanover, situated on the navigable Schwinge, 34 m. above its confluence with the Elbe, 20 m. N.W. of Hamburg on the railway to Cuxhaven. Pop. (1903), 10,837. It carries on a number of small manufactures and has some shipping trade, chiefly with Hamburg, but the rise of Harburg has deposed it from its former position as the chief port of Hanover. In the neighbourhood are deposits of granite and salt. The Hanseatic rights, erected in 1755 and strengthened in 1816, were dissolved in 1822.

According to the legend, Stade was the oldest town of the Saxons and was built in 321 B.C. Historically it cannot be traced farther back than the 10th century, when it was the capital of a line of counts. In the 13th century it passed to the archbishopric of Bremen. Subsequently entering the Hanseatic League, it rose to some commercial importance. In 1648 Stade became the capital of the principality of Bremen under the Swedes; in 1719 it was ceded to Hanover, the fate of which it has since shared. The Prussians occupied it without resistance in 1866. See Jobedmann and Wittenpennig, Geschichte der Stadt Stade (Stade, 1898).

STADION, JOHANN PHILIPP KARL JOSEPH (1762-1824), Austrian statesman, entered the diplomatic service and rose early to a high position. In 1790-1793 he was ambassador in London. After some years of retirement he was entrusted (1806) with a mission to the Prussian court, where he endeavoured in vain to secure an alliance with Austria. He had greater success as envoy at St. Petersburg, where he played a large part in the formation of the third coalition against Napoleon (1805). Notwithstanding the failure of this alliance he was made foreign minister, and in conjunction with the archduke Charles pursued a policy of quiet preparation for a fresh trial of strength with France. In 1808 he abandoned the policy of procrastination, and with the help of Metternich hastened the outbreak of a new war. The unfortunate results of the campaign of 1809 compelled his resignation, but in 1813 he was commissioned to negotiate the convention which finally overthrew Napoleon. The last ten years of his life were spent in a strenuous and partly successful attempt to reorganize the disordered finances of his country.

See A. Beer, Zehn Jahre österreichischer Politik, 1801-1810 (Leipzig, 1877); Die Finanzen Oesterreichs im 19. Jahrhundert (Prague, 1877); Krones, Zur Geschichte Oesterreichs, 1792-1810 (Gotha, 1886).

STADIUM, the Latin form of this Greek name for a standard of length, a stadion (400 square ft), or 1 fathom 63 ft.; a chain (600 Eng. ft.); as being about one-eighth of the Roman mile, it is often translated by "furlong." The course for the foot-race at Olympia (q.v.) was exactly a stade in length, and hence the name was given to the Greek foot-race and to the amphitheatre in which the races took place (see GAMES, CLASSICAL).

STADTHOLDER (Du. stathouder, a delegate or representative), the title of the chief magistrate of the seven states which formed the United Netherlands by the union of Utrecht in 1579. Though the word stads means a town, it has also the force of the kindred English "stead." A stadthouder was not the governor of a "städ" or "stead" in the sense of a place or town. He was in the place, or stead, of the sovereign. The word is translated into Latin by legatus, gubernator and praefectus. The office of stadtholder is a proconsulatus, and the High German equivalent is Staktholder, a delegate. When the northern Netherlands revolted from Philip II. of Spain, who had inherited his sovereign rights from the house of Burgundy (see NETHERLANDS: HISTORY), the stadtholder became the chief magistrate of the seven United Provinces, and it was imposed upon all goods carried up the Elbe, and were levied at the village of Brunsbäcken, at the mouth of the Schwine. The tax was abolished in 1667 by the Hanseatic League, but it was revived by the Swedes in 1681, and confirmed by Hanover. The dues were imposed on the growing trade of Hamburg, and in 1861, when they were redeemed (for £437,600) by the nations trading in the Elbe, the exchequer of Prussia received in the yearly receipt of about £45,000 from this source. Hamburg and Great Britain each paid more than a third of the redemption money.

houver passed from being the representative of an absent sovereign prince and became the chief magistrate of the states in whom the sovereignty resided. Six of the seven states forming the confederation of the United Netherlands took as their stadtholder William of Orange-Nassau, called "the Silent," and his descendants during three generations. The seventh, Groningen, had as stadtholder Wijbrand of Cleve, and his grandson John "the Old," and his descendants. The younger line became stadtholders of the other states after the extinction of the elder, and were the ancestors of the present royal family of the Netherlands. Though the stadtholders of the house of Orange-Nassau were of princely rank and intermarried with the royal families of Europe, they were not sovereign princes. They exercised large administrative powers, and commanded the land and sea forces, but it was with delegated authority given them by each state in domestic affairs, and by the states-general of the confederation in internal and foreign affairs. The states-general regulated the individual states not only claimed but exercised the right of suspending the stadtholdership, as for instance after the death of William II., 1650, and of William III., 1702.

STÆL, MADAME DE. ANNE LOUISE GERMAINE NECKER, BARONNE DE STAEL-HOLSTEIN (1766-1817), French novelist and miscellaneous writer, was born at Paris on the 22nd of April 1766. Her father was the famous financier Necker, her mother Suzanne Curchod, almost equally famous as the early love of Gibbon, as the wife of Necker himself, and as the mistress of Voltaire and the most popular salons of Paris. Between mother and daughter there was a notable rivalry. Madame Necker, despite her talents, her beauty and her fondness for philosophic society, was strictly decorous, somewhat reserved, and disposed to carry out in her daughter's case the rigorous discipline of her own childhood. The future Mme de Stael was from her earliest years a romp, a coquette, and passionately desirous of prominence and attention. There seems moreover to have been a sort of rivalry between mother and daughter for the chief place in Necker's affections, and it is not probable that the daughter's love for her mother was increased by the consciousness of her own inferiority in personal charms. Mme Necker was of a most refined though somewhat lackadaisical style of beauty, while her daughter was a plain child and a plainer woman, whose sole attractions were large and striking eyes and a buxom figure. She was, however, a child of unusual intellectual power, and she began early to write though not to publish. She is said to have written her father a letter on his famous Compte-Rendu and other matters when she was not fifteen, and to have injured her health by excessive study and intellectual excitement. But in reading all the accounts of Mme de Stael's flight from herself or her intimate friends, it must be carefully remembered that she was the master spirit of a characteristic and personalised characteristic product of the foot of sensibilité—the singular fashion of ultra-sentiment which required that both men and women, but especially women, should be always palpitating with excitement, steeped in melancholy, or dissolved in tears. Still, there is no doubt that her father's dismissal from the ministry, which followed the presentation of the Compte, and the consequent removal of the family from the busy life of Paris, were beneficial to her. During part of the next few years they resided at Coppet, her father's estate on the Lake of Geneva, which she had made famous in her other position. They travelled much, and the travel! was, at least to its neighbourhood, in 1785, and Mlle Necker resumed literary work of a miscellaneous kind, including a novel, Sophie, printed in 1786, and a tragedy, Jeanne Grey, published in 1790. It became, however, a question of marrying her. Her want of beauty was compensated by her fortune. But her parents are said to have objected to her marrying a Roman Catholic, which, in France, considerably limited her choice. There is a legend that William Pitt the younger thought of her. The somewhat notorious lover of Mlle de Lespinasse, Guibert, a cold-hearted coxcomb of some talent, certainly paid her addresses. But she finally married Eric Magnus, Baron of Stael-Holstein, who was first an attaché of the Swedish
legation, and then minister. For a great heiress and a very ambitious girl the marriage scarcely seemed brilliant, for Staël had no fortune and no very great personal distinction. A singular series of negotiations, however, secured from the king of Sweden a promise of the ambassadorship for twelve years and a pension in case of its withdrawal, and the marriage took place on the 14th of January 1786. The husband was thirty-seven, the wife twenty. Mme de Staël was accused of extravagance, and latterly an amicable separation of goods had to be effected between the pair. But this was a mere legal formality and on the whole the marriage seemed to have merriment of both parties, neither of whom had any affection for the other. They had three children; there was no scandal between them; the baron obtained money and the lady obtained, as a guaranteed ambassador of a foreign power of consideration, a much higher position at court and in society than she could have secured by marrying almost any Frenchman, without the inconveniences which might have been expected had she married a Frenchman superior to herself in rank. Mme de Staël was not a persona grata at court, but she seems to have played the part of ambassador, as displayed most parts, in a rather tidy and exaggerated manner, but not ill. Then in 1788 she appeared as an author under her own name (Sophie had been already published, but anonymously) with some Lettres sur J. J. Rousseau, a fervid panegyric showing a good deal of talent but no power of criticism. She was at this time, and indeed generally, enthusiastic for a mixture of Rousseanism and constitutionalism in politics. She exulted in the meeting of the states-general, and most of all when her father, after being driven to Brussels by a state intrigue, was once more recalled and triumphantly escorted into Paris. Everyone knows what followed. Her first child, a boy, was born the very day Necker finally left France, in unpopularity and disgrace; and the increasing disturbances of the Revolution made her privileges as ambassador very important safeguards. She visited Copert once or twice, but for the most part in the early days of the revolutionary period she was in Paris taking an interest in, and, as she thought, a part in the councils and efforts of the Moderates. At last, the day before the September massacres, she fled, befriended by Manuel and Tallien. Her own account of her escape is, as usual, so florid that it provokes the question whether she was really in any danger. She displayed more courage than her father; but she had generously spared the privileges of the embassy to protect some threatened friends, and this was a serious matter.

She betook herself to Copert, and there gathered round her a considerable number of friends and fellow-refugees, the beginning of the quasi-court which at intervals during the next five-and-twenty years made the place so famous. In 1793, however, she made a visit of some length to England, and established herself at Mickleham in Surrey as the centre of the Moderate Liberal emigrants—Talleyrand, Narbonne, Jaquot and others. There was not a little scandal about her relations with Naronne; and this Mickleham sojourn (the details of which are known from, among other sources, the letters of Fanny Burney) has never been altogether satisfactorily accounted for. In the summer she returned to Copert and wrote a pamphlet (Réflexions sur le procès de la reine) on the queen's execution. The next year her mother died, and the fall of Robespierre opened the way back to Paris. M de Staël (whose mission had been in abeyance and himself in Holland for three years) was accredited to the French republic by the regent of Sweden; his wife reopened her salon and for a time was conspicuous in the polite and eccentric society of the Directory. She also published several small works, the chief being an essay De l'Influence des passions (1796), and another De la Littérature considérée dans ses rapports avec les institutions sociales (1800). It was during these years that Mme de Staël was of chief political importance. Narbons' place had been supplied by Benjamin Constant, whom she first met at Copert in 1792, and who had a very great influence over her, as in return she had over him. Both personal and political reasons threw her into opposition to Bonaparte. Her own preference for a moderate republic or a constitutional monarchy was quite sincere, and, even if it had not been so, her own character and Napoleon's were too much alike in some points to admit of their getting on together. For some years, however, she was able to alternate between Copert and Paris without difficulty, though not without knowing that the First Consul disliked her. In 1797 she, as above mentioned, separated formally from her husband. In 1799 he was recalled by the king of Sweden, and in 1802 he died, duly attended by her. Besides the eldest son Auguste Louis, they had two other children—a son Athan and a daughter Albertine, who afterwards became the duchesse de Braine.

The exact date of the beginning of what Mme de Staël's admirers call her duel with Napoleon is not easy to determine. Judging from the title of her book Dix années d'exil, it should be put at 1804; judging from the time at which it became pretty clear that the first man in France and she who wished to be the first woman in France were not likely to get on together, it might be put several years earlier. The whole question of this duel, however, requires consideration from the point of view of common sense. It displeased Napoleon no doubt that Mme de Staël should show herself recalcitrant to his influence. But it probably pleased Mme de Staël to quite an equal degree that Napoleon should apparently put forth his power to crush her and fail. Both personages had a curious touch of charlatanerie. If Mme de Staël had really desired to take up her parlable against Napoleon seriously, she need only have established herself in England at the peace of Amiens. But she lingered on at Copert, constantly hankering after Paris, and acknowledging the hankering quite honestly. In 1802 she published the first of her really noteworthv books, the novel of Delphine, in which the "femme incomprise" was in a manner introduced to French literature, and in which she herself and not a few of her intimates appeared in transparent disguise. In the autumn of 1803 she returned to Paris. Whether, if she had not displayed such extraordinary anxiety not to be exiled, Napoleon would have exiled her remains a question; but, as she began at once appealing to all sorts of persons to protect her, he seems to have thought it better that she should not be protected. She was directed not to reside within forty leagues of Paris, and after considerable delay she determined to go to Germany. She journeyed, in company with Constant, by Metz and Frankfort to Weimar, and arrived there in December. There she stayed during the summer of 1804, where she made the acquaintance of August Wilhelm Schlegel, who afterwards became one of her intimates at Copert. Thence she travelled to Vienna, where, in April, the news of her father's dangerous illness and shortly of his death (April 8) reached her. She returned to Copert, and found herself its wealthy and independent mistress, but her sorrow for her father was deep and certainly sincere. She spent the summer at the château with a brilliant company; in the autumn she journeyed to Italy accompanied by Schlegel and Sismondi, and there gathered the materials of her most famous work, Corinne. She returned in the summer of 1805, and spent nearly a year in writing Corinne; in 1806 she broke the decree of exile and lived for a time undisturbed near Paris. In 1807 Corinne, the first aesthetic romance not written in German, appeared. It is in fact, what it was described as being at the time of its appearance, "a picturesque tour couched in the form of a novel." The publication was taken as a reminder of her existence, and the police of the empire sent her back to Copert. She stayed there as usual for the summer, and then set out once more for Germany, visiting Mainz, Frankfort, Berlin and Vienna. She was again at Copert in the summer of 1808 (in which year Constant broke with her subsequently marrying a German Military gentleman) and set to work at her book, De l'Allemagne. It took her nearly the whole of the next two years, during which she did not travel much or far from her own house. She had bought property in America and thought of moving thither, but chance or fatality made her determine to publish De l'Allemagne in Paris. The submission to censorship which this entailed was sufficiently inconsistent and she wrote to the emperor one of the unfortunate letters, at once undignified and provoking, of which she had the
secret. A man less tyrannical or less mean-spirited than Napoleon would of course have let her alone, but Napoleon was Napoleon, and she perfectly well knew him. The reply to her letter was the condemnation of the whole edition of her book (ten thousand copies) as "not French," and her own exile, not as before to a certain distance from Paris, but from France altogether. The act was unquestionably one of odious tyranny, but it is impossible not to ask why she had put herself within reach of it when her fortune enabled her to reside anywhere and to publish what she pleased. She retired once more to Coppet, where she was not at first interfered with, and she found consolation in a young officer of Swiss origin named Rocca, twenty-three years her junior, whom she married privately in 1811. The intimacy of their relations could escape no one at Coppet, but the fact of the marriage (which seems to have been happy enough) was not certainly known till after her death.

The operations of the imperial police in regard to Mme de Staël are rather obscure. She was at first left undisturbed, but by degrees the château itself became taboo, and her visitors found themselves punished heavily. Mathieu de Montmorency and Mme Récamier were exiled for the crime of seeing her; and she at last began to think of doing what she ought to have done years before and withdrawing herself entirely from Napoleon's sphere. In the complete subjection of the Continent which preceded the Russian War this was not so easy as it would have been earlier, and she remained at home during the winter of 1811, writing and planning. On the 23rd of May she left Coppet almost secretly, and journeyed by Bern, Innsbruck and Salzburg to Vienna. There she obtained an Austrian passport to the frontier, and after some fears and trouble, receiving a Russian passport in Galicia, she at last escaped from the dungeon of Napoleonic Europe.

She journeyed slowly through Russia and Finland to Sweden, making some stay at St Petersburg, spent the winter in Stockholm, and then set out for England. Here she received a brilliant reception and was much lionized during the season of 1813. She published De l'Allemagne in the autumn, was saddened by the death of her second son Albert, who had entered the Swedish army and fell in a duel brought on by gambling, undertook her Considérations sur la révolution française, and when Louis XVIII had been restored returned to Paris. She was in Paris when the news of Napoleon's landing arrived and at once fled to Coppet, but a singular story, much discussed, is current of her having approved Napoleon's return. There is no direct evidence of it, but the conduct of her close ally Constant may be quoted in its support, and it is certain that she had no affection for the Bourbons. In October, after Waterloo, she set out for Italy, not only for the advantage of her own health but for that of her second husband, Rocca, who was dying of consumption. Her daughter married the Duke Victor de Broglie on the 28th of February 1816, at Pisa, and became the wife and mother of French statesmen of distinction. The whole family returned to Coppet in June, and Byron now frequented visited Mme de Staël there. Despite her increasing ill-health she returned to Paris for the winter of 1816-1817, and her salon was much frequented. But she had already become confined to her room, if not to her bed. She died on the 14th of July, and Rocca survived her little more than six months.

Mme de Staël occupies a singular position in French literature. The men of her own time exalted her to the skies, and made magnificent estimates of her (as "the greatest woman in literary history," as the "foundress of the romantic movement," as representing "ideas," while her contemporaries Chateaubriand only represented words, colours, and images, and so forth) are to be found in minor histories of literature. On the other hand, it is acknowledged that she was soon very little read. No other writer of such eminence is so rarely quoted; none is so entirely destitute of the tribute of new and splendid editions. The abundant documents in the hands of her descendants, families of Broglie and Haussonville, have indeed furnished material for books and papers, but these are almost wholly on the social aspect of Mme de Staël, not on her literary merit. Nor, when the life and works are examined is the neglect without excuse. Her books are seen to be in large part merely clever reflections of other people's views or views current at the time. The sentimentality of her sentiment and the florid magniloquence of her style equally disgust the reader. But to state this alone would be in the highest degree unfair. Mme de Staël's faults are great; her style is of an age, not for all time; her ideas are mostly second-hand and frequently superficial. But nothing save a very great talent could have shown itself so preceptive. Take away her assiduous frequentation of society, from the later philosophe coteries to the age of Byron, take away the influence of Constant and Schlegel and her other literary friends—and probably little of her will remain. But to have caught from all sides in this manner the floating notions of society and of individuals, to reflect them with such vigour and clearness, is not anybody's task. Her two best books, Corinne and De l'Allemagne, are in all probability almost wholly unoriginal, a little sentiment in the first and a little constitutionalism in the second being all that she can claim. But Corinne is still a very remarkable exposition of a certain kind of aestheticism, while De l'Allemagne is still perhaps the most remarkable account of one country, by a native and inhabitant of it, which exists in literature.

Baron Auguste de Staël (d. 1827) edited the complete works of his mother in seventeen volumes (Paris, 1820-1821), with a notice by Mme Necke de Saussure, and the edition was afterward republished in the form of a monumental work entitled some Cours indélices, is still obtainable in three volumes, large 2avo (Didot). The Considérations and the Dix années d'exil had been published after Mme de Staël's death. Some Lettres indélices to H. Meisler were published in 1903. There is no recent reissue of the whole, and the minor works have not been reprinted, but Corinne, Delphine and De l'Allemagne are easily accessible in cheap and separate forms. Of separate works on Mme de Staël, or rather on Coppet and its society, besides those of MM Caro and Othenin d'Haussonville, may be mentioned the capital work of A. Sorel in the Grands écrivains français. In English there are biographies by A. Stevens (London, 1880), and Lady Blennerhasset (1889).

STAFF (O. Eng. staef, c. Du. staf, Ger. Stab, &c.; Icel. stafr) meant also a written letter, and O. Eng. staflas, the letters of the alphabet, "stave," one of the thin pieces of wood of which a cask is made, is a doublet), a long stick or pole, used either as an aid in walking, as a weapon as in the old quarter-staff (q.v.) or as a symbol of dignity and office, e.g. the pastoral staff (q.v.). Further the word is applied to the pole on which a flag is hoisted and to various measuring instruments. Probably from the early use of the word for the letters of the alphabet, "staff" and its doublet "stave" came to be used of a line, verse or stanza, and in musical notation (q.v.) of the horizontal lines on which notes are placed to indicate the pitch. A particular use, perhaps derived from the sense of an aid or help, is that of the battlefield (q.v.), as "the staff of the chief assistants," i.e. the assistant commanders of the battle.

The military staff organization of to-day, with its subdivision and specialization, is a modern product. Although generals have always provided themselves with aides-de-camp and orderlies, the only official corresponding to a modern staff officer in a 16th or 17th century army was the "sergeant-major-general" or "major-general," in whom was vested the responsibility of forming the army in battle array and also the command of the foot. In those days armies, large and small, were arrayed in deep formations, and, occupying but a narrow front both in camp and in battle, were easily manageable by one man and his messengers. In the 18th century, both the division of the army into divisions, and the establishment of a "quartermaster-general" and his assistants charged with the duties of selecting camps, reconnoitring the country and collecting information generally. The quartermaster-general himself was sometimes used, as Marlborough used Cadogan (q.v.), not only as chief-of-staff and as quartermaster-general in the strict sense, but also as the general's authorized representative with detachments, advanced guards, &c. But there was no subdivision of functions in the modern sense. A staff was a group of officers attached temporarily to headquarters and available for any mission which the commander thought fit to give them, and in the highly centralised armies of those days these missions
(as regards junior officers) were practically limited to orderly work and reconnaissance, especially topographical reconnaissance. Subordinate generals had aides-de-camp only. Apart, then, from the "adjudants" or personal staffs (amongst whom must be reckoned the commander-in-chief's secretary, generally a civilian), the staff in the field in Frederick the Great's day was the quartermaster-general's staff, and it was chiefly concerned, both in peace and war, with military engineering duties.

In the Seven Years' War Frederick's Q.M.G. staff 1 comprised two to six officers, usually engineers, and by 1806 the quartermaster-general had practically monopolized engineering and scientific work at headquarters. Summer the staff officers devoted to surveying and topographical reconnaissance; winter to the codification of the information obtained.

None of them were employed or trained with troops, although Frederick the Great sometimes made the quartermaster-general's officers at Berlin do duty with the guards.

With the French Revolution, however, the organization of the staff gradually modified itself to suit the new conditions of warfare. The size of armies necessitated subdivision and separate staffs for the subordinate leaders, their mobility reduced the importance of being a diligent reporter of facts, and the necessity of communicating between the several groups of an army produced an increased demand for orderly officers. But naturally a fully developed staff system did not spring to life immediately. Only by degrees were generals evolved who could handle large and mobile armies, and the highly gifted army leaders who in time appeared, Napoleon of course above all, scarcely needed a general staff. Napoleon had a chief of staff, Marshal Berthier, who bore the old title of "major-general," but Berthier was practically a chief clerk, a man of extraordinary aptitude for business. Berthier's staff was distinctly a mobile war office, and the great captain who needed not advice, but obedience, was wont to despatch his orders by a crowd of subalterns. The principal contribution, therefore, made by Napoleon to the development of staff organization was the thorough establishment of the principle of corps and divisional autonomy. Corps and divisions to be self-contained required, and they were furnished with, their own staffs. The old type of "quartermaster," whose "castration" and engineering science had been essential in the days of rigid indivisible armies, disappeared and gave way to a type of staff officer, "a clerk of war," who translated the general's instructions (other than those delivered in the field by the gallopers of the personal staff) into orders for the various subordinate commanders. The general staff officer's functions as strategic assistant to his chief were non-existent. This system worked satisfactorily in the main while Berthier was at the head of the central office, somewhat less satisfactorily in the Waterloo campaign when Marshal Soult occupied his place, and worst of all it worked in various wars of the 19th century in which the self-contained great general was not forthcoming.

The general staff became a mere bureau, divorced from the army. Thus on the French side in 1870 Marshal Bazaine so far distrusted his general staff that he forbade it to appear on the battlefield, and worked the army almost wholly by means of his personal staff. Thus the latter, the mere mouthpiece of the marshal, issued sketchy strategical orders for movements, and so reduced the rate of marching of the army to five or six miles a day; while the former, kept in the dark by the commander-in-chief, issued either no orders or all orders that had no reference to the real condition of affairs and the marshal's intentions. The army at large distrusted both staffs equally.

The Prussian general staff was as different from this staff of bureaucrats and amateurs as day from night. Even before 1806 Massenbach (g.r.) had added the preparation of strategic plans to the work of the quartermaster-general's staff, obtaining thus at the expense of the adjudant-general's side the powers of a general staff in the modern sense. That he was incapable of using these powers is shown by the mournful history of Jena. But another quartermaster-general in the war of 1806, Scharnhorst (g.r.), took up his work and in a very different spirit. In Scharnhorst's first instructions of 1806 it was laid down that an accurate knowledge of troops and a general knowledge of country were essential to a staff officer who was to be practised in exercises with troops and also in surveying. Scharnhorst, moreover, distributed general staff officers in peace to the provincial commands. The business-like habits which he instilled into his pupils, and their close touch with commanders and troops, began a tradition of efficient and accurate staff work in the field, work in which the previous Prussian staff (and indeed all contemporary staffs except Napoleon's) had failed. Thus it was that although the battle of Gravelotte-Saint-Privat was fought on the German side by over 200,000 men and in two or three distinct phases with little central direction, and, moreover, was not finished until after dark, Moltke had in his hands at dawn next morning a complete account of the events of the battle, and of the losses and condition of the troops of each corps. This was the fruit not only of methodical training in the theory of staff duties but of constant practice with troops in field manoeuvres.

Another very important feature of the Scharnhorst system was the periodical return of all general staff officers to regimental duty. This indeed has often been considered the keynote of efficiency. It did not at first meet with universal approval, but, like so many other military institutions in Prussia, financial considerations helped to ensure its retention until its intrinsic merits were proved in war. Just as the army was kept at a low peace effective and augmented on mobilization from a numerous reserve, so the staffs were small in peace, but as many officers as possible were passed through them so as to form a staff reserve within the regimental strength of the army.

But above all, the circulation of staff officers made it possible to educate the regimental officer in the approved doctrines of strategy and tactics. "Unity of doctrine" meant that instead of the complicated instructions hitherto issued for any operation, a brief note or even a hint was sufficient. In an army with a "doctrine" all ranks from general to subaltern speak the same language and use the same term in the same sense. There must always be shades of interpretation, varying with the individual officer, as was notably the case in all that Prince Frederick Charles and Blumenthal did in execution of Moltke's doctrine. But the general line of action in such an army are thoroughly fixed.

A further consequence of the new conception of staff work was an enormous increase in the "discretionary" powers of all officers. If there is to be one and only one doctrine, that doctrine must be comprehensive and elastic, and education in it must consist chiefly in applying the general principle to the specific case. Thence it was not a long step to the notion that an officer could disregard a superior's orders if the situation on which they were based was wrongly conceived or had changed in the meantime. For the test of such independent action is that the "inferior should be conscientiously satisfied that the superior, in his place, would act as he himself proposes to do," and this, of course, is the very purpose of unity of doctrine. The exercise of initiative was peculiarly useful and necessary in the case of the staff officer. He could not only disobey superior orders, but give orders in the name of superior authority. He was better able than any other person to say, not only what action the Field Service Regulations laid down generally for such problems as that in hand, but also what solution his own general, possessing better information than the regimental officers, would adopt if present. The latitude in this respect accorded to German staff officers as well as to German commanders, is a most striking phenomenon of the war of 1870 (e.g. Colonel von Caprivi before Vionville and Colonel von der Esch at Würth). The result of unity of doctrine, then, was that a properly qualified officer could act as a substitute for his superior, and that the orders which he gave in that capacity were obeyed even by officers higher in rank than the originator of the order. This principle, owing to the peculiar circumstances of the
German army, was carried to an extreme in the case of the
chiefs of staff. Moltke himself was a chief of staff, the king,
although more experienced than any officer in his army, delib-
erately accepting Moltke's guidance and assuming the respon-
sibility for the orders that Moltke issued in his name. On several
occasions the king indeed formed a different conclusion from
Moltke's and gave his orders accordingly, but these were
exceptions. In the majority of cases, he has never done this,
not to relieve the actual commander from the responsibility for
the results of his action, whether that action was suggested by
his own brain or by his staff officer's. Such an arrangement
depends moreover on mutual confidence. The self-sufficing
great commander does not need a Moltke, an average general
is wholly ruled by his mentor; and between these two extremes
the influence of the chief of staff varies according to circum-
stances and the character of the general. In the German
armies of 1870, for example, the chief staff officer was in one
case the reflector of his chief's views, in another he was the
army commander, in a third the characters of the two men
were opposed in an almost paralysing equilibrium, while in a
fourth the staff officer's business was to soothe and encourage an
dishonest and disheartened commander and at the same time to
"keep him straight."

This delicate adjustment is a necessary result of the absorp-
tion—inevitable under modern conditions of war—of strategical
and even tactical functions by the general staff. The serious
risks of disunion within the headquarters—and 1870 proves
this—prompted in the first instance the elimination of this
disunion—has to be faced, and is best insured against by
selection of officers appropriate to each other. The imagina-
tion and technique of Hess supplemented the vigorous common-
sense of Radetzky; Blücher, with the single supreme military
quality of character, could leave all the brain-work to his Gneis-
enau. But usually, unless other than purely military considera-
tions determine the selection of the general-in-chief (in which
case he can make the best soldier in the army—irrespective
of seniority—his adviser), smooth and efficient working is
best secured when the general and his chief of staff possess
the same military qualities in vifewen balance, each compensat-
ing the other's weaknesses and deriving strength from the
other's good qualities. In the Prussian account of the war of
1859 Moltke writes:

"Great captains have no need of counsel. They study the ques-
tions which arise, and decide them, and their entourage has only
this function, that of presenting an opinion. But in great
matters, in matters of strategy and responsibility, the advice of
magnitudes, who scarcely appear once in a century. In the great
majority of cases the leader of the army cannot do without advice.
This advice may be the outcome of the deliberations of a small
number of qualified men, but within this small number one or
only one opinion must prevail. The organization of the military
hierarchy must ensure subordination even in thought, and give the
right and duty of presenting a single opinion for the examination
of the general-in-chief to one man, and one only. He will be
appointed, not by seniority, but by reason of the confidence he
inspires. The general-in-chief will always have, as compared with
his adviser, the infinitely weightier merit of having assumed the
responsibility of executing what he advises."

Thus the chief of the general staff is defined in the British
Field Service Regulations as the general's "responsible adviser
on all matters affecting military operations, through whom
he exercises his functions of command and by whom all orders
issued by him will be signed."

Staff Duties in the Field.—The manifold duties essential and
incidental to commanding and administering an army, which the
general performs, as above defined, through his staff, are in the
British service classified broadly into three headings—general staff
work, adjutant-general's work and quartermaster-general's work.
The former includes the work of the general staff, and (if the general
delegates the duty) the supervising authority over the other staffs, is the
chief of the general staff. The link between the army and the inspector-
general or controller of its lines of communication is the quarter-
master-general, all details required for insertion in general staff
(i.e. "operation") orders that come within the adjutant-general's
or the quartermaster-general's branch are drafted by those branches
in spective general line, but drawn up by the general staff, and
inserted in the orders issued by the general staff. Routine
orders are drafted and issued by the other staffs themselves.

a. General Staff Duties (Operations).—The study of proposed opera-
tions; the framing, issue and despatch of the operation orders; plans
and orders, communications to the general staff and special staffs;
logistic deployment; general allotment of areas for quarters; measures
of security; intercommunication; reconnaissance; acquisition,
collation and distribution of information as to the enemy and the
terrain; the use of wireless telegraphy in general, division, army and
brigade; provision, distribution and revision of maps; reports and
despatches relating to operations; furnishing of the adjutant-general's
headquarters and the army, and of the chief of the general staff, with
information and probable requirements of the troops, and receiving from
these branches such information as affects the operations in prospect.
b. Adjutant-General's Staff (Personal).—Discipline; application
of the law, martial and civil, to officers and men; police, arrest of
officers and men; the officer and to the civil population of occupied areas;
questions of promotion, appointments of officers, pay, rewards, enlistments;
chaplain's services; casualties and invaliding; medical and sanitary
services; organization and conduct of convicts and prisoners of war; police;
routine and interior economy; ceremonial.
c. Quartermaster-General's Staff (Material).—Distribution of camps
and quarters within allotted areas; supplies, equipment and material
(except medical stores); transport by land and sea; railway
administration; remounts; veterinary service; postal service.
The work of the lower staffs—divisions and brigades—is similarly
subdivided as far as necessary. There are, moreover, the small
personal staffs (aides-de-camp) of the army and divisional
commanders. The work of the latter is not of course as important as
that of the former in the old system, and is partly of a social character,
partly orderly work. Generally the divisional staff consists of an
infantry and one cavalry divisions consists of: Personal Staff, 5
officers; General Staff, chief and to other officers; Adjutant-General's
headquarters, 3 officers; quartermaster-general's, 3 officers; General's,
3 or 4 officers; Adjutant-General's, 1 officer; Quartermaster-
General's, 1 officer; adjutant, 8 officers; rank and file attached, 60-80
men. A brigade staff consists of one general staff officer for opera-
tions, a brigade major for administration, and one aide-de-camp:
attached, 1 officer; rank and file, 8-35.

Staff Duties in Peace.—In modern conditions peace is normal
and war exceptional; moreover, as between European nations, the
peace of the state is not the peace of the individual. As a conse-
quently, the staff department is still more important after
mobilization and concentration, if not indeed during these
preliminaries, the decisive action of the war may be begun. Success
in the subsequent operations is due to the wise use of national spirit in the first
place and of the peace training of all ranks in the second. The direction
and supervision of the latter is the principal duty of a staff in time
of peace, and the specialization of staff functions, referred
to above, in the three branches of operations, personnel and material,
is as well marked in peace as in war. The two latter branches,
which are concerned with the maintenance rather than the use
of an army, are necessarily quite as fully occupied in peace as in war,
the former with the administration and education of the troops,
and the second with the organization and training. The staff
branch would not have enough work to justify a separate existence,
were it not for the fact that on the battlefield nothing can be reap-
ded that has not been seen before. Not only, as the decisive battle
immediately follows the concentration of the armies, the action
reputed to be reaped must be sown in peace time. To this end the modern
general staff in peace not only has an existence apart from the
immediate service, but must carry on the same war work in peace as in war:
the field training of the troops, the education of staff of the officers,
and the instruction of Lieutenants. In Great Britain, perhaps more than in any
other state, the functions of training and administration are very sharply
differentiated. Each commander-in-chief of a large group of garri-
onial commands under him not only a brigadier-general at the head of
the general staff, but a major-general "in charge of administration,"
who in all questions of administration is the alter ego of the com-
mader-in-chief. The latter is the actual commander, is responsible
for the training of his troops, which he carries out through the medium
of his general staff officers. Only those administrative questions
that involve important decisions come before him, the whole of the
remainder being being carried out by the general in chief of adminis-
tration in his own office and on his own responsibility.

In the War Office, the general staff work, under the Chief of the
Imperial General Staff, is classified into three main heads, for each
of which there is an officer of the rank of General, who com-
mands the staff: (a) Military Operations, in which all strategical matters connected
with imperial defence and operations overseas are studied. (b)
Military Training, which organizes and co-ordinates the work of the whole
staff, and (c) Military Education, and also the Staff College and
other educational institutions and the Officers' Training Corps, and
conducts the training of officers and candidates for commissions. Under
this branch is placed the section which arranges questions of home defence.

The administrative work is divided between the three depart-
ments: (a) Adjutant-General's (personnel), (b) Quartermaster-
General's, (c) Staff and General's (traffic). The clerical and
arrangements, record offices and routine orders, medals, regimental
distinctions, titles, &c.; certain artillery and engineer services; and the large and exceedingly important service of personnel, discipline, roads, bridges, stations, and camps of the Line of Communication (movements and quartering, barracks, railway administration, mobilization arrangements for rail and sea transportation; remounts and registration of horses for service in war; Army Service Corps work, including horse and mechanical transport, vehicles, &c.; training of administrative personnel; veterinary duties; provision and maintenance of supplies, clothing and stores); the Master- Gunners, who keep the armament in good order and supply ammunition and explosive stores, military engineering and fortifications, barrack and building construction). Besides these three departments there are the civil departments of the Civil Member of the Army Council (under who an account of its citizen character has been placed the administration of the Territorial Force, and who has further all duties connected with war department lands, roads, &c.; and of the Finance Minister, which works out the estimates, except those for the purchase of the contracts; and contracts, administers the Army Pay Department, and deals with accounts and audits.

Directly under the Army Council is the department of the Inspector-General of the Forces, whose duties are to review and report on the training and efficiency of all troops under the home government, the state of stores, remounts, &c., with regard to war requirements, and the condition of fortifications.

Jansen, Generals and Gunners; Frieden (1901); French official Aide-Mémoire de l'officier d'état-major.

STAFFA (Norse for staff, column, or pillar island), an island of the Inner Hebrides, Argyllshire, Scotland, 54 m. W. of Oban by steamer, about 7 m. from the nearest point of Mull, and 5 m. N. N.W. of the island. Its circumference is 2 m. long, and its highest point is 135 ft. above sea-level. In the north-east it shelves to a shore, but otherwise the coast is rugged and much indented, numerous caves having been carved out by rain, stream and ocean. There is enough grass on the surface to feed a few cattle, and the island contains a spring, but it is uninhabited. During the tourist season it is visited every week-day by steamer from Oban. The island is of volcanic origin, a fragment of an ancient stream of lava. In section the island is seen to possess a threefold rock character: there is first a basement of tufa, from which rise, secondly, colonnades of basalt in pillars forming the faces and walls of the principal caves, and these in turn are overlaid, thirdly, by a mass of amorphous basalt. Only the chief caves have been named. On the south-east coast is the Clam-shell or Scallop Cave. It is 30 ft. high, about 18 ft. wide at the entrance, and some 130 ft. long, and on one side of it the ridges of basalt stand out like the ribs of a ship. Near this cave is the rock of Bunchaillie ("The Herdsman," from a supposed likeness to a shepherd's cap), a pile of columns, fully seen only at low water. On the south-west, where the Boat Cave and the Rental come together, and just below the sound, Staffa's Cave is, however, the most famous of all. It was discovered in 1772 by Sir Joseph Banks, who visited Staffa on his expedition to Iceland. The grotto, situated in the southern face of the isle, is 227 ft. long, 42 ft. wide, 66 ft. high and 25 ft. deep at ebb. On its western side the pillars are 36 ft. high, on its east 18 ft. high. From its mouth to its extremity a pavement of broken pillars runs up one side. The cave is the haunt of seals and sea birds. In suitable atmospheric conditions its beauty is unique. The play of colour is exquisite, the basalt combining every tint of warm red, brown and green maroon; sea water and lichen stain the cave green and gold. The water that has filtered through has crusted the pillars here and there a pure snow-white. From the sombre roof of smooth rock or broken pillars hang yellow, crimson and white stalactites. The floor of the cave is the green sea, out of which the columns rise on either side with a regularity so perfect as to suggest the hand of man rather than the work of Nature. The murmur of the sea won for the cave a Gaelic name meaning "the Cave of Music." At times of storm the compressed air, as it rushes out, produces a sound as of thunder. When the sea is very smooth visitors may be rowed directly in the ship into the cave, and the usual entrance to the Clamshell Cave, where the columns have been worn down until they form a kind of terrace running all the way to Fingal's Cave. The Wishing Chair is formed out of a column that has broken short. From the Causeway a ladder affords access to the summit of Staffa.

**STAFFORD (Family)**

This famous English house was founded in England by Robert, a younger brother of Ralph de Tosny (Toeni), of a noble Norman house, who was standard-bearer of the duke that he had received, like his elder brother, at the Conquest: a great fief which extended into seven counties and became known as Robert de Stafford from his residence at Stafford Castle. The military service due from the fief was no less than sixty knights, as is proved by his grandson Robert's return in 1166. With this Robert's son the male line became extinct, and his sister's husband, Hervey Bagot, one of his knightly tenants, succeeded to the fief in her right (1194): their descendant Edmund de Stafford (that surname having been assumed) was summoned as a baron in 1269. His son, Ralph, a warrior like his father, attained fame in the French wars. He conducted the brilliant defence of Aiguillon against the host of France, fought at Crecy and in the siege of Calais. Chosen a Knight of the Garter at the foundation of the order, he was further created earl of Stafford in 1357.

His son Hugh, who succeeded as 2nd earl in 1372, served in the French wars. From 1376 he became prominent in politics, probably through his marriage to a daughter of the earl of Warwick, being one of the four lords on the committee in the Good Parliament, and also serving on the committee that controlled Richard II., 1378-1380. He was friendly, however, with his son-in-law, and when he died in London, 1377, he was buried in the cathedral there. On his marriage in 1387 he was created a Knight of the Garter, and in 1388 was appointed lieutenant of the Black Tower and Keeper of the Wardrobe. His son, Humphrey (1407-1460), the 1st Stafford, who succeeded in the office of the old nobility, while his recovery of the ancestral office of lord high constable in 1500 increased his prestige. He had not sufficient force of character to take an active part in politics, but the king's easily roused suspicions were excited by private accusations in 1521, and, after a nominal trial by his peers, he was beheaded on the 17th of May 1522, a subsequent act (1523) confirming his attaint. His fate, even under such a king, made a great sensation, exciting sympathy at home, and moving the emperor Charles V. to say that a butcher's dog (Wolsey) had pulled down the noblest buck in England. It is noteworthy that the 2nd and 3rd dukes were both beheaded, while the 1st duke fell in the Wars of the Roses.

Henry (1591-1663), the son of the last duke, was granted by the Crown some of his father's manors for his support, and, espousing the Protestant cause (though married to a daughter of Margaret, countess of Salisbury and sister of Cardinal Pole), was restored in blood on Edward VI.'s accession and declared Lord Stafford, as a new creation, by act of parliament. His second surviving son, Thomas, eventually assumed the royal arms, on the ground of his lofty descent, sailed from Dieppe with two ships in April 1557, landed at Scarborough, seized the castle, and proclaimed himself protector. He was captured and executed for high treason. His father's new barony, in 1637, passed to a cadet in humble circumstances, who was called on, as
a pauper, to surrender to it the king, which he did (illegally, it is now held) in 1639. The king thereupon beheaded it. Sir John Stafford, a Chevalier general of the Scots and her husband, William Howard, in whose descendants it is now vested. Roger, who had surrendered the title, died in 1640, the last heir male, apparently, of the main line of this historic house.

Of the junior lines the most important that was known as Stafford of Hooke (Co. Dorset), which had branched off from the parent stem at a very early date. Sir John Stafford of this line married his kinswoman, a daughter of the 1st earl of Stafford. From their younger son, Ralf, descended the Staffords of Grafton and other families; the elder, who fought in the French wars, was a son of John (Stafford), archbishop of Canterbury. This prelate came to the front under Henry VI., becoming treasurer (1422), bishop of Bath and Wells (1425), and lord chancellor (1432-1450). Archbishop from 1443 to his death in 1452, he steered an even course between parties as a moderate man and useful official. His elder brother obtained Hooke by marriage, and left two sons, of whom the younger was grandfather of Humphrey Stafford, who succeeded to Hooke, fought for Edward IV. at Tewton, and was summoned as Lord Stafford of Southwick in July 1461, and was advanced to the earldom of Desmond by May 1462. Sir John (Stafford), 2nd earl of Desmond, by marriage, became bishop of Exeter in 1395, and was lord chancellor from 1396 to 1399. He lost the office on Henry IV.'s accession, but held it again from 1401 to 1403. He then devoted himself to his diocese till his death in 1419. His patronage of learning is commemorated by Exeter College, Oxford. The male line of the Staffords of Clifton ended about 1445.

One of younger sons of the main line who attained peerage rank Sir Hugh Stafford, K.G., a son of the 2nd earl, was summoned as a baron from 1411 to 1413 (probably in right of his wife, a Bourchier heiress), but died childless in 1420. John, a son of the 1st duke of Buckingham, received the garter and an earldom of Wiltshire (1470), which became extinct with his son in 1490, but was revived in 1510 for Henry Stafford, K.G., a son of the 2nd duke, who, however, died childless in 1533. The Staffords made illustrious marriages from the day of the 1st earl; a son of the 1st duke married the mother of Henry VIII. The badge of the family was “the Stafford knot,” at one time as famous as “the ragged staff” of the earls of Warwick.

See Dugdale, Baronage (1675), vol. 1; G. E. Cokayne, Complete Peerage; Wrottesley, History of the Family of Bagot (1908) and Crewe and Gallet (1853). The important Stafford MSS. in Lord Bagot's possession are calendared in the 4th Report on Historical MSS., and the Salt Arch. Soc.'s collections for the history of Staffordshire are valuable for early records. Harcourt's His Grace the Steward and the Trial of Piers (1907) should also be consulted. The bishop of Exeter's Register was edited by Hingston-Randolph in 1886. Papers relating to the 2nd Burgraves of Stafford (1867), and Campbell's The Stafford Peerage (1818) are useful for the pedigree. There are collections for a history of the family in Add. MSS. (Brit. Mus.) 14,409; 19,150.

(John H. R.)

STAFFORD, EARLS AND MARQUESSES OF. The earldom of Stafford, created in 1351, was held at first by the family of Stafford (see above). In 1581 it became extinct, and in September 1649 Sir William Howard (1614-1680), a son of Thomas Howard, earl of Arundel and Surrey, having three years previously married Mary (d. 1604), sister and heiress of Henry Stafford, 5th Baron Stafford, was created Baron Stafford and two months later viscount of Stafford. Accused by Titus Oates of participating in the popish plots, he was found guilty, and was beheaded on the 29th of December 1660, his titles being forfeited.

His son, Henry Stafford Howard (1658-1719), who, but for his father's attainder, would have inherited the barony and the viscountcy of Stafford, was in 1700 made 4th Duke of Grafton, being created countess of Stafford at the same time; he was succeeded by his nephew William (c. 1690-1734). When John Paul, the 4th earl (1700-1762), died, the earldom became extinct, but the title to the barony, which was under attainder, fell into abeyance.

The 4th earl's sister Mary (d. 1765) married Francis Powliden (d. 1712), and in 1824 their descendant, Sir George William Jerningham, Bart. (1717-1831), of Costessey Park, Norfolk, obtained a reversal of his ancestor's attainder and was recognized in 1826 as 5th Earl of Stafford. The barony is still held by the Jerninghams.

In 1758 Granville Leveson-Gower (1721-1803) was created marquess of Stafford. He was the son of John Leveson-Gower (d. 1754), who was created Viscount Trentham and Earl Gower in 1746. The public positions held by him included that of lord privy seal, which he filled from 1755 to 1757, and again from 1754 to 1755; of master of the horse; of lord chamberlain of the royal household; and of lord president of the council, which he held from 1767 to 1769 and in 1773-1784. This wealthy and influential nobleman, who was the last survivor of the associates of the duke of Bedford, the Bloomsbury gang," died at Trentham Hall, in Staffordshire, on the 26th of October 1803. His son and successor, George Granville Leveson-Gower, was created duke of Sutherland in 1833. A younger son was Granville Leveson-Gower, who was created Earl Granville in 1832. The title of marquess of Stafford is now borne by the eldest son of the duke of Sutherland.

STAFFORD, a market town, municipal and parliamentary borough, and the county town of Staffordshire, England, on the river Sow, a western tributary of the Trent. Pop. (1901), 20,863. It is an important junction on the main line of the London & North-Western railway, by which it is 133 m. N.W. from London. Branches of this company diverge to Wolverhampton and Birmingham, and to Walsall; a joint line of the North-Western and Great Western companies to Shrewsbury and Walsall; the Great Northern serves the town from the eastern counties, and the North Staffordshire runs north through the Potteries district. The town, while largely modernized, contains a number of picturesque half-timbered houses. The church of St Mary, a fine cruciform building having a transitional Norman nave, and Early English and Decorated in other parts, was formerly collegiate, its canons having mention in Domesday, though the complete foundation is attributed to King John. It contains a memorial of a member of the royal family, born at Stafford in 1593. The older church of St Chad contains good Norman details, but is chiefly a reconstruction. It formerly provided sanctuary. There are county council buildings, a shire hall and a borough hall. The grammar school is an ancient foundation enlarged in 1550 by Edward VI. The county technical institution is in Stafford. A museum, consisting principally of the collections of Clement Wragge, and called by its name, contains a specially fine series of fossils. The William Salt library, presented to the borough in 1872 after the death of the collector, has a large collection of books and MSS., deeds and pictures relating to the county. Charitable institutions include a general infirmary, county asylums, and the Coton Hill institution for insane. The burgesses of Stafford had formerly common rights over a considerable tract known as Coton Field and Stone Flat; the first is now divided into allotments and the second is a recreation ground. The staple trade is the manufacture of
Geology.—The Peninne folding gently pianes the northern part of two Carboniferous tracts interrupting the Midland Triassic plateau in Staffordshire, but affects the unconformable Trias less. It isolates the pottery and smaller coalfields mainly in synlines, but elevates the intervening ridges of the former regions. The country arches the South Staffordshire Coal Measures, with minor saddles disclosing Silurian inliers, intermediate formations being absent there. Faults depressing the Trias bound the southern coalfield in Staffordshire, while the central district, the Middle Llanoverly Sandstone with Stricklandina lens and Bar (Woolhope) Limestone (Ilaenus barrienti) underlie Wenlock Shales, succeeded, as at Wren's Nest and Dudley, by Wenlock Limestone. It is in two basins with flat, gently sloping sides, famous for tilorobates. At Sedgley there follow Lower Ludlow Shales, Sedgley (Aymestry) Limestone (Pentamerus knightii) and some Coal Measures. The Downton Shale, with thin beds of calcareous sandstone, along the slope of hills and deep valleys, enters the northern region on the east. It contains brachiopods and corals of the Dibunophyllum zone, with lead and copper, once worked at Ecton. Marine Pseudeside (Yoredale) Shales, with thin limestones and higher sandstones, are also found around a central syncline and the northern margins of the coalfields into the Millstone Grit, whose four grits in massive escarpments, only the Tris and Thirle, one persisting, westward, alternate with shales. The Pottery Coalfield, the centre of pottery manufacture, though local clays now furnish only coarse ware and the "saggars" in which pottery is baked, includes some 6000 ft. of Coal Measures. It contains some 1600 ft. of the "coal band" ironstones with thin Spirirbis-limestones, Entomorhachia, and Antaracomena philippsii (Blackband Series), and 200 to 1000 ft. of equivalent measures with the Bicrystalline fireclay, New Mine, Heathen, the composite Tenyear and other clays, besides ironstones to which the Black Country originally owed the character of "band iron" and the "commonware" brown" or "black" ironstones. It contains limestones with rare brachiopods, fresh-water shells (Carbonicola acuta, C. robusta) and fish are characteristic fossils; but the roof of the North Staffordshire Cranberry Coal (Lower Measures) and several higher bands of the Coal Measures. The Blackband Series includes the valley of the Trent from its source to the point, at which it becomes navigable, Burton-on-Trent. It rises in the extreme north of the county, and follows a southerly course, turning eastward and finally north-eastward through the centre of the county. Its tributaries on the left bank follow a course roughly parallel with it; the chief are the Blythe and the Dove, which receives the Churnet from the west, and forms the county boundary with Derbyshire. The country between Trent, Churnet and Dove is undulating and beautiful; the hills rise to some 800 ft. on the Derbyshire border in Axe Edge near Buxton, and continue by Mow Cop or Congleton Edge along the Cheshire border to the coal-bearing hills above the Potteries district. Dovedale, the name applied to a portion of the upper valley of the Dove (q.v.), attracts many visitors on account of its beauty, and is in favour with anglers for its trout-fishing. South of the Trent, about the middle of the county, an elevated area is known as Cannock Chase, formerly a royal preserve, now a wealthy coalfield, and the high ground, generally exceeding 500 ft., continues south to surround the great manufacturing district of south Staffordshire (the Black Country), and to merge into the Clent and Lickey Hills of Worcestershire. A small area in the north-west drains to the Weaver, and so to the Mersey, and from the west and south-west the Severn receives some small feeders and itself touches the county in the extreme south-west. The only considerable sheet of water is Aqualate Mere, in the grounds of the mansion of that name near Newport in Shropshire.

Stafford. (Stafford, Stafford, Stafford) is said to have originally been called Bethene by Bethelin, a hermit who lived here about 717. The place is mentioned in the Anglo-Saxon Chronicle, where it is stated that Aethelheard, lady of the Mercians, in 913 built a fort at Stafford. It was a place of considerable importance in later Anglo-Saxon times, and the evidence of coins shows that a mint then existed here. Stafford is described as a borough in Domesday Book, and at the time of the survey it was the chief place in the county though many of the houses were "wasted." The king received all the dues, two-thirds coming to him as king, the other third as earl of Stafford. From the Domesday Survey it appears that the Conqueror took certain lands in the manor of Cheshire in order to found a castle at Stafford; this stronghold in the heart of the county was the castle of the 13th century. A charter from John in 1266 constituted Stafford a free borough. In 1399 the government was by bailiffs. In 1501 it was ordered that two bailiffs should be elected annually out of a council of twenty-five burgesses. Charters were granted by Edward VI., 1551 and by James I., 1605, the latter incorporating it under the title of the mayor and burgesses of the borough of Stafford: owing to irregularities in elections, another almost similar charter was given by George IV., under which the town was governed until 1835. In Elizabeth's reign Stafford was in a depressed state. The area of the manor of Stafford in the time of Richard II. was 15,718 acres, of which the town built one of the largest and most ancient in the country, as far as the survey shows. It consisted of the area of Stafford, and included the valley of the Trent from its source to the point, at which it becomes navigable, Burton-on-Trent. It rises in the extreme north of the county, and follows a southerly course, turning eastward and finally north-eastward through the centre of the county. Its tributaries on the left bank follow a course roughly parallel with it; the chief are the Blythe and the Dove, which receives the Churnet from the west, and forms the county boundary with Derbyshire. The country between Trent, Churnet and Dove is undulating and beautiful; the hills rise to some 800 ft. on the Derbyshire border in Axe Edge near Buxton, and continue by Mow Cop or Congleton Edge along the Cheshire border to the coal-bearing hills above the Potteries district. Dovedale, the name applied to a portion of the upper valley of the Dove (q.v.), attracts many visitors on account of its beauty, and is in favour with anglers for its trout-fishing. South of the Trent, about the middle of the county, an elevated area is known as Cannock Chase, formerly a royal preserve, now a wealthy coalfield, and the high ground, generally exceeding 500 ft., continues south to surround the great manufacturing district of south Staffordshire (the Black Country), and to merge into the Clent and Lickey Hills of Worcestershire. A small area in the north-west drains to the Weaver, and so to the Mersey, and from the west and south-west the Severn receives some small feeders and itself touches the county in the extreme south-west. The only considerable sheet of water is Aqualate Mere, in the grounds of the mansion of that name near Newport in Shropshire.
and at Tunstall, glassworks at T Kutub; there are also a considerable textile industry, as at Newcastle-under-Lyme, paper-mills in that town and at Tamworth, and manufactures of boots and shoes at Stafford and Stone.

Communications.—The main line of the London & North-Western railway runs from south-east to north-west by Tamworth, Lichfield (Trent Valley), Rugeley and Stafford. This company and the Great Western serve the towns of the Black Country by many branches from Birmingham, and jointly work the Stafford-Shrewsbury line. The London & North-Western have branches from Trent Valley to Burton-upon-Trent, and from Rugeley through the Cannock Chase coalfields. The North Staffordshire railway runs from Stafford and from Burton-upon-Trent northward through the Potteries, with a line from Uttoxeter through Leek to Macclesfield. The Manifold Valley light railway serves part of the Dove Dale district. The west-and-north line of the Midland railway (Bristol-Derby) crosses the south-eastern part of the county from Birmingham by Tamworth and Burton, with a branch to Wolverhampton. The Great Northern, with a branch from its main line at Grantham, serves Uttoxeter, Burton and Stafford. A considerable amount of coal-transport takes place along canals, the Black Country especially being served by numerous branches. The principal canals are the Grand Trunk, which follows the Trent over the greater part of its course within the county, the Coventry, Birmingham and Fazeley, Daw End and Essington canals, connecting the Grand Trunk with Warwickshe, the Black Country and Cannock Chase; the Liverpool and Birmingham junction; the Staffordshire and Worcestershire, running from the Severn at Stourport by Wolverhampton and Penkridge to the Canal Junction near Stafford, and the Cannock canal running eastward from the Potteries into the Churnet Valley.

Population and Administration.—The area of the ancient county is 749,602 acres, with a population in 1891 of 1,683,424; and in 1901 of 1,234,506. The area of the administrative county is 744,084 acres. Staffordshire contains five hundreds, each having two divisions. The municipal boroughs are: in the southern industrial district, Smethwick (pop. 54,530), Walsall (56,430), Wednesbury (29,554), West Bromwich (65,175), Wolverhampton (94,878); in the northern industrial district, Newcastle-under-Lyme (19,914), and the several formerly separate boroughs amalgamated under the Potteries Federation "Scheme" (1908) under the name of Stafford-on-Trent (q.v.); elsewhere, Burton-upon-Trent (50,386), Lichfield (7902), Stafford (20,805), Tamworth (7721). Burton, Hanley, Smethwick, Walsall, West Bromwich and Wolverhampton are county boroughs; Lichfield is a city, and Stafford is the county town. The urban districts are—in the southern industrial district, Amblecote (3218), Bilston (24,334), Brierley Hill (12,042), Cosley (22,219), Darlaston (15,305), Handsworth (22,921), Heath Town or Wednesfield Heath (9441), Perry Bar (2348), Quarry Bank (3522), Rowley Regis (34,670), Sedgley (15,051), Short Heath (3531), Tipton (9231), Wednesfield (4883), Willenhall (18,515); in the northern industrial district, Audley (13,083), Biddulph (6247), Fenton (22,742), Kidsgrove (3522), Smallthorne (6263), Tunstall (19,492), Wolstanton (24,075); elsewhere, Brownhills (15,252), Cannock (23,974), Leek (15,484), Rugeley (4447), Stone (5680), Uttoxeter (5133). Among other towns may be mentioned Abotts Bromley (1318), Brewood (2535), Cheadle (5186) and Eccleshall (3799). The county is in the Oxford circuit, and assizes are held at Stafford. It has one court of quarter sessions, and is divided into 23 petty sessional divisions. The boroughs of Hanley, Lichfield, Newcastle-under-Lyme, Walsall, West Bromwich and Wolverhampton have separate commissions of the peace and courts of quarter sessions, and those of Burslem, Burton, Longton, Stafford, Stoke-upon-Trent, Smethwick, Tamworth and Wednesbury have separate commissions of the peace only. The total number of civil parishes is 277. The county is almost wholly in the diocese of Lichfield, but has small parts in those of Birmingham, Wolverhampton and Chester; it contains 348 ecclesiastical parishes or districts, wholly or in part. Staffordshire is divided into seven parliamentary divisions each returning one member—Burton, Hands-worth, Kingswinford, Leek, Lichfield, North-West and West. The parliamentary borough of Wolverhampton returns a member for each of three divisions, and the boroughs of Hanley, Newcastle-under-Lyme, Stafford, Stoke-upon-Trent, Walsall, Wednesbury and West Bromwich each return one member.

History.—The district which is now Staffordshire was invaded in the 6th century by a tribe of Angles who settled about Tamworth, afterwards famous as a residence of the Mercian kings, and later made their way beyond Cannock Chase, through the passages afforded by the Sow valley in the north and Watling Street in the south. The district was frequently overrun by the Danes, who in 910 were defeated at Tettenhall, and again in the year 921, and was again attacked by the Danes, and in 928 by Hubert, who had already expelled the Northmen from Mercia that the land of the south Mercians was formed into a shire around the fortified burgh which he had made in 914 at Stafford. The county is first mentioned by name in the Anglo-Saxon Chronicle in 1016 when it was harried by Canute. The resistance which Staffordshire opposed to the Conqueror was punished by ruthless harrying and confiscation, and the Domesday Survey supplies evidence of the depopulated and impoverished condition of the county, which at this period contained but 64 mills, whereas Dorset, a smaller county, contained 272. No Englishman was allowed to retain estates of any importance after the Conquest, and the chief lay proprietors at the time of the survey were Earl Roger of Montgomery; Earl Hugh of Chester; Henry de Ferrers, who held Burton and Tutbury castles; Robert de Stafford; William Fitz-Ansculf, afterwards created first Baron Dudley; Richard Forester; Rainald Baulgol; Ralph Fitz Hubert and Nigel de Stafford. The Ferrers and Staffords long continued to play a leading part in Staffordshire history, and Turstin, who held Drayton under William Fitz-Ansculf, was the constable of the Bassets of Drayton. At the time of the survey Burton was the only monastery in Staffordshire, but foundations of canons existed at Stafford, Wolverhampton, Tettenhall, Lichfield,
Penkridge and Tamworth, while others at Hanbury, Stone, Strensall and Trentham had been either destroyed or absorbed before the Conquest. The five hundreds of Staffordshire have existed since the Domesday Survey, and the boundaries have remained practically unchanged. Edington, however, was then included under Derbyshire, and Tiley under Shropshire, while Cheswardine, Chinnall and part of Boffington, now in Shropshire, were assessed under Staffordshire. The hundreds of Ollow and Totmonslow had their names from squalid monuments of Saxon commanders. The shire court for Staffordshire was held at Stafford, Tamworth, Etrington, Stafford and Lichfield, until by act of parliament of 1528 the assizes and sessions were fixed at Stafford, where they are still held.

In the 13th century Staffordshire formed the archdeaconry of Stafford, including the deaneries of Stafford, Newcastle, Alton and Leek, Tamworth and Tutbury, Lapley and Creigull. In 1353 the deanery of Newcastle was combined with that of Stone, the deaneries remaining otherwise unaltered until 1866, when they were increased to twenty. The archdeaconry of Stoke-on-Trent was formed in 1875, and in 1866 the deaneries were increased to their present number; the archdeaconry of Stafford comprising Handswood, Himley, Lichfield, Penkridge, Rugeley, Stafford, Tamworth, Trosull, Tutbury, Walsall, Wednesbury, West Bromwich and Wolverhampton; the archdeaconry of Stoke-on-Trent comprising Altonfleld, Cheadle, Eccleshall, Hanley, Leek, Newcastle-under-Lyme, Stoke-on-Trent, Trentham and Uttoxeter.

In the wars of the reign of Henry III. most of the great families of Staffordshire, including the Bassetts and the Ferrers, supported Simon de Montfort, and in 1263 Prince Edward ravaged all the lands of Earl Robert Ferrers in this county and destroyed Tutbury Castle. During the Wars of the Roses, Eccleshall was for a time the headquarters of Queen Margaret, and in 1459 the Lancastrians were defeated at Blore Heath. In the Civil War of the 17th century Staffordshire supported the parliamentary cause and was placed under Lord Brooke. Tamworth, Lichfield and Stafford, however, were garrisoned for Charles, and Lichfield Cathedral withheld a siege in 1643, in which year the Royalists were victorious at Hopton Heath, but lost their leader, the earl of Northampton. In 1745 the Young Pretender advanced as far as Leek in this county.

The county of Staffordshire had a Roman time; there was waste and uncultivated ground, but the moorlands of the north afforded excellent pasturage for sheep, and in the 14th century Wolverhampton was a staple town for wool. In the 13th century mines of coal and iron are mentioned at Walsall, and ironstone was procured at Sedgley and Eccleshall. In the 15th century both coal and iron were extensively worked. Thus in the 17th century the north of the county yielded coal, lead, copper, marble and millstones, while the rich meadows maintained great dairy; the woodlands of the south supplied timber, salt, black marble and alabaster; the clothing trade flourished about Tamworth, Burton, and Newcastle-under-Lyme; and hemp and flax were grown all over the county. The potteries are of remote origin, but were improved in the 17th century by two brothers, the Elers, from Amsterdam, who introduced the method of salt glazing, and in the 18th century they were rendered famous by the achievements of Josiah Wedgwood.

Staffordshire was represented by two members in the parliament of 1290, and in 1295 the borough of Stafford also returned two members. Lichfield was represented by two members in 1304, and Newcastle-under-Lyme in 1335. Tamworth returned two members in 1553. Under the Reform Act of 1832 the county returned four members in four divisions, and the boroughs of Stoke-on-Trent and Wolverhampton were represented by two members each, and Walsall by one member. Under the act of 1868 the county returned six members in three divisions and Wednesbury returned one member.

Antiquities.—Early British remains exist in various parts of the county; and a large number of barrows have been opened in which human bones, urns, fibulæ, stone hammers, armlets, pins, pottery and other articles have been found. In the neighbourhood of Wetton, near Dove Dale, on the site called Borough Holes, no fewer than twenty-three barrows were opened, and British ornaments have been found in Needwood Forest, the district between the lower Dove and the angle of the Trent to the south. Several Roman camps also remain, as at Knave's Castle on Watling Street, near Brownhills. The most noteworthy churches in the county are found in the large towns, and are described under their respective headings. Such are the beautiful cathedral of Lichfield, and the churches of Eccleshall, Leek, Penkridge and Stafford, Tipton, Tiverton, Tutbury, and St. Peter's at Wolverhampton. Checkley, 4 m. south of Cheddle, shows good Norman and Early English details, and there are carved stones of pre-Norman date in the churchyard. Armitage, south-east of Rugeley, has a church showing good Norman work. Brewood church, 4 m. south-west of Penkridge, is Early English. This village gives name to an ancient forest. Audley church, north-west of Newcastle-under-Lyme, is a good example of Early Decorated work. Remains of ecclesiastical foundations are generally slight, but those of the Cistercian abbey of Croxden, north-west of Uttoxeter, are seen. The abbey church of Etruria at Stoke, was built after the fire of 1745. Portions of the priory of Tutbury, the Perpendicular tower and other portions of an Augustinian foundation remain. Among medieval domestic remains may be mentioned the castles of Stafford, Tamworth and Tutbury, with that of Chartley, north-east of Stafford, which dates from the 13th century. Here is also a timbered hall, in the park of which a breed of wild cattle is maintained. Beaudesert, south of Rugeley, is a fine Elizabethan mansion in a beautiful undulating demesne. In the south-west, near Stourbridge, are Enville, a Tudor mansion with grounds laid out by Leech, Lench, Penkridge, and Stourton Castle, embodying portions of the 15th century, where Reginald, Cardinal Pole, was born in 1500. Among numerous modern seats may be named Ingestre, Ilam Hall, Alton Towers, Shugborough, Pattehall, Keele Hall, and Trentham.

STAG (O. Eng. stagga, a Norse word, cf. Icel. steggi, steggi, a male animal, cf. Steddangr, a drake; it is usually referred to stigan, to climb, to mount, but this is doubtful), the common name of the male of many species of the deer tribe, but usually confined to the male of the red deer (Cervus elaphus), "buck" being used in other cases, as of the fallow-deer (see Deer and Fecora). In Stock Exchange slang the term is used of an operator who applies for a portion of a new security being issued, not with a view to holding it, but with the intention of immediate realization, at a profit if possible.

STAGE (Fr. étage; from Lat. stare, to stand), in architecture, an elevated floor, particularly the various storeys of a bell-tower, &c. The term is also applied to the plain parts of buttresses between cap and cap where they set back, or where they are divided by horizontal string and panelling. It is used, too, by William of Worcester to describe the compartments of windows between transom and transom, in contradistinction to the word bay, which signifies a division between mullion and mullion (see Screen). From the sense of the floor or platform on which stage doors were acted the term came to signify both the theatre (pl.) and the drama (q.v.). And from its etymological meaning of a station comes the sense of a place for rest on a journey, the distance between such places, &c.

STAHLE, FRIEDRICH JULIUS (1802-1867), German ecclesiastical lawyer and politician, was born at Munich on the 16th of January 1802, of Jewish parentage. Although brought up strictly in the Jewish religion, he was allowed to attend the
STAIR, G. E.—STAINES, 1ST VISCOUNT

700

gymnasium, and, as a result of its influence, was at the age of nineteen baptized into the Lutheran Church. To this faith he clung with earnest devotion and persistence until his death. Having studied law at Würzburg, Heidelberg and Erlangen, Stahl, on taking the degree of doctor juris, established himself as privadozent in Munich, was appointed (1832) ordinary professor of law at Würzburg, and in 1840 received the chair of ecclesiastical law and polity at Berlin. Here he immediately made his mark as an ecclesiastical lawyer, and was appointed a member of the first chamber of the synod. Elected in 1850 a member of the Reichsparlament, he bitterly opposed the ideas of German federation, and Stahl was even looked upon as the influence of Schelling, and at the latter's insistence, began in 1827 his great work: Die Philosophie des Rechts nach geschichtlicher Ansicht (an historical view of the philosophy of law), in which he bases all law and political science upon Christian revelation, denies rationalistic doctrines, and, as a deduction from this principle, maintains that a state church must be strictly confessional. This position he further elucidated in his Der christliche Staat und sein Verhältniss zum Deismus und Judenthum (The Christian State and its relation to Deism and Judaism; 1824). As Oberkirchenrat (counsellor) Stahl used all his influence to weaken the Evangelical Union (i.e. that compromise between the Calvinist and Lutheran doctrines which is the essence of the Prussian Evangelical Church) and to strengthen the influence of the Lutheran Church (cf. Die Lutherische Kirche und die Union, 1859). The Prussian minister von Bunsen attacked, while King Friedrich William IV. supported, Stahl in his ecclesiastical policy, and the Prussian Evangelical Church would probably have been dissolved had not the regency of Prince William (afterwards the emperor William I.) supervened in 1858. Stahl's influence fell under the new régime, and, resigning his seat on the synod, he retired into private life and died at Brückenau on the 10th of August 1861.

See "Biographie von Stahl," in Unser Zei, 1866, vii. 419-447 (anonymous, but probably by Gneist); Pernice, Savigny, Stahl (anonymous; Berlin, 1862).

STAHLE, GEORG ERNST (1660-1734), German chemist and physician, was born on the 21st of October 1660 at Anspach. Having graduated in medicine at Jena in 1683, he became court physician to the duke of Weimar in 1687. From 1694 to 1716 he held the chair of medicine at Halle, and was then appointed physician to the king of Prussia in Berlin, where he died on the 14th of May 1734. In chemistry he is chiefly known in connexion with his doctrine of phlogiston, the essentials of which, however, he owed to J. J. Becher; and he also propounded a view of fermentation which in some respects resembles that supported by Liebig a century and half later. In medicine he professed an animistic system, in opposition to the materialism of Hermann Boerhaave and Friedrich Hoffmann.

The most important of his numerous writings are Zymotechnia fundamentalis sive fermentationis theoria generalis (1697), which contains the phlogistic hypothesis; Specimen Becherianum (1702); Experimenta, observationes, animadversiones ... chymicae et physicae (1731); Theoria medica vera (1707); Arti sanitatis cum expectatione (1730).

STAINES, SIR JOHN (1840-1901), English composer and organist, was born at Southwark on the 6th of June 1840. He was the second son of the schoolmaster of the parish school of St Thomas's, Southwark, who was enough of a musician to teach his son the organ and the art of reading music, in which he was already proficient when, in 1847, he entered the choir of St Paul's Cathedral. He remained there till 1856, and often under the tuition of the organist, E. G. Rimbault. In 1856 he was appointed assistant organist of St Benet's and St Paul's, Upper Thames Street, during the last year of his choristership; and in 1856 was given the appointment of organist at St Michael's College, Tenbury, where his musical and general education benefited greatly from the intercourse with Sir Frederick Gere Ouseley. He was appointed to Magdalen College, Oxford, in 1860, and became university organist in the following year. While at Oxford he did much to bring the choir of Magdalen to a remarkable state of excellence; he took a keen interest in the foundation of various musical societies; and as a sign of his appreciation of the value of general culture, it is worth recording that he took the degree of B.A. in 1864, that of Mus. D. in 1865, and procured M.A. in 1867, being appointed a university examiner in music in the same year. In 1868 he was engaged frequently as solo organist at the Crystal Palace; and in 1872 was appointed organist of St Paul's, where he raised the standard of choral music to something very like perfection. He was professor of the organ in the National Training School of Music from 1876, and in 1881 succeeded his lifelong friend Sullivan as principal. In 1878 he was a member of the Paris Exposition, and was created Chevalier of the Légion d'Honneur. In 1882 he became regius professor of music in training colleges. In 1888 he retired from the organistship of St Paul's owing to failing eyesight, and was knighted. In 1889 he succeeded Ouseley as professor of music in the university of Oxford, holding the post till 1899. Besides these official distinctions he received a great number of honorary degrees: he was vice-president of the Royal College of Organists, and president of the Plain-song and Medieval Music Society, the London Gregorian Association, and the Musical Association. His compositions include four cantatas, Gideon (1865), The Daughter of Jairus (Worcester, 1878), St Matthew Passion (Gloucester, 1887). Crucefixion (London, 1887); forty-two anthems, some of them very elaborate; many hymn-tunes, organ pieces, madrigals, &c. His professorial lectures were of great value, and he made many contributions to the literature of music. He was a man of wide influence, with a remarkable faculty of organization, and his work in regard to the conditions of the musical profession was of considerable importance. His own music has many of the defects of his qualities, for his breadth of artistic views led him to admire and adopt many styles that are not always compatible with each other. He died while on a holiday at Verona on the 31st of March 1901.

STAINES, a market town in the Uxbridge parliamentary division of Middlesex, England, on the river Thames at the junction of the Colne, 10 m. W.S.W. of London on the London & South Western and Great Western railways. Pop. of urban district (1901), 6688. Breweries and mustard mills employ many hands. A rifle range for the Metropolitan Volunteers and others was opened in 1892. A British village was situated here at the crossing of the Thames on the main road from South-western Britain, and the crossing was certainly one of the most important in the kingdom. According to the Windsor forest for the repair of the bridge is recorded in 1262. The existing bridge, from the designs of George Rennie, was opened in 1831, after three bridges had failed in the previous forty years. The name of Staines appears in the Domesday Survey, and it has been supposed that the town is so called from a stone which marks the limit of the former jurisdiction of the City of London over the lower Thames. This is still considered to be the boundary between the upper and lower Thames. In the immediate neighbourhood, though included in the parish of Egham, Surrey, is Runn mede Island, where King John signed the Magna Carta.

STAIR, JAMES DALRYMPLE, 1ST VISCOUNT (1619-1695), Scottish lawyer and statesman, was born in May 1619, at Drummurchie in Ayrshire. He was descended from a family for several generations inclined to the principles of the Reformation, and had ancestors both on the father's and the mother's side amongst the Lollards of Kylle. His father, James Dalrymple, laird of the small estate of Stair in Kylle, died when he was an infant; his mother, Janet Kennedy of Knockdaw, is described as "a woman of excellent spirit," who took care to have him well educated. From the grammar school at Mauchline he went, in 1633, to the university of Glasgow, where he graduated in arts on the 26th of July, 1637. Next year he went to Edinburgh, probably with the intention of studying law, but the troubles of the times, then approaching a crisis, led him to change his course, and we next find him serving in the earl of Glencairn's regiment in the War of the Covenant. What part he took in it is not certainly known, but he was in command of
a troop when recalled in 1641 to compete for a regency (as a tutorship or professorship was then called) in the university of Glasgow. He was elected in March. Mathematics, logic, ethics and politics were the chief subjects of his lectures, and a notebook on logic by one of his students has been preserved. His activity and skill in matters of college business were praised by his colleagues, who numbered amongst them some of the leading Covenanting divines, and his zeal in teaching was gratefully acknowledged by his students. After nearly seven years' service he resigned his regency, and removed to Edinburgh, where he was admitted to the bar on the 17th of February 1648. This step had probably been rendered easier by his marriage, four years before, to Margaret Ross, co-heiress of Balnass in Wigtown. Stair's practice at the bar does not appear to have been large; his talents lay rather in the direction of learning and business than of oratory or advocacy. His reputation and the confidence reposed in him were shown by his appointment in 1649 as secretary to the commission sent to the Hague to treat with Charles II. by the parliament of Scotland. The negotiation having been broken off through the unwillingness of the young king to accept the terms of the Covenanters, Stair was again sent in the following year to Broda, where the failure of Montrose's expedition forced Charles to change his attitude and to return to Scotland as the covenanted king. Stair had preceded him, and met him on his landing in Aberdeenshire, probably carrying with him the news of the execution of Montrose, which he had witnessed.

During the Commonwealth Stair continued to practise at the bar; but like most of his brethren he refused in 1654 to take the oath of allegiance to the Commonwealth. Three years later, on the death of Lord Balcomie, Stair was appointed one of the commissioners for the administration of justice in Scotland, on the recommendation of Monk. His appointment to the bench on the 1st of July 1657, by Monk, was confirmed by Cromwell on the 26th. Stair's association with the English judges at this time must have enlarged his acquaintance with English law, as his travels had extended his knowledge of the civil law and the modern European systems which followed it. He thus acquired a singular advantage when he came to write on law, regarding it from a cosmopolitan, or international, rather than a merely local or national point of view. His actual charge of judicature at this time was short, for after the death of Cromwell the courts in Scotland were shut—a new commission issued in 1660 not having taken effect, it being uncertain in whose name the commission ought to run. It was during this period that Stair became intimate with Monk, who is said to have been advised by him when he left Scotland to call a full and free parliament. Soon after the Restoration Stair went to London, where he was received with favour by Charles, knighted, and included in the new nomination of judges in the court of session on the 13th of February 1661. He was also put on various important commissions, busied himself with local and agricultural affairs, and, like most of the Scottish judges of this and the following century, acted with zest and credit the part of a good country gentleman.

In 1662 he was one of the judges who refused to take the declaration that the national covenant and the solemn league and covenant were unlawful oaths, and, forestalling the deposition which had been threatened as the penalty of continued non-compliance, he placed his resignation in the king's hands. The king, however, summoned him to London, and allowed him to take the declaration under an implied reserve. The next five years of Stair's life were comparatively uneventful, but in 1669 a family calamity, the exact facts of which will probably never be ascertained, overtook him. His daughter Janet, who had been betrothed to Lord Rutherglen, was married to Dunbar of Baldoon, and some tragic incident occurred on the wedding night, from the effects of which she never recovered. As the traditions vary on the central fact, whether it was the bride who stabbed her husband, or the husband who stabbed the bride, no credence can be given to the mass of superstitions and spiteful slander which surrounded it, principally levelled at Lady Stair. 1 In 1670 Stair served as one of the Scottish commissioners who went to London to treat of the Union; but the project, not seriously pressed by Charles and his ministers, broke down through a claim on the part of the Scots to what was deemed an excessive representation in the British parliament. In January 1671 Stair was appointed president of the court of session. In the following year, and again in 1673, he was returned to parliament for Wigtownshire, and took part in the important legislation of those years in the department of private law. During the bad time of Lauderdale's government Stair used his influence in the privy council and with Lauderdale to mitigate the severity of the orders passed against ecclesiastical offenders, but for the most part he abstained from attending a board whose policy he could not approve. In 1679 he went to London to defend the court against charges of partiality and injustice which had been made against it, and was thanked by his brethren for his success. When, in the following year, the duke of York came to Scotland Stair distinguished himself by a bold speech, in which he congratulated the duke on his coming amongst a nation which was entirely Protestant. This speech can have been little relished, and the duke was henceforth his implacable enemy. His influence prevented Stair from being made chancellor in 1681, on the death of the duke of Rothes.

The parliament of this year, in which Stair again sat, was memorable for two statutes, one in private and the other in public law. The former, relating to the testing of deeds, was drawn by Stair, and is sometimes called by his name. The other was the infamous Test Act, probably the worst of the many measures devised at this period with the object of fettering the conscience by oaths. Stair also had a minor share in the form which this law finally took, but it was confined to the insertion of a definition of "the Protestant religion"; by this he hoped to make the test harmless, but his expectation was disappointed. Yet, self-contradictory and absurd as it was, the Test Act was at once rigidly enforced. Argyll, who declared he took it only in so far as it was consistent with itself and the Protestant religion, was tried and condemned for treason and narrowly saved his life by escaping from Edinburgh Castle the day before that fixed for his execution. Stair, dreading a similar fate, went to Holland, and took up residence with the king, who had more than once befriended him, perhaps remembering his services in Holland; but the duke of York intercepted his access to the royal ear, and when he returned to Scotland he found a new commission of judges issued, from which his name was omitted. He retired to his wife's estate in Galloway, and occupied himself with preparing for the press his great work, The Institutions of the Law of Scotland, which he published in the autumn of 1681, with a dedication to the king.

He was not, however, allowed to pursue his legal studies in peaceful retirement. His wife was charged with attending conventicles, his factor and tenants severely fined, and he was himself not safe from prosecution at any moment. A fierce dispute arose between Claverhouse and Stair's son, John, master of Stair, relative to the regality of Glenluce; and, both having appealed to the privy council, Claverhouse, as might have been expected, was absolved from all the charges brought against him and the master was deprived of the regality. Stair had still powerful friends, but his opponents were more powerful, and he received advice to quit the country. He repaired to Holland in October 1682, and took up his residence, along with his wife and some of his younger children, at Leiden. While there he published the Decisions of the Court of Session between 1666 and 1671, of which he had kept a daily record, and a small treatise on natural philosophy, entitled Physiologia nova experimentalis. 2

In his absence a prosecution for treason was raised against

1 Sir Walter Scott took the plot of his Bride of Lammermoor from this incident, but he disclaimed any intention of making Sir William Ashton a portrait of Lord Stair.
him and others of the exiles by Sir G. Mackenzie, the lord advocate. He was charged with accession to the rebellion of 1679, the Rye House plot, and the expedition of Argyll. With the first two he had no connexion; with Argyll's unfortunate attempt he had no doubt sympathized, but the only proof of his complicity was slight, and was obtained by torture. The proceedings against him were never brought to an issue, having been continued by successive adjournments until 1687, when they were dropped. The cause of their abandonment was the appointment of his son, the master of Stair, who had made peace with James II., as lord advocate in room of Mackenzie, who was dismissed from office for refusing to relax the penalties imposed on Covenanters. Sir John held the office of advocate for a year, when he was "degraded to be justice clerk"—the king and his advisers finding him not a fit tool for their purpose. Stair remained in Holland till the following year, when he returned under happier auspices in the suite of William of Orange. William, who had made his acquaintance through the pensionary Fagel, was ever afterwards the firm friend of Stair and his family. The master was made lord advocate; and, on the murder of Lockhart of Carnwath in the following year, Stair was again placed at the head of the court. He was successively president of the court of chancery and head of the secretariat of the Privy Council, Montgomery of Skelmorlie, who covered the office of registrar-general of Scotland, and Lord Ross, who aimed at the presidency of the court, sprang up in the Scottish parliament; and an anonymous pamphleteer, perhaps Montgomery himself or Ferguson the Plotter, attacked Stair in a pamphlet entitled The Late Proceedings of the Parliament of Scotland Stated and Vindicated. He defended himself by publishing an Apology, which, in the opinion of impartial judges, was a complete vindication.

Shortly after its issue he was created Viscount Stair (1690). He had now reached the summit of his prosperity, and the few years which remained of his old age were saddened by private and public cares. In 1692 he lost his wife, the faithful partner of his good and evil fortune for nearly fifty years. The massacre of the Maconalds of Glencoe (Feb. 13, 1692), which has marked his son, the master of Stair, with a stain which his great services to the state cannot efface—for he was undoubtedly the principal adviser of William in that treacherous and cruel deed, as a signal way of repressing rebellion in the Highlands—was used as an opportunity by his adversaries of renewing their attack on the old president. His own share in the crime was remote; it was alleged that he had an ancestor, John Montgomery, secretary to receive Glencoe's oath of allegiance, though tendered, on the technical ground that it was emitted after the day fixed, but even this was not clearly proved. But some share of the odium which attached to his son was naturally reflected on him. Other grounds of complaint were not difficult to make up, which found willing supporters in the opposition members of parliament. A disappointed suitor brought in a bill in 1693 complaining of his partiality. He was also accused of domineering over the other judges and of favouring the clients of his sons. Two bills were introduced without naming him but really aimed at him—one to disqualify peers from being judges and the other to confer on the Crown a power to appoint temporary presidents of the court. The complaint against him was remitted to a committee, which, after full inquiry, completely exculpated him; and the two bills, whose incompetency he demonstrated in an able paper addressed to the commission and parliament, were allowed to drop. He was also one of a parliamentary commission which prepared a report on the regulation of the judicial system. It formed the basis of a statute in 1695 supplementary to that of 1679, and governed the future of the judicial procedure in the Scottish courts for many years. On the 29th of November 1695 Stair, who had been for some time in failing health, died in Edinburgh, and was buried in the church of St Giles.

In 1695 there was published in London a small volume with the title To my Friends of the Presbyterian Church in Holland, Concerning the Nature of Idolatry, and the God in them by Reason and Revelation, methodically digested—By a Person of Honour. It was edited by the two Nonconformist divines, William Bates and John Howe, who had been in exile in Holland along with Stair, and is undoubtedly his work. Perhaps it had been a sketch of the "Inquiry Concerning Natural Theology," which he had contemplated writing in 1681. It is of no value as a theological work, for Stair was no more a theologian than he was a mathematician or scientist, but it is of interest as showing the serious bent of his thoughts and the genuine piety of his character.

Stair's great legal work, The Institutions of the Law of Scotland deduced from its Originals, and collated with the Civil, Canon and Natural Laws, and the Miscellany of Neighbours' Opinions, affords evidence of the advantage he had enjoyed from his philosophical training, his foreign travels and his intercourse with Continental jurists as well as English lawyers. Unfortunately for its permanent fame and use, much of the law elucidated in it has now become antiquated through the decay of the feudal part of Scottish law and the large introduction of English law, especially in the departments of the law of real property and criminal procedure.

The Physiologia was favourably noticed by Boyle, and is interesting as showing the activity of mind of the exiled judge, who returned to the studies of his youth with fresh zest when physical science was approaching its new birth. But he was not able to emancipate himself from a formula which had cramped the education of his generation, and had not caught the light which Newton spread at this very time by the communication of his Principia to the Royal Society of London.

Stair was fortunate in his descendants. "The family of Dalrymple," observes Sir Walter Scott, "produced within two centuries as many men of talent, civil and military, of literary, political and professional eminence, as any house in Scotland." His five sons were all remarkable in their professions. John, master of Stair (1648–1707), who was created 1st earl of Stair in 1703, an able lawyer and politician, who is, however, principally remembered for his part in the massacre of Glencoe, is dealt with above. Sir James Dalrymple of Borthwick, created a baronet in 1698, was one of the principal clerks of session, and a very thorough and accurate historical antiquary. Sir Hew Dalrymple of North Berwick (1652–1737) succeeded his father as president, and was reckoned one of the best lawyers and speakers of his time; he, too, was created a baronet in 1698. Thomas Dalrymple became physician to Queen Anne. Sir David Dalrymple of Hailes (d. 1721), who was created a baronet in 1700, was lord advocate under Anne and George I.; and his grandson was the famous judge and historian, Lord Hailes (q.v.).

Stair's grandson, John, 2nd earl (1673–1747), who rose to be a field-marshal, gained equal credit in war and diplomacy. He was ambassador in Paris (1715–1720), and, besides seeing service under Marlborough, was commander-in-chief of the British forces in the Continent in 1742, showing great gallantry at the battle of Dettingen. He had his own son, and John 3rd, born in 1725, had inherited his nephew John (1702–1789) as heir to the title; but through a decision of the House of Lords in 1748 he only became 5th earl, after his cousin James and James's son had succeeded as 3rd and 4th earls. John's son, the 6th earl, died without issue, and a cousin again succeeded as 7th earl, his two sons becoming 8th and 9th earls. The 8th earl (1771–1853) was a general in the army, and keeper of the great seal of Scotland. The 9th earl's son and grandson succeeded as 10th and 11th earls.

STAIR (O. Eng. stægur, step, from stigen, to climb, cf. Ger. steigen; the root is also seen in "stilt" and "stirrup"), in architecture, the term (Fr. escalier) given to a series of steps rising one above the other, either in one straight line or with returns, or round a newel, or open well-hole, either square, rectangular, circular or elliptical. A series of continuous steps is called a "flight." The ordinary staircase of two flights with landing between is known as a "pair"; "two pair back" therefore would be the room at the back on the second floor; in houses where the space occupied by the staircase is very limited there is no landing, but the stairs wind round the corner post or newel, and are known as "winders." The steps of a stair consist of "tread" and "riser," the
STAIRCASE

respective dimensions of which vary according to the importance of the staircase and the space which has been given to it; in external flights or stairs, such as those at Persepolis, the tread is so wide and the riser so small in height as to allow of a horse ascending, and generally in garden terraces there is the same slight rise. For the stairs of a palace or municipal building, 14 in. tread and 5 in. riser would be required, but as a rule 12 in. tread and 6 in. riser is adopted. In the stone staircase in the town of Aten Crete there were 18 in. and the risers 12 in. In ordinary houses 9 in. or 10 in. is generally given for the tread, and 6½ in. to 7 in. for the riser. In the stairs leading to lofts, and in yachts or steamers, the ascent is much steeper, having sometimes 10 in. rise and 5 in. tread. The series of stairs provided to ascend from one floor to another when enclosed with walls is known as a staircase (q.v.). Unenclosed flights of steps placed in front of a building are known by the French term perron (q.v.), usually applied to a structure like the horseshoe staircase of the palace at Fontainebleau, the stairs of which are carried on a support independent of the main wall of the palace. From this point of view the great return flight of steps at Persepolis might be looked upon as a staircase, because on one side the steps are all embedded in the main wall of the platform.

Belonging to the same type are the great flights of steps which led to the successive stages of the Ziggurats or Assyrian stage towers; those in front of the Propylaea, leading to the Acropolis at Athens; the stairs leading to the Propylaea (150 ft. in width) at Baalbek; others in Palmyra; and generally all the Roman temples. In medieval times should be included the great flights of steps which stood in front of the cathedrals of Europe, some of which, as those at Le Puy in France, Ste Gudule at Brussels, the cathedral at Erfurt in Germany, S. Minuato at Florence in Italy, and others, still exist, not having yet been buried by the gradual raising of the ground-level in great towns; also the immense flights of steps in Rome, leading up to the Trinita del Monte and the Capitol, and those found in all towns built on hills, when an architectural composition has guided their plan.

In Egyptian architecture inclined planes took the place of stairs, as in the sloping corners of the Great Pyramid, the descent leading to the temple of the Sphinx, and the approaches to the two temples of Deir el-Bahri, one of them the oldest temple found. Inclined planes were also provided in front of some of the Greek temples, where the steps of the stylobate were of great height; similar contrivances were adopted by the Mahommedans in Egypt to ascend the minaret of Ibn Tulun and el Hakim; in the great circular tower at Amboise, and in the fallen campanile of St Mark’s, Venice. (R. P. S.)

STAIRCASE, the term usually applied (Fr. cage d’escailler, Ger. Treppenhaus) to the stairs leading to the upper floors in a building, including the enclosure walls. In the ordinary house a single staircase only is provided; in larger ones a second or service staircase; in those of more importance, especially where the principal reception rooms are on the first floor, a grand staircase leading to the latter, and other subsidiary stairs or staircases.

Architecture.—Among the earliest examples are those found in Egypt, generally built in the thickness of the walls, as in the pylons and temples; a remarkable example was found by Dr Arthur Evans in Crete, consisting of a staircase in stone, 6 ft. wide, with return flights of stairs, rising though twelve stages. The Chaise in the temple of Zeus at Olympia, leading to the gallery, is supposed to have been in wood, but in some of the Greek temples have been found stairs in stone with return flights. In the Tabularium at Rome there is a long flight of 67 steps leading up from the Forum to a hall at the back, but otherwise there are few examples of ancient Roman staircases, and none of any importance have been found in Pompeii. Of medieval staircases the principal examples are those in stone built round a circular newel, to provide means of ascent to the various stages of the church towers. One of these, at St Gilles in Provence, is covered with a semicircular rising vault, which is known as Vis St Gilles; some of these circular staircases are 12 ft. in diameter, others, like those in the campanile of Pisa, are built in the thickness of a circular hall with well-hole in centre. In the 15th century some of the stone staircases leading to the rood loft, with open tracery round the edge, are of great elaboration and beauty, as at St Maclou, Rouen. In the 16th century in France, in the châteaux of the Loire, are many examples, among which the circular staircases at have been regarded as part of the great external octagonal in plan and on one side open at intervals to the court, has a great circular newel enriched with arabesque carving, and a rising elliptical barrel vault with ribs and bosses. In the château of Chambord the great staircase in the middle, which is built round a circular well-hole, had two separate flights, one over the other, so that, starting from opposite sides on the ground floor, two persons could ascend without seeing one another. At Azay le Rideau, Loire, and in the château of St Germain-en-Laye, the staircases in return flights are built between walls, and the same is found in the ducal palace at Venice and most of the palaces of Rome. At Venice, in the Palazzo Minelli, the staircase is in a circular tower with open arcades and balustrades. The most famous staircase in Spain is that in the north transept of Burgos Cathedral, remarkable for the magnificent iron-work of its balustrade; and in England the staircase leading to the hall of Christ Church, Oxford, with a magnificent fan vault, is a fine example. In the 16th and 17th centuries in England the grand staircases of the great mansions were usually in wood, the finest examples being those at Hatfield, Knole, Audley End, &c. They would seem also to have been regarded in part of the great exterior staircases in France and Italy they assumed greater importance, being always in stone or marble, with colonnades or arcades round the staircase on the first floor. Of these there were three types. The first is the straight staircase with two or more landings, of which examples existed in Paris in the Tuileries and the old Hôtel de Ville, having been reproduced in the new Hôtel de Ville, and the staircase in the Vatican. The second is the staircase with return flights right and left, at the top of a first flight, sometimes built in long rectangular halls, but unsatisfactory owing to the want of concentration and to the difficulty of deciding whether to turn to the right or left; at the top of the first flight; examples are in the Herrenchiemsee Palace, Bavaria, the Palazzo Reale at Naples, the Madama Palace at Turin, and the government offices in London. In the new opera house in Paris, J. L. Garnier (q.v.) solved the problem better by placing his staircase in a square hall, which, seen from the first floor surrounded with open balconies, forms one of the finest staircase halls known. The third alternative is that of the staircase in three flights, built round a square well-hole, of which the staircase in Holford House is the best example. The vestibule staircases in Genoa which lead to a raised ground-storey, such as those in the Palazzo Durazzo, or in the university, are extremely fine in effect and are executed all in white marble. As the vestibules are open to the narrow streets, it is possible that the title of the “marble palaces of Genoa” refers to those marble staircase halls, because the external walls of the palaces are either in ordinary stone or in brick covered with stucco. (R. P. S.)

Construction.—The primary object of stairs, in house-building, is to afford a safe and easy communication between floors at different levels. To make the communication easy the “rise,” and width (or “tread”) of the steps should be regular and suitably proportioned to each other with convenient landings; there should be no winding steps, and the rail which is fixed to render the use of the staircase safe should be strongly fixed with its top at a convenient height for the hand.

The first person that attempted to fix the relation between the height and width of a step upon correct principles was, we believe, Blondel, in his Cour d’architecture. His formula is applicable to very large buildings but not to ordinary dwellings. Adopted, who investigated the subject at length (in Handrails and Staircases), gives the following rules for different proportions of treads and

Figs 2.
STAIRCASE

Width of tread in inches.  Height of rise in inches.

12 in 10 in
11 11
10 9
9 8

These dimensions give angles of ascent varying from 24° to 37°.

The projection of the nosings is not reckoned in the width of the treads and must be added to determine the full width of the treads.

The form of staircases is various, the simplest being a straight flight, which type should only be used to a low storey.

In towns, where space cannot be allowed for convenient forms, they are often made angular, circular or elliptical, with winding steps, or are constructed of composite form partly straight and partly circular.

In large buildings, where convenience and beauty are the chief objects of attention, winding steps are seldom introduced when it is possible to avoid them. Well-designed stairs should be planned as simply as possible to afford easy and convenient access to the higher level.

The staircase must be placed in a position easy of approach, and convenient for both the lower and upper apartments. It must be well ventilated and lighted—the absence of sufficient light may prove the cause of serious accidents. At no part should the head room (that is, the height between the level of a tread and that portion of the structure immediately above it) be less than 7 ft. Straight flights should be composed of not less than four and not more than twelve steps. If it is desired to continue more than this number of steps in a straight line, a landing equal in length at least to the width of the stairs should be provided before starting up the next flight. Winders should be avoided if possible, but should be found necessary it is advisable to put them at the bottom of a flight rather than at the top, the reason being that they should be the cause of an accident the unfortunate individual will not have far to fall.

Besides the straight flight of stairs, staircases may be designed in almost numberless different ways to suit the position which they are to occupy or with a view to architectural effect; but whatever position or form they are made to take their chief purpose of providing convenient and easy access to a higher level must be steadily borne in mind. One of the most ordinary forms of American staircases of a more ambitious character are elaborated the dog-legged or newel stair, open newel stair, geometrical stair, circular newel stairs (see fig. 1).

Geometrical stairs usually enclose a well, which may vary very much in size and shape from merely a narrow slit between the flights to a square opening admitting of ample ventilation for the room. This form has continuous strings and handrail, and may be rectangular, circular or elliptical in plan, although it is especially adapted for the curved forms and most satisfactory when so treated. Such stairs are more difficult to construct than the newel stairs already mentioned and lack their strength, as in the absence of the strong framed newel posts the handrail depends for support entirely upon the balance, which must be rigidly and accurately cut to the treads. When wood balusters for the most part are used, newel posts of iron are often introduced at intervals to afford additional stiffness. Circular geometrical stairs are built on a circular plan around a well. Each step is necessarily a winders radiating from the wall string. If in wood they must be very carefully framed, especially if the well-hole is small, owing to the difficulty of introducing proper care for support, and the number of pieces of the work must be built up on account of the curvature. The use of stairs is more suitable for building in stone, and in this case support is obtained by pinning the end of the stone step well into the wall and supporting each step upon the one below. The balusters and handrail also, in the case of stone, are much more firmly fixed by the former, which are usually of iron, being let into mortices in the tread or end of the step and run in with molten lead and caulked to secure a firm fixing.

Solid newel or spiral stairs are circular or polygonal on plan and built around a central pillar or newel, which may be square, polygonal or circular in section. This also is a form of stair-building especially suitable for erection in stone, the solid core being formed on the step itself, and the other end well pinned into the masonry of the wall. Each succeeding step should be dowelled at the newel to the one below and should be of a material of already three inches at least for its entire length over the one below and in this way obtain extra support.

The newel stair was at its best in Elizabethan and later Renaissance. The circular forms represented a new departure and narrow winding stairs was found ill adapted to the altered conditions when convenience and elegance were becoming more sought after. Most of the steps of this period found in the open newel stair a construction capable of being developed into a dignified and beautiful feature of domestic architecture, and they certainly brought out its possibilities in a remarkable manner. This is evidenced by the many fine examples, handed down to us by the Tudor period, to be found in the great mansions which date back to the time of the early Renaissance. Steps were arranged in broad short flights with wide treads and easy rise. Landings were freely used, and in many cases were large enough to be used as galleries for the display of pictures. The work was generally solidly executed in oak, and carved and moulded decoration was lavish upon every detail. The newels, much enriched, were frequently carried up to the ceiling and formed a portion of the arcing which was often a prominent feature around the well. In the period of the later Renaissance the newel principle of construction was still retained and the main changes were the omission of the newel with longer flights and the manner of decoration partook of a more severely classic nature. One of the first examples is that of the Château de Blois, and of modern treatment that of the Grand Opera House, Paris. With the geometrical staircases of the Georgian era the staircase was much favoured and very generally used in domestic buildings. Although more difficult to build it must be admitted that this type of stair is not so satisfactory in a number of ways as the newel form. With its continuous curving strings and handrail it has a certain elegance of its own, but in principle of construction it is not so good, nor can it compete with the open newel stair in regard to the ease with which the latter lends itself to schemes of artistic decoration. As before remarked, however, it is well adapted for stairs circular and elliptical in plan.

Experience has proved concrete to have fire-resisting properties of the most effective character, and it does not possess the propensities for splitting and flying under the action of heat that belong to stone. Steel or iron is often employed as an additional support for stone and concrete stairs.

In the case of concrete work iron bars are frequently used either to reinforce the steps for their full length, and are in this way hidden from view and are at the same time serving the purposes of support. When a more ornate appearance is desired they are sometimes hidden by the use of plain concrete steps which may be ensased in other material to secure a richer effect. Martles, tiles and mosaic are the principal materials used for this.
purpose. Stairs of fine concrete to which is given the name of "artificial stone" have largely superseded those constructed of granite, marble or other hard stones. They are being largely employed in the new construction by the introduction of steel core bars without detriment to its appearance; it is consistent in quality and special shapes are readily moulded; it is very hard-wearing, especially when the aggregate is a hard granite gravel. The stairs are built by pinning each step in the wall either at one or at both ends. In the first case they are termed cantilever or hanging steps, and it is advisable to have the hearting of the end of the step at least 9 in. into the wall. When fixed at both ends the pinning need not be so deep, and built unless the steps are very wide the steel core may be omitted. The steps are either rectangular or spanned-shaped in (figs. 2 and 3); the former are stronger and easier to fix than the latter, which, however, give a better appearance and can be finished with a plain smooth soffit. Iron balusters are generally used for stone stairs.

The construction of wood staircases forms a special branch of the joinery craft, and many books have been written on the subject. Numerous methods of forming the basic angle and the head of the case have been put forward by different authors, among them being the tangent system, which gives excellent results at perhaps the smallest cost compatible with good work. There are also the five methods known as the Logman, Tichmarsh, Springill, and Freshman, which are spaced to wood stairs to frame and finish the worked in the workshop and fix it bodily in the position in which it has to occupy. In America, especially in the eastern states, the finished staircase is built up piece by piece upon a rough framework which has been used by the workmen during the erection of the carcass of the building. In many instances the stairs consist of easings and panelings nailed upon the rough skeleton work. Such stairs are built in many kinds of materials, such as wood, stone, concrete, iron and brick. Often two or more kinds of materials are used in the same staircase, as when constructions of concrete or stone are reinforced with iron or steel. It is recommended to fit a staircase handrails, balusters and newels of a different nature from the steps themselves. The spanelled or triangular-shaped space between a flight of stairs and the floor is frequently enclosed with wood-panelled framing and fitted with a staircases, and are made of for cupboard accommodation.

There are a number of technical terms connected with staircases which require some explanation to enable the drawings to be easily understood:

Staircase.—This comprises the whole of the stair construction and is the name given to the space or enclosure which contains it.

Well-hole, the open space enclosed by the stairs.

Flight, a continuous series of steps between two landings.

Landing, a platform forming a kind of halting-place between two flights of the same staircase. Circular stairs are usually formed of a circle, a rectangle, equal in width and length to the breadth of the two flights which it separates. A half-space landing extends the total width of the staircase.

Flier.—Fliers are steps that have the nosings of the treads parallel or in one to another.

Winder.—This is an angular-shaped step. A winder fitted into a wall angle is often termed a kite winder, from the fact that it resembles a kite. In planning stairs the width of the winder tread at a distance of 18 or 20 in. from the handrail should equal the width of a flier.

Carriage.—This may be either a flier or a winder. One or both ends of the step are projected to form a base for the newel and are shaped to a scroll which often follows the line of the curve terminating the handrail. It is usually the step or steps at the base of a staircase consists of a half-space landing in this case.

- Bull-nosed step, one having a blunt rounded end. It may be shaped to a quarter or half circle.

Dancing Stairs.—This introduction of winders in geometrical staircases brings about awkward complications in the curve of the handrail and strings, for the width of the steps at the handrail being much less than that of the fliers, while at the same time the rise is necessarily equal, causes an Enlighten knee in the handrail and in the strings.

To obviate this whole of the steps are made to dance, that is, they are all shaped as winders in order to divide the going equally between them and thus obtain a regular slope for the strings and handrail. Of the many shapes of the steps of a flight are made ordinary fliers. In a polygonal or elliptical staircase the whole of the flight is constructed in this way so as to obtain a regular sweep up from the bottom to the top step. Each step may be divided into several different parts such as the tread, the newel, the string, the stringer, and sometimes the lower horizontal upper space of the step which supports the foot when ascending or descending the stairs. The riser is the upright member of a step which supports the tread. It fills the vertical space between the lower edge of the tread and the back edge of the one below. The edge of the tread usually projects some little distance beyond the face of the riser and is formed into a rounded or moulded nosing. Stone stairs and other concrete structures are frequently reinforced with a solid piece of stone of square or triangular section, and these are fixed in position by being pinned into the wall at one or both ends with each step resting upon the back edge of the one below. Stairs are usually built up in a manner somewhat similar to that adopted for wood construction.

Rise, the vertical distance between the surface of one tread and that of the next.

Going, the horizontal measurement between two adjacent risers.

Newel, strong posts occurring at intervals in a newel staircase. They are placed at the ends of flights where junction is made to landings, at turnings, and at the top and bottom of the staircase. They should be strongly framed in the stair construction, and have the string and handrail housed into them. Newels are sometimes of elaborate form and often designed as a pedestal carrying a lamp or statuette, or they may be carried up to form part of some ornamental framework. A newel in this case is termed a newel post, where the stairs begin, and the remainder of the posts used in the framing are termed angle posts.

Handrail.—This is a rail commonly of hard wood which runs up as a half-space landing at the side of a stepladder, and is fixed about 2 ft. 8 in. (that is 3 ft. minus half a rise) to the upper surface of the rail. On the level, such as on landings, it is usually fixed 3 ft. above the surface. These are the heights at which a handrail is usually fixed. It is frequently parallel to the periphery of the flight of stairs, but is sometimes used as a guide for the feet in descending the steps. Handrails are made in other materials such as iron and bronze. A handrail is generally upheld by balusters, which are vertical bars or posts filling in the space between the handrail and the string or framing. If they are made in many shapes and in many different materials such as wood, iron, bronze, stone and marble. Sometimes in the place of balusters the space usually occupied by them is filled with a balustrade or a framework of iron, wood, or bronze, or with panels of wood perforated, perhaps, and richly carved.

Core-rail.—An iron band is frequently used in geometrical stairs to give extra strength and stiffness to the handrail. It is generally about 1 in. thick, being screwed into place formed in the under side of the handrail. It is especially necessary for the curved portions of the handrail, where the grain of the wood is often cut across.

String.—Strings are the members that carry the treads and risers which in wood stairs are housed into them or else fitted into notches cut in the strings to receive them. In the former case the supporting member is termed a framed string, but if mortices are cut out for the strings as is known as a cut string (see details, fig. 4). A cut and mitred string is similar to this last, but has the vertical cut of each notch spayed and the riser is mitred to it so as not to show the joint. Strings are either straight or curved strings, the latter being used when it is necessary to change the direction of the handrail or string. The former are used when it is necessary to change the direction of the handrail or string. The latter runn up from newel to newel or in geometrical stairs ramp and curve according to the nosing line. Rough strings or rough carriages are placed between the inner and outer strings to support the stringer, and equal the height of the stringer. They are sometimes cut to the same height as the stringer, and are fixed about 1 in. thick are fitted into the steps and spiked to the carriages.

Ramp.—This is a concave curve formed in one plane when changing the direction of the handrail or string. In America it is known as an easine.

Knee.—This is a convex curve in one direction. When used in conjunction with a ramp it forms a round-neck, which is a combination of ramp and knee.

Wraith.—This is a curve formed both horizontally and vertically in the handrail or string. It is often necessary in geometrical stairs where change of direction is necessary.

Although more in the nature of a mechanical lift or elevator than a stairs, moving stairways may perhaps find a place in this article owing to their resemblance to and the fact that they convey the passenger quickly and easily to his destination. To a higher level without the necessity of a tedious climb up stairs, or of a wait such as is often entailed with a passage of elevators. The introduction of windsers in geometrical staircases brings about awkward complications in the curve of the handrail and strings, for the width of the steps at the handrail being much less than that of the fliers, while at the same time the rise is necessarily equal, causes an Enlighten knee in the handrail and in the strings.

To obviate this whole of the steps are made to dance, that is, they are all shaped as winders in order to divide the going equally between them and thus obtain a regular slope for the strings and handrail. Of the many shapes of the steps of a flight are made ordinary fliers. In a polygonal or elliptical staircase the whole of the flight is constructed in this way so as to
STALACTITES

to the passenger. For high buildings, underground railways and
similar positions, a spiral form is used which winds round in a circular
shaft to the highest level and returns in the opposite direction in
a similar manner, taking up and setting down passengers as it
revolves. Although this type of elevator is probably not so rapid as
the vertical lift working in a straight line to the point it is desired
to reach, its great advantage is that it does away with the waiting
which often causes so much annoyance with ordinary lifts.

The Factory and Workshop Act 1901 contains somewhat similar
conditions, but in this case the staircases communicate with each
floor and the roof... The maximum height shall
and the maximum rise 7½ in. Steps of spandrel section may be
used having a thickness of 3 in. at the smallest part for staircases
3 ft. 6 in. wide, and not less than 4½ in. thick for staircases 4 ft. 6 in.
wide. Fire-escape staircases shall be constructed with dead bearings and
without cantilever work. They must comply with the require-
ments for enclosed staircases as regards width, going, width of treads, height of risers, doors
and windows, etc. They must be so arranged that they shall deliver at the ground-level into a public
way or some large space. Where in general use the staircases shall be
constructed with non-slippery material as distinguished from perforated iron or chequered iron plates.

The second schedule of the London Building Act 1894 sets forth the materials that are deemed fire-resist-
ing under the act, and specifies in the case of staircases "oak or teak or other hard timber with treads and
risers not less than 2 in. thick."

The law regulating the construction of buildings in the city of New York provides that "stairsways
serving for the exit of fifty people must, if straight, be at
least 4 ft. wide between railings or between walls, and
if curved or winding 5 ft. wide. If the number of fire
escape staircases be so considered as to constitute a
public fireway for the accommodation of fifty people it shall be
provided in such staircases that the width in all cases shall
not be less than 7½ in."

pt. ii. (J. Br.)

STALACTITES (Gr. σταλακτίτης, from σταλάκτες, to drip), pendent masses formed where water
containing mineral solutions drops very slowly from
an elevation. They are seen, for example, beneath
bridges, arches and old buildings as water per-
coating through the joints of the masonry has dissolved very
small quantities of the lime present in the cement and mortar
between the stones. On freezing, the water imbibed by the pores of the lime limestone
edges, and the solution of carbonate of lime becomes
supersaturated; a deposit of this substance ensues and as the drop continues to fall from the same spot a small column of
white calcite very slowly grows downwards in a vertical direc-
tion from the roof of the arch. In a very similar manner
stalactites of ice are produced in frosty weather as the water
dropping from caves of buildings, beams, branches of trees,
&c., very gradually freezes. Other minerals than ice and
calcite often occur in stalactitic growths. Thus we find in
mines and in the cavities of mineral veins stalactites of limonite,
fluorspar, opal, chalcedony and gibbsite. These stalactites
are never of great size, usually not more than 2 or 3 in.
length, and probably the method of origin is exactly the same
as that of the larger and more common stalactites of ice and of
calcite.

The conditions essential to the perfect development of stalac-
tites appear to be (1) a very slow trickle of water from a fissure;
(2) regular evaporation; (3) absence of disturbance, such as
currents of air. If the discharge of water is fast, irregular
encrustations may be produced, or the precipitate of solid matter
may be entirely washed away by the mechanical force of the
currents. Changes of temperature will interfere with the forma-
tion, sometimes accelerating and sometimes retarding it, and
the stalactites tend under such circumstances to stop growth
or to develop irregularities and excrescences. Currents of
wind produce the same effect. For these reasons ice stalactites
form most readily on calm cold nights, and stalactites of ice or
calcite are seen in greatest perfection in the interior of caves,
where the sun's light does not penetrate, the temperature is steady, and there are no strong currents of air.

In all limestone caves stalactites form in great abundance as glistening white columns covered with a thin film of water. The great caves, such as those of Adelberg (in Styria), Jenolan (Australia), the Mammoth Cave (Kentucky), the Caves district in France, and the grottos of Belgium, are divided into chambers which are richly festooned with stalactites, and fanciful names are given to various groups according to their similarity to different objects, natural or artificial. Ice caves of considerable size occur in the Arctic and Antarctic regions, and are draped with ice stalactites often wonderfully like those of limestone caves.

Where the water drops upon the floor of one of these caves evaporation still goes on and an encrustation forms which may cover the whole surface of an irregular sheet. If the air be perfectly still, however, the drop which falls from a stalactite on the roof will always land on the same place and a pillar of deposit will rise vertically, till in course of time it meets and joins with the stalactite above. In this way a column is produced, which sometimes has a graceful form with a long straight shaft expanding somewhat at its upper and lower extremities. As the stalactites thicken by deposit of layer upon layer of carbonate of lime, they rarely continue to be cylindrical but assume tapering forms with irregular surfaces. They seldom branch, but sometimes they give off excrescences which may curve upwards or downwards and exceptionally long thin stalactites take their rise from these and grow downwards parallel to the main stalactite. Large stalactites may be three or four feet thick, but in that case they have usually formed by the coalescence of adjacent ones which enlarged till they met and were then covered with a continuous layer of deposit. Single stalactites 2 ft. in diameter are not rare. It is known that they are of very slow growth, and much speculation has gone on regarding the length of time required for the formation of some of the largest stalactites. From data obtained by measurement of the rate of growth of certain stalactites it has been estimated that as much as two hundred thousand years may have elapsed since certain thick stalactites began to grow.

We know that many caves are of great antiquity from the fossil remains they contain, but these estimates are probably ill-founded, seeing that there is no certainty that the conditions have remained the same during the whole period of growth. Sir Archibald Geikie records that stalactites 1½ in. in diameter had formed beneath a bridge in Edinburgh which was a hundred years old; in caves, however, the rate of formation is rarely so great as this. Inscriptions on stalactites in the Adelberg cave after thirty years had been covered with a scarcely perceptible film of new deposit. In one of the Moravian caves a stalactite, about as thick as a goose quill, was broken across in 1830 and in 1831 it had grown three or four centimetres; from careful observations it has been calculated that one of these stalactites, 7 ft. long, may have been formed in 4000 years. The stalagmitic crust on the floor of caves is usually mixed with blocks which have fallen from the roof, sand, mud and gravel carried in by floods, and the bones of animals and men which have inhabited the cave if it had an accessible entrance. Its formation must have been interrupted by many changes in the physical conditions of the district, and consequently it often occurs in layers which alternate with beds of a different character.

Some particulars regarding the internal structure and growth of stalactites have been ascertained by Professor W. Rinz of Brussels. The first stage of every stalactite is a low circular ring of deposit on the roof of the cave. The diameter of this ring corresponds to the height to which the tube may rise before it is completely filled. At the outer surface of the drop evaporation goes on and supersaturation results in the deposit of a thin ring-shaped band. At the centre of the drop no deposition takes place, and as this goes on after some time a short tube is produced; the width of this tube is about 5 millimetres and is fairly constant. The tube very slowly lengthens as deposit gathers at its lower end; water is constantly dropping from it and its interior is always full. Very little material is deposited except at the orifice—hence in many caves long straight tubular stalactites can be seen not much more than a quarter of an inch wide, and with this width it is growing. These have the rhombohedral faces of calcite, and are usually in a simple description; their corresponding faces are parallel, and an examination of the material of the tube proves that the whole mass has the same crystallographic structure. We may consequently regard the stalactites as rounded, tubular crystals continuously growing but provided with crystalline facets only at their lower ends. Small isolated stalactites sometimes have scarcer deposit over the sides and apertures, so that the diameter of the tube and its apertures become surrounded with lime deposits. In this way horns, twigs and branches arise, often curving upwards or downwards; they are always provided with a central tubule which is in some cases a mere incrustation. The body of the stalactite is in crystalline continuity with that of the main stalactite, and the whole mass has a uniform optical orientation. In the majority of cases the long axis of the stalactite corresponds to the optic axis of the calcite crystal, but in one group of stalactites these two make an angle of 15° with one another. An interruption in the supply of water or an accidental fracture of the stalactite induces abnormal growth. The end of the tube becomes obstructed or completely closed, and nodular or tuberculate growths are often the result. If the outer surface dries the next layer which is laid down may often be readily detached, as it is not firmly united with the previous layers. A stalactite may consist of a series of these fragments, which eventually arrives, when the central tube is no longer the chief conduit but a general drip of water from the roof bathes the whole outer surface of the stalactite. Then small, flat crystals of calcite appear which develop into stalactitic plaits or stalactitic curtains, and the stalactite grows as before till they cover the whole mass, and as they grow outwards they develop into prisms whose axes are directed radially. In very old stables these initial stalactite crystals have grown into stalagmite calcite crystals deposited from the mineral solutions which trickle down along the external surface. When they are cut across they show concentric rings, some of which are due to stains of iron or manganese oxides or insoluble materials brought down by the water; others are lines of cavities produced by interrupted or irregular crystallization. They resemble the rings of the wood of trees, but probably do not depend on seasonal changes but on purely accidental factors, so that they afford no clue to the time of growth.

Stalactites also occur in the interior of lava caves in the Sandwich Isles, Samoa, &c. Often the upper surface of a lava flow has cooled to form a crust, while the interior is still perfectly fluid, and it sometimes happens that the liquid basalt has made its escape, leaving great cavities below the hollow roof of the lava. The interior of these caves is covered with a black shining film of glassy basalt, and black stalactites of lava hang downwards. Their surface is sometimes changed to brown or red by the oxidizing action of the acid vapours which occupied the cave after the lava retired. These stalactites are tubular, with bluntly rounded ends, and probably their mode of growth is somewhat analogous to that of ice-stalactites. In microstructures the ends are seated with thicknesses of radial calcite, olivine and augite; in this they differ from the ice and calcite stalactites which are crystalline throughout.

STALL (O. Eng. stell, steal, cf. Du. stel, Gér. and Swed. stall, a common Teutonic word for a place, station, place for standing in; the root is the Indo-European *stel-, to stand, see also in Latin stabulum, Greek σταθμός, and in stallion, an entire horse, properly one kept in a stall and not worked), a word which means literally a place where one may stand, and so is applied to a separate division in a stable, shed, &c., in which a single horse, cow or other domestic animal may be kept, to a separate booth, box or cell in a manor in which a number of cattle, or in the street, on which goods are exposed for sale by the person owning or licensed to use the same, and in England to the higher-priced seats on the ground floor of a theatre. The word is more particularly applied to a special form of seat in an ecclesiastical building. In cathedrals, monastic churches and the larger parish churches the stalls are fixed seats enclosed at the back and separated at the sides by high projecting arms, and placed in one or more rows on the north and south sides of the choir or chancel, running from the sanctuary to the screen or chancel arch. These separate enclosed seats are usually reserved for the clergy, and more usually the choir are seated in open benches in front of the stalls. In a cathedral the canons and prebendaries have each a stall assigned to them.
In the chapels of the various knightly orders the stalls are assigned to the members of the order, thus, in St. George's Chapel, Windsor, are the stalls of the Knights of the Garter, in Henry VII's Chapel, Westminster, where the Knights of the Bath, adorned with the stall plates emblazoned with the arms of the knight occupying the stall, above which is suspended his banner.

Architecturally and artistically considered, the stalls of a cathedral or church are a marked feature of the interior adornment. They are richly carved, and are frequently surmounted by canopies of tabernacle work. The seats generally can be folded back so as to allow the occupant to stand upright or kneel; beneath the seat, especially in monastic churches, is fixed a pillar, surmounted by a mitre or bishop's hat, which affords a slight rest for the person while standing. Among beautiful specimens of carved stalls may be mentioned the Early Decorated stalls in Winchester Cathedral, the Early Perpendicular ones in Lincoln Minster, and the early 15th-century canopics in Norwich Cathedral. The stalls, especially the towering corner-stalls with their ornate carving filled with figures, in Amiens Cathedral are very fine; they date from 1508–1520.

STALBAUM, JOHANN GOTTFRIED (1703–1801), German classical scholar, was born at Zasach, near Delitzsch in Saxony, on the 13th of September; he died at Bath, on the 24th of January 1806. Stalbaum was connected with the Thomasschule at Leipzig, from 1835 as rector. In 1840 he was also appointed extraordinary professor in the university. His reputation rests upon his work on Plato, of which he published two complete editions: the one (1821–1825) a revised text with critical apparatus, the other (1827–1860) containing exhaustive prolegomena and commentary written in excellent Latin, a fundamental contribution to Platonic exegesis. A separate edition of the Parmenides (1859), with the commentary of Proclus, deserves mention. Stalbaum also edited the complete works of Homer, and his works for editors of Latin and Greek literature in Germany. The Drama sacrae latinae institutionis of Thomas Ruddiman. See C. H. Lipsius in the Osterprogramm of the Thomasschule (1861); R. Hoche in Allgemeine deutsche Biographie, vol. xxxv.

STALBRIDGE, a municipal and parliamentary borough of Cheshire, England; the parliamentary borough extending into Lancashire. Pop. (1901), 27,673. It lies on the river Tame, in a hilly district, 6 m. E. of Manchester, and is served by the London & North-Western, Great Central, and Lancashire & Yorkshire railways. Immediately to the west lie the towns of Ducrow and the river is the river, Lyne; while 2 m. south of Stalbridge is the town of Hyde. The whole district is thus very densely populated. Stalbridge is one of the oldest seats of the cotton manufacture in this locality, the first cotton mill having been erected in 1726, and the first steam engine in 1795. There are also machine works, nail works, paper mills, and iron and brass foundries. The development of the town is modern, as it was created a market town in 1828, incorporated in 1837, and created a parliamentary borough, returning one member, in 1867. The town has a mayor, 7 aldermen and 22 councillors. Area, 3,300 acres.

STAMBOLOV, STEFAN (1854–1893), Bulgarian statesman, was born on the 31st of January 1854 at Trnovo, the ancient Bulgarian capital, where his father kept a small inn. Under Turkish rule it was impossible to obtain a liberal education in Bulgaria, and young Stambolov, after attending the communal school in his native town, was apprenticed to a tailor. During the politico-religious agitation which preceded the establishment of the Bulgarian exarchate in 1870, a number of Bulgarian youths were sent to Russia to be educated at the expense of the Imperial Government among them, Stambolov, who was entered at the seminary of Odessa in order to prepare for the priesthood. His wayward and independent nature, however, rebelled against the discipline of school life; he was expelled from the seminary on the ground of his association with Nikolitsis, and, making his way to Rumania, he entered into close relations with the Bulgarian revolutionary committees at Bucharest, Giurgo and Galatz. In 1875, though only twenty years of age, he led an insurrectionary movement at Nova Zagora in Bulgaria, and in the following year organized another rising at Oreshkovitsa. In the autumn of 1876 he took part as a volunteer in the Servian campaign against Turkey, and subsequently joined the Bulgarian irregular contingent with the Russian army in the war of 1877–78. After the signature of the Berlin Treaty in 1878, Stambolov settled at Trnovo, where he set up as a lawyer, and was soon elected deputy for his native town in the Sobranje. His force of character, his undoubted patriotism, his brilliant eloquence, and his disinclination to accept office—a rare characteristic in a Bulgarian politician—combined to render him one of the most influential men in Bulgaria. The overthrow of the Zankoff ministry in 1884 was largely due to his influence, and in the following year he was elected to the Bulgarian National Assembly as a deputy for Trnovo. He held this important office for the next two years, a critical period in the national history. The revolution of Philippopolis, which brought about the union of Bulgaria with eastern Rumelia, took place on the 18th of September 1885, and it was largely owing to Stambolov's advice that Prince Alexander decided to identify himself with the movement. The war with Servia followed, and Stambolov, notwithstanding his official position, served as an ordinary soldier in the Bulgarian army. After the abdication of Prince Alexander by a band of military con-

STAMBOLOV—STAMBOLOV

ven, Stambolov, like his colleagues, the latter, however, soon made his way to Jivkov, a friend and to the town of Galatz. Invested with supreme power at this perilous juncture, Stambolov displayed all the qualities of an able diplomatist and an energetic ruler. He succeeded in frustrating the mission of General Kaulbars, whom the Tsar despatched as special commissioner to Bulgaria; in suppressing a rising organized by Nabokov, a Russian officer, at Burgas; in quelling military revolts at Silistra and Rustchuk; in holding elections for the Grand Sobranje, despite the interdict of Russia, and in securing eventually the election of Prince Ferdinand of Coburg to the vacant throne of Bulgaria. In 1887, he was created a count; in 1885, he was elected president of the National Assembly, and in 1887, he was created a count. He continued in office for nearly seven years (see BULGARIA). The aim of his foreign policy was to obtain the recognition of Prince Ferdinand, and to win the support of the Triple Alliance and Great Britain against Russian interference in Bulgaria. In his dealings with Turkey, the suzerain power, he displayed considerable acuteness; he gained the confidence of the Sultan, whom he flattered and occasionally menaced; and aided by the ambassadors of the friendly powers, he succeeded in obtaining on two occasions important concessions for the Bulgarian episcopate in Macedonia (see MACEDONIA), while securing the tacit sanction of the Porte for the technically illegal situation in the principality. With the assistance of Austria-Hungary and Great Britain he negotiated large foreign loans which enabled him to develop the military strength of Bulgaria. Under Prince Ferdinand he pursued the same despotical methods of government which had characterized his administration during the regency; Major Panitza, who had organized a revolutionary conspiracy, was tried by court-martial and shot at Sofia in 1890; four of his political opponents were hanged at Sofia in the following year, and Karavelov was sentenced to five years' imprisonment. His tyrannical disposition was increased by the assassination of his colleague, Belchev, in 1891, and of Dr Vlkovitch, the Bulgarian representative at Constantinople, in 1892, and eventually proved intolerable to Prince Ferdinand, who compelled him to resign in May 1894. He was now exposed to the vengeance of his enemies, and subjected to various indignities and persecutions; he was refused
permission to leave the country, and his property was confiscated. On the 15th of July 1695 he was attacked and barbarously mutilated by a band of Macedonian assassins in the streets of Sofia, and succumbed to his injuries three days later. His funeral, which was attended by the representatives of the powers at Sofia, was interrupted by disgraceful riots, and an effort was made to perpetrate an outrage on his remains. No attempt was made to arrest his murderers; two persons were, however, arraigned for the crime in 1696, and subjected to almost nominal penalties.

(Thomas D. B.)

**STAMFORD, HENRY GREY, 1st Earl of (c. 1599-1673),** eldest son of Sir John Grey, succeeded his grandfather, Henry Grey as Baron Grey of Groby in July 1614. He married Anne, daughter of William Cecil, 2nd Earl of Exeter, the heiress of the borough and manor of Stamford, and in March 1628 was created earl of Stamford. Just before the outbreak of the Civil War he ranged himself definitely among the king’s opponents, and was made lord-lieutenant of Leicestershire. After some operations around Leicester he occupied Hereford, and, when compelled to abandon the city, marched into Cornwall. At Stratton, in May 1643, his troops were beaten by the Royalists; driven into Exeter, Stamford was forced to surrender this city after a siege of three months. The earl, who was certainly no general, was charged with cowardice, and took no further part in the military operations of the war, although once or twice he was employed on other business. The ravages of the Royalists had reduced him to poverty, and, distrusted by the House of Commons, he had great difficulty in getting any compensation from Parliament. A period of retirement Stamford declared for Charles II, during a rising in August 1659, and was arrested, but was soon released. He died on the 21st of August 1673. One of his sons was Architell Grey (d. 1702), the compiler of the **Debates of the House of Commons, 1667-1694** (10 vols. 1766). His eldest son, Thomas, Lord Grey of Groby (c. 1623-1657), was member of parliament for Leicester during the Long Parliament, and an active member of the parliamentary party. In January 1643 he was appointed commander-in-chief of the forces of the parliament in the midland counties and governor of Leicester. In 1645 he won some credit for his share in the pursuit and capture of the duke of Hamilton; he assisted Colonel Pride to "purge" the House of Commons later in the same year; and he was a member of the court which tried the king, whose death-warrant he signed. A member of the council of state under the Commonwealth, Grey fought against the Scots in 1651, and in February 1655 he was arrested on suspicion of conspiring against Cromwell. He was, however, soon released, but he predeceased his father in April or May 1657.

Thomas (c. 1654-1720), only son of the last named, succeeded his grandfather as 2nd Earl of Stamford. He took some part in resisting the arbitrary actions of Charles II., and was arrested in July 1685; but after his release he took up arms on behalf of William of Orange, after whose accession to the throne he was made a privy councilor and lord-lieutenant of Devonshire. In 1697 he became chancellor of the duchy of Lancaster, and in 1699 president of the board of trade, being dismissed from his office on the accession of Anne in 1702. From 1707 to 1711, however, he was again president of the board of trade. On his death without children on the 31st of January 1720 his titles passed to his cousin Henry (d. 1739), a grandson of the first earl, from whom the latter earls were descended.

**STAMFORD,** a market town and municipal borough, chiefly in the South Kesteven or Stamford parliamentary division of Lincolnshire, but partly in Northamptonshire, on the river Welland, at the landward edge of the fen country. Pop. (1901), 8,229. The town stands picturesquely on the steep banks of the river, and is of the highest antiquarian interest. It formerly possessed fourteen parish churches, but now has only six, viz. St Mary’s, erected at the end of the 13th century, possessing an Early English tower, with Decorated spire, the principal other parts of the building being Perpendicular; All Saints’, also of the 13th century, the steeple being built at the expense of John Browne, merchant of the staple at Calais, in the beginning of the 15th century; St Michael’s, rebuilt in 1526 on the site of one erected in 1260; St George’s, Early English, Decorated, and Perpendicular, for the most part rebuilt in 1450 at the expense of William Bruges, first garner king-at-arms; St John Baptist’s, Perpendicular, erected about 1450; and St Martin’s, Perpendicular, in which Lord Treasurer Burghley is buried. Formerly there were several religious houses: the Benedictine monastery of St Leonard’s, founded in the 7th century, of which there are some Norman and later remains; the Carmelite monastery (1291), of which the west gate still stands; and houses for Grey Friars (time of Henry III), Dominicans (1246), Gilbertines (1291), and Augustinians (1316). The principal secular buildings are the town hall (rebuilt 1776), the corn exchange (1859), and the library and scientific institute (1842), with a library of 6000 volumes. There are a large number of charitable institutions, including the Stamford and Rutland Infirmary (1828), Browne’s hospital, founded in the time of Richard III., with its picturesque Late Perpendicular building, Snowden’s almshouses (1604), Truesdale’s almshouses (1700), and Burghley hospital, founded by Lord Treasurer Burghley (1597). The modern grammar school building incorporates remains of the John of St Paul. To the south of Stamford, in Northamptonshire, is Burghley House, the seat of the marquis of Exeter, a fine quadrangular mansion dating from 1587, containing a noteworthy art collection. It stands in a well-wooded park. The prosperity of the town depends chiefly on its connexion with agriculture. It possesses iron foundries, agricultural implements works, wagon factories and breweries. There is also some trade in coal, timber, stone and slates. The town is governed by a mayor, 6 aldermen and 18 councillors. Area, 1918 acres.

Apart from the tradition preserved by Henry of Huntington that the Saxons here defeated the Picts and Scots in 449, Stamford (Staunford) is a place of great antiquity. The Danes built
STAMMERING

a fort here on the north bank of the Welland, round which a town existed when in 922 King Edward fortified the opposite side of the stream. It passed again into Danish hands and was one of the five boroughs recaptured by Edmund Ætheling in 941. The priory of St Leonard was a cell of Durham, and a charter of Edgar dated 972 mentions a market and a mint. At that time of Edward the Confessor Stamford was a royal borough governed by twelve lawmen, reduced in 1086 to nine, and divided into six wards. The Norman castle, built before 1086, was thrice besieged by Henry II. while Duke of Normandy, but only yielded in 1153. Two years later he granted it and the manor to Richard Humet; forfeited by his son it was given to John, earl of Warenne, in 1206. In 1337 it passed to William de Bohun, earl of Northampton, and thence to Edmund Langley, afterwards duke of York, finally reverting to the Crown on the death of Richard III. in 1485. It was granted it to the first Lord Burghley. The barons met here in 1215 on their march to London, and in 1309 a parliament was held at Stamford. In 1256 Henry III. gave the burgesses freedom from tolls, the right of receiving tolls and immunity of their goods from arrest; privileges confirmed and enlarged in the following year. William, earl of Warenne, in 1275 permitted the burgesses to choose their chief officer or alderman, who was still sworn in at the manor court as late as 1615 and was first called " mayor " in 1663. Edward IV. incorporated Stamford by the name of the alderman and burgesses in 1461 and granted the town immunity from external jurisdiction and gave it a town seal. The charters have been frequently confirmed. As early as 1292 Stamford was well known for its monastic schools, and in 1333 was chosen as the headquarters of the students who seceded from Oxford, and an Early Decorated gateway remains of Brasnose Hall. The attempt to establish a regular university was prohibited by royal authority. The defeat of the Yorkists here was followed by the decay of the castle in the reign of Richard III., and the history of the place henceforth centred chiefly round the family of Cecil, whose ancestor, David Syceld, settled here about 1506. Stamford occasionally returned two members to parliament from 1295 until 1312. The representation was reduced to one by the act of 1807, and was abolished in 1885. The fairs are of ancient origin, and are mentioned in 1245 and the reign of Edward I. These are the May fair, town fair, and spring fair, and fairs on various dates representing Candlemas, mid-Lent, the feasts of Corpus Christi, St James and SS. Simon and Jude. A market is still held every Friday. In 1182 there were dyers, weavers and fullers here, but these were only the usual home industries. In 1822 silk throwing was successfully carried on, but this has long ceased. Edward E. Mackenzie-Walcutt, Memorials of Stamford, past and present (Stamford, 1867); John Drakard, The History of Stamford in the County of Lincoln, comprising its ancient progressive and modern state (Stamford, 1822); Charles Nevinsan, History of Stamford (Stamford, 1879); Victoria County History: Lincoln.

STAMMERING, or STUTTERING, a spasmodic affection of the organs of speech in which the articulation of words is suddenly checked and a pause ensues, often followed by a repetition in rapid sequence of the particular sound at which the stoppage occurred. Of this distressing affection there are many grades, from a slight inability to pronounce with ease certain letters or syllables, or a tendency to hesitate and to interject meaningless sounds in a spoken sentence, to the more severe condition in which there is a paroxysm of spasms of the muscles, not only of the tongue and throat and face, but even of those of respiration and of the body generally. To understand in some degree the explanation of stammering it is necessary to consider shortly the physiological mechanism of articulate speech. Speech is the result of various muscular movements affecting the current of air as it passes in expiration from the larynx through the mouth. If the vocal cords are called into action, and the sounds thus produced are modified by the muscular movements of the tongue, cheek and lips, we have vocal speech; but if the glottis is widely open and the vocal cords relaxed then the current of air may be moulded by the muscular apparatus so as to produce speech without voice, or whispering (see VOICE). In both cases, however, the mechanism is very complicated, requiring a series of nervous and muscular actions, all of which must be executed with precision and in accordance. In vocal speech, for example, it is necessary that the respiratory movements, more especially those of expiration, occur regularly and with nice adjustment to the kind of articulate expression required; that the vocal cords be approximated and tightened by the muscles of the larynx acting with delicate precision, so as to produce the sound of the pitch desired; that the rima glottidis (or aperture of the larynx) be opened so as to produce prolonged sounds, or suddenly closed so as to cut off the current of air; that the movements of the muscles of the tongue, of the soft palate, of the jaws, of the cheeks and of the lips occur precisely at the right time and to the requisite extent; and finally that all of these muscular adjustments take place with rapidity and smoothness, gliding into each other without effort and without loss of time. Exquisite co-ordination of muscular movement is therefore necessary, involving also complicated nervous actions. Hence it is that speech is acquired by long and laborious effort. A child possesses voice from the beginning; it is born with the capacity for speech; but articulate expression is the result of education. In infancy, not only is knowledge acquired of external objects, and signs attached in the form of words to the ideas thus awakened, but the nervous and muscular mechanisms by which these signs or words receive vocal expression are trained by long practice to work harmoniously. It is not surprising, therefore, that in certain cases, owing to some obscure congenital defect, the co-ordination is not effected with sufficient precision, and that stammering is the result. Even in severe cases no appreciable lesion can be detected either in the nervous or muscular mechanisms, and the condition is similar to what may affect all varieties of finely co-ordinated movements. The mechanism does not work smoothly, but the pathologist is unable to show any organic defect. Thus the co-ordinated movements necessary in writing are disturbed in scriver's palsy, and the skilful performer on the piano or on any instrument requiring minute manipulation may find that he is losing the power of delicate adjustment. Stammering is occasionally hereditary. It rarely shows itself before the age of four or five years, and as a rule it is developed between this age and puberty. Men stammer in a much larger proportion than women. It may occur during the course of nervous affections, such as hysteria, epilepsy or locomotor ataxia; sometimes it follows febrile disorders; often it develops in a child in a feeble state of health, without any special disease. In some cases a child may imitate a stammerer and thus acquire the habit. Any general enfeeblement of the health, and especially nervous excitement, aggravates the condition of a constitutional stammerer.

Stammerers, as a rule, find the explosive consonants b, p, d, t, and hard g the most difficult to articulate, but many also are unable easily to deal with the more continuous consonants, such as f, th, s, sh, n, m, y, and in severe cases even the vowels may cause a certain amount of spasm. Usually the defect is not observed in whispering or singing; but there are exceptions to this statement. In pronouncing the explosive sounds the part of the oral apparatus that ought suddenly to open or close remains spasmodically closed, and the stammerer remains for a moment voiceless or strives pitifully to overcome the obstruction, uttering a few successive bursts of sounds like the beginning of the sound he wishes to utter. The lips thus remain closed at the attempted utterance of b and p; the tip of the tongue is pressed against the hard palate or the back of the upper front teeth in d and t; and the back of the tongue presses against the posterior part of the palate in pronouncing g hard and k. In attempting the continuous consonants, in which naturally the passage is not completely obstructed, the stammerer does not close the passage spasmodically, but the parts become fixed in the half-opened condition, or there are intermittent attempts at closure, with a resulting shrill or grating sound or coming to a full stop. In severe cases, even when vowels cannot be freely uttered, the spasm appears to be at the rima glottidis.
STAMP

Duties below; For the second class, of which the most familiar are the small adhesive pieces of paper used as the sign that postal charges have been duly paid on letters, parcels, &c., transmitted by the postal service of a country, see Post and Postal Service and Philately.

Stamp Duties.—The stamp duty is a tax imposed upon a great variety of legal and social relations, and forms a branch of the national revenue. The stamp is a legal and convenient mode of certifying that the revenue regulations have been complied with. Stamp duties appear to have been invented by the Dutch in 1624. They were first imposed in England by an act of 1694 as a temporary means of raising funds for carrying on the war with France. Stamp duties in the United Kingdom form part of the inland revenue, and are placed under the control of the commissioner of inland revenue. The principal acts in force on the subject are the Stamp Act 1891 and the Stamp Duties Management Act 1891. Amendments of the law are also included in the Customs and Inland Revenue Act 1893, the Finance Acts of subsequent years, and the Revenue Act 1898. The death duties, the corporation duty, the duties on patent medicines and playing cards, and postage duties, are also technically "stamp duties"; but in ordinary use the expression is limited to those imposed on the various classes of legal instruments, such as conveyances, leases, transfers, mortgages, bonds, &c., on bills of exchange, promissory notes, contract notes, bank notes and bankers' drafts, receipts, insurance policies, bills of lading, and a few other documents. Stamps are either adhesive or impressed. The adhesives, which can only be used for certain documents, can be obtained at inland revenue offices throughout the United Kingdom, and at all post offices which are money order offices. Stamps can only be impressed at the inland revenue offices in certain of the larger towns. For duties not exceeding 2s. 6d. the adhesive inland revenue or postage stamps may (in most cases) be used indiscriminately. This arrangement was first introduced in 1881, when it was applied to the penny stamp, and it has since been extended to other denominations. The commissioners of inland revenue are authorized to make allowance under certain conditions for stamps which have been inadvertently spoiled or rendered useless for their intended purposes. In order to obtain such allowance the parties must present the stamps within two years from the time when they became useless. The commissioners may be required by any person to express their opinion as to the amount of duty, if any, which is chargeable on any instrument; and such person, if dissatisfied with the assessment made, may appeal to the courts.

The stamp duty on the transfer of certain kinds of securities can be commuted by the payment of a lump sum or (in some cases) an annual composition, and the transfers then become exempt from duty.

Stamp duties are either fixed, such as the duty of one penny on every cheque irrespective of its amount, or ad valorem, as the duty on a conveyance, which varies according to the amount of the purchase money. The duty is denoted generally by an impressed, less frequently by an adhesive, stamp, sometimes by either at the option of the person stamping. Thus an inland bill of exchange (unless payable on demand) must have an impressed stamp, a foreign bill of exchange, while an agreement adhesively stamped, while a receipt stamp may be of either kind. It should be noticed that certain documents falling within a class which as a rule is subject to stamp duty are for reasons of public policy or encouragement of trade exempted from the duty by special legislation. Examples of such documents are Bank of England notes, agreements within § 17 (but not those within § 4) of the Statute of Frauds (see Fraud), instruments of partnership, agreements between a shipowner and his masters, or his agents, deeds of gift, transfers of ships or shares in ships, indentures of apprenticeship for the sea service, petitions forwarded by post to the Crown or a House of Parliament and most instruments relating to the business of building and shipowning.

As a general rule a document must be stamped at the time of execution, or a penalty (remissible by the commissioners of inland revenue) is incurred. The penalty is in most cases £10, sometimes £50, in other cases, in the case of certain stamps, £100. Some instruments cannot be stamped at all after execution, even with payment of the penalty. Such are bills of exchange and promissory notes (where an impressed stamp is necessary), bills of lading,
STANCHION—STANDISH

proxies for voting at meetings of proprietors of joint-stock companies and receipts after a month from date. An unstamped instrument cannot be pleaded or given in evidence except in criminal proceedings. The instrument is evidence in a court of law which is stamped but not produced with duty be produced as evidence in a court, the officer whose duty it is to read the instrument is to call the attention of the judge to any omission or insufficiency. The rules governing the admission to evidence of a document which may legally be stamped after execution, it may, on payment of the amount of the unpaid duty and the penalty payable by law, and a further sum of £1, be received in evidence, saving all just exceptions.

The rules of the supreme court, 1883 (Ord. xxix. r. 8, re-enacting a provision of the Common Law Procedure Act), provide that a new trial is not to be granted by reason of the ruling of a judge that the stamp upon any document or instrument does not require a stamp. The stamp upon a document subject to the stamp laws of a foreign state is usually admissible in evidence in a court of the United Kingdom if it conform in other respects to the local laws governing the admission to evidence of documents, even though it be improperly stamped according to the law of the foreign country. The admissibility of documents belongs to the ordinaria lieta rather than the decivit lieta, and is governed by the lex fori rather than the lex loci contractus, unless indeed that law makes a stamp necessary to the validity of the instrument. Certain offences, such as forging a die or stamp, selling or using a forged stamp, &c., are made felonies punishable with penal servitude for life if fraudulently or maliciously.

United States.—The subject of stamp duties is of unusual historical interest, as the passing of Greenville's Stamp Act of 1765 (see United States. History) directly led to the American War of Independence. The act was, indeed, repealed the next year as a matter of expediency, but an act of the same year dealing with the dependency of American colonies declared the right of the British legislature to prescribe all acts. The general yield of the stamp duties under the act of 1765 was, owing to the opposition in the American colonies, only £4000—less than the expenses of putting the act into force.

The stamp duties of the United States are now under the superintendence of the commissioner of internal revenue.

STANCHION (Fr. élançon, a wooden post), an architectural term applied to the upright iron bars in windows which pass through the eyes of the saddle bars or horizontal irons to steady the lead lights. The French call the latter traverses, the stanchions montants, and the whole arrangement arrangement. Stanchions frequently finish with ornamental heads forged out of the iron.

STANDARD, a term with three main meanings: (1) an ensign or flag; (2) a fixed weight, measured in pounds or units established by law or customarily used as a unit of comparison by which the correctness of others can be determined; (3) an upright or standing object, such as a large candelabrum, or, particularly, a fruit-tree which stands without support. With regard to the derivation, the word which appears in most European languages, e.g. Du. standaard, Ger. Standarte, ita. stendardo, Fr. estandard, is to be referred to the Teut. standan, to stand, and refers to the fixed pole to which an object or a pole was attached. The "standard" as a military ensign was properly stationary and served as the signal of the position of its owner on the ordered field of battle. The O. Fr. form estendard points to the influence of Lat. extendere, to spread out, extend, of the flag when hung upon the pole (see further FLAG for the various meanings of the word and its history). The use of the term for a recognized unit of comparison is due probably to the fact that it is something fixed or set up, stable, and not, to any fanciful reference to the ensign or flag as the object to which one turns as a rallying-point. For the standard weights and measures see Weights and Measures and Standards Department below. There are many other standards, such as electrical standards (see Electricity), standard solutions in chemistry for the purpose of volumetric analysis, &c. In engineering, the component parts of machines or other structures are "standardized" in accordance with agreed measurements. For "standard time" see Time, Standard.

STANDARD, BATTLE OF, a name given to the battle of the 22nd of August 1138 near Northallerton, in which the Scottish army under King David was defeated by the English levies of Yorkshire and the north Midlands, who arrayed themselves round a chariot carrying the consecrated banners of St. Peter of York, St John of Beverley, St Wilfrid of Ripon and St Cuthbert of Durham.

See C. Oman, Art of War: Middle Ages, pp. 389 sqq.

STANDISH, DEPARTMENT, a department of the English Board of Trade, having the custody of the imperial standards of weights and measures. As far back as can be traced, the standard weights and measures, the primary instruments for determining the justness of all other weights and measures used in the United Kingdom, were kept at the exchequer, and the duties relating to the standards were imposed upon the commissioners of the exchequer. The office of chamberlains was abolished in 1826, under the operation of 23 Geo. III. c. 82, passed in 1783, but the custody of the standards and any duties connected therewith remained attached to an officer in the exchequer (q.v.) until that department was abolished in 1866. Meanwhile, in pursuance of recommendations of Standard Commissions of 1841 and 1854 and a House of Commons Committee of 1862, the Standards of Weights, Measures and Coinage Act 1866 was passed. This act created a special department belonging to the Board of Trade, called the "Standard Weights and Measures Department" and a head of that department styled the "Warden of the Standards." His duty was to conduct comparisons, verifications and operations with reference to the standards in aid of scientific research and otherwise. The first—indeed, the only real holder—of the office was Henry Williams Chisholm (1800-1901), previously chief clerk of the old exchequer, under whose direction the department was organized; and before his retirement in 1877 it embraced not merely the re-verification of the imperial standards, but the making of local standards for local authorities, the re-verification of standards and instruments for all parts of the United Kingdom and colonies, for foreign countries which did not have local standards; and the supervision of the verification of manufacturers' standards and instruments, gas-measuring standards, apparatus for determining the flash-point of petroleum, &c. The Weights and Measures Act of 1875 left out all reference to the title and office of warden of the standards, and this opportunity was taken, in the words of the then permanent secretary of the Board of Trade, T. H. (afterwards Lord) Farrer, to make the office "more strictly a department of the Board of Trade." It was put in charge of an officer (Mr H. J. Chaney) termed "Superintendent of Weights and Measures," but on his death in 1906 the approach was made to restore dignity and importance to the office by the appointment of Major P. A. MacMahon, F.R.S., with the title of "Deputy Warden of the Standards."

There are Standards departments under the charge of experienced scientists in Berlin, St Petersburg, Paris, Vienna, Rome, Madrid, Lisbon, Brussels, Bucharest and Constantinople and at Ottawa, Melbourne and Sydney. The United States Bureau of Standards is in the department of Commerce and Labor. It was established in 1901 and is under the charge of a director. Its work follows that of the English department and embraces also research in the domain of physics, extending from chemistry on the one side to engineering on the other. It also tests and investigates standards and methods of constructing measuring-instruments for scientific societies, educational institutions, manufacturers and others.

STANDISH, a town of the Transvaal, 114 m. S.E. of Johannesburg, on the railway from that city, via Newcastle to Durban, distant 356 m. Pop. (1904), 4589, of whom 2136 were white. Standerton is 5025 ft. above the sea and is built on the north bank of the Vaal, here spanned by two fine bridges. It is the chief town of a district of the same name and the centre of an important agricultural and pastoral region. A government stud farm is maintained here. In the neighbourhood are coal-fields. The name of the town is derived from that of the former owner of the site, an Adrian Standter, who fought against the British at Boompas in 1848. The town was laid out in 1870. Since 1903 it has been governed by a municipality.

STANDISH, MILES, or MYLES (c. 1584-1650), American colonist, was born about 1584 in Lancashire, probably of the family of Sir Henry Standish, who commanded the flagship of the English squadron which in 1601 captured the Spanish armada. The act of 1795, which repealed the act of 1866, merely declared that the Board of Trade had all the powers and performed all duties relative to the standards vested in or imposed upon the warden of the standards by the act of 1866 or otherwise, and the title "deputy warden of the standards" is therefore a departmental creation.
Duxbury Hall branch of the family. Nothing definite is known of him before 1630, when with his wife, Rose (d. 1621), he emigrated to New England in the "Mayflower." He became the military leader of the Plymouth colony; was sent to London in 1625 on an unsuccessful mission to secure the intervention of the Council for New England in the affairs of the colony; and in 1628 was one of the eight members of the colony who pledged themselves to pay £1,800 and thus buy out the merchant adventurers. In 1631 with William Brewster and others he settled at Duxbury, where he died on the 3rd of October 1656, and where on "Captain's Hill," near the site of his home, there is a monument to him, consisting of a stone shaft, 110 ft. high, and a bronze statue of him. Longfellow's "Courtship of Miles Standish" apparently has no basis in fact; Standish's second wife, Barbara, a sister of Rose, must have been summoned to Plymouth a year before the marriage of John Alden to Priscilla Mullins. Lowell's "Interview with Miles Standish" misrepresents him: he was not a typical Puritan.

See William Bradford's "History of Plymouth Plantation," Tudor Jenks's "Captain Myles Standish" (New York, 1908) and Henry Johnson's "Exploits of Myles Standish" (New York, 1897) for popular sketches.

STANFIELD, WILLIAM CLARKSON (1794–1867), English marine painter, was born of Irish parentage at Sunderland in 1794. As a youth he was a sailor, and during many long voyages he acquired that intimate acquaintance with the sea and shipping which was admirably displayed in his subsequent works. In his spare time he diligently occupied himself in sketching marine subjects, and so much skill did he acquire that, after having been incapacitated by an accident from active service, he received an engagement, about 1818, to paint scenery for the "Old Drury," a theatre in Welclose Square, London. Along with David Roberts he was afterwards employed at the Cobourg theatre, Lambeth; and in 1826 he became scene-painter at Drury Lane theatre, where he executed some admirable work, especially distinguishing himself by the production of a drop-scene, and by decorations for the Christmas pieces for which the house was celebrated. Meanwhile he had been at work upon some eared pictures of small dimensions, and was elected a member of the Society of British Artists. Encouraged by his success at the British Institution, where in 1827 he exhibited his first important picture—"Wreckers off Fort Rouge"—and in 1828 gained a premium of 50 guineas, he before 1830 abandoned scene-painting, and in that year made an extended tour on the Continent. He now produced his "Mount St Michael," which ranks as one of his finest works; in 1832 he exhibited his "Opening of New London Bridge" and "Portsmouth Harbour"—commissions from William IV.—in the Royal Academy, of which he was elected an associate in 1832 and an academician in 1835; and until his death on the 18th of May 1867 he contributed to its exhibitions a long series of powerful and highly popular works, dealing mainly with marine subjects, but occasionally with scenes of a more purely landscape character. Among these may be named: the "Battle of Trafalgar" (1836), executed for the United Service Club; the "Castle of Ischia" (1841), "Isola Bella" (1841), among the results of a visit to Italy in 1837; "French troops Fording the Margra" (1847), "The Victory" Bearing the Body of Nelson Towed into Gibraltar" (1853), "The Abandoned" (1856). He also executed two notable series of Venetian subjects, one for the banquetting-hall at Bowood, the other for Trentham. He was much employed on the illustrations for The Picturesque Annual, and published a collection of lithographic views on the Rhine, Moselle and Meuse; and forty of his works were engraved in 1848 in lieu of a title of "Stanfield's Coast Scenery." The whole course of Stanfield's art was powerfully influenced by his early practice as a scene-painter. But, though there is always a touch of the spectacular and the scenic in his works, and though their colour is apt to be rather dry and hard, they are large and effective in handling, powerful in their treatment of broad atmospheric effects and telling in composition, and they eviscerate the most complete knowledge of the artistic materials with which their painter deals.

STANFORD, SIR CHARLES VILLIERS (1852– ), Irish musical composer, was born in Dublin on the 30th of September 1852, being the only son of Mr John Stanford, examiner in the court of chancery (Dublin) and clerk of the Crown, Co. Meath. Both parents of the composer were accomplished amateur musicians, the father being the possessor of a splendid bass voice, and the mother a very clever pianist. Under R. M. Levey (violin), Miss Meeker, Mrs Joseph Robinson, Miss Flynn and Michael Quarry (piano), young Stanford's musical powers were encouraged, and in October 1865, and October 1866, at the Town Hall, he played himself composition and organ. Various feats of precocity are recorded in an article in the Musical Times for December 1898. He came to London as a pupil of Arthur O'Leary and Ernst Bauer in 1862, and in 1870 won a scholarship at Queen's College, Cambridge, whence he migrated to Trinity College in 1873, and succeeded J. L. Hopkins as college organist, a post he held till 1892. His appointment as conductor of the Cambridge University Musical Society gave him great opportunities, and the fame which the society soon obtained was in the main due to Stanford's energies. Before his time ladies were not admitted into the college, but through his efforts, Miss Hopkins and Miss Stanford, and second most interesting performances and revivals took place. In the years 1874 to 1877 he was given leave of absence for a portion of each year in order to complete his studies in Germany, where he learnt from Reinecke and Kiel. He took the B.A. degree in 1874 and M.A. in 1878, and was given the honorary degree of Mus. D., at Oxford in 1883, and at Cambridge in 1888. He first came prominently before the public as a composer with his incidental music to Tennyson's Queen Mary (Lyceum, 1876); and in 1881 his first opera, The Veiled Prophet, was given at Hanover (revived at Covent Garden, 1903); this was succeeded by Savonarola (Hamburg, April, and Covent Garden, July 1884), and The Canterbury Pilgrims (Drury Lane, 1884). A long interval separates these from his later operas, Shamus O'Brien, a delightful piece of Irish dramatic writing (Opera Comique, 1896) and Much Ado About Nothing (Covent Garden, 1901). For the main provincial festivals, works by Stanford were commissioned as follows; "Orchestral serenade" (Birmingham, 1888); "Elegiac Ode" (Norwich, 1884); The Three Holy Children (Birmingham, 1885); The Revenge (Leeds, 1886); The Voyage of Macaulay (Leeds, 1888); The Battle of the Baltic (Hereford, 1891); Eden (Birmingham, 1891); The Kent Chapter (Manchester, 1895); Fordham (Norwich, 1896); Requiem (Birmingham, 1897); Te Deum (Leeds, 1898); The Last Post (Hereford, 1900); Stabat Mater (Leeds, 1907). Besides these, his music includes a few chorals works of importance, such as The Resurrection (Cambridge, 1873); Psalm XLVI. (Cambridge, 1877); Carmen Saeculare (Jubilee Ode, 1887); "Installation Ode" (Cambridge, 1892); East to West (London, 1893); Psalm CL. (Manchester, 1887); Mass in G (Brompton Oratory, 1893). He was appointed professor of composition at the Royal College of Music, 1883; conductor of the Bach choir in 1885; professor of music in the university of Cambridge, succeeding Sir G. A. Macfarren, 1887; conductor of the Leeds Philharmonic Society, 1887, and of the Leeds Festival from 1901 onwards. He was knighted in 1902. His instrumental works include six symphonies, many chamber compositions, among them two string quartets; besides many songs, part-songs, madrigals, &c., and incidental music to the Eumenides and Oedipus Rex (as performed at Cambridge), as well as to Tennyson's Becket. His church music holds an honoured place among modern Anglican compositions; and his editions of Irish and other traditional songs are well known. In 1908 he published an essay on the "History of English Church Music," and in 1914 a collection of contributions to reviews, &c., in past years.

STANHOPE, EARLS. James Stanhope, Ist Earl Stanhope (c. 1673–1721), English statesman and soldier, was the eldest son of Alexander Stanhope (d. 1707), a son of Philip Stanhope, 1st earl of Chesterfield. Educated at Eton and at Trinity College, Oxford, he accompanied his father, then British minister at Madrid, to Spain in 1690, and obtained some knowledge of that country which was very useful to him in later life. A little later, however, he went to Italy where, as afterwards in Flanders,
he served as a volunteer against France, and in 1695 he secured a commission in the British army. In 1701 Stanhope entered the House of Commons, but he continued his career as a soldier and was in Spain and Portugal during the earlier stages of the War of the Spanish Succession. In 1705 he served in Spain under Charles Mordaunt, earl of Peterborough, and in 1716 he was appointed British minister in Spain, but his duties were still military as well as diplomatic, and in 1708, after some differences with Peterborough, who favoured defensive measures only, he was made commander-in-chief of the British forces in that country. Taking the offensive he captured Port Mahon, Minorca, and after a visit to England, where he took part in the impeachment of Sacheverell, he returned to Spain and in 1710 helped to win the battles of Almenara and of Saragossa, his perseverance enabling the archduke Charles to enter Madrid in September. However, at Brihuega he was overwhelmed by the French and was forced to capitulate on the 9th of December 1710. He remained a prisoner in Spain for over a year and returned to England in August 1712. He now definitely abandoned the army for politics, and became one of the chief supporters of the Whig opposition in the House of Commons. He had his share in establishing the house of Hanover on the throne, and in September 1714 he was appointed secretary of state for the southern department, sharing with Walpole the leadership of the House of Commons. He was mainly responsible for the measures which were instrumental in crushing the Jacobite rebellion of 1715, and he forwarded the passing of the Septennial Act. He acted as George I’s foreign minister, and only just failed to conclude a treaty of alliance with France in 1716. In 1717, comptroller of the navy, and after the abdication of George I he became the first lord of the treasury, but a year later he returned to his former office of secretary for the southern department. In 1717 he was created Viscount Stanhope of Mahon and in 1718 Earl Stanhope. His activity was now shown in the conclusion of the quadruple alliance between England, France, Austria, and Holland in 1718, and in obtaining peace for Sweden, when threatened by Russia and Denmark, while at home he promoted the bill to limit the membership of the House of Lords. Just after the collapse of the South Sea Scheme, for which he was partly responsible but from which he did not profit, the earl died. London on the 5th of February 1721. Stanhope married Lucy, daughter of Thomas Pitt, governor of Madras, and he was succeeded by his eldest son Philip (1717–1788), a distinguished mathematician and a fellow of the Royal Society.

Charles Stanhope, 3rd Earl Stanhope (1753–1816), statesman and man of science, son of the 2nd earl, was born on the 3rd of August, 1753, and educated under the opposing influences of Eton and Geneva, devoting himself whilst resident in the Swiss city to the study of mathematics, and acquiring from the associations connected with Switzerland an intense love of liberty. In politics he took the democratic side. As Lord Mahon he contested the city of Westminster without success in 1774, when only just of age; but from the general election of 1780 until his accession to the peerage on the 7th of March 1786 he represented through the influence of Lord Shelburne the Buckinghamshire borough of High Wycombe, and during the sessions of 1785 and 1786 he gave his support to the administration of William Pitt, whose sister, Lady Hester Pitt, he married on the 10th of December 1774. When Pitt ceased to be inspired by the Liberal principles of his early days, his brother-in-law severely他们的connexions and opposed with all the impecuniosity of his fiery heart the arbitrary measures which the ministry favoured. Lord Stanhope's character was without any taint of meanness, and his conduct was marked by a lofty consistency never influenced by any petty motives; but his speeches, able as they were, had no weight on the minds of his colleagues in the upper chamber, and, from a disregard of their prejudices, too often drove them into the opposite lobby. He was the chairman of the "Revolution Society," founded in honour of the Revolution of 1688, the members of which in 1770 expressed their sympathy with the aims of the French republicans. He brought forward in 1794 the case of Muir, one of the Edinburgh politicians who were transported to Botany Bay; and in 1795 he introduced into the Lords a motion deprecating any interference with the internal affairs of France. In all these points he was hopelessly beaten, and in the last of them he was in a "minority of one"—a sobriquet which stuck to him throughout life—whereupon he seceded from parliamentary life for five years. He was elected a fellow of the Royal Society so early as November 1772, and devoted a large part of his income to its maintenance. His first wife died in 1786, and he married in 1797 Louise, a method of securing buildings from fire (which, however, proved impracticable), the printing press and the lens which bear his name and a monochord for tuning musical instruments, suggested improvements in canal locks, made experiments in steam navigation in 1795-1797 and contrived two calculating machines. When he acquired an extensive property in Devonshire, he projected a canal through that county from the Bristol to the English Channel and took the levels himself. Electricity was another of the subjects which he studied, and the volume of Oeuvres de Lord Electricity which he issued in 1779 contained the rudiments of his theory on the "return stroke" resulting from the contact with the earth of the electric current of lightning, which were afterwards amplified in a contribution to the Philosophical Transactions for 1787. His principal labours in literature consisted of a reply to Burke's Reflections on the French Revolution (1790) and an Essay on the rights of juries (1792), and he long meditated the compilation of a digest of the statutes. The lean and awkward figure of Lord Stanhope figured in a host of the caricatures of Sayers and Gillray, reflecting on his political opinions and his personal relations with his children. The second earl's wife died in 1798, and he married his daughter and sole heiress of the Hon. Henry Grenville (governor of Barbadoes in 1746 and ambassador to the Porte in 1762), a younger brother of the 1st Earl Temple and George Grenville; who survived him and died in March 1829. By his first wife he had three daughters, one of whom was Lady Hester Stanhope (q.v.). His youngest daughter, Lady Lucy Rachael Stanhope, eloped with Thomas Taylor of Sevenoaks, the family apothecary, and her father refused to be reconciled to her; but Pitt made Taylor controller-general of the customs, and his son was one of Lord Chatham's executives. His second wife was the mother of three sons. Lord Stanhope died at the family seat of Chevening, Kent, on the 15th of December 1816, being succeeded as 4th earl by his son Philip Henry (1781–1855), who inherited many of his scientific tastes, but is best known, perhaps for his association with Kaspar Hauser (q.v.).

Philip Henry Stanhope, 5th Earl Stanhope (1805–1875) English historian, better known as Lord Mahon, son of the 4th earl and his wife, the daughter of the 1st Baron Carrington, was born on the 30th of January 1805. He took his degree at Christ Church, Oxford, in 1827, and entered parliament in 1830. He was under secretary for foreign affairs for the early months of 1835, and secretary to the India Board in 1845, but though he remained in the House of Commons till 1852, he made no special mark in politics. He was chiefly interested in literature and antiquities, and in 1842 took a prominent part in passing the Copyright Act. He was a trustee of the British Museum, and in 1856 he proposed the foundation of a National Portrait Gallery; its subsequent creation was due to his executors. It was mainly due to him that in 1869 the Historical Manuscripts Commission was started. As president of the Society of Antiquaries (from 1846 onwards), it was with who called attention in England to the need of supporting the excavations at Troy. And in 1855 he founded the Stanhope essay prize at Oxford. Of his own works the most important are his Life of Belisarius (1829); History of the War of Succession in Spain (1832), largely based on the first earl's papers; History of England from the Peace of Utrecht to the Peace of Versailles (1836–1853); Life of William Pitt (1861–1863); and History of England, comprising the reign of Queen Anne until the Peace of Utrecht (1870). A new edition of this last work was published in 1908. The two histories and the Life of Pitt are of great importance on account of Stanhope's unique access to manuscript authorities, and they remain
and his colleagues in political life for a quarter of a century before his death. See also Mrs Charles Roundell, Lady Hester Stanhope (1910).

STANIMARA, a town of Bulgaria in Eastern Rumelia; on the Dérin Déré, an affluent of the Maritsa, 12 m. S.S.E. of Philippopoli. Pop. (1906), 14,120. It is an important seat of the wine trade and also possesses a distillery. Sericulture is carried on under British auspices. To the south of the town are the ruins of the medieval citadel. Under its Greek name Stenimachos, the town is frequently mentioned in connexion with the Bulgarian wars from the 11th century onwards.

STANISLAW (Polish, Stanislawow), a town in Galicia, Austria, 87 m. S.S.E. of Lemberg by rail. Pop. (1900), 30,410, about half Jews. It possesses a beautiful parish church, which contains the tombs of the Potocki family. The principal industries include tanning, dyeing, tile-making, milling, the production of yeast and there is a large establishment for the manufacture of railway stock. Stanislaw is an important railway junction, and has a considerable trade, principally in agricultural produce. Stanislaw was founded by Stanislav Potocki (d. 1693), and has been newly rebuilt since it was devastated by a great fire in 1868.

STANISLAUS I. [LESZCZYNSKI] (1677-1766), king of Poland, born at Lemberg in 1677, was the son of Rafael Leszcynski, palatine of Posen, and Anne Catherine Jablonowska. He married Catherine Opalinska by whom he had one daughter. In 1697, as cupbearer of Poland, he signed the confirmation of the articles of election of Augustus II. In 1703 he joined the Lithuanian Confederacy, which the Sapiehas with the aid of Swedish gold had formed against Augustus, and in the following year was selected by Charles XII. to supersede Augustus. Leszczynski was a young man of blameless antecedents, respectable talents, and ancient family, but certainly without sufficient force of character or political influence to sustain himself on so unstable a throne. Nevertheless, with the assistance of a bribing fund and an army corps the Swedes succeeded in procuring his election by a scratch assembly of half a dozen castellans and a few score of gentlemen (July 2, 1704). A few months later Stanislaus was forced by a sudden inroad of Augustus to seek refuge in the Swedish camp, but finally on the 24th of September 1705 he was crowned king with great splendour, Charles himself supplying his nominee with a new crown and sceptre in lieu of the ancient regalia which had been carried off to Saxony by Augustus. The first act of the new king was to conclude an alliance with Charles XII. whereby Poland engaged to assist Sweden against the tsar. Stanislaus did what he could to assist his patron. Thus he induced Mazaeppe the Cossack hetman to desert Peter at the most critical period of the war, and placed a small army corps at the disposal of the Swedes. But he depended so entirely upon the success of Charles's arms that after Poltava (1709) his authority vanished as a dream at the first touch of reality. The vast majority of the Poles hastened to repudiate him and make their peace with Augustus, and Leszczynski, henceforth a mere pensioner of Charles XII., accompanied Krassau's army corps in its retreat to Swedish Pomernania. On the restoration of Augustus, Stanislaus resigned the Polish Crown (though he retained the royal title) in exchange for the little principality of Zweibrücken. In 1716 he was saved from assassination at the hands of a Saxon officer, Lacroix, by Stanislaus Potocki, the father of the future king. He now resided at Weissenburg in Lorraine, and in 1725 had the satisfaction of seeing his daughter Maria elected queen of France. His son-in-law supported his claims to the Polish throne after the death of Augustus II. in 1733, which led to the war of the Polish Succession. On the 9th of September 1733 Stanislaus himself arrived at Warsaw, having travelled night and day through central Europe disguised as a coachman, and on the following day, despite many protests, was duly elected king of Poland for the second time. But Russia, opposed to any nominee of France and Sweden, at once protested against his election; declared in favour of the new elector of Saxony, as being the candidate of her Austrian ally; and on the 30th of June

STANHOPE, LADY HESTER LUCY (1776-1839), the eldest child of the 3rd Earl Stanhope by his first wife Lady Hester Pitt, was born on the 12th of March 1776, and dwelt at her father's seat of Chevening in Kent until early in 1800, when her excitable and wayward disposition drove her to her grandmother's house at Burton Pynsent. She spent two or three years abroad, but her cravings after distinction were not satisfied until she became the chief of the household of her uncle, William Pitt, in August 1803. She sat at the head of his table and assisted in welcoming his guests, gracing the board with her stately beauty and enlivening the company by her quickness and keenness of conversation. Although her brightness of style cheered the declining days of Pitt and amused most of his political friends, her satirical remarks sometimes created enemies when more consideration for the feelings of her associates would have converted them into friends. Her passion for art was so strong that she once instructed her maid to bring her a picture of Lady Mary Wortley Montagu. The celebrated companion, Miss Williams, and her trusted medical attendant, Dr Charles Lewis Meryon (1783-1877), dwelt with her for some time; but the forlorned in 1828, and Meryon left Mt Lebanon in 1831, only returning for a final visit from July 1837 to August 1838. In this lonely residence, the villa of Djoun, 8 m. from Sidon, in a house "hemmed in by arid mountains," and with the troubles of a household of some thirty servants, only waiting for her death to plunder the house, Lady Hester Stanhope's strength slowly wasted away, and at last she died on the 23rd of June 1839. The disappointments of her life, and the necessity, as well as the grief which surrounded Djoun, had intensified a temper naturally imperious. In appearance as in voice she resembled her grandfather, the first Lord Chatham, and like him she domineered over the circle, large or small, in which she was placed.

Some years after her death there appeared three volumes of Memoirs of the Lady Hester Stanhope as related by herself in Conversations with her Physician (Dr Meryon, 1845), and these were followed by the biography by Hester Stanhope, forming the Completion of her Memoirs narrated by her Physician. They presented a lively picture of this strange woman's life and character, and contained many anecdotes of Pitt and
STANISLAUS II.—STANLEY (FAMILY)

1734 A Russian army of 20,000 under Peter Lacey, after proclaiming Augustus III at Warsaw, proceeded to besiege Stanislaus in Danzig where he had intrenched himself with his partisans (including the prime rate and the French and Swedish ministers) to await the promised succour from France. The siege began in October 1734. On the 17th of March 1735 Marshal Mitchull superseded Lacey, and on the 20th of May the long expected French fleet appeared in the roads and disembarked 24,000 men. A week after its arrival this little army gallantly attempted to force the Russian intrenchments, but was beaten off and finally compelled to surrender. This, by the way, was the first time France and Russia met as foes in the field. On the 30th of June 1735 Danzig capitulated unconditionally, after sustaining a siege of 135 days which cost the Russians 8,000 men. Stanislaus, disguised as a peasant, had contrived to escape two days before. He was first heard of again at Königsberg, whence he issued a manifesto to his partisans which resulted in the formation of a confederation on his behalf, and the dispatch of a Polish envoy to Paris to urge France to invade Saxony with at least 49,000 men. In the Ukraine too, Count Nicholas Potocki kept on foot to support Stanislaus a motley host of 50,000 men, which was ultimately scattered by the Russians. In 1736 Stanislaus again abdicated the throne, but received by way of compensation the dukedom of Lorraine and Bar, which was to revert to France on his death. He settled at Lunéville, founded there the Académie Stanislás, and devoted himself for the rest of his life to science and philosophy. In 1735, on the 17th of March, Thaddeus Bestuzhev-Ryumin, Born in 1732 he owed his advance in life to the influence of his uncle the powerful Czartorysky, who sent him to St Petersburg in the suite of the English ambassador Hanbury Williams. Subsequently, through the influence of the Russian chancellor, Bestuzhev-Ryumin, he was accredited to the Russian court as the ambassador of Saxony. Through Williams he was introduced to the grand duchess Catherine, who was irresistibly attracted to the handsome and brilliant young nobleman, for whom she abandoned all her other lovers. Poniatowski was concerned in 1737 when he sailed for Germany on private business. His set aside the succession of the grand duke Peter and his son Paul in favour of Catherine, a conspiracy frustrated by the unexpected recovery of the empress Elizabeth and the consequent arrest of the conspirators. Stanislaus returned to Warsaw much discredited, but nevertheless was (Sept. 7, 1764) elected king of Poland through the overwhelming influence of Catherine (she had promised him the crown as early as October 1763), and was crowned on the 25th of November, to the disgust of his uncles, who would have preferred another nephew, Prince Adam Casimir Czartoryski, but were obliged to submit to the dictate of the Russian court. The best that can be said for Stanislaus as king of Poland is that with all his romantic ideas and excellent intentions he remained from first to last the creature of circumstances. He had climed to the throne by very slippery ways, he was dependent for a considerable part of his enormous income on the woman who had compensated him with a crown for the loss of her affections, he was detested by the nobility, who regarded him as a base-born upstart and yet had to put up with him. Thus in every way his position was most difficult; yet he tried to do his duty. In the beginning of his reign he was supine to the legations of his uncles and inaugurated some useful economical reforms. After the first partition (as a result of which, by the way, his debts amounting to 7,000,000 gulden were paid by the Diet and his civil list was raised to 216,000 gulden per annum) he entered enthusiastically into the attempts of the patriots to restore the power and prosperity of their country, while the eloquent oration which he delivered before the Diet on taking the oath to defend the Constitution of the 3rd of May 1772, moved the susceptible deputies to tears. But when the confederation of Targowica, with the secret support of Russia, was formed against the constitution, he was one of the first to accede to it, thus completely paralysing the action of the army which, under his younger brother Prince Joseph and Thaddæus Kosciuszko, was performing prodigies. In fact, by the end of his life, Stanislaus had become an expert in the art of "accusing" and "hedging." Of resolute and independent action he was quite incapable; in fact, his whole career is little more than a record of humiliations. Thus in 1782 when he waited upon Catherine at Kanion during her triumphal progress to the Crimea, she kept her ancient, grey haired lover waiting for weeks, and while half contemptuously promising to respect the integrity of Poland, she curtly declined to be present at a supper which he had prepared for her at great cost. A few years later he was forcibly abducted by the Confederates of Bar, who did not know what to do with their captive, and allowed him to return to his court in a confused, bedraggled condition. On the outbreak of the insurrection of 1794 he was obliged to sue for his very life to Kosciuszko, and suffered the indignity of seeing his effigy expunged from the coinage a year before he was obliged to abdicate his throne. The last years of his life were spent on private property, and after the partition of Poland (where he died in 1798) in writing his memoirs. Of his innumerable mistresses the most notable was Mme Lulliéd, the widow of an upholsterer, on whom he lavished a fortune. He also contracted a secret marriage with the countess Grabowska. Yet he was capable of the most romantic friendships, as witness his correspondence with Mme Geoffrin, whom he invited to Warsaw, where on her arrival she found rooms provided for her exactly like those she had left at Paris—the same size, the same kind of carpets, the same furniture, down even to the very book which she had been reading the evening before her departure, placed exactly as she had left it with a marker at the very place where she had left off. Stanislaus had indeed a generous heart, frequently paid the debts of his friends or of deserving scholars whose cases were brought to his notice, and was exceedingly good to the poor. He also encouraged the arts and sciences, and his Wednesday literary suppers were for some time the most brilliant social functions of the Polish capital. The best description of Stanislaus is by the Swedish minister Engeström, who was presented to him early in 1788. "The king of Poland," he says, "has the finest head I ever saw, but an expression of deep melancholy descends from the beauty of his countenance.... He is broad-shouldered, deep-chested, and of such lofty stature that his legs seem disproportionately short.... He has all the dazzling qualities necessary to sustain his dignity in public. He speaks the Polish, Latin, German, Italian, French and English tongues perfectly... and his conversation fills strangers with admiration.... As a grand-master of the ceremonies he would have done the honours most brilliantly. Moral courage he altogether lacks and allows himself to be completely led by his eunuchaire, which for the most part consists of women." See Lars von Engeström, Minnen och Anteckningar, vol. i. (Stockholm, 1876); Correspondance inédite de Stanislas Poniatowski avec Madame Geoffrin (Paris, 1875); Jan Kiliński, Recollections of the Times of Stanislaus Augustus (Pol. Cracow, 1899); Mémoires secrets et inédits de Stanislas Auguste (Làpzig, 1862); Stanislaw and Prince Joseph Poniatowski in the Light of their Private Correspondence, in French, edited in Polish by Bronislaw Dembiński (Lemberg, 1900). Stanislaus's diaries and letters, which were for many years in the Russian foreign office, have been published in the Vestnik Eupros, 1908. See also R. N. Bain's, The Last King of Poland and his Contemporaries (1909). (R. N. B.)

STANLEY (FAMILY). This ancient and historic English family derived its name from Stanley in Leek (in the Staffordshire "molinards"). Its founder was Walter, brother of Lilulf de Audley, ancestor of the lords Audley, who lived in the time of King Stephen. His descendant William de
Stanley acquired the forestiership of Wirral, with an heiress, in 1284, and was ancestor of two brothers, Sir William and Sir John Stanley. The former married the heiress of Hooton in Wirral and was ancestor of the Stanleys of Hooton, whose baronetcy, created in 1661, became extinct in 1803. The younger brother was lieutenant of Ireland under Richard II. and Henry IV., obtained from the latter the Isle of Man in fee, built a fortified house at Liverpool, and became K.G. He married the heiress of the Lathom, a native family who had held Lathom in channage from the Conquest at least and Knowsley by knight-service from the 12th century. His grandson Thomas was father of the second Earl of Derby (see DERBY). His younger son, Edward, 6th Earl of Derby (b. 1839), who in 1903 succeeded his brother Henry Edward John (1827-1903) as 4th baron, had previously had an active career as an educationist and a Liberal politician. He was a fellow of Balliol College, Oxford, and was M.P. for Oldham from 1880 to 1885. He was for many years a member of the London School Board. In 1909 on the death of the 3rd earl of Sheffield, he inherited the barony of Sheffield, and that of Stanley of Alderley now became merged in it.

**Stanley, Arthur Penrhyn** (1815-1881), English divine, dean of Westminster, was born on the 13th of December 1815, a son of Arthur Penrhyn Stanley, in Cheshire, and was connected with the Stanley family by marriage. He was educated at Rugby and New College, Oxford, and in 1837 was elected fellow of University College, and in the same year took orders. In 1840 he travelled in Greece and Italy, and on his return settled at Oxford, where for ten years he was tutor of his college and an influential element in university life. His personal relations with his pupils were of a singularly close and affectionate nature, and the charm of his social gifts and genial character won him the affection of both sides. His literary reputation was established by his *Life of Arnold*, published in 1844. In 1845 he was appointed select preacher, and published in 1847 a volume of *Sermons and Essays on the Apostolic Age*, which not only laid the foundation of his fame as a preacher, but also marked his future position as a theologian. In university politics, which at that time were mainly the form of theological controversy, he was a strong advocate of comprehension and toleration. As an undergraduate he had entirely sympathized with Arnold in resenting the agitation led by, but not confined to, the High Church party in 1836 against the appointment of R. D. Hampden to the regius professorship of divinity. During the longer agitation which followed the publication in 1847 of *Tract No. XC*, and which ended in the withdrawal of J. H. Newman from the Anglican Church, he used all his influence to protect from formal condemnation the leaders and tenets of the "Tractarian" party. In 1847 he resisted the movement set on foot at Oxford against Hampden's appointment to the bishopric of Hereford. Finally, in 1859, in an article published in the *Edinburgh Review* in defence of the "Gorham judgment" he asserted two principles which he maintained to the end of his life—first, "that the so-called supremacy of the Crown in religious matters was in reality nothing else than the supremacy of law;" and, secondly, "that the Church of England, by the very condition of its being, was not High or Low, but Broad, and had always included and been meant to include, opposite and contradictory opinions on points even more important than those at present under discussion."

It was not only in theoretical but in academical matters that his sympathies were on the liberal side. He was greatly interested in university reform and acted as secretary to the royal commission appointed in 1850. Of the important changes in administration and education which were ultimately carried out, Stanley, who took the principal share in drafting the report printed in 1852, was a strenuous advocate. These changes included the transference of the initiative in university legislation from the sole authority of the heads of houses to an elected and representative body, the opening of college fellowships and scholarships to competition by the removal of local and other
restrictions the non-enforcement at matriculation of subscription to the Thirty-nine Articles, and various steps for increasing the usefulness and influence of the professoriate. Before the report was issued, Stanley was appointed to a canonry in Canterbury Cathedral. During his residence there he published his Memoir of his father (1851), and completed his Commentary on the Epistles to the Corinthians (1855). In the winter and spring of 1852-1853 he made a tour in Egypt and the Holy Land, the result of which was his well-known volume on Sinai and Palestine (1856). In 1857 he travelled in Russia, and collected much of the materials for his Lectures in Eastern Europe (1858). He published his Essay on Egypt (1853), displayed the full maturity of his power of dealing with the events and characters of past history. He was also examining chaplain to Bishop A. C. Tait, his former tutor.

At the close of 1856 Stanley was appointed regius professor of ecclesiastical history at Oxford, a post which, with the attached canonry at Christ Church, he held till 1863. He began his treatment of the subject with "the first dawn of the history of the church," the call of Abraham; and published the first two volumes of his History of the Jewish Church in 1863 and 1865. From 1860 to 1864 academic and clerical circles were agitated by the storm which followed the publication of Essays and Reviews, a volume to which two of his most valued friends, Benjamin Jowett and Frederick Temple, had been contributors. Stanley's part in this controversy may be studied in the second and third of his Essays on Church and State (1870). The result of his action was to alienate the leaders of the High Church party, who had endeavoured to procure the formal condemnation of the views advanced in Essays and Reviews. In 1836 he published a Letter to the Bishop of London, advocating a relaxation of the terms of clerical subscription to the Thirty-nine Articles and the Prayer-book. An act amending the Act of Uniformity, and carrying out in some degree Stanley's proposals, was passed in the year 1863. In 1862, Stanley, at Queen Victoria's wish, accompanied the prince of Wales on a tour in Egypt and Palestine.

Towards the close of 1863 he was appointed by the Crown to the deanship of Westminster. In December he married Lady Augusta Bruce, sister of Lord Elgin, then governor-general of India. His tenure of the deanship of Westminster was memorable in many ways. He recognized from the first two important endowments—his indifference to music and his slight knowledge of architecture. On both these subjects he availed himself largely of the aid of others, and threw himself with characteristic energy and entire success into the task of rescuing from neglect and preserving from decay the treasure of historic monuments in which the abbey is so rich. In 1865 he published his Memorials of Westminster Abbey, a work which, despite occasional inaccuracies, is a mine of information. He was a constant preacher, and gave a great impulse to Trench's practice of inviting distinguished preachers to the abbey pulpit, especially to the evening services in the nave. His personal influence, already unique, was much increased by his removal to London. His circle of friends included men of every denomination, every class and almost of every nation. He was untrilling in literary work, and, though this consisted very largely of occasional papers, lectures, articles in reviews, addresses, and sermons, it included a third volume of his History of the Jewish Church, a volume on the Church of Scotland, another of Addresses and Sermons preached in America, and another on Christian Institutions (1881). He was continually engaged in theological controversy, and, by his advocacy of all efforts to promote the social, educational, and religious amelioration of the poorer classes and his chivalrous courage in defending those whom he held to be unjustly denounced, undoubtedly incurred much and growing odium in influential circles. Among the causes of offence might be enumerated not only his vigorous defence of one from whom he greatly differed, Bishop Colenso, but his invitation to the Holy Communion of all the revisers of the translation of the Bible, including a Unitarian among other Nonconformists. Still stronger was the feeling caused by his efforts to make the recital of the Athanasian Creed optional instead of imperative in the Anglican Church. In 1874 he spent part of the winter in Russia, whither he went to take part in the marriage of the duke of Edinburgh and the grand duchess Marie. He lost his wife in the spring of 1876, a blow from which he never entirely recovered. But in 1878 he was deeply interested by a tour in America, and in the following autumn visited for the last time northern Italy and Venice. In the spring of 1881 he prepared funeral sermons in the abbey on Thomas Carlyle and Lord Beaconsfield, concluding with the latter a series of sermons preached on public occasions. In the summer he was preparing a paper on the Westminster abbey in order to the abbeys being read with Lectures on the Beatitudes. He died on the 18th of July, and was buried in Henry VII's chapel, in the same grave as his wife. His pall-bearers comprised representatives of literature, of science, of both Houses of Parliament, of theology, Anglican and Nonconformist, and of the universities of Oxford and Cambridge. The recumbent monument placed upon the spot, and the windows in the chapter-house of the abbey, one of them a gift from Queen Victoria, were a tribute to his memory from friends of every class in England and America.

Stanley was undoubtedly the leading liberal theologian of his time in England. Throughout his writings we see the impress, not great, but incontestable, of his views were in great part due to his mental and religious experience, a constant, indissoluble connexion of the intellectual and spiritual. From his earliest days, and also of his special views, aims and aspirations. He looked on the age in which he lived as a period of transition, to be followed either by an "epoch of faith" or by a "revival of Christianity in a new and more complete form," or by a "reappraisal of Christianity" that "might yet overcome the world." He was never tired of asserting his belief "that the Christian Church had not yet presented the most perfect aspect to the world"; that "the believer in each successive age of Christendom had as a matter of fact varied enormously from the belief of his predecessor"; that "all confessions and similar documents are, if taken as final expressions of absolute dogma, misleading"; and that "there still remained, behind all the controversies of the past, a higher Christianity which neither assailants nor defenders had fully exhausted." The first duty of a liberal theologian was "to study the Bible, not for the sake of proving or defending systems out of it, but for the purpose of discovering what it actually contains." To this study he looked for the best hope of such a progressive development of Christian theology as should avert the danger arising from "the apparently increasing divergence between the intelligence and the faith of our time." He enforced the duty of placing in the background whatever was accidental, temporary or secondary, and of bringing into due prominence what was primary and essential. In the former group Stanley would, without doubt or hesitation, have placed all questions connected with Episcopal or Presbyterian ordinations, and even without his belief in the historical accuracy of the Gospels or with the authorship or the age of the books of the Old Testament. Even to the question of miraculous and external evidence he would have been inclined to assign a secondary place. He held that the "essential and supernatural" elements of religion, he would have reserved for its moral and spiritual truths, "its chief evidence and chief essence," the truths to be drawn from the teaching and from the life of Christ, in whose character he did not hesitate to recognize "the greatest of all miracles."

With such views it was not to be wondered at, that from first to last, as has already been indicated, he never lost an opportunity of supporting a policy of width, toleration and comprehension in the Church of England. So again he was always eager to insist on the essential points of union between various denominations of Christians. He was throughout his life an unflinching advocate of the connexion between Church and State. By this he understood: (1) "the recognition and support on the part of the state of the religious expression of the faith of the community," and (2) "that this religious expression must be under the control of the state on the most sacred and most vital of all its interests should be controlled and guided by the whole community through the supremacy of law." At the same time he was in favour of making the creed of the Church as wide as possible—not narrower than that which is even now the test of its membership, the Apostles' Creed—and of throwing down all barriers which could be easily dispensed with and which could be drawn to its minimum. His impiest conception indicated the admission under due restrictions of English Nonconformists and Scottish Presbyterians, to preach in Anglican pulpits. Apart from the great impulse which he gave to the study alike of history and Church and State, Stanley left a work, in a very true sense to colour the writings of many of those who most differ from him. The subjects to which he looked as the most essential and universal, the most beautiful and noble, were the moral and spiritual elements of religion, the supremacy of conscience, the sense of the central citadel of Christianity as being contained in the character, the history, the spirit of its divine
Founders—have impressed themselves more and more on the teaching and the preaching of every class of clergy the Church.

See G. G. Bradley, Recollections of A. P. Stanley (1883); R. E. Proctor, from G. G. Bradley, Life and Correspondence of Dean Stanley (2 vols., 1893).

STANLEY, EDWARD (1779-1840), bishop of Norwich, the younger brother of the 1st Baron Stanley of Alderley, was born in London and educated at St John's College, Cambridge (10th wrangler, 1802). He was ordained in 1802 and became rector of Alderley, Cheshire, three years later. Here he took a great interest in education, and encouraged especially the teaching of secular subjects at his school. In 1837 he was consecrated bishop of Norwich. The diocese at this time was conspicuous for laxity and want of discipline, and this he proceeded to remedy, although at first he met with much opposition. Ordinations and confirmations were held more regularly and frequently, the schools were properly inspected, the Plurality Act was enforced and undesirable clergy were removed. He was tolerant towards Dissenters and supported all missionary undertakings without regarding their sectarian associations. In politics he was a Liberal and devoted himself especially to educational questions. Dean Stanley (see above) was his third son.

Stanley's letters, Before and after Waterloo (edited by J. H. Adene and M. Grenfell, 1907), are full of interest to students of Napoleonic history.

STANLEY, SIR HENRY MORTON (1822-1904), British explorer of Africa, discoverer of the course of the Congo, was born at Denbigh, Wales, on the 10th of June 1822. His parents were named Rowlands or Rollant, and his father, who died in 1843, was the son of a small farmer. John Rowlands, by which name Stanley was baptized, was brought up first by his maternal grandfather, and after his death was boarded out by his mother's brothers at half a crown a week. In 1847 he was taken to the St Asaph Union workhouse, where he was noted for his activity and intelligence. The schoolmaster at the workhouse, James Francis (who eventually died in a madhouse), was a tyrant of the Squeers type, and in May 1856, Rowlands, after giving Francis a thrashing, ran away from school. He sought out his paternal grandfather—a well-to-do farmer—who refused to help him. A cousin, however, who was master of a national school at Brynford, took him in as a pupil teacher. But within a year he was sent to Liverpool, where he lived with an uncle who was in straitened circumstances. The lad, after working at a haberdasher's and then at a butcher's shop, engaged himself as a cabin boy on a sailing ship bound for New Orleans, in which city he landed early in 1859. There he obtained a situation through the good offices of a merchant named Henry Morton Stanley, who subsequently adopted the lad as his son, designing for him a mercantile career. To the end young Stanley (as he was henceforth known) was sent to a country store in Arkansas. The merchant shortly afterwards died, without having made further provision for his protégé.

When the Civil War broke out in 1861 Stanley enlisted in the Confederate army; he was taken prisoner at the battle of Shiloh (April 1862), and after two months' experience of the hardships of Camp Douglas, Chicago (where the prisoners of war were confined), he obtained release by enrolling in the Federal artillery. In less than a month he was discharged as unfit. In November 1862 he returned to Liverpool "very poor, in bad health and in shabby clothes". He made his way to Denbigh, but was turned away from his mother's door. This incident deeply affected him. Naturally of a sensitive, affectionate nature, henceforth he practised strong self-suppression and reserve. For a livelihood he took to the sea—was wrecked off Barcelona—and in August 1864 enlisted in the United States navy. According to an apparently authentic story he obtained promotion for swimming 500 yds. and tying a rope to a captured steamer, while exposed to the shot and shell of a battery of ten guns. After the war he crossed the plains to Salt Lake City, Denver, and other petty, acquiring a reputation as a vivid descriptive writer for the press.

Thus began a series of adventures in search of "copy." In the autumn of 1866 we hear of him travelling in Asia Minor "en route for Tiflis and Tibet," and as being attacked, with his two companions, by brigands, robbed and imprisoned, the Porte subsequently paying through the American ambassador the sum of $200 for the outrage. In December of the same year Stanley revisited Denbigh and St Asaph, returning thence to America. In 1867 he joined General Hancock's expedition against the Red Indians, acting as correspondent for the Missouri Democrat and other papers. His reports induced the New York Herald to send him to accompany the British expedition of 1867-68 against the emperor Theodore of Abyssinia. Succeeding in sending through the first news of the fall of Magdala, Stanley attracted the special attention of the proprietor of the Herald, James Gordon Bennett, and received from him a roving commission. He went to Crete, then in rebellion, in the latter part of 1868, and thence to Spain, where he arrived in time to witness the scenes following the flight of Queen Isabella from Madrid. He chronicled the events of the Republican rising in 1869 and was at Madrid in October of that year, when he received a telegram from Mr Gordon Bennett, Jun., summoning him to Paris.

Arrived in Paris Stanley was informed that he was to go and find Livingstone.2 Stanley then shared the common opinion that Livingstone had died somewhere in Central Africa, but Bennett was sure he was alive and Stanley was to find and help him to the best of his ability. The journey, which was to be kept secret to avoid suspicion, was to begin next day. Stanley was enough, though so urgent in the matter, Bennett cumbered Stanley with a large number of commissions to fulfil before the quest for Livingstone could be begun. In accordance with these instructions, Stanley went to Egypt to witness the opening of the Suez Canal in November, thence to Philae, and in January 1870 he arrived in Jerusalem, where he met Captain (afterwards Sir) Charles Warren. Next, by way of Constantinople, he visited the battlefields of the Crimea, and, passing through the Caucasus from Baku, he made an adventurous journey across Persia to Isfahan. He then went to Cairo, where he was strongly coloured by the storm of abuse and the wholly unjustifiable reports circulated about him then. A series of public lectures in England and America followed. In 1873, as war correspondent of the Herald, he accompanied Wolseley's expedition to Ashanti, which he described, together with his Abyssinian experiences, in a volume entitled Coomaissie and Magdala: Two British Campaigns (London, 1874). On reaching the island of St Vincent from Ashanti in 1874 he first heard that Livingstone was dead, and that the body was on its way to England. After the funeral of Livingstone some time was spent in negotiations for sending Stanley again to Africa, 3

4 This is the usually accepted date, but from Stanley's Autobiography it would appear that the year of his birth was 1842.

1868, Stanley had been sent to Egypt by the Herald to "meet Livingstone." The time reported to be on his way home. Stanley got as far as Aden when he was recalled.
STANLEY, H. M.

there to determine geographical problems left unsolved by the deaths of Livingstone and Speke, and the discovery by Sir Samuel Baker of Albert Nyanza, a lake then reputed to extend illimitably in a southerly direction. Finally, Sir Edward Lawson (afterwards Lord Burnham), the editor and proprietor of the Daily Telegraph, Stanley at Marseilles, when he was actually on board, and Sir Edwin Arnold of that journal, induced Mr Gordon Bennett to join them in raising a fund for an Anglo-American expedition under Stanley's command. This expedition lasted from October 1874 to August 1877 and accomplished more than any other single exploring expedition in Africa. Politically, also, the journey had momentous consequences; it led directly to the foundation of the Congo State and to the partition of the hitherto unappropriated regions of Africa between the states of western Europe. Stanley started from the east coast and reached the source of the Nile at about the mouth of the Congo, having demonstrated the identity of that river with Livingstone's Lualaba by navigating its course from Nyangwe—the point at which both Livingstone and Lovett Cameron had turned aside. This wonderful achievement was accomplished in the face of difficulties so great that they could have been overcome only by such a man as Stanley proved himself to be—a man of inflexible will, who having conceived a vast design carried it to its conclusion regardless of any obstacles, sparing neither himself nor his associates and, if opposed, prepared to shed blood to attain his object. Of the three white men who accompanied him all died during the journey except Stanley himself, who had reached the prematurely aged. The discovery of the course of the Congo, though the greatest, was but one of many geographical problems solved during this memorable expedition. The part played by the Kagera in the Nile system, the unity and approximate area of Victoria Nyanza, the true length and area of Tanganyika and the whereabouts of its outlet, and the discovery of a new lake, Dweru, which at the time Stanley believed to be a branch of Albert Nyanza, are some of the other discoveries made by Stanley at this time. The story of this expedition was given at length in Through the Dark Continent (London, 1878). Stanley's letters from Uganda and his call for missionaries to go to the court of Mtesa met with an immediate response and proved the first step in bringing the region of the Nile sources under the protection of Great Britain. Important as was this result of his journey it was eclipsed by the events which followed his revelation of the Congo as a magnificent waterway piercing the very heart of Africa. Of the commercial possibilities of the region he had made known Stanley was well aware. The one other man who at once grasped the situation was Leopold II, king of the Belgians, who sent commissioners to intercept Stanley. Leopold II, himself a keen observer of the world, and the man to whom the name of Leopold is richly due for his knowledge of the Congo and his appreciation of its economic possibilities, was an ardent believer in the natural rights of nations, and the idea of a great commercial empire, rich enough to repay exploitation. Stanley reached the Congo in August 1879, and the work he accomplished there in the ensuing five years enabled the Comité, which had meantime changed its name to that of Association internationale du Congo, to obtain the recognition of America and Europe to its transformation into an independent state ("The Congo Free State") under the sovereignty of King Leopold. Stanley described his labours in The Congo and the Founding of its Free State (London, 1883), a book which throws valuable light on the manner in which the promoters of that enterprise set to work, and the object at which from the beginning, they aimed. For the political aspects of this question see AFRICA (§ 5) and CONGO FREE STATE. Here it is only necessary to indicate what Stanley actually accomplished. On the coast the area of his activities was restricted by the enterprise of the French traveller de Brazza, who, reaching Stanley Pool by a more northern route, placed—September and October 1880—the neighbouring districts on the north bank of the Congo under French protection. De Brazza's journey, which was directly inspired by Stanley's discoveries, led to international rivalries. Notwithstanding this clash Stanley, without much trouble with the natives, founded stations for his association along the banks of the river as high up as Stanley Falls. A more difficult task was the making of a road through the cataract region and the carrying over it in sections of four small steamers, all of which were launched on the middle river. This road-making exploit earned for Stanley from the natives the name of Bula Matari, the rock-breaker, the all-powerful—a fit description of the man who allowed no obstacles to turn him from the achievement of his noblest ambition.

Stanley returned to Europe in the middle of 1884 and attended the Berlin Conference of 1884–1885, which dealt with African affairs, acting as technical adviser of the American plenipotentiaries. While in Germany he lectured in various cities on the benefits which would result from the opening up of Central Africa, and found the Germans more alive than the British to the great interests at stake. The revelation of what the Association internationale had done intensified the struggle among the powers for the possession of African territory. Stanley did not return to the Congo in the recognition of the Free State but took up his residence in London. With James F. Hatton, a leading Manchester merchant, he promoted the Royal Congo Railway Company to connect Stanley Pool with the lower river, but the scheme at the time came to nought, partly owing to the indiffer-ence of English capitalists and partly in consequence of a clause inimical to British interests in the charter which King Leopold proposed to grant the company.

Though still an American citizen Stanley's interests and ambitions were becoming distinctly British, his sympathies in that country were increasing, and he joined to his personal loyalty to the king of the Belgians, a desire to serve both parties was one of the leading motives in his next African adventure. Stanley had become deeply interested in the schemes of Mr (afterwards Sir) William Mackinnon, chairman of the British India Steam Navigation Company, for establishing a British protectorate in East Equatorial Africa, and it was believed that this object could be furthered at the same time that relief was afforded to Emin Pasha (q.v.), governor of the Equatorial Province of Egypt, who had been isolated by the Mahdist rising of 1881–1885. Stanley agreed to conduct an expedition, nominally in the service of the company. The major part of the funds needed was supplied by a committee, of which Mackinnon was chairman. Instead of choosing the direct route via Zanzibar or Mombasa, Stanley decided to go by way of the Congo, as thereby he would be able to render services to the infant Congo State, then encountering great difficulties with the Zanzibar Arabs established on the upper Congo. Stanley left Europe in January 1887 and at Zanzibar entered into an agreement with Tippoo Tib, the chief of the Congo Arabs, appointing him governor of Stanley Falls station on behalf of the Congo State, and making an arrangement with him under which the Free State would pay the early relief expenses. Stanley and Tippoo Tib travelled together up the Congo as far as Bangala, reached on the 30th of May. Thence Tippoo Tib went on to Stanley Falls and Stanley prepared for a journey to Albert Nyanza, where he expected to meet Emin. On the 15th of June Yambuya, on the lower Aro-wimi, was reached, and here Stanley left his rear-guard under command of Major E. M. Bartlett and Mr J. S. Jameson. On the 28th Stanley and the advance-guard set out for Albert Nyanza, and on the 5th of December, for 150 days, we marched through the forest, bush and jungle, without ever having seen a bit of greensward of the size of a cottage chamber floor.

1 Of the later policy pursued in the Congo State Stanley wrote, in 1896, that it was "erring and ignorant." To go back to the Congo "would be to disturb a moral malaria injurious to the recogizer."

(Autobiography, p. 537).
Nothing but miles and miles, endless miles of forest." Starvation, fever, the hostility of the tribes, were daily incidents of this terrible march, during which Stanley lost nearly 50% of his men. On the 13th of December Albert Nyanza was reached, and after some delay communication was opened with Emin, who came down the lake from the Nile to sign a treaty. The two parties met on the 20th of April 1888. Disappointed by the non-arrival of his rearguard, Stanley retraced his steps, and on the 17th of August, a short distance above Yambuya, found that Tippoo Tib had broken faith, that Barttelot had been murdered, that Jameson (who soon afterwards died of fever) was absent at Stanley Falls, and that only one European, William Bonny, was left in the camp. Collecting those who survived of the rearguard Stanley for the third time traversed the primeval forest, and in January 1889 all that was left of the expedition was assembled at Albert Nyanza. Of 466 men with whom he entered the Congo, but 246 remained. In April the return journey to Zanzibar by way of Uganda was begun, Emin reluctantly accompanying Stanley. On this homeward journey Stanley discovered Ruwenzori (the Mountains of the Moon), traced the course of the Semliki River, discovered Albert Edward Nyanza and the great south-western gulf of Victoria Nyanza. During his stay in the Congo forests he had also obtained much information concerning the pygmy tribes. As to the political results of the expedition, Stanley's proposals to Emin to hold the Equatorial Province for the Congo State or to move nearer Victoria Nyanza and enter the service of Mackinnon's British East Africa Company had not been accepted, but he concluded agreements with various chiefs in the region south of the frontier of Great Britain, agreements which were handed over to the East Africa Company. Zanzibar was reached on the 6th of December 1889 and the expedition was at an end. Stanley's account of it, *In Darkest Africa*, was published (in six languages) in 1890.

Returning to England, Stanley was received with much honour, among the many distinctions conferred upon him being the degrees of D.C.L. from Oxford and of L.L.D. from Cambridge and from Edinburgh. On the 12th of July 1890 he married a lady whose graceful work as an artist was well known, Miss Dorothy Tennant, second daughter of Mr. Charles Tennant, sometime M.P. for St. Alban's. Later in the year he visited the United States, where he made a pilgrimage to the places where his youth had been spent, and in 1891-1892 went to Australia and New Zealand on lecturing tours. On his return he was renaturализed as a British subject, and—at the solicitation of his wife—he stood at the general election in the summer of 1893 as candidate for North Lambeth in the Liberal Unionist interest, being defeated by a small majority. In 1895 he again stood for the same constituency and was elected, but he had no liking for parliamentary life, and (being also in ill-health) he did not seek re-election in 1900.

In 1890 Stanley published *My Early Travels and Adventures in America and Asia*, in which he retold the story of his experiences with the Red Indians and of his eastern journey of 1869-1870. In 1897 Stanley paid his last visit to Africa. He went to the Cape as the guest of the British South Africa Company, spoke at the opening of the railway from the Cape to Bulawayo, visited the Victoria Falls of the Zambezi and had an interview with President Kruger, of whom he gives a characteristic picture. One result of this journey was *Through South Africa* (1899), the last of his published works. In 1899 in recognition of his services in Africa he was made a Knight Grand Cross of the Order of the Bath on the 29th of April 1888.

In geographical discoveries Stanley accomplished more than any other explorer of Africa, with which continent his name is indissolubly connected. Notwithstanding his frequent conflicts with Arabs and negroes, he possessed in extraordinary degree the power of managing native races; he was absolutely fearless and ever ready to sacrifice either himself or others to achieve his object. His books differ widely from the ordinary books of travel. Stanley had a gift of dramatic narrative, and his power of portraiture was remarkable. Curiously, the infrastructure of his work was the only one which he cast in the form of fiction, *My Kalulu, Prince, and King and Slave*. Another volume from his pen, *My Dark Companions and their Strange Stories* (1893), is a valuable contribution to folklore.

**STANLEY, THOMAS** (1625-1678), English poet and philosopher, son of Sir Thomas Stanley of Cumberlow, in Herts, was born in 1625. His mother, Mary Hammond, was the cousin of Richard Lovelace, and Stanley was educated in company with the son of Edward Fairfax, the translator of Tasso. He proceeded to Cambridge in 1637, in his thirteenth year, as a gentleman-commoner of Pembroke Hall. In 1641 he took his M.A. degree, but seems by that time to have proceeded to Oxford. He was wealthy, married early, and travelled much on the Continent. He was the friend and companion, and at nearly the helper, of many poets, and was himself both a writer and a translator of verse. His Poems appeared in 1647; his *Europa, Cupid Cursified, Venus Vigilis*, in 1650; his *Aurora and the Prince*, from the Spanish of J. Perez de Montalvan, in 1647; *Oronta, the Cyprian Virgin*, from the Italian of G. Preti (1659); and *Anacreon; Bion; Moschus; Kisses by Secundus*. . . . a volume of translations, in 1651. Stanley's most serious work in life, however, was his *History of Philosophy*, which appeared in three successive volumes between 1655 and 1661. A fourth volume (1662), bearing the title of *History of Chaldæick Philosophy*, was translated into Latin by J. L. Clerc (Amsterdam, 1690). The three earlier volumes were published in an enlarged Latin version by Godfrey Olearius (Leipzig, 1711). In 1664 Stanley published in folio a monumental edition of the text of Aeschylus. He died at his lodgings in Suffolk Street, Strand, on the 12th of April 1678, and was buried in the church of St. Martin-in-the-Fields. His portrait was painted by Sir Peter Lely; his wife was Dorothy, daughter and coheir of Sir James Emyon, of Flower, in Northamptonshire. Stanley is a very interesting transitional figure in English literature. Born into a later generation than that of Waller and Denham, he rejected their reforms, and was the last to cling obstinately to the heroic and pastoral traditional forms of poetry. He is the frankest of all English poets in his preference of decadent and Alexandrine schools of imitation; among the ancients he admired Moschus, Ausonius, and the *Periplus Veneris;* among the moderns, Joannes Secundus, Gongora and Marino. The English metaphysical school closes in Stanley, in whom it finds its most delicate and autumnal exponent, who went on weaving his fantastic conceits in elaborately artificial measures far into the days of Dryden and Butler. When Stanley turned to prose, however, his taste became transformed. He abandoned his decadents for the gravest masters of Hellenic thought, was an elegant scholar, of the illuminative order, he secured a very high place indeed throughout the second half of the 17th century. His *History of Philosophy* was long the principal authority on the progress of thought in ancient Greece. It took the form of a series of critical biographies of the philosophers, beginning with Thales; what Stanley aimed at was the providing of necessary information concerning all "those on whom the attribute of Wise was conferred." He is particularly full on the great Attic masters, and introduces, "not as a comical diversion for the reader, but as a necessary supplement to the life of Socrates," a blank verse translation of the *Clouds of Aristophanes*. Bentley is said to have had a high appreciation of his scholarship, and to have made use of the
poet's copious notes, still in manuscript (in the British Museum), on Callimachus.

Stanley's original poems, which had been collected in 1651, were imperfectly reprinted in Sir S. Egerton Brydges's edition of 150 copies in 1814, but never since; his "Anacreon" was issued, with the Greek text, by Mr Bullen in 1892. His prose works have not been collected.
